Poster Title: Development of pharmacist-driven dyslipidemia and hypertension clinics in rural Alaskan villages

Primary Author: Leanna Waalkens, Norton Sound Health Corporation, AK; Email: lwaalkens@nshcorp.org

Additional Author(s):
Robyn Goff
Heather Bailey
Anthony Shelton

Purpose: People living in remote regions of Alaska face many barriers in receiving healthcare including limited access to and availability of healthcare providers, facilities, and medications. As a result, rural Alaskans often receive less follow-up and treatment for their chronic medical conditions than Alaskans living in more populated areas. The goal of this project is to improve treatment accessibility, medication adherence and health outcomes by implementing pharmacist-driven dyslipidemia and hypertension clinics that will serve patients in the remote Alaskan villages of the Norton Sound region.

Methods: Locations that would benefit from pharmacist driven dyslipidemia and hypertension ambulatory clinics were assessed using state reported population data on chronic diseases. The estimated number of patients with chronic diseases living Norton Sound villages was calculated by applying state reported percentages of the population with chronic diseases to the population living in the villages as reported by the United States Census Bureau. The number of patients with both dyslipidemia and hypertension was estimated using data from the National Health and Nutrition Surveys. The estimated number of ambulatory clinic hours was calculated assuming each visit would take 30 minutes and each patient would be seen twice a year. This data was used to develop a protocol for the pharmacist-driven dyslipidemia and hypertension clinics which will be presented to the Norton Sound Health Corporation’s Pharmacy and Therapeutics Committee for approval.

Results: Approximately, 1,420 adult patients living in Norton Sound villages have dyslipidemia and 1,055 have hypertension. Of these 2,475 patients, it is expected that 570 have only
dyslipidemia, 205 have only hypertension, and 850 have both dyslipidemia and hypertension. A total of 1,625 patients are expected to need treatment for dyslipidemia, hypertension, or both. The estimated number of clinic hours needed to service this population is 1,625.

**Conclusion:** Dyslipidemia and hypertension are often undertreated in rural Alaska because of limited healthcare resources. Under-treatment contributes to negative health outcomes such as heart attack and stroke. Pharmacist-based dyslipidemia and hypertension clinics located in Norton Sound villages are being developed to decrease physician burden and improve clinic accessibility and treatment adherence. Over 1,600 Norton Sound village patients are expected to benefit from these clinics.
**Submission Category:** Ambulatory Care

**Submission Type:** Research-in-Progress

**Session-Board Number:** 1-042

**Poster Title:** Providers' and pharmacists' knowledge, attitudes, and beliefs regarding medication assisted treatment (MAT) for opioid addiction and intranasal naloxone in the Nuka System of Care

**Primary Author:** Natalie Li, Southcentral Foundation of the Alaska Native Medical Center, AK; 
**Email:** nli@southcentralfoundation.com

**Additional Author(s):**
Mike Beiergrohslein
Josh Crowe
Cathy Arnatt
Kristin Allmaras

**Purpose:** According to the CDC, more than two million Americans are addicted to opioids. In order to treat this addiction, demand for medication assisted treatment and naloxone grows, requiring an increased need for education and support for healthcare teams. The purpose of this project is to assess primary care providers’ and pharmacists’ knowledge, attitudes, and beliefs regarding the use of buprenorphine and naltrexone to treat opioid addiction and the utilization of naloxone for opioid-overdose. We anticipate that the results can assist the institution in developing supplemental education, protocols, and additional supportive services that may enhance opioid addiction treatment at our facility.

**Methods:** Study investigators will design a survey using a variety of questions (eg. Likert-like scale, multiple choice, true/false) to assess providers’ and pharmacists’ knowledge, attitudes, and beliefs regarding medication assisted treatment for opioid addiction and intranasal naloxone use for prevention of opioid overdose-related deaths. The survey will be created using Survey Monkey, which will then be distributed to providers and pharmacists through email. We will receive appropriate tribal permissions and human protections to disseminate the survey and collect survey responses. Responses generated through Survey Monkey will then be analyzed using descriptive statistics in order to identify and distinguish providers’ and pharmacists’ perceptions regarding MAT.

**Results:** Pending
Conclusion: Pending
**Submission Category:** Ambulatory Care

**Submission Type:** Research-in-Progress

**Session-Board Number:** 1-043

**Poster Title:** Use of telepharmacy in medication management of hypertension and diabetes in a veteran population to improve clinical outcomes

**Primary Author:** Meredith Thompson, Birmingham VA Medical Center, AL; **Email:** meredith.thompson@va.gov

**Additional Author (s):**
Patricia White

**Purpose:** Pharmacist involvement in the medication management of chronic disease states has been shown to be beneficial for patients. Additionally, telemedicine allows for more easily accessible medical care for veterans who are unable to maintain close follow-up with their primary care provider for chronic disease state management. Involving pharmacists in the interdisciplinary healthcare team through telemedicine helps ensure veteran patients do not fall through the cracks. The objective of this study is to evaluate how telepharmacy can improve clinical outcomes associated with hypertension and diabetes, utilizing appropriate and timely medication management within a veteran population.

**Methods:** Prior to initiation, this study will be submitted to the institutional review board for approval. This study consists of a retrospective and prospective review of patients enrolled in a program entitled "Care Coordination Home Telehealth" (CCHT). For the retrospective component, computerized patient medical records of veterans enrolled will be reviewed to assess for timely management of electronically submitted blood glucose (BG) and blood pressure (BP) values. The following outcomes will be assessed: time to medical intervention, number of medical interventions/changes performed, mean change in BP, BG or hemoglobin A1c, and number of adverse events experienced, if any. The prospective review will incorporate pharmacist-managed care through the use of telepharmacy. Patients receiving care under consenting providers will have telephone follow-up with authors of this study for medication management of hypertension and diabetes. Authors will review BP and BG values electronically submitted and perform an interview with patients via telephone. Timely follow-up will be provided and interventions will be made if necessary. The same data points will be collected as the retrospective portion of the study. The study will be conducted with application of
appropriate policies guided by ethical principles regarding all research involving human subjects.

**Results:** Results pending upon completion of research.

**Conclusion:** Data collection is currently ongoing and will be conveyed at the Southeastern Residency Conference.
**Submission Category:** Cardiology/ Anticoagulation  

**Submission Type:** Research-in-Progress  

**Session-Board Number:** 1-044  

**Poster Title:** Establishment of a pharmacist-managed heart failure medication management clinic in a veteran population  

**Primary Author:** Courtney Beindorf, Birmingham VA Medical Center, AL; **Email:** ceb0011@auburn.edu  

**Additional Author(s):**  
Mary Martin McGill  
Bridget Roop  

**Purpose:** The American Heart Association estimates that more than 1 million patients are hospitalized for a heart failure (HF) exacerbation annually, with readmission rates of 25% at 1 month and more than 50% at 6 months. Preventing readmission for HF has become a national priority. It has been found that a multi-disciplinary approach to management of HF improves clinical outcomes. Pharmacy and Cardiology at Birmingham VA Medical Center (BVAMC) have worked together to develop a service agreement establishing a pharmacist-managed heart failure medication management clinic in order to optimize heart failure therapy and reduce readmission rates.  

**Methods:** This study will be submitted to the Institutional Review Board for approval. An admission list will be run daily to identify potential HF admissions. Patients admitted with a HF exacerbation will be educated while inpatient and offered close follow-up in the HF medication management clinic. If agreeable, these patients will be called within 48 to 96 hours of discharge to re-educate, assess HF symptoms, and confirm compliance. They will then be scheduled into clinic within 7 to 10 days of discharge for medication management and followed-up with as appropriate.  

Readmission rates prior to establishment of the HF clinic, as well as 1, 3, and 6 months after clinic establishment will be determined. The following data will be collected in clinic and upon retrospective chart review: age, gender, vitals, ejection fraction, laboratory values, current medications, whether or not the patient was on guideline-directed treatment on enrollment into clinic, interventions made at clinic visits, and any readmission for heart failure within 6 months of clinic establishment.
The primary objective of this study is to determine the effect of participation in the newly established Clinical Pharmacy Cardiology Medication Management Clinic at BVAMC on heart failure readmission rates. As secondary endpoints we will evaluate interventions made and the impact of clinic participation on compliance, proportion of patients on guideline-recommended HF therapy, and HF symptoms.

Results: N/a

**Poster Title:** Supratherapeutic international normalized ratio (INR)? A retrospective chart review evaluating the potential interaction between azithromycin and warfarin

**Primary Author:** Charisma Caldwell, Birmingham VA Medical Center, AL; **Email:** charismak.caldwell@gmail.com

**Additional Author(s):**
Courtney Berg

**Purpose:** Current data shows that there is no known interaction between azithromycin and warfarin. According to the drug interaction study performed by Pfizer, the manufacturer of Zithromax®, there was no effect on the prothrombin time. Unlike other macrolides, azithromycin is less likely to cause drug interactions as it does not undergo hepatic metabolism. However, there have been case reports of supratherapeutic INRs associated with azithromycin in patients taking warfarin. The objective of this study is to determine if there is a true interaction between azithromycin and warfarin with potential to cause a supratherapeutic INR.

**Methods:** This study was submitted to the Institutional Review Board for approval. A retrospective chart review was conducted within a veteran population to identify those who were prescribed warfarin and azithromycin between August 2013 and August 2016. Patients considered to be clinically stable on warfarin (defined as having three consecutive therapeutic INRs) who had a concomitant short-term prescription for azithromycin were included in the study. Patients were excluded if they were receiving chronic azithromycin therapy, “new start” warfarin patients, and patient who did not have a therapeutic INR prior to azithromycin initiation. Patients meeting criteria were then evaluated to assess their azithromycin course and their stability on their warfarin regimen. Data recorded included patient demographics, warfarin dose, warfarin indication, azithromycin dose, azithromycin indication, duration of azithromycin therapy, contributing factors (vitamin k intake, alcohol intake, liver disease, liver function tests, and thyroid function tests), three months of INR levels prior to azithromycin initiation, one month of INR levels following azithromycin initiation, and the time frame between azithromycin initiation and subsequent INR. Primary outcome was incidence of supratherapeutic INR following azithromycin initiation. Secondary endpoints evaluated incidence of bleeding after azithromycin initiation and rate of hospitalization.
Results: This project is currently research-in-progress.

Conclusion: Data collection is currently ongoing and will be conveyed at the Southeastern Residency Conference.

Poster Title: Effects of academic detailing on the treatment of urinary tract infections in a veteran population

Primary Author: William Edwards, Birmingham VA Medical Center, AL; Email: wze0001@auburn.edu

Additional Author(s):
James Carr
Bridget Roop

Purpose: With urinary tract infections (UTI’s) being one of the most common infectious diseases in the United States, evidence-based antibiotic therapy is essential for proper UTI treatment, antimicrobial stewardship, and decreasing antibiotic-induced adverse effects. Patients are often treated inappropriately for asymptomatic bacteriuria as outpatients and often will be treated for extended durations with broad-spectrum, empiric antibiotic coverage. In the VA population, most patients are elderly males who are at higher risk of UTI’s when compared to younger males. Our study will evaluate the effects of provider education and use of a UTI treatment algorithm on UTI diagnosis and treatment of outpatients.

Methods: First, a retrospective analysis of outpatient urinary tract infection cases will be conducted. Specifically, we will be looking at the patient’s symptoms, urine culture data, antibiotic selection and duration of therapy. We will implement a urinary tract infection treatment algorithm along with physician education related to the guideline-recommended treatment of urinary tract infection. Following these interventions, a prospective analysis of urinary tract infection treatment regimens will be completed to compare differences in treatment before and after academic detailing. With these results, we will also evaluate treatment success and antibiotic selection.

Poster Title: Quality improvement project: usage of antipsychotic medications for the treatment of post-traumatic stress disorder (PTSD) in patients without severe mental illness

Primary Author: Jamie Chambers, Tuscaloosa VA Medical Center, AL; Email: jamie.chambers@va.gov

Additional Author(s):
Allison Marshall

Purpose: The purpose of this project is to identify and reduce the proportion of post-traumatic stress disorder (PTSD) patients without severe mental illness prescribed antipsychotics to PTSD patients not prescribed antipsychotics at the Tuscaloosa Veterans Affairs Medical Center to below the national average. The project will involve providing education to patients on the risks versus benefits of utilizing antipsychotics for the treatment of PTSD. It is our goal that through identification and education, providers will be encouraged to evaluate current patients who are prescribed an antipsychotic for PTSD to see if continued use of the medication is clinically warranted.

Methods: This study will be submitted to the Institutional Review Board for approval. The initial assessment will include obtaining a total number and list of actionable patients defined as having both a diagnosis of post-traumatic stress disorder (PTSD) without severe mental illness and an active medication order for an antipsychotic by utilizing the Real-Time Psychotropic Drug Safety Initiative (PDSI) dashboard and the computerized patient record system (CPRS). The project team will then educate providers on this initiative, the possible risks associated with antipsychotics, lack of supporting evidence of antipsychotics in PTSD, and alternative treatment options. An educational component highlighting the risks of using antipsychotics for treatment of PTSD will be implemented in the weekly pharmacist-led PTSD patient education groups. The final assessment will include obtaining an updated number of actionable patients monthly for four months following the completion of the provider education session and emailing the providers to determine if the additional education incited a change in local prescribing habits. The goal of this initiative is to determine whether or not this education can lower the percentage score of the Tuscaloosa Veterans Affairs Medical Center to below the national average on the PDSI dashboard.

**Poster Title:** Quality improvement project: Therapeutic drug monitoring of lithium  

**Primary Author:** Michelle Krichbaum, Tuscaloosa VA Medical Center, AL; **Email:** michelle.krichbaum@va.gov  

**Additional Author(s):**  
Kimberly Roberts  

**Purpose:** Lithium's narrow therapeutic range and adverse drug events secondary to toxicity can be severe and life-threatening. The Department of Veterans Affairs (VA) recently issued a national bulletin focused on the issue of lithium safety, specifically in regards to routine monitoring of lithium serum concentrations as recommended by the Veterans Affairs/Department of Defense (VA/DOD) Clinical Practice Guideline for Management of Bipolar Disorder in Adults. The purpose of this project is to review the Tuscaloosa VA’s adherence to the VA/DOD guidelines regarding lithium monitoring and to provide education to providers to improve the percentage of veterans receiving semiannual lithium lab draws.  

**Methods:** This study will be submitted to the Institutional Review Board for approval. An electronic list of patients (age 19 and older) in the outpatient setting who meet the inclusion criteria of having an active lithium prescription will be generated from the Office of Mental Health Operations (OMHO) dashboard as part of the Psychotropic Drug Safety Initiative (PDSI). This list of patients will be reviewed for dates of most recent lithium serum concentrations and any changes in lithium doses. A recommended date for next lab draw will be generated for provider information. Data will be recorded and maintained confidentially. The VA Adverse Drug Events Reporting System (ADERS) will also be reviewed for lithium related adverse drug events. The next step will be to communicate these findings at an educational session with providers. Lastly, a chart review of patients on lithium will be re-conducted approximately 3 months post provider education session to assess for improvements.

Poster Title: Comparison of insulin glargine versus insulin neutral protamine Hagedorn (NPH) on glycemic control and overall diabetic outcomes

Primary Author: Haley Ervin, Tuscaloosa Veterans Affairs Medical Center, AL; Email: haley.ervin@va.gov

Additional Author (s):
Allison Marshall

Purpose: The purpose of this project is to compare the effectiveness of insulin glargine vs. insulin neutral protamine Hagedorn (NPH) by assessing mean change in HgbA1C, fasting blood glucose changes, and hypoglycemic events. In addition overall diabetic outcomes will be assessed by comparing cardiovascular events, such as a myocardial infarction, in each group. The analyzed data will then be used to assess the clinical appropriateness of the long acting insulin consult currently being utilized at the Tuscaloosa VA Medical Center (TVAMC).

Methods: This project will be submitted to the Institutional Review Board for approval. This evaluation is a medication use evaluation which will be performed by conducting a retrospective chart review. Using predetermined criteria (delineated in protocol), the patients whom are receiving either insulin glargine or NPH from January 1st 2016 to June 1st 2016 will be identified and their charts evaluated. The charts will be reviewed for data including: HbgA1c, fasting blood glucose levels, hypoglycemic events (blood glucose < 70 or documented signs or symptoms of hypoglycemia in a note), total daily doses of either NPH or insulin glargine, other antidiabetic medications, and heart attack. This data will be assessed to determine any differences in glycemic control or diabetic outcomes between the two groups. The findings of this project could potentially streamline the process for obtaining insulin glargine and promote use of a clinically effective insulin product, when clinically indicated.

Poster Title: Primary care provider-initiated screening of Veterans at high risk for hypoglycemia at Central Arkansas Veterans Healthcare System (CAVHS)

Primary Author: Kate O’Connor, Central Arkansas Veterans Healthcare System, AR; Email: katewoconnor@gmail.com

Additional Author (s):
Tabitha King
Bhavika Patel

Purpose: The Veterans Healthcare Administration first proposed the Hypoglycemia Safety Initiative in 2014 to target hypoglycemia safety via a patient-centered approach. Evidence suggests that hypoglycemia is often the result of intensive blood glucose control, and specific patient factors have been identified as increasing risk of hypoglycemia. Currently at the Central Arkansas Veterans Healthcare System (CAVHS), hypoglycemia is managed via a reactive rather than proactive approach. The purpose of this study is to improve and prevent hypoglycemia in the primary care setting in Veterans with diabetes mellitus who have documented risk factors for hypoglycemia.

Methods: This quality improvement project is a retrospective cohort study. Patients with diabetes mellitus who are currently enrolled in primary care services at CAVHS will be identified from the electronic medical record. Additional inclusion criteria are hemoglobin A1c (HbA1c) less than 7 percent in the last 18 months; an active prescription for insulin or a sulfonylurea; and either age greater than or equal to 75 years of age, a diagnosis of dementia or cognitive impairment in last 2 years, or serum creatinine greater than 1.7 milligram per deciliter in last 18 months. A list of identified patients will be provided to six designated primary care providers. The primary care provider will contact the patient, perform a hypoglycemia screen using a list of predetermined questions, and modify antihyperglycemic therapy as appropriate. Patient follow-up will be performed 1 month after the intervention using the same questionnaire. The primary outcome is the incidence of hypoglycemic events after the implementation of a provider-initiated hypoglycemia screening. Secondary outcomes include identification of patient-specific HbA1c goal, use of hyperglycemic therapy, and medication modifications. Diagnoses will be determined using ICD-9 and ICD-10 codes. Outcomes will be analyzed via
descriptive statistics. This study will be submitted to the facility’s Institutional Review Board for approval.

**Poster Title:** Evaluation of oral antineoplastic waste at Central Arkansas Veterans Healthcare System

**Primary Author:** Neelam Barot, Central Arkansas Veterans Healthcare System, AR; **Email:** nbarot12@gmail.com

**Additional Author (s):**
Heather Todd  
Sidney Keisner  
Rangaswamy Govindarajan

**Purpose:** Oral antineoplastic agents are notoriously expensive, and prudent inventory management is warranted. Observations reveal that antineoplastic agents are occasionally refilled just prior to reevaluation of the patient’s disease status and/or toxicity assessment leading to significant waste if therapy is discontinued or dose is changed. The purpose of this medication use evaluation (MUE) is to determine if oral antineoplastic agents are being filled within 10 days of planned restaging of disease and/or toxicity assessment which results in discontinuation of therapy or dose change.

**Methods:** The MUE will be a retrospective chart review of all patients who filled an oral antineoplastic agent from 1/1/2015 through 12/31/15. The project was approved by the MUE subcommittee at Central Arkansas Veterans Affairs Healthcare System (CAVHS). Data to be collected for each patient include the following: name of antineoplastic agent, reason for discontinuation or dose change. For patients whose therapy was discontinued or dose changed due to progression of disease or toxicity based on planned restaging evaluation or due to a planned assessment toxicity, the following data will be collected: diagnosis, date of last fill of oral antineoplastic agent, date of planned restaging evaluation or toxicity assessment, date of discontinuation or dose change of oral antineoplastic agent. If date of last fill is < 10 days before discontinuation/dose change, this instance will be counted as an opportunity to have prevented waste. If this issue is identified at CAVHS, methods to prevent this type of waste will be explored.

Poster Title: Evaluation of appropriateness of proton pump inhibitors continued at discharge from a Veterans Health Administration hospital

Primary Author: Britney Cothren, Central Arkansas Veterans Healthcare System, AR; Email: britney.cothren@va.gov

Additional Author(s):
Lisa Barnes

Purpose: Proton pump inhibitors (PPIs) are one of the most widely utilized medications in the United States healthcare system. A recent literature review revealed evidence that patients prescribed proton pump inhibitors during a hospital admission are often discharged on long term PPI therapy without a proper indication. Additionally, the growing concerns for adverse effects associated with chronic PPI therapy identify a need to limit the unnecessary use these medications. The purpose of this medication utilization evaluation is to assess appropriateness of continuation of proton pump inhibitors at discharge in a Veterans Health Administration hospital.

Methods: Patients who were discharged from Central Arkansas Veterans Healthcare System with an outpatient prescription for pantoprazole or omeprazole from January 1, 2015 to December 31, 2015 will be included in a retrospective medication use evaluation. Diagnoses will be gathered based upon International Classification of Diseases 9 and 10 codes to determine the presence of an indication for continued proton pump inhibitor therapy. Data obtained from the electronic medical record will be maintained confidentially without patient identifiers. Outcomes for this project include the number of patients discharged with a PPI prescription and the presence of an appropriate indication for continued PPI therapy.

**Poster Title:** Assessment of a pharmacist-run new patient clinic at a Veterans Health Administration hospital.

**Primary Author:** Kelsey Van Gorkom, Central Arkansas Veterans Healthcare System, AR; **Email:** kelsey.vangorkom@gmail.com

**Additional Author(s):**
David Dillinger
Richard Morris

**Purpose:** Access to care is a problem all across healthcare. Increasing access is a prime opportunity for pharmacists because of our extensive training in medication therapy, particularly in chronic disease state management, and experience in formulary management. A new patient intake clinic was implemented at our facility in June 2016 to increase access to care and ease the transition from non-VA to VA primary care for patients. The purpose of this study is to assess the impact and cost-savings of this new service.

**Methods:** This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients who have been contacted by the New Patient Clinic between June 16th, 2016 and March 31st, 2017. Data on encounters completed in the New Patient Clinic will be collected by the clinical application coordinator and reported confidentially to the primary author, who will conduct chart reviews to gather the remainder of the information. Access to the data will be limited to study investigators only. The following data will be collected using retrospective patient chart review: patient age, gender, number of medications at intake visit, number of Beers List medications at intake visit, medications changed to formulary options, dose adjustments made by pharmacists, medications discontinued, and Beers List medications discontinued. Percentages of medications converted to formulary, medications discontinued, Beers List medications discontinued, and dose adjustments made will be calculated. Cost savings from changing to formulary options and discontinuing medications will be calculated as projected annual cost-savings in dollars.

**Poster Title:** Mirtazapine and megestrol use for appetite stimulus in the older Veteran population

**Primary Author:** Megan Fenney, Central Arkansas Veterans Healthcare System, AR; Email: meganmfenney@gmail.com

**Additional Author(s):**
Lewis Krain
Cassandra Thomas

**Purpose:** Currently there is a lack of data and guidelines about the use of appetite stimulants in older adults with unintentional weight loss. At the Central Arkansas Veterans Healthcare System the most commonly prescribed appetite stimulants are mirtazapine and megestrol. Therefore, the objective of this study is to determine whether or not mirtazapine and megestrol lead to an increase in weight gain over a 4 and 12 week period in the Veteran population 65 years and older with unintentional weight loss.

**Methods:** This study will be conducted via retrospective chart review. Patients will be chosen based on being prescribed mirtazapine or megestrol due to unintentional weight loss. Those diagnosed with cancer, HIV/AIDS, end stage renal disease on dialysis, or receiving palliative care will be excluded. Weights will be collected at baseline, 4 weeks, and 12 weeks to determine if these medications are improving weights. Information pertaining to other methods previously tried, underlying causes, and side effects will also be collected. All data will be recorded without patient identifiers in order to maintain confidentiality.

Poster Title: Impact of serum procalcitonin monitoring on sepsis and pneumonia outcomes

Primary Author: Meredith Stefanik, Central Arkansas Veterans Healthcare System, AR; Email: meredith.stefanik@va.gov

Additional Author(s):
Britney Cothren
Barry Napier

Purpose: Procalcitonin, a biomarker of bacterial infection, has previously been shown to be beneficial in guiding antibiotic therapy in hospitalized patients. Studied most extensively in pneumonia or sepsis, procalcitonin is strongly correlated to the extent and severity of bacterial infection. The Central Arkansas Veterans Healthcare System began utilizing the serum procalcitonin assay in February 2016. The purpose of this project is to assess the appropriate utilization of procalcitonin assays obtained in patients with pneumonia or sepsis at our facility.

Methods: This retrospective chart review will include patients at least 18 years of age with a diagnosis of sepsis or pneumonia and more than one procalcitonin level from February 16, 2016 to August 16, 2016. Diagnoses will be determined based on the International Classification of Diseases 9 and 10 codes, and data will be extracted from the electronic medical record. Patients with less than 2 procalcitonin levels, death within 72 hours of admission, chronic antibiotic use, non-bacterial infections, and a diagnosis other than sepsis or pneumonia will be excluded. The following data will be collected: age, gender, length of stay, primary diagnosis, diagnostic criteria for pneumonia or sepsis, serum procalcitonin, and antibiotic use. Data obtained will be maintained confidentially without patient identifiers. Outcomes include the number of procalcitonin levels drawn, duration of antibiotics, number of antibiotic medications prescribed, de-escalation of therapy, cessation of therapy, and length of hospitalization for each patient. Outcomes will be analyzed using descriptive statistics. A cost savings analysis will also be conducted.

Poster Title: Evaluation on the appropriateness of benzodiazepine use amongst veterans in primary care

Primary Author: Misty McRae, Veterans Health Care System of the Ozarks, AR; Email: mmcrae2@harding.edu

Additional Author(s):
Candace Stacy
Amanda Chapman

Purpose: Benzodiazepines are among the most commonly prescribed of all medication, and this class is correlated with significant negative outcomes like physical dependence, abuse, and central nervous system depression. The objective of this project is to assess the appropriate usage of benzodiazepines in a primary care setting through documentation of approved indications, presence of contraindications, Posttraumatic Stress Disorder, usage in veterans age 65 years and older, concurrent opioid use, and utilization for greater than three months.

Methods: This study will be submitted to the Institutional Review Board for approval. A retrospective chart review of 200 outpatient veterans will be conducted to determine prescribing practices and appropriateness of benzodiazepine usage. The following data will be collected: patient’s gender, whether a benzodiazepine was prescribed or refilled at the primary care visit, any contraindications to benzodiazepine use, diagnosis of Posttraumatic Stress Disorder, concurrent use with opioids, and benzodiazepine use greater than three months. The following patients will not be included: receiving benzodiazepines in inpatient, acute care settings, mental health admissions during study period, or documented history of substance abuse. The data collected will be analyzed to identify the most common inappropriate prescribing habits in the outpatient primary care setting. Investigators will use the results to create and implement a multidisciplinary education initiative at the end of 2016 and the beginning of 2017.

Poster Title: Evaluating use of a deprescribing protocol and blister packaging for elder Native Americans at increased risk of non-adherence and poor outcomes due to polypharmacy

Primary Author: Joellen Friedman, Fort Defiance Indian Hospital, AZ; Email: joellen.friedman@fdihb.org

Additional Author(s):
Rebecca Wong
Ginger Turner
Tabitha Dillinger

Purpose: Care goals change as patients age. For elder patients, complex medication regimens are difficult to remain adherent to and may no longer be appropriate. Deprescribing protocols may be enacted when the provider and patient agree that a medication may be systematically removed from a drug regimen based on specific safety and efficacy factors. Adherence is also an issue for all patients on chronic medications, with about 50% adherence among elders. In order to simplify understanding medication regimens and create a visual reminder, blister packaging may play a role in increasing medication adherence among elder patients.

Methods: This project aims to establish the use of a deprescribing protocol for elder patients and provide adherence blister packaged medications to those that may benefit most. A pharmacist will perform a medication review at the referral of a primary care clinic provider for any elder patients over 65 years old. The care team of the provider, pharmacist, patient, and caregivers will agree upon a plan for safely removing inappropriate medications from the regimen. The pharmacist will follow up with the patient during the deprescribing protocol and monitor for adverse events. Patients will be offered medication refills in an adherence reminder blister package if they meet the following criteria: over 65 years old, five or more chronic medications, lack of full time aid or family care, and a history of nonadherence through chart evaluation. The use of blister packaging will be integrated into the outpatient pharmacy workflow. Patients on stable chronic medications and their caregivers will receive education on the use of the adherence blister package. To evaluate adherence, patients will return their used blister packages each month in exchange for their refills in order to calculate missed doses. Patients will also be followed for the duration of the study for hospital admissions and health
outcomes based on chronic conditions, such as changes from baseline in A1c or blood pressure, through chart reviews.

**Results:** NA

**Conclusion:** NA
Post Title: Retrospective analysis of adherence to aromatase-Inhibitor therapy and correlates to early discontinuation of therapy in American Indian and Alaska Native women with breast cancer

Primary Author: Brieanna Flores-Keown, Phoenix Indian Medical Center, AZ; Email: brieanna.flores-keown@ihs.gov

Additional Author(s):
Derek Teschler
Tim Mathews

Purpose: Although the incidence of breast cancer is lowest among American Indian and Alaska Native women compared to all other ethnic groups, the mortality rate in this ethnic group is highest per incident observed. Currently, there is limited data regarding adherence rates to aromatase inhibitor therapy among American Indian and Alaska Native women. The objective of this study is to determine how many breast cancer patients who initiated aromatase inhibitor therapy discontinued early and to evaluate adherence in patients who persisted with therapy. A secondary objective will be to identify possible risk factors which may correlate to early discontinuation of therapy.

Methods: This study will be submitted to the Institutional Review Board for approval. This will be a retrospective chart review from 1/1/2006 to 1/1/2016 using electronic medical records. All post-menopausal women that were newly prescribed aromatase inhibitors in the specified time frame and receiving care in the Phoenix Indian Medical Center (PIMC) oncology clinic will be reviewed. There will be no direct patient contact and no individual consents obtained. The data set for this study will be created with the assistance of a PIMC data specialist. All data will be stored in a password protected Excel spreadsheet with minimal patient identifiers. Data will be collected from electronic health records of the patients that meet the criteria for the chart review. Data will include demographic data, adverse drug reactions (ADR’s), descriptions of ADR’s, specific aromatase inhibitor used, total time on aromatase inhibitor therapy, time to discontinuation of therapy and additional therapy or steps taken to aid with side effects.

Poster Title: Assessment of real-world effectiveness and safety of glucagon-like peptide-1 receptor agonists for treatment of type 2 diabetes in a veteran population

Primary Author: Anthony Albert, Phoenix VA Health Care System, AZ; Email: anthony.albert@va.gov

Additional Author(s):
Lindsay Kittler
Niru Gupta

Purpose: The American Diabetes Association guidelines recognize metformin as the gold-standard for patients with type-2 diabetes due to effectiveness and safety profiles. If specific A1c targets are not achieved after at least 3 months of monotherapy, additional agent(s) may be added to patient’s regimens, including glucagon-like peptide-1 receptor agonists. Studies have shown a typical A1c reduction of 1 to 1.5 percent with the addition of these agents, however, formulary restrictions may limit use. The purpose of this study is to evaluate clinical outcomes in patients with diabetes with the addition of these agents at a veterans’ institution.

Methods: This study will be submitted to the Institutional Review Board for approval. A retrospective chart review will be completed at the Carl T. Hayden Veterans Affairs Medical Center. Males and females 18 years of age or older with a diagnosis of type 2 diabetes mellitus on at least 2 anti-hyperglycemic agents (including a glucagon-like peptide-1 receptor agonist) will be included in this analysis. Patients on a glucagon-like peptide-1 receptor agonist for at least three months of stable therapy in addition to pre-existing anti-hyperglycemic regimens will be evaluated. The primary outcome of this study is to assess a change in A1c with addition of glucagon-like peptide-1 receptor agonists in this patient population. A1c values will be evaluated at baseline, six months, and one year time intervals as available. Secondary outcomes will include changes in weight, rates of clinically significant adverse events (pancreatitis, medullary thyroid tumors) over the entire study period and drug discontinuation within three months of initiating therapy. A paired t-test will be used to analyze primary and secondary outcomes. Descriptive and inferential statistics will be used to evaluate demographic data.

Poster Title: Allopurinol dosing and the effect of uric acid levels to prevent acute gout flares

Primary Author: Courtney Corcoran, Phoenix VA Health Care System, AZ; Email: courtney.corcoran@va.gov

Additional Author(s):
Sarah Nguyen
Christopher Taylor
Dustin Whiteman

Purpose: Gout is a debilitating form of arthritis that is caused by crystallization of uric acid in the joints. The American College of Rheumatology guidelines recommend a reduction of serum uric acid (UA) to less than 6mg/dL to prevent relapse of gouty flares. The purpose of this retrospective study is to evaluate the treatment of gout within the Phoenix VA Healthcare System in order to determine if patients have been receiving optimal therapy.

Methods: This study is pending approval from the Institutional Review Board. Subjects will be pulled from a computerized patient record system which will identify those who have a clinical diagnosis of gout being started on allopurinol between January 1, 2012 and December 31, 2012. The following data will be collected: age, gender, ethnicity, allopurinol initiation dose, titrated allopurinol dose, uric acid levels at baseline/during titration/after 6 months, and number of recurring flares after starting urate lowering therapy. Subjects will not be reviewed if they were being treated for active cancer while using allopurinol, managed by non-VA providers, or prescribed xanthine oxidase inhibitors other than allopurinol. The primary endpoint of this study will be to compare the number of gouty flares that occur when serum uric acid levels are above or below 6 mg/dL.

Results: To be presented at the conclusion of the study.

Conclusion: To be presented at the conclusion of the study.

Poster Title: Evaluation of clinical outcomes using a procalcitonin-guided treatment protocol for acute COPD exacerbations

Primary Author: Bryant Wong, Phoenix VA Health Care System, AZ; Email: bcwong91@email.arizona.edu

Additional Author(s):
Jennifer Jiang
Christina Suguitan
Christopher Taylor

Purpose: Current guidelines recommend the use of antimicrobial agents in all patients admitted for chronic obstructive pulmonary disease (COPD) exacerbation. However, current literature reveals that many of these exacerbations may be non-bacterial in origin. A paucity of literature has demonstrated the utility of the biomarker procalcitonin in differentiating between bacterial and non-bacterial causes of COPD exacerbations. The purpose of this study is to evaluate a procalcitonin-guided treatment protocol in veteran subjects admitted with acute exacerbation of COPD.

Methods: This prospective, randomized, controlled study will be submitted to the institutional review board for approval. The electronic medical record will be used to identify subjects who have been admitted with acute COPD exacerbation. Subjects who consent to participate in the study will have a procalcitonin level determined by the laboratory using a point-of-care testing method. Subjects will then be randomized to one group receiving the standard of care based on current guidelines (including antimicrobials, systemic corticosteroids, and inhaled bronchodilators); the second group will receive care based on procalcitonin level. Subjects with procalcitonin levels less than 0.1 nanograms/milliliter will receive systemic corticosteroids and bronchodilators only. Subjects with procalcitonin levels greater than or equal to 0.1 nanograms/milliliter will receive standard care based on current guidelines, including antibiotics. Outcome measures will include utilization of the healthcare system for worsening or persistent COPD symptoms at 30 and 90 days after discharge, antibiotic-related adverse events, and overall utilization of antimicrobials.

Poster Title: Short and long term effects of clinical pharmacy management on type 2 diabetes treatment outcomes in an ambulatory care setting

Primary Author: Brandon Ladd, Phoenix VA Healthcare System, AZ; Email: merrillladd90@yahoo.com

Additional Author(s):
Stephanie Knecht
Courtney Pawula
Shannon Mentzel
Shamama Burney

Purpose: In 2012 uncontrolled type 2 diabetes mellitus (DM) affected 27.85 million people (8.9%) in the United States population alone. Poorly controlled type 2 DM puts patients at risk for cardiovascular disease related deaths, increased stroke occurrence, nephrotic deterioration, and increased risk of limb amputations. Studies have shown that uncontrolled type 2 DM can be managed well with interventions from pharmacy based ambulatory care clinics. This research project aims to demonstrate the long-term effects that ambulatory care pharmacy interventions have on the maintenance of patient hemoglobin A1C goals after discharge from a pharmacy clinic.

Methods: This study will be submitted to the Institutional Review Board for approval and is a retrospective chart review. The primary objective of this study is to determine the median time it takes for patients in Pharmacy Patient Aligned Care Team (PACT) clinics to reach their provider specified A1C goals. The study will also measure the time that patients remain at A1C goals after discharge from Pharmacy PACT clinics and identify which patients are at target A1C goals 1-year post discharge from their pharmacy clinics. The electronic medical record system will identify patients who have had at least 2 Pharmacy PACT Therapy Management notes and who have uncontrolled type 2 DM defined as A1C > 8% at the index date. The following data will be collected: A1C (index date, date of discharge from the clinic, and 1 year from discharge date), age, gender, ethnicity, race, number of clinic visits, number of DM medications at the start and end of study period, date of first and last Pharmacy PACT Therapy Management note, and method by which patients were referred to pharmacy clinic (e.g. referral from provider,
primary care almanac). After the data is collected, descriptive statistics will be conducted to identify the significance of clinical interventions from index date to 1 year after discharge from Pharmacy PACT clinic.

Poster Title: Assessment of efficacy and safety of dipeptidyl peptidase 4 inhibitors and sodium-glucose cotransporter 2 inhibitors for treatment of type 2 diabetes in a veteran population

Primary Author: Olaide Aiyegbushi, Phoenix Veterans Affairs Health Care System, AZ; Email: olaide.aiyegbushi@va.gov

Additional Author(s):
Lindsay Kittler
Niru Gupta

Purpose: American Diabetes Association guidelines recognizes metformin as the gold-standard for type 2 diabetes patients due to efficacy and safety profiles. If specific A1c targets are not achieved after at least three months of monotherapy, additional agent(s) may be added to patient’s regimens, including dipeptidyl peptidase 4 inhibitors and sodium-glucose cotransporter 2 inhibitors. Studies have shown an A1c reduction of 0.5 to 1.1 percent with the addition of these agents, however, formulary restrictions limits use in many institutions. The purpose of this study is to evaluate clinical outcomes in diabetes patients with the addition of these agents at a veterans' institution.

Methods: This study will be submitted to the Institutional Review Board for approval. A retrospective chart review will be completed at the Carl T. Hayden Veterans Affairs Medical Center. Males and females 18 years of age or older with a diagnosis of type 2 diabetes mellitus on at least 1 anti-hyperglycemic agent will be included in this analysis. Patients on novel agents, defined as dipeptidyl peptidase 4 inhibitors or sodium-glucose cotransporter 2 inhibitors for at least three months of stable therapy in addition to pre-existing diabetic regimens will be evaluated. The primary outcome of this study is to assess a change in A1c with addition of novel agents in this patient population. A1c values will be measured at baseline, six months, and one year time intervals. Secondary outcomes will include changes in weight, rates of clinically significant adverse events (pancreatitis, admissions for diabetic ketoacidosis, changes in renal function, urinary tract infections/genital mycotic infections) intolerability, and drug discontinuation within three months of initiating therapy. A paired t-test will be used to analyze primary and secondary outcomes. Descriptive and inferential statistics will be used to evaluate demographic data.

Poster Title: Safety and effectiveness of very low low density lipoprotein (LDL) in a veteran population

Primary Author: Morgan Robertson, Southern Arizona VA Health Care System, AZ; Email: mmr1@email.arizona.edu

Additional Author (s):
Kendrick Murphy
Kristen Allison

Purpose: The 2013 ACC/AHA Guideline on the Treatment of Blood Cholesterol to Reduce Atherosclerotic Cardiovascular Risk in Adults advises clinicians to consider decreasing a statin dose if two consecutive values of low density lipoprotein (LDL) are less than 40 mg/dL, but do not provide further recommendations regarding initiation of statin therapy in these subjects. This retrospective chart review aims to determine the safety and effectiveness of statin use in veterans with an LDL less than 40 mg/dL.

Methods: Veterans with at least four LDL levels less than 40 mg/dL at the Southern Arizona VA Health Care System (SAVAHCS) between January 1, 2000 and September 1, 2011 will be evaluated. The primary outcome will be a composite of cardiovascular (CV) related death, myocardial infarction (MI), and cerebrovascular accidents (CVA). The primary outcome will be compared between statin and non-statin users with chi-square analysis. Secondary outcomes will include time to first event (CV related death, MI or CVA), death from any cause, hospital admissions for unstable angina, incidence of rhabdomyolysis, and adverse drug reactions to statins.

Poster Title: Perioperative bridging in atrial fibrillation subjects on concomitant warfarin therapy

Primary Author: Elizabeth Jing, Southern Arizona VA Health Care System, AZ; Email: elizabeth.jing@va.gov

Additional Author(s):
Jonathan Merchen

Purpose: Much of the recent literature on bridging in atrial fibrillation patients focuses on patients with low to moderate risk of stroke. In these studies, bridging was found to cause more major bleeding with no additional benefits compared to no bridging. Nonetheless, the 2012 CHEST guideline recommends bridging atrial fibrillation patients receiving temporary warfarin interruption if the patient is at high risk for stroke. As such, current practice at many hospitals reflected that recommendation. This study aims to assess the safety and efficacy of bridging in high risk atrial fibrillation patients requiring temporary warfarin interruption.

Methods: This is a retrospective study analyzing the electronic health record of patients who received their care at the Southern Arizona VA Healthcare System between October 1999 and August 2016. Subjects were identified based on concomitant International Classification of Diseases Codes for either a stroke or transient ischemic attack, history of warfarin use, and a history of inpatient surgical or procedural interventions. The efficacy and safety of bridging will be analyzed by comparing the frequency of bleeds and thrombus in subjects who were bridged versus not bridged. Statistical significance will be analyzed using Chi-Square tests.

Poster Title: Morphine use in patients with ST-elevation myocardial infarctions (STEMI) and non-ST-elevation myocardial infarctions (NSTEMI) undergoing percutaneous coronary interventions

Primary Author: Alicia Vu, Southern Arizona VA Health Care System, AZ; Email: alacoala@msn.com

Additional Author(s):
Mark DiGiacomo
Jonathan Merchen

Purpose: Morphine has been used as part of the initial management of patients with myocardial infarctions for many decades. However, recent studies suggest that morphine use may be associated with adverse outcomes in this patient population. In-vitro studies imply a potential drug-to-drug interaction between morphine and P2Y12 inhibitors that may render P2Y12 inhibitors less effective. The purpose of the study is to evaluate the outcomes of subjects diagnosed with myocardial infarction who were given morphine in addition to a P2Y12 inhibitor within 24 hours before undergoing percutaneous coronary intervention.

Methods: This is a retrospective one-year study that will focus on chart reviews of veterans age≥18 with ICD-9 and ICD-10 documented diagnoses of ST-elevation myocardial infarction (STEMI) or non-ST-elevation myocardial infarction (NSTEMI) who underwent percutaneous coronary interventions and received a P2Y12 inhibitor within 24 hours prior to the procedure. Subjects will be divided into two cohorts based on whether or not they received morphine in addition to the P2Y12 inhibitor. They will be followed for 30 days from the day of their procedure. The following baseline data will be collected: age, gender, cardiovascular risk factors, use of heparin, aspirin, nitroglycerin, or beta blockers during hospitalization, outpatient morphine prescription within last 30 days, and ventricular assist device use during percutaneous coronary intervention. Cardiology, medicine, and primary care progress notes will be reviewed to determine if any of the following adverse outcomes occurred during the 30-day follow up period: death, post-admission myocardial infarction, cardiogenic shock, new onset heart failure, or a composite outcome of death or myocardial infarction.

**Poster Title:** Assessing safety of dual alpha-blockers in PTSD

**Primary Author:** Trang Nguyen, Southern Arizona VA Health Care System, AZ; **Email:** trang.nguyen.12691@gmail.com

**Additional Author(s):**
Kristyn Straw-Wilson

**Purpose:** Prazosin is a centrally active alpha1-blocker that works to counteract the excessive brain noradrenergic activity reported in posttraumatic stress disorder (PTSD). Another condition that is a concern for this aging veteran population is benign prostatic hyperplasia (BPH), for which the primary treatment is an alpha1-blocker, such as doxazosin, terazosin, alfuzosin, or tamsulosin. Studies have not been conducted to determine the safety of prescribing prazosin and another alpha1-blocker when treating veterans with PTSD and BPH. This retrospective study will evaluate the safety and tolerability of prazosin and another α-blocker in the treatment of PTSD and BPH.

**Methods:** This study will be submitted to the Institutional Review Board for approval. The electronic medical record will identify male Veterans diagnosed with PTSD and BPH at the Southern Arizona VA Health Care System (SAVAHCS) who were prescribed prazosin and another alpha1-blocker concurrently at any time between August 1, 2010 to August 1, 2015. The following data will be collected: age at the time of initiation of overlap of therapy, indication for each alpha1-blocker, if the patient has hypertension, number of antihypertensive medications, and reason for discontinuation if applicable. Provider documentation will be reviewed to determine reasons for discontinuation. All data will be recorded without patient identifiers and maintained confidentially.

**Poster Title:** Evaluation of the effectiveness and safety of pharmacological intervention versus no pharmacological intervention for the treatment of delirium in hospitalized veterans

**Primary Author:** Krista Noll, Southern Arizona VA Health Care System, AZ; **Email:** krista.noll2@va.gov

**Additional Author(s):**
Jeannie Lee
Jonathan Merchen

**Purpose:** Delirium is a prevalent complication that occurs in up to 80 percent of hospitalized patients and can result in negative outcomes including increased mortality. Both pharmacological and nonpharmacological interventions have been used to reduce severity and duration of delirium. Antipsychotics have been used for delirium treatment in hospitalized patients, and recent evidence has shown that melatonin may be an effective agent too. However, there is inconclusive evidence among studies evaluating these agents and no general consensus in guiding therapy. This study aims to evaluate the effectiveness and safety of pharmacological intervention versus no pharmacologic intervention for hospitalized veterans with delirium.

**Methods:** A retrospective review of up to 500 charts will be conducted to evaluate the use of antipsychotics (quetiapine, olanzapine, risperidone, aripiprazole, haloperidol) and/or melatonin for the treatment of delirium in hospitalized veterans aged 18 years or older from October 1, 1998 to August 1, 2016. Veterans will be excluded if they had an outpatient prescription for an antipsychotic or melatonin in the 90 days prior to hospital admission. Length of hospital stay and length of intensive care unit (ICU) stay (if applicable) will be used to evaluate the effectiveness of pharmacological treatment in these veterans. Other variables for collection include delirium risk factors, treatment factors, and adverse effects.

**Results:** N/A

**Conclusion:** N/A
**Submission Category:** General Clinical Practice

**Poster Title:** Twice Daily Lisinopril in Chronic Kidney Disease (TDL in CKD Trial)  
**Primary Author:** Dezranique Stansberry, Southern Arizona VA Health Care System, AZ; **Email:** dezranique.stansberry@yahoo.com  

**Additional Author(s):**  
Dory Hardy  
Ashley Tritz  

**Purpose:** Evidence-based treatment guidelines recommend angiotensin converting enzyme inhibitors in chronic kidney disease (CKD) to preserve renal function and delay the progression of end organ damage. Lisinopril is traditionally dosed once daily despite its documented 12 hour half-life. Based on its pharmacokinetics, it may be reasonable to dose twice daily to achieve optimal results. This study primarily aims to demonstrate twice daily lisinopril reduces the number of patients whose serum creatinine doubles over a four year period. In a retrospective, cohort study, adult Veterans with CKD Stage II-IV, documented serum creatinine and new prescription for lisinopril will be randomized for review.  

**Methods:** A database search will be performed to identify subjects with new outpatient lisinopril prescriptions at Southern Arizona VA Health Care System between January 2001 and January 2011. An estimated 180 patients will be included in the study. Patients will be divided into two groups: one group which received once daily dosing (n = 90), and another group received twice daily dosing (n = 90). The serum creatinine (SCr) at baseline and four years later will be recorded and analyzed to determine if doubling occurred. Other outcomes to be measured if available include change in estimated glomerular filtration rate (eGFR), change in urine albumin-creatinine ratio (UACR), need for hemodialysis and reported adverse drug reactions (ADRs). It is hypothesized that twice daily lisinopril dosing will reduce the number of subjects whose SCr doubles over four years.

Poster Title: Incidence of venous thromboembolism in surgical oncology patients

Primary Author: Brian Do, Southern Arizona VA Health Care System, AZ; Email: bcd0411@gmail.com

Additional Author(s):
Russell Crawford
Megan Banaszynski

Purpose: Oncology patients undergoing abdominal or pelvic surgeries are at high-risk of developing postoperative venous thromboembolism (VTE). Current guidelines published by the American Society of Clinical Oncology (ASCO), National Comprehensive Cancer Network (NCCN), and American College of Chest Physicians (ACCP) recommend at least 4 weeks of pharmacologic thromboprophylaxis postoperatively in high-risk oncology patients. The purpose of this study was to assess the incidence of VTE in high-risk surgical oncology patients at a Veterans Affairs institution.

Methods: The institutional review board approved this retrospective study. Electronic medical records were utilized to identify oncology patients aged 18 to 89 years old undergoing general or urologic surgeries from June 1, 2013 to June 30, 2015. The primary objective was the incidence of VTE up to 30 days postoperatively in patients receiving optimal (OT) (4 weeks of anticoagulation if no contraindications) versus suboptimal (ST) thromboprophylaxis. Secondary objectives included incidence of early (days 0 to 7) and late (days 8 to 30) postoperative VTE, severity of VTE, and hematologic toxicities associated with VTE prophylaxis.

Results: A total of 167 patients were assessed (136 patients in the ST group and 31 patients in the OT group). There were 4 (2.9 percent) and 1 (3.2 percent) VTEs in the ST and OT groups, respectively (OR = 0.10; 95 percent CI, negative 2.13 to 2.32; P greater than 0.05). All VTEs occurred during the late postoperative period. In the ST group, 3 patients had an uncomplicated pulmonary embolism (PE) or deep venous thromboembolism and 1 patient died due to thromboembolic complications. In the OT group, 1 patient had an uncomplicated PE. There were no significant differences in postoperative bleeding (11.4 percent versus 14.4
percent) or thrombocytopenia (45.7 percent versus 47.4 percent) in patients receiving pharmacologic versus non-pharmacologic thromboprophylaxis.

**Conclusion:** Provision of optimal thromboprophylaxis was low for high-risk surgical oncology patients; however this was not associated with an increase in VTEs. Use of pharmacologic thromboprophylaxis did not increase rates of bleeding or thrombocytopenia. Education is needed to increase compliance with guideline recommendations for postoperative thromboprophylaxis in high-risk surgical oncology patients at our institution.

Poster Title: Therapy sequencing and its impact on clinical outcomes in castrate resistant prostate cancer

Primary Author: Eric Ly, Southern Arizona VA Health Care System, AZ; Email: ely@email.arizona.edu

Additional Author (s):
Megan Banaszynski
Russell Crawford

Purpose: Treatment of castrate resistant prostate cancer has evolved over recent years with the introduction of several new therapeutic agents, including enzalutamide and abiraterone. This study is aimed to examine the clinical outcomes of different sequences of castrate resistant prostate cancer treatment and to elucidate whether there is an optimal sequence in which to give the first line agents.

Methods: The study will be submitted to the Institutional Review Board for approval. The study will be conducted as a retrospective chart review spanning from January 1, 2011 to July 1, 2016. Veterans who are identified as at least 18 years old, with an ICD-9 or 10 code documented for prostate cancer diagnosis, disease that was documented to be castrate resistant, and who had received at least one dose of either enzalutamide, abiraterone or docetaxel will be included in this study. The primary clinical outcome of the study is the duration of response to each treatment received. The secondary clinical outcome is the number of subjects who experienced a greater than or equal to fifty percent decline of prostate specific antigen from baseline as a result of treatment. Data to be collected includes patient age, gleason score, serum prostate specific antigen and testosterone level at baseline, nadir, and time of treatment discontinuation, reason for treatment discontinuation, and duration of response. Statistical analysis will consist of one-way ANOVA for the primary outcome and Fisher’s exact test for the secondary outcome.

Poster Title: Clinical characteristics of Clostridium difficile-associated diarrhea (CDAD) among the Veteran population.

Primary Author: Tyler Stuntz, Southern Arizona VA Health Care System (SAVAHCS), AZ; Email: stuntz@pharmacy.arizona.edu

Additional Author (s):
Jonathan Merchen
Linda Tristani

Purpose: This retrospective cohort study will evaluate correlation between positive Clostridium difficile (C. difficile) tests and type of antibiotic use, duration of antibiotic treatment, length of stay, documented penicillin allergy, and other factors that may increase the burden of C. difficile associated diarrhea (CDAD) for the Veterans at the Southern Arizona VA Health Care System (SAVAHCS).

Methods: Veterans admitted to the Southern Arizona VA Health Care System (SAVAHCS) who had a positive primary or secondary C. difficile polymerase chain reaction (PCR) result between July 31, 2015 and July 31, 2016 will be evaluated. The primary outcomes will be specific antimicrobial agent selected, duration of antimicrobial treatment, and whether diagnosis is a primary occurrence or recurrence. Secondary outcomes will include length of hospital stay, admission diagnosis, and presence of penicillin allergy recorded in the electronic health record.

**Session-Board Number:** 1-073

**Poster Title:** Implementation of a specialized pharmacy-based chronic non-cancer pain management clinic at an Indian Health Service facility in northern Arizona

**Primary Author:** Kimberly Frantz, Tuba City Regional Health Care Corporation, AZ; **Email:** kimberly.frantz@tchealth.org

**Additional Author (s):**
Mary Byrne

**Purpose:** Native Americans possess certain risk factors that make them more likely to experience chronic pain. Therefore, this population is particularly vulnerable to the adverse effects of opioid medications. Several Indian Health Service facilities that have established pharmacy-based chronic pain clinics have reported success in improving patient outcomes. The primary objective is to establish a specialized pharmacy-based chronic non-cancer pain (CNCP) management clinic in order to optimize pain management regimens and decrease the incidence of opioid-related adverse effects. Secondary objectives are to facilitate safe medication use, align prescribing practices with current guidelines, and support providers in the burden of managing CNCP.

**Methods:** Pharmacists who are credentialed providers and have completed more in-depth training in pain management will operate this clinic under a collaborative practice agreement with medical staff. Training includes a certificate program on the pathophysiology, assessment, and management of pain, continuing education hours related to pain management, and a number of supervised practice visits in this area.

Inclusion and exclusion criteria will be defined in order to identify CNCP patients at increased risk for opioid-related adverse effects. Patients who meet these criteria will be referred by their primary care physicians to the pharmacy-based CNCP management clinic. Clinic visits will consist of pharmacist assessment of pain control using validated assessment tools, along with pharmacist assessment of side effects, treatment goals, medication usage patterns, and adherence to the treatment plan. Utilizing standardized policies and protocols for pain management, the pharmacist will determine an appropriate pain management plan. This plan will be communicated with the primary care physician upon completion of each visit.
This study will measure outcomes as follows: patient pain scores, measures of functionality and goals as defined by the patient, and patient and provider satisfaction surveys. Although this study is exempt from IRB review, the Pharmacy and Therapeutics Committee, Medical Executive Committee, and Tuba City Regional Health Care Corporation Governing Board will review it prior to implementation.

Poster Title: Multidisciplinary Heart Failure Clinic in a small, rural hospital

Primary Author: Kristen Parker, Whiteriver Indian Hospital, AZ; Email: kristen.parker@ihs.gov

Additional Author(s):
Eun Jeon
Rowdy Atkinson
Matthew Rydberg

Purpose: Heart failure (HF) is a complex clinical syndrome which accounts for significant morbidity, mortality and negatively impacts quality of life. Prevalence of HF among Native Americans ages 60-79 is approximately 1.8 times higher than the general United States population. The objective of this project is to improve patient care by providing greater accessibility and continuity of care through HF disease management services. Studies show HF management programs effectively increase use of recommended medications, reduce hospitalizations and improve patient quality of life. In this multidisciplinary clinic, services will focus on medication management, patient education for self-management and coordination of care.

Methods: Patients who have previous or new HF diagnosis from September 2014 through September 2016 will be identified through the electronic health record. Chart reviews of these patients will be performed to determine the percent of patients on target medication therapy, mortality rate and number of HF-related emergency room visits and hospitalizations before implementation of the clinic. The multidisciplinary HF clinic team will include the PGY1 pharmacy resident, a pharmacist, an internal medicine physician and a cardiologist. Patients will be referred by their primary care providers or cardiologist to the HF clinic for disease management. This will include titration of medications to recommended target doses per current 2013 American College of Cardiology Foundation/American Heart Association guidelines following an evidence-based protocol. Upon admission to the clinic, patients will complete an initial HF functional assessment and quality of life (QOL) questionnaire which will be repeated after 3-6 months in the clinic. Primary outcomes measured will include percent of patients receiving recommended medications and percent of patients at target doses of medications. Secondary outcomes will include all-cause mortality rate, rate of HF-related
emergency room visits or hospitalizations, percent of patients with documented echocardiogram in the past year, change in patient functional status in heart failure by New York Heart Association Class and change in QOL assessment.

Poster Title: Evaluation of energy drink consumption on electrocardiographic, vascular, and hemodynamic parameters in young healthy volunteers: A randomized, double blind, controlled, clinical trial

Primary Author: Sarah Kelly, David Grant Medical Center, CA; Email: sarahekelly3@gmail.com

Additional Author (s):
Sachin Shah
Tracey McGaughey
Joseph Sky

Purpose: Energy drinks have been linked to emergency room visits and over 30 deaths. A large number of adverse events have been cardiovascular in nature. The purpose of this study is to determine if caffeinated energy drinks change the QTc interval, blood clotting time, and central and peripheral systolic blood pressures compared to an active and placebo control.

Methods: The Institutional Review board approved this randomized, double blind, active-controlled, crossover study. Fifty healthy volunteers aged 18-40 who provide informed consent will be enrolled. Volunteers with any clinically significant medical conditions including pregnancy or breastfeeding will be excluded. In addition, patients who have blood pressure greater than 140/90, hypokalemia, liver abnormalities, or take a medication more than twice weekly will be excluded. A baseline electrocardiogram (ECG), serum potassium level, liver function tests, and peripheral blood pressure will be obtained to make sure no underlying medical conditions exist. On three separate days (days 1, 8, 15), either the energy drink, active control (moxifloxacin) drink, or placebo control drink will be given. People who meet inclusion and exclusion criteria will be instructed to fast twelve hours and abstain from caffeinated substances for 48 hours before day one, day eight, and day fifteen when data will be collected. At each session, baseline ECG and peripheral and central blood pressures will be obtained as well as at hours 1, 2, 4, and 6 after consuming the study drink. Clotting time will be analyzed at baseline and two hours after drink consumption. Data will be analyzed using a repeated measures Analysis of Variance (ANOVA) with Bonferroni post-hoc analysis if needed.

Poster Title: Impact of Combination Ranolazine and Class III Antiarrhythmic Use on ECG Parameters

Primary Author: Danielle Pender, David Grant United States Air Force Medical Center, CA; Email: dpenderpharmed@gmail.com

Additional Author(s):

Purpose: Ranolazine is an antianginal with properties of an antiarrhythmic agent. Ranolazine prolongs the QT interval by 6msec, making it controversial to use in conjunction with other QT prolonging agents. However, recent studies have indicated that ranolazine in combination with a class III antiarrhythmic may lead to better arrhythmia control. This may be possible as the combination does not significantly impact transmural dispersion of repolarization (TDR) which is a better indicator of the risk of developing life threatening arrhythmias. This study will assess TDR in patients taking ranolazine plus a class III antiarrhythmic.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients from 2005-2015 who have taken ranolazine plus a class III antiarrhythmic (amiodarone, dronedarone, dofetilide, sotalol) concomitantly for at least 90 days. The primary endpoints will be the corrected QT interval and TDR before and after combination therapy. The following data will be collected: patient age, gender, ethnicity, current medications, and past medical history. A 12-lead electrocardiogram (EKG) will be collected for each patient, one from no more than 6 months before and one at least 90 days after concomitant therapy initiation. EKGs will be used to determine the corrected QT interval and the TDR before and after combination therapy. Hand measurement of the QT and Tpeak to Tend (Tp–Te) interval will be performed from usable V5 leads using the tangent methodology. When available, three continuous V5 leads will be measured using the digital calipers in Microsoft Adobe Acrobat® at 800% magnification. Rehospitalization 1 year after the start of the combination will be assessed. A paired students t-test comparing all endpoints before and after combination therapy will be performed with a p-value less than 0.05 considered significant.

Poster Title: Assessment of unrestricted carbapenem use at an academic medical center

Primary Author: Collin Yu, Riverside University Health System, CA; Email: collin.yu@ruhealth.org

Additional Author(s):
Nikita Patel
Jenny Ly
Pablo Rosete
Made Sutjita

Purpose: Antimicrobial stewardship programs (ASPs) promote the judicious use of antimicrobials in order to improve patient outcomes, minimize patient toxicities, eliminate unnecessary costs and minimize the emergence of antimicrobial resistance. A part of the ASP strategy is to restrict broad-spectrum antibiotics to Infectious Diseases (ID) specialists via pre-authorization. Currently, the use of carbapenems at the Riverside University Health System (RUHS) is not restricted to the ID service due to resource limitations. The purpose of this study is to evaluate the unrestricted use of the carbapenem antibiotic class at RUHS and assess the appropriateness of indication and duration of therapy.

Methods: Appropriate indications and durations of therapy for doripenem, ertapenem, imipenem and meropenem were collaboratively defined by the ID physician and ID pharmacist. Structured query of electronic medical records will identify patients who were at least 18 years of age and received a carbapenem during a six-month study period. Chart reviews of these patients will be conducted to determine the appropriate indication and duration of carbapenem use, and assess physician prescribing patterns of these unrestricted, broad-spectrum antibiotics. Data collection includes patient demographics, patient clinical status, physician status, unit of service, microbiology sensitivities, medication therapies, adverse drug effects and clinical outcomes. Proportional statistics will describe the results of the chart review. Recommendations and educational initiatives will be developed from these findings to advance ASP initiatives.

Poster Title: Evaluating the impact of pharmacists on inpatient patient aligned care teams (iPACT) at the San Francisco Veteran Affairs Health Care System (SFVAHCS)

Primary Author: Jin Chae, San Francisco Veterans Affairs Health Care System, CA; Email: hjinchaegmail.com

Additional Author (s):
Sharya Bourdet

Purpose: The purpose of this quality improvement (QI) project is to evaluate the impact of Inpatient Patient Aligned Care Team (iPACT) structure on methods of communication and discharge flow as related to medication ordering and pharmacy processing. This project will also aim to describe the number and type of interventions documented by team-based clinical pharmacists, to measure the estimated cost-avoidance per pharmacist intervention, and to illustrate team members’ perceptions of communication, team structure, and pharmacy services.

Methods: The quality improvement project will describe three measures of pharmacy services including communication, interventions, and discharge flow on both traditional and patient aligned medicine teams. Methods of communication will be illustrated by documenting incoming and outgoing phone calls, pages, and private messages experienced by clinical pharmacists in both team structures. The project will also describe the number and types of interventions recommended by clinical pharmacists and will be determined through retrospective chart reviews and by tally sheets provided to the clinical pharmacists to record informal recommendations. These recommendations will then be used to determine the estimated cost avoidance for clinical pharmacist interventions. In order to describe the clinical pharmacists’ role in discharge process and flow, the number of medication related addenda to discharge instructions, the number of discharge prescriptions processed by pharmacy, and the mean turn-around time for prescription processing will be measured. The project will also measure the time difference between various steps of discharge processes related to medication ordering and processing. Lastly, team-members will be asked to complete a questionnaire regarding their experiences to document perception of communication, team structure, and pharmacy services.

Poster Title: Impact of pharmacist safety review of patients with migraine diagnosis on chronic opioid therapy

Primary Author: Nicole Camela Tomboc, San Francisco Veterans Affairs Health Care System, CA;
Email: nicolecamela.tomboc@va.gov

Additional Author(s):
Sara Jacobs
Elizabeth Son

Purpose: Migraines diagnoses are common in primary care clinics and there are many non-pharmacological and pharmacological treatment options. Using opioids for treatment of migraines is controversial and can lead to medication overuse headache and overdose. Pharmacists can play an important role in migraine management by assessing the appropriateness of opioid use. Recommendations from pharmacists can lead to utilization of evidence-based, non-pharmacological and non-opioid alternatives to reduce opioid use. The objective of this project is to evaluate the impact of pharmacist recommendations for patients on opioid therapy with a migraine diagnosis based on recommendation implementation and improvement in safe opioid prescribing.

Methods: The electronic medical records will identify Veterans who are prescribed chronic opioid therapy, defined as a 90 day supply dispensed in the last 120 days, with a migraine diagnosis. A standardized note template will be developed to evaluate chronic opioid therapy in relation to migraine diagnosis. The following patient-specific data will be evaluated to assess for migraine therapy: current opioid regimen, morphine equivalent daily dose, date of last neurology visit, migraine-related VA emergency department within 12 months, and trials of non-opioid medications for migraine. The following patient-specific data will be evaluated to assess opioid safety: signed consent for long term opioids, pain clinical assessment within 6 months, state prescription drug monitoring query within 3 months, completed opioid overdose education and naloxone distribution training, date of last urine drug screen, and date of last electrocardiogram if on methadone. Recommendations will be made to primary care providers through the electronic medical record two to four weeks prior to each patient’s primary care visit. In addition, patients will be mailed two migraine education pamphlets from the American
Board of Internal Medicine’s Choosing Wisely campaign. Evaluation of providers’ implementation of pharmacist recommendations will be conducted through chart review at one month from the first primary care visit subsequent to initial pharmacist review. This project is IRB-exempt as it is a quality improvement initiative.

Poster Title: Treatment Effects on Serum Cholesterol in Veterans with Hepatitis C Successfully Treated With Direct-Acting Antiviral Agents

Primary Author: Jerick San Mateo, VA Central California Health Care System, CA; Email: jerick.smateo@gmail.com

Additional Author(s):

Purpose: Hepatitis C virus (HCV) is a blood borne pathogen that chronically infects an estimated 7.3% of the veteran population. Current guidelines recommend the use of direct-acting antiviral agents (DAAs) with or without ribavirin depending on the virus genotype, the presence of cirrhosis, and treatment history of the individual. Previous studies revealed that HCV infection stimulates the expression of low-density-lipoprotein (LDL) receptors, resulting in lower serum cholesterol levels during chronic infection. This project is intended to describe the changes seen in a small population of veterans who were successfully treated for HCV with DAAs.

Methods: In this retrospective chart review, eligible veterans were diagnosed with HCV and successfully treated with DAAs at the VA Central California Health Care System. The following data was collected: age, gender, HCV genotype, specific DAA regimen, and baseline and post treatment TC and LDL levels. Baseline and post treatment lipid panels were then compared. Results were stratified based on genotype and DAA regimen. No statistical analysis was performed, but rather descriptive statistics were employed in order to describe the effects on TC and LDL of successful treatment with HCV.

Results: Baseline and post treatment TC and LDL were compared for 47 veterans. After successful treatment, there was an overall average increase in TC and LDL of 20.8mg/dL and 20.9mg/dL, respectively. Genotype 1A virus was the most prevalent infection treated. This group showed an average increase in TC and LDL of 22.7mg/dL and 23.0mg/dL, respectively. All other genotypes combined showed an average increase of 18.9mg/dL and 17.8mg/dL in TC and LDL, respectively. Lastly, a large proportion of veterans were successfully treated with ledipasvir/sofosbuvir. This group showed an average increase in TC and LDL of 18.7mg/dL and 20.7mg/dL, respectively. Treatment with all other DAA regimens showed an average increase in TC and LDL of 25.7mg/dL and 21.3mg/dL, respectively.
Conclusion: Among veterans, a rise in TC and LDL after successful treatment was found regardless of the HCV genotype or DAA regimen. Monitoring of lipid levels after successful treatment of HCV is not a common practice. Our findings suggest patients who are successfully treated for HCV should be monitored for lipid changes, which could warrant lipid lowering therapy initiation.

Poster Title: Follow up on a conversion to Anti-Xa from aPTT for unfractionated heparin monitoring

Primary Author: Christopher Lam, VA Central California Health Care System (VACCHCS), CA; Email: chrislam629@gmail.com

Additional Author(s):

Purpose: Unfractionated heparin (UFH) indications include the prevention and treatment of venous thrombosis, pulmonary embolism, and the prevention of thrombosis following myocardial infarction and unstable angina. Heparin monitoring at our facility historically used aPTT, but in 2014 Veterans Affairs Central California Healthcare System (VACCHCS) shifted to using anti-factor Xa monitoring. The objective of this project is to ensure continued safe and effective UFH monitoring. This objective will be determined by incidence of bleeding episodes and venous thromboembolism (VTE) recurrence within 30 days of UFH use.

Methods: This is a retrospective chart review involving VACCHCS patients who were monitored using anti-Xa from January 1st, 2016 to September 29th, 2016. Inclusion criteria for the study includes patients on UFH therapy for greater than or equal to 12 hours for deep vein thrombus (DVT)/pulmonary embolism (PE) indications and age greater than or equal to 18 years. Exclusion criteria are as follows: patients with baseline elevated INR (greater than or equal to 1.5), hyperbilirubinemia (greater than 6.6 mg/dL), hypertriglyceridemia (greater than 360mg/dL), active malignancy, and heparin held for any length of time (excluding supratherapeutic value).

This chart review examined age, gender, hospital stay duration (days), UFH indication, UFH duration (days), major bleeding episodes, overt bleeding episodes, VTE recurrence in 30 days, and cardiovascular and all-cause mortality. Major bleeding episodes are any fatal bleeding or bleeding into a critical organ (e.g. retroperitoneal, intracranial, intraocular, or intraspinal). Overt bleeding is greater than or equal 2 g/dL drop in hemoglobin level or requiring 2 units of blood transfusion.
Results: Out of the 176 patients examined, twelve patient met inclusion criteria. There were eleven males and one female with average age of 73.6 years. Nine patients had a diagnosis of PE, while the others had a diagnosis of DVT. The average UFH duration was 3 days, and hospital duration was 8 days. There was no VTE reoccurrence in 30 days, major bleeding episodes, and overt bleeding episodes after initial use of UFH. No mortality was observed during the examination period.

Conclusion: Overall, the shift in UFH monitoring from aPTT to anti-Xa labs has not shown an associated increase in bleed risk or VTE recurrence in our patient population. A major limitation to this observational study is the small population size, as a majority of patients on UFH during the evaluation period were excluded based on indication or duration of use.

Submission Type: Evaluative Study

Session-Board Number: 1-082

Poster Title: The Impact of a Prescription Drug Monitoring Program (PDMP) at Veteran Affairs Greater Los Angeles Healthcare System (VAGLAHS)

Primary Author: Kevin Van, VA Greater Los Angeles Healthcare System, CA; Email: kev.van88@gmail.com

Additional Author(s):
Kirby Lim
Diep Seversen
Wayman Lee

Purpose: Controlled Substance Utilization Review and Evaluation System (CURES) is a prescription drug monitoring program (PDMP) that provides a resource at the Veteran Affairs Greater Los Angeles Healthcare System (VAGLAHS) to detect overlapping prescriptions. Urine drug screenings (UDS) may detect controlled and/or illegal medications. Patient informed consents are agreements for patients not to fill controlled medications at non-VA pharmacies. At VAGLAHS, the opioid safety initiative (OSI) requires documentation of CURES reports, UDS, and patient informed consents. The purpose of this project was to evaluate prescribing decisions of controlled medications at VAGLAHS based on CURES reports data, UDS, and patient informed consents.

Methods: This retrospective evaluation looked at outpatients with a documented CURES report at VAGLAHS within the enrollment period of January 1, 2014 to March 31, 2015. Patients who filled non-VA controlled medications within 12 months prior to their first CURES report in the enrollment period (considered “positive CURES”) were included for evaluation. The "Initial Visit" was the visit associated with the first CURES report, where we observed if overlapping prescriptions were found and UDS were available. If the physicians prescribed the medication, we also checked to see if a patient informed consent was documented. "Checkpoint #1" was the first follow-up visit within 6 months since the Initial Visit. The presence of a repeat CURES report and/or urine toxicology test was recorded. The continuation of the controlled medication based on these results was observed. "Checkpoint #2" was the second follow-up visit within 6 months from the Initial Visit. A repeat CURES report, UDS, and continuation of the controlled medication based on the results were observed. Finally, a
subgroup evaluation was completed for patients who specifically had overlapping prescriptions in the initial CURES report note. This subgroup was followed through at the Initial Visit, Checkpoint #1, and Checkpoint #2 and the findings were compared with the overall population results.

**Results:** 752 patients had a documented CURES report note. 328 (44%) patients had a "positive" CURES report showing non-VA medications were filled within the previous 12 months. In these 328 patients, 193 (59%) had overlapping prescriptions. 137 (42%) patients had medications continued with 80 (58%) having agreements not to fill the medications at non-VA pharmacies. At Checkpoint #1, 117 patients followed up and repeat CURES were documented in 24 (21%) patients with 8 (33%) showing a positive CURES report. At Checkpoint #2, 80 patients followed up and repeat CURES reports were documented in 13 (16%) patients with 4 (31%) showing a positive CURES report.

The subgroup evaluation included the 193 patients that were found to have overlapping prescriptions in their initial CURES report. 47 (24%) of these patients had their medications continued with 34 (72%) agreements not to fill at non-VA pharmacies documented. At Checkpoint #1, 10 (23%) patients had a repeat CURES report with 4 (40%) showing a positive CURES report. At Checkpoint #2, 3 (10%) had a repeat CURES report with 2 (67%) showing a positive CURES report. Other findings included that less than 30% of patients had available UDS at all encounters for the general and subgroup populations.

**Conclusion:** CURES reports aid in finding patients that obtain overlapping prescriptions. Many patients had overlapping prescriptions in VA and non-VA sources in the enrollment period. Patients with overlapping prescriptions were more likely to have their medications discontinued at the Initial Visit. Patient agreements to not fill at non-VA pharmacies were more likely completed for patients with overlapping prescriptions. Repeat CURES and UDS were not regularly completed at follow-up appointments. Limitations of this evaluation include not being able to enroll patients that did not have a properly documented CURES report and prescribers that didn't analyze if patients had overlapping prescriptions between different VAs. Future considerations include improving prescribing practice by increasing the use of CURES reports and UDS information. It may also be useful to run this evaluation in a more recent time period to see if the implication of the Opioid Safety Initiative (OSI) at VAGLAHS has improved.

**Poster Title:** Antipsychotic-induced gynecomastia without prolactin elevation

**Primary Author:** Roxana Lang, VA Loma Linda Healthcare System, CA; **Email:** roxanalang@email.arizona.edu

**Additional Author(s):**
Risa Ishino

**Purpose:** Typical antipsychotic agents and risperidone are known to increase the risk of developing gynecomastia, galactorrhea and/or amenorrhea by increasing prolactin levels. Gynecomastia with normal prolactin levels as a result of antipsychotic medication use has not been reported. This case series illustrates two possible cases of antipsychotic-induced gynecomastia in the absence of hyperprolactinemia. Mr. O is a 36-year-old male with a psychiatric history of recurrent major depressive disorder, amphetamine-induced psychotic disorder, and substance use disorder. He presented with gynecomastia on both sides of his chest starting 5-6 months ago when haloperidol was initiated to target auditory hallucinations. He denied galactorrhea but reported chest sensitivity to pressure. Haloperidol was effective in reducing the frequency of auditory hallucinations from daily to weekly. A prolactin level was then ordered and found to be within normal limits (13.6ng/mL). Of note, three months prior to the onset of gynecomastia he also resumed taking efavirenz/emtricitabine/tenofovir for Human Immunodeficiency Virus treatment. He was previously on other regimens containing efavirenz but were unsuccessful for years due to concomitant methamphetamine use. Although efavirenz has been associated with gynecomastia with a delayed onset of up to 5 to 15 months, Mr. O did not report gynecomastia or related symptoms with previous efavirenz trials in the years prior to this onset. He was subsequently switched to aripiprazole, an antipsychotic agent with less incidence of gynecomastia. The second case involves Mr. J who is a 40-year-old male with a psychiatric history including schizophrenia and substance abuse. His psychotic symptoms had been stable on risperidone long-acting injection for many years. His concomitant medication included hydrocodone/acetaminophen, which he was taking on a daily basis. He reported unilateral gynecomastia over the past few months and requested to be off risperidone. Prolactin level was checked, which came back normal (6.0 ng/mL). During this period of time, his weight remained relatively stable and even decreased around the time he initially noticed gynecomastia. A mammogram showed moderate to severe right gynecomastia with no
evidence of malignancy. Per his request, his dose of long-acting risperidone injection was decreased from 37.5mg to 25mg which resulted in no change of gynecomastia. Mr. J was then switched to paliperidone long-acting injection as he had a previous side effect from aripiprazole, which has the minimum effects on prolactin, and he needed to stay on a long-acting injectable formulation for a better medication adherence. He continued to report chest sensitivity and discomfort on paliperidone. After two months of paliperidone treatment, he experienced worsening of auditory hallucinations and was admitted for inpatient treatment. Upon discharge he was restarted on risperidone, as he was willing to tolerate gynecomastia from risperidone due to the benefit of better psychosis control.

Both cases represent gynecomastia with normal prolactin levels, which is not the proposed mechanism for antipsychotic induced gynecomastia. Concurrent medications in these cases are also the possible cause of gynecomastia but excluded as the cause. The history of substance abuse in both cases is of interest and may possibly contribute to the results. Further research is needed to support this clinical suspicion of a correlation between antipsychotics and gynecomastia without hyperprolactinemia.

**Poster Title:** Rates and reasons for discontinuation of prazosin among veterans with posttraumatic stress disorder at the Veterans Affairs Loma Linda Health Care System

**Primary Author:** Stephanie Lee, VA Loma Linda Healthcare System, CA; **Email:** stephlee@email.arizona.edu

**Additional Author (s):**
Risa Ishino

**Purpose:** Prazosin is frequently utilized to target nightmares and other sleep disturbances associated with posttraumatic stress disorder (PTSD). However, analysis of national prescription data has shown that prazosin treatment persistence beyond one year is very low, and many patients never reach the minimum target daily dose recommended by guidelines. A medication use evaluation will be conducted to characterize the rates and reasons for discontinuation of prazosin among veterans with PTSD at the facility in order to help determine whether or not a pharmacist-run prazosin titration clinic would be a valuable service to formally establish.

**Methods:** This study will be submitted to the Institutional Review Board for approval. A retrospective chart review will be performed to evaluate veterans diagnosed with PTSD who were initiated on prazosin at the facility between January 1, 2014 and December 31, 2014. The one-year time period following prazosin initiation will be assessed. Data collected will include reasons for discontinuation, timing of last fill before discontinuation, maximum daily dose achieved during treatment course, and medication possession ratio as a marker of adherence. Descriptive statistics will be used to analyze the collected data.

Poster Title: Analysis of the efficacy and safety of direct oral anticoagulants in patients of extremes of weight

Primary Author: Ashley Rogers, VA Northern California Health Care System, CA; Email: ashley.rogers6@va.gov

Additional Author(s):
Chandra Steenhoek
Sian Carr-Lopez
Richard Martinez
Julio Lopez

Purpose: The 2016 American College of Chest Physicians guidelines recommend the use of rivaroxaban, apixaban, and dabigatran over warfarin in patients with venous thromboembolism without cancer induced hypercoagulability. There is a lack of information in the safety and efficacy of the direct acting oral anticoagulants in certain patient populations including underweight and high body weight patients. Adjustment for weight is not currently recommend for oral anticoagulants. The objective of this study is to assess if body mass index is associated with differences in efficacy and safety of standard doses of direct acting oral anticoagulants.

Methods: This review will be submitted to the Northern California Veterans Affairs Research Services for approval as a Quality Improvement Project. Veterans treated with direct acting oral anticoagulants (apixaban, rivaroxaban, or dabigatran) within Veterans Affairs Northern California Health Care System between October 1, 2010 to September 1, 2016 will be identified using the electronic medical record. The following demographic data will be collected: age, weight, gender, renal function, direct acting oral anticoagulant prescribed and presence of malignancy. Veterans will be categorized by their body mass index category (BMI) as: underweight (BMI less than 18.5 percent), normal or overweight (BMI 18.5 to 29.9 percent), obese (BMI 30 to 39.9 percent), or morbidly obese (BMI over 40 percent). Veterans will then be evaluated for the incidence of primary and secondary safety and efficacy outcomes. Clinical outcomes of arterial thromboembolism (stroke, transient ischemic attack, systemic embolism) and major bleeding events will be assessed. Chart review will be used to determine the timeline of anticoagulant prescribing and thromboembolic or bleeding event. The co-primary outcomes

Poster Title: Population health approach to improve hepatitis C virus screening rates among veterans

Primary Author: Tatiana Sawyer, VA Northern California Health Care System, CA; Email: tatiana.sawyer@va.gov

Additional Author(s):
Robert Malmstrom
Karsten Duncan
Julio Lopez

Purpose: The Center for Disease Control and the United States Preventative Service Task Force recommend performing a one-time antibody test screening for hepatitis C virus (HCV) among all adults who were born between 1945-1965. Veterans in this birth cohort are six times more likely to have a positive antibody screen compared with those born in other years. The overall aim of the study is to describe how pharmacy-performed interventions affected HCV screening and treatment among veterans in this birth cohort within VA Northern California Health Care System (VANCHCS).

Methods: This retrospective review looked at VANCHCS patients born between 1945-1965 who did not have an HCV antibody screen performed as of July 1, 2016. Veterans with no assigned primary care provider and patients with no mailing addresses were excluded. Patients in the cohort were identified using a Veterans Integrated Service Network (VISN 21) Dashboard report. In this cohort, an automated program to order laboratory screening tests for HCV infection was created. All patients received a letter with the following components: (1) tailored information indicating patient meets birth cohort recommendation for HCV screening, (2) details about HCV risks and its health implications, (3) a dedicated pharmacist telephone number to ask questions or opt out. Our outcome of interest is to determine the effectiveness of the interventions in increasing HCV screening among veterans in the birth cohort. Increases in the number of screenings performed will be measured as a percent change from baseline. A secondary outcome is the seropositivity among the VANCHCS cohort who had testing performed due to the interventions, and its comparison to a nationally reported score. Another outcome is treatment initiation rate among those who tested positive for HCV infection.

Poster Title: Impact of non-adherence to guideline-directed medical therapy and the risk for arrhythmic events in Veterans with heart failure and implantable cardioverter-defibrillators

Primary Author: Jenny Le, VA San Diego Healthcare System, CA; Email: jennyle909@gmail.com

Additional Author(s): Felix Yam

Purpose: Treatment with guideline-directed medical therapy (GDMT) in heart failure with reduced ejection fraction (HFrEF) is recommended before and after primary prevention implantable cardioverter-defibrillator (ICD) placement. The impact of adherence to GDMT regimens on arrhythmic event rates post ICD implantation is unknown. The objective of this study is to determine the impact of non-adherence to GDMT on arrhythmic event rates post ICD implantation. We hypothesize that non-adherence to GDMT will be associated with a higher incidence of arrhythmic events.

Methods: This study will be submitted to the Institutional Review Board for approval. This will be a retrospective observational cohort study that includes Veterans with HFrEF and ICD placement. Data will be collected by chart review including prescription refill records and ICD device interrogation reports. Adherence to GDMT and arrhythmic events will be assessed in the first 12 months following ICD placement. Appropriate GDMT regimens will include the use of renin-angiotensin aldosterone inhibitors and beta-blockers. Adherence will be determined by evaluating the overall prescription rates for GDMT recommended therapy in eligible patients and evaluating patient adherence to GDMT regimens. Patient adherence to GDMT regimens will be determined using the proportion of days covered (PDC) method. Adherence to GDMT will be defined as having a PDC greater than or equal to 80 percent. Arrhythmic events will include the detection of ventricular tachycardia or ventricular fibrillation (VT/VF) during ICD interrogation. Additional demographic data including New York Heart Association (NYHA) functional class, baseline QRS interval, left bundle branch block, history of VT/VF, will be collected to evaluate risk factors associated with non-adherence to GDMT or increased arrhythmic events. Statistical analysis will include chi-square tests to compare the proportion of patients with an arrhythmic event among patients adherent and non-adherent to GDMT.
Multivariate regression analysis will be performed to determine risk factors associated with arrhythmic events or non-adherence to GDMT.

**Submission Type:** Evaluative Study  

**Session-Board Number:** 1-088  

**Poster Title:** Utilization Evaluation of Injectable Acetaminophen  

**Primary Author:** Karen Cham, VA San Diego Healthcare System, CA; **Email:** cham.karen@gmail.com  

**Additional Author(s):**  

**Purpose:** Injectable acetaminophen (APAP) is approved for mild to moderate pain, moderate to severe pain with adjunctive opioid analgesics, and fever reduction. VA National Criteria for Use (CFU) limits the use of the IV APAP to patients with acute postoperative pain, are unable to take analgesics orally, or are unlikely to have sufficient gastrointestinal absorption from oral APAP. Injectable APAP has been evaluated for up to 48 hours for postoperative pain; thus orders are limited to 48 hours. Due to a recent increase in cost, this evaluation is aimed to determine whether injectable APAP is utilized appropriately in the inpatient setting.  

**Methods:** Data was pulled from Vista for all patients who received injectable APAP from August 1, 2016 thru August 26, 2016. Barcode administration data was also collected to identify the start and stop time of injectable APAP administrations and the number of doses a patient received. To evaluate the appropriateness of injectable APAP use, a chart review was conducted on all patients who received one or more doses of injectable APAP. We evaluated the reason for injectable APAP, the patient’s dietary status at the time the medication was started, and other oral medications the patient was taking concurrently with injectable APAP.  

**Results:** Of the 79 patients that received injectable APAP over the month of August, the most common indication (94%) was management of postoperative pain. Injectable APAP orders were active on average for 1 day (range: 1 to 3 days) and the average number of doses a patient received was 4.8 (range: 1 to 14 doses). A total of 21 patients received a one-time dose of injectable APAP post procedure, while 58 patients received scheduled injectable APAP. A greater proportion of patients who received 1 or 2 doses of injectable APAP (95%) discontinued it once other oral medications were resumed compared to those patients who received 3 or more doses (15%). Throughout the period where injectable APAP was utilized, 46 patients (58%) were tolerating solid foods (regular, carb, and soft food diet). Among patients who were NPO for more than 48 hours, 3 patients had injectable APAP discontinued once they started on
oral medications. Of the 75 patients of patients who were NPO for less than 48 hours, 28 patients (37%) discontinued injectable APAP once oral medications were restarted while 47 patients (63%) received additional injectable APAP after restarting oral medications.

**Conclusion**: Results of this study show that the most common reason patients received injectable APAP was for postoperative pain management. Based on the National CFU, injectable APAP is indicated for postoperative pain management; however it would not be indicated for patients who tolerate oral analgesics. Over half of the patients reviewed received injectable APAP concurrently with other oral medications. This suggests that a large proportion of patients should be able to tolerate oral APAP. Furthermore, concurrent administration of injectable APAP with other oral medications occurred more frequently among those who had scheduled injectable APAP compared to those who received one to two doses following surgery. Based on these findings, it would be appropriate to limit orders of injectable APAP to a 1 time dose and/or limit the active orders to 24 hours. Limiting the duration of the active order will allow patients to be reevaluated if subsequent doses are requested.

Poster Title: Evaluation on the management of upper respiratory infections (URIs) in VA San Diego outpatient setting: a retrospective study

Primary Author: Charisma Maria Urbizondo, VA San Diego Healthcare System, CA; Email: charisma.urbizondo@gmail.com

Additional Author(s):

Purpose: Based on recent studies, antibiotics are often inappropriately utilized and overprescribed in the outpatient treatment of URIs, thus potentially leading to increased risk of resistance, adverse effects, and other complications. As a result, the CDC guidelines provide recommendations on the diagnosis, treatment, and overall outpatient management of URIs. The purpose of this research is to identify potential areas of intervention by assessing providers’ compliance of the CDC guidelines and the potential complications arising from inappropriate management of ARIs in the VA San Diego (VASD) primary care setting.

Methods: This study will be submitted to the Institutional Review Board for approval. This investigation will be performed as a localized single-center study modeled under the national medication use evaluation (MUE) of antibiotic utilization for URI treatment in participating Veterans Affairs facilities. A retrospective chart review will be performed using the Veteran Affairs electronic medical record (EMR) to categorize patients to the following URI diagnosis per the CDC guidelines: acute pharyngitis, acute bacterial rhinosinusitis, acute bronchitis, non-specified URI. The following data will be collected: signs/symptoms, diagnostic criteria used, primary URI diagnosis, antibiotics prescribed, duration of therapy, antibiotics’ documented adverse effects, outpatient return visits with acute respiratory infection (ARI) as primary diagnosis, ARI-related hospital admission post-encounter, patient’s comorbidities, clinical outcomes, and mortality (if applicable). Collected data will be analyzed using descriptive statistics. Each prescribed antibiotic with a documented URI will be evaluated for appropriateness based on the CDC guidelines.

Poster Title: Comparison of serotonergic antidepressants to bupropion mono- or combination therapy in comorbid PTSD and methamphetamine use disorder

Primary Author: Jamie Kneebusch, VA San Diego Healthcare System, CA; Email: jcsanders29@gmail.com

Additional Author(s):
Sanaz Farhadian
Jonathan Lacro

Purpose: Serotonergic antidepressants are a staple treatment of post-traumatic stress disorder (PTSD). Selective serotonin reuptake inhibitors are first-line treatment options, while bupropion is often reserved as a last-line agent due to the concern that its noradrenergic properties may worsen anxiety symptoms. Up to fifty percent of individuals with PTSD have reported ever using methamphetamine. Bupropion has been found effective in the treatment of mild methamphetamine use disorder. It is hypothesized that patients with comorbid PTSD and methamphetamine use disorder will respond better to medication regimens containing bupropion due to its noradrenergic and dopaminergic properties mimicking the neurochemicals associated with methamphetamine use.

Methods: This is an IRB approved study. Data will be collected via retrospective chart review from patients admitted to the VA San Diego ASPIRE Center from February 2014 through September 2016. The data to be collected include: patient age, gender, ethnicity, psychiatric diagnoses, engagement in trauma-focused therapy, psychotropic medication trials, PTSD Checklist (PCL) scores, time to relapse, and number of relapses. SQL software will be used to extract data from the chart regarding patient demographics. Chart review will be utilized for all remaining data points. All data will be collected without patient identifiers and stored securely in a password protected computer. The primary outcome to be assessed is difference in PCL scores between patients on serotonergic agents versus those on bupropion. Secondary outcomes to be assessed include rates of relapse and average time to relapse.

Poster Title: Impact of a pharmacist-run pain clinic on opioid use in Veterans with chronic nonmalignant pain

Primary Author: Jessica Cerullo, VA San Diego Healthcare System, CA; Email: cerulloja@vcu.edu

Additional Author(s):
Bailey Crandall
Jonathan Lacro

Purpose: Opioid medications are associated with dependence, tolerance, abuse, and the risk of accidental overdose. There has been a nationwide initiative by the Department of Veterans Affairs (VA) to reduce the use of opioid medications among Veterans. At the VA San Diego Healthcare System, patients may be referred to a pharmacist-run pain clinic where pharmacist duties include patient education, consultation with physicians for opioid weaning, and prescribing of non-opioid pain medications. The objective of this study is to analyze the impact of a pharmacist-run pain clinic on opioid use and utilization of healthcare resources by Veterans with chronic nonmalignant pain.

Methods: This retrospective chart review has been approved by our local Institutional Review Board. The electronic medical record system will identify adult patients with chronic nonmalignant pain who have been referred to the pharmacist-run pain clinic and who were on at least one opioid medication. The first visit to the pharmacist-run pain clinic will be designated as the index visit, and patients will be followed for one year. The following data will be collected from the index visit: age, gender, pain diagnosis, and mental health diagnosis. Daily morphine equivalent dose, adjuvant pain medications, adherence to universal precautions, abnormal urine drug screens, and consults placed for nonpharmacological pain management will be recorded at time of index visit, 6 months, and 12 months. Pain related emergency department visits, walk-in primary care visits, and hospitalizations in the 12 months before and after the index visit will be recorded. The number of pharmacist-run pain clinic visits and total contact time with a pain pharmacist will be documented. All data will be recorded without patient identifiers and maintained confidentially. Data will be analyzed to determine change in daily morphine equivalent dose over the study period, and patient characteristics associated
with successful opioid weaning will be identified. Pre- versus post-index 12 month data will be analyzed to determine differences in healthcare utilization.

**Poster Title:** Improving medication safety performance measures for lithium, valproic acid and carbamazepine at the San Francisco VA Health Care System

**Primary Author:** Annie Lee, VA San Francisco Health Care System, CA; Email: anniechoulee@gmail.com

**Additional Author (s):** Maureen Boro

**Purpose:** Every year, performance measure goals are set for the San Francisco VA Health Care System (SFVAHCS) to improve medication safety for veterans on high-risk medications. Three particular drugs of interest are lithium, valproic acid and carbamazepine as these drugs require timely drug monitoring in order to prevent adverse effects. The measures for these drugs aim to decrease the number of patients missing appropriate follow-up labs. The purpose of this quality improvement study is to identify barriers to and opportunities for obtaining follow-up labs for lithium, valproic acid and carbamazepine, and implement methods to meet and maintain medication safety goals.

**Methods:** This quality improvement study was submitted to the SFVAHCS Office of Research and Development for approval. The current performance measure goals for veterans on lithium are biannual lithium and annual serum creatinine levels; annual liver function test (LFT) and complete blood count (CBC) for veterans on valproic acid; and lastly, annual LFT, CBC and sodium levels for veterans on carbamazepine. A clinical dashboard will identify SFVAHCS veterans on lithium, valproic acid and carbamazepine who have not met the performance measures and therefore are not at goal. The computerized patient record system (CPRS) will be utilized to collect the following data: patient age, sex, medication of interest, duration on target medication, prescribing provider and service, time and value of the last two corresponding performance measure labs, any missed opportunities including clinical appointments or lab draws, and reasons for missing labs. After the reasons and barriers to missing labs are identified, the appropriate system protocol will be implemented in CPRS to improve timely drug monitoring and to meet and maintain performance measure goals long-term. Snapshots of performance measure scores will be collected throughout this study, including prior to system protocol implementation and three months after. A post-analysis of veterans missing follow-up...
labs at three months after system protocol implementation will be conducted to analyze the efficacy of the system protocol.

Poster Title: Evaluating the impact of a proton pump inhibitor de-escalation program in low-risk extended trial patients at the San Francisco Veterans Affairs Health Care System (SFVAHCS)

Primary Author: Andrea Nguyen, VA San Francisco Health Care System, CA; Email: andrea.l.nguyen@gmail.com

Additional Author(s):
Beth Keeney
Audrey Lee

Purpose: San Francisco Veterans Affairs Health Care System (SFVAHCS) utilizes a clinical dashboard to enhance medication safety monitoring for Veterans prescribed high risk medications. One feature of the dashboard allows users to view data for low-risk patients prescribed chronic proton pump inhibitor (PPI) therapy, defined as Veterans who have been on therapy for greater than one year. The purpose of this quality improvement project is to implement and evaluate a clinical pharmacist-driven PPI de-escalation program to decrease the percentage of low-risk extended PPI trial patients identified as actionable patients on the medication safety dashboard.

Methods: This quality improvement project was submitted to the Veterans Health Administration Office of Research and Development for approval. The medication safety dashboard low-risk extended PPI trial measure will be used to identify patients in whom to de-escalate therapy. The primary endpoint includes the percentage of low-risk extended PPI trial patients who are initiated on de-escalation therapy. Secondary endpoints consist of determination of the program’s direct total annualized drug cost savings and comparison of the low-risk extended chronic PPI performance measure scores before and after program implementation. The following data will be collected from the computerized patient record system: patient age, gender, height, weight, serum creatinine, creatinine clearance, hemoglobin, hematocrit, current medications, date of PPI initiation, indication for therapy, current dose, patient adherence, history of previous trial on histamine-2 antagonist therapy or step-down PPI therapy, and risk factors for gastrointestinal symptoms. Implementation of the de-escalation program will include an initial assessment note with recommendations for therapy de-escalation based upon a treatment algorithm recommended by the Veterans Affairs...
Integrated Service Network and clinical judgment. Evaluation of the program will include chart review one month after the next clinic appointment to determine if recommendations for de-escalation were accepted and implemented. The percentage of recommendations accepted by providers will be determined. The performance measure score for low-risk extended trial therapy will be collected for SFVAHCS before and after program implementation.

**Poster Title:** Outcomes of pharmacists in diabetes care at a veterans affairs healthcare system  
**Primary Author:** Francis Wang, Veterans Affairs Greater Los Angeles Healthcare System, CA;  
**Email:** francisyiwang@gmail.com  

**Additional Author (s):**  
Janette Lie  
Jennifer Kryskalla  
Diep Seversen  
Wayman Lee  

**Purpose:** The Department of Veterans Affairs serves 5.3 million patients annually. Close to one in five patients in the VA have diabetes. In many of the VA’s interdisciplinary team models, pharmacists are involved with managing diabetes as mid-level providers under a scope of practice agreement. Their scope of practice includes responsibilities such as developing and managing medication regimens, monitoring and evaluating pharmacotherapeutic effects, ordering and evaluating laboratory tests, requesting referrals to specialists, and providing disease education. The purpose of this study was to evaluate the clinical and economic impact of pharmacists in managing diabetes when incorporated into an interdisciplinary team.

**Methods:** This was a retrospective study, which included veterans who were enrolled in a pharmacist-run clinic at the VA Greater Los Angeles Healthcare System between November 1, 2012, and November 1, 2014. Diabetic patients with an A1c greater than 6.5 percent or on one or more antidiabetic medication(s) at the time were included in the study. Patients were excluded if they had only one visit with a clinical pharmacist, no documented baseline A1c, or no documented A1c at discharge from the clinic. Data between November 1, 2011 and November 1, 2015 was gathered and evaluated. Our primary outcome measured the change in A1c from initial to last pharmacist visit. Secondary outcomes measured the percent of patients who reach their A1c goal, percent of patients maintaining their A1c goal, and differences in clinical outcomes in diabetes-related hospitalizations, Emergency Department (ED) visits, and hypoglycemic episodes. The cost benefit of incorporating pharmacists on interdisciplinary teams was also evaluated.
Results: Of the 576 patients evaluated, a total of 303 patients with diabetes mellitus type I and II met the inclusion criteria. The average reduction in A1c was 1.83 percent (P < 0.0001). The average number of days between the initial and last visit was 11.9 months with an average of 10.23 visits with a pharmacist. Forty nine percent of patients were able to reach their individualized A1c goal before discharge. Of the patients that were able to reach their A1c goal (n=284), 68 percent of patients maintained their A1c for at least a year. There was an overall reduction in ED visits (P=0.038), while the overall reduction in hospitalizations was not statistically significant (P=0.09). Sub-analysis of four patients referred to a clinical pharmacist solely for hypoglycemia management had hypoglycemic symptoms eliminated in 1 to 2 visits. A net savings of 61,440 – 96,392 dollars, or 904 - 1,418 dollars per patient, was estimated for patients with a greater than or equal to 1 percent drop in A1c at 1 year.

Conclusion: Pharmacists involved with diabetes management trends towards providing a cost effective service that contributes to reductions in A1c, ED visits, and hypoglycemic frequency.

**Poster Title:** Healthcare utilization in patients labeled with a beta-lactam allergy compared to unlabeled patients

**Primary Author:** Lynn Nguyen, Veterans Affairs San Diego Healthcare System, CA; **Email:** lynnnguyen@utexas.edu

**Additional Author(s):**
Brett Venker
Jonathan Lacro

**Purpose:** Beta-lactam antibiotics are recommended as first-line therapy in many infections due to their high efficacy. Unfortunately, self-reported allergies to beta-lactam antibiotics, particularly penicillin, are common in the United States. Once patients are labeled with a beta-lactam allergy, they are more likely to receive alternative antibiotics, many of which are associated with inferior clinical outcomes, poorer safety profiles, and a higher risk of inducing drug resistance compared to beta-lactam antibiotics. The purpose of this study is to evaluate healthcare utilization and infection-related outcomes in patients labeled with a beta-lactam allergy compared to unlabeled patients.

**Methods:** This is an IRB-approved retrospective cohort study to be conducted using Veterans Health Administration (VHA) electronic health data. All patients who received at least one antibiotic during a predefined time frame will be included. A cohort of patients with a beta-lactam allergy label (defined as a documented allergy to a penicillin, penicillin-derivative, cephalosporin, or carbapenem antibiotic) will be compared to a matched cohort of patients without a beta-lactam allergy label.

The primary outcomes will be 1) infection-related readmission or ED visit within 30 days of receipt of an outpatient antibiotic and 2) receipt of an outpatient antibiotic within 30 days of discharge from an infection-related hospital admission where the patient received inpatient antibiotic treatment.

Secondary outcomes include the use of reserve antibiotics (fluoroquinolones, macrolides, vancomycin, aztreonam, aminoglycosides) in both the inpatient and outpatient settings, cost and duration of antibiotic therapy, the number of antibiotics received, overall and in-hospital
mortality, the incidence of *Clostridium difficile* infection, ICU admission, and, for those patients admitted for an infection, length of hospital stay and infection-related readmission. Student t tests will be used to compare means and proportions. Chi square tests will be used to compare categorical variables. P values < 0.05 will be considered statistically significant.

**Results:** To be presented at the meeting.

**Conclusion:** To be presented at the meeting.

Poster Title: Comparison of Testosterone Dosage Forms at Various Altitudes within the Veterans Affairs

Primary Author: Alfredo Guzman, VA Eastern Colorado, CO; Email: alfredo.guzman.ahc@gmail.com

Additional Author(s):
Sherri Hawk
Elizabeth O’Brien
Lauren Leonard
Margaret Wierman

Purpose: Testosterone replacement therapy is recommended for men diagnosed with hypogonadism. However, testosterone replacement has been associated with erythrocytosis and polycythemia. Living at high altitude (>3,500 feet above sea level) has also been shown to increase hemoglobin and hematocrit. This study will compare patients on testosterone replacement therapy at high and low altitudes to assess effect on hematocrit. There is currently no available evidence comparing hematocrit levels in the various dosage forms of testosterone at different altitudes. This information will aid providers in selecting dosage forms and provide greater reasoning for prescription of testosterone therapy in areas of high altitude.

Methods: This will be a multicenter, retrospective cohort study of patients receiving testosterone therapy through two cohorts within the Veterans Affairs (VA). The two cohorts will be identified as eight VA stations at high altitude (>3,500 feet above sea level) and eight VA stations at low altitude (<50 feet above sea level). Subjects will be stratified into six groups: injectable testosterone in areas of high altitude, injectable testosterone in areas of low altitude, testosterone patch in areas of high altitude, testosterone patch in areas of low altitude, testosterone gel in areas of high altitude, and testosterone gel in areas of low altitude. Participants will be identified based on testosterone treatment date, testosterone prescription refill history, obtainment and dates of hematocrit levels, obtainment and date of testosterone level, and ICD-9 codes. The observation period will be between October 1st 2010 to September 30th 2015. Inclusion criteria will be male patients initiating testosterone replacement therapy within the two study cohorts, a hematocrit level six months prior to initiation, through
testosterone prescription, and 6-12 months after initial testosterone prescription date, and must also be treated with testosterone for two years during study duration. Exclusion criteria will be patients using testosterone for gender transition. Data measures will be stored and analyzed on the secure VA database, with study investigators as the only persons with access to the data.

**Poster Title:** Impact of pharmacist interventions on the treatment of hepatitis C patients at a Veterans Affairs healthcare facility

**Primary Author:** Bennett Doughty, VA Connecticut Healthcare System, CT; **Email:** bennett.doughty@gmail.com

**Additional Author (s):**
Eric Kuszewski
Seth Cioffi

**Purpose:** The hepatitis C virus (HCV) is a contagious, generally chronic liver disease that affects approximately 3-4 million people in the United States. Medication therapies for HCV have evolved in both tolerability and efficacy, with some regimens showing upwards of a 99% sustained virologic response at 12 weeks (SVR12) for select genotypes. The purpose of this project is to evaluate the impact associated with pharmacist recommendations on therapy selection, drug-drug interactions, adherence history, and other interventions when treating this disease state within a single institution.

**Methods:** This project is a retrospective analysis of patient data obtained from this single facility's Computerized Patient Record System (CPRS) between 5/1/2014 and 9/30/2016 and has been approved by the institution's Research Office as quality improvement. Evaluation of all patients selected to begin HCV treatment within this timeframe at this facility will examine the following data: HCV genotype and subtype, HIV status, cirrhosis status, treatment history, regimens requested and initiated, pharmacist interventions and reasoning, any additional pharmacist interventions, and SVR12 status. Data will be analyzed to evaluate the impact of pharmacist recommendations and interventions. The amount and types of pharmacist interventions, in the form of therapy adjustments, drug-drug interactions, adherence analyses, and any additional suggestions, will be analyzed primarily in terms of percentage of patients affected to measure pharmacy impact on patient care. This overall impact will serve as the primary outcome of this project. Further, the SVR12 value associated with each patient will be utilized as a secondary endpoint to assess the treatment course as a whole. The results will be utilized to provide support for further pharmacist involvement in liver clinics within similar institutions.

**Additional Author (s):**  
Alex Guirguis  
Kevin Burton  
Danielle Wojtaszek  

**Purpose:** GLP-1 agonists have had an expanded role in diabetes management in recent years, after first line metformin, but are associated with increased direct costs compared to other diabetes alternatives. The objective of this medication use evaluation is to identify recent prescribing trends of GLP-1 agonists and to determine therapeutic effects on diabetes disease state goals, especially A1c and weight.  

**Methods:** This medication use evaluation has been approved as a Quality Improvement project. A retrospective chart analysis of the electronic medical record will be conducted to identify patients receiving GLP-1 agonists for the management for type 2 diabetes mellitus. The following patient data will be collected: age, A1c trends, weight, BMI, prescribing service, initiation date, diabetes medication regimen at baseline, previous diabetes medication trials, current diabetes medication regimen, insulin dose if applicable, and discontinuation date of GLP-1 agonist if applicable. Provider documentation will be reviewed to determine the rationale for initial prescription of a GLP-1 agonist, and in those patients who had GLP-1 agonist therapy stopped, the reason for discontinuation. All data will be recorded in such a manner to maintain confidentiality. The collected data will be analyzed to determine GLP-1 agonist prescribing trends as well as GLP-1 agonist effect on A1c, weight, and BMI in the veteran population. Results will be compiled for healthcare provider education and to provide guidance on appropriate prescribing of GLP-1 agonists.

Poster Title: Medication use evaluation of diclofenac gel at the Veterans Affairs Connecticut Healthcare System

Primary Author: Catherine Liu, VA Connecticut Healthcare System, CT; Email: catherine_liu@my.uri.edu

Additional Author (s):
Anna Chmielewska
Seth Cioffi
Catherine Kulis-Robitaille
Leslie Lin

Purpose: The Veterans Affairs (VA) National Formulary recently added diclofenac gel to the formulary in May 2016. Since its addition, the number of patients prescribed diclofenac gel has increased drastically. However, patients and providers are often unaware of its approved indications for use and thus diclofenac gel may be overprescribed. This medication use evaluation (MUE) will assess whether diclofenac gel is being appropriately prescribed and if its use is in line with available evidence. This retrospective MUE will attempt to provide further education to practitioners to improve diclofenac gel therapy and reduce the costs associated by potentially decreasing inappropriate prescribing.

Methods: This medication use evaluation will be a retrospective chart analysis of 265 patients from the VA Connecticut Healthcare System. Patient data will be collected from May 1, 2016 to September 30, 2016. All patients prescribed diclofenac gel during that time will be included. The following information will be collected and analyzed for patients previously or currently treated with diclofenac gel: patient characteristics, age, location prescribed, indication for therapy, treatment site, total daily dose of diclofenac gel, duration of therapy, other analgesics prescribed (including oral NSAIDs, topical lidocaine cream), nonpharmacological therapies, and pain scores, if available. Data collected will be analyzed to improve the quality of care to Veterans and to provide education to healthcare professionals within the VA Connecticut Healthcare System.

Poster Title: Evaluation of sodium-dependent glucose transporter (SGLT-2) inhibitor prescribing patterns in the Veterans Affairs setting

Primary Author: Amber Rollins, VA Connecticut Healthcare System, CT; Email: amber.rollins2@va.gov

Additional Author(s):
Kevin Burton
Bridget Hurd
Joanna Musial

Purpose: Sodium-dependent glucose transporter-2 (SGLT-2) inhibitors are a class of antihyperglycemic agents that target proximal tubules in the kidneys to inhibit reabsorption of glucose. Clinical studies have shown that SGLT-2 inhibitors decrease fasting plasma glucose and HbA1c levels (0.7%–0.8%) when compared to placebo or when used in combination with other antihyperglycemic agents. The purpose of this quality improvement project is to evaluate the current prescribing patterns and use of SGLT-2 inhibitors in the Veterans Affairs (VA) setting.

Methods: This study has been approved by our institution as a quality improvement initiative, exempt from approval by the institutional review board. To identify patients in this retrospective analysis, prescription records for SGLT-2 inhibitors from April 2016 to September 2016 will be extracted from the electronic medical record. Provider documentation, lab values, and medication administration records will be used to collect patient data. The following data will be collected via retrospective chart review: patient age, sex, weight, height, serum creatinine, pertinent past medical history, hemoglobin A1c (HbA1c), service of prescriber, active medications, and prescribed SGLT-2 therapy and dosage. All patient data will be de-identified and maintained confidentially. For the purpose of this study HbA1c at SGLT-2 initiation will be documented, along with the next recorded HbA1c greater than 30 days after SGLT-2 initiation. If available, provider documentation of any adverse effects after initiation of SGLT-2 inhibitor will be recorded. Data collected will be analyzed to assess for safety, efficacy, and appropriateness of SGLT-2 inhibitor use within the VA Connecticut Healthcare System. Results from this study are meant to improve quality of care to Veterans and to provide education to healthcare professionals at our institution.

Poster Title: Utilization of the basal-bolus-correction (BBC) protocol in medical inpatients

Primary Author: Christopher Tarantino, VA Connecticut Healthcare System, CT; Email: chrisjt18@gmail.com

Additional Author (s):
Rebecca Curtin

Purpose: The purpose of this medication use evaluation is to analyze the utilization of the basal-bolus-correction insulin protocol and subsequent glycemic control during hospital admission. The data from this medication use evaluation will be used to improve awareness of insulin usage in the hospital setting and identify areas for improvement.

Methods: This retrospective chart review will include patients admitted between June 1, 2016 and August 31, 2016 who had inpatient orders for any type of insulin (glargine, aspart, novolin mix, or regular). The objective is to determine if providers are adhering to the basal-bolus-correction protocol and to assess the differences in glycemic control. The data that will be collected will include: adherence to the basal-bolus-correction protocol or not, the number of blood glucose readings (in mg/dL) greater than: 200, 300, and 400, number of blood glucose readings (in mg/dL) less than: 70 and 50. Other data will include most recent hemoglobin A1C, amount of sliding scale insulin used, type of insulin(s) used, how the insulin doses were being titrated, if the patient was being treated with corticosteroids during their admission, and where the patient was located in the hospital. Inclusion criteria will include both type 1 and type 2 diabetics with current inpatient orders for any type of insulin, and a current or historical hemoglobin A1C of greater than 6.9 percent. Individuals will be excluded from this study if their inpatient duration was less than three days, if they were admitted to the medical or surgical intensive care unit, or if they were receiving less than 10 units of insulin per day most recently as an outpatient.

**Poster Title:** An interprofessional education initiative to reduce pharmaceutical risk in older adults at a VA healthcare facility

**Primary Author:** Macayla Landi, VA Connecticut Healthcare System, CT; **Email:** macayla.land@gmail.com

**Additional Author(s):**
Marcia Mecca
John Thomas
Kristina Niehoff
Rebecca Brienza

**Purpose:** Polypharmacy is a growing concern in older adults, however, limited training is provided to healthcare trainees in medication management for geriatric patients. Approximately 50% of older adults take one or more prescribed medication that is not medically necessary. Polypharmacy and use of unnecessary medications has been associated with increased health care costs, risk of adverse drug events, drug-interactions, medication non-adherence, reduced functional capacity and potential geriatric syndromes. The purpose of this study is to evaluate outcomes for older adults after providing education to healthcare trainees to identify and analyze complex medication regimens and deprescribe potentially inappropriate medications.

**Methods:** The IMPROVE polypharmacy clinic (Initiative to Minimize Pharmaceutical Risk in Older Veterans) occurs one half-day per month and involves a team of interdisciplinary healthcare trainees, including residents in Internal Medicine, advanced practice nursing, pharmacy, and health psychology. Veterans age 65 and older, taking 10 or more medications, and who are appropriate for a group visit, are referred to IMPROVE for a full medication assessment. The clinic involves three sequential sessions: a pre-clinic “lunch and learn,” a trainee-led group visit, and individual trainee visits with precepting provided by a geriatrician, geriatric pharmacist, and primary care faculty. Trainees work with preceptors to optimize medication regimens and reduce the number of potentially inappropriate medications. The health outcomes measured include hospitalization and emergency department visits, urgent
visits to primary care providers, and number of medications. These outcomes will be compared with a control cohort of Veterans who receive primary care services through the Veterans Affairs healthcare system but who were not enrolled in the clinic.

**Results:** In progress

**Conclusion:** In progress

Poster Title: Evaluation of adherence to Veterans Affairs (VA) criteria for monitoring lithium concentrations

Primary Author: Alyssa Taqi, VA Connecticut Healthcare System, CT; Email: alyssa taqi pharmd@gmail.com

Additional Author(s):
Douglas Boggs

Purpose: Lithium is an effective treatment for bipolar disorder and augmentation in depression. However, it is important to monitor lithium regularly to ensure that patients do not experience toxicity. A review of national VA data found that of approximately 17,000 Veterans prescribed lithium, 19.5 percent had not had a lithium level checked in the past nine months, despite VA guidelines that recommend monitoring lithium concentrations at least every six months. This project aimed to evaluate the compliance of providers at VA Connecticut in their lithium monitoring practices.

Methods: A national lithium monitoring dashboard was created to help assess lithium monitoring adherence at the VA by totaling the number of patients with active lithium prescriptions, the number of patients with greater than six months since the last lithium lab, and the lab completion rate. It provided information on who prescribed the lithium, the last prescription fill date, the date and result of the last lithium lab, as well as any pending lithium lab orders. We conducted a chart review of each patient’s last lithium level and any pending lithium lab orders to verify the accuracy of the dashboard. Next, each patient’s last mental health progress note (and progress of notes of other specialties if warranted) were reviewed, to assess the last visit date and plan for medication therapy, as well as monitoring. Through this evaluation, we identified patients who were currently being treated with lithium, but had no lithium monitoring for at least the past six months and required follow-up monitoring.

Results: As of July 21, 2016, among 235 patients at VA Connecticut who had active lithium prescriptions, 75/235 (32 percent) did not have lithium levels checked within the last six months. Approximately 54/75 (72 percent) were currently on lithium therapy, as documented on recent provider progress notes, but levels had not been obtained for the recommended
monitoring timeline. Labs were ordered but never completed for 6/54 (11 percent) of those patients. Alternatively, 11/75 (15 percent) had active prescriptions, but medications were not addressed in recent provider progress notes, or the patient was not recently seen at the VA. The remainder of patients didn’t have recent lithium levels for other miscellaneous reasons. As a result of this analysis, reminder letters were sent on August 29, 2016, to providers to follow-up with patients requiring lithium level monitoring. Consequently, providers started to discontinue active lithium prescriptions for patients that were no longer taking lithium, and do follow-up lab work for those patients whose lithium was not being monitored every six months. With this intervention, the number of patients without a lithium level in the last 6 months decreased to 60/206 (29 percent), as of September 19, 2016.

**Conclusion:** Lithium level monitoring is an important part of lithium medication therapy due to its narrow therapeutic index. Current VA recommendations suggest monitoring lithium levels every six months, regardless of indication or length of therapy. An evaluation of lithium monitoring practices at VA Connecticut revealed a 68 percent compliance rate with recommended guidelines but improved compliance to 72 percent with intervention through reminder letters to prescribing providers. Preliminary results suggest that clinical pharmacy staff can help improve lithium monitoring adherence.

Poster Title: Treatment sequencing in patients with metastatic castration-resistant prostate cancer at the Washington DC, Veterans Affairs Medical Center

Primary Author: Bi Kim, DC Veterans Affairs Medical Center, DC; Email: kimbichuy@gmail.com

Additional Author(s):
Shrina Patel
Steven Krasnow

Purpose: Management of metastatic castration-resistant prostate cancer (mCRPC) has undergone a major transformation since the turn of the 21st century. Despite this, mCRPC remains incurable and questions surrounding how to sequence the six available agents including chemotherapeutics (Docetaxel and Cabazitaxel), second generation antiandrogens (Abiraterone and Enzalutamide), immunotherapeutic (Sipuleucel-T), and radio-active isotope (Radium-223) remain unclear. The purpose of this study is to determine whether an optimal sequence of drugs to treat mCRPC exists. Outcome of this study could help with selecting future treatments for mCRPC in an identifiable sequence as the patient progress with mCRPC and thus, potentially extend their survival.

Methods: In determination of the optimal treatment sequences in mCRPC patients in Washington, DC Veterans Affairs Medical Center, a retrospective cohort study was conducted using local registry data. All patients with mCRPC who failed first line, second line, third line, and fourth line will be selected from the time period of July 1, 2011 through July 1, 2016. Patients who are identified by specific treatment sequences using ICD-9 and ICD-10 codes will then be evaluated for their response to therapy. We will obtain prescription and order data from the Veterans Health Information Systems and Technology Architecture (VistA). This may include prescriptions/orders for Docetaxel, Cabazitaxel, Abiraterone, Enzalutamide, Sipuleucel-T, and Radium-223. The PSA response rate and duration of PSA response rate will be reviewed sequentially as the primary and secondary endpoints, respectively. We defined PSA response rate as decrease in PSA levels by greater than or equal to 50 percent and we defined PSA progression as two consecutive increase in PSA levels of at least 1 mcg/dL one month apart from each other. We will continue to evaluate additional data points including age, medical
history, Gleason score, staging at the time of diagnosis through Computerized Patient Record System (CPRS).

Poster Title: Retrospective quality assurance review of atrial fibrillation patients without heart failure currently on digoxin without beta blocker or non-dihydropyridine calcium channel blocker therapy

Primary Author: Steven Cindric, Bay Pines VA Healthcare System, FL; Email: steven.cindric@va.gov

Additional Author (s):
Ramona Billings

Purpose: Beta blockers and non-dihydropyridine calcium channel blockers (non-DHP CCB) are used in atrial fibrillation (AF) patients as first line therapy for rate control. Digoxin can be useful in patients with AF and heart failure (CHF) but have been shown to increase mortality when used as monotherapy in AF patients without CHF. The purpose of this medication use evaluation (MUE) is to assess monotherapy digoxin use for the treatment of AF in patients without CHF who have no documented prior use of first line beta blockers or non-DHP CCB, and in which there are no contraindications for these first line agents.

Methods: This medication utilization review was reviewed by the Bay Pines VA Healthcare System Research and Development Service and was deemed a quality improvement project and not research. This MUE, which is part of a nationwide Centrally-Aggregated MUE (CAMUE), will utilize a retrospective database extraction (performed by VAMedSAFE) which will identify patients receiving outpatient digoxin monotherapy who have a diagnosis of AF without a diagnosis of CHF during Q4 of 2015 and Q1 of 2016 based on ICD-9 codes. Identified patients will undergo a chart review in which confirmation of AF diagnosis and absence of CHF will be verified prior to collection of other pertinent information including: non-VA past/concomitant use of beta blockers or non-DHP CCB therapy; contraindications to first line AF therapy; indication, dose, and duration of digoxin therapy; monitoring of serum creatinine, potassium, and digoxin levels; signs/symptoms of digoxin toxicity; prescriber specialty; demographics; and place of residence. All data collected will be de-identified and stored in an excel spreadsheet within the controlled access pharmacy group drive folder. This information will be used to determine if individual patients are candidates for discontinuation of digoxin therapy.

**Poster Title:** Evaluation of fluoroquinolone utilization within Bay Pines VA Healthcare System

**Primary Author:** Ivonne DelValle, Bay Pines VA Healthcare System, FL; **Email:** ivonne.delvalle@va.gov

**Additional Author(s):** Lindsey Childs-Kean
Joseph Hong

**Purpose:** Fluoroquinolones are no longer first-line antibiotics in the treatment of uncomplicated urinary tract infections (UTIs) or upper respiratory infections (URTI). A safety review conducted by the Food and Drug Administration found fluoroquinolone use to be associated with disabling and potentially permanent side effects. Additionally, fluoroquinolones have also been linked to an increased risk of Clostridium difficile infections and have suboptimal local susceptibility rates. Given the concerns surrounding fluoroquinolone use, an evaluation of their current utilization is warranted. The purpose of this medication use evaluation is to evaluate the appropriateness of fluoroquinolone utilization within the Bay Pines VA Healthcare System.

**Methods:** This evaluation has been reviewed by the Institution’s Office of Research and Development and has been determined to be exempt from review by an Institutional Review Board. A retrospective chart review will be performed on patients with outpatient prescriptions for fluoroquinolones prescribed between July 1, 2016 and July 31, 2016 with a treatment indication for a UTI or URTI. The following orally-administered fluoroquinolones will be reviewed: levofloxacin, ciprofloxacin, and moxifloxacin. The corresponding indication and duration of therapy will be gathered through the patient record and evaluated for appropriateness. Probable pseudomonal infection based on culture history, infection caused by an organism that is not susceptible to alternative antibiotics, or empiric therapy for which no reasonable alternative antibiotic exists will be considered appropriate. Empiric therapy with fluoroquinolones will be considered appropriate if there is a documented penicillin and/or sulfa allergy which preclude the use of an alternative susceptible antibiotic or treatment failure of an alternative antimicrobial agent. Collected data will be stored in a limited-access folder within the pharmacy group drive. The fluoroquinolone used and the indication will be documented as...
categorical variables and presented as percentages without statistical analysis. The duration of therapy will be documented as the number of days and will be summarized using descriptive statistics.

**Results:** N/A

**Poster Title:** Quality assurance review to determine the effectiveness of a conversion of lidocaine 5 percent ointment to lidocaine 4 percent cream  

**Primary Author:** John Leonard, Bay Pines VA Healthcare System, FL; **Email:** john.leonard5@va.gov  

**Additional Author(s):**  
Amanda Schmig  

**Purpose:** Topical lidocaine is a medication used to numb tissues and treat localized pain. In a September 2015 cost-savings initiative, the pharmacy and therapeutics committee approved a conversion of lidocaine 5 percent ointment to lidocaine 4 percent cream, a product which could potentially be used to result in similar amounts of topical anesthesia. The purpose of this medication utilization evaluation is to evaluate the effectiveness of lidocaine 4 percent cream compared to lidocaine 5 percent ointment in patients who were converted due to this initiative.  

**Methods:** This medication utilization review was reviewed by the Bay Pines VA Healthcare System Research and Development Service and was deemed a quality improvement project and not research. A retrospective chart review will be performed on patients converted from lidocaine 5 percent ointment to lidocaine 4 percent cream from September 2015 to July 2016. Success will be defined as patients remaining on the lidocaine 4 percent cream. Failure will be defined as patients who have been changed to an alternative topical lidocaine product. Data will be collected in an excel spreadsheet and stored in a limited access folder.

**Poster Title:** Retrospective quality assurance review to compare the effectiveness of filgrastim versus tbo-filgrastim by assessing changes in neutrophils counts and occurrence of complications following use

**Primary Author:** Jacqueline Mark, Bay Pines VA Healthcare System, FL; **Email:** jacqueline.mark@va.gov

**Additional Author(s):**
Manoranjan Boddapati
Patricia Burd
Chad Lewis
Robert Stewart

**Purpose:** Filgrastim and tbo-filgrastim are human granulocyte colony stimulating factors (G-CSF) used in patients with non-myeloid malignancies after receipt of myelosuppressive chemotherapy to reduce the extent and duration of severe neutropenia. In September 2015, a hospital-wide formulary change resulted in the replacement of filgrastim with tbo-filgrastim at Bay Pines Veterans Affairs Health Care System (VAHCS). It was determined that a retrospective comparison should be performed to assess the effectiveness of filgrastim versus tbo-filgrastim at increasing neutrophil counts and in improving patient outcomes. The purpose of this medication use evaluation is to determine if these two agents yield similar results following administration.

**Methods:** This evaluation was reviewed by the institution's Office of Research and Development and has been determined to be exempt from review by an institutional review board. Retrospective chart review will be performed on Veteran patients receiving chemotherapy who were treated with filgrastim from January 1st through September 30th, 2015 and those treated with tbo-filgrastim from October 1st, 2015 through June 30th, 2016. Patient records will be evaluated to determine the impact filgrastim and tbo-filgrastim had on the following outcomes: duration and extent of neutropenia, number of doses needed to reverse neutropenia and, if applicable, the number of days chemotherapy was withheld due to neutropenia. Neutrophil counts as well as duration of neutropenia in days (defined here as absolute neutrophil count (ANC) less than 1,500 cells per cubic millimeter) will be evaluated
separately for prophylaxis and treatment. As complete blood counts are not monitored on a daily basis in outpatients, admissions for complications such as febrile neutropenia, septic episodes, and treatment with antibiotics following G-CSF administration will also be queried. Collected information will be maintained in an excel spreadsheet format and stored in a limited access folder. Most data will be analyzed using descriptive statistics with the exception of complications, which will be analyzed as documented occurrence of infection and will be reported as binary results. Data will be presented as averages or percent occurrences.

**Poster Title:** Retrospective quality assurance review to determine the effects of routine use of melatonin on INR in chronic warfarin therapy

**Primary Author:** Jessica Smith, Bay Pines VA Healthcare System, FL; Email: jessica.smith4@va.gov

**Additional Author(s):**
Kimberly Hall
Megan Martinez

**Purpose:** Melatonin is an herbal supplement used for insomnia and is thought to be relatively safe with few drug interactions. However, melatonin may moderately interact with warfarin. In the Veterans Affairs Healthcare System, warfarin is a formulary medication frequently used for blood clot prevention. The concurrent use of warfarin and melatonin may present an increased risk of bleeding along with an elevated International Normalized Ratio (INR). The purpose of this medication utilization evaluation is to determine if the INR of patients on chronic warfarin therapy is altered due to the routine use of melatonin and to assess occurrence of bleeding events.

**Methods:** This medication utilization evaluation was reviewed by the Bay Pines VA Healthcare System Research and Development Service and was deemed a quality improvement project and not research. A retrospective chart review will be performed on patients who utilized the BPVAHCS anticoagulation clinic for INR monitoring while on warfarin therapy from June 1, 2014 to August 1, 2016. Of these patients, only those with a least one recorded therapeutic INR, as defined by the VA/DOD Guidelines, and used warfarin along with melatonin on a regular basis will be reviewed. Regular basis use of melatonin will be defined as melatonin use for three or more days per week during the study trial period. Patient data that will be recorded from every patient chart include age, gender, reason for warfarin therapy, and any changes in adjuvant medication therapy. Each patient meeting criteria will have their INR recorded from subsequent clinic visits as well as their melatonin therapy, including dose and frequency of use, any bleeding events, and medication changes. The previously described information will be collected and stored in a controlled-access folder using an excel format. Data will be analyzed
as observational occurrences and will be documented as binary results. The data will be presented as percent occurrences without statistical analysis.

Poster Title: Quality assurance review of appropriate buprenorphine use and strategies to streamline the review process

Primary Author: Albert McKee, Bay Pines VA Healthcare System-Bay Pines, FL; Email: albert.mckee@va.gov

Additional Author(s):
Amanda Schmig

Purpose: Buprenorphine (or buprenorphine/naloxone) was the first agent in the United States available for the treatment of opioid dependence in an outpatient setting. Buprenorphine is indicated for the induction and maintenance therapy of opioid dependence. Due to buprenorphine’s mechanism of action there is a potential for abuse and requires close monitoring. The VA outpatient use of buprenorphine should meet specific criteria to be appropriate. The growing number of buprenorphine prescriptions has produced an increasingly time consuming review process. The purpose of this medication use evaluation is to assess the appropriateness of buprenorphine prescribing and to streamline the review process.

Methods: A retrospective chart review will be performed on patients who received an outpatient prescription for buprenorphine or buprenorphine/naloxone during 2015. The appropriateness of the prescriptions will be evaluated based on the following criteria: prescription was written at a recent appointment with an authorized prescribing practitioner (defined as plus or minus 14 days from written prescription date), recent clean urine drug screen (defined as plus or minus 14 days from written prescription date), and that the patient is not concomitantly treated with a benzodiazepine, patient is not concomitantly treated with an opioid. Inpatient orders for buprenorphine will be excluded. Patients treated with high dose chronic diazepam or methadone will not be required to have clean urine drug screens prior to induction. Collected information will be maintained in an excel spreadsheet and stored in a controlled access folder under the pharmacy group drive. The data will be analyzed as integers, ratios and percent. The chart review procedure for evaluating each prescription will be reengineered to streamline the review process. The above information is intended solely for usage on this medication use evaluation and is not to be distributed or utilized for any other purpose.

Poster Title: Quality assurance review of a prescription voucher program in a Department of Veterans Affairs Healthcare System

Primary Author: Jordan Lund, Bay Pines VA Healthcare System-Sarasota CBOC, FL; Email: jordan.lund@va.gov

Additional Author (s):
Rachel Turner
Steven Totterdale
Joshua Long

Purpose: The Heritage Health Solutions (HHS) prescription voucher program is utilized to provide acute care prescriptions to Veterans assigned to Veterans Affairs community based outpatient clinics. With this program, Veterans are able to fill acute care medications at local contracted pharmacies at no co-pay at the time of service. HHS is a company that manages the finances of Heritage program prescriptions. Reviewing submitted invoices from HHS is critical to ensure the proper management of funds. The purpose of this project is to assess the current utilization of the Heritage prescription voucher program with regards to quality assurance.

Methods: This evaluation has been reviewed by the institution's Office of Research and Development and has been determined to be exempt from review by an institutional review board. A retrospective review will be performed comparing the clinical pharmacists’ prescription database with the invoices received from Heritage Health Solutions from July 1, 2016 to September 30, 2016. The aforementioned database and invoices will be reconciled for discrepancies. The electronic medical record (EMR) will be utilized to elucidate the etiology of inconsistencies. Discrepancies will be presented as percent occurrences per month and total cost variances per month. Collected information will be maintained in an excel spreadsheet and stored on a pharmacy group drive in a controlled-access folder.

Poster Title: Impact of recent labeling changes for metformin on the potential for increased use in patients with type 2 diabetes, in a Veterans Affairs outpatient population

Primary Author: Derek Pearson, Bay Pines Veterans Affairs Healthcare System, FL; Email: derek.o.pearson@gmail.com

Additional Author (s):
Sally Cushnie
Michael Torlone

Purpose: Metformin is first-line for treatment of type 2 diabetes mellitus (T2DM). It was previously contraindicated in patients with a serum creatinine (SCr) of 1.4 mg/dL or greater in females and 1.5 mg/dL or greater in males due to risk for metformin associated lactic-acidosis. In 2016, the Food and Drug Administration published recommendations for utilizing estimated glomerular filtration rate (eGFR) to predict appropriate levels for starting and discontinuing metformin in patients with reduced renal function. The purpose of this evaluation is to identify patients with uncontrolled T2DM and reduced renal function who may be eligible for metformin treatment under new recommendations.

Methods: This MUE has been deemed a quality improvement project by the Bay Pines VA Research and Development Service. A database query from July 2015 to July 2016 will be conducted to identify patients with a diagnosis of T2DM, a hemoglobin A1c of 7 percent or greater, absence of an active prescription for metformin, SCr of 1.4 mg/dL or greater in females or 1.5 mg/dL or greater in males, and eGFR of greater than 45 ml/minute/1.73 m2. Patients with a documented allergy or intolerance to metformin will be excluded. Patients will then be stratified based on prior metformin use. A retrospective chart review will be performed to identify alternative factors that may preclude metformin use such as a comorbidity that may increase the risk for lactic acidosis. Information will be converted into YES/NO data and maintained electronically in a controlled-access drive. Data collected will be used to establish quality improvement initiatives based on updated FDA recommendations for metformin prescribing.

**Poster Title:** ENDORSE (ENcouragement for Dose of Opiate Reduction for Safety and Engagement) project: Opioid reduction via utilization of a direct-to-consumer brochure

**Primary Author:** Courtney Deshauer, Gulf Coast Veterans Health Care System - Joint Ambulatory Care Center, FL; **Email:** cdeshauer@gmail.com

**Additional Author(s):**
Joseph Glovacz
Tiffany Jagel

**Purpose:** The goal of this quality improvement project is to reduce high dose opioid use in the Gulf Coast Veterans Health Care System (GCVHCS) through patient empowerment via education.

**Methods:** The ENDORSE brochure “Opioid Medications,” written at an eighth grade reading level, discusses some of the risks associated with high dose opioid use. This project will involve mailing the ENDORSE brochure to GCVHCS patients prescribed a 100 mg or greater morphine equivalent daily dose. Mailing will occur two to six weeks prior to an upcoming scheduled appointment. The expectation is that after receiving the brochure, patients will be more likely to engage in discussions regarding opioid tapers, alternative ways to manage pain, and the dangers of high dose opioid use. By October 28th 2016, all remaining high dose opioid patients will be mailed the brochure if they have not already received it. Prior to mailing the brochures, education will be provided to healthcare professionals in the GCVHCS to familiarize them with the project and ensure they have access to additional information regarding pain management and opioid tapers. Six months after the ENDORSE brochures have been mailed to patients, the high dose opioid patients will be reviewed to determine if an opioid taper has been started and what percentage the opioid dose has been reduced by, if they are now on less than a 100 mg morphine equivalent daily dose, or if they are no longer using opioids.

**Results:** Project is ongoing at this time.

**Conclusion:** Project is ongoing at this time.

Poster Title: Implementation and evaluation of an opioid overdose education and naloxone distribution clinic at a Veterans Affairs outpatient ambulatory care center

Primary Author: Andrea DeLaney, Gulf Coast Veterans Health Care System
Joint Ambulatory Care Center, FL; Email: andreastadther@gmail.com

Additional Author (s):
Joseph Glovacz
Tiffany Jagel

Purpose: Recent statistics from Centers for Disease Control and Prevention reveal the United States has been confronted by an unrelenting opioid epidemic, with the number of fatalities caused by prescription opioids quadrupling since the end of the 20th century. Data indicates that compared to the non-Veteran population, Veterans are twice as likely to die from accidental overdose. The objective of this quality improvement initiative is to demonstrate that opioid education and naloxone prescribing will lead to a reduction in opiate-related overdose, while potentially influencing opiate prescribing trends and cost savings in a Veterans Affairs healthcare system.

Methods: This is a quality improvement initiative that will be submitted to the local Institutional Review Board for exemption determination. Veterans at an increased risk for opioid overdose will be identified through utilization of the Department of Veterans Affairs (VA) Stratification Tool for Opioid Risk Mitigation. Based on risk severity, Veterans will be contacted and offered the opportunity to receive opioid education and a naloxone prescription. The following data will be recorded and maintained confidentially: patient demographics, opioid name, dosage in milligrams of morphine equivalents, units dispensed per 30 days, clinical indication, initial prescribing date of naloxone, time spent per encounter, naloxone refills requested, naloxone administration outcomes, and emergency department visits related to opioid use during initiative. Opioid Overdose Education and Naloxone Distribution educational materials created by the VA Academic Detailing Services will be utilized and distributed within the clinic. Patients who complete overdose and naloxone training will be offered the opportunity to receive a naloxone prescription. Documentation of naloxone education, dispensing, administration, or patient refusal will be performed with the issuance of the first
prescription and upon each renewal using the VA Computerized Patient Record System. Data will be analyzed utilizing standard descriptive statistics. Results will help identify if opioid education and naloxone prescribing decreased opiate-related overdose and opiate prescribing in a cost-effective manner.

**Poster Title:** Standardization of contrast media at the Miami Veterans Affairs Medical Center

**Primary Author:** Navene Shata, Miami VA Health Care System, FL; **Email:** navenejb@live.com

**Additional Author (s):**
Sarah England
Jacqueline Meaney

**Purpose:** Imaging procedures are increasingly common today, using a wide variety of imaging modalities and contrast media. The goal of this project is to consolidate the oral and intravenous radiologic contrast products that are used for various procedures at the Miami Veterans Affairs (VA) Medical Center. This is a quality improvement project that will not only streamline ordering of products for physicians, but will also reduce the financial impact associated with these products. In completing the project, we will be able to identify the most cost-effective radiology products, in order to optimize the products that are stocked in the pharmacy.

**Methods:** This study has been submitted to the Institutional Review Board for approval. An extensive retrospective review will be conducted on all radiopharmaceuticals that were ordered and removed from the automated dispensing unit (ADMU) at the Miami VA Medical Center between August 1st, 2015 and August 1st, 2016. Variables that will be assessed include contrast media and other radiopharmaceuticals, dose, route, administration records, the imaging procedure that the product was ordered for, and patient allergies. This data will be collected using the Computerized Patient Record System (CPRS) at the Miami VA Medical Center and through a review of ADMU removals. The data will be stratified based on the route, radiopharmaceutical product, and imaging procedure. With the background data and hospital-wide usage data, we will analyze the cost of each product per year. We will then be able to identify cost-effective ways to use these radiologic products for our patients. Lastly, we will take the finalized data that we have collected, and we will present it to the physicians who commonly order radiology products, in order to come up with a standardized set of radiology medications, which will allow us to optimize the products that are stocked in the pharmacy, while eliminating radiology medications that are less cost-effective. The data will be analyzed using descriptive statistics.

Poster Title: Product standardization initiative at the Miami Veterans Affairs Medical Center's spinal cord pharmacy

Primary Author: Lilien Guzman, Miami VA Healthcare System, FL; Email: lilyg16@hotmail.com

Additional Author (s):
Idalmys Milo
Alga Ramos-Morales
Alexandria Cabrera
Mara Carrasquillo

Purpose: It is estimated that around 42,000 American veterans have a serious spinal cord injury. To meet the needs of this population, the Miami VA has a spinal cord pharmacy designated to dispense essential medical supplies and medications. The objective of this quality improvement project is to facilitate the dispensing process of spinal cord products by standardizing current inventory to match the items dispensed from the mailing facility. Additionally, different vendors will be evaluated for further cost savings. As part of multiple improvement projects, we estimate this venture will improve access to these products and optimize utilization of pharmacy resources.

Methods: Spinal cord products on hand will be reviewed and compared to products listed in the Miami VA’s drug file in an effort to assure products in the pharmacy match products selected for dispensing. We will then compare products supplied by two different vendors, Medline and Independence Medical. After equivalence is established, we will perform a cost savings analysis evaluating the cost of the product and availability at the mailing facility to select a vendor of spinal cord medical supplies and medications. After ensuring product standardization, we will run a report of all products dispensed within a year, from August 31, 2015 to September 1, 2016, in the spinal cord pharmacy. After review of report, we will prioritize the stock of the most frequently dispensed products in the spinal cord pharmacy in an effort to optimize pharmacy space. Furthermore, after evaluating quantity of dispensed products, we will designate a sufficient amount to keep stocked in the spinal cord pharmacy in order to provide only an initial supply of medical supplies; allowing the remainder of the supply to be mailed via the mailing facility.

**Session-Board Number:** 1-117

**Poster Title:** Post-implementation assessment of intravenous drug administration policy at the Miami Veterans Affairs Medical Center

**Primary Author:** Michael Serbun, Miami VA Medical Center, FL; **Email:** michael.serbun@va.gov

**Additional Author(s):**
Karl-Eric Solius
Alga Ramos

**Purpose:** The Miami Veterans Affairs Medical Center recently updated the medication administration policy to identify intravenous (IV) medications that could be rapidly injected. Previous literature had shown that rapid infusion minimizes delays in time to administration, and achieves cost-minimization. This project was designed to assess the application of the policy set forth and the financial impact on the facility. The project will also identify additional drugs that could potentially be administered as IV push.

**Methods:** A retrospective analysis will be conducted on Intravenous drug orders processed between August 2015 to August 2016 at the Miami Veterans Affairs Medical Center. Variables assessed will be medication, dose, infusion rate, medical unit, and administration schedule. The following orders will be excluded from the analysis: intravenous drips, electrolyte solutions, crystalloids and colloids solutions. Remaining orders will be stratified by medication and infusion rate and evaluated for observance of policy. Cost-savings will be evaluated using the difference in material costs between the procurement of the IV push dose versus IV mini bag dose. Orders currently not included in the medication administration policy will be considered for possible IV push inclusion based upon patient safety, cost containment, and workload encumbrance. Descriptive statistics (frequency, percentages) will be used to measure compliance with the medication administration policy.

Poster Title: Evaluation of the 'Choosing Wisely: Hypoglycemia Safety Initiative' at the North Florida/South Georgia Veterans Health System

Primary Author: Samantha Orth, North Florida/South Georgia Veteran Health System, FL; Email: samanthalorth@gmail.com

Additional Author(s):
Kelly Kyrourac
Rebecca Beyth

Purpose: The ‘Choosing Wisely: Hypoglycemia Safety Initiative’ (HSI) is a national Veterans Health Administration (VHA) directive aimed at identifying patients at high risk for hypoglycemia. It utilizes evidence supported within both primary literature and guideline recommendations to construct a model for tailoring patient-specific treatment goals, with a focus on creating an environment suitable for shared decision making between patients and providers. The purpose of this report is to assess the efficacy of the ‘Choosing Wisely: Hypoglycemia Safety Initiative’ within the North Florida/South Georgia Veterans Health System and to propose a plan for further expansion throughout the health system.

Methods: This project is approved as Continuous Quality Improvement (CQI) through the University of Florida Institutional Review Board. The cornerstone of the Hypoglycemia Safety Initiative is to identify patients at high risk for hypoglycemia and screen them for the occurrence of hypoglycemic episodes. The initiative defines ‘high-risk’ for hypoglycemia as any patient with a hemoglobin A1c less than or equal to 7% with an active prescription for either insulin or a sulfonylurea, plus at least one additional risk factor: age greater than or equal to 75 years old, a diagnosis of dementia or cognitive impairment, or serum creatinine greater than 1.7 mg/dL. Hypoglycemia assessments are conducted through the use of a Clinical Reminder in the Computerized Patient Record System (CPRS) that prompts for completion in patients that meet these criteria. The Clinical Reminder consists of a series of four questions focused primarily on the frequency and severity of hypoglycemic episodes. Screening takes place in the clinic setting as well as via telephone by either a primary care provider or clinical pharmacist. A secondary yet significant aim of this project is to create and perform education surrounding the
HSI through the process of academic detailing. Seminars are planned in both large and small forums as well as in one-on-one sessions to educate healthcare providers about this important safety and quality assurance initiative.

**Results:** A review of the HSI database revealed that over 2,200 patients within the North Florida/South Georgia Veterans Health System are at high-risk for hypoglycemia, which is compared to over 82,000 patients nationally. The HSI pilot period began in April 2015 with select primary care physicians and pharmacists within the North Florida/South Georgia Veterans Health System. Following a grand rounds presentation in August 2015, all primary care providers in attendance were educated on the initiative and encouraged to participate. Other supplementary educational efforts were performed as needed in various settings within pharmacy, primary care, diabetes focus groups, and informal exchanges. Collectively during the first year of implementation, 62 patients were identified by the HSI and assessed for hypoglycemia. Of those 62 patients, 17 patients reported at least one episode of hypoglycemia resulting in 16 cases of relaxation of therapy. Of the 45 patients that did not report at least one episode of hypoglycemia, 10 patients warranted relaxation of therapy as determined by their provider. Overall, a total of 26 out of 62 patients [42%] had diabetic regimens relaxed.

**Conclusion:** The ‘Choosing Wisely: Hypoglycemia Safety Initiative’ aims to create an environment in which patients and caregivers, alongside providers, are extended the opportunity to make shared decisions regarding diabetes management. Nearly half of patients identified by the HSI had diabetic therapy relaxed regardless of hypoglycemic episodes, leading the authors to believe that the HSI is indeed encouraging these shared conversations. Looking ahead, complete implementation of the HSI within the North Florida/South Georgia Veterans Health System is expected January 2017 as clinical pharmacists accept a major role in executing this initiative. Until that time, ongoing educational efforts and data collection will continue.
**Submission Category:** Clinical Services Management

**Submission Type:** Descriptive Report

**Session-Board Number:** 1-119

**Poster Title:** Assessment of a pharmacist managed nintedanib and pirfenidone phone clinic for the treatment of idiopathic pulmonary fibrosis in a veterans health system

**Primary Author:** Courtney Guidry, North Florida/South Georgia Veterans Health System, FL; Email: courtney.guidry@va.gov

**Additional Author(s):**
Mark Burlingame

**Purpose:** Two drugs, nintedanib and pirfenidone, were recently approved for treatment of idiopathic pulmonary fibrosis (IPF). While not curative, these medications demonstrated a slowing of disease progression in clinical trials. Use of these medications is associated with treatment-limiting adverse effects, elevations in liver function enzymes and substantial cost. Frequent monitoring is needed, especially early on in treatment, to assure safety, tolerability, adherence and appropriate use. This quality assurance project assessed an existing pharmacist managed phone clinic of patients using nintedanib or pirfenidone for IPF as a means of assuring optimal clinical and fiscal outcomes.

**Methods:** A retrospective chart review was conducted on all patients initiated on either pirfenidone or nintedanib within a veterans health system since the medications were approved for use by the Food and Drug Administration (FDA). Patients were reviewed from February 2015 to May 15, 2016. Patients were evaluated in accordance with the VA Pharmacy Benefits Management (PBM) criteria for use (CFU). Patients met criteria and were eligible to receive pirfenidone or nintedanib if they were followed by a VA pulmonologist and had a diagnosis of IPF that met American Thoracic Society, European Respiratory Society, Japanese Respiratory Society, and the Latin American Thoracic Association (ATS/ERS/JRS/ALAT) diagnostic requirements. Once approved for treatment, all patients received a telephone call from the pharmacist prior to starting treatment for medication counseling and were provided with an initial 2 week supply of medication to ensure tolerability and minimize drug waste. Pharmacists followed up with the patient within 10 days of starting medication to assess tolerability. Patients were then provided with a 30 day supply of medication. Pharmacists followed up with the patient monthly via phone to address medication compliance, tolerance, arrange required monthly laboratory monitoring, and arrange medication refills. Pharmacists
coordinated with the pulmonary provider to order labs, address adverse effects and recommend dosage adjustments when necessary. All pharmacist encounters with the patient were recorded in the electronic medical record.

Results: A total of 32 patients were identified as receiving either pirfenidone or nintedanib since February 2015. Twenty-one (66%) patients received nintedanib only, nine (28%) received pirfenidone only, and two (6%) patients had separate trials of both agents. The average patient age was 71.5 years, and average duration of therapy was 5.8 months. All patients reviewed met VA PBM CFU for nintedanib or pirfenidone. At the time of chart review, 41% of patients had discontinued treatment. Eleven (48%) nintedanib patients and two (18%) pirfenidone patients discontinued therapy. The most common reason for discontinuation was liver function test elevations with nintedanib followed by nausea/abdominal pain and diarrhea with nintedanib. Five (16%) patients had a fall-out of greater than 60 days between required lab monitoring. Fourteen (44%) patients experienced an adverse event while on therapy. Most (78%) adverse events occurred while on nintedanib. Diarrhea was the most common adverse event, followed by abdominal pain/nausea. The medication possession ratio for patients on therapy was 99.7% and all patients reported taking the prescribed dosage when questioned. A total of 136 patient/pharmacist phone calls were documented since clinic inception. Pharmacists sent 39 requests for lab monitoring and were alerted or contacted 8 times regarding adverse events.

Conclusion: All patients evaluated in this review met VA PBM CFU to receive either pirfenidone or nintedanib. The high frequency of adverse events with these medications often requires dosage adjustments or discontinuation of therapy. Specialty drug clinics provide pharmacists the unique opportunity to ensure safe and appropriate use of high-cost medications. Additional indications and combination therapy are on the horizon for nintedanib and pirfenidone. Inclusion of a dedicated pharmacist with a scope of practice to the IPF clinic could streamline current processes, improve adherence rates for lab monitoring and continue to ensure appropriate use of these medications while optimizing fiscal outcomes.
**Submission Category:** Critical Care

**Submission Type:** Evaluative Study

**Session-Board Number:** 1-120

**Poster Title:** Evaluation of a bedside computerized clinical decision support tool for intravenous insulin infusion management in critically ill medical patients.

**Primary Author:** Julia Balazh, North Florida/South Georgia Veterans Health System, FL; **Email:** jbalazh@gmail.com

**Additional Author(s):**
Evan Telford
Andrew Hendrickson
Nicole Maltese Dietrich
Andrew Franck

**Purpose:** Blood glucose control is a fundamental aspect of care for critically ill patients as both hyper- and hypoglycemia are associated with negative outcomes. A validated intravenous insulin infusion protocol targeting a blood glucose range of 140-180 mg/dl is the recommended method of blood glucose control for most intensive care unit (ICU) patients. Validated protocols with computerized clinical decision support tools targeting this blood glucose range are needed. The purpose of this study was to evaluate the safety and effectiveness of a computerized clinical decision support tool for insulin infusion protocol developed at North Florida/South Georgia Veterans Health System (NF/SG VHS).

**Methods:** The clinical pharmacy service at NF/SG VHS developed a bedside computerized clinical decision support tool to assist the ICU nursing staff with the management of our intravenous insulin infusion protocol. The tool incorporated the paper-based intravenous insulin infusion protocol developed by the University of Pittsburgh Medical Center. To evaluate the safety and effectiveness of this tool, a retrospective case series was conducted including all patients who were admitted to the medical intensive care unit (MICU) between May 1, 2015 and December 15, 2015 and who were treated with the intravenous insulin infusion protocol for at least 12 hours for blood glucose control. Patients receiving intravenous insulin infusion for the treatment of hyperglycemic crises or for indications other than blood glucose control were excluded. Baseline demographic data was collected. The effectiveness outcomes included time to achieve target blood glucose range (140-180 mg/dl), proportion of blood glucose readings within target blood glucose range, and median blood glucose value once target blood
glucose range was achieved. The safety outcome was frequency of hypoglycemia (blood glucose less than 70 mg/dl) while receiving the insulin infusion protocol. Local institutional review board approval was obtained.

**Results:** Twenty-four male patients with a mean age of 63 years were included in this analysis. Five patients (21 percent) were considered to have normal body weight, six patients (25 percent) were overweight, and 13 patients (52 percent) were obese. The mean BMI for all patients was over 35 kg/m2. Twenty-two patients (92 percent) had a history of diabetes prior to MICU admission. The mean baseline APACHE II score was 17. The mean baseline blood glucose prior to initiation of insulin infusion was 331 mg/dl. The mean time to achieve goal blood glucose (less than 180 mg/dl) was 8.3 hours from the start of the insulin infusion. After goal blood glucose was reached, the median blood glucose was 164 mg/dl (IQR 144-187 mg/dl). Blood glucose was within the desired range for 48 percent of blood glucose values. Blood glucose was within the range of 100-180 mg/dl and 100-200 mg/dl for 67 percent and 82 percent of blood glucose values, respectively. The median duration of insulin infusion was 26 hours. One episode of mild hypoglycemia occurred (blood glucose 67 mg/dl), translating to 0.09 percent of all BG values and 0.06 events per 100 hours of insulin infusion.

**Conclusion:** The protocol utilized in this analysis was found to be safe as defined by a low occurrence of hypoglycemia. The effectiveness of the protocol in achieving and maintaining blood glucose within a target blood glucose range was similar to previously reported data. Our bedside computerized clinical decision support tool appeared to be useful in the management of an intravenous insulin infusion protocol for blood glucose control in MICU patients.
**Submission Category:** Infectious Diseases

**Submission Type:** Case Report

**Session-Board Number:** 1-121

**Poster Title:** Decreased renal function after initiating treatment with sofosbuvir/ledipasvir: A Patient Case

**Primary Author:** Aleia Judd, North Florida/South Georgia Veteran's Health System, FL; **Email:** aleiajudd@gmail.com

**Additional Author (s):**
Adam Clark

**Purpose:** Case Report: This case series shows the effect of ledipasvir/sofosbuvir on creatinine levels.

Patient A is a 65 year old African American male who was evaluated to begin treatment for his genotype 1a hepatitis C infection in June 2016. Patient was treatment naïve, had no evidence of cirrhosis, and had less than 6 million copies of HCV RNA so an 8-week course of ledipasvir/sofosbuvir was chosen to treat his infection. Patient started treatment on 6/27/16 and his baseline serum creatinine level was 1.0 mg/dL. After 4 weeks of treatment with ledipasvir/sofosbuvir, the patient’s viral load was undetected and his serum creatinine increased to 1.4 mg/dL, an increase of 0.4 mg/dL. Patient A denied medication changes that could account for the increased creatinine level. As his creatinine clearance was still above 30 mL/min, which is the creatinine clearance value at which ledipasvir/sofosbuvir should be continued, his HCV treatment was continued for the remainder to treatment. After 8 weeks of therapy, patient A’s viral load was still undetected, but his serum creatinine decreased to 1.3 mg/dL; however, this is still above his baseline. A review of his renal function after 12-weeks off therapy will help determine if this is a transient or permanent increase in creatinine associated with ledipasvir/sofosbuvir.

Patient B is a 64 year old African American male who was also evaluated to begin treatment for his genotype 1a hepatitis C infection in June 2016. Patient was treatment naïve, had no evidence of cirrhosis, and had more than 6 million copies of HCV RNA at baseline so a 12-week course of ledipasvir/sofosbuvir was initiated. Patient started treatment on 6/24/16 and his baseline serum creatinine was 1.2-1.3 mg/dL (patient’s creatinine fluctuated between the two values for 6 months prior to treatment). After 4 weeks of treatment his viral load was still detected and his serum creatinine increased to 1.6 mg/dL, and increase of 0.3 mg/dL. As his creatinine clearance remained above 30 mL/min, ledipasvir/sofosbuvir was continued. After 10
weeks of treatment, patient A’s viral load was undetected and his serum creatinine had decreased to 1.4 mg/dL, but was still above baseline. At the end of treatment, or 12 weeks, patient’s serum creatinine returned to his baseline with a value of 1.2 mg/dL. As this case series suggest, initiation of ledipasvir/sofosbuvir may be associated with an increase in creatinine. While more studies will be needed to determine if this increase in creatinine is seen in a majority of patients who start ledipasvir/sofosbuvir, it is important for providers to be aware that this increase in creatinine could occur in their patients.

**Poster Title:** Impact of rapid antigen detection testing (RADT) on antibiotic prescribing patterns for acute pharyngitis in ambulatory care clinics of a Veteran Affairs (VA) Medical Center

**Primary Author:** Conny He, Orlando VA Medical Center, FL; Email: conny.he2@va.gov

**Additional Author(s):**
Deylen Aponte-Rosario
Teresa Geide

**Purpose:** The Infectious Diseases Society of America (IDSA) guidelines recommend RADT as a quick and valid alternative diagnostic test to throat cultures for diagnosing Group A streptococcus pharyngitis. The first phase of this study was conducted to assess adherence of prescribed antibiotics to current treatment recommendations for acute pharyngitis. The purpose of this second phase is to evaluate the impact on antimicrobial prescribing as a result of RADT implementation in March 2015.

**Methods:** This study has been approved by the Institutional Review Board. A retrospective chart review of patients diagnosed with acute pharyngitis from March 2015 to March 2016 will be conducted. Patients 18 years of age and older with a single diagnosis of acute pharyngitis during the study period will be included. The following patients will be excluded: chronic diagnosis of pharyngitis, subsequent patient visits with diagnosis of acute pharyngitis, concomitant infections, incorrect primary diagnosis code or restricted health records. A patient list will be obtained through a computer-generated report using billing codes from the International Classification of Diseases, 9th (ICD-9) and 10th Revision (ICD-10) for acute pharyngitis. Data points collected will include: patient age, race, gender, tobacco and alcohol usage, immunocompromising conditions, chronic diseases, antibiotic use or hospitalization within the previous three months, chief complaint, drug allergies, serum creatinine, RADT and throat culture results, provider type, type of interaction between provider and patient, and antibiotic prescription information. Antibiotics will be classified as adherent with guidelines if the medication dosage, frequency, and duration match the guideline recommendations. Adherence frequencies before and after implementation of RADT will be compared to determine the impact of RADT on antibiotic prescribing patterns.

Poster Title: Evaluation of influenza and pneumococcal vaccinations in patients receiving intravenous chemotherapy at a Veterans Affairs Medical Center

Primary Author: Thierry Phouthavong, Orlando VA Medical Center, FL; Email: thierry.phouthavong@va.gov

Additional Author(s):
Rebecca Greene
Melissa Butler

Purpose: Patients receiving chemotherapy are at high risk for complications from influenza and pneumonia. Complications may result in treatment delays, hospitalizations, increased healthcare costs, and increased mortality. Despite concern for inability to mount optimal immunological response, studies show patients receiving chemotherapy benefit from vaccinations. Therefore, the Advisory Committee on Immunization Practices (ACIP) recommends influenza and pneumococcal vaccinations at least two weeks prior to chemotherapy initiation. Timing of vaccinations for patients already receiving chemotherapy remains unclear. The aim of this evaluation is to determine rates of influenza and pneumococcal vaccinations among patients receiving chemotherapy in accordance with ACIP guidelines.

Methods: This quality initiative does not require IRB approval. The initiative will evaluate rates of influenza and pneumococcal vaccinations among patients receiving intravenous chemotherapy at a Veterans Affairs Medical Center. Patients receiving intravenous chemotherapy from September 2015 – February 2016 will be identified via a computer-generated report from the electronic medical record. The evaluation will include age, gender, comorbidities, cancer diagnosis and treatment frequency, administration of rituximab/obinutuzumab, documentation of an offering of influenza and pneumococcal vaccinations, timing of administration of vaccinations in relation to chemotherapy treatment, absolute lymphocyte count at time of administration, adverse reactions to vaccinations, and documented cases of influenza. The evaluation will exclude patients with a documented allergy to any of the vaccinations, contraindication to intramuscular injections, receiving chemotherapy...
for a non-cancer diagnosis, or who have undergone previous stem cell transplant. Further process intervention will be determined based on the findings of this evaluation.

**Results:** N/A

**Conclusion:** N/A
**Purpose:** In the VAMC, Veterans receive prescriptions primarily by picking-up at the pharmacy, mail from the local VAMC, or mail from a Consolidated Mail Outpatient Pharmacy (CMOP). Literature has shown that a delay in antimicrobial therapy may be associated with increased mortality. The utilization of mail-order pharmacy services for acutely-indicated outpatient antimicrobial prescriptions may cause a delay in the time-to-treatment initiation. The goal of this process improvement project is to analyze dispensing processes of acutely-indicated antimicrobials in order to identify opportunities for improvement and subsequently develop and implement interventions, as necessary, to reduce time-to-prescription receipt.

**Methods:** To determine the scope and direction for this project, a report containing all outpatient antimicrobials dispensed from August 2015 to July 2016 from a VAMC will be generated from a Veterans Affairs (VA) database and analyzed. CMOP dispensing and delivery information will be reviewed via an integrated CMOP web application. Time-to-prescription receipt for acutely-indicated outpatient antimicrobial prescriptions dispensed by mail will be calculated by determining the difference in time (days) from the prescription issue date to the prescription delivery date. Outpatient antimicrobial prescriptions must meet the following inclusion criteria: dispensed by mail, days’ supply of 14 days or less, marked as original (as opposed to refill). Prescriptions will be excluded if they meet any of the following criteria: antimicrobials that are only indicated for chronic infections, marked as a refill, contain a significant of prophylaxis for a procedure, unavailable tracking information. The development and implementation of an intervention will be determined. A post-intervention data analysis will assess the effectiveness in reducing time-to-prescription receipt. This process improvement project will not require institutional review board (IRB) approval.

Poster Title: Design and implementation of a 24-hour ambulatory blood pressure monitoring (ABPM) service at a veterans affairs medical center

Primary Author: Norman Hooten, Orlando Veterans Affairs Medical Center, FL; Email: norman.hooten@va.gov

Additional Author(s):
Emiliya Khazan
Christina Coakley

Purpose: Current clinic blood pressure measurement techniques are insufficient in the diagnosis and management of hypertension. 24-hour ABPM is endorsed by several organizations and considered the gold standard in evaluating blood pressure. Implementation of 24-hour ABPM, pharmacist-managed service will enable clinicians to refer appropriately selected, ambulatory patients who will likely benefit from a more accurate assessment of blood pressure, guiding optimization or reduction of anti-hypertensive therapy. This strategy can potentially improve clinical outcomes and provide cost-savings associated with the management of hypertension.

Methods: The objective of this project is to establish a pharmacist-managed, 24-hour ABMP clinic at the medical center. This will include creation of a business plan including recommendation for selection of the 24-hour ABPM device. The ABPM clinic will be a consult service independently managed by the cardiology clinical pharmacy specialist (CPS). The consult will initially be limited to referral by providers within the cardiology service. Candidates for the 24-hour ABPM service will include patients with suspected white coat hypertension or white coat effect and suspected nocturnal hypertension, with potential for expansion to other indications in the future. Patient specific ABPM results will be evaluated by the cardiology CPS, recommendations will be reviewed with a cardiologist, and interventions will be implemented via shared decision making with the patient and referring provider. The service business proposal will be presented to pharmacy administration and chief of cardiology for approval and concurrence.

Poster Title: Process improvement regarding outpatient prescribing practices in Veterans with myasthenia gravis within a multi-campus Veterans Affairs Medical Center

Primary Author: Justin Dorotheo, Orlando Veterans Affairs Medical Center (OVAMC), FL; Email: justin.dorotheo@va.gov

Additional Author(s):
Natasha Antonovich
Christina Coakley

Purpose: The results of a previous medication use evaluation (MUE) indicate prescribing of potentially inappropriate medications (PIMs) occurs in Veterans with myasthenia gravis (MG) without documented acknowledgement of risk or plan for closer monitoring. The objective of this process improvement (PI) project is to determine if increased awareness by prescriber or pharmacist will be recorded in the electronic medical chart after implementation of a clinical reminder order check (CROC).

Methods: A CROC will be developed and implemented to alert both prescriber and pharmacist when a PIM is ordered in a Veteran identified with MG. PIM severity will be pre-determined based on recommendations published by the Myasthenia Gravis Foundation of America (MGFA). Data collected will include: patient’s name, number of CROCs triggered, PIM and directions, prescriber and pharmacist acknowledging the CROC, presence of an intervention, source of documented intervention, and prescriber practice area. The primary outcome will be the percent of documented interventions. Data collected from a previous and related MUE will be compared and analyzed to identify changes in prescribing practices of PIMs in patients with MG before and after implementation of the CROC.

Poster Title: Assessment of outcomes following opioid tapering in a veterans healthcare system

Primary Author: Lauren Hundley, PGY2 Palliative Care/Pain Management Pharmacy, FL; Email: laurenwhundley@gmail.com

Additional Author(s):
Shelley Spradley
Mark Richman
Patrick Chan

Purpose: The purpose of this study is to describe and assess the impact of high dose opioid therapy tapers in veterans with chronic non-cancer pain completed within the North Florida/South Georgia Veterans Healthcare System (NF/SG VHS) prompted by the initiation of the Opioid Safety Initiative (OSI) in 2013. The ultimate goal is to determine whether expanding the role of a clinical pain pharmacist in assisting with opioid tapers is warranted to improve patient outcomes, safety, and quality of life, i.e. by providing medication management recommendations.

Methods: This will be a single center, retrospective, observational chart review conducted at the NF/SG VHS. The VA corporate data warehouse and computerized patient record system will be used to identify patients on 300mg morphine equivalents per day (MED) or greater as of January 1, 2012 who are identified as having opioid therapy tapered based on decreasing MED and an opioid agreement discontinuation note documented in the chart. Veterans treated for cancer pain or under palliative care will be excluded. Descriptive outcomes regarding the tapering of opioids will include the average duration of taper, rate of relapse, duration of abstinence, percentage of patients who seek non-VA health care, percentage of patients lost to follow-up, number of referrals to substance abuse treatment and/or pain specialty services, number of naloxone prescriptions, and number of buprenorphine prescriptions. Patient outcomes will include suicide attempts and mortality rate including death due to drug overdose. Differences in the year prior to tapering compared to the year following discontinuation of opioid therapy will be determined, including the average number of emergency room visits, primary care visits, hospitalizations, urine drug tests, prescription drug monitoring program queries, patient weight, number of non-opioid pain medications per
patient, number of benzodiazepine prescriptions, and number of complementary and alternative medicine modalities utilized before and after tapering.

**Poster Title:** Analysis of proton pump inhibitor utilization to promote patient safety and cost avoidance within the medical center

**Primary Author:** Umima Baig, West Palm Beach VA Medical Center, FL; **Email:** umimabaig@gmail.com

**Additional Author (s):**
Tina Cha

**Purpose:** Proton pump inhibitors (PPIs) are prescribed for stress ulcer prophylaxis but often not discontinued when the patient is discharged from the hospital. Without appropriate indications, there is unnecessary exposure to health risks and increased costs for the facility. The objective of this project is to assess the frequency of patients being discharged on a PPI after hospitalization as well as the appropriateness of indications for prescribing. Additionally, choice of PPI will be evaluated to ensure fulfilling of criteria for use at this facility as well as an analysis of potential cost avoidance.

**Methods:** A retrospective medical record review of approximately 100 patients discharged with PPIs over the past 12 months will be conducted to assess for indication at the medical center. Data collected will include demographics such as age and gender and will focus on length of PPI use, indication, and outpatient usage post-discharge. An analysis of potential cost avoidance will be conducted.

**Poster Title:** Assessment of medication use in bipolar disorder

**Primary Author:** Melissa Waineo, West Palm Beach VA Medical Center, FL; **Email:** mfw87@hotmail.com

**Additional Author(s):**
Molly Leach
Nicole Elharar

**Purpose:** The objective of this project is to summarize prescribing habits with mood stabilizers and second generation antipsychotic (SGA)s in patients with a bipolar disorder (BD) diagnosis at this Veterans Affairs Medical Center (VAMC). The secondary objective is to identify potential reasons why these medications would not be prescribed. Based on results, proposals of ways to aid or remind prescribers that these medications are recommended in BD will be proposed.

**Methods:** This project was approved by the VAMC Scientific Advisory Committee. The evaluable population will be selected from the Veterans Health Administration (VHA) quarterly Psychotropic Drug Safety Initiative (PDSI) dashboard report that includes patients with a BD diagnosis but no mood stabilizer or SGA prescribed for fiscal year 16, quarter 3 at this VAMC. This number will be divided by the total population of BD patients, including those that are prescribed a mood stabilizer or SGA. Approximately 400 patients are expected to be identified that are not prescribed the above medications. Twenty-five percent of this population, or a maximum of 100 patients, will be included for review by systematically selecting every nth patient based on the total number. Patient demographics will be collected from the Computerized Patient Record System (CPRS) along with length of diagnosis, types and durations of past treatments, documented adverse reactions to these medications, concomitant psychiatric disorders, appointment attendance, treatments for BD, and BD hospitalizations. These data will be used to identify potential reasons that these medications are not prescribed so that an effective intervention can be proposed. Data will be analyzed by descriptive statistics.

Poster Title: Characterizing antipsychotic compliance barriers in Veterans diagnosed with schizophrenia or schizoaffective disorder

Primary Author: Daniela Valencia, West Palm Beach VA Medical Center, FL; Email: dv361@nova.edu

Additional Author (s):
Nicole Elharar
Molly Leach

Purpose: Schizophrenia and schizoaffective disorder are chronic and severe mental health conditions characterized by psychotic symptoms and mood disorders that interfere with patients’ overall functioning. First generation antipsychotics and second generation antipsychotics are used in the treatment of schizophrenia and schizoaffective disorder; however, patients face constant challenges in managing their condition due to non-compliance with medications. The purpose of this retrospective review is to assess patients with schizophrenia or schizoaffective disorder and characterize reasons for antipsychotic non-compliance among the Veteran population. In addition, provide information to health care professionals on how to improve medication compliance in these patient population.

Methods: A report of actionable patients is routinely generated through the Psychototropic Drug Safety Initiative for low medication compliance, defined as an antipsychotic medication possession ratio less than 80 percent in Veterans with schizophrenia and schizoaffective disorder. Patients will be selected from fiscal year 16 report, quarter 3. Patients with a primary diagnosis of schizophrenia or schizoaffective disorder who receive medical care at the medical center and have a prescription for a first generation or second generation antipsychotic will be included. A retrospective medical record review will be performed to identify barriers for non-compliance (e.g., inaccurate diagnosis of schizophrenia or schizoaffective disorder, lack of follow-up appointment, lack of medication refills, comorbid mental health condition, hospitalizations within the 6 months, substance abuse history within the last 6 months, medication compliance percentage determined by the dashboard, and antipsychotic discontinuation due to side effects).

Poster Title: Frequency of polypharmacy and potentially inappropriate medications in blind geriatric Veterans

Primary Author: Marina Ishak, West Palm Beach VA Medical Center, FL; Email: marinaeishak@gmail.com

Additional Author(s):
Sandra DiScala
Jennifer Quellhorst
Ann Marie Taffe
Michael Silverman

Purpose: Visually impaired Veterans who enroll into blind rehab centers throughout the country are at an increased risk of polypharmacy and inappropriate prescribing. Polypharmacy is defined as 5 or more medications. Potentially inappropriate medications (PIMs) can contribute to polypharmacy. There is currently a paucity of data on the harms associated with polypharmacy and PIMs in blind Veterans. The primary objective of this quality improvement project is to describe the frequency of PIMs and polypharmacy amongst visually impaired Veterans. The secondary objective is to characterize blind Veteran co-morbidities and determine if they correlate with frequency of PIMs to improve inappropriate prescribing practices.

Methods: A retrospective chart review will be conducted involving patients who were admitted to the blind rehab center during July 1, 2015 through July 1, 2016. Exclusion criteria will be defined as patients less than 65 years of age and patient admissions that were repeated throughout the year. Inclusion criteria will be defined as Veterans 65 years old or greater and will only include first admission to the blind rehab unit. For patients admitted more than once, only the initial admission will be reviewed. Data collection will include age, ethnicity, gender, cause of blindness, number of patients requiring transfer to higher level of care, classification of drug related problems, total number of medications, co-morbid disease states, and inappropriate duration of therapy. PharmD resident will complete medical record review, cataloging type of drug related problems such as therapeutic duplications, omission of medications, and medications without an indication. Descriptive statistics will be used.

**Poster Title:** Assessing the impact of inpatient hospice pharmacist interventions at a Veterans Affair medical center

**Primary Author:** Danny Basri, West Palm Beach VA Medical center, FL; Email: dannyb718@gmail.com

**Additional Author(s):**
Sandra DiScala
Christine Vartan
Abigail Brooks
Jennifer Quellhorst

**Purpose:** The primary objective of this project is to characterize inpatient hospice pharmacists’ interventions and evaluate cost-savings associated with these interventions. The secondary objectives are to assess the validity and applicability of the Pharmacists Achieve Results with Medications Documentation (PhARMD) tool in the hospice setting and determine physician offloading time associated with pharmacist interventions.

**Methods:** This project has been approved by the Scientific Advisory Committee as part of the facility’s ongoing performance improvement efforts. At the West Palm Beach VA Medical Center (WPB VAMC), the Pharmacists Achieve Results with Medications Documentation (PhARMD) tool provides the ability to document and track pharmacist interventions in various settings. The PhARMD tool will be used to identify interventions made by inpatient hospice pharmacists between August 1, 2016 and November 30, 2016. Through retrospective review of clinical notes in the computerized patient record system (CPRS), each intervention will be reviewed to record patient age, gender, reason for visit, disease state or symptom for intervention, and intervention type. Examples of intervention types include: dose adjustments, initiation of new therapies, and discontinuation of existing medications. Before the aforementioned data are collected, a quality assurance evaluation will be conducted to assess the accuracy of documentation with the PhARMD tool by the pharmacists working in the hospice unit. A random sample of at least 10 documented interventions per pharmacist from the WPB VAMC inpatient hospice unit between July 15, 2016 and July 30, 2016 will be reviewed. Cost savings based on interventions will be calculated using published estimations of
cost avoidance associated with various intervention types. Physician offloading times will be determined using documented times spent per intervention. Data will be analyzed using descriptive statistics.

**Results:** N/A

**Conclusion:** N/A
Approval of with patient manage will January neurology disease and this multidiagnostic approach often required. 

Purpose: Parkinson’s disease (PD) is a progressive, debilitating neurodegenerative disease that often requires complex pharmacologic treatment regimens and interventions from a multidisciplinary team. To date, there is no involvement of a clinical pharmacy specialist (CPS) in the outpatient neurology clinic at our Veteran’s Affairs (VA) medical center. The objective of this project is to develop an outpatient neurology telephone clinic and evaluate pharmacologic and non-pharmacologic interventions in an effort to improve quality of care for Parkinson’s disease patients.

Methods: Patients who have a diagnosis of PD and have been assessed by a neurologist at our VA medical center will be enrolled into the Pharm Neurology Phone clinic via consult from neurology, primary care or speech pathology providers. The clinic will be piloted between January 6, 2017 through March 31, 2017. During the outpatient telephone clinic visit, patients will have their PD medications and neuropsychiatric non-motor complications from PD managed by a CPS in lieu of a face-to-face visit. At the conclusion of clinic time on March 31, 2017, providers will receive a satisfaction questionnaire. The following data will be collected: patient demographics, social history, assessment for the presence of non-motor complications and number of pharmacologic and non-pharmacologic interventions made. Data will be recorded without patient identifiers and maintained in a confidential and secured electronic file. The CPS will conduct medication education groups to patients with PD and their caregivers with the purpose of promoting patient knowledge and medication awareness. At the conclusion of each PD medication group, patients will receive an anonymous patient’s satisfaction questionnaire. This project was approved by the facility scientific advisory committee. IRB approval was not required.

Poster Title: Glycemic control in diabetics after successful hepatitis c (HCV) eradication

Primary Author: Christopher Green, Atlanta VA Medical Center, GA; Email: christopher.green6@va.gov

Additional Author(s):
Vian Nguyen
Bonnie Chan
Kathryn DeSilva
Emily Cartwright

Purpose: There have been multiple associations between the treatment of hepatitis C (HCV) and improvement in extra-hepatic outcomes including reductions in end-stage renal disease, ischemic stroke, and acute coronary syndrome. Hepatitis C infection has been associated with an increase in insulin resistance and the development of type 2 diabetes, and successful treatment of hepatitis C is associated with improvement in fasting plasma glucose. The objective of this study is to quantify the change in glycemic control after successful HCV treatment with subgroups evaluating the impact from cirrhosis and human immunodeficiency virus (HIV).

Methods: This study will be submitted to the Institutional Review Board for approval to be conducted as a retrospective cohort review. Patients will be selected based on successful HCV treatment and being a type 2 diabetic. Data will be collected on those patients to judge outcomes of interest including the primary outcome which is changes in glycosylated hemoglobin (HA1C) from before to after treatment. Baseline data will also include patient demographics as well as baseline labs including HCV genotype, direct-acting antiviral regimen chosen, post-treatment viral load, cirrhosis as measured by Child-Pugh score, HIV status, any antiretroviral therapy patient is on, diabetic status, and if patient is on insulin or any oral hypoglycemic agents. We will exclude patients on systemic steroids longer than one month during the three months before until three months after direct-acting antiviral therapy. Also excluded will be patients on tacrolimus, cyclosporine, sirolimus, or interferon-alpha. Paired t-tests will be utilized to assess if successful hepatitis C treatment decreased HA1C from before
treatment baseline to after treatment. All data will be collected and patient identifiers will be removed to maintain confidentiality.

**Poster Title:** Assessment of vancomycin trough concentrations compared to AUC/MIC as a predictor of efficacy for documented MRSA infections within the Atlanta VA Medical Center (AVAMC)

**Primary Author:** Samantha Kolofske, Atlanta VA Medical Center, GA; Email: sammy.kolofske@gmail.com

**Additional Author(s):**
Tiffany Goolsby

**Purpose:** In 2009, the Infectious Disease Society of America released their recommendations on improving vancomycin surveillance which acknowledged the benefit of achieving an area under the concentration-time curve to minimum inhibitor concentration (AUC/MIC) of greater than or equal to 400. The primary objective of this study is to evaluate how frequently patients on vancomycin with a methicillin resistant Staphylococcus aureus (MRSA) infection are achieving the AUC/MIC goal of greater than or equal to 400 and to determine if higher goals of vancomycin troughs correlate more with an AUC/MIC greater than or equal to 400.

**Methods:** This study will be submitted to the Institutional Review Board for approval. Using the electronic medical record to identify patients, this will be a retrospective chart review of patients who were started on vancomycin for a documented MRSA infection who achieved a steady state random or trough level. The following data will be collected: patient age, gender, infectious diagnosis, minimum inhibitor concentration (MIC) of the organism, prescribed dose of vancomycin, dosing interval, vancomycin trough levels, vancomycin random levels, vancomycin administration times, vancomycin duration, serum creatinine (Scr) at baseline and at steady state, height, weight, length of stay, number of comorbidities, adverse events related to vancomycin, and vancomycin medication failures. AUC will be calculated based on trough level, or calculated true trough level if a random level was drawn, which will be defined as a level drawn no earlier than prior to the 4th dose. All data will be recorded using a de-identified number to avoid the use of patient identifiers with the key maintained on a password encrypted drive. The data will be analyzed to determine how often the target attainment of AUC/MIC greater than or equal to 400 is achieved and stratified into trough level groups of less than 10 mg/dL, 10 to 14.9 mg/dL, 15 to 20 mg/dL, and greater than 20 mg/dL.
Results: N/A

Conclusion: N/A
Purpose

The aim of this study is to determine if provider education regarding minimizing antibiotic use for acute respiratory infections (ARIs) will impact the issuance of antibiotics across the Atlanta VA Medical Center’s (AVAMC) hospital-based primary care clinics, community based outpatient clinics (CBOC), and emergency department (ED) and to assess the appropriateness of agents prescribed for ARIs.

Methods: This study will be a retrospective chart review of AVAMC patients seen in a primary care clinic, CBOC, or ED and diagnosed with an ARI. Adult outpatients > 18 years of age seen in an AVAMC based primary care clinic, CBOC, or ED and diagnosed with ARI will be included. Patients with concurrent infectious processes or comorbid conditions placing them at high risk for serious bacterial infection will be excluded.

A report will be obtained from the AVAMC Clinical Applications Coordination department to include all primary care patients with International Classification of Disease, Tenth Revision, Clinical Modification (ICD-10-CM) codes indicative of ARI’s between October 1, 2016 and January 31, 2017. Once this list is generated patients will first be divided based on the locations that did or did not receive education, then further divided into those who were prescribed an antibiotic and those who were not.

A retrospective chart review of CPRS® will be completed for all patients included in the study. Information recorded will include patient age, gender, location of the visit, type of provider seen, presence of clinical features of infection such as temperature greater than 100.4°F (38°C) and positive rapid antigen detection test (RADT) for suspected pharyngitis, specific diagnosis, and type of antibiotic prescribed. The results will be compared to a previously conducted retrospective chart review from 2014 of similar AVAMC patients.

Poster Title: Implementation of an osteoporosis risk-assessment template to improve the prevention of osteoporosis-related fractures in community living centers at the Carl Vinson Veterans Affairs Medical Center

Primary Author: Erin Gaughran, Carl Vinson VA Medical Center, GA; Email: erin.gaughran09@gmail.com

Additional Author(s):
Michael Riner
Deborah Hobbs
Marci Thomson

Purpose: One out of five men will have an osteoporosis-related fracture in their life-time. By ensuring that proper prevention therapy is implemented, we can continue to provide exceptional health care at the Carl Vinson Veterans Affairs Medical Center. The purpose of this project is to implement a risk-assessment template to improve the prevention of osteoporosis-related fractures and initiate calcium and vitamin D supplementation for high risk Veterans.

Methods: Prior to the implementation of an osteoporosis risk assessment template, Veterans in community living centers (CLCs) at the Carl Vinson VAMC will be evaluated. A thorough chart review will be performed and the following data will be collected: age, weight, previous fracture as an adult or history of hip fracture, race, current tobacco use, baseline serum vitamin D and calcium levels, current alcohol intake, history of rheumatoid arthritis, risk of falls, and current medications that may increase the risk of osteoporosis. This information will be used to determine the number of Veterans at risk for an osteoporosis-related fracture and the number of those on proper prevention therapy. The template will be created to facilitate documentation and to recommend prevention therapy if appropriate. A comparison will be made between the number of Veterans on preventative therapy before and after template implementation.

**Poster Title:** Establishing an opioid overdose education and naloxone distribution (OEND) shared medical appointment at the Carl Vinson Veterans Affairs Medical Center

**Primary Author:** Kirby Goins, Carl Vinson Veterans Affairs Medical Center, GA; **Email:** kirby.goins2@va.gov

**Additional Author (s):**
Marci Swanson
Deborah Hobbs
Jinan Ghali
Mathew Mathai

**Purpose:** According to Centers for Disease Control and Prevention, more than 260 million opioid prescriptions are filled yearly in the United States. In 2014, more than 19,000 deaths were attributed to overdose involving prescription opioids. Veterans are considered to be twice as likely to experience a fatal accidental overdose compared to non-veterans according to a 2011 study of Veteran patients. Through opioid overdose education and naloxone distribution, the goal of this projects is to ensure that high risk Veterans have access to lifesaving naloxone in the event of an overdose situation.

**Methods:** Prior to implementation of a shared medical appointment (SMA), a screening tool utilizing opioid overdose risk factors will be used to identify Veterans at high risk for overdose. A Veteran will be considered “high risk” if they meet one or more of the following criteria: a Risk Index for Overdose or Serious Opioid-induced Respiratory Depression (RIOSORD) risk class greater than or equal to two; opioid therapy with concomitant benzodiazepine therapy; multiple, as needed, opioid medications; or a positive urine drug screen for illicit opioids. Once Veterans are screened, those identified at high risk will be scheduled for a shared medical appointment that will provide opioid overdose education by an interdisciplinary team and naloxone distribution. The shared medical appointment will focus on identifying risk factors for opioid overdose, naloxone education, naloxone kit training, and prescribing a naloxone to participating Veterans. After implementation, additional data will be collected to determine if
the shared medical appointment increased the number of naloxone kits provided to Veterans at high risk for opioid overdose.

**Results:** N/A

Submission Type: Evaluative Study

Session-Board Number: 1-140

Poster Title: Prescribing patterns of stimulant medications at the Iowa City Veterans Affairs Health Care System

Primary Author: Christie Hart, Iowa City Veterans Affairs Healthcare System PGY2 Psychiatric Pharmacy, IA; Email: christiehart11@gmail.com

Additional Author(s):
Tami Argo
Lucas Watson
Jason Egge
Traviss Tubbs

Purpose: A recent review of the literature reported a trend of increased stimulant medication prescribing nationally. In this review, it was noted that total stimulant prescription sales in adults have surpassed those for youth. Off-label use is reported to be approximately 33% of total use and appears to be more common in adults. Additionally, stimulants have the potential to cause or exacerbate anxiety, insomnia, and/or hypertension. This retrospective chart review will help determine if there is a need for pharmacy-focused efforts to optimize stimulant use.

Methods: This project was designed as a quality improvement project to be conducted by retrospective chart review. Veterans within the Iowa City Veterans Affairs Health Care System (ICVAHCS) prescribed a stimulant medication from April 18, 2016 through July 18, 2016 were reviewed. Data was collected from the local VA Computerized Patient Record System (CPRS) electronic medical record. Variables collected include: demographic characteristics, medication, dose, indication for use, prescriber, comorbid conditions, concurrent medications, and urine drug screening rates. A minimum of 50 charts were randomly reviewed to align with recommendations from the Joint Commission on the Accreditation of Healthcare Organizations based on statistical significance and sensitivity to an organization’s population size. The data was compiled to show trends of prescribing, patient characteristics, appropriate drug-disease and drug-indication use, and incidence of adverse effects.

Results: Majority of patients were prescribed methylphenidate as this is one preferred agent within the ICVAHCS. Of 281 unique patients, 100 charts were reviewed revealing 11% were
prescribed a dose above the FDA recommended dose, 31% were prescribed for a non-FDA approved indication, and 31% were using another controlled substance. Nearly half (44%) were prescribed one or more agents to treat insomnia during treatment with a stimulant. Depression was a concurrent diagnosis in 69% of the patients reviewed; 40% had PTSD, 29% had an anxiety disorder, and 7% had a history of substance use disorder. Of 38 patients in the sample with a previous diagnosis of hypertension, 32% (12 patients) had uncontrolled hypertension. History of cardiac disease was found in 5% of patients and heart failure was found in 2% of patients.

**Conclusion:** Results are similar to previously published literature and suggest a high use of stimulants for non-FDA approved indications. Almost half of the patients prescribed a stimulant had comorbid insomnia which required treatment. Additionally, almost 30% of patients had concurrent diagnosis of anxiety which may be worsened by stimulant use. Polypharmacy resulting from the management of side effects may be avoided in a subset of patients prescribed stimulants. Strategies to improve safety and monitoring with stimulant treatment are warranted. Overall, use of stimulants could be optimized by pharmacy intervention at the ICVAHCS by targeted educational efforts regarding appropriate prescribing and utilization.

**Submission Category:** Quality Assurance/ Medication Safety

**Submission Type:** Research-in-Progress

**Session-Board Number:** 1-141

**Poster Title:** Effectiveness of a pharmacist-driven academic detailing program on appropriate antibiotic use in outpatient urinary tract infections

**Primary Author:** Geena Hopwood, VA Central Iowa Health Care System, IA; **Email:** geena.bricksom@va.gov

**Additional Author(s):**
Kimberly Redeker
Jenny Phabmixay

**Purpose:** Antimicrobial stewardship teams tackle appropriate prescribing of antibiotics. These teams are often well established in the acute care setting with fewer strategies developed for outpatient clinics. Academic detailing, a method that has been successfully used in the VA for mental health initiatives, may be used to bridge this gap. A recent medication use evaluation demonstrated an opportunity to improve inpatient urinary tract infection treatment. It is speculated this need is also present in the outpatient arena. In this pilot project, pharmacist-driven academic detailing will be used to provide targeted evidence-based information on urinary tract infection treatment to outpatient providers.

**Methods:** This quality improvement project is exempt from Institutional Review Board review. It will be reviewed by the Chief of Pharmacy, Chief of Staff and Pharmacy and Therapeutics Committee. In this pilot project, clinics will be selected based on the number of prescriptions written for urinary tract infections in one year. Clinics with the highest volume of prescribing will be included in this pilot. Providers in selected clinics will receive one-on-one academic detailing visits regarding antibiotic use in urinary tract infections. These visits will be conducted by the pharmacy resident and/or an academic detailing-trained clinical pharmacist. Optimal antibiotic selection, duration of treatment and omission of treatment in asymptomatic bacteriuria will be discussed during the visit. Educational material including evidence-based treatment guidelines and the facility's antibiogram will be presented to each provider. The visit will also allow for open discussion of barriers to optimal urinary tract infection management and how those barriers can be resolved. Data on antibiotic use will be collected before and after academic detailing visits. The primary outcome assessed will be the change in antibiotic prescribing consistent with current practice guidelines. Secondary outcomes will be change in
number of fluoroquinolones prescribed, a composite of barriers/resolutions to appropriate antibiotic selection, and time required for each academic detailing visit.

Poster Title: Implementation of the Veterans Health Administration’s Hypoglycemia Safety Initiative at a local community based outpatient clinic: A focus on patient safety

Primary Author: Christy Marchiando, VA Central Iowa Health Care System, IA; Email: christy.marchiando@va.gov

Additional Author(s):
Anna Schneider
Jenny Phabmixay

Purpose: In effort to address aggressive blood glucose targets in high risk diabetes patients, the Veterans Health Administration has implemented an optional, nationwide Hypoglycemia Safety Initiative. This initiative targets patients at high risk for hypoglycemic episodes. High risk is defined as an A1c less than 7%, insulin or sulfonylurea use, and an additional risk factor(s): 75 years or older, dementia or cognitive impairment, or serum creatinine greater than 1.7 mg/dL. The objective of this project is to implement fundamentals of this initiative at a community based outpatient clinic to assist in the management of patients at high risk for hypoglycemia.

Methods: This quality improvement project will be reviewed and approved by the Chief of Staff, Chief of Pharmacy, and Pharmacy and Therapeutics Committee. Providers will be educated on the Hypoglycemia Safety Initiative through an academic detailing approach involving a pharmacist-led discussion on the initiative. Provider-specific information on their patients that fall into the high risk category will be provided. Pharmacists will request permission from providers to assist in the effort to improve patient care. With provider support, a pharmacist will complete chart reviews and patient interviews to discuss and evaluate current diabetes management. Chart reviews will focus on documentation of hypoglycemic events, hemoglobin A1c trends, and diabetes medication regimens. Patients will be interviewed by telephone to assess hypoglycemic event occurrence and to discuss current diabetes therapy. Education on the signs and symptoms of hypoglycemia and appropriate medication use will also be addressed in patient interviews. The primary outcome will be the occurrence of a hypoglycemic event(s) prior to and post pharmacist intervention. Secondary outcomes include recommendations accepted by provider, patient referral to the Patient Aligned Care Team (PACT) pharmacist clinic, and change in high risk status or hemoglobin A1c goal. Additional
secondary outcomes include the evaluation of glucagon and glucose tablet prescribing, cost savings for the patient and facility, and time dedicated to each patient.

**Poster Title:** Evaluation of prescriber compliance with metabolic monitoring guidelines in patients treated with second-generation antipsychotics

**Primary Author:** Shelby White, Boise VA Medical Center, ID; **Email:** shelby.white@va.gov

**Additional Author (s):**

**Purpose:** Second-generation antipsychotics (SGAs) have a well-known association with unfavorable changes in metabolic parameters. Guidelines recommend regular metabolic monitoring after initiation of any medication in this class. The primary objective of this study is to determine the rate of provider compliance with metabolic monitoring guidelines for patients who are prescribed an SGA. A secondary objective is to determine the proportion of patients being monitored on SGAs stratified by provider type, indication for use, patient demographics, and whether the monitoring was done at baseline or 12 weeks.

**Methods:** The Computerized Patient Record System (CPRS) will be utilized to conduct a retrospective chart review of 100 profiles of patients who have been prescribed a second-generation antipsychotic before the date of September 30, 2016. Patients will be selected from the most recent prescription of an SGA and reviewed in reverse chronological order until the aforementioned sample size is achieved. Lab monitoring data will be assessed and compared to 2004 consensus treatment guidelines. This will start on the date the SGA was prescribed until a follow-up endpoint of 12 weeks. Patients will be included in this evaluation if an SGA was prescribed for them by a VA provider during the retrospective study period, and they received the medication for at least 12 consecutive weeks. Patients will be excluded from this evaluation if they were previously prescribed an antipsychotic medication (first generation or second generation) at any time in the past as determined by outpatient fill history. They will also be excluded if their medication was prescribed outside the VA healthcare system. Data will be collected on dates fasting lipid panel and HbA1C or fasting plasma glucose were ordered to assess compliance with guidelines at baseline and 12 weeks after initiation of the SGA. Descriptive statistics will be used to assess rates of prescriber compliance.

Poster Title: Evaluation of broad-spectrum antimicrobial utilization for community-onset pneumonia in patients treated at the Boise Veterans Affairs Medical Center

Primary Author: Brent Sasaki, Boise VA Medical Center, ID; Email: brent.sasaki@va.gov

Additional Author(s):
Karl Madaras-Kelly
Jefferson Bohan

Purpose: The health care associated pneumonia (HCAP) guidelines for use of broad-spectrum antimicrobials are no longer valid. The objective of this evaluation is to investigate the use of broad-spectrum antimicrobials in the treatment of community-onset pneumonia at the Boise Veterans Affairs Medical Center (BVAMC). This evaluation will determine the effectiveness of the recently implemented community-onset pneumonia order set menus, compare the prescribing rates of broad-spectrum antimicrobials for between the emergency department and inpatient settings, and compare the predictive performance of the Drug Resistance in Pneumonia (DRIP) Score to the new order set menus in identifying drug-resistant pathogens.

Methods: This evaluation will consist of a retrospective analysis of patients who presented to the BVAMC emergency department or were admitted to the BVAMC with a diagnosis of community-onset pneumonia. The retrospective review of medical records will compare data between two time periods: twelve months prior to and six months after implementation of the new order set menus. Pertinent data collected will include patient demographics, patient risk factors for drug-resistant pathogen pneumonia, antimicrobial use, and microbiology reports. Patients included in the evaluation must be admitted to the Boise VAMC within 48 hours of presentation, have a documented admitting diagnosis of community-onset pneumonia, and received at least one dose of an antimicrobial in the emergency department or hospital. Patients will be excluded from the evaluation if they present with multiple infections requiring broad-spectrum antimicrobials, hospital-acquired pneumonia (HAP), ventilator-associated pneumonia (VAP), or if transferred from an outside hospital with pneumonia. Primary endpoints will include a comparison of the mean percentage of patients administered broad-spectrum antibiotics before and after order set menu implementation, the percentage of patients receiving discordant antibiotics between the emergency department and inpatient
setting, and a comparison of predictive performance in identifying drug-resistant pathogens between the DRIP score and new order set menus.

Poster Title: Two-year outcomes of a pharmacy resident-facilitated leadership and advocacy elective for professional pharmacy students

Primary Author: Joseph Berendse, Boise VA Medical Center, ID; Email: joseph.berendse@va.gov

Additional Author(s):
Lindsey Hunt
Andrea Winterswyk
Barb Mason
Rebecca Hoover

Purpose: Current accreditation standards for colleges of pharmacy emphasize the need for curriculum intended to promote student leadership and advocacy. To meet these standards, local pharmacy residents designed, implemented, and assessed a pilot leadership and advocacy course at Idaho State University-College of Pharmacy one year ago. The course continued this year as a resident-facilitated offering for second-year professional pharmacy students. With each seminar, residents pair with a non-resident healthcare leader to discuss various leadership- and advocacy-related topics. As such, the elective was designed to meet accreditation standards and increase teaching opportunities for local pharmacy residents interested in leadership, management, and/or academia.

Methods: For both years, course assessment was completed through anonymous written and electronic surveys. Students completed pre- and post-surveys about their leadership abilities/beliefs at the beginning and end of each semester, respectively. Students were also assessed regarding the perceived quality and utility of each seminar and required project throughout the semester. Finally, an additional survey was sent to participating residents and non-resident healthcare leaders to garner general, qualitative feedback. Survey results were analyzed utilizing descriptive statistics.

Results: Across both years during which the course was offered, there were 15 residents who taught over 20 lectures, four resident facilitators, and approximately 15 non-resident healthcare leaders who contributed to the elective. Survey data revealed that all students
strongly agreed the course was valuable in developing their leadership skills. Self-perceived improvement was reported through greater understanding of effective leadership and self-awareness of strengths. Student assessments of the quality and utility of each seminar topic and project are presented. Residents and non-resident healthcare leaders consistently reported that they would participate again if given the opportunity.

**Conclusion:** The pharmacy resident-facilitated leadership and advocacy elective simultaneously facilitated resident teaching and improved students' engagement in leadership and advocacy. Strengths of this course include a) the use of pharmacy residents to facilitate an elective that meets accreditation standards, b) the provision of teaching and networking opportunities to students and residents, and c) improved understanding of the importance of leadership and advocacy among professional pharmacy students. Limitations of this course include small class size, time-intensive input from facilitators, and incomplete survey participation.

**Poster Title:** Implementation of a pharmacist-managed hepatitis C clinic in the rural primary care setting

**Primary Author:** Nicole Lopez, VA Outpatient Clinic Pocatello, Idaho, ID; **Email:** nicole.lopez4@va.gov

**Additional Author (s):**
Paul Otto
JoEtte Ballard
Angela Casperson

**Purpose:** Novel oral direct-acting antiviral agents for hepatitis C virus have substantially improved patient outcomes by increasing cure rates, patient adherence, and tolerance. In a geographical location with limited local access to medical specialties for management of hepatitis C, a unique opportunity exists for pharmacists to provide hepatitis C treatment services. This project aims to provide comprehensive medication management for hepatitis C by a pharmacist in a rural primary care setting. Treatment outcomes and viral response will be documented. Also patient satisfaction, adherence to medication and appointment attendance information will be collected and analyzed.

**Methods:** This prospective quality improvement project will be performed including all patients referred to pharmacists for hepatitis C treatment from the clinic’s implementation on September 1, 2016 through the completion of each patient’s treatment. Pertinent baseline information will be obtained from electronic medical records and will include patient demographic information, liver disease characteristics, treatment history, and laboratory results. Patients will meet with pharmacists (who will be the primary treatment clinician) in 28 day increments for initial education of hepatitis C treatment and ongoing assessment of tolerance, adherence, medication reconciliation, and laboratory monitoring. In addition to treatment outcomes and viral response, this study will also collect a survey to assess patient satisfaction of pharmaceutical care provided by the pharmacists throughout the duration of their hepatitis C treatment.

Poster Title: Evaluation of a team-based approach to control blood pressure using home-monitoring technology in Veterans with hypertension

Primary Author: Krisma DesPortes, Captain James A. Lovell Federal Health Care Center, IL; Email: krisma-amor.desportes@va.gov

Additional Author (s):
Jessica Johnson
Megan Grischeau
Aeman Choudhury

Purpose: Given the rapidly evolving technology and the emphasis to provide patient-centered care, Captain James A. Lovell Federal Health Care Center (FHCC) utilizes a team-based approach among providers, nurses and pharmacists as an effort to improve blood pressure control using home tele-monitoring technology. The purpose of this study is to describe the process of implementing a team-based approach protocol, and to evaluate the summative findings in Veterans enrolled in the Veterans with Hypertension Home Telehealth Program (VHHTP). The primary objective of this study is to describe the process of VHHTP, and evaluate the factors needed to sustain the program over time.

Methods: This study is a retrospective cohort study evaluating the demographic changes in Veterans participating in VHHTP. Descriptive statistics will be used to evaluate the protocol process using averages and percentages. Secondary outcomes will be analyzed using paired T-tests to assess for statistical significance, using an alpha level less than 0.05.

Poster Title: Evaluating rates of metabolic monitoring for second generation antipsychotics after implementation of a new pop-up alert

Primary Author: Shannon Furbish, Captain James A. Lovell Federal Health Care Center, IL; Email: shannon.furbish@va.gov

Additional Author(s):
Michael Shuman
Yinka Alaka

Purpose: Second generation antipsychotics (SGAs) are commonly prescribed for psychiatric conditions. Although there are many advantages over first generation antipsychotics, SGAs are known to cause metabolic side effects including diabetes, obesity, dyslipidemia, and metabolic syndrome. Because of these adverse effects, the American Diabetes Association, the American Psychiatric Association, the American Association of Clinical Endocrinologists, and the North American Association for the Study of Obesity developed consensus statement monitoring guidelines in 2004. The aim of this study is to evaluate the rate of metabolic monitoring at baseline and twelve weeks for newly prescribed SGAs after implementation of a new pop-up alert.

Methods: This study is a retrospective cohort study comparing two groups of veterans at the Captain James A. Lovell Federal Health Care Center: those newly prescribed a SGA prior to when the pop-up was implemented and those newly prescribed an SGA after the pop-up was implemented. The time frame for retrospective chart review will be May 1, 2015 to December 15, 2015 for metabolic monitoring rates prior to the pop-up alert, and May 1, 2016 to December 15, 2016 for metabolic monitoring rates after implementation of the pop-up alert. Those included in the study will be veterans at the Captain James A. Lovell Federal Health Care Center who are at least 18 years old and are newly prescribed an SGA within the time periods listed above. Any patient prescribed an SGA for less than 90 days or “as needed” will be excluded. The following data will be collected: patient age, gender, inpatient or outpatient status, SGA name, psychiatric diagnosis, date of original prescription, type of provider ordering baseline and twelve week labs, whether or not baseline and twelve week labs were monitored, and type of interventions made, if any. The Chi-squared test will be used to compare the two
cohorts, as well as compare the rates of inpatient metabolic monitoring and outpatient metabolic monitoring. A p-value of less than 0.05 will be considered significant.

Poster Title: Association of chronic proton pump inhibitor therapy and anemia

Primary Author: Dillon Moyer, Captain James A. Lovell FHCC, IL; Email: dlmoyer@presby.edu

Additional Author (s):
Lyuba Dragilev

Purpose: Proton pump inhibitors are commonly used in the treatment of a variety of gastrointestinal disorders and cause few adverse effects with short-term use. However, long-term use has been scrutinized for appropriate duration of use and the potential for adverse effects. Proton pump inhibitors suppress gastric acid and may decrease iron absorption. Without adequate iron concentrations, hemoglobin will not be properly produced. Thereby, decreasing hemoglobin levels and potentially leading to the development of microcytic, hypochromic anemia over the long term. The objective of this study is to evaluate the relationship between proton pump inhibitor use and iron deficiency anemia.

Methods: This study is a retrospective cohort study comparing three groups of patients: those that have received proton pump inhibitor therapy for less than 1 year; greater than or equal to 1 year and less than 3 years; greater than or equal to 3 years and less than 5 years. The primary outcome of this study will be changes in hemoglobin, hematocrit, mean corpuscular volume, and ferritin levels from baseline. The secondary objective is to analyze the number of patients meeting the World Health Organization’s definition of anemia pre-proton pump inhibitor use versus post-proton pump inhibitor use. The following data will be collected: age, gender, past medical history, initial start date of proton pump inhibitor therapy, indication for proton pump inhibitor use, specific proton pump inhibitor and dose, complete blood counts, concurrent medications, and dates of proton pump inhibitor medication refills. If available, results of iron studies will be collected. All data will be recorded without patient identifiers and maintained confidentially. One-way ANOVA test will compare the changes in hemoglobin, hematocrit, mean corpuscular volume, and ferritin levels from baseline among the groups. Chi-square test will examine the association between proton pump inhibitor use and anemia. This study will be submitted to the Institutional Review Board for approval.

**Poster Title:** Evaluation of fenofibrate therapy in a Veteran population  

**Primary Author:** Heather Harnvanich, Edward Hines, Jr. VA Hospital, IL; **Email:** heather.harnvanich@va.gov  

**Additional Author (s):**  

Sue Kim  

Jennifer Mucksavage  

**Purpose:** Fibrates are characterized by their ability to lower serum triglycerides. The degree of hypertriglyceridemia warranting treatment has evolved over time. Although there is a lack of evidence showing cardiovascular benefit with fibrate utilization, the Endocrine Society’s clinical practice guidelines recommend fibrates to decrease the risk of triglyceride-induced pancreatitis in at-risk patients. Due to changes in clinical practice guidelines, a retrospective medication use evaluation will be conducted to evaluate if fenofibrate use at our facility aligns with current practice guidelines.

**Methods:** A retrospective chart review will be conducted using the patient chart and electronic medical record. This medication use evaluation will utilize prescription data to identify patients currently prescribed fenofibrate. Data to be collected includes demographic information (patient age, gender, height, weight), serum triglycerides and serum creatinine, previous or concurrent use of fish oil, history of pancreatitis, average daily dose of fenofibrate and last fill date. Data collected will be stored in an encrypted file and saved in a secure location. The reviewers will utilize the information to either recommend to continue, discontinue, or change fenofibrate to another therapy based on current practice guidelines.

**Poster Title:** Evaluation of Vaccine Errors at the Jesse Brown VA Medical Center

**Primary Author:** Atit Patel, Jesse Brown VA Medical Center, IL; **Email:** atit.patel1227@gmail.com

**Additional Author(s):**
Isabel Karceski
Leena LaForte
Nisha Mehta
Richard Rooney

**Purpose:** Vaccines are vital for protection against communicable diseases and have been considered one of the most significant public health achievements, preventing an astounding two to three million deaths per year worldwide. Jesse Brown VA Medical Center (JBVAMC) recognizes the importance of preventative care through vaccination. Vaccine use has increased at JBVAMC over time. With the complex administration schedules and nuances of each vaccine, it is especially important that vaccines are ordered, dispensed, administered, and documented appropriately. Therefore, the purpose of this study is to evaluate the vaccine-related errors in the facility and to propose system solutions that may reduce them.

**Methods:** This study will be a retrospective, electronic chart review of patients at JBVAMC that will evaluate vaccine-related errors that occurred between March 1, 2015 and August 31, 2015. The primary endpoint of the study is to evaluate the processes related to vaccine errors and to identify the root cause. Secondary endpoints include the incidence of various types of vaccine related errors and the contributing factors of these errors.

**Results:** One-hundred and sixty six (n=166) patient charts with a vaccine error were reviewed. Nearly 73% percent (n=121) of the patients’ vaccine errors were related to documentation, 11% (n=19) related to the ordering process, 10.8% (n=18) related to the administration process, and five percent (n=8) related to the verification process. Fifty-seven percent of the vaccine errors occurred at the main facility with 76% of the errors contributed by nursing staff. The contributing factors associated with the most common errors were related to the nurses’
unfamiliarity with how to properly document vaccines and system inefficiencies that have made it difficult for providers and nurses to order and administer vaccines, respectively.

**Conclusion:** The study showed that majority of the vaccines errors were related to the ordering and documentation process and were likely due to system issues and a lack of standardization in education.

**Poster Title:** Retrospective evaluation of a pharmacist-led safety initiative to assess the appropriateness of fibrate discontinuation when used in combination with statins  

**Primary Author:** Kristin Crees, Jesse Brown VA Medical Center, IL; **Email:** kmcrees10@gmail.com  

**Additional Author(s):**  
Anthony Tardi  
Tania John  
James Sluis  
Sarah Flaherty  

**Purpose:** Due to the lack of evidence regarding the ability of fibrates to reduce mortality and the increased risk of adverse effects when combined with statins, the Veterans Affairs National Pharmacy Benefits Management Services advised medical centers to evaluate the appropriateness of statin-fibrate dual therapy. The pharmacy service at the Jesse Brown Veteran Affairs Medical Center (JBVAMC) conducted a review of patients on statin-fibrate therapy to determine the appropriateness of combination therapy. The purpose of this study was to evaluate whether the pharmacist-driven discontinuation of fibrate therapy resulted in maintenance of triglyceride levels below an acceptable threshold as supported by guidelines.  

**Methods:** This was a retrospective, electronic chart review of outpatients taking combination statin and fibrate therapy during the pharmacist-led safety initiative. Patient data were collected from 9/28/2013 to 9/28/2015. Baseline data were the most recent labs prior to fibrate discontinuation. Endpoint data were the most recent labs completed at least 4 weeks after fibrate discontinuation. The primary endpoint was the percentage of patients with triglycerides less than 500 mg/dL prior to fibrate discontinuation compared to the percentage of patients with triglycerides less than 500 mg/dL after fibrate discontinuation. Secondary endpoints such as worsened triglycerides, fibrate re-initiation, incidence of pancreatitis and myopathy, change in statin therapy, adherence with follow-up labs, and average time to lab follow-up were evaluated. This research was approved by the institutional review board and research and development committee at JBVAMC.
Results: One-hundred and twenty-nine patients had their fibrate discontinued. A total of 116 patients were included in this retrospective analysis. Of the 13 excluded patients, 10 patients were excluded due to a lack of baseline lipid levels. Prior to fibrate discontinuation, the most common statins prescribed were simvastatin (39.7%) and atorvastatin (24.1%). Majority of patients were prescribed a moderate intensity statin (56.9%). The most common fibrate prescribed was gemfibrozil (81.9%). Eighty-four percent of patients obtained follow-up labs after fibrate therapy was discontinued. Before fibrate discontinuation, 95.9% (n=94) of patients had triglycerides less than 500 mg/dL. After fibrate discontinuation, 96.9% (n=95) of patients had triglycerides less than 500 mg/dL (p = 1). After fibrate discontinuation, there was a 60.7% increase in atorvastatin prescriptions. Prescribing of high intensity statin therapy also increased by 46.7%. Low-density lipoprotein (LDL) and total cholesterol were significantly reduced after discontinuation of fibrate therapy (p < 0.001). No patients developed pancreatitis, myopathy, or rhabdomyolysis. Four patients resumed a fibrate after follow-up; 3 patients resumed due to an increase in triglycerides. Only 2 of the 4 patients had elevations in triglycerides greater than 500 mg/dL after statin discontinuation.

Conclusion: Pharmacists, in collaboration with the healthcare team, can play an integral role in direct patient care. This pharmacist-driven safety initiative proved effective in that patients who had their fibrate discontinued maintained triglycerides below an acceptable threshold as supported by clinical guidelines.

**Poster Title:** Impact of vitamin D supplementation in chronic heart failure in the veteran population

**Primary Author:** Erica Hartwig, Jesse Brown VA Medical Center, IL; **Email:** erica.hartwig@va.gov

**Additional Author (s):**  
Judith Toth  
Molly Heneghan  
Claresta Bergman

**Purpose:** To identify whether chronic heart failure patients supplemented with vitamin D experience clinical benefit.

**Methods:** The institutional review board approved this retrospective, electronic chart review of patients at Jesse Brown VA Medical Center with a diagnosis of chronic heart failure as determined by ICD-9 codes and a 25(OH)D vitamin D level drawn between August 1st, 2010 and July 31st, 2013. Exclusion criteria included serum creatinine greater than 2mg/dL and/or hemotoneal or peritoneal dialysis, hyperparathyroidism, vitamin D supplementation within 1 year prior to start of the study period, or receipt of a vitamin D supplement outside the VA medical system. Outcomes were analyzed between two study groups: those supplemented with vitamin D, and those not supplemented. The primary endpoint was a composite of heart failure exacerbations leading to hospitalization and/or mortality within two years following vitamin D supplementation compared to chronic heart failure patients not supplemented. Each component of the composite primary endpoint was also evaluated and reported as secondary endpoints. A subgroup analysis comparing patients with heart failure with preserved ejection fraction to patients with heart failure with reduced ejection fraction was completed for the primary endpoint. Subgroup analyses of primary and secondary endpoints were also completed in patients with a baseline 25(OH)D less than 20ng/mL, less than 30ng/mL, and greater than or equal to 30ng/mL. Additionally, a subgroup analysis was completed comparing supplementation with ergocalciferol only, cholecalciferol only, and a combination of the two for the primary endpoint.
Results: Thirty-two patients met inclusion criteria and were included in the study. Nineteen of the 32 patients were supplemented with vitamin D; 13 patients were not supplemented. No significant differences were identified for the primary composite endpoint, or for the secondary endpoints. Additionally, no significant differences were identified in the subgroup analyses.

Conclusion: Overall this study did not identify any clinical benefit in chronic heart failure patients supplemented with vitamin D. Thus, the benefits of vitamin D supplementation in the chronic heart failure population remain unclear. Given the significant limitations of this study, future studies remain warranted.

**Poster Title:** Colchicine prescribing patterns for gout prophylaxis in a VA population

**Primary Author:** Alexandra Riskus, Jesse Brown VA Medical Center, IL; **Email:** alexandra.riskus@va.gov

**Additional Author(s):**
- Judith Toth
- Marissa Mahoney
- Nisha Mehta
- Laurie Noschese

**Purpose:** Colchicine is an anti-mitotic medication with complex regulatory history and risk of significant toxicity. The purpose of this study was to evaluate the use of colchicine when prescribed for a duration greater than or equal to 30 days for gout prophylaxis. Appropriate use of colchicine for this duration is in combination with urate lowering therapy (ULT). Other factors that contribute to appropriate prescribing include proper dose adjustment of colchicine for renal impairment and drug-drug interactions. We suspect that there may be a high incidence of inappropriate colchicine prescribing at our facility.

**Methods:** This study was a retrospective, electronic chart review of patients filling colchicine prescriptions for a supply of ≥30 days from October 1, 2012 through June 30, 2014. Patients age 18 years and older who filled new (no colchicine prescription filled within prior six months) colchicine prescriptions within the designated time frame were included, and charts were followed for 15 months after initial fill of colchicine. Patients were excluded if colchicine was not for treatment of gout, if colchicine was not prescribed for daily or every-other-day dosing, and if patients were taking concomitant urate oxidase therapy. The primary endpoint was the percent of patients initiated on concomitant ULT with allopurinol, febuxostat, or probenecid within 30 days of filling the colchicine prescription. Secondary endpoints included incidence of appropriate dose adjustments, additional encounters for gout-related problems, duration of colchicine treatment, adherence rates, and monitoring of serum uric acid after initiation of ULT. Based on a previous study, it was calculated that 101 patients would be required to meet 80% power to detect a 27% rate of lack of concomitant ULT prescription. The Chi square test was
used to compare results of nominal data and the student’s t-test was used to compare results of continuous data.

**Results:** Urate lowering therapy within 30 days of the issued colchicine prescription was prescribed for 72 out of 122 patients (59%), while ULT was not prescribed for the remaining patients. The vast majority of patients’ colchicine doses were deemed appropriate per product labeling (1 patient with creatinine clearance of 29 mL/min and 1 patient with concomitant diltiazem warranted dose adjustment). For patients prescribed ULT within 30 days versus those not prescribed ULT within 30 days, use of ancillary services for gout-related problems were similar (19 encounters versus 31 encounters, $p=0.24$). Duration of colchicine therapy was also similar in both groups (7.9 ± 5.8 months versus 8.8 ± 5.2 months, $p=0.49$). Adherence rates were found to be suboptimal for colchicine and ULT. Monitoring of serum uric acid levels in patients prescribed ULT occurred in 74% of patients; however, ULT was further titrated within 3 months for uric acid $>6$ mg/dL only 21% of the time. Most patients did not achieve uric acid $\leq 6$ mg/dL during the study period. For patients who achieved uric acid $\leq 6$ mg/dL, colchicine was continued for $>3$ months in 36.4% of patients without tophi, which was considered to be a potentially inappropriate continuation of colchicine.

**Conclusion:** The majority of patients were prescribed ULT within 30 days of colchicine prescription with instructions for daily or every-other-day dosing; however, the remaining 41% of patients may have suboptimal management of gout. Reasons for these findings may include intended use of the colchicine prescription for acute flare dosing only, or lack of follow up by the patient after treatment for an acute flare. For those patients prescribed ULT, most did not achieve target serum uric acid level of $\leq 6$ mg/dL within 15 months, thus indicating an opportunity for better optimization of gout management with ULT.

**Poster Title:** Evaluation of prescribing patterns of acetylcholinesterase inhibitors at Jesse Brown VA Medical Center  

**Primary Author:** Joshua Adams, Jesse Brown VA Medical Center, IL; **Email:** adamsjosh80@gmail.com  

**Additional Author(s):**  
Jaclyn Ng  
Charity Anicete  
Nicholas Super  
Katherine Steel  

**Purpose:** The American Psychiatric Association dementia treatment guidelines recommend offering acetylcholinesterase inhibitors (AChEIs) to patients with mild dementia. The AChEIs 2014 Veterans Affairs (VA) Pharmacy Benefits Management Services criteria for use recommend re-evaluation within three months after initiation and then every 12 months for renewal. At the time of this study, prescribing of AChEIs was open to all providers at Jesse Brown VA Medical Center (JBVAMC), with donepezil being the preferred agent since 2011. The purpose of this study was to examine the prescribing patterns and follow-up of AChEIs for dementia treatment in general medicine clinics (GMC) compared to specialty services.  

**Methods:** This study was a retrospective, electronic chart review of patients at JBVAMC newly initiated on AChEIs for dementia between January 1, 2012 and July 31, 2014. The primary endpoint of this study was to compare the types and timing of first follow-up for patients started on AChEIs between GMC and specialty prescribers. Secondary endpoints included evaluation of changes in cognitive function, referrals to specialty clinics and neuropsychological testing, and evaluation of adverse drug reactions.  

**Results:** In total, 373 patient charts were randomly reviewed, of which, 136 patients were included in this study. The primary endpoint of follow-up dementia assessment within 6 months of AChEi initiation occurred in 30.2% of GMC patients versus 56.6% of specialty patients (p=0.0026). Additionally, 43.4% of patients initiated by GMC providers were assessed (either subjectively or objectively) at the first follow-up appointment, compared to 63.9% by specialty
services (p=0.019). Specialty services also had more objective assessments compared to GMC providers (20.5% and 3.8%, respectively; p=0.0061). The median time to first follow-up assessment for GMC providers was 3.48 months, as opposed to 1.83 months by specialty services. In total, 60.6% of evaluable patients had no change in cognitive function staging from AChEI initiation to time of last prescription renewal. Twelve GMC patients were referred to specialty services during the study timeframe. In addition, 45.6% of patients completed neuropsychological testing within a year of AChEI initiation. Altogether, 41.9% of patients had documentation of an ADR during the study timeframe, leading to discontinuation in 14.7% of patients.

**Conclusion:** At JBVAMC, specialty services had more timely and objective follow-up appointments assessing dementia after AChEI initiation compared to GMC providers.

Poster Title: Efficacy of vancomycin versus metronidazole for the treatment of Clostridium difficile infections in a veteran population

Primary Author: Rohini Dave, Jesse Brown VA Medical Center, IL; Email: rohini.dave@va.gov

Additional Author(s):
Mark Knaub
Lisa Young

Purpose: Clostridium difficile infection (CDI) accounts for 15-25% of nosocomial antibiotic-associated infections, resulting in significant morbidity and mortality. In 2010, the Infectious Diseases Society of America and the Society for Healthcare Epidemiology of America published updated guidelines for CDI. Per these guidelines, mild/moderate initial infections should be treated with oral metronidazole, while oral vancomycin is preferred for severe CDI. A recent study found higher rates of success with vancomycin, regardless of severity, providing evidence for the exclusive use of vancomycin. The purpose of this study was to compare the efficacy of vancomycin to metronidazole as CDI treatment in a veteran population.

Methods: This was a retrospective, electronic chart review of patients receiving oral metronidazole or vancomycin for the treatment of an initial CDI between January 1, 2003, and December 31, 2014. CDI was defined as a documented physician diagnosis in addition to positive laboratory testing. Clinical cure and recurrence rates were determined for all subjects. This study also evaluated clinical cure and recurrences rates in patients stratified by CDI severity. The research protocol was approved by the VA Institutional Review Board and VA Research and Development Committee.

Results: The investigators randomly selected 349 charts for review. Two hundred patients met inclusion criteria of which 152 received metronidazole and 48 received vancomycin as CDI treatment. Clinical cure occurred in 119 (78%) patients receiving metronidazole and 47 (98%) patients receiving vancomycin (p=0.002). For patients with mild disease, clinical cure was achieved in 77% of patients in the metronidazole group and 97% of patients in the vancomycin group (p=0.007). For patients with severe disease, clinical cure rates were 84% and 100% for the metronidazole and vancomycin groups, respectively (p=0.11). Recurrence occurred in 24
(16%) patients receiving metronidazole and 6 (13%) patients receiving vancomycin (p=0.58). Recurrence rates between both groups were similar when stratified by severity (p greater than 0.05).

**Conclusion:** Clinical cure rates were significantly higher in patients receiving treatment with vancomycin versus metronidazole, regardless of severity. Larger, randomized trials are needed to support changes to current guidelines.

**Session-Board Number:** 1-158  

**Poster Title:** Efficacy of Antimicrobials Agents in Resolving Asymptomatic Bacteriuria in Patients with Fluoroquinolone and Sulfamethoxazole-Trimethoprim Resistant Enterobacteriaceae Prior to a Planned Urologic Procedure  

**Primary Author:** Jenna Lopez, Jesse Brown VA Medical Center, IL; **Email:** jlopez65@midwestern.edu  

**Additional Author(s):**  
Patrick Waters  
Erica Richey  
Milica Jovic  
Claudia Rakhman  

**Purpose:** Bacteremia occurs in 25-80% of patients with untreated asymptomatic bacteriuria that are undergoing a urologic procedure with high risk for mucosal bleeding. Out of all incidences of bacteremia that occur, 10-16% progress to septicemia. Studies show that pre-procedural prophylaxis with antimicrobials is beneficial for preventing bacteremia and sepsis in these patients. Fluoroquinolones and sulfamethoxazole-trimethoprim (SMX/TMP) have been studied in this setting, however, resistance of gram-negative urinary isolates in the United States is seen in 16.4-25% and 34%, respectively. In this setting there is limited data to guide treatment options for patients with asymptomatic bacteriuria prior to urologic procedures.  

**Methods:** The primary outcomes are to determine the efficacy of antimicrobial agents used for the eradication of urinary isolate(s) and the prevention of sepsis in subjects with a positive urine culture that displays an Enterobacteriaceae resistant to fluoroquinolones and SMX/TMP prior to a urologic procedure. This is a retrospective, electronic chart review at Jesse Brown VA Medical Center (JBVAMC). A list of subjects who had a positive urine culture resistant to fluoroquinolones and SMX/TMP between January 1, 2009 and August 17, 2015 was generated. These subjects were enrolled in two separate arms: arm I assessed the efficacy of antimicrobials used for the eradication of an Enterobacteriaceae urinary isolate(s) that display resistance to fluoroquinolones and SMX/TMP in asymptomatic veterans prior to a urologic procedure. Arm II aimed to assess the incidence of sepsis in veterans after a urologic procedure. Inclusion criteria are: males aged 18 years and older, who had first episode of asymptomatic bacteriuria and a
Develop antibiotic resistance to fluoroquinolones and SMX/TMP. Participants were excluded if the urinalysis (UA) had moderate to many or > 15 epithelial cells in the initial or follow-up culture, concern for prostatitis, no UA at the time of initial or follow up urine culture, subsequent episodes of asymptomatic bacteriuria, or no upcoming urologic procedure planned.

**Results:** Twenty-five subjects were included in this study. Each subject was only included once for each primary outcome, however a subject can be included in both arms. Arm I consists of 9 subjects who had a positive urine culture resistant to fluoroquinolones and SMX/TMP that were treated with antimicrobials and had a repeat urine culture prior to a urologic procedure. Repeat urine culture was negative in 7 subjects. Five subjects had a chronic indwelling foley catheter, of these 4 subjects had a negative repeat urine culture. The most commonly prescribed antibiotic was cefuroxime which was given to 5 subjects, 4 of which had a negative repeat urine culture. Nitrofurantoin, amoxicillin-clavulanate, cephalexin, and ertapenem were other antibiotics prescribed for the treatment of asymptomatic bacteriuria. Arm II consists of 21 subjects that were assessed for the occurrence of septic events. Majority of the subjects (86%) in arm II received appropriate antimicrobial therapy prior to a urologic procedure. Three subjects (14%) were not treated in accordance to current guidelines. One of these subjects developed sepsis and the other 2 subjects did not receive antibiotics as their urine cultures did not result as positive until the day of the procedure.

**Conclusion:** The majority of subjects with asymptomatic bacteriuria resistant to fluoroquinolones and SMX/TMP were treated with and responded to cefuroxime. Patients whom were treated with cefuroxime experienced an 80% cure rate. Presence of a chronic indwelling foley catheter resulted in a 20% rate of bacteriologic treatment failure. Treatment of asymptomatic bacteriuria prior to a planned urologic procedure varied widely at JBVAMC, as multiple antimicrobial strategies were utilized. Antimicrobial therapy was in accordance with guidelines in 86% of the subjects. This study provides insight on prescribing habits and the efficacy of alternative agents for treating asymptomatic bacteriuria.

**Poster Title:** Evaluation of smoking cessation outcomes in the patient aligned care team and smoking cessation clinic

**Primary Author:** Arohi Desai, Jesse Brown Veterans Medical Center, IL; **Email:** arohid@gmail.com

**Additional Author (s):**
Brett Geiger
Jaclyn Ng
Molly Heneghan

**Purpose:** Smoking is the number one preventable cause of death in the United States. The transdermal nicotine patch is a pharmacotherapy for smoking cessation and has been shown to double quit rates. Combining behavioral support and medications can further increase success rates. In July 2014, nicotine patches were made available to all providers at Jesse Brown Veterans Affairs Medical Center (JBVAMC). Previously, nicotine patches were restricted to specialty clinics. Since the patch was made available, the use of the nicotine patch and smoking cessation outcomes have not been compared between patient aligned care team (PACT) and smoking cessation clinic (SCC).

**Methods:** This institutional review board approved study was a retrospective, electronic chart review of patients newly initiated on nicotine patch at JBVAMC. Smoke free status was defined as smoke free documentation in a progress note. Data was collected from April 1, 2014 to September 30, 2015 to allow for review 3 months prior to prescription and a 6 month follow-up period.

Patients were included if they received a nicotine replacement therapy (NRT) patch between July 1, 2014 and March 31, 2015. The following patients were excluded: pregnant females, those using smokeless or chewing tobacco, patients on varenicline, bupropion, or non-formulary NRT including inhaler or nasal spray formulations. Patients were also excluded if they received NRT from other services besides SCC or PACT, or if they received a NRT patch within 3 months prior to the initial prescription. Included patients were classified into either SCC or PACT groups. Patients that were initiated on NRT in PACT but followed up in SCC were included in the SCC group. The primary endpoint was the efficacy of the nicotine patch for smoking
cessation in the PACT clinic compared with the specialty SCC. The secondary endpoints included time to smoking cessation and time to follow-up.

**Results:** One hundred and twenty-six patients were randomly evaluated in this study, of which 52 were included and 74 were excluded. The percent of patients achieving a smoke free status was greater in the SCC group but not significantly different between the groups (28 percent vs 15 percent, p equals 0.51). Time to smoking cessation was similar in the two groups (2.0 vs 2.4 months, p equals 0.72). Number of follow-up appointments was significantly higher in the SCC group (3.2 vs 1.7, p equals 0.01). Time to follow-up appointments was significantly less in the SCC group (1.1 vs 2.9 months, p less than 0.01). The number of patients prescribed combination NRT (nicotine replacement therapy) was significantly higher in the SCC group (14 vs 7, p less than 0.01).

**Conclusion:** Smoke free status was achieved in a higher percentage of patients treated in the SCC compared to PACT at JBVAMC. Veterans were more likely to be prescribed combination NRT and had sooner and more frequent follow-up in the SCC.
**Poster Title:** Risk of pancreatitis in hypertriglyceridemic Veterans with fibrate use

**Purpose:** Hypertriglyceridemia (HTG) is one of the most common causes of acute pancreatitis. The use of fibrates is prevalent for high triglycerides due to their theorized prophylactic effect on pancreatitis. However, the biggest meta-analyses addressing this topic showed that fibrate therapy may be associated with increased pancreatitis risk. It is therefore important to determine the overall safety of fibrate use in patients with HTG. The purpose of this project is to assess impacts of fibrate use related to risk of pancreatitis, and implement changes to minimize inappropriate prescribing of fibrates in the primary care setting at VA Illiana Health Care System.

**Methods:** The project will consist of a retrospective chart review of Veterans who received fibrates at VA Illiana. Computerized Patient Record System (CPRS) will be searched for the presence or absence of acute pancreatitis as the primary endpoint. The secondary outcome is a composite atherosclerotic cardiovascular disease (ASCVD) event including acute coronary syndromes, myocardial infarction, stable or unstable angina, coronary or other arterial revascularization, stroke, transient ischemic attack, or peripheral arterial disease presumed to be of atherosclerotic origin. A manual subgroup analysis will be reviewed for specific patient characteristics of patients who developed pancreatitis while on a fibrate. This will include A1c level, use of statin, chronic alcohol consumption, and history of gallstones. The results of this quality improvement analysis would allow providers to better serve the Veteran population through improved understanding of possible outcomes with fibrate use in hypertriglyceridemic management, and determine if a change in practice is warranted.

**Results:** N/A

**Conclusion:** N/A

Poster Title: Evaluation of the need for pharmacy managed inpatient INR monitoring at Veterans Affairs Illiana Health Care System

Primary Author: Josephine Fuentes, VA Illiana Health Care System, IL; Email: josephine.fuentes2@va.gov

Additional Author(s):
Jason Tipton
Andrew Schaefer

Purpose: The 2015 Hospital National Patient Safety Goals address the need to reduce patient harm associated with the use of anticoagulation therapy. Warfarin is a commonly used anticoagulant for the following conditions: atrial fibrillation, deep vein thrombosis, pulmonary embolism, and heart valve replacements. Previous studies have shown the effectiveness of pharmacist-managed warfarin protocols in the inpatient setting. The benefits of pharmacist involvement are increased patient safety and fewer INRs outside of therapeutic goal. The goal of this study is to assess the need for pharmacist managed warfarin in the inpatient setting of VA Illiana Health Care System to improve patient care.

Methods: Data for this study was collected through a retrospective chart review. The patient population consisted of patients managed with warfarin while inpatient and who continued care with the outpatient warfarin clinic at Veterans Affairs Illiana Health Care System. This study includes patients managed from September 2014 to September 2016 by the warfarin clinic either prior to inpatient admission or after discharge. Patients with any of the following indications for warfarin were included: recurrent DVT/PE, atrial fibrillation, or heart valve replacement. The primary outcome was to determine the percent time in therapeutic range INR when comparing inpatient physician managed warfarin and outpatient pharmacist managed warfarin. Secondary endpoints include adverse bleeding events or thromboembolic event while inpatient. Subgroup analysis included indication for warfarin, warfarin dose, INR values, gender, age 60 or older, CHADS2 score, length of time on anticoagulant, and percentage of INR levels within therapeutic range while inpatient and outpatient. Based on these results, the inpatient pharmacy may develop an inpatient warfarin management protocol to be maintained by staff pharmacists. This quality improvement study was approved by the residency advisory
committee prior to commencement. All information remained confidential throughout the study.

Poster Title: National evaluation of lithium laboratory monitoring in a Veteran population

Primary Author: Jessica Zacher, Veterans Health Administration Pharmacy Benefits Management Service and Center for Medication Safety, IL; Email: jessica.zacher@my.rfums.org

Additional Author(s):
Francesca Cunningham
Greg Stahly
Ben Sharples
Brent Bell

Purpose: Lithium, a medication which is used in the treatment of bipolar disorder, possesses a narrow therapeutic index. It is recommended that patients have their lithium levels monitored every 4-14 days during the initial titration period, then every 3 to 6 months thereafter to assure appropriate levels and minimize the potential for adverse events. The purpose of this medication use evaluation (MUE) was to assess and characterize Veterans on chronic lithium therapy who did not have a serum lithium concentration documented within a 9-month timeframe.

Methods: Per VHA Handbook 1058.05, this activity does not constitute research and, therefore, did not require IRB review. Centralized chart review of patients from across the Department of Veteran’s Affairs (VA) health care system was conducted retrospectively. Male and female Veterans aged 18 years and older who were prevalent users of lithium between April 1, 2015 and June 30, 2016 and did not have a concentration assessed in the prior 9 months were included in this evaluation. A computer-generated, random sample of 150 patients (5%) from the overall national population of approximately 3,000 lithium users who did not have a concentration drawn in the past 9 months was used for the evaluation. VA databases were utilized to obtain demographics, diagnostic information, prescription history, and laboratory information. In-depth chart reviews were performed to determine the date the most recent lithium concentration was drawn and the location of the laboratory test (i.e., VA versus non-VA). Progress notes were reviewed to find documentation as to why lithium levels were not drawn and to describe any potential adverse drug events (ADEs) related to lithium therapy and their management. Chart review was also used to assess adherence with obtaining other
required annual labs in patients receiving lithium, including a serum creatinine, calcium, CBC with differential, and thyroid profile. Once collected, data were assessed using descriptive statistics.

**Results:** When the date of the most recent lithium concentration was assessed, 32% of patients (N=48) never had a lithium level documented in the chart. Of these patients, 54% (N=26) were a new start, or had been re-initiated on lithium in the past 12 months. Twenty-seven percent (N=41) of patients had their most recent lithium level drawn in the previous 9-12 months. Of the 150 lithium users who did not have a concentration drawn in the prior 9 months, 22% (N=33) had been initiated or re-initiated on lithium in the past 12 months. When assessing potential reasons why the lithium level was not drawn, thirty-two percent (N=48) of patients had a lithium level ordered, but it was never collected. Forty percent of patients (N=60) did not have a reason stated as to why a lithium concentration was not ordered, and 11% (N=16) were lost to follow-up or missed their appointment. Other labs recommended annually in patients taking lithium, including serum creatinine, calcium, CBC with differential, and a thyroid profile, were completed in 72-87% (N=108-130) of patients. Adverse drug events related to lithium were documented in 13% (N=19) of patients; the most common complaints were neurologic or gastrointestinal.

**Conclusion:** Of the lithium patients without a concentration documented within 9 months, 22% were new starts; one-third never had a level documented, and more than half of these patients were new starts. Common reasons, when stated, for not having a lithium concentration were lab ordered and not collected and patient lost to follow-up/missed appointment. Based on these findings, providers have been re-educated about the monitoring requirements for lithium patients. In addition, a tool that was previously created to identify patients without a lithium level in over 6 months will be updated to include prospective monitoring of patients newly initiated on lithium.

**Poster Title:** Evaluation of appropriate referrals, discharges, and no-show rates to optimize pharmacist time in patient-aligned care teams (PACT)

**Primary Author:** Kyle Mohler, Indianapolis VA Medical Center, IN; **Email:** kmohler@butler.edu

**Additional Author(s):**
Allison McFerran
William Malloy

**Purpose:** The primary purpose of this research is to assess and evaluate the no-show rates of veterans in the primary care setting at the Richard L. Roudebush VA Medical Center while also evaluating whether or not patients are appropriately referred and/or discharged to the pharmacist for chronic disease state management by the primary care physician. Additional targets will be developing standard practices to reduce overall no-show rates as well as formulating standard referral and discharge criteria for the facility. The ultimate goal of this process improvement project is to optimize pharmacist utilization within the patient-aligned care team (PACT) health delivery model.

**Methods:** Current methods for patient communication regarding appointment reminders, definition of no-shows, and documentation for patient no-shows have been evaluated and are deemed to be inconsistent across different primary care clinics within the Richard L. Roudebush VA Medical Center. Similarly, the patient referral and discharge process has been shown to be inconsistent across primary care clinics as well, potentially leading to inappropriate pharmacist utilization within the PACT team. Researchers have and will continue to facilitate focus groups from the respective clinics to identify current problems within the system, trial potential solutions, and implement best practices from the findings. Results from this project will be used to change standard practice for within primary care clinics at the Richard L. Roudebush VA Medical Center with hopes to maximize pharmacist involvement in clinics, ensure pharmacists are practicing at the top of their license, and ultimately increase patient access within the health system.

**Poster Title:** Assessment of the ordering process for antipsychotic long-acting injections between care transitions

**Primary Author:** Benjamin Daunais, Richard L. Roudebush VA Medical Center, IN; **Email:** daunaib@gmail.com

**Additional Author(s):**
Talia Miles

**Purpose:** Long-acting injectable (LAI) antipsychotics have become a useful tool for treating patients with psychiatric disorders. Currently, however, there is no process in place that ensures a patient’s LAI antipsychotic medication will be on their inpatient medication profile when then are transferred from outpatient to inpatient status. This may result in duplication of therapy, errors of omission, unanticipated drug interactions, and potential harm to patients. Additionally, there is no data available that addresses medication errors associated with LAI antipsychotic use and care transitions. The aim of this project is to create a process that prevents these medication discrepancies from occurring.

**Methods:** A retrospective chart review will be performed using Computerized Patient Record System (CPRS) and Decentralized Hospital Computer Program (DHCP). Charts will be assessed for medication discrepancies for patients who were admitted to the VA on an LAI antipsychotic. Using the data compiled from the chart review, rapid experiments will be developed and performed within CPRS will to determine how to best document LAI antipsychotic use in order to prevent medication errors. Upon completion of rapid experiments recommendations for processing changes in CPRS will be formulated and implemented.

**Poster Title:** Implementation and evaluation of a transitional plan of care (TPOC) for pharmacy service at a single veterans affairs medical center

**Primary Author:** Eric Elsasser, Richard L. Roudebush Veterans Affairs Medical Center, IN; **Email:** ejelsasser@gmail.com

**Additional Author (s):**
Marshall Jones  
Christina White

**Purpose:** To facilitate strategic and tactical planning for Pharmacy Service that leads to the development of process improvement initiatives. The implementation of these projects will align with the departmental vision to be a nationally recognized leader in the provision of quality pharmaceutical care across the healthcare continuum.

**Methods:** Prior to the start of FY17, pharmacy administration met to participate in a strategic planning retreat. This meeting was conducted utilizing the principles of LEAN process improvement. The creation and continuation of process improvement initiatives within Pharmacy Service was emphasized throughout the retreat. After determination of projects with highest value-added potential, focus was placed on the prioritization of projects among various value streams created by the administration team: USP 800, People, Standard Work, Technology, and Physical Space. Upon completion of the retreat, tasks will be distributed among various members of the Pharmacy Service for execution. The status of projects, staff involvement, and impact on both pharmacy and facility outcome measures will be continually assessed throughout the year to determine efficacy.

Poster Title: Improving attendance at an interdisciplinary smoking cessation drop-in group medical appointment by utilizing lean process improvement principles

Primary Author: Samantha Schulte, Richard L. Roudebush Veterans Affairs Medical Center, IN; Email: s-schulte.1@onu.edu

Additional Author(s):
Darin Ramsey
Kristoffer Schnur
Elizabeth Phelps

Purpose: Approximately 16.8% of adults in the United States smoke, including 30% of active military personnel and 22% of veterans. In 2015, a motivational interviewing based interdisciplinary smoking cessation drop-in group medical appointment (DIGMA) was formed at the Richard L. Roudebush Veterans Affairs Medical Center. The objective of this study is to improve patient attendance at the group to better combat tobacco use by veterans.

Methods: This quality improvement study will utilize lean process improvement principles to assess barriers to patient attendance at a smoking cessation drop-in group medical appointment (DIGMA). Attendance forms will be used to determine the baseline attendance. The Computerized Patient Record System (CPRS) will be utilized to identify patients who were referred to the smoking cessation DIGMA, but did not attend. Voice of the customer questionnaires will be utilized to assess the barriers that prevent these patients from attending the group appointment. Perceived successes and benefits of the group will be collected from patients who are currently attending or who have attended the group through questionnaires. Barriers that prevent members of the healthcare team from referring patients to the smoking cessation group will be determined through the use of questionnaires. Themes and data will be extracted from these questionnaires. Subsequent modifications will be made to current practices via rapid experiments to enhance the referral process and attendance surrounding the smoking cessation DIGMA. No personal identifiers, aside from healthcare workers’ credentials, will be attained from the voice of the customer questionnaires.

**Poster Title:** Establishing clinical pharmacy services for chronic obstructive pulmonary disease (COPD) in a primary care setting at a Veterans Affairs Medical Center

**Primary Author:** Brent Simpkins, Richard L. Roudebush Veterans Affairs Medical Center, IN; 
**Email:** brent.simpkins@va.gov

**Additional Author (s):**
Susan Bex
Ashley Berkeley
Amy Boldt

**Purpose:** Within the VA population, patients with COPD have significantly higher rates of all-cause and respiratory-related health care utilization than patients without COPD. Currently there are several VA sites that offer clinical pharmacy services in COPD management, but this service is not offered at the Richard L. Roudebush VA Medical Center. A recent study at this VA facility showed that with current standard of care, 16% of patients had a COPD exacerbation within one year. The goal of this project is to establish clinical pharmacy services for COPD in a primary care setting.

**Methods:** This project will be piloted in two primary care clinics with the clinical pharmacy specialists being incorporated into the management of COPD. Scope of practice will be established to allow the initiation, adjustment, and monitoring of medications under protocols decided by both medical and pharmacy staff. The scope of practice will follow both VA/DoD Clinical Practice Guidelines and Global Initiative for Chronic Obstructive Lung Disease (GOLD) guidelines. In addition to medication management the clinical pharmacy specialists will also ensure proper inhaler technique, evaluate immunization and smoking status, determine medication adherence, and perform the COPD Assessment Test (CAT) or Modified Medical Research Council (mMRC) dyspnea scale.

Poster Title: Targeted interventions to improve time in therapeutic range in a pharmacist-run anticoagulation clinic

Primary Author: Lindsey Smith, Richard L. Roudebush Veterans Affairs Medical Center, IN; Email: lindseyesmith2@gmail.com

Additional Author(s): Cassandra Otte
Jiji Thomas

Purpose: Time in therapeutic range (TTR) of international normalized ratio (INR) is important for both the safety and efficacy of therapy with warfarin. Within the Veterans Health Administration, TTR for the anticoagulation service is evaluated each quarter with a goal TTR of 60% or greater. Although the anticoagulation clinic at Richard L. Roudebush Veterans Affairs Medical Center has met this goal, there are still a number of veterans spending a significant time out of therapeutic range. These patients are at higher risk for increased complications such as major bleeding, stroke, and thromboembolism.

Methods: Patients with a TTR of less than 40% during the time period of April 1 and June 30, 2016 were reviewed to assess the factors contributing to a low TTR. Based on the identified factors, interventions were identified to improve TTR for this group of patients. Suggested interventions include transition to a new oral anticoagulant, discontinuation of anticoagulation, assignment to one pharmacist until time in therapeutic range is improved, or other interventions as determined to be indicated based on evaluation by the anticoagulation clinical pharmacy specialists. An initial list of patients with a TTR < 20% for the identified quarter was developed. The anticoagulation clinical pharmacy specialists in the clinic will be responsible for assessing these patients and implementing an appropriate targeted intervention. Interventions will be implemented by the clinical pharmacy specialists from October 1 through December 31, 2016. At the conclusion of this period, the TTR for the entire clinic and the number of patients with a TTR of less than 20% will be assessed to determine if the identified interventions had an impact. Additionally, the implemented interventions will be reviewed for effectiveness and practicality and an improved process will be attempted in the following quarter.

**Poster Title:** Assessment of outcomes in a secondary and tertiary level pain clinic

**Primary Author:** Rachel Wilden, Richard L. Rouebush Veterans Affairs Medical Center, IN; Email: rwilden@butler.edu

**Additional Author(s):**
Kelly Henderson

**Purpose:** The Physical Medicine and Rehabilitation Service (PMRS) Pain Clinic within the Richard L. Rouebush Veteran Affairs Medical Center (VAMC) offers secondary and tertiary level interdisciplinary programs for veterans with chronic non-cancer pain. Outcomes data is collected via the Pain Outcomes Questionnaire-Short Form (POQ-SF), a validated pain scale designed to score multidimensional pain interventions. The objective of this study is to assess the outcomes of patients enrolled in the PMRS secondary and tertiary level pain clinics at the Richard L. Rouebush VAMC to minimize risks of opioid therapy and improve veteran care.

**Methods:** Data collection and analysis will be completed via a retrospective chart review in the Computerized Patient Record System (CPRS). Inclusion criteria will include age greater than or equal to 18 years old, diagnosis of chronic non-cancer pain, opioid use on admission to program, and enrollment in the PMRS Pain Clinic secondary or tertiary level program. Exclusion criteria includes patients lost to follow-up or patients not completing the POQ-SF. Data collected will include the baseline characteristics, adjunctive non-opioid pharmacologic treatment, morphine equivalent daily dose (MEDD), POQ-SF total score, and POQ-SF individual domain scores on admission and discharge from the tertiary program and on admission and three, six, and nine months post-admission for the secondary program. Data regarding length of enrollment and adjunctive non-pharmacologic therapy will also be collected for secondary level patients. Each program will be assessed individually and data will not be compared. Approval for this study is being sought from the Indiana University institutional review board.

Poster Title: Effect of DPP4 Inhibitors on Heart Failure Admission Rates in the Veteran Population: An Observational Review

Primary Author: Michael Cobretti, VA Eastern Kansas Health Care System - Topeka, KS; Email: michael.cobretti@va.gov

Additional Author(s):
Benjamin Bowman
Emily Potter
Ted Grabarczyk
Michael Buck

Purpose: In the treatment of type 2 diabetes mellitus, dipeptidyl peptidase-4 inhibitors are not only widely considered effective modulators of fasting and postprandial hyperglycemia, but also have shown potential protective benefits for the cardiovascular system. In 2013 the SAVOR-TIMI 53 clinical trial found an increased risk of heart failure hospitalization among users of saxagliptin as a secondary outcome. Follow-up studies have largely been unable to replicate these findings. This study aims to be one of the largest investigations to date examining the safety and efficacy of dipeptidyl peptidase-4 inhibitors in type 2 diabetes mellitus in relation to heart failure hospitalizations.

Methods: This is an observational, multi-center cohort study that will utilize data from patients to understand the potential correlation between dipeptidyl peptidase-4 inhibitors and heart failure hospitalizations in patients diagnosed with type 2 diabetes mellitus. Data will be extracted and maintained within the Informatics and Computing Infrastructure workspace. Duration of data collection will be 3 years, consisting of records from August 2013 until August 2016. The primary outcome of this study will be to determine heart failure hospitalization rates for patients taking dipeptidyl peptidase-4 inhibitors in addition to standard of care therapy for type 2 diabetes mellitus versus patients taking standard of care therapy for type 2 diabetes mellitus alone.

**Poster Title:** Impact of alcohol abuse on mortality following hepatitis C treatment with direct-acting antivirals: A national cohort study of Veterans Affairs patients

**Primary Author:** Michael Buck, VA Eastern Kansas Health Care System - Topeka, KS; **Email:** michael.buck1@va.gov

**Additional Author(s):**
Emily Potter
Benjamin Bowman
Michael Cobretti
Mary Oehlert

**Purpose:** The treatment of hepatitis C (HCV) has changed dramatically over the past several years with the approval of several direct-acting therapies that have increased the treatment success while decreasing adverse side effects. In many of the clinical trials patients who are alcohol dependent were excluded from participation in the studies. As a result, the effect of these treatments remains unknown within this population. This observational study looks to analyze the mortality effect on those who have a history of alcohol dependency and have been treated with a direct-acting antiviral.

**Methods:** This is an observational, multi-center cohort study utilizing nation-wide data from within the Veterans Affairs network to describe the mortality effect of HCV treatment with direct-acting antivirals (DAA) on alcohol dependent persons. The data is managed by the National Corporate Data Warehouse (CDW) and will be accessed via the VA Informatics and Computing Infrastructure (VINCI). Clinical data from subjects that meet inclusion criteria (prescription fill history for any DAA) will be collected then screened for exclusion criteria. Data will be collected from October 1, 2013 through August 31, 2016. The primary outcome of the study will be survival. Secondary outcomes will include a time to death analysis and incidence of hepatocellular carcinoma. Alcohol abuse will be determined by the combination of ICD9/10 codes and Alcohol Use Disorders Identification Test (AUDIT-C) scores. Additional information collected will include viral genotype, hepatic function tests, dates of birth and death (if applicable), and others. Statistical analysis of patient demographic data of between group differences will be evaluated by paired t-test for continuous variables or chi-squared tests if
categorical. Outcome data will be analyzed using a chi-squared test for categorical outcomes. Kaplan-Meier curves will be prepared for the time to death outcome and analyzed with a log-rank test to determine statistical significance. A p-value of less than 0.05 will be considered statistically significant in all cases.

**Poster Title:** Characterizing the utility of melatonin for sleep disorders in the veteran population

**Primary Author:** Jenna Gilbert, Lexington VA Medical Center, KY; **Email:** jenna.gilbert@va.gov

**Additional Author(s):**
Courtney Eatmon

**Purpose:** Sleep disorders are widespread and affect overall health and well-being. Current treatments for insomnia include medications with addiction potential and harmful side effects. Melatonin is a naturally-produced hormone which is thought to aid in regulation of the sleep cycle. As an herbal sleep aid, melatonin lacks addictive properties and has a low potential for side effects. Little data exists on melatonin use or prescribing patterns for sleep disorders in clinical practice. The objective of this study is to characterize the utility of melatonin for sleep disorders within a single VA Medical Center.

**Methods:** This study will utilize retrospective chart review to obtain data. Patients will be included if they received a prescription for melatonin as an outpatient from the Lexington VA Medical Center at any time from December 1, 2015 to August 31, 2016, as identified by the electronic medical record system. Patients who received melatonin for an indication other than a sleep disorder will be excluded. The following data regarding melatonin will be collected: duration of treatment, dose, adherence, and use in special populations including the elderly or those with a history of substance use disorder. Prior sleep disorder treatment will be assessed, along with concomitant sedating medications indicated for sleep. Additionally, presence of medications and conditions that can contribute to insomnia will be analyzed. Descriptive statistics will be used to analyze data. This study will be submitted to the Institutional Review Board for approval.

Poster Title: Implementation of a pharmacist-led benzodiazepine taper clinic

Primary Author: Ali Saghaian, Lexington Veterans Affairs Medical Center, KY; Email: asaghaian@gmail.com

Additional Author(s):
Courtney Eatmon
Justin Butler

Purpose: Long-term use of benzodiazepines leads to the development of tolerance and a loss of efficacy. Use of benzodiazepines exceeding two to four weeks will increase the risk of dependence, making it important to gradually taper the medication to avoid the potential for withdrawal symptoms or rebound of the underlying condition. The objective of this project is to facilitate safe tapering by providing a helpful new service in the form of a pharmacist-led benzodiazepine taper clinic, thereby reducing inappropriate benzodiazepine use and increasing taper success.

Methods: Eligible patients will be referred to the benzodiazepine taper clinic by their provider. Once referred, patients will meet with the psychiatric pharmacy resident or mental health pharmacist to undergo a brief educational session regarding benefits, risks, and expectations of their benzodiazepine taper. Patients who agree to the benzodiazepine taper will then be provided an individualized taper protocol. The referring provider will maintain prescriptive responsibility for the duration of the taper. The psychiatric pharmacy resident or mental health pharmacist will coordinate with the provider for benzodiazepine prescribing during the taper. Patients will be followed by phone or face-to-face at least every two weeks while their taper is ongoing. Generalized Anxiety Disorder-7 (GAD-7) and Insomnia Symptom Questionnaire (ISQ) self-assessment tools will be utilized at targeted intervals. Based on clinical assessment, further outpatient management of the benzodiazepine taper will be modified or continued as clinically appropriate. Data for all patients, including initial benzodiazepine, dosage, indication, duration of use, details of the taper regimen, and ultimate success will be recorded and saved without patient identifiers. This study is considered a quality improvement project and as such is IRB exempt. It will be submitted to the research and development committee for publishing approval upon its completion.
Results: N/A

**Poster Title:** Evaluation of the management of type 2 diabetes mellitus outpatient insulin users in an inpatient setting within a Veterans Affairs Medical Center

**Primary Author:** Stephanie Keca, Lexington Veterans Affairs Medical Center, KY; Email: stephanie.keca@va.gov

**Additional Author(s):**
John Emmons
Lisa Tannock
Indu Mathew

**Purpose:** Maintaining adequate blood glucose control in the inpatient setting has been associated with decreased mortality, shorter lengths of stay, and lower complication rates. However, literature regarding inpatient insulin requirements of type 2 diabetic outpatient insulin users remains unclear. The purpose of this study is to review inpatient insulin dosing for type 2 diabetics managed with insulin in the outpatient setting and analyze resultant glycemic control. This study hopes to either provide clinical evidence to support the practice of decreasing insulin doses upon admission or contribute an alternate inpatient insulin management strategy to better guide future practice.

**Methods:** The study is a retrospective case-series utilizing database analysis and chart review and is pending Research and Development Committee approval. The computerized patient record system (CPRS) will be reviewed for type 2 diabetics admitted between 1/1/2013 and 12/31/2015 who filled an outpatient prescription at the study site for either basal/bolus or premixed 70/30 insulins within 90 days prior to admission. The following data will be collected: patient demographics (age, race, weight, height, body mass index [BMI], diagnosis of renal or cardiovascular disease), admitting diagnosis, HbA1c pre- and post-hospitalization, total daily doses of insulin before, during, and after hospitalization, dietary status during hospitalization, number of blood glucose levels classified as low (below 70mg/dL), target (70-180mg/dL), high (180-300mg/dL), and very high (above 300mg/dL), administration of glucose or glucagon for hypoglycemic episodes, length of stay, and pertinent concomitant medications (angiotensin-converting enzyme inhibitors [ACEI], angiotensin receptor blockers [ARB], beta-blockers, antibiotics, corticosteroids, atypical antipsychotics, non-insulin antihyperglycemics, HGM-CoA
reductase inhibitors, aspirin, and medication used to manage diabetic neuropathy). All data will be de-identified to maintain confidentiality. Patients will be stratified according to their HbA1c before admission (below 8, 8-8.99, 9 and above). Total daily doses will be calculated as total insulin units administered during admission divided by length of stay and inpatient glycemic control will be measured by the percentage of time patients spend hypoglycemic, hyperglycemic, and within target glycemic range.

**Poster Title:** Outcomes of an inpatient proton pump inhibitor stewardship program post hospital discharge

**Primary Author:** Randal Steele, Lexington Veterans Affairs Medical Center, KY; **Email:** randalsteele@ucwv.edu

**Additional Author (s):**
Kelly Davis  
Rebekah Wahking  
Sean Lockwood  
Rachel Hanners

**Purpose:** Proton pump inhibitors (PPIs) are widely used in the treatment of acid-related disorders, however, studies suggest that up to 80% of PPIs are prescribed without an evidence-based indication. PPIs have been associated with adverse events, including pneumonia, fractures, and Clostridium difficile infection. Based on this information, a PPI stewardship program was created at a single institution, to evaluate for appropriateness of inpatient and outpatient PPI continuation and to subsequently discontinue inappropriate PPI therapy. The purpose of this study is to evaluate the success of a PPI stewardship program in discontinuing PPIs without proper indications upon hospital discharge.

**Methods:** Institutional Review Board approval has been obtained to conduct this retrospective cohort study. All patients admitted to an internal medicine service from 3/14/16 to 8/14/16 on a home PPI were evaluated by the PPI stewardship team for appropriate indications to continue therapy. All patients who were counseled to discontinue their PPI at hospital discharge will be included in this study. The primary objective of this study is to determine the percentage of patients who successfully discontinued their PPI upon hospital discharge as a result of the PPI stewardship program. Successful discontinuation will be defined as no refill of a PPI within 90 days of discharge, or other documentation in the electronic medical record of successful discontinuation. The secondary objective of this study is to compare those patients with successful and unsuccessful discontinuation to evaluate risk factors that may contribute to patients’ failure to successfully discontinue PPI therapy.

**Session-Board Number:** 1-176

**Poster Title:** Effect of high-dose ergocalciferol on rate of falls in a community-dwelling, veteran population: a case-crossover study.

**Primary Author:** Ryan Albers, Lexington Veterans Affairs Medical Center, KY; **Email:** ryan.albers1@va.gov

**Additional Author (s):** Tara Downs

**Purpose:** Previous research has identified a benefit associated with vitamin D supplementation on risk and rate of falls in advanced age. Recent evidence suggests a negative impact of high-dose vitamin D3 supplementation on the same measures. At this time, there is scarce literature available describing fall outcomes related to high-dose vitamin D2 supplementation. The purpose of this study is to evaluate the effect of high-dose ergocalciferol on rate of falls in a community-dwelling, veteran population with low 25-hydroxy vitamin D.

**Methods:** This retrospective, case-crossover study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients enrolled in home-based primary care who are 65 years of age or older, have had a level of 25-hydroxy vitamin D less than 20 ng/mL, and subsequently received vitamin D supplementation with high-dose ergocalciferol. Patients who were enrolled in home-based primary care for less than 30 days prior to supplementation and those with chronic conditions that inherently increase the risk of falls will be excluded. Data to be collected will include age, sex, levels of 25-hydroxy vitamin D, ergocalciferol prescription data as well as additional forms of vitamin D supplementation if prescribed, total falls and fallers prior to and during supplementation, and medications that increase risk of falls actively prescribed prior to and during supplementation. The primary outcome measure will be a change in rate of falls between the time periods prior to supplementation and during supplementation. The secondary outcome will be the rate of falls according to the level of 25-hydroxy vitamin D as a result of supplementation.

Poster Title: Readmission rates after the establishment of a stable oral loop diuretic regimen prior to discharge following hospitalization for heart failure exacerbation

Primary Author: Luke Newman, Robley Rex Veterans Affairs Medical Center, KY; Email: lukednewman@yahoo.com

Additional Author(s):
Holly Holladay
Grace McCoy
Crystal Owens
Maria Shin

Purpose: When patients are admitted to the hospital for heart failure (HF) exacerbation, loop diuretics are dosed aggressively and variably. Patients are often discharged before an optimal outpatient diuretic regimen is determined. The objective of this analysis is to determine if there is a difference in 30-day rate of readmission for patients admitted for HF exacerbation who were established on a stable oral loop diuretic regimen for 24 hours prior to discharge compared to patients who were not. Stable oral loop diuretic regimen for 24 hours is defined as receiving the discharge diuretic regimen on the day prior to discharge.

Methods: Patients discharged from the Robley Rex VAMC with a discharge diagnosis of HF exacerbation will be selected and the inclusion and exclusion criteria will be applied to identify the analysis population. Once a patient is included in the analysis, the following data will be collected: demographics, age, height, weight, co-morbidities, pre-admission HF medication regimen, inpatient diuretic regimen, serum creatinine (SCr) and blood urea nitrogen (BUN) on admission and discharge, and date of original admission. Each patient will then be followed for 30 days following discharge and the following data will be recorded: HF medication changes at outpatient follow-up, any patient readmissions, and any patient deaths. For patients who are readmitted, the time to readmission as well as the SCr and BUN at readmission will be collected. Rate of 30-day readmission will be calculated as well as percentage change in diuretic dose from admission to discharge, mean duration of original admission in days mean time in days from discharge to readmission, rate of acute kidney injury and dehydration on readmission
using BUN:SCR ratios and change in SCR, mortality data, and rate of readmission based on medication-related risk factors. All data will be de-identified and maintained confidentially.

Poster Title: Evaluation of pharmacist impact on antipsychotic and benzodiazepine utilization in veterans with dementia

Primary Author: Chelsea Maier, Robley Rex Veterans Affairs Medical Center, KY; Email: chelsea.maier@va.gov

Additional Author(s):
Morgan Camille Snyder
Crystal Owens
Christina Taylor
Holly Long

Purpose: It has been well established that use of Antipsychotics (APs) and Benzodiazepines (BZDs) in the elderly population is associated with increased incidence of adverse effects including sedation, falls, and cognitive impairment. The Veterans Health Administration (VHA) introduced the Psychotropic Drug Safety Initiative (PDSI) to improve evidence-based psychotropic drug prescribing for Veterans with mental illness. This initiative aims to address possible issues with pharmacotherapy such as overprescribing, clinical management, and inappropriate indications. The purpose of this project is to assess the impact of recommendations made by a pharmacist on the utilization of APs and BZDs in patients with dementia.

Methods: This retrospective review will be conducted at the Robley Rex Veterans Affairs Medical Center in Louisville, Kentucky. All Veterans identified as actionable through the PDSI dashboard on September 15, 2016 will be eligible for selection. Veterans will be excluded if they are receiving hospice care or have had their AP or BZD therapy reviewed by a pharmacist with recommendations documented in the Computerized Patient Record System (CPRS) within the previous 12 months. A report of actionable Veterans meeting inclusion criteria will be generated on September 15, 2016 from the PDSI dashboard. Once this list is generated, demographic information and data will be obtained from CPRS, the Veterans Health Information Systems and Technology Architecture (VISTA), and the PDSI dashboard. Following the collection of demographic information and chart review, a recommendation on the utilization of the AP or BZD agent will be documented by the pharmacist in CPRS. The
provider will receive a notification to review the note and follow-up will be performed via chart review 90 days after entry date of the recommendation. All information will be collected in a de-identified Excel spreadsheet to evaluate the provider’s response to the recommendation. Descriptive statistics of primary and secondary endpoints will be compiled using Microsoft Excel. Data will be reported in numbers and percentages. Percent change will be evaluated over a 90 day time period.

Poster Title: Retrospective analysis of the efficacy and safety of add-on therapy of liraglutide to insulin glargine for the treatment of type 2 diabetes mellitus

Primary Author: Katherine Czarnowski, VA Boston Healthcare System, MA; Email: katherine.czarnowski@va.gov

Additional Author(s):
Gary Lane Smith

Purpose: Glucagon-Like Peptide-1 (GLP-1) is an incretin hormone that stimulates insulin release, suppresses glucagon levels, and delays gastric emptying in response to meal ingestion. Patients with diabetes have an impaired secretion of GLP-1. Combination therapy of GLP-1 receptor agonists and basal insulin offer many benefits over traditional basal, bolus insulin regimens including fewer injections, additional weight reduction, and fewer hypoglycemic events. Similar to bolus insulin, GLP-1 receptor agonists reduce post prandial glucose. The primary objective will be to examine the hemoglobin A1c reduction when liraglutide is added to basal insulin. Secondary objectives will include reduction in weight, hypoglycemia, and insulin requirements.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients who have outpatient prescriptions from January 2010 to December 2016 for either insulin glargine, liraglutide, or both at the VA Boston Healthcare System. The following data will be collected: patient age, gender, hemoglobin A1c, body weight, and insulin doses. Provider documentation will be reviewed to determine incidence of hypoglycemia. The investigators will evaluate the average reduction in hemoglobin A1c, body weight, hypoglycemic episodes, and insulin. All data will be kept confidential.

**Poster Title:** Establishing the Necessity of a Fracture Liaison Service to Optimize Post-fracture care in Osteoporotic Patients

**Primary Author:** Sahil Jain, VA Boston Healthcare System, MA; **Email:** sahil.jain@va.gov

**Additional Author (s):**
David Schnee
Bryan Wood
Patricia Underwood
Paul Conlin

**Purpose:** Osteoporotic-related fractures dramatically impact patients’ health and quality of life. These fractures result in significant morbidity and mortality, while burdening the healthcare system as a whole. The primary prevention of these events is ideal; however, preventing future fractures following the first one is a critical part of caring for patients with osteoporosis. The purpose of our research is to determine the need for a standardized treatment program known as the Fracture Liaison Service in the VA Boston system. This service will identify patients with osteoporosis-related fractures in a timely manner and provide optimal care in concurrence with Primary Care.

**Methods:** We will utilize a data warehouse to retrospectively analyze data and identify osteoporotic veterans who have had hip and vertebral fractures. The data query will collect information regarding the types of fractures, recent DXA scan(s), laboratory results, and whether the patient is receiving appropriate therapy for treatment of osteoporosis. After identifying these individuals, we will perform a comprehensive chart review to determine whether the cause of the fracture is osteoporosis-related. This review will also serve to recognize and exclude patients from eligibility for osteoporosis work-up and management at the VA (patients receiving hospice, non-VA care). We will proceed to analyze the data to determine if the patients have received correct testing for osteoporosis work-up. The appropriateness of these tests will be based upon recommendations from the 2014 Osteoporosis Foundation guidelines. If it is determined that post-fracture care in our osteoporotic patients is inadequate, we will work with the Endocrine team to develop the Fracture Liaison Service (FLS). The FLS will order further tests, when necessary. In concurrence
with primary care, the FLS will utilize the results of these tests to determine the severity of the veteran’s osteoporosis. This information will establish the need for further osteoporosis work up, if necessary. Any contraindications to medications used for the treatment of osteoporosis can be identified as well. Finally, the FLS will provide recommendations to optimize post-fracture management.

Poster Title: Phenobarbital for the treatment of acute alcohol withdrawal in the medical ICU in a veteran population

Primary Author: Chelsea Henderson, VA Boston Healthcare System, MA; Email: ceh57@pitt.edu

Additional Author(s):
Bryan Wood
Tekikil Mekuria

Purpose: The purpose of this study is to evaluate the safety and efficacy of phenobarbital compared to benzodiazepines for acute alcohol withdrawal in a veteran population. Benzodiazepines are a standard treatment for acute alcohol withdrawal (AAW) in the inpatient setting. However, patients with multiple admissions for detox can become refractory to benzodiazepine therapy and require much higher doses to manage their withdrawal. Case reports and retrospective studies document benefit of using phenobarbital in high risk patients who have a history of complicated withdrawal symptoms such as delirium tremens and prolonged ICU stays requiring intubation.

Methods: Phenobarbital augments GABA inhibitory response and reduce the effect of glutamate excitatory response. This dual mechanism of action makes it an effective treatment for AAW in benzodiazepine resistant patients. This retrospective, observational study has been submitted to the Institutional Review Board for approval. Patients admitted to the medical ICU (MICU) who had been initiated on a weight-based intravenous phenobarbital protocol for AAW will be included. The intervention was a weight-based phenobarbital loading dose followed by a twice daily oral taper based on Riker Sedation-Agitation scoring. Patients admitted to the MICU prior to the implementation of the phenobarbital protocol who received symptom-based benzodiazepine therapy will be used as the comparator group. The primary efficacy endpoint will be ICU length of stay. Secondary efficacy endpoints will include time to resolution of symptoms, seizure activity, and adjunct medication use. Safety endpoints will include respiratory depression, change in mental status, and intubation. Statistical analysis will include nominal variable analysis using the Fishers Exact Test and continuous data using the Mann-Whitney U Test.
**Results:** Results in progress.

**Conclusion:** Not applicable at this time.

Poster Title: Retrospective analysis of the impact of a conversion between tiotropium inhalation mechanisms in a veteran population with chronic obstructive pulmonary disease

Primary Author: Brittany Pietruszka, VA Boston Healthcare System, MA; Email: brittany.pietruszka@gmail.com

Additional Author (s):
Charles Berds

Purpose: Tiotropium is a long acting muscarinic antagonist used to manage patients with chronic obstructive pulmonary disease (COPD) and asthma. Patients at the VA Boston Healthcare System (VABHS) who were previously on tiotropium dry powder inhaler were converted to an aqueous solution based system for device ease of use. A study comparing the two different inhalation mechanisms found comparable improvements in pulmonary function and risk for COPD exacerbations. This study is aimed to evaluate alterations in COPD control and its medication management in a veteran population before and after inhalation mechanism conversion.

Methods: Prior to commencement, this 16-month retrospective chart review will be submitted to the VABHS institutional review board for approval. Patients at the VA Boston Healthcare System with an active diagnosis of COPD defined by International Classification of Diseases (ICD-10) diagnosis code J44.9 on tiotropium during the time period from May 1st, 2015 to September 30th, 2016 will be identified and studied. In order to minimize confounders, patients will serve as their own controls eight months prior to and eight months after the conversion. Data collection will be performed by extracting information from VABHS electronic medical records and will include: patient demographics, smoking status, respiratory-related emergency department visits, COPD exacerbation admission rates, percent of predicted forced expiratory volume in one second (FEV1), alteration of COPD medication regimens, rescue inhaler usage, and medication refill histories. All data will be recorded without patient identifiers and maintained confidentially.

**Poster Title:** Application and validation of 7-day antibiotic therapy for hospital-acquired pneumonia: a collaborative antimicrobial stewardship initiative

**Primary Author:** Stephanie Tolg, VA Boston Healthcare System, MA; **Email:** maria-stephanie.tolg@acphs.edu

**Additional Author (s):**
Michael Brennan
Donald Smith

**Purpose:** The most recent updates to the Infectious Disease Society of America (IDSA) clinical practice guidelines recommend a 7-day course of antimicrobial therapy for hospital-acquired pneumonia (HAP) to reduce antibiotic usage and emerging multi-drug resistant (MDR) pathogen infections. This study will aim to evaluate a hospital-wide initiative to promote and validate this recommendation.

**Methods:** Inpatient clinical pharmacists at the VA Medical Center-West Roxbury will monitor all patients receiving antibiotic therapy for HAP, and document a note in each patient’s charts when they have received 6 days of antimicrobial therapy for HAP. These notes will alert the ordering physicians about the IDSA 7-day duration recommendation. If continuation beyond 7-days of therapy is to be considered, then the physicians will request approval from an infectious disease physician. After review of the patient, the infectious disease physician can decide concurrently with the ordering physician if longer therapy is clinically indicated. This study will evaluate this initiative, and will be first submitted for approval from the Institutional Review Board (IRB). The study investigators will determine if this initiative can successfully reduce the 28-day antibiotic-free days for HAP patients. Patient data on antibiotic administration for this indication will be collected for a 6-month period, which will be compared to data from 6 months prior to initiating this protocol. Validation of this recommendation will be evaluated by collecting the following: reinfections, microbiology culture/sensitivity reports, hospital length of stay, and death. Baseline demographics of patients will also be reported to assess applicability of results to other populations.

Poster Title: Improving medication reconciliation in a veterans affairs nursing home: Participation in the medication reconciliation quality improvement study (MARQUIS)

Primary Author: Laura Driscoll, VA Boston Healthcare System, MA; Email: lkd07001@gmail.com

Additional Author(s):
Amy Baughman

Purpose: Unintentional medication discrepancies are common and may cause patient harm. Medication reconciliation is recognized by the Joint Commission as a National Patient Safety priority. The Brockton Community Living Center (CLC) of the VA Boston Healthcare System will participate in a national quality improved study, MARQUIS2, to improve medication reconciliation practices. Currently, medication reconciliation is performed by the physicians and nurses without pharmacy involvement. The process is not standardized and varies by healthcare provider. The primary objective of this study is to reduce medication discrepancies by implementing interventions from the Medication Reconciliation Quality Improvement Study (MARQUIS) toolkit.

Methods: This is a quality improvement study that has been submitted to the Institutional Review Board for approval. In phase one, existing medication reconciliation performance will be examined and CLC providers will be surveyed to assess the current medication reconciliation process and to identify areas in need of improvement. A baseline rate of medication reconciliation discrepancies will be determined by chart review. Phase two will include implementation of interventions according to the MARQUIS toolkit. One intervention will be to stratify patients according to risk in order to provide additional pharmacy support for high risk patients. Specifically, patients identified as high risk will receive intensive interview and reconciliation performed by a pharmacist to obtain the best possible medication history. High risk patients will be considered those in which provider has clinical concern, or those with the presence of any two of the following: patient or caregiver cannot provide medication list or pill bottles, more than ten pre-admission medications or more than three high risk medications. High risk medications include anticoagulants, antiplatelets, insulin, oral hypoglycemics, opioids and digoxin. Data collected will include the number and types of discrepancies. Discrepancies will be categorized as omitted drug, discrepant brand, incorrect drug, incorrect dose, missing
dose, incorrect frequency, missing frequency, previously stopped medication or duplicate medication.

Poster Title: Implementation of Chronic Obstructive Pulmonary Disease (COPD) Medication Management by a Pharmacist within a Shared Medical Appointment

Primary Author: Anita Wong, VA Maryland Health Care System, MD; Email: anita.wong@va.gov

Additional Author(s):
Sarah Pierce
Lakshmi Singh

Purpose: COPD causes significant morbidity and mortality. Guideline-based inhaler regimens can reduce symptoms, exacerbations, and hospitalizations. Studies have shown most patients are non-adherent to maintenance inhalers. At the VA Maryland Health Care System, an existing pharmacist managed COPD education group clinic provides disease state and inhaler education for veterans with COPD. This group clinic covers COPD pathophysiology, pharmacotherapy and exacerbations, and provides individualized inhaler teaching. No medication management services are provided. The purpose of this project is to describe the expansion of the COPD group clinic into a shared medical appointment (SMA) that includes COPD medication management by a clinical pharmacist.

Methods: Under the supervision of a clinical pharmacy specialist with an advanced scope of practice that includes prescriptive authority, PGY2 ambulatory care pharmacy residents will provide COPD medication management services within a SMA to ensure each patient is receiving an individualized, evidence-based inhaler regimen. Nicotine replacement therapy may also be prescribed for smoking cessation. The group discussion and education as well as individualized inhaler teaching that comprise the existing COPD group clinic will remain. Patients are eligible for participation in the SMA if they have a diagnosis of COPD and are prescribed at least one inhaler. All patients in the group are eligible for medication management services unless they are followed by a pulmonary specialist for COPD or another lung condition. The SMA will consist of two monthly sessions each lasting two hours with up to eight veterans scheduled per session. Each session will begin with group discussion and education. During the latter half of each session, patients will be seen individually for inhaler teaching and medication management. A separate clinic will be created that will allow for one-on-one follow-up appointments with the pharmacist following the final session of the SMA. A
voluntary patient survey will be administered to assess patient satisfaction and identify strengths and weaknesses of the SMA. Review by an institutional review board will not be required for this descriptive report in progress.

Poster Title: Characterize and Evaluate Treatments for Second and Subsequent Recurrences of Clostridium difficile Infections in a Veteran Population

Primary Author: Aparna Nanduri, VA Maryland Health Care System, MD; Email: aparna.nanduri@va.gov

Additional Author (s):
Kathleen Hess
Lindsey Crist

Purpose: Clostridium difficile infection (CDI) accounts for a significant number of hospital-associated gastrointestinal illness. Recurrence occurs in 10-20 percent of patients with CDI, and rates of further recurrence increases to 40-65 percent. Guidelines specify treatment for initial infection and first recurrence. Guidelines then recommend treating second and subsequent recurrences with a pulsed and/or tapered oral vancomycin regimen but do not have recommendations on specific regimens. Fidaxomicin is another antibiotic approved for CDI, clinically used for multiple recurrences. The study’s purpose is to characterize regimens and compare recurrence rates across treatments for second and subsequent recurrences of CDI at the VAMHCS.

Methods: A retrospective chart review will be performed. All patients at the VAMHCS with a positive C. difficile PCR test from January 2012-September 2016 will be included. These patients will then be screened to exclude all patients who do not have a second or subsequent recurrence of CDI. Additional exclusion criteria include patients started on a vancomycin taper at a private facility and patients who passed away during the data collection period. An initial CDI infection is defined as a positive C. difficile PCR result or signs and/or symptoms of infection, and no documented need for treatment of CDI 90 days prior to positive result. Recurrence is defined as documented need for treatment of CDI up to 90 from the last day of prior CDI treatment. The primary objective is to characterize the pharmacologic regimens prescribed at the VAMHCS for second and subsequent recurrences of CDI. The secondary objective is to compare recurrence rates across pharmacologic regimens prescribed at the VAMHCS for second and subsequent recurrences of CDI. Data collection includes age, gender, and ethnicity, location of care, number of prior recurrences, severity, treatment regimen (drug,
dose, route, frequency, and duration), additional concomitant medications for CDI, treatment for prior CDI, and antibiotics for concurrent infections. IRB approval at the VAMHCS is pending. The primary endpoint will be analyzed using descriptive statistics and secondary endpoint using chi-square.

Poster Title: Implementation of a physical examination course utilizing patient simulation technology for ambulatory care clinical pharmacy specialists at a Veteran's Affairs Hospital

Primary Author: Elizabeth Flippin, VA Maryland Health Care System, MD; Email: elizabeth.flippin2@va.gov

Additional Author(s):
Sarah Pierce
Karen Korch Black

Purpose: Within the Veterans’ Affairs Maryland Health Care System, Ambulatory Care Clinical Pharmacy Specialists act under a scope of practice to provide direct patient care. The ability to perform accurate and pertinent physical examinations, and subsequently document the findings appropriately, are key components for clinical pharmacists providing this enhanced level of care. The purpose of this project is to design and implement a physical assessment training course utilizing patient simulation technology in an effort to aid ambulatory care clinical pharmacy specialists in enhancing their skills in performing and documenting physical examinations.

Methods: A voluntary interest survey administered to all VAMHCS Ambulatory Care Clinical Pharmacy Specialists (CPS) will be used to develop a curriculum tailored to needs and practice of those CPS’s. The physical examination curriculum will include a mix of didactic and simulation lab education delivered over a series of three, three-hour sessions. The didactic portion of each session will include: pre-session, guided reading activities from the Bates’ Guide to Physical Examination and History Taking textbook. The first hour of each session will include a group didactic portion to review key concepts found in the readings. The remaining hours of each session will be used for hands-on physical examination practice utilizing patient simulation technology. Body systems covered in this course will include: vital signs, respiratory, cardiovascular, peripheral vascular and dermatologic. The final session will include a formal physical examination skills assessment utilizing a simulated patient case. Prior to the first session, two surveys will be administered to assess participants’ perceived barriers to performing physical examinations as well as their confidence in performing physical examinations. Immediately following session 3, the confidence survey will be re-administered.
to assess for any change in participants’ confidence in their physical examination skills. Four weeks following course completion, a survey will be administered to participants to assess the impact of the course on patient care and individual practice.

**Results:** Service development and implementation are currently in progress. To date, the results for the general interest survey have been compiled. The survey was sent to fifteen individual Ambulatory care clinical pharmacists, nine of which replied. The most common areas of interest were the cardiovascular system, peripheral vascular system, respiratory system and hair, skin and nails.

**Submission Type:** Research-in-Progress

**Session-Board Number:** 1-188

**Poster Title:** Prazosin prescribing patterns for veterans with posttraumatic stress disorder (PTSD) at the Veterans Affairs Maryland Health Care System (VAMHCS)

**Primary Author:** Deanna Bauerlein, Veterans Affairs Maryland Health Care System, MD; **Email:** deanna.bauerlein@va.gov

**Additional Author(s):**
Kathryn Bradly
Christopher Gallagher

**Purpose:** Prazosin is recommended as a first-line treatment for sleep disturbances in PTSD because it blocks excessive norepinephrine that produces these symptoms. However, a recent study using national administrative VA data to analyze prazosin use in PTSD patients suggests that prazosin is commonly underdosed (< 6mg/day) and/or discontinued early (< 1 year). The primary objective of this study is to characterize prazosin prescribing patterns for the treatment of PTSD-related sleep disturbances in the VAMHCS. The secondary objective is to identify the clinical factors driving early discontinuation and/or underdosing of prazosin.

**Methods:** This retrospective chart review will be submitted to the Institutional Review Board for approval. Patients who obtained their index prescription for prazosin in 2014 and had a diagnosis of PTSD will be included. The following data will be collected: patient demographics, use of antihypertensive(s) at baseline, history of substance abuse, diagnosis of benign prostatic hyperplasia, prazosin start date, prazosin initial dose, maximum prazosin dose (within one year of start date), time to maximum prazosin dose, prazosin last fill date and/or discontinuation date (up to one year after start date), setting of initial prescription (inpatient or outpatient), and prescribers’ credentials and practice setting. Medical records will be reviewed to determine the reason for discontinuation and/or underdosing. The following will be calculated: mean maximum prazosin dose, mean duration of prazosin use, mean time to maximum dose, percentage of patients with early discontinuations, and percentage of patients achieving a dose of 6mg/day or greater. Reasons for discontinuing and underdosing prazosin will be reported.

Poster Title: ASHP Midyear Poster Abstract: Research-In-Progress

Primary Author: Stephanie Grant, VA Maine Healthcare System, ME; Email: stephanie.grant@va.gov

Additional Author (s):
Katelin Secord
Robin Scanlon
Brad Bouton

Purpose: The Heritage Health Solutions program is a voucher system that allows veterans to have short-term prescriptions for emergency medications filled at non-VA pharmacies when geographical challenges would otherwise prevent same-day access. Over the last several years, utilization of the program has increased exponentially. Vouchers are being distributed for non-emergent medications, as well as to patients who have continually failed to request refills for their maintenance medications or who have missed appointments. This project seeks to empower patients to proactively manage their healthcare, as well as to establish guidelines for the appropriate use of the program.

Methods: The project will be divided into three phases. The first phase will be data collection. Overall cost per quarter, number of prescriptions, types of medications, day’s supply provided, and individual provider utilization will be analyzed. From this data, the three highest utilization community-based outpatient clinics (CBOC) will be identified. During phase two, all- staff presentations will be given at each high-utilization clinic to encourage patient education surrounding the medication refill process, as well as on the appropriate use of the vouchers. Education on the process to request expedited medication delivery will also be provided. Phase three will focus on quality improvement and data analysis. Three to six months after the interventions, overall cost per quarter, number of prescriptions, types of medications, day’s supply provided, and individual provider utilization data will be compared to baseline data. Strategies will be devised to maintain any gains achieved in phase two. These strategies may include new provider voucher training programs and periodic utilization reviews and interventions.

**Poster Title:** Medication Use Evaluation for Chronic Use of Direct Oral Anticoagulants at VA Maine Healthcare System

**Primary Author:** Sarah Howard, VA Maine Healthcare System, ME; **Email:** sarah.leonido@gmail.com

**Additional Author(s):**
Allison Marshall
Phillip Gall

**Purpose:** At VA Maine Healthcare System, direct oral anticoagulants (DOACs) require non-formulary approval by the pharmacist-run anticoagulation clinic (ACC). If approved, initiation and the first three months of therapy are managed and monitored by ACC pharmacists, after which the responsibility is resumed by the Veteran’s primary care provider within the VA. The purpose of this medication use evaluation (MUE) is to evaluate the ongoing use and monitoring of apixaban, rivaroxaban and dabigatran at VA Maine Healthcare System. This project aims to assess if current monitoring practices comply with local and national criteria for use after patients are discharged from pharmacy follow-up.

**Methods:** A retrospective chart review will be conducted for this MUE. Veterans with active prescriptions for DOACs will be included in the final report. Information to be collected includes: indication for use, concomitant aspirin or diltiazem use, and clinical lab parameters including height, weight, BMI, hemoglobin, platelets, renal function, and hepatic function. Upon completion of data collection, results will be presented to the ACC team to identify opportunities for quality improvement initiatives among the ACC clinic.

**Results:** Results in progress - will be presented at Midyear Clinical Meeting

Poster Title: Olanzapine use and monitoring in patients with a body mass index (BMI) greater than 30 at VA Maine

Primary Author: Brett Glasheen, VA Maine Healthcare System, ME; Email: brett.glasheen@va.gov

Additional Author (s):
Nicole Brunet

Purpose: The main goal of the Psychotropic Drug Safety Initiative (PDSI) is to improve safety in Veterans taking psychotropic medications. The use of olanzapine in obese Veterans was identified as a metric by the PDSI. At VA Maine, the percentage of obese patients prescribed olanzapine is significantly higher than the national VA average. The purpose of this project is to use data highlighted by the PDSI to identify specific areas for, and guide clinical pharmacist intervention to improve patient safety.

Methods: Data collection for this quality assurance project will be done through retrospective chart review using the Computerized Patient Record System of Veteran’s identified as being obese (BMI greater than 30) with an active outpatient prescription for olanzapine. The data collected on these patients will be used to determine if appropriate metabolic monitoring is being completed and if olanzapine is being prescribed judiciously in patients at high risk of metabolic side effects. Specific information will be collected to assess adherence to the American Psychological Association/American Diabetes Association guidelines on metabolic monitoring of atypical antipsychotics as well as local VA guidelines. Data obtained will include BMI (at baseline, at 4, 8 and 12 weeks, and current), hemoglobin A1c (baseline and current), lipids (baseline and current), ordering provider of labs, if VA clinical reminders for atypical antipsychotic metabolic monitoring and obesity (exercise referral) have been completed, previous antipsychotic trials, and indication for olanzapine. This information will be used to identify potential areas for academic detailing, guide local formulary decisions, and identify opportunities for direct clinical pharmacist intervention.

**Submission Category:** Small and Rural Pharmacy Practice  
**Submission Type:** Research-in-Progress  
**Session-Board Number:** 1-192  
**Poster Title:** Evaluation of the impact of a pharmacist lead opioid overdose and naloxone distribution (OEND) patient education group at VA Maine: A rural healthcare setting  
**Primary Author:** Emily Stoukides, VA Maine Healthcare System, ME; **Email:** emily.stoukides@va.gov  
**Additional Author (s):** Nicole Brunet  

**Purpose:** Opioid overdose rates nationally, and specifically in Maine have increased in recent years. Naloxone is an opioid receptor antagonist that is available as injectable and nasal formulations that can be used to reverse an opioid overdose. Based on the current efforts of the OEND academic detailing initiative, naloxone prescription rates at VA Maine have increased, but remain lower than other VA locations in the northeast. This project will complement the efforts of the OEND academic detailing initiative by adding educational opportunities for Veterans and their caregivers about overdoses, and increase access to naloxone for Veterans.  

**Methods:** Prior to beginning the group education, data on the number of naloxone kits that have been distributed at VA Maine will be collected from the VA OEND risk dashboard, an online database containing information about the progress of OEND interventions at the VA, including total number of kits prescribed, and specialty and main location of prescribing providers. Then, pharmacist-lead group education will begin for Veterans referred to naloxone education by consult, or may be identified through VA accessible risk reports. The education session will consist of information about naloxone, risks and identification of overdose, administering naloxone, and methods of reduction of overdose risk. At the completion of group education, patients will be prescribed naloxone kits as the pharmacist/pharmacy resident determines to be appropriate. The group will made mainly available at the main hospital campus, however may be made available at other clinics as needed. As the group continues, the number of naloxone kits distributed to patients at VA Maine will be reassessed to determine if the addition of pharmacist lead education improves naloxone distribution rates.  

**Results:** n/a
Conclusion: n/a
Purpose: Alcohol is the most common substance of abuse that leads veterans to be admitted for substance use treatment. The majority of patients with alcohol use disorders are identified in the primary care setting. Even though ambulatory alcohol detoxification (detox) has an established place in clinical care, it is consistently underutilized. This project will evaluate current practices and policies related to the ambulatory management of alcohol detox in the veteran population within the Battle Creek Veterans Affairs Medical Center (VAMC) to develop and implement a policy detailing an evidence-based ambulatory alcohol detox protocol to improve veteran care and facility outcomes.

Methods: Veterans who have received ambulatory alcohol detox treatment per current local guidance will be identified through a database search for relevant notes entered in Veteran electronic medical records, from the date of initiation of the current protocol and until the date of initiation of this project. Protocol adherence will be assessed by reviewing identified records for appropriate use of defined procedures. The facility’s current ambulatory alcohol detox protocol will be compared to clinical practice guidelines and national directives. An updated, evidence-based protocol for ambulatory alcohol detox will be developed that addresses any gaps in care discovered through the course of this quality improvement initiative. Battle Creek VAMC clinical staff will be educated on the newly developed ambulatory alcohol detox protocol. Effectiveness of this initiative and adherence to the updated protocol will be assessed by reviewing applicable Veteran records for appropriate use of protocol defined notes and orders. Pre- and post-implementation adherence to ambulatory alcohol detox protocols will be compared using descriptive statistics. Based on the results of this comparison a continuous quality improvement plan will be proposed to ensure the sustained clinical relevancy and optimal utilization of the updated protocol.

**Poster Title:** Length of stay in heart failure patients hospitalized with acute exacerbations of chronic obstructive pulmonary disease treated with beta-blockers

**Primary Author:** Jennifer Froomkin, Detroit Medical Center, MI; **Email:** jfroomki@dmc.org

**Additional Author(s):**
Caitlin Maendel
Mark Pangrazzi
Stacy Otremba

**Purpose:** Although current literature has shown the benefit and safety of cardioselective beta-blockers in patients with chronic obstructive pulmonary disease (COPD), including those with concomitant heart failure with reduced ejection fraction (HFrEF), there is a paucity of data surrounding hospital length of stay for COPD. It is pertinent to evaluate the length of stay for patients with HFrEF on metoprolol or carvedilol admitted with a COPD exacerbation and on home oxygen therapy. Determining if beta-blocker cardioselectivity impacts this specific patient population could lead to better drug selection, cost savings, and improved outcomes.

**Methods:** This single-center, retrospective, observational study has been submitted to the Institutional Review Board for approval. The Detroit Medical Center (DMC) electronic medical record (EMR) will be utilized to identify and obtain a sample of adult patients 40 years of age and older over a two-year period admitted for at least 48 hours to non-intensive care unit (ICU) medical services at Sinai-Grace Hospital who have a primary diagnosis of acute exacerbation of COPD on admission as well as a past medical history of HFrEF and home oxygen therapy. The following data will be collected: age, sex, left ventricular ejection fraction, chest x-ray results, bicarbonate and/or arterial blood gas carbon dioxide levels, total steroid doses administered (standardized to prednisone-equivalents), total inpatient days of steroids, discharge prescription for chronic steroids, total days of antibiotic use, doses of metoprolol tartrate and succinate and carvedilol, and non-invasive bilevel positive airway pressure requirement.

Poster Title: Impact of a pharmacist-led cardiology pharmacotherapy clinic on chronic heart failure management

Primary Author: Joy Hoffman, VA Ann Arbor Healthcare System, MI; Email: joy.hoffman2@va.gov

Additional Author(s):
Michael Brenner
Scott Hummel
Allison Brenner

Purpose: Heart failure (HF) is a chronic disease that is expected to impact a growing population in the United States. Management of heart failure reduced ejection fraction (HFrEF) includes therapies that can provide mortality benefit, reduce hospitalizations, and increase symptomatic relief. The purpose of this retrospective chart review is to identify the impact of a pharmacist-run cardiology pharmacotherapy clinic versus a general cardiology clinic on medication titration and patient outcomes during chronic HF management in a Veterans Affairs (VA) healthcare system.

Methods: This study has been submitted to the Institutional Review Board for approval. Patients with HFrEF (ejection fraction 40 percent or less) who are New York Heart Association Functional Class II – IV and enrolled in either the general cardiology or pharmacotherapy clinic will be included. Exclusion criteria will be defined as terminal illness, severe cognitive impairment, non-VA cardiology care, use of an investigational drug, residence at a nursing home or skilled nursing facility, hospitalization in the last month, and less than six months of follow-up. Baseline characteristics will be collected, and patients will be stratified according to the Heart Failure Patient Severity Index (HFPSI). The study will be powered to detect a difference in non-fatal HF events between clinics, which will be defined as emergency department visits or hospital admissions for HF exacerbation. In addition, titration of angiotensin-converting enzyme inhibitors, angiotensin II receptor blockers, and beta-blockers to target doses as well as prescribing rates of aldosterone antagonists will be compared. Secondary outcomes will include time to all-cause mortality; time to first lab after medication initiation or titration; use of adjunct therapies including digoxin, diuretics, and
hydralazine/isosorbide dinitrate; medication adherence; and number of HF medication changes per visit. Safety endpoints will include angioedema, gynecomastia, symptomatic hypotension, syncope, renal dysfunction or impairment, hyperkalemia, asthma, chronic obstructive pulmonary disease, bradycardia, atrioventricular node block, and pacemaker implantation.

Preadmission beta-blocker in critically ill septic patients: Effects on post-discharge mortality in a veteran population

Primary Author: Kelsey Norman, VA Ann Arbor Healthcare System, MI; Email: kelsey.norman@va.gov

Additional Author(s):
Michael Brenner
Lori Huang

Purpose: Outpatient use of beta-blockers prior to all cause intensive care hospitalization has shown a reduction in 30-day mortality rates post-discharge in the Danish National Patient Registry. Use prior to intensive care hospitalization for sepsis has also shown reduction in 28-day mortality rates post-discharge in an Italian population. Currently, there is a lack of literature to provide evidence that the benefit of beta-blockers detected at a month post-discharge persists. The present study will compare the mortality rates in patients admitted to the ICU with a diagnosis of sepsis with preadmission beta-blocker use versus patients without preadmission beta-blocker use.

Methods: This study is a retrospective cohort study of all patients admitted to an intensive care unit at a VA medical center with a diagnosis of sepsis between January 1, 2014 and January 1, 2016 utilizing the national VA database. The study group is defined as patients with preadmission beta-blocker use, defined as at least 1 refill of a beta-blocker medication within 30 – 120 days prior to admission. The control group will be patients without preadmission beta-blocker use. Baseline patient information that will be collected includes age, gender, height, weight, and comorbidities. Hospital admission data that will be collected include source of sepsis, positive culture growth, IV beta-blocker administration, IV vasopressor administration, blood pressure, respiratory rate, mental status, blood lactate, serum creatinine, and liver function tests. Outpatient medication history will also be assessed for use of a beta-blocker preadmission and post-discharge. Specific beta-blocker agents identified during chart review will be recorded and reported. The primary endpoint is to compare the rate of 30-day and 90-day mortality between patients admitted to the ICU with preadmission beta-blocker therapy versus those whom were not. The secondary endpoints are to compare the rate of 30-day and
90-day mortality between patients based on type of preadmission beta-blocker and source of sepsis.

**Poster Title:** Impact of emergency department pharmacy services on the time to administration of antibiotics

**Primary Author:** Abigail Ellis, Veterans Affairs Ann Arbor Healthcare System, MI; **Email:** abigail.ellis@va.gov

**Additional Author(s):**
Joseph Granata
Andrew Siler

**Purpose:** Implementation of an emergency department (ED) pharmacy service may decrease time to administration of antibiotics. Timely administration of antibiotics has been shown to improve outcomes in patients with severe infections such as sepsis, and subsequently antibiotics are recommended within one hour of diagnosis of septic shock and severe sepsis. The impact of the time to first dose in other infections, however, is unclear. Therefore, the purpose of this study is first to evaluate an ED pharmacy service’s impact on time to administration of antibiotics at a Veterans Affairs (VA) ED, and to then identify any potential impact on patient outcomes.

**Methods:** A retrospective chart review of time to administration of antibiotics in a VA ED will be conducted, evaluating patients treated with and without the presence of an ED pharmacy service. Patients receiving at least one dose of an antibiotic in the ED will be included, and the timeliness of antibiotic administration will be compared for two equivalent timeframes, one before and the other after the introduction of ED pharmacy services. Patient outcomes to be assessed will include; total length of antibiotic therapy, length of hospital stay, 90-day hospital readmission rates related to the principle diagnosis, and 90-day mortality. Appropriateness of antibiotic dosing will be determined based on pre-specified ranges in accordance with current clinical guidelines and institutional practices. Other demographic data to be collected includes: patient age, gender, weight, renal function, antibiotic and dose administered, time of order entry by physician, time of administration, and diagnosis (ICD9/10 codes). Patients will be excluded if they are discharged home directly from the ED or were transferred to or from another institution.

Poster Title: Characterizing Naloxone Distribution at the Minneapolis Veterans Affairs Health Care System (VAHCS)

Primary Author: Ashley Lane, Minneapolis Veterans Affairs Health Care System, MN; Email: ashley.lane3@va.gov

Additional Author(s):
Beth DeRonne
Elzie Jones
Jennifer Bolduc
Todd Naidl

Purpose: Naloxone is a medication intended to be used as a reversal agent during a life threatening opioid overdose. Despite the effectiveness as a reversal agent, use of naloxone as a risk-mitigation strategy remains low within the Minneapolis VAHCS. Opioid initiatives within the Veterans Health Administration (VHA) have made it a focus to educate Veterans about opioid use, opioid overdose, and opioid rescue medication. The Minneapolis VAHCS opioid initiatives strive to reduce life threatening opioid related overdose deaths among Veterans. The objective of this study is to characterize naloxone prescribing before and after Minneapolis VAHCS expansion of opioid education initiatives.

Methods: Conducted a retrospective chart review of approximately 160 patients dispensed a naloxone prescription during a pre-education period July 1, 2015 to July 1, 2016 and a post-education period October 1, 2016 to December 1, 2016. Patients excluded from the chart review included any patient on chronic opioids for cancer pain or palliative care and patients who did not have an active opioid prescription at the time naloxone was dispensed. Opioid overdose risk-related data collected included history of overdose, substance use disorder, morphine equivalent dose of 50mg or greater and concomitant use with benzodiazepines. These data align with guidance from the 2016 CDC Guideline for Prescribing Opioids for Chronic Pain on who to offer naloxone. Naloxone prescriptions were assessed to determine whether they met CDC Guideline recommendations for use. Additional data collected included: patient age, gender, provider name, provider clinic location, and provider practice area. The data will be characterized to ascertain if outreach opportunities to promote naloxone distribution are
needed in a particular location of the health care system (community clinic vs medical service, rural vs. urban) or needed in a particular practice setting (mental health vs primary care). Additionally, data will be evaluated to determine if certain risk groups (e.g. individuals concomitantly prescribed benzodiazepines) should be targeted for further education to minimize opioid-related harms.

Poster Title: Evaluation of benzodiazepine use for outpatient insomnia treatment at the Minneapolis Veterans Affairs Health Care System.

Primary Author: Martin Bloch, Minneapolis Veterans Affairs Health Care System, MN; Email: martin.bloch@va.gov

Additional Author (s):
Lisa Drogemuller
Elzie Jones
Tessa Kemp
Kara Wong

Purpose: Benzodiazepines have been identified as high-risk medications, particularly in patients with specific risk factors (older age, high dose, concurrent opioid use, etc.). Recent insomnia guidelines propose that use of sedative hypnotics should be limited to five weeks or less, if at all. The purpose of this medication use evaluation is to determine the appropriateness of benzodiazepine use for outpatient insomnia treatment, as well as the proportion of veterans at increased risk of benzodiazepine adverse effects.

Methods: A site-specific pharmacotherapy dashboard for insomnia treatment will be used to identify “actionable patients”: veterans prescribed benzodiazepines for insomnia, veterans on chronic benzodiazepine regimens for sleep, and veterans taking benzodiazepines above recommended doses. The dashboard includes patient demographic information, an insomnia medication history from the past five years, and patient-specific risk factors related to benzodiazepine use (sleep apnea; active CNS depressant; dementia; age greater than 74; diagnosis of posttraumatic stress disorder, substance use disorder, or traumatic brain injury). History of falls and use of cognitive behavior therapy for insomnia will be extracted from the electronic medical record. The data collected will be used to describe current prescribing patterns and to guide updates to outpatient insomnia order sets. This medication use evaluation will not require IRB approval, as it will not meet the definition of research.

Poster Title: Assessment of inpatient fluoroquinolone utilization at the Minneapolis Veterans Affairs Health Care System

Primary Author: Randa Fahim, Minneapolis Veterans Affairs Health Care System, MN; Email: randa.fahim@va.gov

Additional Author(s):
Lauren Estkowski

Purpose: The FDA recently strengthened the existing statement regarding fluoroquinolone use and associated safety risks to state that fluoroquinolones, when used to treat uncomplicated infections such as acute sinusitis, acute bacterial exacerbations of bronchitis, and uncomplicated urinary tract infections, should be reserved only for patients without other antibiotic treatment options. Disabling adverse effects may involve the tendons, muscles, joints, nerves and central nervous system. This safety concern, in addition to increasing antimicrobial resistance, further supports the need to decrease unnecessary fluoroquinolone use. A better understanding of fluoroquinolone prescribing patterns will allow for identification of areas for targeted intervention within our facility.

Methods: An electronically generated report will identify patients who received at least two doses of a systemic fluoroquinolone (ciprofloxacin, levofloxacin, or moxifloxacin) while admitted to an inpatient hospital unit between January 1, 2016 and September 1, 2016. The following data points will be collected for 100 randomly selected patients: patient name, age, weight and BMI, height, serum creatinine, documented drug allergies, medication name, dose, route (intravenous or oral), indication/diagnosis, dates of administration and hospital ward to which the patient was admitted. A random subset of 50 patients will be selected for more extensive chart review to gather the following information: correlation of antibiotic selection with current treatment guidelines and the health system antibiotic ordering system, availability of culture and susceptibility data and its correlation with drug selection, availability of alternative treatment options, and when available, reasoning for using a fluoroquinolone when other treatment options existed. This information will be compiled and patterns assessed to further determine potential areas for interventions to improve antibiotic order selection and optimize overall fluoroquinolone use.

**Poster Title:** Evaluation of most commonly prescribed medications, disease states, and admission diagnoses in veterans admitted to facilities outside the Minneapolis Veteran Affairs Health Care System

**Primary Author:** Lindsey Garner, Minneapolis Veterans Affairs Health Care System, MN; **Email:** lindsey.garner@va.gov

**Additional Author(s):**
Lisa Anderson
Anna Sciegienka

**Purpose:** A Community Care nursing team was previously established at the study site with the intent to transition veterans back into the study site's system after discharge from an outside facility. The purpose of this study was to assess the most commonly prescribed medications, disease states, and admission diagnoses trends for patients admitted to outside facilities while still actively receiving care at the study site.

**Methods:** This study is a retrospective chart review of patients receiving transitional care coordination via the Community Care nursing team. Patients were identified in the electronic medical record based on the presence of a “Community Care RN Case Manager Note” in the selected time frame of June 1, 2016 to August 31, 2016 (N=568). After identifying appropriate patients, the following data was collected: patient name, last 4 of their social security number, gender, date of birth, age, assigned primary care physician, assigned primary care clinic, active outpatient medication orders, and all diagnosis codes (ICD-9 and ICD-10). All medications were categorized in two ways: a treatment group and by mechanism of action. For example: metformin, insulin, and glipizide would be assigned the same treatment group (Diabetes), but would be further classified by their individual mechanisms. All diagnosis codes were grouped based on core diagnostic cause (e.g. Type 2 Diabetes Mellitus without Complications and Type 2 Diabetes Mellitus with Hyperglycemia were assigned the group Diabetes). Of the eligible patients, 100 were randomly selected for chart review and primary diagnosis upon admission to outside facility was assessed. The information collected will be used to identify the most commonly prescribed outpatient medications by name, treatment group, and mechanism of action.
action. The results of this study will be used to establish pharmacist-led Medication Therapy Management in the Community Care team.

**Poster Title:** Use of Guideline-Directed Medical Therapies for Heart Failure Reduced Ejection Fraction (HFrEF) at the Minneapolis Veterans Affairs Medical Center (MVAMC)  
**Primary Author:** Travis Liebhard, Minneapolis Veterans Affairs Health Care System, MN; Email: travis.liebhard@va.gov  
**Additional Author(s):**  
Tessa Kemp  
Simon Akerman  

**Purpose:** Heart failure (HF) is a complex disease that is known for frequent hospitalizations and high mortality. Current pharmacologic therapies that reduce morbidity and mortality are effective in stage C HFrEF patients. These agents include angiotensin-converting enzyme inhibitors (ACEi), angiotensin-receptor blockers (ARBs), beta blockers (BBs), aldosterone antagonists (AAs), hydralazine-isosorbide dinitrate, and sacubitril-valsartan, which are titrated to doses effective in clinical trials. If symptoms persist despite reaching target doses, digoxin and ivabradine may be considered next as they have also been shown to reduce morbidity. The purpose of research is to evaluate use of these drugs in clinical practice at our institution.  

**Methods:** An informatics pharmacist will identify patients who meet the inclusion criteria through the computerized patient record system (CPRS) at our institution. Patients will be included if they have primary care established at our institution, have an ICD 9 or 10 diagnosis code for systolic heart failure, and were seen between September 2014 to September 2016. Patients will be excluded if they passed away, are currently consulted for palliative or hospice care, or are co-managed (defined by receiving HF medications from another pharmacy). This cohort will then be analyzed based on use of ACEi, ARBs, BBs, AAs, hydralazine-isosorbide dinitrate, sacubitril-valsartan, ivabradine, and digoxin. Analysis will include total number of patients on each therapy, percent of patients on each drug class, and percentage of patients at target doses. Additional analysis will be performed on patients with at least one admission between September 2014 to September 2016 for any admission diagnosis, primary diagnosis related to HF, or secondary diagnosis related to HF. Additionally, a chart review will be performed on 200 random patients from the above cohort to determine why patients are not
taking or have not reached target doses of ACEi, ARBs, and/or BBs. This medication use evaluation will not require IRB approval.

**Poster Title:** Improving access to behavioral health services in rural communities: An innovative pharmacist collaborative practice model.

**Primary Author:** Jennifer Lamermayer, Red Lake Indian Health Service, MN; **Email:** jennifer.lamermayer@ihs.gov

**Additional Author(s):**
CAPT Cynthia Gunderson
CDR Kailee Fretland

**Purpose:** In the United States, one in five adults experiences a mental illness. The prevalence of behavioral health conditions is significantly higher in rural communities due to behavioral health specialty provider shortages. In one American Indian community in rural Minnesota, there are currently no full-time licensed psychiatrists or midlevel practitioners. Rather, primary care providers must manage psychotropic medications. A collaborative practice model for clinical pharmacists was developed to meet the increasing demand for behavioral health services within the community and assist primary care physicians with both assessment and medication optimization.

**Methods:** There were three main elements to establishing the clinic: credentialing and training clinical pharmacists to manage behavioral health conditions, developing a collaborative practice agreement, and identifying appropriate methods for pharmacy reimbursement. At this Indian Health Service facility, clinical pharmacists are credentialed and privileged members of the medical staff. Two pharmacists and one pharmacy practice resident were credentialed to practice within a behavioral health clinic by participating in a specialized training developed through a novel collaboration between the Indian Health Service facility and a local pharmacy school. This training ensured clinical pharmacists were knowledgeable in behavioral health assessment and medication management. A memorandum of understanding between the two entities afforded clinical pharmacists the opportunity to learn from two Board Certified Psychiatric Pharmacists, one of whom was faculty at the pharmacy school. The training involved a series of experiential learning opportunities, case discussions, and self-study. The two pharmacists and one pharmacy practice resident who participated in this program developed a collaborative practice agreement with the facility’s medical staff to grant pharmacists the
autonomy to appropriately care for patients who were referred to the service. To ensure a sustainable practice model, a system for patient referral to the pharmacy service was identified and behavioral health pharmacists began generating revenue using current procedural terminology billing codes.

**Results:** The training program developed by this Indian Health Service facility and pharmacy school involved pharmacists’ self-study of board certification materials, four hours of behavioral health focused case-based discussions, and twenty-four direct observation hours with a board certified pharmacist in an urban clinical pharmacy practice. The psychiatric pharmacists served as expert resources for complex patient cases. The collaborative practice agreement allowed credentialed pharmacists to assess and treat chronic behavioral health conditions such as depression, anxiety, post-traumatic stress disorder, schizophrenia, bipolar disorder, and tobacco abuse disorder. After assessment, pharmacists could initiate, change, or discontinue psychotropic medications, and order appropriate labs to ensure safety of medications. Pharmacists could refer patients to behavioral health counseling services as necessary. Outcomes identified to track were percentage of patients routinely screened for depression, improvement from baseline in widely accepted behavioral health assessment tools, and patients with tobacco abuse as concurrent diagnosis. Referrals to this behavioral health program could be generated from psychologists, social workers, primary care providers and other pharmacists. Services were billable using current procedural terminology codes for evaluation and management of an established patient with a problem-focused history and examination with straightforward medical decision-making.

**Conclusion:** With specialized training, an appropriate collaborative practice model, and revenue generation, clinical pharmacists in rural areas can manage behavioral health conditions in the same way they manage other chronic disease states. In the future, the Indian Health Service facility will explore utilizing advanced pharmacy technicians in behavioral health case management roles, and explore avenues for creation of an interactive web-based resource for behavioral health care professionals in rural areas, similar to an Extension for Community Healthcare Outcomes model. Through these initiatives, pharmacy staff in rural areas can positively impact the behavioral health of their patients.

Poster Title: Incidence of steroid-induced hyperglycemia in non-diabetic veterans admitted to the intensive care unit at G.V. (Sonny) Montgomery VA Medical Center

Primary Author: Andrew Burton, G.V. (Sonny) Montgomery VA Medical Center, MS; Email: burtoam@gmail.com

Additional Author(s): Angela Hamilton

Purpose: Hyperglycemia is a commonly seen phenomenon in the intensive care unit (ICU). It has been demonstrated that the rise in serum glucose in critically ill patients is associated with increased morbidity and mortality. Corticosteroids are known to cause an increase in serum glucose levels and are utilized for a variety of conditions in the ICU. Currently, there is limited data on the epidemiology of steroid-induced hyperglycemia in non-diabetic ICU patients. The objective of this study is to determine the incidence, prevalence, and potential risk factors for steroid-induced hyperglycemia in non-diabetic Veterans admitted to the ICU.

Methods: This retrospective study has been submitted to the Institutional Review Board for approval. Data will be collected from the Computerized Patient Record System for Veterans who meet the criteria for inclusion. This study will include Veterans admitted to the ICU at G.V. (Sonny) Montgomery VA Medical Center from August 2014 through July 2016 and received systemic steroids for at least 48 hours. Veterans will be excluded if they have any of the following: documented random blood glucose levels greater than or equal to 200 mg/dL in the year prior to admission, a documented A1c of 6.5 percent or greater within two years before admission, systemic steroids within thirty days before admission, a diagnosis of diabetes mellitus, a change in weight of greater than ten percent in one year, a diagnosis of HIV or cancer, pregnant or lactating, or received other medications that can increase glucose levels. The following data will be collected for each patient: age, weight, gender, race, baseline A1c, glucose levels during systemic steroid therapy, indication for steroids, duration of steroid use, daily prednisone equivalent received, length of ICU stay, reason for ICU admission, APACHE II score, estimated creatinine clearance, and if insulin was received while on systemic steroids and how much. Descriptive statistics, the Chi-squared test, and the Fisher’s exact test will be used to analyze the data of this study.

Poster Title: Evaluation of empiric outpatient antibiotic treatment for urinary tract infections at G.V. (Sonny) Montgomery VA Medical Center

Primary Author: Phuong Khanh Nguyen, G.V. (Sonny) Montgomery VA Medical Center, MS; Email: phuong.nguyen8@va.gov

Additional Author(s):
Kristin Otting

Purpose: Urinary tract infections (UTIs) are one of the most commonly encountered infections in the outpatient setting. Several published studies have demonstrated that prescribing patterns for uncomplicated UTIs have low concordance with practice guidelines. Antimicrobial resistance patterns and potential adverse effects of antimicrobials may have an impact on the treatment of UTIs. The objective of this study is to evaluate the appropriateness of empiric outpatient treatment for UTIs in male Veterans at G.V. (Sonny) Montgomery VA Medical Center.

Methods: This retrospective study has been submitted to the Institutional Review Board for approval. The study will include a random sample of up to 500 male Veterans who were diagnosed with a UTI, acute cystitis, or unspecified cystitis in the outpatient setting from July 2015 through June 2016. These Veterans will be identified by International Classification of Diseases diagnosis codes. Veterans will be excluded if they were treated in the emergency department or have complicating factors, such as pyelonephritis, acute prostatitis, nephrostomy tube(s), or a chronic foley catheter. The following data will be collected from the Computerized Patient Record System: age, clinic name, urine culture collection, organism(s) isolated from the urine, organism susceptibility results to certain antibiotics, empiric antibiotic selection, treatment duration, susceptibility results of empiric antibiotic prescribed, and any treatment adjustments (antibiotic switch or discontinuation) based on urine culture and susceptibility results. Data will be recorded without patient identifiers and maintained confidentially. Descriptive statistics will be used to analyze the proportion of patients who received appropriate empiric treatment and the proportion of patients who were switched to an appropriate antibiotic or discontinued therapy based on urine culture and susceptibility results.

Poster Title: Pharmacist run diabetes care clinic effects on hemoglobin A1c.

Primary Author: Ellen Dixon, Gulf Coast Veterans Health Care System, MS; Email: endixon2016@gmail.com

Additional Author(s):
Michelle Richard

Purpose: This study hopes to answer the following question, “Will implementation of a new pharmacy run diabetes pharmacotherapy clinic lead to better diabetes outcomes for our veteran patients?” The focus of this project will be on reduction in A1c and trends in patient blood glucose levels as measured during appointments.

Methods: A new diabetes clinic has been established at Gulf Coast Veterans Health Care System (GCVHCS) in Biloxi within the primary care clinic. Patients will be included in this study as long as they have been seen in the pharmacy run diabetes clinic or in the nursing diabetes/primary care clinic for the control group. The clinic has been set up to provide education and evaluation of patients’ medications and outcomes. Pharmacists will adjust patient medications under practice agreements at GCVHCS. Clinic procedures include, A1c collection at baseline and every three months if deemed clinically appropriate. A1c and blood glucose trends will be monitored through patient chart review. These results will be compared to a group of patients that are enrolled in a diabetes education group that is run by the nursing staff at GCVHCS to compare outcomes. Data will be collected by doing a chart review of patients who are enrolled in the clinic during the months of August through October, and data will be analyzed for these patients through March 2017, using descriptive statistics to look at overall change in A1c for patients and t-test will be used to compare the two groups. We hypothesize before the start of our data collection that this intervention will lead to an equal or greater decrease in A1c for patients enrolled in the pharmacist run clinic.

**Poster Title:** Benefits of a clinical pharmacist led outpatient mental health metabolic syndrome monitoring clinic

**Primary Author:** Wendy Wong, Gulf Coast Veterans Health Care System, MS; **Email:** wwong@email.arizona.edu

**Additional Author(s):**
Michelle Richard

**Purpose:** Multiple studies have shown that pharmacist managed clinics in various fields have improved medication adherence and patients’ quality of life. Due to the increase in mental health diagnoses and metabolic syndrome in the military community, the primary objective of this study is to determine if health outcomes improve for veterans taking antipsychotic medications enrolled in the pharmacist metabolic monitoring clinic compared to veterans taking antipsychotics not enrolled in the clinic. The secondary objective is to determine if veterans enrolled in the clinic improved other quality of life risk factors such as increased exercise, improved diet, and reduced alcohol intake/tobacco use.

**Methods:** This will be a retrospective chart review study. Data will be collected from the new clinical pharmacist led outpatient mental health metabolic syndrome monitoring clinic at Gulf Coast Veterans Healthcare System (GCVHCS). Data collected will include: demographics (age, sex, race, and ethnicity), exercise routine, diet, drinking/tobacco use, name of the current antipsychotic prescribed, the duration they have been on this medication, duration they have been taking any antipsychotic, lipids, HbA1C, fasting blood sugar, waist circumference, blood pressure, weight, and height. Baseline measures will be compared to the 3 and 6 months mark to assess for any changes and to a control group of veterans taking antipsychotics and not enrolled in the clinic. The amount of referrals to the MOVE program, a dietician, and the quit tobacco clinic, and “no-shows” appointments will also be collected. All data will be analyzed through descriptive analysis. Veterans enrolled in the metabolic syndrome monitoring clinic that are taking an antipsychotic will be included in this study and those who were lost to follow up in the clinic will be excluded from the analysis. The primary study outcomes are fasting blood glucose, lipids, waist circumference, and blood pressure control and the secondary
measures include: changes in exercise, smoking/drinking, and diet routines. Success is classified when a subject no longer meets one or more of the metabolic syndrome criteria.

Poster Title: The Impact of Educational Intervention on Utilization of the Prescription Monitoring Program (PMP) in a Community Pharmacy Setting

Primary Author: Sienna Miller, University of Mississippi School of Pharmacy, MS; Email: smiller5@umc.edu

Additional Author(s):
Leigh Ann Ross
Laurie Fleming
Anne Marie Liles
Olivia Strain

Purpose: According to the Centers for Disease Control and Prevention, residents of Mississippi were prescribed more than 3.2 million opioid prescriptions in 2015, the 5th highest rate in the country. Like many states, Mississippi has implemented the Prescription Monitoring Program (PMP) to help identify and prevent prescription drug abuse and diversion. The purpose of this study is to determine if the educational intervention about the PMP increases the number of self-reported interventions made by pharmacists in the community setting.

Methods: This study will be submitted to the University of Mississippi Institutional Review Board for approval. Pharmacists licensed in the state of Mississippi who practice in a community pharmacy setting will be invited to participate. Study enrollees will participate in an educational session regarding the Mississippi PMP. Content of the program will include a description of the PMP, suggestions for when to access the PMP, how to assess for possible misuse or abuse, and recommendations for interventions to identify and prevent opioid abuse and misuse. Prior to the educational session, study participants will complete a pre-survey evaluating knowledge of the PMP, frequency of PMP use, and quantity and type of self-reported interventions. Two months after the educational session, an identical post-survey will be administered to assess the effectiveness of the intervention. The primary outcome is the number of community pharmacist PMP self-reported interventions. Secondary outcomes include change in PMP knowledge parameters, frequency of use, and type of interventions.

**Poster Title:** Improving diabetes outcomes through pharmacist interventions in an urgent and emergent care setting  
**Primary Author:** Bryan Gunter, Cherokee Indian Hospital Authority, NC; **Email:** bryan.gunter@cherokeehospital.org  
**Additional Author(s):**  
Jason White  
Eric Metterhausen  
Melissa Gonzalez  
Weston Thompson  

**Purpose:** Emergency departments and urgent care clinics are often used by patients as their sole access to the healthcare system. For patients with chronic disease states, transitioning and establishing primary care follow-up is crucial for optimal outcomes. In this study, pharmacists will meet with and establish primary care follow-up for out-of-control diabetic patients presenting to the emergency department or urgent care clinic. The objective of this study is to determine if pharmacist interventions in the urgent and emergent care setting leads to improved patient follow-up and clinical outcomes in the primary care setting.  

**Methods:** This study will be conducted at a rural hospital and ambulatory clinic serving a Native American population. This study will compare two intervention groups. Diabetic patients presenting to the emergency department or urgent care clinic will be screened by a provider for out-of-control diabetes defined as either an A1c greater than 9 percent or requiring insulin administration. The provider will contact a clinical pharmacist who will meet with the patient, assess current therapies for diabetes, and establish a follow-up visit with the pharmacist in the primary care setting. Patients presenting after pharmacist hours will be screened by a pharmacist using iCare, an electronic population health tool. A pharmacist will contact the patient to establish care and schedule a primary care appointment. Initial interventions will occur over a 90 day period. Reduction in A1c will serve as the primary endpoint and will be collected at the initial primary care visit and at a 3 month follow-up appointment. Secondary endpoints include medication refill history, appointment attendance, appropriate lipid and renal therapies, and blood pressure control. The percentage of patients lost to follow-up and
patients using urgent and emergent care services as their only care will be calculated. Finally, endpoints will be compared between the two intervention groups to determine if a benefit exists.

**Poster Title:** Impact of Investigational Drug Service training modules on trainee knowledge and confidence  

**Primary Author:** Sara Britnell, Durham VA Medical Center, NC; **Email:** sara.britnell@va.gov  

**Additional Author (s):**  
Jamie Brown

**Purpose:** Investigational drug service pharmacists serve an important role in the coordination of research involving drug products, as there are many unique responsibilities. Investigational drug service pharmacists fulfill many roles in the life cycle of a research protocol, but resources providing practical strategies for successfully managing these roles are lacking. The primary objective of this study is to evaluate the impact on pharmacist knowledge of educational training modules regarding the provision of investigational drug services. Secondarily, this study aims to evaluate the impact of educational training modules on participants’ confidence in their ability to develop and maintain an investigational drug service.

**Methods:** This study is a survey-based questionnaire and educational assessment. Participants will be recruited to participate in the training modules and associated study through the Veterans Affairs Research Pharmacists listserv. Participants will first be directed to complete a survey, which will present a series of questions related to participant demographics and site characteristics. Participants will then be asked to complete a pre-test, which will contain knowledge-based questions and a self-assessment of participant confidence in the provision of investigational drug services. After completing the survey and pre-test, participants will be able to complete four educational modules regarding the provision of investigational drug services. Once the modules are completed, participants will then be instructed to complete a post-test with the same knowledge-based questions and confidence assessments as were included on the pre-test. Upon successful completion of the program, participants will receive 4 hours of continuing education credit. Descriptive statistics will be utilized to compare baseline characteristics and test scores. Changes in pre-test and post-test scores will be analyzed using paired t-test. Where applicable, Wilcoxon-signed rank will be used to compare Likert scale questions between pre-test and post-test.

**Poster Title:** Evaluation of sofosbuvir-based regimens for the treatment of hepatitis C in patients with decompensated cirrhosis

**Primary Author:** Alicia Watkins, Durham VA Medical Center, NC; **Email:** awatkins88@gmail.com

**Additional Author(s):**
Mohamed Hashem
Rachel Britt
Mary Townsend
Janine Bailey

**Purpose:** It is estimated that 2.7-3.9 million Americans are infected with chronic Hepatitis C virus (HCV). Prior to the introduction of direct acting antivirals, patients with decompensated cirrhosis had limited treatment options. The AASLD-IDSA guidelines recommend four different sofosbuvir (SOF)-based regimens for treatment of HCV in patients with decompensated cirrhosis. However, there is still limited data evaluating the use of these medications in this population. The purpose of this study is to assess the efficacy and safety of SOF-based regimens for treatment of HCV in patients with decompensated cirrhosis within the Veteran Affairs (VA) healthcare system.

**Methods:** This study is a retrospective chart review evaluating VA patients with chronic HCV and decompensated cirrhosis who have completed and received HCV treatment with a SOF-based regimen through the VA. Patients with decompensated liver disease will be included in the study if they initiated HCV treatment with a SOF-based regimen between October 10, 2014 and December 31, 2015 and completed treatment by June 30, 2016. Patients who have filled prescriptions for SOF or ledipasvir(LDV)/SOF during this time period will be extracted from the National VA Corporate Data Warehouse. ICD 9 and 10 codes for hepatic encephalopathy, ascites, spontaneous bacterial peritonitis, bleeding esophageal varices, and liver cell carcinoma will be utilized to identify patients with decompensated cirrhosis. Presence of decompensated cirrhosis in these patients will be confirmed through manual chart review. Efficacy will be determined using rates of sustained virologic response at least 12 weeks after completion of therapy (SVR12). SVR12 will also be assessed among subgroups based on prior treatment experience and age, as well as concomitant use of proton pump inhibitors at higher than
recommended doses in patients on LDV/SOF. Safety will be assessed using rates of adverse effects and hospital admissions during therapy. Descriptive statistics will be used to assess efficacy and safety data.

Poster Title: Evaluation of VTE prophylaxis practices in multiple myeloma patients receiving a lenalidomide-based regimen at the Durham VA Medical Center

Primary Author: Kelly Chillari, Durham VA Medical Center, NC; Email: kelly.chillari@gmail.com

Additional Author(s):
Julia Hammond
William Bryan

Purpose: With the development and use of newer therapies multiple myeloma has become a chronic disease for many patients. Thus, additional focus has shifted toward mitigating adverse effects from both disease and the associated treatments. Lenalidomide is an immunomodulatory agent (IMiD) routinely utilized for the treatment of multiple myeloma. All IMiDs include a black box warning for arterial and venous thromboembolism (VTE) and multiple practice guidelines recommend VTE prophylaxis for myeloma patients taking IMiD therapy. The purpose of this study is to determine the prescribing rate of medical VTE prophylaxis and documented incidence of clot in multiple myeloma patients receiving lenalidomide.

Methods: The study is a retrospective chart review of patients who received treatment for multiple myeloma with a lenalidomide-based regimen at the Durham VA Medical Center. Subjects will be selected by identifying individuals with an ICD-9 or ICD-10 code for multiple myeloma present between July 1, 2006 and July 1, 2016. They will then be screened for lenalidomide treatment. Data collected from the computerized patient record system will include the following: prophylactic agent prescribed, documented reason for no medical prophylaxis, lenalidomide refill history, duration of therapy, concurrent chemotherapy agents given, dose of dexamethasone, VTE risk factors and documented incidence of VTE or bleeding events. Descriptive statistics will be used to report baseline characteristics and for the evaluation of primary and secondary outcomes. Institutional review board approval is pending.

Poster Title: Prescribing Rates of Anti-infective Prophylaxis in Veterans Receiving Bortezomib Therapy

Primary Author: Heather Moore, Durham VA Medical Center, NC; Email: heather.moore28@va.gov

Additional Author(s):
Julia Hammond
William Bryan

Purpose: The National Comprehensive Cancer Network Guidelines on Prevention and Treatment of Cancer-Related Infections recommends varicella zoster virus (VZV) prophylaxis while on bortezomib and pneumocystis pneumonia (PCP) prophylaxis consideration for intermediate infection risk including multiple myeloma (MM) and lymphoma. This study’s primary objective is to determine the prescribing rate of anti-infective prophylaxis in veterans receiving bortezomib therapy. Evaluation of anti-infective agents selected, documented reasons for no prophylaxis, and rates of PCP & VZV infections will also be included.

Methods: The proposed study is a retrospective chart review of patients with multiple myeloma (MM) or mantle cell lymphoma (MCL), who received bortezomib therapy at the Durham Veterans Affairs Medical Center (DVAMC). To be included, patients must be at least 18 years of age and have an order for bortezomib between June 20, 2008 (date of FDA approval of bortezomib) and August 1, 2016. Data regarding time of initiation of anti-infectives will be identified as < 30 days, 30-180 days, and > 180 days from initiation of bortezomib. Prescribing rates will be calculated as percentages: number of patients that received specific therapy divided by the number of patients on bortezomib therapy. Documented reasons for not initiating anti-infective prophylaxis will be identified by utilizing the computerized medical record (CPRS). IRB approval is pending.

**Poster Title:** Determining the prevalence of potentially inappropriate medication prescribing in older community-dwelling veterans with chronic kidney disease and adverse drug outcomes

**Primary Author:** Megan Gee, Durham VAMC, NC; **Email:** megangee@buffalo.edu

**Additional Author (s):**
William Bryan
Marc Pepin
Jason Moss
Adam Vanderman

**Purpose:** The United States elderly population is rapidly growing. By 2050, the number of individuals over 65 will nearly double to 83.7 million. Over the last several decades, there have been significant advances in medicine. As a result, patients are living longer with chronic diseases. The prevalence of chronic kidney disease in people 60 years of age and older increased from 18.8 percent during 1988 to 1994 up to 24.5 percent in 2003 to 2006. As the life expectancy for older patients with CKD increases, it is essential to review current practice habits to improve patient care and optimize healthcare expenditure.

**Methods:** A retrospective review of patients managed by a Primary Care Provider or a Nephrologist at the Durham Veterans Affairs Medical Center (VAMC) from January 1, 2015 to December 31, 2015 will be conducted. Customizable computerized reports will be utilized to analyze the prescribing of potentially inappropriate medications (PIMs) to patients who are at least 60 years of age and have diagnosed chronic kidney disease (CKD). As a secondary outcome, adverse drug events including emergency department (ED) visits, hospitalizations, and death will also be collected and compared to individuals without any active PIM prescriptions.

Multiple variables will be collected including patient demographics, appointment information, prescription information, and outcome data. The data collected will be used to evaluate the association between PIM prescribing and 90 day outcomes for patients with CKD. Such outcomes will be compared to the same patient population without an active PIM medication. Descriptive statistics will be used to assess the incidence of PIM prescribing, the number of
active medications, the number of encounters, patient complexity, and the number of unique diagnoses for each encounter. Research is pending IRB approval.

Poster Title: Incidence of drug interactions identified by clinical pharmacists in Veterans initiating treatment for chronic hepatitis C infection

Primary Author: Andreina Ottman, Durham Veterans Affairs Medical Center, NC; Email: andreina.ottman@gmail.com

Additional Author(s):
Rachel Britt
Mary Townsend
Vincent DiMondi
Mohamed Hashem

Purpose: New Hepatitis C Virus (HCV) direct-acting antivirals (DAAs) have superior cure rates, improved side effects, and shortened treatment duration. Despite improvements, many DAAs have significant drug-drug interactions (DDIs) that can negatively impact efficacy and safety. There is also considerable cost associated with DAAs, further necessitating proactive therapy optimization. Pharmacists can play a key role in optimizing therapy, but there is limited evidence describing the types of interactions encountered in practice. The primary objective of this study is to describe the incidence and severity of DDIs with HCV DAAs identified by the HCV clinical pharmacist at initial screening for HCV therapy.

Methods: This is a retrospective study of Veterans with chronic HCV infection that had an initial prior authorization drug request for HCV DAA therapy between July 15, 2015 and July 14, 2016 at the Durham Veterans Affairs Medical Center. Using data from the electronic medical record, the initial approval note will be assessed. Primary endpoints will include: total number of identified DDIs, number of approval notes with at least one DDI, average number of DDIs per approval note, and number of DDIs by severity category based on University of Liverpool’s HEP Drug Interactions Resource. Secondary endpoints will include: number of drugs that interact with DAAs categorized by name and therapeutic class; directionality of interaction; proportion of DDIs expected to result in reduced efficacy of DAA, reduced efficacy of interacting drug, or safety concern; proportion of actionable interventions recommended and proportion of actionable recommendations that did not occur; achievement of sustained virologic response greater than 12 weeks after end of therapy; monetary value of cost avoidance when optimizing
regimen selection; and number of critical DDIs by drug interaction resource (University of Liverpool's HEP Drug Interactions Resource, Lexicomp, Micromedex). Primary and secondary endpoints will be analyzed using descriptive methods including mean, median, and mode.

Poster Title: Overactive bladder medication management: an assessment of drug utilization and potential cost savings opportunities in a Veterans Affairs Medical Center

Primary Author: Erin Amadon, Fayetteville Veterans Affairs Medical Center, NC; Email: erin.amadon@va.gov

Additional Author(s): Stephanie Hopkins

Purpose: Veterans Affairs and Department of Defense guidelines currently offer criteria for use for the medication mirabegron, but do not offer clinical guidance on alternative overactive bladder (OAB) medications. No tier-based approach to anticholinergic medication selection currently exists and extended-release oxybutynin is restricted for use locally. Therefore, we seek to investigate current overactive bladder (OAB) medication use within the Fayetteville Veterans Affairs Medical Center (FVAMC) to determine if current prescribing habits align with standard of care practices and to devise a tier-based, cost savings approach to anticholinergic medications.

Methods: Reports were generated identifying all patients with a prescription for an OAB medication originating between 08/01/2015 and 08/01/2016. Refills from prescriptions that originated outside of this timeframe were excluded. Composite of overall potential cost savings opportunities served as the primary endpoint. Current dispensation costs per unit were compared against actual real-time prices from both FVAMC medication vendors to determine the accuracy of current local pricing. Differences in pricing were compared against total quantities dispensed for included medication fills to determine overall cost savings potential. Formulary utilization was assessed in an effort to identify areas of improvement within FVAMC. Prescribing trends were compared with current recommendations for anticholinergic medications from the American Geriatrics Society Beers Criteria for potentially inappropriate medication use in older adults. Secondary endpoints included rates of anticholinergic medications use by patients 65-years of age and older, changes to OAB therapy, and documented adverse side effects associated with a change in therapy throughout the evaluation period.
Updated pricing was utilized to propose a cost-based, tiered approach to OAB medication prescribing. Formulary utilization data and updated pricing were utilized to propose removal of local formulary restrictions on oxybutynin 5 mg extended-release tablets.

**Results:** Generated reports identified a total of 909 prescription fills for OAB medications within FVAMC. Overall medication utilization costs based on current drug file pricing were calculated to be approximately $53,800. Actual costs based on updated pricing from each vendor were found to be $40,646 and $44,284. Individual dispensation costs differences ranged between $0.03 and $5.57 per unit from current drug file pricing. Of the 909 prescription fills for OAB medications, oxybutynin immediate-release tablets accounted for 639 (70%) medication dispensations. Of this, 368 (58%) dispensations were for patients aged 65-years of age or older. Changes to OAB medication therapy in patients over age 65-years occurred in 17 (5%) patients. Reasons for medication changes were cited as due to adverse side effects related to anticholinergic therapy (n = 7) and poor efficacy (n = 10). Extended-release oxybutynin (all strengths) accounted for 57 (6%) dispensations, of which, 38 dispensations were for patients aged 65-years of age and older.

**Conclusion:** Updated drug file price listings result in a potential cost savings average of $11,335 annually. Additionally, updated drug pricing provides the foundation to devise a cost-based, tiered approach for OAB medication prescribing. Analysis of existing drug utilization rates indicate that immediate-release oxybutynin is most commonly prescribed in the treatment of OAB. However, current guidelines recommend the use of extended-release oxybutynin, particularly in patients over 65-years of age. Given both the cost comparison between the oxybutynin immediate-release and oxybutynin extended-release formulations and current guideline recommendations, data from this analysis supports the need to revise local OAB formulary restrictions.

Poster Title: Evaluation of direct oral anticoagulant monitoring in a veteran population

Primary Author: Sara Carlisle, Fayetteville Veterans Affairs Medical Center, NC; Email: sara.carlisle@va.gov

Additional Author (s):
Brittney Howard
Stephanie Ring
William Elliott

Purpose: Prescribing of direct oral anticoagulants (DOACs) as alternatives to warfarin has recently grown, and it is anticipated that this trend will likely continue in light of the 2016 CHEST update on the use of DOACs in venous thromboembolism (VTE). At this facility, prescribing of DOACs has increased by 123.8% within the last year. With this amplification of prescribing, it is essential to ensure that this increasing number of patients on DOACs is receiving appropriate laboratory and safety monitoring. This review will assess the percentage of Veterans in a representative sample receiving appropriate monitoring and assessment by Clinical Pharmacist Specialists (CPS).

Methods: A retrospective chart review will be conducted to evaluate whether the Veteran population at this facility are receiving appropriate laboratory and safety monitoring while on DOAC therapy. A representative sample of patients greater than or equal to 18 years of age who have an active prescription for apixaban, dabigatran, or rivaroxaban between September 1, 2015 and September 1, 2016 will be included in this data analysis. Computerized patient records will be reviewed to determine if patients were monitored at appropriate VA-specified intervals defined as baseline, 2 weeks, 4 weeks, 3 months, 6 months, and every 6 months thereafter. Additional data collected to determine appropriateness of use and dosing will include DOAC indication, serum creatinine, blood urea nitrogen, hemoglobin, hematocrit, platelets, creatinine clearance, weight, and age.

Poster Title: Medication use evaluation (MUE) of liraglutide in a Veterans Affairs Medical Center

Primary Author: Emily Heubel, Salisbury - W.G. (Bill) Hefner VA Medical Center, NC; Email: emily.heubel@va.gov

Additional Author(s):
Sarai Ibrahim
Alyssa Kunkel
Sarah Leonall
Lindsay Thompson

Purpose: The 2016 American Diabetes Association guidelines have identified liraglutide as a potential first line monotherapy option for patients with Type 2 Diabetes. In addition, liraglutide has also been shown to be one of the first newer antidiabetic agents to demonstrate improved cardiovascular outcomes. Currently, the VHA limits liraglutide use to individuals that meet predefined criteria (i.e., poor glycemic control despite treatment with metformin combined with either another oral antidiabetic agent or insulin). The objective of this MUE is to retrospectively evaluate the use and clinical outcomes of liraglutide therapy in the Veteran population at the Salisbury VAMC.

Methods: This MUE's protocol was approved by the Pharmacy and Therapeutics (P&T) Committee. All patients with an active or inactive prescription for liraglutide from January 1, 2015 through August 26, 2016 were identified and a sample size of 150 patients will be randomly selected and analyzed. All patient identifiers will be removed prior to analysis and stored confidentially. The following data will be collected from the VAMC database: baseline patient demographics, liraglutide prescription information, antidiabetic therapy, HgbA1c, and adverse events. Descriptive data will be used to determine if liraglutide was prescribed in accordance with the criteria for use that have been developed by the Veterans Healthcare Administration Pharmacy Benefits Management (VHA PBM). Changes in HgbA1c, body weight, liraglutide dosing, diabetic medication regimens, and rates of liraglutide discontinuation will all be assessed.

**Poster Title:** Evaluation of a pharmacist run direct oral anticoagulant (DOAC) monitoring at a Veteran Affairs medical center  

**Primary Author:** Shayla Bigley, VA Nebraska - Western Iowa Health Care System - Grand Island Division, NE; **Email:** shayla.bigley@va.gov  

**Additional Author (s):**  
Maria Xu  
Lisa Bilsend  

**Purpose:** The direct oral anticoagulants are becoming an increasingly popular alternative to warfarin nationwide. In October 2015, pharmacists at VA Nebraska-Western Iowa (NWI) established the DOAC pharmacist monitoring clinic to evaluate and adjust DOAC therapy. Due to the novelty of these agents, uncertainty arose regarding the optimal approach to therapy, such as the appropriateness of proactively converting patients to a more evidence-based agent prior to an adverse event. This project was designed to assess the impact of a pharmacist-run DOAC clinic, evaluate medication monitoring patterns, and determine if follow-up education is necessary.  

**Methods:** The project was approved as non-research and data was collected utilizing the Pharmacist Achieve Results with Medication Documentation tool (PhARMD tool) dashboard reporting site which retrieves encounter information from the centralized data warehouse. Information collected included dose changes, medication discontinuation, and medication initiation. Pharmacists can also document education provided, which includes items such as peri-procedural instructions, medication education, disease state education, lifestyle counseling, education materials given, home monitoring devices provided, and referrals for additional care. Data analysis included a review of all patients for whom interventions were completed in the DOAC clinic using the PhARMD tool from October 2015 through June 2016. Patients who did not have a prescription for dabigatran, rivaroxaban, or apixaban from a VA pharmacy within this timeframe were excluded from analysis. The primary outcome was data tabulated via chart review to determine the reason for the medication adjustment. The data was then used to determine whether pharmacists are following NWI policies and to identify best practices for patient care. Secondary objectives include evaluation of the PhARMD tool for
better tracking of DOAC interventions, determination if education or revision of current policies is necessary to clarify areas of misunderstanding, and assessment of the need for additional education for pharmacists at NWI on proper monitoring of DOACs.

**Results:** From a total of 3743 encounters documented within the PhARMD tool throughout the project timeframe, 171 interventions were included in the analysis. A focus was made on medication changes based on age, incidence of bleed, renal function, or coronary artery disease to compare reasons for change among DOAC agents. After comparative evaluation, the vast majority of interventions were related to apixaban, whether patients were switched to the agent or dosage adjustments were made. At Grand Island, the most common reasons for converting to apixaban were age, renal function, and incidence of bleed or bleeding risk. At Lincoln, the most prevalent reason for change to apixaban from another agent was renal function. In patients initially on rivaroxaban, renal function was the most common cause for requiring a change in therapy and the majority of the renal adjustments occurred in Lincoln. The bulk of patients initiated on dabigatran were switched based on age or coronary artery disease and both of these changes only occurred in Grand Island. Between the two campuses, Grand Island pharmacists are much more likely to convert patients from other DOACs to apixaban while Lincoln pharmacists prefer to keep the patient on their current agent.

**Conclusion:** Drug-use evaluation is helpful in identifying pharmacists’ impact on DOAC monitoring and practice patterns. Overall, pharmacists have a large impact on patients’ DOAC regimen, especially on the basis of bleeding risk, age, renal function and coronary artery disease. It is of note that Lincoln and Grand Island developed different approaches based their interpretations of the same protocol. Therefore, further discussions may be necessary to determine whether it is more beneficial to proactively convert patients to another agent or to keep patients on their current regimen.

Poster Title: Streamlining medication lists on discharge from the community living center (CLC) in a veterans affairs medical center

Primary Author: Emily Eddy, VA Nebraska-Western Iowa Health Care System - Grand Island Division, NE; Email: emilyalyson33@aol.com

Additional Author (s):
Amy Thompson

Purpose: According to The Joint Commission long term care national patient safety goal (NSPG.03.06.01), the resident or family should be provided with a list of medications they should be taking when leaving the organization’s care. The list should be given to the primary care physician to update when changes are made. Currently at the CLC it is estimated that up to five medication lists are given to the patient in the discharge process. The purpose of this project is to decrease the number of medication lists that are given to patients when they are discharged from the CLC.

Methods: The pharmacist on the CLC and pharmacy resident will work together to condense information from multiple current documents. Currently, the provider’s signs pre-typed discharge medication orders and handwrites dietary instructions and physical activity limitations. The nurse completes a nursing discharge summary which may or may not include active inpatient and outpatient medication orders as well as other patient specific instructions. The pharmacist provides a medication list for patients to take to appointments with other providers and a medication worksheet that specifies the time of day each medication should be taken.

The newly standardized document will convey provider’s orders (outpatient medication orders, dietary instructions, physical activity limitations) as well as nursing instructions on discharge. Previously, this information was on two to three different documents. The pharmacist will continue to provide a separate medication list that the patient can have at home that makes it easy for the patient to organize and determine what time of day to take their medications when they are home.
Once this document is developed, provider and nursing staff on the CLC will be educated on proper use and spot checks will be performed by the pharmacy resident to determine adherence to using the standardized document and process. These spot checks will consist of the pharmacy resident observing discharges or reviewing patient’s medical charts occasionally throughout the timeline of the project.

Poster Title: Improving appropriate use of proton pump inhibitors through provider education in the ambulatory care setting

Primary Author: Rosetta Persaud, VA New Jersey Health Care System, NJ; Email: rosetta1persaud@gmail.com

Additional Author (s):
Li Li
Jennifer Woo

Purpose: Proton pump inhibitors (PPIs) are highly effective at reducing gastric acid secretion, which could lead to unnecessary use beyond approved duration. When continued chronically, patients can be exposed to potential risks such as clostridium difficile. Given these risks, it is prudent that providers reassess patients’ needs for continuation of chronic treatment. The purpose of this evaluation is to implement quality improvement in the form of education to providers on the risks of long-term use of PPIs. This evaluation was conducted at the Veterans Affairs in New Jersey to determine the number of patients receiving inappropriate therapy before and after education.

Methods: In this quality improvement evaluation, a retrospective and prospective analysis will be conducted on patients who are receiving proton pump inhibitors (PPIs). Patients visiting the primary care clinic in East Orange on any PPI will be randomly selected for evaluation of appropriate therapy. The retrospective analysis will include those from June 2016 to August 2016, and the prospective analysis will include those from October 2016 to December 2016. In-service education through verbal and written communication will be provided during September 2016. Patients were identified for evaluation using the Computerized Patient Record System (CPRS). Patients were excluded if PPIs were obtained outside the Veterans Affairs. Data will be collected on age, gender, weight, estimated creatinine clearance, documented allergies to either a PPI or histamine2 receptor antagonist, indication for PPI or lack thereof, name of PPI, dose, schedule, and length of therapy. Appropriate indications for PPIs will be evaluated from American College of Gastroenterology and American Gastroenterological Association guidelines. These include symptomatic gastroesophageal reflux disease less than 60 days, treatment for Helicobacter pylori 10 to 14 days, previous...
gastrointestinal bleed or high risk of gastrointestinal bleed, peptic ulcer disease, esophageal strictures, erosive esophagitis, Zollinger-Ellison syndrome, Barrett’s esophagus, bariatric patients for two years after gastric bypass surgery, and gastric malignancy or previous esophageal or gastric surgery.

Poster Title: Evaluating appropriateness of the use of laxatives in opioid-induced constipation

Primary Author: Stacy Tse, Not Applicable, Not Applicable; Email: stacytse@gmail.com

Additional Author (s):
Rosina Stamati
Mei Chang

Purpose: Opioids commonly cause constipation, and this is an adverse effect that does not mitigate over time. Constipation can decrease quality of life or cause patients to decrease use of pain medications and compromise pain relief. Implementing a bowel regimen to prevent and manage constipation is essential when starting opioids. This medication use evaluation will determine the proportion of patients prescribed appropriate bowel regimens with opioids in the outpatient setting. These findings may help determine if interventions are needed to ensure appropriate use of laxatives and optimize patient care.

Methods: This is a retrospective, single center, medication use evaluation. A list generated from the Veterans Health Information Systems and Technology Architecture (VISTA) will be used to review all outpatient prescriptions for a new oral opioid for pain between July 1, 2015 and July 1, 2016. Patients with a “new opioid” will be defined as a patient without a prescription for an opioid in the last six months. Opioids will include hydromorphone, hydrocodone/acetaminophen, oxycodone, oxycodone/acetaminophen, oxymorphone, and morphine. Patients will be included if they are at least 18 years old, and have a designated primary care provider at the site. Patients will be excluded if they have spinal cord injuries or any type of ileus or bowel obstruction. Patients from the emergency room, substance abuse clinic, gastrointestinal clinic or spinal cord clinic will be excluded. Patients recently discharged will be excluded. Patients receiving prescriptions for transdermal fentanyl, codeine, methadone, tramadol, and other combination opioid products will be excluded. The following data will be collected: patient age, sex and race; prescribed opioid, morphine equivalent daily dose, prescribed laxatives (includes docusate, lactulose, magnesium citrate, polyethylene glycol 3350, senna, sorbital, bisacodyl enema, mineral oil enema, phosphate enema), and prescriber location. Descriptive statistics will be used.

Poster Title: Impact of pharmacist delivered post-discharge telephone follow-up calls on reducing heart failure readmission rates

Primary Author: Joanne Cho, Veterans Affairs New Jersey Healthcare System, NJ; Email: Joanne.Cho@va.gov

Additional Author (s):
Andrew Tsiattalos
Ann Verghese
Jennifer Nguyen

Purpose: More than half of heart failure patients are readmitted within 6 months of discharge. A pharmacist coordinated clinical service involving post-discharge follow up has been shown to reduce the rate of readmission for heart failure. Veterans Affairs New Jersey Healthcare System (VANJHS) recently has had a 21.4% 30-day readmission rate. Though lower than the national average of 23.1%, this percentage remains above the VA goal. The objective of this project will be to evaluate the impact of a pharmacist delivered post-discharge telephone follow-up on heart failure 30-day hospital readmissions and observe possible trends that pose as risk factors for readmission.

Methods: In this quality improvement project, a retrospective and prospective analysis will be conducted on patients who have been discharged from the VANJHS with a diagnosis of heart failure. The retrospective analysis will include a random sample of those patients from November 2015 to February 2016 and the prospective analysis will include a random sample of those patients from November 2016 to February 2017. The exclusion criteria includes patients with a private cardiologist, language barriers, without telephone access, or are discharged to an outside long term care facility or hospital. Data will be collected on readmission rates, adherence, NYHA class, AHA stage, length of hospital stay, appropriate medication regimen, tele-health enrollment, and patient factors such as age, gender, co-morbidities, serum creatinine, serum sodium, weight, and body mass index. Patients were identified for the retrospective analysis using the Computerized Patient Record System (CPRS) by the informatics pharmacist. For the prospective analysis, the discharge list will be filtered every two days for diagnoses of heart failure within the past four days. After conducting a thorough chart review,
eligible veterans will be contacted via telephone using a structured telephone template to be interviewed, assessed, and educated on the proper management of heart failure. Based on information gathered from the chart review and patient interview, changes to the drug regimen may be suggested to the cardiologist.

Poster Title: Assessing the effectiveness of a pharmacy based immunization clinic among adult Native American patients in the outpatient setting

Primary Author: Taylor Morris, Albuquerque Indian Health Center, NM; Email: taylor.morris@ihs.gov

Additional Author(s):
Steven Rodgers
Phuong Nguyen
Judith Mather
Michael Shuster

Purpose: Healthy People 2020 list target goals to achieve by the year 2020 for immunizations. According to the Center for Disease Control’s latest statistics, vaccination rates fall short for both the annual influenza vaccine and the pneumococcal vaccine for adults. The objective of this study is to assess the impact on vaccination rates of the influenza vaccine for adults ages 19 years and older as well as the pneumococcal vaccine for adults ages 65 years and older after the initiation of an outpatient pharmacy based immunization clinic.

Methods: This study will be submitted to the Institutional Review Board for approval. This study will take place in an outpatient clinic located in Albuquerque, New Mexico. The electronic medical record will identify all patients 19 years and older who received an influenza vaccine and separately all patients 65 years and older who received a pneumococcal vaccine between the timeframe of September 2015 – May 2016. This data will be used to determine the percentage of all active patients within the outpatient clinic who received each respective vaccine. This percentage data will be compared to the current study during the same timeframe for the year 2016-2017 and used to assess the impact on vaccination rates due to the initiation of a pharmacy based immunization clinic.

Poster Title: Pharmacist-managed adult and pediatric asthma clinic at a rural Indian Health Service site

Primary Author: Alexandria VanBuren, Crownpoint Healthcare Facility, NM; Email: alexandria.vanburen@ihs.gov

Additional Author (s):
Dakota McMurray

Purpose: American Indian and Alaska Native (AI/AN) persons have a higher prevalence of asthma compared to the general, non-AI/AN population. Poorly controlled and uncontrolled asthma are burdens to the United States healthcare system and result in avoidable hospitalizations, emergency department visits, and premature death among others. The objective of this study is to determine the effectiveness of a pharmacist-managed asthma clinic by reducing the frequency of albuterol inhaler use, increasing adherence to maintenance asthma medications, and minimizing urgent care and emergency department visits where the purpose of the visit is to receive maintenance asthma care.

Methods: Visit General Retrieval (VGEN) reporting in the electronic health record (EHR) was used to identify patients with at least one visit to the emergency department, urgent care clinic, or inpatient ward since October 1, 2015 at the Crownpoint Healthcare Facility under the following International Classification of Diseases, Tenth Revision (ICD-10) codes: J45.21, J45.31, J45.32, J45.41, J45.901, and J45.902. VGEN reporting was also used to identify albuterol fills and refills. This method identified approximately thirty high-risk patients for potential inclusion in the pharmacist-managed asthma clinic. Upon hospital approval of the Asthma Management Clinic (AMC) policy, healthcare providers will be notified for high-risk patient referral. Initial clinic visits will be scheduled through the Resource and Patient Management System (RPMS) for 60 minutes in duration and follow-up appointments for 30 minutes in duration. Follow-up visits will be determined by asthma severity and degree of control. Clinic visits will follow visit specific checklists found in the AMC policy and will include patient completion of the Asthma Control Test (ACT), medication management and counseling, immunization review/administration, patient education, and review of the patient’s asthma action plan. Quality assurance reviews will be performed every 3 months by the AMC manager to determine individual patient...
albuterol inhaler use, maintenance medication adherence, and location of asthma care. This study will be submitted to the Navajo Institutional Review Board for approval.

**Poster Title:** Assessment and analysis of developing a pharmacist clinician program in a rural healthcare system

**Primary Author:** Falisha Begay, Gallup Indian Medical Center, NM; **Email:** flbegay14@gmail.com

**Additional Author(s):**
Phillip O'Bourke
Joe Anderson
Christina Andrade
Kerri Culligan

**Purpose:** In 1993, the Pharmacist Prescriptive Authority Act granted New Mexico pharmacists prescriptive authority, in collaboration with physicians, to manage chronic disease states. Pharmacists' unique experiences and training in medication management, drug therapy assessments, and public health are essential to the healthcare team in terms of improved health outcomes, patient safety, and reduced costs. This project will increase our understanding of the pharmacist clinician’s role, its effect on patient care, and how it can be integrated into outpatient services. The pharmacist clinician program can decrease physician work load, increase pharmacist satisfaction, and serve as a source of income for the hospital.

**Methods:** The pharmacist clinician program consists of the following: obtaining a New Mexico pharmacist license, successful completion of a 60-hour board approved physical assessment course, and a 150-hour or 300-patient contact preceptorship by a supervised provider with prescriptive authority. The cost of this program will vary by type of pharmacist: practicing pharmacist, pharmacy resident, or pharmacy student nearing graduation from the University of New Mexico College of Pharmacy. A comparative analysis will assess the productivity, cost, and value of developing a pharmacist clinician program for a rural health care system. Items assessed will include direct and indirect costs to the system, a proposed timeline to train incoming and current clinical pharmacists, a summation of potential benefit gained by the hospital for providing the additional training, and increased patient access to healthcare.

**Results:** In progress

Poster Title: Development of a multidisciplinary wellness clinic at a rural Indian Health Service (IHS) hospital

Primary Author: Christopher Mendoza, Gallup Indian Medical Center, NM; Email: christopher.mendoza@ihs.gov

Additional Author(s):

Purpose: The Navajo people struggle with some of the worst health outcomes in the United States. For example, one-in-three Navajo are diabetic or pre-diabetic. In the Navajo Nation, healthcare workers diagnose diabetes in every other patient. The development of a multidisciplinary wellness clinic is highly needed to make positive changes in patient’s lives and the community. This clinic would be aimed at motivating and educating patients on nutrition and physical activity with the goal of decreasing polypharmacy and improving quality of life.

Methods: This pharmacy run wellness clinic would require the involvement of various departments at GIMC: Pharmacy, Physical Therapy, Diabetes Clinic, Nutrition, Family Medicine, and Internal Medicine. A collaborative agreement will be developed to enroll patients into the clinic on a referral basis. Inclusion criteria for clinic referral will be newly diagnosed, adults (< 40 years old), highly motivated individuals who are looking to change their health picture through a Therapeutic Lifestyle Change perspective. A cohort of 20 patients will be followed for one year. Baseline labs will be obtained at the initial visit and every 3 months to assess health outcomes such as A1C, total cholesterol, HDL, BMI and number of daily medications. In the initial stages, patients will be scheduled on a one-on-one basis to gather initial data. Group classes would be utilized for educational purposes on physical activity, nutrition, and primary prevention. Liaisons within the various departments will be established to aid in communication and dissemination of information. At the end of the probationary period, a cost-benefit analysis will be conducted to assess direct and indirect costs in relation to health outcomes.

Results: In progress

Conclusion: In progress

**Poster Title:** Assessment and optimization of pharmacy point-of-sale billing at an Indian Health Service facility

**Primary Author:** Sophia Yang, Northern Navajo Medical Center, NM; **Email:** sophia.yang@ihs.gov

**Additional Author(s):**
Fiona Chao
Thad Koppenhafer
Kevin McDermott

**Purpose:** The purpose of this project is to assess and improve the current situation of pharmacy point-of-sale (POS) billing at the Northern Navajo Medical Center (NNMC). Through evaluation, collaboration, and implementation of pharmacy involvement in the billing and pharmacy claims rejection process, this project aims to optimize billing efficiency and increase collections by decreasing the proportion of medication claims rejected by private and government third party payors. This will increase the facility’s fiscal capacity to provide additional patient care services. This project will also highlight the value added by pharmacy involvement in the POS process.

**Methods:** This is a multi-phase quality improvement project aimed at improving the pharmacy POS billing processes in an Indian Health Service (IHS) facility. The initial phase consists of basic groundwork including attending training, site visits to other IHS facilities, connecting with experts in POS within the Resource and Management Patient System (RPMS), and understanding payor regulations due to a lack of published and standardized literature on improving POS billing within the IHS system.

The second phase will include completing an assessment of the current pharmacy billing processes by analyzing the following POS data: percent and cost of rejected claims, percent and cost of rejected claims which have been fixed, the total amount of paid claims, and the total drug expenditures. The project will establish relationships with all departments in the facility that are associated with the billing process (i.e. the business office, pharmacy, and patient registration office), to allow for thorough evaluation of current practices and help determine the baseline pharmacy prescription billing efficiency.
Interventions will include pharmacy monitoring within the RPMS-generated rejection report and implementation of the CoverMyMeds program for medication prior authorizations, with system-wide changes implemented when system problems are identified within the billing process. The reports used to initially assess billing efficacy will then be tracked and analysed every three months to determine the effectiveness of implemented interventions.

Poster Title: Implementing a sequential antibiotic therapy protocol in a rural Indian Health Service hospital

Primary Author: Julia Olson, Northern Navajo Medical Center, NM; Email: julia.olson@ihs.gov

Additional Author(s):
Clint Krestel
Kevin McDermott

Purpose: Switching from intravenous (IV) to oral (PO) medications, or sequential therapy, is an important part of any antimicrobial stewardship program. The purpose of this project is to validate the use of an IV to PO switch protocol at a rural Indian Health Service hospital, to show the potential for reduction in cost of delivering treatment, and demonstrate a decrease in the length of hospitalization for patients receiving antibiotics in the inpatient care setting.

Methods: The electronic health records system will notify pharmacists of any patients receiving a qualifying antibiotic intravenously. Qualifying antibiotics will include ampicillin, azithromycin, clindamycin, ciprofloxacin, doxycycline, fluconazole, levofloxacin, and metronidazole. Pharmacists will follow the IV to PO switch protocol and contact the attending physicians to recommend sequential therapy. For the purpose of data collection, the electronic health records system will be utilized to create a list of patients receiving a qualifying antibiotic for three months after the implementation of the protocol. A similar list will be created of patients who received a qualifying antibiotic during the same three months in the previous year. The following information will be collected for each patient: age, gender, comorbid conditions, source of infection, recent hospitalizations within the past six months, the primary physician responsible for managing antibiotic therapy, the results of any microbiology cultures and sensitivities, and any other antibiotics prescribed during the same admission. The cost of administering antibiotics, rates of hospital readmissions, rates of phlebitis, rates of catheter-associated infections, and the length of hospital stay will be compared between pre- and post-implementation groups. All data will be recorded without any patient identifiers.

Results: Not applicable. Research in progress.
Conclusion: Not applicable. Research in progress.

Poster Title: Evaluating the impact of clinical decision support on outpatient antibiotic prescribing within the Alaska Native and American Indian population

Primary Author: Angela Kao, Santa Fe Indian Hospital, NM; Email: angela.kao@ihs.gov

Additional Author(s):
Keith Adcock
Dewey Foutz
Elizabeth Peters

Purpose: A predominantly outpatient, multicenter facility serving the Alaska Native and American Indian population is developing an up-to-date clinical decision support (CDS) system in efforts to slow antimicrobial resistance and improve patient care and safety. The objective of this study is to assess the impact of the CDS system in reducing the proportion of inappropriate antibiotics prescribed.

Methods: This study is exempt from institutional review board evaluation since it is a quality improvement study that involves the collection of existing data recorded in a manner that prevents subject identification. Treatment algorithms for the most common infectious disease states identified at the facility are in development using the facility antibiogram and evidence-based guidelines, such as the Infectious Diseases Society of America (IDSA) guidelines. These algorithms will then be programmed into the electronic health record (EHR) as a CDS system for provider use. This CDS system will contain quick orders with disease-specific antibiotic recommendations to help facilitate provider prescribing. Once fully implemented, this study will look at prescribing practices during two separate six-month periods before and after implementation of the CDS system. Inclusion criteria include all outpatient office visits with an initial diagnosis among those identified common infectious disease states. Exclusion criteria include visits by patients less than 18 years of age. Chart reviews will be performed to determine if antibiotic prescribing practices during those visits are congruent with current practice guidelines based on disease-specific treatment algorithms. The primary outcome of interest is the proportion of inappropriate antibiotics prescribed. Inappropriate prescribing practices are defined as practices not in congruence with treatment algorithms. Analysis of the
primary outcome before and after the intervention will be performed to evaluate the impact of this quality improvement project.

**Results:** N/A

**Conclusion:** N/A

Session-Board Number: 1-232

Poster Title: Expanding healthcare delivery and access to care for rural veterans, by leveraging clinical pharmacy specialist providers.

Primary Author: Brenna Lindsey-Swecker, VA Sierra Nevada Health Care System, NV; Email: brenna042@gmail.com

Additional Author(s):
Scott Mambourg
Jeffrey Blanchet

Purpose: Rural populations are uniquely susceptible to limited access to healthcare services. Given the high rurality of the VA Sierra Nevada Health Care System (VA SNHCS) and its Community Based Outpatient Clinics (CBOCs), it is important to utilize resources effectively to provide equivalent access and quality of care across the entire veteran population. Leveraging Clinical Pharmacy Specialists (CPS) with advanced scope of practice may impact accessibility of quality healthcare. Pharmacists offering chronic disease states management services may reduce the growing demand on VA physicians, improving availability of providers.

Methods: Grant funding available through the VA Office of Rural Health (ORH) Enterprise Wide Initiative (EWI) provides an opportunity to expand Clinical Pharmacy Specialist (CPS) roles in ways that influence rural veteran access. The increased CPS staffing may help develop more robust services in rural veteran healthcare. A rural healthcare gap analysis was conducted using VA identified core measures impacting patient care outcomes within VASNHCS. Further, workload and encounter data for CBOC pharmacists were used to justify and prioritize pharmacy based positions for the ORH funding application. Potential positions were identified with a goal to optimize VASNHCS staff utilization for increased rural access to CPS care. Once the positions have been approved, functional statements and scopes of practice will be developed. A PGY1 resident clinical practice area will be developed to contribute to rural patient care, improve access, and help define new rural CPS provider roles. Identified targets and outcomes will frame the evaluation of expanded services. Assessments will be performed to rate progress toward the goal of increased access and association to clinical outcomes of care. Long term goals of service expansion and sustainability will be explored. The above
outlined process was determined to be a quality improvement based analysis by the local institutional review board.

**Results:** Based on the rural healthcare gap analysis, seven positions were identified to offer progress toward outlined goals of healthcare service to veterans. These positions include direct CPS involvement, adequate support staff, and depend on work-load redistribution strategies. Justifications of the positions have been submitted to Office of Rural Health in August 2016. Official approvals for the selected positions will be announced in October 2016. Results will be presented in May of 2017 at Western States Conference.

**Conclusion:** Leveraging CPS providers may help develop more robust services in rural healthcare for veterans. It is expected that rural Veteran health care outcomes will be positively impacted with enhanced Clinical Pharmacy Specialist position utilization. Target measures have the potential to define and propel projects toward sustainability, prioritizing quality health care for our rural veterans as valued members of the growing VA community.
Purpose: Antimicrobial stewardship programs were shown effective in optimizing antibiotic use and promoting prescriber adherence to clinical practice guidelines. The developed a pilot Outpatient Antibiotic Stewardship Program last year. The objectives of this quality improvement project are to fully operationalize the program for sustainability and to expand in many clinical areas with improved provider centric order sets for outpatient antibiotic therapy. The project is expected to improve patient-centered outcomes by decreasing health care utilization, including clinic and emergency room visits, due to failed antibiotic therapy.

Methods: New provider-centric electronic order sets will be created specific to upper and lower respiratory tract infections, otitis media, dental infections, and animal bites considering Infectious Diseases Society of America (IDSA) guidelines, local antibiogram, and the Veteran Affairs national and local formulary. These will complement existing order sets for pneumonia, influenza, urinary tract infection (UTI), and cellulitis. They provide preferred treatment options and renal/hepatic dose adjustments as necessary. Patients prescribed antibiotics in the outpatient setting will be identified through a Clinical Dashboard. Chart reviews will be conducted against relevant labs to determine if antibiotic therapy was appropriate, including dose, duration, and drug-bug mismatches. Follow-up telephone calls to those patients will be made three to five days after antibiotic initiation to assess symptom improvement, possible antibiotic side effects, and adherence. A standard progress note will be used for documenting encounters and alerting prescribers of any recommendation for changes to therapy or worsening of symptoms. Further, a ‘4-day antibiotic list’ report will be generated daily to identify patients who have not picked up antibiotic prescriptions from the pharmacy. These
patients will be contacted to provide education on completing antibiotic therapy. Assessing the appropriateness of antibiotic selection, dose and duration of therapy following these two identification methods will help to create an ‘Antibiotic Trigger List’ for high-risk antibiotics with stringent criteria for use.

**Results:** The outcomes of the project include identification and assessment of potential overuse and prolonged durations of antibiotics therapy, drug-bug mismatches, interventions taken and clinical response rates. Results will be presented in May at the 2017 Western States Conference.

**Conclusion:** The optimization of antibiotic therapy in the outpatient setting is expected to improve antibiotic prescribing, drug utilization, and patient outcomes. Further, this may reduce the overall healthcare cost and the spread of multi-drug resistant organisms. When fully operational, it is anticipated the antibiotic stewardship program will provide prescribers the necessary tools to achieve the overall goals of adhering to clinical practice guidelines and offer the best standard of care to patients.

Submission Type: Evaluative Study

Session-Board Number: 1-234

Poster Title: Evaluating naloxone rescue therapy and outcomes in patients at risk of opioid overdose in a veteran population.

Primary Author: Marcus Mellberg, VA Sierra Nevada Health Care System, NV; Email: m27mellberg@gmail.com

Additional Author(s): Scott Mambourg
Amy Pullen
Kelly Krieger

Purpose: Naloxone is a life-saving medication for opioid overdose. It has been used by emergency personnel for many years. Recently, the FDA has approved the use of naloxone nasal spray, a device that can be easily administered by the lay person. New laws in many states allow for easy access to this life saving device due to the dramatic rise of opioid related overdose and death. This project is designed to evaluate and identify areas of improvement for appropriate delivery, education, and outcomes of prescribing naloxone to patients at high risk for opiate overdose at the VA Sierra Health Care System.

Methods: This is a quality improvement project reviewed by local IRB. Patient’s electronic medical records will be reviewed to identify patients at risk for possible opioid overdose. These include patients with current or prior history of filling a naloxone prescription, prior ED visit or hospitalization related to opioid overdose, and those on chronic opioids greater than or equal to 90 mg of morphine equivalent daily dose, long acting opioids, or concurrent CNS depressants. Additional high risk groups include patients with substance abuse disorder, sleep apnea, chronic kidney or liver disease, suicide risk, advanced age, and those who recently switched to a new opioid. Once identified, patients will be provided a naloxone device with adequate education. A PGY-1 pharmacy resident will be directly or indirectly responsible for inter-professional education, staff engagement and decreasing barriers to prescribing. VA approved video training and time-effective prescribing will be utilized to reach a goal of providing 100% of patients at risk with a naloxone device. A Telephone follow-up process for those already receiving naloxone devices will be developed to assess use, patient knowledge, and need for refill or further education. Scheduled clinical pharmacy telephone follow up will
be conducted for all newly prescribed rescue devices for sustainability. The outcomes include percentage of high risk patients provided with naloxone kits, successful follow ups, and prevention of opioid related death across intervention period.

Session-Board Number: 1-235

Poster Title: Deprescribing of benzodiazepines in high-risk patients through multifaceted interventions

Primary Author: Vivianne Nguyen, VA Sierra Nevada Health Care System, NV; Email: viiviiix@gmail.com

Additional Author(s):
Danielle Finn
Scott Mambourg

Purpose: Despite the risks of serious adverse effects and potential abuse due to long-term benzodiazepine use, prescribing remains elevated in high risk groups such as those who are greater than 75 years old or those with concomitant narcotic use. The purpose of this project is to develop effective clinical practice strategies in order to deprescribe or taper patients off benzodiazepines. The project is expected to reduce adverse drug events and overall harm in high-risk patients receiving long-term benzodiazepines.

Methods: The project was reviewed by the local IRB and determined as a quality improvement project. High-risk patients (≥ 75 years old) with an active benzodiazepine prescription will be identified using a Clinical Dashboard. The drug utilization review on benzodiazepine use will be performed by a pharmacist. The prescribing provider will be contacted to determine if deprescribing of benzodiazepine is clinically appropriate. Patients identified will be mailed information on potential adverse effects of long-term benzodiazepine use and the pharmacy’s contact information if they decide to taper off the medication. Targeted patients will also be contacted over the phone to discuss their willingness to discontinue benzodiazepine therapy. If patients are not immediately available, a scripted message with a request to contact the pharmacist will be left on voicemail. If no response is received after three attempts, patients will be excluded and providers will be notified. For patients who agree to taper off, the pharmacist will work in collaboration with the prescribing provider on regular basis for assessment of progress. The plan for benzodiazepine tapering will be based on current clinical guidance and patient centered. If complete discontinuation of benzodiazepine is unsuccessful, the goal would be to decrease to the lowest effective dose. Patients will also be offered to see
mental health or other clinical specialties for further evaluations if they were unable to discontinue the benzodiazepine.

**Results:** Results of this project will be presented in May at the 2017 Western States Conference.

**Conclusion:** Conclusion of this project will be presented in May at the 2017 Western States Conference.
**Submission Category:** Geriatrics

**Submission Type:** Descriptive Report

**Session-Board Number:** 1-236

**Poster Title:** Impact of a new patient medication therapy management service in a geriatric primary care clinic

**Primary Author:** Sarah Fussy, VA Sierra Nevada Health Care System Reno, NV; Email: sarah.fussy@va.gov

**Additional Author(s):**
Dawn Currie

**Purpose:** Nearly 250 elderly Veterans will be transferred from traditional primary care teams into a geriatric clinic at the VA Sierra Nevada Health Care System. Traditional primary care teams operate with clinical pharmacists, however the geriatric clinic is currently without a designated pharmacist. This population is considered highly complex with advanced age, comorbidities, and polypharmacy thus the need for geriatric clinical pharmacy services. This is a quality improvement (QI) project aimed to establish the role of a geriatric pharmacist in providing new patient medication therapy management (MTM) services prior to the initial geriatrician visit to improve patient outcomes and clinic efficiency.

**Methods:** This project was deemed QI by local IRB which did not meet criteria for human subjects research or IRB exemption review. It will be conducted in a geriatric primary care clinic, which consists of a PGY-2 geriatric pharmacy resident, geriatrician, and nurse. Approximately 250 Veterans meeting age and complexity criteria who recently transitioned from general primary care teams into a geriatric clinic will be eligible for MTM services. Veterans who opted out of the new geriatric clinic will be excluded. Veterans will be scheduled for face-to-face new patient MTM visits with the geriatric pharmacist at least two hours prior to their initial geriatrician visit. This will allow time for the geriatrician to review pharmacist recommendations. The pharmacist will record the encounter and recommendations in the VA’s computerized patient record system. MTM appointments will be scheduled into a longitudinal clinic on Friday’s and a 6 week block clinic that coordinates with the geriatrician’s schedule from 9/2016 through 2/2017. The pharmacist will collaborate with the geriatrician to provide recommendations for safe drug therapy, formulary management, immunizations, labs, and referrals for ongoing MTM services. Outcomes of the MTM services will be measured against recommendations accepted by the geriatrician; accepted interventions implemented on the
same day of initial visit; number of MTM visits completed prior to the Veterans first geriatrician visit; and clinic utilization rates.

**Poster Title:** Evaluating clinical outcomes of abiraterone and enzalutamide use in castration-resistant metastatic prostate cancer in a veteran population

**Primary Author:** Hugh Nguyen, VA Sierra Nevada Healthcare System PGY1, NV; Email: hugh.nguyen2@va.gov

**Additional Author (s):**
Linda Clifford
Mostaql Huq
Scott Mambourg
Joy Meier

**Purpose:** Abiraterone and enzalutamide are approved by the FDA for treatment of castration-resistant metastatic prostate cancer (cRMPC) in patients who progress despite hormonal therapy or chemotherapy. But it is unclear whether treatment with a second antiandrogen in cRMPC is effective. We seek to validate whether clinical trial results of these agents are applicable in a clinical setting, and how their utilization patterns in clinical practice may affect those results. The current project will also assess whether patients on abiraterone or enzalutamide met appropriate criteria for use while on therapy or were appropriately discontinued according to VA national PBM guidance for discontinuation.

**Methods:** This is a quality improvement (QI) project within the Veterans Affairs healthcare system. Local IRB reviewed the project and it did not meet the criteria of federal definition for research. A list of patients diagnosed with prostate cancer and treated with either abiraterone or enzalutamide in the past 3 years will be pulled from the VA prescription database. Retrospective chart review and data extraction from the electronic health record will be conducted concurrently to assess whether abiraterone or enzalutamide were effective in treating prostate cancer that progressed following androgen deprivation therapy. Baseline patient characteristics will be assessed for appropriateness of therapy initiation and to determine whether defined discontinuation criteria for these agents were met. The effectiveness of these drugs will be evaluated based on several primary outcomes including suppression of PSA, time to response, rate of response, progression free survival, and overall
survival. Secondary outcomes will include assessment of tolerability of one agent over the other.

**Results:** The primary outcomes include a comparison of the rate of response, time to response, progression free survival and overall survival relative to the results from pivotal phase 3 randomized controlled trials (RCT’s) of abiraterone and enzalutamide. In addition, utilization and discontinuation of both drugs will be evaluated based on criteria for use set by the VA and the percentage of patients appropriately treated and discontinued will be calculated.

**Conclusion:** This project offers an opportunity to assess the real world experience of abiraterone and enzalutamide therapy in cRMPC in a clinical setting. The results will enhance the clinical decision making process in treating prostate cancer within the VA population.

Submission Type: Research-in-Progress

Session-Board Number: 1-238

Poster Title: Heuristic and end-user analysis of clinical and operational population management tools in VISN 21

Primary Author: Jason Bena, VA Sierra Pacific Network (VISN 21), NV; Email: jason.bena@va.gov

Additional Author(s):
Jannet Carmichael
Joy Meier
Amy Robinson
Janice Sanders

Purpose: Veteran Integrated Service Network (VISN) 21 pharmacists have created and maintain over 300 clinical and operational population management tools, i.e. dashboards and reports, based on electronic health record data. These population management tools allow for a comprehensive view and analysis of clinical and operational data. Clinicians and managers use this data to more efficiently monitor patient populations and staff for quality, safety, and workload. While use of these tools has been widely adopted in VISN 21, usability has never been formally assessed. This project will evaluate the usability of these tools using heuristic analysis along with end-user testing and surveys.

Methods: The project structure includes the following distinct steps: end-user survey, heuristic evaluation, end-user testing, and repeat end user survey. The end-user surveys will be assessed at the beginning and end of the project. These surveys will collect demographic and use information from current dashboard users (clinicians and staff), opinions on data accuracy, ease, and usability of current population management tools. The pre-survey will also ask the users if they would be willing to participate in user testing at a later date for comparative data. Following pre-survey, a heuristic evaluation will be done of selected population management tools. The heuristic evaluation is a detailed analysis and breakdown of the selected tools by usability and domain experts. A usability expert is a person who understands how these tools are supposed to be built, while a domain expert is a person who understands the underlying information the tools display. The heuristic analysis evaluates confirmation or violation of 14...
established heuristic principles from Zhang. During this phase common problems will also be identified by end-user testing. Design problems will be identified and resolved, and a post-survey will be sent to users to determine if the usability of the dashboards has improved.

**Results:** N/A

**Poster Title:** Evaluating the impact of clinical decision support tools to reduce chronic opioid dose and decrease risk classification in high risk veterans in VISN 21.

**Primary Author:** Shardool Patel, VA Sierra Pacific Network (VISN 21) and VA Sierra Nevada Healthcare System, NV; **Email:** shardool.patel@va.gov

**Additional Author (s):**

Janice Sanders  
Diana Higgins  
Jan Carmichael

**Purpose:** VHA and VISN 21 have implemented two clinical decision support tools (CDST) to address the impact of chronic opioid therapy (COT) on quality of life and adverse event risk. This study will identify high risk COT veterans and evaluate for the following outcomes before and after provider visits: 1) reduction in morphine equivalent daily dose (MEDD), 2) change in Risk Index for Overdose or Serious Prescription Opioid-Induced Respiratory Depression (RIOSORD) risk class, and 3) decrease in MEDD per RIOSORD risk class. Insight on the influence of two CDSTs to reduce chronic opioid dosing will be gained in this study.

**Methods:** This quality improvement project will retrospectively evaluate the impact of two CDSTs (COT – Clinical Reminder [COT-CR] and Stratification Tool for Opioid Risk Mitigation [STORM]) on decreasing opioid prescribing in high risk veterans. COT-CR correlates quality of life to current opioid regimen through a prompted pain assessment. STORM is an information-only tool which includes RIOSORD risk score and corresponding risk class. RIOSORD risk score is calculated using active pharmacotherapy profile and relevant diagnoses. Study subjects will be identified and queried through the VISN 21 data warehouse, comprising records from seven VHA medical centers. Preliminary queries have returned approximately 14,000 veterans meeting study inclusion criteria. High risk COT patients are defined using CDC guidelines and retrospective study data. An index date will separate the before and after provider visit timelines. Index date is defined as the completed COT-CR date or first appointment date after a COT-CR notification is generated. Each outcome will be measured at two time points: pre and 6 months post index date. Results for all high risk COT veterans, with and without a completed COT-CR, will be included to determine if reduction was more likely in the clinical reminder...
group. Evaluating decline in risk class and reduction in MEDD per risk class will shed light on whether priority to decrease opioids is based on higher risk classification.

Poster Title: Drug formulary, drug cost and effect on clinical practice; an evaluation of a large medical facility’s mental health prescribers

Primary Author: Patrick Stolz, VA Southern Nevada Healthcare System, NV; Email: patrick.stolz@email.wsu.edu

Additional Author (s):
Ted Turner
Dennis Chang

Purpose: Consideration of the medication costs in mental health drugs is important for managing healthcare resources efficiently and providing good patient care. For patients without insurance or co-pays, mental health medication costs have been shown to negatively affect medication compliance and are correlated with readmissions to psychiatric facilities. In 2003, a large medical facility in Oregon reported how provider discussions over costs played a role in reducing SSRI costs. The purpose of this study is to access awareness and the impact of medication costs on mental health providers’ decisions.

Methods: Mental health prescribers of the large medical facility will be administered an in-person survey assess current considerations toward medication costs and its effect upon clinical decisions. The survey will also assess provider knowledge of current medication costs, and what methods they would prefer to learn about current medication costs and the local and national formulary of the health system. Over the course of 2 months, meetings will be schedule with providers to administer the survey. Once all of the meetings have been completed, a 45 minute workshop will be held to show the results as well as educate provider about drug costs what tools and resources are available for them. For providers unable to attend the workshop, the provider will have the option to setup a personal meeting to review the workshop content. The workshop will be held in February, and the same survey will be repeated 1 month after

Poster Title: Impact of providing education to pharmacists and prescribers on Beers criteria: will it show a reduction in prescribing these medications?

Primary Author: Arnold Sano, VA Southern Nevada Healthcare System, NV; Email: amsano07@gmail.com

Additional Author(s):
Roseann Visconti
Travis Einertson

Purpose: Currently, Beers criteria is the gold standard for identifying potentially inappropriate medications in the geriatrics population. There have been studies that have shown the efficacy of therapeutic management in the geriatrics population. Prescribing inappropriate medications to the geriatrics population has been a problem for quite some time. This study is to provide education to the pharmacists and prescribers and to see if there will be a reduction in prescribing habits listed in the Beers criteria. This may lead to an implementation of a program which monitors medications on the Beers criteria.

Methods: The pharmacists and prescribers will receive a PowerPoint presentation on the potential harm of prescribing these types of medications. The patient population will be patients over the age of 65 who are seen by prescribers at a large medical facility. Prospective cohort design will be used to assess the reduction in prescribed medications on the Beers criteria. Geriatric patients who are taking the top prescribed medications at the large medical facility (omeprazole, terazosin, temazepam, pantoprazole, ibuprofen) will be pulled at random. Baseline number of patients will be recorded. Approximately 100 charts will be reviewed, interventions will be made and documented in the electronic medical record about a possible change in therapy, with the prescribers co-signing the notes. After all the interventions have been made and notes are co-signed by the prescribers, the number of interventions accepted will be observed.

Poster Title: Evaluation of patient empowerment tool targeted to high risk benzodiazepine population

Primary Author: Stanley Tran, VA Southern Nevada Healthcare System, NV; Email: stanleytran@gmail.com

Additional Author(s):
Alyssia Jaume
Roseann Visconti

Purpose: To evaluate the impact of a patient empowerment tool targeted to high risk benzodiazepine users

Methods: As part of a quality improvement project, patients receiving benzodiazepines and identified as high-risk for adverse drug events were mailed a letter describing side effects and dangers of chronically taking a benzodiazepine and encouraged to speak to their doctor about tapering their medication. Patients were identified from population health dashboards and defined as high risk if they received a chronic benzodiazepine and met one the following high risk criteria: dementia or post-traumatic stress disorder diagnosis, concurrent chronic opioid prescription, or age 75 or older. All patients receiving a letter will be included in this evaluation. Patients without a valid address, whose mail was returned, or without a baseline medication possession ratio will be excluded.

The primary outcome of this study is to observe a change in medication possession ratio 6 months after the letter was mailed. Secondary outcomes will include rate of benzodiazepine discontinuation in the cohort at 3 and 6 months, analysis of patient characteristics that may contribute to decreased benzodiazepine medication possession ratio, and a calculation of risk avoidance.

**Poster Title:** Improving the use of potentially teratogenic medications in women Veterans of child-bearing age receiving mental health care

**Primary Author:** Sara Schroedl, Veterans Affairs Sierra Nevada Health Care System, NV; **Email:** schroedlsam@gmail.com

**Additional Author (s):**
Heather Mooney
Kelley Krieger

**Purpose:** Veterans Affairs (VA) facilities are experiencing a demographic shift that includes more female Veterans, particularly younger females. These Veterans are now seeking care at VA facilities across the country, and the VA will be responsible for these Veterans during their reproductive years and beyond. The purpose of this project is to improve counseling and education for patients of child-bearing age who are prescribed and/or currently receiving potentially teratogenic medications without an active order for contraception. Additionally, emphasis will be placed on developing educational interventions and system tools to improve prescribing, counseling, and education for patients of child-bearing age.

**Methods:** Patients will be identified using a local clinical dashboard, which identifies female patients of child-bearing age who are currently prescribed a pregnancy category C, D, and/or X medication without an active order for some form of contraception. Prioritization will include those between the ages of 18 to 45 years, and those who receive care for a mental health condition at this facility. Patients identified will then be reviewed for education regarding safety during pregnancy and lactation, appropriateness of medications and potentially safer alternatives. These patients will be contacted by mental health pharmacists to provide education and make recommendations for contraception if appropriate. Patients will also be referred to women’s health services for further evaluation when necessary. Additional educational interventions will target health care providers regarding updated FDA guidance and available resources for safe prescribing in this patient population. System improvements will target documentation, which may include developing note templates to be utilized in the electronic medical record (EMR), clinical reminders, and tools for improved documentation to
include items such as non-VA contraception, pertinent procedure history, and education provided to patients.

**Poster Title:** Comparison of Enoxaparin and Dalteparin for the use of Perioperative Bridging in Hypercoagulable Patients Enrolled in Anticoagulation Clinic at Stratton VA  

**Primary Author:** Amanda Mogul, Albany Stratton VAMC, NY; **Email:** amanda.mogul@va.gov  

**Additional Author(s):**  
Margaret Stack  

**Purpose:** The CHEST guidelines for perioperative management of anticoagulation recommend use of unfractionated heparin, enoxaparin, and dalteparin for bridging. However there is insufficient data to recommend a preferred agent. Perioperative bridging is utilized to reduce risk of thrombotic events while holding warfarin. Patients with hypercoagulability are especially susceptible to thrombotic events. The purpose of this study is to analyze enoxaparin and dalteparin for perioperative bridging of hypercoagulable patients at the Stratton VA to determine if choice of regimen and dosing impacts outcomes. Ultimately, this study aims to determine if one anticoagulant regimen should be recommended over another for this high-risk group.  

**Methods:** This study is a retrospective chart review including all patients who received a bridging consult from 10/06/09-07/31/16, since the implementation of such consults at the Stratton VA. Included patients will be those with known or presumed hypercoagulable conditions. Patients who received bridging with an indication other than hypercoagulable state, including atrial fibrillation and mechanical valves, will be excluded. An electronic chart review will be performed on patients who meet inclusion criteria to collect pertinent data relating to bridging procedure and outcomes. Data collected will include hypercoagulable state, procedure type, anticoagulation agent and dose used, concomitant medications, pertinent labs, and outcomes including bleeding and thromboembolic events. Outcomes will then be analyzed to determine if choice of bridging regimen impacted outcomes.  

**Results:** Research in progress.  

**Conclusion:** N/A

Poster Title: Off-label Use of Trazodone and Mirtazapine in the Community Living Center (CLC)

Primary Author: Jamie Haase, James J Peters VA Medical Center, NY; Email: haase.jamie@gmail.com

Additional Author(s):
Rosina Stamati
Noor Fattouh
Jane Wong

Purpose: The purpose of this medication use evaluation was to assess the prevalence of and factors associated with off-label use of antidepressants in the CLC. The primary objective was to perform a drug regimen review for each resident of concomitant psychoactive medications and all medication side effect profiles. The secondary objective aimed to explore the efficacy of trazodone or mirtazapine for insomnia and the efficacy of mirtazapine for appetite stimulation.

Methods: The hospital’s computerized patient record system was used to perform a retrospective chart review of CLC residents who received at least one dose of trazodone and/or mirtazapine from July 2015 to June 2016. Residents were excluded for any of the following reasons: length of stay less than 30 days, palliative care admission, or indication other than insomnia or appetite stimulation. For the primary objective, medication administration records were reviewed for concomitant psychoactive medications and those received four weeks prior to initiation of trazodone or mirtazapine. For insomnia, the chart reviews specifically focused on antipsychotics, antidepressants, sedative hypnotics, benzodiazepines, and first generation antihistamines. Furthermore, for appetite stimulation, the charts were also reviewed for medications used as appetite stimulants (e.g. dronabinol, megestrol, dexamethasone). Additionally, Micromedex was used to review the side effect profiles of all medications administered during each resident’s respective evaluation period, specifically focusing on drowsiness, fatigue, weight gain, or appetite stimulant properties. For the secondary objective, geriatric psychiatry and primary provider notes were reviewed for a four week period after initiation for insomnia or a twelve week period after initiation for appetite stimulation for documentation of efficacy. Additionally, the number of nutrition notes and all recorded weights
were collected for mirtazapine, regardless of indication. Descriptive statistics were used to evaluate the data.

**Results:** During one year, 92.1% (35/38) of prescriptions for trazodone or mirtazapine were for an off-label indication. The average CLC resident in this evaluation was a geriatric male with an average stay of 772 days. A total of 16 patients were included for further analysis. On average, residents received nine concomitant medications. Overall, 50% (8/16) of residents received concomitant psychoactive medications, with 62.5% (5/8) of those residents receiving more than one psychoactive medication. The majority were antipsychotics and antidepressants. Several medications were reported in Micromedex to cause sedation, somnolence, and fatigue. A few were also reported to cause increased appetite or weight gain. Of note, three residents received zolpidem and two received melatonin prior to starting trazodone or mirtazapine. Only 18.2% (2/11) of geriatric psychiatry notes and 9.3% (7/75) of nurse practitioner notes described the efficacy of trazodone or mirtazapine. The majority 87.5% (7/8) of the mirtazapine residents had recorded weights. Overall, trends in recorded weights showed weight loss for all but one resident. There was no mention of discontinuing mirtazapine noted for any resident.

**Conclusion:** Our results provide insight into the prescribing patterns in the CLC regarding off-label use of trazodone and mirtazapine for insomnia and appetite stimulation. There was a high rate of off-label prescribing with multiple concomitant psychoactive medications and medications with potential side effects. Limited documentation on efficacy was available to justify continuation of the medications. Additionally, residents on mirtazapine showed a weight loss trend with no discontinuation for inefficacy. Therefore, education will be provided to the prescribers and nursing staff in the CLC on the importance of monitoring efficacy of trazodone and mirtazapine, and ultimately discontinuing the medications for treatment failure.
Purpose: Chlamydia trachomatis is a common sexually transmitted disease (STD) that can be treated with a single oral dose of azithromycin 1g. Effective strategies to combat the spread or recurrence of infections include partner referral by the patient or provider. The CDC recommends expedited partner therapy (EPT) as an alternative in which prescriptions or medications are provided to the patient for his/her partner(s). The purpose of this medication use evaluation was to determine if EPT decreased recurrent chlamydial infections. Overall chlamydial reinfection and STD infection rates, prescribing practices, clinical management, and counseling by providers at the institution were also assessed.

Methods: The institution’s computerized patient record system was used to perform a retrospective chart review of outpatient orders for azithromycin from July 2015 to June 2016. Patients were included if a prescription for azithromycin greater than or equal to 1g was received for a diagnosis of chlamydia. The primary outcome was the number of recurrent chlamydial infections within 12 months in those who received EPT. The secondary outcome was the number of chlamydial reinfections and STD infections within 12 months among the sample population. Patient specific time frames for evaluation started from the initial date azithromycin was dispensed to one year post-treatment. The appropriateness of dosing, patient-facilitated partner notification, repeat testing after treatment, and reported symptoms were also examined. Descriptive statistics were used to analyze the data.

Results: Of the 286 prescriptions reviewed, only 29 met inclusion criteria. According to the dose of azithromycin dispensed, 5/29 appeared to have received EPT; however, only one documented that partner therapy was prescribed without any subsequent reinfection within 12
months. Overall, 3/29 had documented recurrent chlamydial infections, all of whom received 1g. Two patients had documented gonorrheal infections within 12 months. As expected, most of the prescriptions for azithromycin were appropriately dosed; however, three of the 2g orders were written with instructions as a single dose. Provider documentation of advice for patient-partner(s) notification was found in 11/29 charts reviewed. Documentation of a repeat STD test within 12 months of treatment was found in 14/29 charts. The most commonly reported symptoms included discharge (7/33), painful urination (7/33), and other symptoms (3/33). Surprisingly, 13 charts had no documentation of symptoms and three patients were asymptomatic.

**Conclusion:** This medication use evaluation appears to demonstrate that EPT decreased recurrent chlamydial infections although only one instance of EPT was documented. Some patients treated with a single oral dose of azithromycin 1g were reinfected. Increase provider awareness of EPT and better documentation of advice for patient-partner(s) notification are warranted.

Poster Title: Evaluating the efficacy and tolerability of abiraterone acetate and enzalutamide in a veteran population

Primary Author: Karin Yamazaki, James J. Peters VA Medical Center, NY; Email: yamazaki.k@husky.neu.edu

Additional Author(s):
Rosina Stamati
Daniel Sarpong
Cassandra Youmans
Kristi Rapp

Purpose: The purpose of this medication use evaluation was to assess the efficacy and tolerability of abiraterone acetate (Zytiga) and enzalutamide (Xtandi) in veterans with metastatic castration-resistant prostate cancer at the medical center. The primary objective was to evaluate the PSA response rate, defined as the number of patients with at least a 50% reduction in PSA levels at four weeks after initiation of each agent. The secondary objectives were to assess the duration of therapy and report documented adverse drug events, reasons for treatment discontinuation, and subsequent therapies.

Methods: This medication use evaluation was a retrospective chart review using the Veteran Health Administration’s computerized patient record system. A computer-generalized list of all outpatient prescriptions for abiraterone acetate and enzalutamide from April 2011 through December 2015 was reviewed. Patients were included if they picked-up at least one prescription for either medication prior to December 2015. Patients were excluded if their primary oncologist practiced outside of the institution (characterized as dual-care patients), medication was initiated during hospital admission or continued from an outside facility, and if patients had a documented compliance issue in the progress note or were lost to follow-up. The non-formulary medication consults and outpatient hematology/oncology progress notes were reviewed to collect information such as patient demographics and clinical characteristics, prior therapies for prostate cancer, reported adverse drug reactions (ADRs), reasons for discontinuation, and subsequent therapies as of June 30, 2016. For patients who tried both abiraterone and enzalutamide, their response to each medication was assessed separately for
the purpose of reporting the study’s outcomes. Subgroup analyses were conducted to assess PSA response and duration of therapy in chemotherapy-naïve patients, chemotherapy-experienced patients, and in those who were treated with both abiraterone and enzalutamide.

**Results:** Of the 89 outpatient prescriptions screened, 32 (74.4%) abiraterone and 11 (25.5%) enzalutamide prescriptions were included in this evaluation. All (except one) enzalutamide patients had tried abiraterone prior to enzalutamide, and thus a total of 33 patients overall were included in this evaluation. Sixteen (50%) abiraterone patients achieved the primary endpoint, compared to 2 (18.2%) in the enzalutamide group. The mean duration of therapy for abiraterone and enzalutamide was 12.1 months and 6.1 months, respectively. The most common ADRs were: edema, weight loss, and fatigue with abiraterone, and fatigue, hypertension, and diarrhea with enzalutamide. One patient taking abiraterone was admitted to the hospital for congestive heart failure of unknown origin. Rising PSA was documented as the main reason for treatment discontinuation (63% abiraterone and 30% enzalutamide). For subsequent therapy, 40.7% of abiraterone patients who discontinued treatment tried enzalutamide, while 60% of enzalutamide patients went on to pursue supportive care. Half of both chemotherapy-naïve and experienced patients receiving abiraterone exhibited a PSA response at 4 weeks. In the enzalutamide group, 28.6% of chemotherapy-naïve patients and none of the chemotherapy-experienced patients achieved a response. Of the ten patients who tried both medications, 20% achieved a PSA response with enzalutamide.

**Conclusion:** At our institution, the majority of patients were treated with abiraterone first, followed by enzalutamide. Patients exhibited a more favorable response with abiraterone, as indicated by the higher rate of those achieving the primary endpoint and longer treatment duration. This may be due to its use earlier in the course of the disease or an acquired resistance predicting treatment failure with subsequent enzalutamide, as suggested in recent studies. Based on documentation in the outpatient hematology/oncology notes, most treatments were discontinued based on rising PSA only, which is not consistent with the VA criteria listed for use of each agent.

Poster Title: Evaluation of treatment outcomes after sustained virologic response in hepatitis C patients with cirrhosis or advanced fibrosis treated with interferon-free regimens
Primary Author: Andrew Aziz, James J. Peters VA Medical Center, NY; Email: andrew.aziz09@gmail.com
Additional Author(s):
Mei Chang
Kirsten Woelfel
Troy Kish
Stephen Kuczynski

Purpose: Prolonged inflammation of the liver due to chronic hepatitis C virus (HCV) infection can be associated with devastating outcomes, such as cirrhosis and hepatocellular carcinoma (HCC). Such complications can lead to increased rates of hospitalizations and increased mortality. Studies have demonstrated that complications are less frequent in patients who were successfully treated for HCV; however, most of this data is derived from patients treated with interferon (IFN)-based regimens. The objective of this retrospective review is to examine outcomes in patients with cirrhosis or advanced fibrosis after successful HCV eradication with IFN-free regimens.

Methods: A retrospective chart review was conducted, examining patients diagnosed with HCV, cirrhosis or advanced fibrosis, and who were successfully treated with an IFN-free regimen. Cirrhosis or advanced fibrosis was defined as a METAVIR score of F3 or greater obtained by transient elastography (FibroScan, Echosens, Paris, France). Treatment success was defined as sustained virologic response at 12 weeks (SVR12), plus or minus 2 weeks, post-treatment. Included patients required a minimum follow-up length of 365 days from SVR12 to time of data collection. Patients were excluded if they were diagnosed with HCC prior to treatment, had a history of hepatitis B co-infection, or were lost to follow-up after treatment. Endpoints included all-cause mortality, number of hospitalizations, number of hospitalizations directly attributed to liver disease, change in liver enzyme and liver function tests, proportion of patients with worsening fibrosis/cirrhosis, change in Child-Turcotte-Pugh (CTP) score, diagnosis of HCC post-treatment, and proportion of patients requiring liver transplantation post-treatment.
**Results:** Fifty two patients were included in the review (45 cirrhotic; 7 advanced fibrosis). Five (11%) of the 45 cirrhotic patients had symptoms of decompensation prior to treatment. The average length of follow-up from SVR12 was 514 days. Four (8%) patients had expired at the time of data collection; one patient’s cause of death was attributed to liver disease. Twenty (39%) patients were hospitalized at least once after SVR12 for a total of 32 separate hospitalizations. Eight (25%) of those hospitalizations were attributed to liver disease. There was a statistically significant decrease in aspartate transaminase and alanine transaminase levels (p < 0.001, p < 0.001, respectively), and increase in albumin and platelet levels (p < 0.001, p=0.035, respectively) after SVR12. There were no significant changes in alkaline phosphatase, total bilirubin, prothrombin time, or international normalized ratios. None of the patients with advanced fibrosis progressed to cirrhosis, while two (5%) patients with compensated cirrhosis progressed to decompensated cirrhosis after SVR12. The average CTP score was 5.4 pre-treatment and 5.5 after SVR12 (p=0.205). Only one patient was diagnosed with HCC after SVR12. No patients received nor are in consideration for a liver transplant.

**Conclusion:** Patients with cirrhosis or advanced fibrosis who were successfully treated with IFN-free regimens had a statistically significant decrease in aspartate transaminase and alanine transaminase levels, along with a significant increase in albumin and platelet levels. Risk for liver-related morbidity and mortality appears to be low; only one patient expired due to liver-related complications and only one patient developed HCC after SVR12. No significant change in CTP scores was observed. The results of this review quantify the benefits HCV eradication may have on patients with cirrhosis or advanced fibrosis successfully treated with IFN-free regimens.

**Poster Title:** Evaluation of chronic hepatitis C virus treatment failures with direct-acting antiviral regimens in veterans

**Primary Author:** Yasmin Saafan, James J. Peters VA Medical Center, NY; **Email:** saafany@gmail.com

**Additional Author (s):**
Rosina Stamati
Stephen Kuczynski
Mei Chang
Henry Poon

**Purpose:** Chronic hepatitis C virus (HCV) affects an estimated 3.3 million people in the United States. Data suggest that HCV infection has a higher prevalence among the veteran population as compared to the general U.S. population. In the past, treatment was largely dependent on interferon-based regimens, which are associated with numerous adverse events and suboptimal treatment success rates. The new direct-acting antivirals (DAAs) have modernized chronic HCV treatment with improved tolerability and sustained virologic response rates. The purpose of this study was to explore patient-specific factors that may contribute to the failure of HCV treatment with DAA regimens.

**Methods:** A retrospective chart review of all subjects at the James J. Peters VA Medical Center with hepatitis C virus (HCV) who had failed a DAA regimen was performed. Subjects that received prescriptions between January 2014 and March 2016 for the following DAA regimens, with or without ribavirin, were evaluated: elbasvir/grazoprevir, ledipasvir/sofosbuvir, ombitasvir/paritaprevir/ritonavir with or without dasabuvir, sofosbuvir with simeprevir, sofosbuvir with daclatasvir, or sofosbuvir with ribavirin. Failure of any DAA regimen, defined as failure to achieve a sustained virologic response (SVR) 12 weeks after completion of therapy, was a requirement for inclusion in the study. The exclusion criteria consisted of any antiviral regimen containing interferon or pegylated interferon and any subjects that expired before the end of treatment. Infectious disease clinic progress notes, imaging studies, and labs were analyzed through the electronic medical record. Pertinent data including previous history of failed treatment, HCV genotype, HCV RNA levels, liver function tests, diagnosis of
hepatocellular carcinoma, and history of polysubstance abuse were collected. Concurrent prescriptions for gastric acid-reducing agents were noted, as well as relevant drug-drug interactions. Descriptive statistics were utilized to analyze the results.

Results: The electronic medical records of 25 subjects that failed HCV treatment with DAAs were analyzed. Four of these subjects were excluded; two failed regimens containing pegylated interferon and another two expired before completion of therapy. Of the 21 subjects included, 12 received ledipasvir/sofosbuvir. Simeprevir with sofosbuvir, ledipasvir/sofosbuvir with ribavirin, and ombitasvir/paritaprevir/ritonavir with dasabuvir represented 5, 3, and 1 out of the 21 subjects, respectively. Eleven subjects experienced relapse of hepatitis C virus after achieving undetectable HCV RNA at the completion of therapy. Two subjects experienced breakthrough of HCV RNA during the course of therapy. Six subjects did not complete therapy due to perceived or reported adverse events from the DAA prescribed. Another two subjects were lost to follow up during treatment and unable to complete DAA therapy. All subjects evaluated had a Child-Pugh score of A at initiation of therapy and expressed genotype 1. Twelve subjects were treatment experienced and 9 were treatment naïve. Eight subjects had stage F4 cirrhosis and one subject had a diagnosis of hepatocellular carcinoma. Twenty patients had a positive history of polysubstance abuse. Four subjects had active prescriptions for omeprazole and ledipasvir/sofosbuvir concurrently.

Conclusion: Similarities among subjects that experienced HCV treatment failure on DAA regimens include polysubstance abuse and stage F4 cirrhosis. Several subjects reported adverse events from DAAs and subsequently discontinued therapy. Treatment failure with DAAs did not appear to be affected by past treatment experience. This evaluation offers some guidance for our providers when subjects are screened prior to initiation of DAA therapy to assess risk of DAA treatment failure.

**Poster Title:** Evaluating the effect of insulin delivery method on glycemic control in patients with type 2 diabetes in a veteran population

**Primary Author:** Liliana Argento, James. J Peters VA Medical Center, NY; **Email:** largeto9@gmail.com

**Additional Author (s):**
Rosina Stamati
Stephen Kuczynski
Michelle Mak

**Purpose:** The purpose of this medication use evaluation was to determine if the insulin delivery method impacts the change in A1c in insulin-naïve patients. The primary objective was to evaluate the change in A1c 12 months after initiation. The secondary objectives were to evaluate the number of hypoglycemic or hyperglycemic episodes documented in the patient charts and to assess the percentage of patients achieving an A1c of 9 percent or less.

**Methods:** This retrospective chart review was conducted to evaluate all outpatient prescriptions for basal insulin from July 2014 to June 2015. The basal insulins evaluated included insulins glargine and detemir. Insulin-naïve type 2 diabetic patients with a designated primary care provider at the facility, and receiving insulin therapy for a minimum of one year were included. Dual care patients and patients seen by a pharmacist from the primary care team or endocrine clinic were excluded. The study period was individualized starting from the date of insulin initiation followed forward for one year. The A1c upon insulin initiation was obtained and compared with the average A1c over one year. Documented hypoglycemic or hyperglycemic events were analyzed via a chart review of progress notes. Hypoglycemia was defined as blood glucose less than 70 mg/dL and hyperglycemia was defined as blood glucose > 200 mg/dL. In addition, the number of patients achieving an A1c of 9 percent or less was collected. Descriptive statistics were used to analyze the data.

**Results:** A total of 145 patients were included for evaluation. Of the 145 patients evaluated, 37 patients met the inclusion and exclusion criteria and were further analyzed. Twenty patients were initiated on insulin vials and 17 on an insulin pen. For the primary outcome, those
prescribed insulin vials and insulin pens experienced an average decrease in A1c of 1.9 percent and 2.1 percent respectively. For the secondary outcomes, 45 percent of the patients on vials and 41 percent of the patients on pens had a documented hypoglycemic or hyperglycemic event. Of the patients on vials and pens, 25 percent and 12 percent had a hospital admission respectively. An A1c greater than 9 percent was documented in 12 and 13 patients initiated on insulin vials and pens respectively. An A1c of less than 9 percent was achieved in 65 percent of patients on vials and 88 percent of patients on pens.

**Conclusion:** The results demonstrate that the delivery method of insulin did not have a significant impact on the change in A1c within one year of insulin initiation. Although patients on vials experienced more hospitalizations, the number of hypoglycemic and hyperglycemic events were comparable. However, more patients achieved an A1c of less than 9 percent in the insulin pen cohort. A longer follow up and a more interdisciplinary approach to treating diabetes may have had a greater impact on the results.
Purpose: This quality improvement project is to assess the necessity of bridging patients who have atrial fibrillation and whether we can improve patient outcomes by optimizing medication therapy. This study is based on two recent trials published in the New England Journal of Medicine and Circulation that have assessed forgoing anticoagulant bridging in patients who have atrial fibrillation after warfarin therapy interruption due to elective procedure. In both of these trials, the use of routine bridging was not supported by concluding data.

Methods: Patients will be identified using the medical center’s electronic medical records system. A retrospective chart review will be conducted on patients aged 18 years or older who are receiving warfarin therapy for atrial fibrillation in the outpatient anticoagulation and primary care clinics. The primary outcomes of this study are the number of patients who have had incidents of arterial thromboembolism, major bleed, or hospitalization within 30 days following elective procedure related to dosage of injectable anticoagulation therapy. Patients will be categorized into three different groups based on injectable anticoagulation therapy: prophylaxis, treatment, or no bridging.

**Poster Title:** Retrospective evaluation of oral hepatitis C medication therapy outcomes at Northport Veterans Affairs Medical Center  
**Primary Author:** Jason Lee, Northport Veterans Affairs Medical Center, NY; **Email:** jason.lee10a@gmail.com  
**Additional Author(s):**  
Diana Chen  
Sherry Badloo  

**Purpose:** Although, the new oral direct antiviral agents (DAA) are highly effective and well tolerated for hepatitis C treatment, lack of compliance and monitoring can contribute to hepatocellular complications, viral resistance, or need for additional therapy, significantly impacting healthcare or economic burden. This quality assurance project will assess and evaluate hepatitis C virus (HCV) therapy outcomes among the seven DAAs available (ledipasvir/sofosbuvir, ombitasvir/paritaprevir/ritonavir/dasabuvir, elbasvir/grazoprevir, daclatasvir, ombitasvir/paritaprevir/ritonavir, sofosbuvir, sofosbuvir/velpatasvir). The results from this study may demonstrate the need for more stringent monitoring and emphasize the vital role of clinical pharmacist involvement when prescribing DAAs at the medical center.  

**Methods:** Patients will be identified using the medical center’s electronic medical records system. A retrospective chart review will be conducted from October 1, 2015 to September 30, 2016. This study will include all outpatients with a documented hepatitis C virus (HCV) genotype, who have completed direct-acting antiviral (DAA) therapy prescribed by gastrointestinal (GI) or infectious disease (ID) providers. Patients will be excluded if they have a coinfection with human immunodeficiency virus, hepatitis B virus, if they did not complete therapy or could not obtain their HCV RNA levels by September 30, 2016. Successful therapy will be determined by sustained virologic response (SVR), defined as an undetectable HCV RNA, 12 weeks after the end of treatment. HCV therapy outcomes will be determined by rates of success or failure among the seven DAA agents. Contributing factors to therapy failure will be further assessed by rates of noncompliance, documented adverse drug reactions, drug-drug interactions, and loss of patient follow-up.

**Poster Title:** Use of vancomycin in Veterans’ Affairs patients who have previously experienced vancomycin-associated acute kidney injury (AKI): Predictors and outcomes of secondary vancomycin-associated AKI  

**Primary Author:** Ryan Sangiovanni, Stratton VA Medical Center, NY; **Email:** ryan.sangiovanni16@gmail.com  

**Additional Author(s):**  
Jenna Yager  
Alyssa Donadio  
Georgina Farrow  
Nimish Patel  

**Purpose:** Acute kidney injury (AKI) is a well-known exposure-related adverse effect of vancomycin. For these patients who require subsequent courses of vancomycin therapy, it is unclear if vancomycin is safe to utilize. Specifically, the incidence of secondary vancomycin-associated AKI is unclear. The objectives of this study were to 1) quantify the incidence of secondary vancomycin-associated AKI and 2) determine clinical/demographic risk factors associated with secondary vancomycin-associated AKI among Veterans’ Affairs patients who have previously experienced AKI during primary vancomycin usage.  

**Methods:** A retrospective cohort study was performed among patients receiving care in the Upstate New York Veterans’ Healthcare Administration (VISN-2). Inclusion criteria were: 1) age ≥ 18 years, 2) two courses of vancomycin therapy for ≥ 48 hours between 2000 and 2015, 3) had vancomycin serum concentrations within 5 days of initiating therapy, 4) experienced AKI during primary vancomycin therapy and 5) not receiving dialysis. Trained reviewers abstracted the following variables from patients’ electronic medical records: demographics, laboratory values, antibiotic therapy, concomitant nephrotoxic medication use, comorbidities, history of healthcare exposure, and course of hospitalization. Disease severity and underlying health status were captured using the Acute Physiologic Assessment and Chronic Health Evaluation (APACHE) II Scoring System and Charleston comorbidity index, respectively. Serum creatinine values were captured starting 5 days prior to each vancomycin usage through 10 days post-completion of therapy. Creatinine clearance was calculated using the Cockcroft Gault method.
All vancomycin serum concentrations were collected. To estimate the steady-state trough concentration and area under the concentration-time curve, a series of 5000-subject Monte Carlo simulations were performed. The main study outcome was the presence of AKI, defined as an acute rise in serum creatinine of ≥ 0.5 g/dL or a 50% decline in creatinine clearance

**Results:** In progress

Poster Title: Quality Assurance Alcohol Monitoring by Urine Ethyl Glucuronide Screen in Patients Receiving Chronic Opioid Therapy (COT)

Primary Author: Lisa Dragic, Stratton VA Medical Center, NY; Email: drlisadragic@gmail.com

Additional Author(s):
Jeffrey Fudin

Purpose: Urine Drug Screening is an important risk mitigation tool when monitoring COT consistent with various guidelines. [1-5] SAMHSA’s Drug Abuse Warning Network identified 438,718 opioid-related emergency department visits of which 81,365 (18.5%) involved alcohol. Of almost 4000 opioid-related deaths, 22.1% involved alcohol. These statistics support alcohol monitoring with the standard immunoassay panel for patients on COT. Our purpose is to enhance patient safety, and prospectively minimize opioid risks by employing ethyl glucuronide testing. Laboratory findings will be used to ensure appropriate alcohol counseling, COT and other sedative-hypnotic dose reduction or elimination, and to support routine alcohol testing routinely.

Methods: This quality assurance project will be conducted at the Samuel S. Stratton VA Medical Center. All chronic non-cancer patients receiving chronic opioids should have consented to urine drug monitoring, including alcohol, according to VA policy in accordance with the nationally approved “Consent for Long-term Opioid Use”. All non-cancer patients within the last 6 months that received COT (≥3 months) plus or minus a benzodiazepine will be screened and included in the study. Additionally, the study will sequester data for opioid-consent forms, previous ethyl glucuronide urine testing, and urine drug screening within the last year. All opioids will be included except for buprenorphine of any type, tramadol, butorphanol, or pentazocine. 347 patients have been identified as potential candidates for routine monitoring for alcohol use by ethyl glucuronide urine testing. This study will identify patients receiving chronic opioid therapy missing up-to-date signed Consent for Long-term Opioid Use, track which patients have been monitored for alcohol use by ethyl glucuronide, and ensure that such patients have an order for such monitoring. Additionally, urine drug screens will be updated if the patient did not have one within the last year.

**Poster Title:** Comparison of stroke, embolism, and bleeding in veterans treated with direct oral anticoagulants for nonvalvular atrial fibrillation to rates reported in RE-LY, ROCKET-AF, and ARISTOTLE

**Primary Author:** Lillian Brennan, Syracuse Veterans Affairs Medical Center, NY; **Email:** lillian.brennan@va.gov

**Additional Author (s):**
Michael Schmidt

**Purpose:** Use of direct oral anticoagulants (DOACs) in veterans has increased over the past five years with their approval to the national formulary. While their efficacy and safety endpoints have been well documented in clinical trials, the populations represented in these trials often differ from the veteran population. This project was designed to compare the event rates of stroke, embolism, and major bleeding in veterans treated with a DOAC for nonvalvular atrial fibrillation (NVAF) to the event rates reported in the three major DOAC clinical trials RE-LY, ROCKET-AF, and ARISTOTLE.

**Methods:** This will be a retrospective chart review of veterans treated with a DOAC for NVAF between the dates of 12/01/2010 to 08/30/2015. Patients who received the following DOACs will be included in the study; Dabigatran, Rivaroxaban, and Apixaban. Patients treated with a DOAC for an indication other than NVAF will be excluded. To compare baseline characteristics of the veteran population to the trial population, the following data will be collected; age, sex, race, weight, height, BMI, serum creatinine, CHA2DS2VaSc/CHADS2, DOAC dose, directions, and duration, and use of Aspirin, P2Y12 inhibitors, or NSAIDs. The efficacy endpoint will be a composite of stroke and embolism events including ischemic and hemorrhagic stroke, transient ischemic attack, deep vein thrombosis, and pulmonary embolism. The safety endpoint will be major bleeding events, defined as a clinically overt bleed involving a critical anatomic site, fall in hemoglobin less than 2 g/dl, or transfusion of greater than 2 units. The mean and median of the veteran baseline characteristics will be calculated using descriptive statistics. The rate of events per patient per year will be calculated for the efficacy and safety outcomes. These results will be compared to the results reported in the RE-LY, ROCKET-AF, and ARISTOTLE trials.

**Poster Title:** Impact of antidepressants on dosing of concomitant opioids and benzodiazepines

**Primary Author:** Mark Mann, Syracuse Veterans Affairs Medical Center, NY; **Email:** mcmann3@buffalo.edu

**Additional Author(s):**
Kristen Franklin  
Kyle Hacker  
Christopher Wallen

**Purpose:** The Food and Drug Administration will soon require boxed warnings on opioid and benzodiazepine labeling with information detailing the risks associated with using these medications at the same time. The objective of this study is to assess factors that may lead to decreased dosing of opioids and benzodiazepines in veterans. The study will determine the extent to which antidepressant use impacts daily dosing equivalents of concurrent opioids and benzodiazepines and whether outcomes in dosing are affected by the type of providers that are generating the antidepressant and benzodiazepine prescriptions.

**Methods:** A survey of 200 veterans who received at least two outpatient prescriptions for both an opioid and a benzodiazepine in the 90 days preceding the cohort collection date will be identified. Data collected will include identification of an antidepressant prescription filled for a minimum of a 30-day supply during the 90 days preceding the collection date. Data will also include identification of the providers that generated the antidepressant and benzodiazepine prescriptions. Subjects will be assigned to two cohorts based on presence or absence of an antidepressant prescription. Diazepam equivalent daily dose and morphine equivalent daily dose will be calculated for each subject’s daily benzodiazepine and opioid dose. Daily equivalent doses will then be compared between the two cohorts. Antidepressant and benzodiazepine prescriptions will be assessed according to whether they were generated by behavioral health or primary care providers. Average daily doses of opioids and benzodiazepines will be compared between subjects based on whether the antidepressant and benzodiazepine prescriptions were generated by primary care or behavioral health providers. Data from the study will be used to formulate recommendations when the pharmacy is required to sign off on concurrent opioid and benzodiazepine orders.

Poster Title: Medication use evaluation of pregabalin three times daily (TID) within a Veterans Affairs (VA) medical facility

Primary Author: Taryn Mondiello, VA Hudson Valley Health Care System, NY; Email: mondiellot@gmail.com

Additional Author(s):
Karen Park
Rita Bodine

Purpose: Pregabalin has multiple Food and Drug Administration (FDA) approved indications, and is dosed either twice daily (BID) or three times daily (TID) depending on the indication. Pregabalin is a flat-priced medication. The FDA approved dosing of pregabalin is TID for diabetic peripheral neuropathy (DPN), BID or TID for postherpetic neuralgia (PHN) or adjunctive therapy for adult patients with partial onset seizures, and BID for fibromyalgia or neuropathic pain associated with spinal cord injury. The purpose of this study was to evaluate appropriateness of the TID dosing schedule based upon indication for use and to identify potential for cost avoidance.

Methods: A retrospective chart review was conducted at a Department of Veterans Affairs (VA) medical facility. Veterans with an active outpatient prescription for pregabalin TID on June 29, 2016 were included in the study. Data was collected on the indication for use and analyzed to determine the appropriateness of the TID dosing schedule.

Results: A total of 33 Veterans prescribed pregabalin TID were identified. Eleven Veterans (33.3%) had a documented indication for DPN. None of these Veterans were prescribed pregabalin for PHN or adjunctive therapy for partial onset seizures. The remaining 22 Veterans (66.7%) were prescribed pregabalin for varying off-label indications, including: non-diabetes-associated neuropathic pain (24.2%), lower back pain (6.1%), peripheral nerve disease cervicalgia (6.1%), dysesthesia (6.1%), unspecified pain (6.1%), post laminectomy syndrome (6.1%), radiculopathy (6.1%), spinal stenosis (6.1%), syringomyelia (6.1%), thalamic pain (6.1%), traumatic amputation (6.1%), and trigeminal neuralgia (6.1%). Two Veterans (6.1%) had active
prescriptions for two capsules per dose rather than one capsule per dose when that strength was commercially available.

**Conclusion:** Eleven Veterans (33.3%) had appropriate TID dosing schedules for their prescribed indications. There may have been opportunity to treat 22 Veterans (66.7%) with pregabalin BID dosing and a potential for cost avoidance. There was also a potential for cost avoidance for 2 Veterans (6.1%) who were prescribed two capsules per dose. Now that pregabalin is included on the VA National Formulary, measures are underway at this medical facility to aid prescribers in selecting the appropriate FDA approved pregabalin dosing schedule based upon indication.

Poster Title: Evaluating the appropriate use of clotrimazole topical solution

Primary Author: Rachel Quinn, VA Hudson Valley Health Care System, NY; Email: rachel.quinn@va.gov

Additional Author(s):
Karen Park
Rita Bodine

Purpose: Onychomycosis and tinea pedis are common fungal infections. The first-line treatment for onychomycosis is oral terbinafine, which is associated with a higher cure rate and a shorter duration compared to topical therapy. The first-line treatment for tinea pedis is topical anti-fungal medications. Clotrimazole, an anti-fungal medication is available as a topical product, where the duration of treatment should not exceed four weeks. The utilization of clotrimazole topical solution at a Department of Veterans Affairs medical facility is increasing and associated with significant healthcare costs. This study was designed to evaluate the appropriateness of clotrimazole topical solution prescribing.

Methods: A retrospective chart review was performed of outpatient clotrimazole topical solution orders dispensed between January 1, 2016 and June 30, 2016. A seven percent randomized sample was selected and evaluated to determine the appropriateness of clotrimazole topical solution prescribing, including indication, dosing frequency, duration, and prescriber. Appropriateness was assessed according to four medical databases, which were Lexicomp, Micromedex, Up-To-Date, and Dynamed.

Results: Seven hundred and twenty-two clotrimazole topical solution orders were identified and fifty orders were randomly selected for evaluation. Thirty-six (72 percent) patients were prescribed clotrimazole solely for onychomycosis, one (2 percent) patient solely for tinea pedis, ten (20 percent) patients for both onychomycosis and tinea pedis, and three (6 percent) patients did not have a documented indication. Fifty (100 percent) patients were prescribed clotrimazole at the appropriate dosing frequency of twice daily. Thirty-three (66 percent) patients were found to be inappropriately prescribed clotrimazole topical solution for a duration greater than four weeks. Forty-seven (94 percent) patients were followed by podiatry,
while only three (6 percent) patients were followed by primary care. The three patients that were followed by primary care were also the same patients that did not have a documented indication.

**Conclusion:** At a Department of Veterans Affairs medical facility, clotrimazole topical solution is primarily being prescribed for the treatment of onychomycosis, despite the availability of other first-line medications that offer shorter treatment courses, higher cure rates, and fewer relapses. In addition, clotrimazole topical solution is often prescribed for a longer duration than is recommended. To reduce the inappropriate prescribing of clotrimazole topical solution, steps have been proposed at a Department of Veterans Affairs medical facility to limit refills/renewals on these orders and ensure that the patient returns for follow-up.

Poster Title: Medication use evaluation of inpatient medication tablet-splitting within a Veterans Affairs (VA) medical facility

Primary Author: Catherine Knapp, VA Hudson Valley Healthcare System, NY; Email: catherine.knapp@va.gov

Additional Author (s):
Karen Park
Rita Bodine

Purpose: Tablet-splitting is a practice where tablets of higher strength are broken in half, or quarters, to provide lower doses for patients. This allows for a larger array of medication doses and may allow for improved patient care by facilitating titration and/or customized dosing. Furthermore, studies have shown that medication costs can be substantially reduced by implementing tablet-splitting strategies. However, ASHP encourages limiting medication dose manipulations to reduce errors due to order misinterpretation, in addition to concerns with variability of tablet fragments. The objective of this study is to evaluate the clinical appropriateness of inpatient medication tablet-splitting.

Methods: A retrospective chart review was conducted at a VA medical facility of all inpatient medication orders for half-tablet and quarter-tablet medication doses between August 1, 2015 and August 1, 2016. Data collected included the medication and dose administered to each unique patient, time of administration, inpatient unit, as well as patient demographics. Furthermore, orders were analyzed to determine the appropriateness of medication tablet-splitting, including: indication, previous dosing history, and justification. Clinical justification of medication tablet-splitting is categorized into three categories: no documented justification, clinical justification with supporting evidence, and clinical justification without supporting evidence. Medications provided as half-tablet or quarter-tablet doses were evaluated for tablet-splitting suitability through physical characteristics of the tablets, scoring and size of the tablet, as well as if the medication is considered to have a narrow therapeutic index.

Poster Title: Overutilization of omeprazole for the treatment of gastroesophageal reflux disease (GERD) at the New York Harbor Healthcare System

Primary Author: Caitlyn Bloom, VA New York Harbor Healthcare System, NY; Email: caitlyn.bloom@gmail.com

Additional Author(s):
Mary Ku
Charles Sharkey

Purpose: Proton pump inhibitors (PPIs) are commonly used at higher doses and/or for a longer treatment duration than recommended without appropriate follow-up. Recent medical journals and research have shown long-term use of PPIs may be associated with hip fractures, osteoporosis, community acquired pneumonia (short-term use), Clostridium difficile colitis, spontaneous bacterial peritonitis in patients with decompensated liver disease, increased risk of myocardial infarction, chronic kidney disease, and dementia. The primary objective of this study is to determine the overutilization of omeprazole for the treatment of GERD in an outpatient Veterans Affairs (VA) setting.

Methods: This study is pending approval by the Institutional Review Board. This is a retrospective, computerized database (CPRS) review with de-identified, summative data. All data will be password-protected behind a firewall on secured VA servers. Data will be collected from outpatient electronic medical records. The study will evaluate the incorrect usage of omeprazole in 100 subjects from October 1, 2015 to March 31, 2016. Incorrect usage is defined as exceeding the Food and Drug Administration (FDA) recommended dosage and/or duration of treatment for GERD without a referral to a gastroenterologist (GI) specialist after initial treatment. The dosage, duration of treatment, and GI consult will be recorded and evaluated based on the current FDA approved uses of omeprazole. Inclusion criteria are male and female subjects 18 years of age or older, treated at the VA as an outpatient, taking omeprazole with the diagnosis of GERD, and having at least a 90 day fill or 30 day fill plus one refill within 8 weeks. Exclusion criteria are noncompliance (2 nonconsecutive fills), omeprazole filled at a Non-VA facility, switched from a different PPI to omeprazole, and patients with active duodenal
or gastric ulcer bleed, erosive or Barrett’s esophagitis, pathological hypersecretory conditions, or Helicobacter pylori eradication.

Poster Title: Evaluation of appropriate empiric antibiotic prescribing in a United States veteran population with extended-spectrum beta-lactamase (ESBL)-positive urinary tract infection (UTI)

Primary Author: Wai In Lim, VA New York Harbor Healthcare System, NY; Email: wai.lim@va.gov

Additional Author (s):
Elizabeth Chung
Charles Sharkey

Purpose: Urinary tract infections (UTI) are commonly seen in the inpatient and outpatient settings. Some of the antimicrobial agents that are routinely prescribed to treat UTI are becoming resistant. The emergence of antibiotic resistance is occurring worldwide. It is causing more severe infections, complications, longer hospital stays, healthcare costs, and increased mortality. The overuse and inappropriate use of antibiotics are associated with antibiotic resistance and adverse effects. The purpose of this study is to evaluate the appropriateness of empiric antibiotic therapy in patients with extended-spectrum beta-lactamase (ESBL)-positive urinary tract infections in a Veterans Affairs (VA) setting.

Methods: This study is pending approval from the Institutional Review Board. This will be a retrospective, computerized chart review study performed within the Veterans Affairs (VA) setting. 100 patients with a documented ESBL-positive UTI from June 2015 to June 2016 will be evaluated. The primary objective is to evaluate the appropriateness of empiric antibiotic therapy in patients with ESBL-positive urinary tract infections. The secondary objective is to examine the time to tailor the antibiotic regimen. Appropriate empiric antibiotic therapy is defined by prescriber selection of the correct empiric medication, dose, and duration of therapy. Antibiotic selected will be assessed to determine appropriateness whether it was narrowed/modified based upon previous culture results. The number of days to tailor antibiotic regimen will be assessed as well. Patients with asymptomatic bacteriuria who received antibiotics will also be reviewed for appropriateness. Asymptomatic bacteriuria is defined as an isolation of specified quantitative count of bacteria (at least 105 cfu/mL in 2 consecutive voided urine specimens in women or 1 urine specimen in men, or at least 102 cfu/mL of 1 catheterized urine specimen in men or women), in absence of clinical signs and symptoms suggestive of UTI.
Inclusion criteria are male and female subjects 18 years and older, with a documented diagnosis of ESBL-positive UTI. Exclusion criteria are patients who are in the intensive care unit, on hemodialysis, or chemotherapy.

Poster Title: Factors predictive of relapse in patients treated for alcohol use disorder (AUD) in the substance use disorder medication management clinic

Primary Author: Michele Summerville, VA WESTERN NEW YORK HEALTHCARE SYSTEM, NY; Email: msummerv@gmail.com

Additional Author (s):
Judith Hyatt

Purpose: Alcohol use disorder (AUD) is a chronic relapsing disorder that is a significant contributor to injuries and chronic diseases including hypertension, heart disease, liver disease, cancers, and mental health conditions. Relapse is a common outcome for patients in treatment for AUD There are a variety of factors that may contribute to the likelihood of relapsing. The AUD Medication Management Clinic was established in 2014 to provide medication therapy for patients with AUD already engaged in individual or group counseling. This retrospective chart review aims to identify factors that may contribute to relapse in this population.

Methods: Veterans included in the analysis must be at least 18-years of age and must have been enrolled in the AUD Medication Management Clinic between October 2014 and August 2016. They must have had at least one month of treatment (at least one naltrexone long-acting injection or at least a 30-day supply of oral medication). Patients being treated for opioid use disorder will be excluded. A retrospective chart review will be performed using the electronic medical record. The dependent variable to be assessed is relapse (yes/no) and independent variables that will be evaluated as potential risk factors include age, sex, race, mental health diagnosis, treatment for mental health diagnosis, Brief Addiction Monitoring (BAM) total score and individual components, AUD treatment medication, medication adherence, duration of AUD (years), number of previous relapses, comorbid medical conditions, completion of 28-day program, completion of 90-day program, polysubstance abuse, support system, and ongoing counseling. Chi square analysis will be used to evaluate relationships between the dependent variable, relapse, and the various independent variables (broken out categorically). If sufficient data exists, logistic regression analysis will be used to determine the relationships between the various independent variables and the dependent variable. Significance will be accepted at p <
0.05. Length of therapy prior to relapse will be reported to determine whether there are differences in time to relapse with the different medication therapies.

Poster Title: Returning patients to primary care for ongoing depression management following treatment in a psychiatric pharmacy medication management clinic at VA Western New York Healthcare System

Primary Author: Taylor Ramsdell, VA Western New York Healthcare System, NY; Email: taylor.ramsdell@va.gov

Additional Author(s):
Judith Hyatt

Purpose: Veteran access to mental health treatment has been a significant problem. At our institution, patients are often referred to psychiatry by primary care providers (PCPs) for treatment of depression, increasing treatment access problems. The Psychiatric Pharmacy Patient Aligned Care Team (PACT) Medication Management Clinic (PPPMMC) was implemented to increase Veteran access to medication therapy for depression. This clinic is a collaboration of psychiatric pharmacists and PACT providers. Patients are referred to the clinic with a goal of stabilization and return to their PCP for ongoing depression medication management within 16 weeks of starting therapy.

Methods: Veterans are referred to the PPPMMC by PCPs or mental health professionals in PACT, but are not always returned to their PCPs for ongoing antidepressant therapy within 16 weeks of initiating treatment. The purpose of this retrospective chart review is to determine factors associated with probability of returning Veterans to their PCP within 16 weeks. Veterans enrolled in the PPPMMC between August 2013 and August 2016 will be included if they had at least one follow-up visit within 16 weeks of the initial appointment. Chi square analysis will be used to determine factors predictive of the outcome, return to PCP (yes or no). The independent variables to be evaluated include patient demographics (age, sex, race), misdiagnosis at time of referral, current treatment resistance (non-response to two different antidepressants), noncompliance with medication (medication possession ratio less than 80 percent), noncompliance with follow-up appointments (attending less than 80 percent of scheduled visits), Patient Health Questionnaire-9 (PHQ-9) total and individual component scores, use of other psychotropic medications, number of previous antidepressant trials, substance abuse, comorbid medical and psychiatric conditions, psychotherapy, and
inappropriate continuation of services in the PPPMMC once stabilized. Continuous independent variables will be broken into categories. If sufficient data exists, logistic regression analysis will be used to determine the relationships between the independent variables and the dependent variable with significance accepted at p-value less than 0.05.

Poster Title: Evaluation of Skin and Soft Tissue Infections in Hospitalized Veterans

Primary Author: Brittany Cieri, VA Western New York Healthcare System, NY; Email: brittany.cieri@va.gov

Additional Author(s):
Erin Conway
Hesha Desai
John Sellick
Kari Mergenhagen

Purpose: This retrospective study aims to evaluate appropriateness of antibiotic treatment and duration as well as significant predictors of treatment failure of skin and soft tissue infections of inpatients treated in a Veteran’s Affairs hospital. Secondary outcomes include the impact of age and obesity on treatment outcomes as well as to compare length of stay, treatment duration, and re-admission rates pre-stewardship and post-stewardship.

Methods: Patients aged 18-89 years old with an ICD-9 and ICD-10 code of cellulitis, abscess, mixed (cellulitis and abscess), erysipelas, acute lymphadenitis, and necrotizing fasciitis from January 1, 2005-July 1, 2016 will be included. The diagnosis will be confirmed via retrospective chart review and each patient will be included only on the first admission if multiple admissions were noted. Baseline characteristics, comorbidities, severity of illness, and risk factors will be compared using a bivariate model. Categorical data will be analyzed using the chi-square test whereas continuous data will be analyzed using the student’s t-test. Significant factors will be built into a multivariate logistic regression model to determine the impact of variables on primary and secondary outcomes.

**Poster Title:** Survey of bacteremia and endocarditis in a veterans affairs hospital

**Primary Author:** Kyle Polanski, VA Western New York Healthcare System, NY; **Email:** kyle.polanski@va.gov

**Additional Author (s):**
Alex Tito
Fiona Cheung

**Purpose:** The diagnosis of bacteremia is often associated with increased length of hospital stay, morbidity and mortality among hospitalized patients. Some studies have reported gram-negative bacteremia to have a mortality rate ranging from 27-38 percent while other studies note a mortality of 10-30 percent in patients with Staphylococcus aureus bacteremia. By providing a survey of the incidence of bacteremia and endocarditis, we hope to determine if there is a correlation between population shifts in the types of the bacteremia and identifiable risk factors that may be associated with the diagnosis of endocarditis.

**Methods:** This retrospective cohort study will evaluate bacteremia and endocarditis in adult patients that were admitted to the Veterans Affairs Western New York Healthcare System during the years 2005 to 2016. The primary objective of this study is to identify the types and frequency of bacteremia and endocarditis. Secondary objectives include a comparison between pre and post antimicrobial stewardship implementation on patients’ length of hospital stay, time to discontinuation of antibiotic therapy, readmission rates, mortality, and patient outcomes. Bivariate analysis will be used to determine the difference between success and failure for each of the outcomes. Significant factors will be built into a multivariate logistic regression analysis. For durations of treatment, a least squares regression will be utilized.

Poster Title: Retrospective evaluation of Clostridium difficile infections in a veterans affairs hospital

Primary Author: Michael Mauri, VA Western NY Healthcare System, NY; Email: michael.mauri1@va.gov

Additional Author (s):
Erin Conway
Kari Kurtzhalts
Kari Mergenhagen

Purpose: C. difficile contributes to significant morbidity and mortality in hospitalized patients. There is reported evidence that the C. difficile polymerase chain reaction may over report true cases, when correlated clinically. The objective of this study is to compare the prevalence of active clinical C. difficile infection vs polymerase chain reaction positive C. difficile. Secondary objectives are to determine the impact of stewardship on C. difficile and to investigate various risk factors for C. difficile.

Methods: A retrospective cohort study of veterans with C. difficile infection between January 1st, 2006 and July 1st, 2016 will be performed. The primary endpoint will be to determine the incidence of polymerase chain reaction positive C. difficile without active clinical disease. Secondary endpoints include evaluating the impact of stewardship on C. difficile infections and determining risk factors for development of C. difficile. C. difficile will be defined as diarrhea plus a positive C. difficile test. Diarrhea is defined as 3 or more bowel movements or at least 600mL of rectal or colostomy output within 24 hours. Data collected will include baseline demographics, current and previous antibiotics received within the last 30 days, allergies, prior laxative use, and diarrhea. Descriptive statistics, percentages, and time series analysis will be performed. Significant factors will be built into multivariate logistic regression analysis to determine the risk factors for C. difficile. This retrospective cohort study has been approved by the local Veterans Affairs Institutional Review Board.

Poster Title: A Retrospective Review of the Impact of the Socioeconomic and Psychosocial Factors on Success Rates of Hepatitis C Treatment

Primary Author: Maria Janda, Western New York VA Healthcare System, NY; Email: maria.janda@va.gov

Additional Author(s):
Amy Horey
Kari Kurtzhals
Kari Mergenhagen

Purpose: This study is a retrospective evaluation of psychosocial and socioeconomic factors in patients who received hepatitis C treatment through the Hepatitis C Clinic at a Veterans Affairs healthcare system. The purpose is to identify modifiable psychosocial or socioeconomic factors that can negatively impact hepatitis C treatment success. Mitigating such factors may contribute to increase chance of achieving sustained virologic response in the veteran population.

Methods: A retrospective chart review will be performed through the electronic medical record on patients who were initiated on hepatitis C treatment. Baseline data will be collected regarding patient demographics, comorbidities, baseline liver function, hepatitis C infection characteristics, and treatment regimens received. Socioeconomic and psychosocial characteristics will also be determined through review of provider and social work notes. Compliance throughout treatment will be assessed through review of provider notes. Finally, the end of treatment response and sustained virologic response, ≥12 weeks after the completion of treatment, will be assessed through detection of a hepatitis C viral load.

Poster Title: Evaluation of prescribing practices in complicated outpatient urinary tract infections

Primary Author: Sara DiTursi, Western New York Veterans Affairs Healthcare System, NY; Email: saraditu@buffalo.edu

Additional Author (s):
Kari Mergenhagen
Jennifer Schroeck
Erin Conway

Purpose: Urinary tract infections (UTIs) remain one of the most common infections diagnosed in the United States in both the inpatient and outpatient settings. By definition, UTIs that occur in males are considered complicated, making these patients challenging to treat. This study will evaluate the appropriateness of antibiotic selection and determine significant predictors of appropriate treatment in UTIs in outpatient males. The purpose is to determine what factors are significant in driving inappropriate treatment in order to provide more data related to the outpatient treatment of UTIs in this population.

Methods: A retrospective chart review will be conducted to review the appropriateness of antibiotic selection and determine significant predictors of appropriate treatment in outpatient males with urinary tract infection. Secondary outcomes include the prevalence of various microbes, frequency of treatment in asymptomatic patients, duration of treatment, occurrence of adverse events and presence of imaging studies. Data will be retrospectively obtained the Computerized Patient Record System (CPRS). The years to be studied include 1/1/2005 to 7/1/2016. Baseline characteristics, baseline comorbidities, severity of illness and risk factors will be compared in a bivariate model. Significant factors will be built into a multivariate logistic regression model to determine the impact of variables on the primary outcome. Duration of therapy will be analyzed via least squares regression model to determine if there is a difference in all cause failure.

Poster Title: Decreased mortality in patients prescribed vancomycin after implementation of a stewardship program

Primary Author: Erin Conway, Western New York Veterans Affairs Healthcare System, NY; Email: erin.conway3@va.gov

Additional Author(s):
Amy Horey
Kristen Fodero
John Sellick
Kari Mergenhagen

Purpose: The purpose of this study was to evaluate the impact of an antimicrobial stewardship program on patient outcomes, specifically 30-day mortality, in patients prescribed vancomycin in a Veterans Affairs hospital. Literature evaluating the impact of antimicrobial stewardship has demonstrated importance in areas of resistance, cost savings, avoidance of adverse drug reactions, and toxicity of antibiotics. Mortality is a measurable objective that may shed light on additional benefits in terms of clinical outcomes from antimicrobial stewardship programs.

Methods: This was a retrospective chart review of patients, aged 18 to 89 years old, whom received a minimum of 48 hours of vancomycin at the Western New York VA Healthcare System in Buffalo, New York during the time period of October 1, 2006 to July 1, 2014. Data collection included baseline demographics, Charlson Comorbidity Index, admitting service, indication for treatment, microbiology, total duration of treatment, initial and maximum vancomycin trough, total length of stay and readmission to hospital within 30 days. A bivariate analysis were used to compare patients who died and those who survived within 30 days of vancomycin treatment. A second analysis was done to compare pre-antimicrobial stewardship program and antimicrobial stewardship program patients. Significant factors (p-value less than 0.05) from the bivariate analysis were built into a multivariate logistic regression analysis to determine impact of antimicrobial stewardship program on mortality. Results were presented as odds ratio with a 95% confidence interval.
**Results:** This study included 453 patients of which death occurred in 12.4% (56 patients). Of the 56 mortality events, 64.3% occurred during pre-stewardship years versus 35.7% during the stewardship years (p-value = 0.021). In a multivariate logistic regression, increased mortality was associated with pre-antimicrobial stewardship program years (OR 2.17; 95%CI 1.13-4.27), age (unit OR 1.08; 95%CI 1.05-1.12), nephrotoxicity (OR 3.24; 95%CI 1.27-8.01), and hypotension (OR 3.28; 95%CI 1.42-7.44). Patients treated in the intensive care unit were 3.5 times more likely to experience mortality when compared to medical patients. Medical patients were 7.4 times more likely to experience mortality when compared to surgical patients. Lastly, intensive care unit patients were 26.3 times more likely to experience mortality when compared to surgical patients.

**Conclusion:** Mortality in patients treated with vancomycin was decreased after antimicrobial stewardship was implemented. As to be expected, older age, hypotension, nephrotoxicity, and intensive care unit admission were associated with increased incidence mortality. Although they were non-concurrent time frames, this study demonstrates another potential benefit of antimicrobial stewardship programs.

**Poster Title:** Patient satisfaction of pharmacist provided care via clinical video teleconferencing

**Primary Author:** Jessica Hatton, CareSource, OH; **Email:** hattonja@mail.uc.edu

**Additional Author (s):**
Rachel Chandra  
David Lucius  
Elizabeth Ciuchta

**Purpose:** Patient satisfaction with the use of telehealth in disease state management provided by pharmacists has not been fully studied. We hypothesized that patient satisfaction with pharmacist-provided consultations via clinical video teleconferencing (CVT) would not differ from face-to-face delivery.

**Methods:** Patients were recruited from two primary care provider sites from September 2015 to May 2016. Patients completed a survey to evaluate their satisfaction and quality of provider-patient communication with the method in which consultation with a pharmacist was provided. The survey was a 10-item, patient-self reported questionnaire. The primary outcome evaluated patients’ scores on assessment of the provider’s use of patient-centered communication. Secondary outcomes evaluated patients’ scores on assessment of the provider’s clinical competence and skills, interpersonal skills, and convenience of the visit.

**Results:** There were a total of 57 surveys collected. For both the primary outcome and secondary outcomes, over 80% of collected responses for each question in both clinics were scored a 5 which indicates that patients were very satisfied with the provider’s use of patient-centered communication and clinical competence and skills. For both the primary and secondary outcome, there were no statistically significant differences in patients scores that assessed provider’s use of patient centered communication nor the providers’ clinical competence and skill.

**Conclusion:** The results of this study indicate patients are satisfied with pharmacists’ use of patient centered communication and clinical competence and skills via both CVT and face-to-
face consultations supporting our research hypothesis that patient satisfaction with care provided via CVT did not differ from face-to-face provided care.

Poster Title: Impact of exenatide ER on hemoglobin A1C, weight, and total daily dose of insulin in patients with type 2 diabetes mellitus using U-500 insulin.

Primary Author: Phillip Farwig, Chalmer P Wylie VA Ambulatory Care Center, OH; Email: phillip.farwig@va.gov

Additional Author(s):
Angela Zielinski
Mallory Accursi

Purpose: Use of glucagon-like peptide-1 receptor (GLP-1) agonists in combination with basal insulin is used in clinical practice; however, its use with U-500 insulin is not currently approved by the Food and Drug Administration. The primary objective will evaluate change in hemoglobin A1C over 24 months after addition of exenatide extended-release (ER) to U-500 insulin in Veteran’s Affairs (VA) patients. The secondary objectives will assess the change in weight, total daily dose (TDD) of insulin, and reports of hypoglycemia from baseline to 24 months after the addition of exenatide ER.

Methods: This study will be submitted to the Institutional Review Board for approval. This is a retrospective chart review of outpatients enrolled in a VA clinic. Patients will be identified through the Computerized Patient Record System and will be eligible if they have concomitant prescriptions for regular U-500 insulin and exenatide ER. The following data will be collected: patient gender, age, race/ethnicity, weight, body mass index hemoglobin A1C, TDD of insulin, hypoglycemic episodes, concomitant diabetes medications, and years since diagnosis of type 2 diabetes. Data will be de-identified to protect patient confidentiality. For the primary outcome, the mean A1C at baseline, 3, 6, 12, 18, and 24 months will be evaluated. For secondary outcomes, the mean weight and TDD of insulin at baseline, 3, 6, 12, 18, and 24 months will be evaluated. Any reports of hypoglycemia will also be recorded. Repeated measures ANOVA will be performed on the primary and secondary outcomes to assess the differences in mean scores over six time periods.

**Session-Board Number:** 1-273  

**Poster Title:** Surgical Site Infection Prophylaxis: Using the Standard Antibiotic Administration Ratio to Identify Antimicrobial Stewardship Intervention and Improve Antimicrobial Use  

**Primary Author:** Jefferson Bohan, Not Applicable, Not Applicable; **Email:** jefferson.bohan@va.gov  

**Additional Author(s):** Karl Madaras-Kelly  

**Purpose:** The National Healthcare Safety Network (NHSN) allows medical facilities to report antimicrobial data through their Antimicrobial Use (AU) option. Facilities have access to metrics including Standardized Antibiotic Administration Ratios (SAARs), a novel metric for external comparison. SAARs are risk adjusted observed-to-expected ratios of antimicrobial use categorized into antimicrobial classes including agents used for surgical site infection prophylaxis (TAR-Adult-7) and stratified by ward type. Wards are classified as Medical, Surgical, or Mixed Medical/Surgical units based on case mix and undergo separate risk adjustment. We sought to identify reasons for the persistently elevated TAR-Adult-7 SAAR within a small Veterans Affairs teaching hospital.  

**Methods:** SAARs >1 indicate increased antibiotic use after risk adjustment. Our mean (± SD) quarterly TAR-Adult-7 SAAR was persistently elevated in 2015 at 2.037 (0.302). The antimicrobial agents included in TAR Adult-7 are cefazolin, cefotetan, cefoxitin, intravenously administered cefuroxime, and cephalexin. Days of Therapy (DOT) per 1000 Patient Days were calculated for 2015 for each of the antibiotics within TAR Adult-7. Cefazolin was found to be the primary antibiotic used, and a chart audit of 20 randomly identified patients who were prescribed cefazolin in the hospital from October 2015 through December 2015 was conducted. Data collected through manual chart review included age, date of admission, date of discharge, admission diagnosis, admitting service, number of cefazolin doses received, use of post-surgery order set, procedure type, surgeon, and other reason for cefazolin of than surgical prophylaxis if applicable. Data was analyzed using descriptive statistics. Order menus specific to surgical antibiotic prophylaxis within the facility’s electronic health record were also reviewed. Guideline recommendations for type and duration of antibiotic use for surgical site infection prophylaxis for the procedures performed were identified and compared with the findings of
the evaluation. Facility-wide antimicrobial stewardship interventions were explored to improve antimicrobial use.

**Results:** The mean (± SD) age of the patients reviewed was 68 (5.4) years. 85% (17/20) of patients were admitted to the surgery service while 18/20 (90%) of patients received cefazolin for surgical site infection prophylaxis. Only 10% (2/20) of patients were on cefazolin for treatment of an active infection. The mean (± SD) number of cefazolin doses administered to each patient for surgical site infection prophylaxis was 3.7 (0.7). NHSN defined mean (± SD) cefazolin DOT were 2.1 (0.2). 89% (16/18) of patients underwent orthopedic procedures including those related to hips, knees, shoulders, and spines, and ≤24 hours of antibiotic prophylaxis is recommended for these procedures. Many patients received up to 4 doses of cefazolin, 1 dose administered pre-operatively and 3 doses administered post-operatively. Order menu review identified post-operative quick orders for cefazolin administered every 8 hours for three doses were frequently being used. Order menus were updated to reflect ≤24 hours of cefazolin prophylaxis. The SAAR decreased by 13.2% from 1.982 in the first quarter of 2016 to 1.721 in the second quarter, which was consistent with our estimated DOT reduction of 15 DOT/month based on this intervention.

**Conclusion:** The facility’s TAR-Adult-7 SAAR remained elevated despite chart-level review and excessive antibiotic use correction. Reviewing the facility’s NHSN AU reporting plan, wards where cefazolin prophylaxis was administered were classified as Medicine wards. NHSN requires 40-60% medical/surgical patient case mix to be classified as Mixed Medical/Surgical units, while the wards evaluated had approximately 33% surgical patient case mix. Despite verifying appropriate surgical antibiotic prophylaxis use, risk adjustment procedures appear to penalize wards with higher proportions of surgical patients compared to similar wards with lower proportions within the defined ward classifications artificially elevating the TAR-Adult-7 SAAR—an issue for small facilities especially.

Poster Title: Evaluating pharmacist interventions in a pilot pharmacist-managed chronic obstructive pulmonary disease clinic

Primary Author: Macy Kint, Chalmers P. Wylie VA Ambulatory Care Center, OH; Email: macy.kint@va.gov

Additional Author (s):
Ann Marie Householder
Melinda Amornyard

Purpose: The Global Initiative for Chronic Obstructive Lung Disease guidelines states that chronic obstructive pulmonary disease (COPD) is a complex disease that requires well-organized care and the input of multiple healthcare providers. Numerous pharmacist-managed clinics for various chronic diseases have been successful in improving patient care; however, there is a lack of published data reflecting the design and benefit of pharmacist-managed COPD clinics. The primary objective of this project is to evaluate the impact of pharmacist involvement in the treatment of patients with COPD by identifying the number and type of pharmacist interventions made in a pilot pharmacist-managed COPD clinic.

Methods: This retrospective chart review will include patients that have been enrolled in a pilot pharmacist-managed COPD clinic. Eligible patients are those who are 18 years or older with a diagnosis of COPD, currently prescribed one or more inhalers and able to attend face-to-face appointments. Exclusion criteria include patients that are oxygen dependent, have a diagnosis of congestive heart failure class III or IV, have had a recent lung infection in the past 3 months, or require chronic use of steroids for the treatment of COPD. Completed progress notes between October 1, 2016 and February 28, 2017 will be reviewed to assess the frequencies and percentages of the total number of interventions and the specific types of interventions made by a pharmacist. In addition, the mean, standard deviation, and range of values for the total number of interventions and the specific type of interventions will be examined. All findings will be provided in aggregate form. Individual patient data will not be presented. Types of interventions include the number of corrections in inhaler technique recommended by a pharmacist, recommendations made to primary care providers regarding COPD medications and/or immunizations, and referrals for pulmonary services and/or tobacco cessation.

**Poster Title:** Effect of Implementing A Urinary Tract Infection Order-Set on Antibiotic Use

**Primary Author:** Julianne Mazzola, Cincinnati VA Medical Center, OH; **Email:** julianne.mazzola@va.gov

**Additional Author(s):**
Victoria Tate
Jason Hiett

**Purpose:** In July 2016 the Food and Drug Administration (FDA) Warning regarding fluoroquinolones recommended limiting their use in patients with uncomplicated urinary tract infections to reduce the potential for serious side effects associated with their use. Additionally, the most recent antibiogram at the Cincinnati VA Medical Center (CVAMC) shows a decrease in susceptibilities to fluoroquinolones against common urinary bacteria. The purpose of this quality assurance project is to ensure appropriate prescribing of antibiotics at the CVAMC to improve care provided to Veterans with uncomplicated urinary tract infections.

**Methods:** Prior to initiation, the project will be submitted to the University of Cincinnati Institutional Review Board for approval. The VA health system electronic medical record will be used to retrospectively identify patients with the ICD10 diagnosis code(s) of uncomplicated urinary tract infection from August 1, 2016-October 31, 2016. The following baseline characteristics will be collected: patient age and sex. The following additional data will be collected: antibiotic prescribed, urinary analysis, microbiology cultures, sensitivities, and any adverse events or allergies documented for antibiotics. Future objectives will be to compare the retrospective data obtained to the prospective data collected after the implementation of a Urinary Tract Infection Antibiotic Order Set. The pre versus post data analysis will help determine if the implementation of an order set decreased overall antibiotic use for uncomplicated UTI’s at the CVAMC.

**Session-Board Number:** 1-276  

**Poster Title:** Impact of Clinical Pharmacy Specialists (CPS) on Patient Aligned Care Teams (PACTs) on improving glycemic control in complex diabetic patients  

**Primary Author:** Kathryn Hoffman, Cincinnati Veterans Affairs Medical Center, OH; **Email:** kathryn.hoffman@va.gov  

**Additional Author(s):**  
Jo-Ann Caudill  
Tina Hamilton  

**Purpose:** Diabetes is associated with a variety of vascular complications. Improved glycemic control may reduce incidence and progression of vascular complications. The objective of this study is to measure the impact CPS have on glycemic control in difficult to manage diabetic patients.  

**Methods:** This study will be submitted to the University of Cincinnati Institutional Review Board and Cincinnati VAMC Research and Development Committee. The electronic medical record system will identify patients who had their first appointment with a CPS for diabetes management with a hemoglobin A1c (HbA1c) of at least 9% between January 1, 2006 to December 21, 2015. The following data will be collected: patient age, gender, race, sex, Care Assessment Needs (CAN) score; HbA1c levels at baseline and for up to 18 months after initial CPS encounter; medication refill history at baseline and up to 18 months after initial CPS exposure; type of encounter with CPS (face-to-face or phone); if patient takes metformin and/or insulin; and if patient met with a dietician or attended other patient education classes directed toward diabetes management. Patients that missed at least 3 CPS appointments over 18 month period, had less than 2 face-to-face appointments with a CPS, or were using insulin U-500 were excluded from the trial. All data will be recorded without patient identifiers and maintained confidentially. The following primary outcomes will be measured: difference in HbA1c from initiation of CPS-led diabetes to up to 18 months post-initial visit HbA1c (or sooner if appointments were discontinued due to achieving glycemic goal earlier than 18 months) and HbA1c post-CPS led interventions compared to the VA/DoD Diabetes Treatment Guideline HbA1c targets.

Submission Category: Pain Management

Submission Type: Research-in-Progress

Session-Board Number: 1-277

Poster Title: Comparison of tolerability following initiation of neuropathic pharmacologic therapies at the Cincinnati Veterans Affairs Medical Center (VAMC)

Primary Author: Tyler Dickerson, Cincinnati Veterans Affairs Medical Center, OH; Email: tyler.dickerson@va.gov

Additional Author (s):
Jacqueline Dages
Stephanie Bahrey

Purpose: Chronic non-cancer pain is one of the most common and costly medical conditions in the US, particularly within military veteran populations. While the Center for Disease Control recommends the use of non-opioid therapies for chronic pain where possible, adverse effects of each non-opioid therapy must be considered, especially those that lead to therapy discontinuation. The objective of this project is to determine whether duloxetine, gabapentin, and pregabalin vary in tolerability when used for pain in a veteran population, and whether the likelihood of tolerability varies with several patient-specific factors.

Methods: This project will be submitted to the University of Cincinnati Institutional Review Board and Cincinnati VAMC Research and Development Committee. The Cincinnati VA Medical Center’s Computerized Patient Record System will be used to identify patients with new initiations of duloxetine, gabapentin, and pregabalin. Patients with a new initiation of a study medication for a pain-related indication will be retrospectively reviewed. Patients who choose to have the study medication dispensed from non-VA pharmacies will be excluded. Patient-related information collected will include patient date of birth, gender, renal function, hepatic function, relevant comorbidities, and concomitant interacting medications. Additional information related to the study medications will include dates of initiation, subsequent fills, and discontinuation (if applicable), starting and maximum doses prescribed, and reason for discontinuation. The primary outcome for this project will be the percentage of patients who discontinue the study medication due to intolerance. For the purposes of this project, intolerance will be defined as any documented adverse reaction that led to discontinuation of the study medication within six months of initiation. Secondary outcomes will include type of adverse effect leading to discontinuation, as well as rates of intolerability in correlation to drug-
drug interactions, comorbidities, decreased renal or hepatic function, age, and appropriateness of dosing. Chi-square tests will be used to compare rates of intolerance between groups.

Poster Title: Evaluation of the incidence of hyperglycemia in patients who are on total parenteral nutrition (TPN) at the Cincinnati Veterans Affairs Medical Center (CVAMC)

Primary Author: Kristine Voon, Cincinnati Veterans Affairs Medical Center, OH; Email: voon.3@osu.edu

Additional Author(s):
Victoria Tate
Jason Hiett

Purpose: Studies have shown that patients who develop hyperglycemia while on total parenteral nutrition (TPN) are at a greater risk for negative outcomes, including mortality. The primary objective of this project is to identify the incidence of hyperglycemia in patients who are on TPN at the Cincinnati Veterans Affairs Medical Center. With this information, further research can be conducted to determine if empirically starting certain TPN patients on insulin would lead to better outcomes in the veteran population.

Methods: This quality improvement project will utilize the Veterans Affairs computerized patient record system (CPRS) to conduct a retrospective chart review. The following data will be collected: patient demographics (age, sex, weight, BMI), diabetes status (with most recent A1C if available), glucocorticoid use, ward setting, blood glucose (on admission, prior to TPN administration, during TPN administration), amount of dextrose, amino acid and lipids contained in TPN, if insulin was initiated, and number of days on TPN. All data will be collected and recorded without patient identifiers. Hyperglycemia will be identified as a blood glucose level greater than 180 mg/dL. Data will be collected and evaluated by one PGY1 pharmacy resident and two clinical pharmacy specialists. Results will be used to determine if there are certain patients who would benefit from starting insulin empirically with administration of TPN.

Poster Title: Pharmacist monitoring of direct oral anticoagulants (DOACs): Evaluation of current timeline

Primary Author: Katherine Groh, Dayton VA Medical Center, OH; Email: katherine.groh2@va.gov

Additional Author (s):
Maureen Crossman
Rachel Chandra

Purpose: Direct oral anticoagulants (DOACs) include rivaroxaban, apixaban, dabigatran, and edoxaban. Although they require less monitoring than warfarin, labs and patient adherence should be periodically assessed to reduce bleeding and thrombotic risks. Unlike warfarin, when missed doses occur with DOACs, the patient is not anticoagulated and is at risk. In addition, some DOACs have special storage and administration guidelines. Pharmacists can recommend a change in medication, make a dosage adjustment, or provide medication counseling in order to optimize efficacy and safety. The objective of this medication class evaluation is to assess the timeline of DOAC monitoring used at this institution.

Methods: The DOAC tracking sheet used by the pharmacists in the anticoagulation clinic (ACC) will identify patients that started on a DOAC agent between January 2015 and August 2015. The following data will then be collected from the patient chart: gender, age and weight upon initiation of therapy, date of initial anticoagulation consult, initial DOAC and dose, and indication. Follow-up appointments at 1 month, 3-4 months, 6-7 months, 9-10 months, and 12 months or greater will be assessed for number and type of pharmacist interventions. Interventions will be grouped based on relative severity and type of intervention. All data will be de-identified and maintained in a password protected document. Data analyzed will be used to identify: relative timeline needed for monitoring of DOACs by the ACC, time frame where pharmacists’ interventions peaked, and need for continuous ACC monitoring of DOACs moving forward.

Poster Title: Evaluation of vancomycin dosing protocol at the Dayton VA Medical Center
Primary Author: Shane Naylor, Dayton VA Medical Center, OH; Email: shane.naylor@va.gov
Additional Author (s):
Rachel Chandra
Debbie Quarles

Purpose: Vancomycin, a commonly used bactericidal antibiotic for methicillin-resistant Staphylococcus aureus, is pharmacist-dosed in many hospitals based on a pharmacokinetic protocol. Depending on the type of infection, target trough goals ranging from 10 to 15 or 15 to 20 mcg/mL are closely monitored to prevent resistance, treatment failure, and nephrotoxicity. This medication use evaluation (MUE) will assess the appropriateness of pharmacists’ utilization of the current vancomycin protocol at the Dayton VA Medical Center.

Methods: A retrospective chart review was conducted to include patients who were prescribed intravenous vancomycin at the Dayton VA from May 1st 2016 through July 31st 2016. Exclusion criteria are: absence of trough level, patients on dialysis, amputees, and pre-operative use of vancomycin. Data collected will evaluate: appropriateness of initial calculated dose, percentage of patients whose first and second vancomycin trough levels were within therapeutic range, appropriateness of dosing frequency, renal function throughout treatment, and appropriateness of dose change if first trough was not in therapeutic range. All data will be de-identified and maintained confidentially. The vancomycin dosing protocol will also be compared to other hospitals’ protocols to assess for major variances.

Results: N/A

Conclusion: N/A
**Purpose:** Transitioning between care settings is overwhelming to patients, especially regarding medication changes, putting the patient at increased risk of medication-related problems (MRPs). Pharmacists are trained to identify medication-related problems; studies have shown that pharmacist involvement reduces adverse outcomes from MRPs. In fall 2015, Cleveland VA outpatient clinics began seeing recently discharged patients in a pharmacist-driven Post-Discharge Transitions-of-Care Clinic. No standardized process for this pharmacy service currently exists. The purpose of this project is to describe the current state of the Post-Discharge Transitions-of-Care Clinic, implement a standardized process to guide clinicians’ consulting pharmacy, and to evaluate if standardization improves patient capture.

**Methods:** This quality improvement project will be conducted through utilization of the electronic medical record and survey results. The targeted patient population includes all patients seen by a pharmacist and/or a provider in the outpatient clinics for a follow-up appointment after discharge from an inpatient facility. An electronic chart review of patients seen by the pharmacist and/or provider will be completed, and a survey will be administered to nurses and providers to determine factors leading to pharmacist consultation. Following review, a checklist, process map, and note template will be developed and implemented in the Akron, Mansfield, and Parma community based outpatient clinics (CBOCs). After implementation, prospective chart review will be completed on patients seen for post-discharge follow-up by a pharmacist and/or a provider through early spring 2017. The primary objectives include determination and characterization of the decision process for clinicians’ consulting pharmacy, implementation of a standardized process for consultation to pharmacy service, and to evaluate the feasibility and impact of long-term implementation of a
standardized process on clinicians utilizing the RE-AIM (Reach, Efficacy, Adopt, Implement, Maintenance) Framework. Secondary objectives will be to describe the clinic in terms of interventions, patient population seen, and clinician-patient interactions, as well as assessing re-admissions within 30 days of the visit. Data collected will be analyzed using descriptive statistics.

**Poster Title:** Comparison of the use of aripiprazole and quetiapine for the adjunctive treatment of Major Depression (MDD)

**Primary Author:** Marissa Cullen, Louis Stokes Cleveland VA Medical Center, OH; **Email:** mcullen01@gmail.com

**Additional Author(s):**
Jennifer Roche-Desilets
Colleen Hall
Matthew Fuller
Christopher Burant

**Purpose:** The purpose of this research project is to compare antidepressant augmentation with oral aripiprazole and quetiapine and their effects on inpatient psychiatric admissions and discontinuation rates. Our secondary objective will compare antidepressant augmentation with oral aripiprazole and quetiapine and their influence on reasons for discontinuation.

**Methods:** Patients will be identified for inclusion in the study through a pharmacy generated patient list including all patients with diagnosis of major depressive disorder and bipolar disorder based on ICD 9 and 10 codes who received prescriptions aripiprazole and quetiapine plus a selective serotonin reuptake inhibitor (SSRI) or serotonin norepinephrine reuptake inhibitor (SNRI) from January 1, 2007 to September 1, 2015. Patient charts will then be reviewed retrospectively to identify patients that meet inclusion criteria via electronic medical record. The target enrollment is 200 patients with a diagnosis of major depressive disorder or bipolar disorder who were initiated on oral aripiprazole or quetiapine as adjunctive agents to SSRIs or SNRIs. Patients with current diagnosis of delirium, dementia, amnestic or other cognitive disorders, schizophrenia, and patients on concomitant psychiatric medications (mood stabilizers, antipsychotics other than aripiprazole or quetiapine, antidepressants other than SSRIs and SNRIs, thyroid hormone used as augmentation, stimulants, mirtazapine >15mg, trazadone >300mg, and buspirone) will be excluded.

Poster Title: Potential impact of a clinical pharmacist on treatment of urinary tract infections among older adults diagnosed at the emergency department

Primary Author: Megan Elavsky, Louis Stokes Cleveland VA Medical Center, OH; Email: megan.elavsky@va.gov

Additional Author(s):
Laura Kangas
Robin Jump
Antonio Carson

Purpose: Urinary tract infections (UTIs) are one of the most common infections in patients over 65 years old. Despite the frequency, research has shown many instances where UTIs are over-diagnosed and over-treated. The over-diagnosis is well documented in long-term care, hospitalized, and community-dwelling older adults with new research now focusing on the emergency department. New data has shown the beneficial impact of pharmacy in the emergency department on overall optimization of antimicrobial stewardship. However, the potential impact of pharmacy on the management and follow up care in older adults diagnosed with a UTI in this environment is unknown.

Methods: This evaluation will be a retrospective cohort study of patients discharged from the emergency department with a primary or secondary diagnosis of urinary tract infection. The primary endpoint is the potential for pharmacy to intervene based on urinary culture results. This includes number of antibiotics that could have been discontinued based on negative cultures, number of mismatches between microbiological culture and patient-directed therapy, and number of antibiotics that could have been narrowed based on culture results. Secondary outcomes will evaluate presentation of symptoms in the older adult population based on Loeb criteria, specific use of antibiotics, number of unnecessary days of antibiotic therapy remaining with negative cultures, and incidence of negative urine cultures and negative urinalyses. Patients will be identified based on urinary cultures collected between January and September 2015. Patients will be included if they are ≥65 years old and were prescribed antibiotics on discharge. Exclusion criteria include admission to the hospital, presence of a chronic indwelling urinary catheter or temporary foley catheter, identification of polymicrobial urinary culture, co-
infection with bacteremia, or lack of a provider note describing the patient’s diagnosis. Additional data collected will include patient demographics and co-morbidities, sensitivity and resistance patterns, and incidence of adverse drug events. All data will be presented using descriptive statistics. This study has been submitted to the hospital’s Institutional Review Board (IRB) and is pending approval.

**Poster Title:** Evaluation of the outcomes of the use of lurasidone for the treatment of bipolar depression

**Primary Author:** Melissa Rock, Louis Stokes Cleveland Veterans Affairs Medical Center, OH; Email: melissa.rock@va.gov

**Additional Author (s):**
Colleen Hall
Jennifer Roche
Christopher Burant
Matthew Fuller

**Purpose:** Bipolar I disorder has a prevalence of approximately 1% of the population. While symptomatic, patients experience depressive symptoms threefold longer than manic symptoms and contribute significantly to health care costs. Quetiapine and lurasidone are atypical antipsychotics indicated for bipolar depression. Lurasidone was FDA approved for bipolar depression in 2013 and due to recent use at LSCDVAMC, it is unknown whether patients experience similar benefit as shown in previous clinical trials as compared to quetiapine. The purpose of this study is to assess time to medication discontinuation in patients prescribed lurasidone versus quetiapine for the treatment of bipolar depression.

**Methods:** A retrospective chart review will be conducted in patients prescribed lurasidone versus quetiapine for the treatment of ICD 9 and 10 diagnosis of bipolar depression from January 1, 2014 to January 1, 2016. Time to medication discontinuation will be assessed up to a one year period starting with the first lurasidone or quetiapine prescription up to January 1, 2017. Medication discontinuation will be defined as not receiving a subsequent prescription for lurasidone or quetiapine within thirty days of exhausting the medication day supply for the prior prescription. The reason for medication discontinuation and additional secondary outcomes will be determined by an electronic chart review. Secondary outcomes will assess the average length of medication treatment, the average dose of lurasidone and quetiapine prescribed, the use of adjunctive treatment by medication class for bipolar depression, the percentage and time to psychiatric hospitalizations, and the percentage of accurate medication directions of “take with food” for lurasidone.

**Poster Title:** Impact of beta-lactam allergies on the treatment of methicillin-susceptible Staphylococcus aureus (MSSA) infections

**Primary Author:** Ukwen Akpoji, Louis Stokes Cleveland Veterans Affairs Medical Center, OH; Email: ukwen.akpoji2@va.gov

**Additional Author(s):**
Usha Stiefel
Federico Perez
James Fernandez
Sharanie Sims

**Purpose:** Approximately 3 million U.S. patients have reported beta-lactam “allergies” with unknown to mild reactions. The identification of such reactions is essential when treating patients for MSSA infections, where β-lactams have shown superiority to vancomycin in MSSA bacteremia. The objective of this study is to determine the frequency at which a clinical history is elicited in β-lactam-allergic patients with MSSA infections. The primary endpoint is percent of a β-lactam allergy history as identified by documentation in patients’ allergy tab and/or progress note upon initiation/discontinuation of MSSA therapy. Secondary endpoints include treatment failure, alternative therapy, hospital stay duration, and adverse drug event.

**Methods:** This is a retrospective chart review of patients from June 2006 to June 2016 with a beta-lactam allergy who received treatment for an MSSA infection. MSSA isolates will be identified via microbiological culture results from any bodily source with susceptibilities to oxacillin. The documentation of an allergy history will be identified from the allergy tab or progress note within the VA’s Computerized Patient Record System (CRPS®) at the initial episode of MSSA infection. Documentation of an appropriate allergy history will be satisfied if information including, but not limited to, timing, type of allergic reaction, and subsequent exposure to beta-lactam antibiotics are present in the electronic medical record. Patients with penicillin and/or any beta-lactam listed in the patient allergy tab who were infected with confirmed MSSA isolates will be included, regardless of treatment setting. Two hundred patients that meet the aforementioned criteria will be included in this study, as long as antibiotics were not administered prior to drawn cultures. The authors hypothesize that less
than 50% of the included patients will have a documented history of the beta-lactam allergy. This study has been submitted to the Cleveland VAMC Institutional Review Board and is pending approval.

**Purpose:** New direct acting antivirals (DAAs) have changed the management of hepatitis C (HCV) infection. Manifestations of successful HCV treatment beyond the liver have yet to be explored. This study will expand on a previous study completed at the Louis Stokes Veterans Affairs Medical Center which found that 27% of Veterans with type 2 diabetes successfully treated with DAAs had de-escalation of their diabetes medications. Additionally, a statistically significant decrease in A1C of 0.63% was found. This current study will assess initial and sustained A1C change in patients who have had successful treatment with short course DAAs.  

**Methods:** This study was submitted to the local Institutional Review Board for approval. Medication dispense history will be utilized to identify patients prescribed sofosbuvir, simeprevir, ledipasvir/sofosbuvir, ombitasvir/paritaprevir/ritonavir +/- dasabuvir, elbasvir/grazoprevir, and sofosbuvir/velpatasvir between February 1, 2014 and September 27, 2016 who also have a diagnosis of diabetes per ICD9 and ICD10 codes. Patients will be excluded if they did not complete full hepatitis C treatment or are not taking any diabetic medications prior to the start of hepatitis C treatment. The primary endpoint is the change in A1C from baseline to 4 months post HCV treatment. Secondary endpoints include sustained change in A1C up to 18 months post treatment and changes in diabetes medications at end of treatment, defined as escalation, de-escalation, and no change. Additionally, the changes in A1C and diabetes medications will be compared among those who achieve a cure defined as sustained virologic response 12 weeks post-treatment (SVR12) and those who relapse. A paired t-test will
be used to analyze changes in A1C, while descriptive statistics will be used for other secondary endpoints. The anticipated sample size after inclusion and exclusion will be 160.

Poster Title: Effectiveness of a pharmacist-directed Tdap immunization program for a university campus

Primary Author: BreAnna Meinzer, ONU HealthWise, OH; Email: b-meinzer@onu.edu

Additional Author(s): Michael Rush
Karen Kier
Amy Fanous
Colin Frank

Purpose: Despite a slight increase in Tdap immunization rates, vaccination rates as cited by the CDC still fall short among adolescents and adults. In light of the current shortage of primary care physicians, pharmacists have the unique opportunity to help increase these rates, as they are the most readily accessible health care professionals. Pharmacists in underserved rural communities can help to improve immunization rates in concert with local health departments. The purpose of this study is to determine the effectiveness of a pharmacist-directed immunization program on a university campus in an ambulatory care clinic for employees and students.

Methods: This study is IRB approved and will be conducted as part of an employee wellness program. Employees, retirees, and students (18 years and older) will be screened to see if they meet the criteria for a Tdap vaccination. Patients who meet the CDC ACIP criteria for Tdap will be given an opportunity to schedule an appointment with a pharmacist. At the appointment, past medical history, current medications, demographics, and vaccine history will be collected. All candidates eligible and willing to take the vaccine will be immunized following an approved protocol. During the observation period, patients will be asked to complete a survey about the patient’s understanding of the risk of pertussis and the role of the pharmacist. All subjects will be welcomed to attend a program that will discuss the difference between the Tdap vaccine and tetanus booster, the indications for the Tdap vaccine, and the safety of vaccinations. The primary outcome variable will be overall rates of Tdap vaccinations in the unvaccinated group. Secondary variables will include educational assessments and patient perceptions. Descriptive and inferential statistics will be used to analyze the data. Nonparametric testing will be used to
analyze Likert scale data from the surveys. All data will be protected by HIPAA standards. Screening tools, surveys, and assessments will become part of the medical chart. Data will be presented in aggregate form.

**Poster Title:** Medication safety challenges encountered during electronic health record conversion

**Primary Author:** Lia Jasperse, Cherokee Nation W.W. Hastings Hospital, OK; **Email:** lia-jasperse@cherokee.org

**Additional Author(s):**
Kari Barrett  
Sarah Watkins  
Stacey Thornton  
Gerry Brown

**Purpose:** Implementing an electronic health record (EHR) system efficiently, in a health care facility, is important to provide effective patient care. However, even with the best preparation for installment of the EHR, many challenges still arise. Medication safety is always a priority in health care, especially upon installment of a new EHR system. The objective of this study is to evaluate the implementation of a new EHR system focusing on the medication safety challenges that arise during the implementation process.

**Methods:** A retrospective chart review will be completed to analyze medication processes and documentation parameters in both the inpatient/ambulatory and outpatient settings. The project will be submitted for review to the appropriate health system boards prior to implementation. The main outcome measure for the inpatient/ambulatory setting will assess the incidence of medication/administration documentation reflecting incorrect dose and/or route. The main outcome measure for the outpatient setting will assess the number of discrepancies noted between the medication profiles of the EHR and the outpatient pharmacy software package. Potential interventions for process improvement include developing a standardized medication reconciliation process, education for health care staff, and restriction of modifiable fields in medication administration documentation. Interventions will be approved and implemented by appropriate health system entities following baseline data analysis and presentation. Baseline documentation will be analyzed for fourth quarter fiscal year 2016. Documentation reassessment will be performed, for a comparable time frame, following implementation of approved interventions.

Poster Title: Implementation of a pharmacy-driven metabolic validation testing in a Native American population

Primary Author: Jamie Wroge, Chickasaw Nation Medical Center, OK; Email: jamie.wroge@chickasaw.net

Additional Author(s):
Stacy Gee
Travis Freeze
Carrie Law

Purpose: The use of metabolic validation with genetic testing is the first step towards personalized healthcare. The objective of this study is to determine how metabolic validation in a Native American population at the Chickasaw Nation Medical Center can help improve patient care by tailoring drug therapy to the patient which may help to decrease adverse events, improve targeted therapies and dosing, and help choose a more efficient, cost-effective medication.

Methods: The electronic medical record system will be used to identify patients who qualify for laboratory testing criteria for metabolic validation testing with one or more of 3 panels including neurology, cardiology, or thrombophilia. Patients will be screened by a qualified pharmacist while inputting new orders, counseling patients, or during appointment with pharmacy led clinics. Once screened, patients are educated about the metabolic validation test when they pick up their medication, or at their appointments in the clinic. A pharmacist performs a swab for the metabolic test if consent is given. The test is sent for analysis. A note template was approved and established with the clinical application coordinator team at the Chickasaw Nation Medical Center in the electronic health record. Imperative results are sent to the provider immediately and all results are scanned into the electronic health record note template for the health care team to review.

Poster Title: Pharmacist influence on transitions of care in a rural medical-surgical population

Primary Author: April Belanger, Choctaw Nation Health Care Center, OK; Email: ambelanger@cnhsa.com

Additional Author(s):
Christopher Pack

Purpose: Pharmacists play an integral role in helping prevent drug therapy problems in both the inpatient and outpatient setting. Where medication reconciliation and drug information are known areas of pharmacist expertise, not much is known about how pharmacists can aid in successful and complete transitioning of care for patients between an inpatient and outpatient setting. The objective of this study is to evaluate the effect of pharmacist-driven follow-up with patients transitioning from the inpatient to the outpatient setting.

Methods: This study will be submitted to the Choctaw Nation Institutional Review Board for approval. Eighty medical-surgical patients will be recruited over a period of nine months from the current census at the Choctaw Nation Hospital in Talihina, Oklahoma. In the Transitions of Care (TOC) group, patients with two or more chronic disease states meeting inclusion criteria will have a medication reconciliation completed by a clinical pharmacist on admission and medication counseling upon discharge using a standardized form. Following discharge, a pharmacist will contact the TOC group via phone within 72 hours and at days 7, 14, 30, 90, and 180 to discuss any medication therapy issues and to reiterate any deficits in knowledge. Phone calls will consist of a short, standardized questionnaire with any follow-up counseling deemed appropriate by the pharmacist conducting the telephone session at that time. TOC patients will also receive a short survey regarding their confidence in their knowledge of their disease state and medication therapy within 72 hours of discharge and at 30, 90, and 180 days post-admission. Additionally, patient surveys will assess patient satisfaction with the TOC service. For control groups, patients will be counseled on medications at discharge and receive follow-up using current methods employed at the Choctaw Nation Talihina Hospital. Patients in the control group will also receive follow-up calls at 30, 90, and 180 days post discharge.

Poster Title: Evaluation of pharmacist-led hypertension management on adherence and clinical measures

Primary Author: Alyson Dunlavey, Claremore Indian Hospital, OK; Email: alyson.dunlavey@ihs.gov

Additional Author(s):
John Collins
Timothy Murray

Purpose: Hypertension is one of the most common chronic conditions seen in primary care. Hypertension can lead to myocardial infarction, stroke, and renal failure if not detected early and managed effectively. Studies have shown that pharmacist-led clinics have had a positive impact on clinical outcomes in chronic disease management. The purpose of this study is to evaluate the impact of pharmacist-led hypertension management on medication adherence and guideline recommended treatment goals.

Methods: Patients who are seen in adult medicine clinic for hypertension management will be randomly selected to continue current management within adult medicine clinic, or receive additional follow-up in the pharmacist-led hypertension clinic. Patients will be monitored for medication adherence and clinical outcomes. Statistical analysis will be used to determine the overall impact of pharmacist-led hypertension management by comparing the difference in patients’ clinical outcomes from baseline to follow-up. This study hopes to illustrate the value of pharmacist-led hypertension management through medication adherence and positive clinical outcomes. It is believed that there will be a significant difference in clinical outcomes from baseline to follow-up in patients managed in adult medicine clinic versus patients who received additional follow-up in the pharmacist-led hypertension clinic.

Poster Title: Impact of a pharmacist-managed diabetes clinic on patients with poorly controlled diabetes

Primary Author: Katherine Lutek, Oklahoma City VA Health Care System, OK; Email: krlutek@utexas.edu

Additional Author (s):
Todd Marcy
Lauren Snodgrass
Susan Rourke-Webb

Purpose: Type 2 diabetes poses a significant threat to the health of the United States, affecting approximately 29.1 million Americans. Complications of diabetes occur at higher rates with increasing glycemia and can include blindness, amputation, and end-stage renal disease. Many patients in the United States have poorly controlled diabetes. Clinical pharmacists are well-trained and well-positioned to address barriers in achieving glycemic control. The purpose of this study is to determine the effectiveness of pharmacists in the management of patients with poorly controlled diabetes and to determine the patient-satisfaction of an outpatient pharmacist-managed diabetes service.

Methods: This study will include retrospective evaluation of improvement in glycemic control and a patient satisfaction survey of the pharmacist-managed diabetes service. It will be submitted for approval by the University of Oklahoma Health Sciences Center Investigational Review Board. Patients will be identified from the diabetes pharmacotherapy service within the Oklahoma City Veterans Affairs Health Care System (OK VAHCS). To be included in the study, patients must have a hemoglobin A1c (A1c) value of 9.0 percent or greater in the six months prior to their first clinic appointment, as well as an A1c value taken after at least one clinic appointment and within the three to six months following clinic enrollment. Patients with a diagnosis of type I diabetes mellitus will be excluded. Patient encounters between July 1st, 2015 and December 31st, 2016 will be retrospectively reviewed. Absolute change in A1c and achievement of an A1c less than 9.0 percent and less than 7.0 percent will be measured to determine the improvement in A1c following enrollment in a pharmacist-managed diabetes pharmacotherapy clinic. Data will also be collected to evaluate predictors of successful A1c
lowering as a secondary endpoint. Baseline demographics will be collected. In addition, patients enrolled in the diabetes service will be offered the opportunity to participate in a telephone-conducted patient satisfaction survey.

Poster Title: Impact of a change in service on sustained virological response rates in Veterans receiving ledipasvir/sofosbuvir for management of hepatitis C

Primary Author: Scott Mirgeler, Oklahoma City Veterans Affairs Health Care System, OK; Email: mirgeler@pharmacy.arizona.edu

Additional Author (s):
Riley Williams
Jennifer Bird
Rona Furrh

Purpose: The Veterans Health Administration has proposed initiatives to increase the number of hepatitis C virus-infected Veterans who are treated in order to limit disease progression and improve clinical outcomes. System redesign and increasing the workforce capacity are two initiatives that have been implemented at the study site. Pharmacists facilitate the transition of care of uncomplicated cases from Gastroenterology to Primary Care. This study aims to determine if the system changes at the study site have any impact on rates of sustained virological response, medication adherence, and treatment follow-up of Veterans treated for uncomplicated cases of hepatitis C infection with ledipasvir/sofosbuvir.

Methods: The study will be an institutional review board-approved, retrospective, descriptive chart review. Adult Veterans aged 21 years and older with hepatitis C virus infection who received a prescription for ledipasvir/sofosbuvir between January 2015 through October 2016 from either Gastroenterology or Primary Care providers will be included in the study. Veterans will be excluded if they have biochemical signs of cirrhosis and/or received ribavirin-containing hepatitis C virus regimens. An electronic data extraction form will be used to identify eligible participants and log pertinent data from study participants' electronic medical records. Data to be collected includes Veteran demographics, past medical history, social history, labs, imaging, medication history, and hepatitis treatment and follow-up course per provider documentation. The primary outcome of the study will be sustained virological response achieved between the two groups, and secondary outcomes include compliance to medication treatment and monitoring follow-up. The Chi squared test will be used to determine statistical difference of the primary outcome. All continuous demographic and descriptive independent variables will
be analyzed by using their calculated means and standard deviations to compare data from each group using a t-test. The categorical variables of each group will be compared with the Chi-squared test after calculating frequencies and percentages. All statistical tests will be conducted with a priori alpha level of 0.05 utilizing statistical software.

**Poster Title:** Evaluation of clinical outcomes of a pharmacist-based asthma clinic  
**Primary Author:** Ikjae Chin, United States Public Health Service Lawton Indian Hospital, OK;  
**Email:** ikjae.chin@ihs.gov  

**Additional Author(s):**  
Jessica Steinert  
James Foster

**Purpose:** According to the CDC, asthma affects 25.7 million people in the United States. In 2010, about 1.8 million people visited an emergency department (ED) and 439,000 people were hospitalized due to asthma. Despite many advances in treatment, asthma continues to be poorly managed and there is a significant need for optimized care plans. Over the past decade, pharmacists have expanded their roles in providing direct care and education to patients in ambulatory care settings. The purpose of this study is to evaluate the benefit of a pharmacist-based asthma clinic on improving asthma control and reducing asthma-related ED visits.

**Methods:** This study will be submitted to the Institutional Review Board for approval. The study will evaluate the clinical outcomes of the pharmacy asthma clinic prospectively. Patients with poorly controlled asthma defined by National Heart, Lung, and Blood Institute (NHLBI) guideline will be referred to the asthma clinic. After confirming diagnosis with a respiratory therapist and a provider, patients will be accepted to the clinic per protocol. Inclusion criteria of this study will be patients 18 years of age or older, patients who filled short-acting beta2 agonist (SABA) medications more than two times per year, and patients who had one or more ED visits primarily due to asthma related events. Patients may be referred to the clinic by a provider or may be selected based on a chart review. Exclusion criteria will be patients with chronic oral steroid use, patients who are not diagnosed with asthma, and patients who are not able to fulfill the minimum requirement of three clinic visits. The study will measure clinical outcomes using tools suggested in the guideline such as improvement of asthma symptoms and quality of life, pulmonary function test (PFT), peak flow meter values, and reduced number of ED visits primarily due to asthma-related event. Patients who experience exacerbations during enrollment or whose symptoms are getting worse will be referred to the provider for further evaluation.

**Poster Title:** Capturing inpatient pharmacy workflow to determine relevant productivity metrics

**Primary Author:** Johanna Peragine, VA Portland Health Care System, OR; **Email:** johanna.peragine@va.gov

**Additional Author(s):**
Jeegisha Patel
Amar Patel
Mariah Alford
Kimberly MacKay

**Purpose:** The landscape of clinical pharmacy practice in the inpatient hospital setting is rapidly changing. Within the Veterans Affairs Health Care System, there is a national movement to widen the scope of practice for pharmacists in order to increase Veteran access to care. To better assess the needs of the patient population and greater institution, this project is designed to map the currently daily activities of inpatient clinical pharmacists. By capturing workflow throughout the day, department leaders can define appropriate metrics to benchmark efficiency and performance. Furthermore, managers can utilize this information to expand pharmacy services.

**Methods:** In order to capture this information, data will be gathered from established reports as well as manually collected by inpatient pharmacists. The ten medical and surgical team pharmacists, two central pharmacists, and eight specialists will log their activities by type for a two week period during the hours of 7:00AM and 5PM. Inpatient pharmacists will be asked to take note of the number of chart reviews they perform as well as the number of phone calls or instant message received each day. This will further be broken down by who they are communicating with – attending physicians, resident physicians, nursing staff, social work, pharmacy staff, or other members of the health care team. Participating pharmacists will be asked to record the time spent on face-to-face education as well as the audience – attending physicians, medical residents, nurses, pharmacy residents, and pharmacy students. The amount of time spent on multidisciplinary rounds and administrative work will also be manually recorded. Authors will pull data such as the number of verified orders, discontinued orders,
encounters, and interventions captured by the Pharmacists Achieve Results with Medications Documentation (PhARMD) tool from pre-existing reports.

Poster Title: Evaluating efficacy, safety, and cost effectiveness of liraglutide use in type 2 diabetes mellitus patients receiving VA care

Primary Author: Vache Sharyan, VA Portland Health Care System, OR; Email: vache.sharyan@va.gov

Additional Author (s):
Gail Hirokane
Eileen Wilbur
Jeegisha Patel

Purpose: Approximately one in four Veterans receiving VA care have type 2 diabetes mellitus (T2DM). The most common injectable medications used are injectable insulin. However, use of liraglutide, a glucagon-like peptide 1 receptor agonist (GLP-1RA), has been increasing at the VA Portland Health Care System (VAPORHCS). Many studies suggest a significant reduction in hemoglobin A1c (HbA1c) and body weight in comparison to other anti-hyperglycemic medications. Liraglutide efficacy, side effects and cost effectiveness have not been determined in the VA diabetic patient population. The objectives of this retrospective chart review are to evaluate these parameters.

Methods: This project is a retrospective chart review of VAPORHCS patients diagnosed with T2DM who have been or are being treated with liraglutide, liraglutide with basal insulin, or liraglutide with basal and bolus insulin between January 1, 2013 and February 28, 2016. Use of oral anti-hyperglycemic medication(s) will also be recorded. The purpose of the chart review is to evaluate change in HbA1c and weight, safety as recorded as reports of hypoglycemia and nausea, adherence by analyzing refill history, and cost of the medication. Data gathered from the chart review will be noted at baseline, six months, and 12 months.

Poster Title: Evaluation of Acute Alcohol Withdrawal Treatment in Veterans at VAPORHCS

Primary Author: Christopher Wilming, VA Portland Health Care System, OR; Email: christopher.wilming@va.gov

Additional Author(s):
Mariah Alford
Lynnette Klaus
Eileen Wilbur

Purpose: Benzodiazepines remain the standard of care for managing symptoms of acute alcohol withdrawal in hospitalized patients but their side effect profile can be a significant limitation throughout care. In recent studies, gabapentin has been shown to demonstrate utility in symptom management for alcohol withdrawal when compared to benzodiazepine treatment. Clinicians at VA Portland Health Care System (VAPORHCS) have been using gabapentin in some Veterans admitted as an adjunct to treatment for withdrawal since 2014. The purpose of this project will be to assess use of gabapentin for treatment of acute alcohol withdrawal at the VAPORHCS.

Methods: This project will evaluate the use of benzodiazepines and gabapentin for acute alcohol withdrawal symptoms in an inpatient setting. Patients receiving gabapentin and benzodiazepines will be compared to patients treated only with benzodiazepines. The primary endpoint will assess the total amount of benzodiazepines administered in both groups from the time of admission to the time of discontinuation of the alcohol withdrawal protocol. Secondary endpoints will measure time to Clinical Institute Withdrawal Assessment of Alcohol, revised (CIWA-Ar) score resolution and the incidence and duration of symptoms of delirium. This project will be submitted to the Research Office for approval as a Quality Improvement/Quality Assurance project. A retrospective chart review will be performed for patients admitted to VAPORHCS with a primary or secondary diagnosis of alcohol withdrawal from January 2014 to December 2015. Individuals with a Major Axis I psychiatric disorder, or with an active outpatient prescription for gabapentin or benzodiazepine will be excluded from this evaluation. CPRS will be used to collect data on patient demographics, past medical history, medication history, vital signs, Richmond Agitation Sedation Scale (RASS) scores, CIWA-Ar scores, pertinent
laboratory values, and any documentation regarding progression of symptoms. Data collected will be evaluated to determine the total amount of benzodiazepines administered, rate of CIWA-Ar score resolution, and signs and symptoms of delirium until discontinuation of the alcohol withdrawal protocol.

Poster Title: Evaluation of Patients Receiving Second-Line Antibiotics for Pneumonia Due To Penicillin Allergy and Assessment of the Potential Impact of Utilizing Penicillin Allergy Skin Testing

Primary Author: Paulina Nguyen, VA Portland Health Care System, OR; Email: paulina.nguyen@va.gov

Additional Author (s):
Izabela Chamot

Purpose: Patients are prescribed second-line antibiotic therapy as a result of unclear chart-documentation or patient self-reported allergies instead of indicated first-line penicillin-based antibiotics. Penicillin allergy skin testing has been shown to be effective in clarifying unclear chart-documented penicillin allergies and may assist in providing better antimicrobial stewardship and utilization of more cost-effective, first line therapies. The objectives of this review are to assess the number of patients on second-line broad-spectrum antibiotics for pneumonia due to a documented penicillin allergy and determine potential antibiotic cost-savings of implementing penicillin allergy testing to provide first-line antibiotics.

Methods: This study was submitted to the Veteran Affairs Portland Healthcare System Research/Development department for approval. Data will be collected on patients admitted with pneumonia from October 1st, 2015 to March 31st, 2016. The data collected will be used to determine the number of patients that were a candidate for penicillin-based antibiotic therapy during that time period, but received different antibiotics due to documented penicillin hypersensitivity. Data will be retrieved from electronic medical record systems and entered in a password-protected Microsoft Excel spreadsheet database. All data will be stored securely to maintain patient confidentiality. Patient charts selected by the inclusion criteria will be reviewed for patient demographics, pertinent laboratory values, type of reaction documented for penicillin allergy, antibiotic received, prior administration history of penicillin, beta-lactam, cephalosporin, or carbapenem antibiotics. Percentage of Veterans who received second-line antibiotics, when a penicillin-based antibiotic was indicated, will be calculated and analyzed by descriptive statistics.

**Submission Type:** Descriptive Report  

**Session-Board Number:** 1-299  

**Poster Title:** Pregnancy screening and prevention in female Veterans of child-bearing potential receiving potentially teratogenic mood stabilizer medications  

**Primary Author:** Cassandra Abeyta, VA Portland Health Care System, OR; **Email:** cassandra.abeyta@va.gov  

**Additional Author(s):**  
Jeanne Peterson  
Eileen Wilbur  
Jeegisha Patel  

**Purpose:** The aim of this retrospective quality assurance project is two-fold. First, this review seeks to evaluate whether female Veterans of child-bearing potential who have been prescribed Pregnancy Category C, D, or X mood-stabilizing medications were screened for pregnancy and contraception use both upon initiation of the medication, as well as with each follow-up visit. Second, this review will assess whether Veterans were counseled on medication-specific risks and benefits prior to initiation. The results may help identify possible strategies for improvement in pregnancy screening and prevention in the setting of potentially teratogenic medications, and thus further optimize patient care and safety.

**Methods:** This project will examine the frequency of both pregnancy and contraceptive screening at this facility, as well as contraceptive counseling prior to initiation of a potentially teratogenic therapy. The primary endpoint will be the number of patients who received a Category C, D, or X mood-stabilizing medication and did not have pregnancy and contraceptive screening before initiation and with each subsequent follow-up appointment. The secondary endpoint evaluated for this project will be whether counseling regarding contraceptive use and potential risks of the Category C, D, or X teratogen was documented at the time of prescribing. This will be a single-center retrospective chart review. Females between the ages of 18-52 who received one of the medications in question (divalproex, lamotrigine, lithium, topiramate, or valproic acid) will be identified through prescription data search for the time frame of July 1, 2015 to June 30, 2016. Prescription data will also be used to assess whether or not the Veteran was receiving an oral, vaginal, patch, or injectable contraceptive medication at the same time. Chart review will be done on those Veterans identified to assess for pregnancy screening,
identify if other forms of contraceptive (i.e. IUD, implant) are used, and rule out any women with hysterectomy, tubal ligation, or documented infertility.

**Results:** None to date

Poster Title: Evaluation of cost-savings and sustained virologic response rates between Hepatitis C treatment regimens at VAPORHCS

Primary Author: Julia Mwangi, VA Portland Health Care System PGY1, OR; Email: mwangik05@gmail.com

Additional Author (s):
Long Do
Eileen Wilbur
Lynnette Klaus

Purpose: New oral therapies that directly target HCV have proved to be more effective and have fewer side effects. However, these drugs are very costly. In February 2016, a new VA contract was negotiated which led to a significant price reduction of sofosbuvir/ledipasvir compared to sofosbuvir alone. As a result, treatment for genotype 2 patients at Portland VA Health Care System (VAPORHCS) was changed from sofosbuvir + ribavirin to sofosbuvir/ledipasvir + ribavirin. The aim of this project is to evaluate the cost-savings, sustained virologic response at week 12 (SVR12) and tolerability of sofosbuvir/ledipasvir + ribavirin versus sofosbuvir + ribavirin.

Methods: Records to be reviewed will be obtained from VAPORHCS electronic medical record systems. A search of all patients who received combination sofosbuvir/ledipasvir + ribavirin and sofosbuvir + ribavirin from January 2015 through August 2016 will be conducted in order to identify charts to be reviewed. The investigators will be responsible for identifying and reviewing all records in order to screen for study eligibility. Data to be collected for patients that meet the inclusion criteria includes: age, presence or absence of cirrhosis, prior HCV treatment, SVR12 data, and documented side effects from treatment received. Confidentiality risk will be minimized by de-identifying patient information with a separate file with the key. The SVR12 data of patients who received sofosbuvir + ribavirin will be compared to SVR data from patients that received sofosbuvir/ledipasvir + ribavirin. The main outcome measure will be cost-savings associated with new treatment protocol of HCV genotype 2 patients. The cost savings data will be based on the VA negotiated contract. Secondary outcomes will be any
difference in SVR12 between the two groups, and any documented side effects that may have led to discontinuation of treatment.

**Poster Title:** Impact of decentralization of anticoagulation in an outpatient VA setting

**Primary Author:** Eugenia Su, VA Roseburg Healthcare System, OR; **Email:** eugenia.su@gmail.com

**Additional Author (s):**
Mary Flack
Julie Rodgers

**Purpose:** The Veteran Affairs Roseburg Healthcare System (VARHS) has historically used a centralized model for anticoagulation management, where one clinical pharmacy specialist (CPS) manages all patients receiving anticoagulation therapy. Within the last three years, the VARHS has transitioned to a decentralized model, where CPS manage patients on anticoagulation within their assigned patient aligned care team (PACT). The purpose of this study is to compare the efficacy and safety of decentralized versus centralized management of anticoagulation in an outpatient Veteran population.

**Methods:** Data will be collected using the VA National Data Extract, and the Anticoagulation Management Tool (AMT) built into the Computerized Patient Record System (CPRS). The data will be extracted from patients receiving anticoagulation therapy with warfarin through the Eugene VA Clinic, a community based outpatient clinic (CBOC) that is part of the VARHS. Patients receiving anticoagulation therapy with direct oral anticoagulants (DOAC) will be excluded. Previously the Eugene VA Clinic operated a centralized anticoagulation clinic and transitioned to decentralized management of anticoagulation in January 2016. Retrospective data will be collected from February 2015 to September 2015 and February 2016 to September 2016. In order to determine the clinical effects of centralized versus decentralized anticoagulation management, the efficacy and safety endpoints that will be investigated include: time in therapeutic range (TTR) and adverse events. Secondary endpoints examined will include CPS workload, and patients lost to follow up which is defined patients with no INR value within 42 days.

**Poster Title:** Antibiotic Stewardship Impact on Prescribing Practices and Patient Outcomes at Warm Springs Health and Wellness Center

**Primary Author:** Andrew Portier, Warm Springs Health and Wellness Center, OR; **Email:** andrewportier08@gmail.com

**Additional Author(s):**
Jessie Casberg

**Purpose:** Antibiotic resistance is a serious public health concern and continues to grow with inappropriate antibiotic prescribing. As a result, there is immediate demand for proactive public health strategies that will reduce health care costs and limit development of further bacterial resistance. Warm Springs Health and Wellness Center has implemented the use of guideline directed antibiotic order sets to promote consistent and appropriate prescribing practices. The purpose of this study is to better understand the impact of these order sets as an antibiotic stewardship intervention. If effective, this simple intervention could be a valuable model for other ambulatory care clinics.

**Methods:** An observational chart review will be conducted to measure the effect that guideline directed antibiotic order sets have on prescribing practices and patient outcomes. The antibiotic order sets used in this study will include guidelines for sinusitis, otitis media, community acquired pneumonia, and bronchitis. The impact of the order sets will be measured by the percentage of appropriate antibiotic prescriptions before and after order sets were implemented. Further analysis will look at clinical failure, patient compliance and providers’ opinion of the order sets. Clinical failure will be defined as any of the following three outcomes: treatment failure, recurrent infection, or change in therapy because of an adverse drug event. Chart reviews will also provide some compliance data by measuring the number of patients picking up watchful waiting prescriptions and refills extending antibiotic therapy. Provider surveys will be yes/no, true/false or multiple choice questions used to assess the providers’ order set usage and how much the providers value these resources. Data from the surveys will remain anonymous to encourage honest responses. Once all data is collected, the primary endpoint will be compared to the supplemental endpoints to find an association of interventions and improved patient outcomes.

**Poster Title:** Naltrexone long acting injectable utilization and impact on alcohol detoxification hospitalizations

**Primary Author:** Christine Hancock, Corporal Michael J. Crescenz Department of Veterans Affairs Medical Center, PA; **Email:** christinemhancock@gmail.com

**Additional Author (s):**
Melissa Shiner

**Purpose:** Currently there are four FDA approved treatments for alcohol use disorder (AUD) disulfiram, acamprosate, naltrexone and long acting injectable (LAI) naltrexone. Compliance is a limitation of the three oral medications and it may be lessened by monthly injections. The study objectives are to evaluate utilization of naltrexone LAI on the inpatient psychiatry unit for AUD with regard to 1) continuation of therapy outpatient and 2) readmission to inpatient psychiatry unit with alcohol detoxification as a primary or secondary diagnosis within three months of initiating therapy versus readmission rates for AUD patients not receiving the LAI naltrexone.

**Methods:** This retrospective chart review has been determined to be a quality improvement study by the Institutional Review Board at the Corporal Michael Crescenz Veterans Affairs Medical Center. Eligible patients will be identified from a list of inpatient psychiatry unit alcohol related admissions with a primary or secondary diagnosis of AUD or detoxification and a list of naltrexone oral or LAI prescriptions limited to those on the inpatient psychiatry unit between the dates 07/01/2015 and 06/30/2016. The three months following the first injection or admission will be reviewed. Patients will be excluded if the indication for receiving naltrexone LAI is opioid use. The charts will be reviewed and the following information will be compiled: demographics, date of first naltrexone injection, location and date of subsequent injections, number of naltrexone LAIs prescribed and administered and other pharmacologic treatments for AUD used by the patients. Data will be de-identified, securely recorded and analyzed to determine if the use of naltrexone LAI is decreasing alcohol related admissions in our patient population versus other treatments or no treatments. The clinic or unit where subsequent injections and the number of follow up injections will be assessed for naltrexone LAI to determine the rate of compliance over three month period.

Poster Title: Evaluation of cost associated with management of angiotensin-converting enzyme inhibitor induced angioedema at a Veterans Affairs Medical Center

Primary Author: Himani Doshi, Corporal Michael J. Crescenz VA Medical Center, PA; Email: himani.doshi@va.gov

Additional Author (s):
Andrew Rogalski

Purpose: Angiotensin-converting enzyme (ACE) inhibitors are commonly prescribed within the Veterans Affairs Health Care System. ACE inhibitors are indicated for many disease states including, hypertension, diabetes, chronic kidney disease, heart failure, post-myocardial infarction, and coronary artery disease. Angioedema is a rare but serious side effect that is associated with this drug class. ACE inhibitor induced angioedema management can impact the overall cost to the health-care system. The purpose of this research project is to evaluate the cost associated with management of ACE inhibitor induced angioedema at the Corporal Michael J. Crescenz VA Medical Center (CMCVAMC).

Methods: This study has been submitted to the Institutional Review Board for approval. It is a retrospective chart review examining patients in both inpatient and outpatient settings at the CMCVAMC. We will identify relevant charts using the VA adverse drug event reporting system (VA ADERS). Patient charts used for analysis will be of adult (18 and over) male and female patients who had reported angioedema while on an ACE inhibitor for any indication. We will estimate the cost for procedures, consults, and physician services from Centers of Medicaid and Medicare Services allowable charges, internal procurement cost, and Healthcare Bluebook. Drug treatment costs will be estimated based on average wholesale price. We will evaluate trends from our data to encourage future cost effectiveness studies comparing ACE inhibitors to alternative therapies. We anticipate reviewing up to 400 total patient charts for data analysis.

**Poster Title:** Quality improvement to limit fluoroquinolone use for urinary tract infections in the outpatient setting

**Primary Author:** Kimmy Nguyen, Corporal Michael J. Crescenz Veterans Affairs Medical Center, PA; **Email:** kimmy.thy.nguyen@gmail.com

**Additional Author (s):** Katie Ang
Darren Linkin

**Purpose:** Fluoroquinolones are often used for the treatment of urinary tract infections (UTIs) since they achieve extensive urinary concentrations with historically high activity against common causative pathogens. However, the Infectious Diseases Society of America (IDSA) guidelines and the Corporal Michael J. Crescenz Veterans Affairs Medical Center (CMCVAMC) antibiogram report significant fluoroquinolone resistance. A recently updated black box warning to include potentially permanent and disabling adverse effects highlights the need for limited fluoroquinolone use as last line options. The study aims to determine the incidence of inappropriate fluoroquinolone use in the outpatient setting before and after guideline feedback and education.

**Methods:** This quality improvement project focuses on fluoroquinolone use in the treatment of UTI before and after an intervention. Phase one of the project is a retrospective chart review to examine the number of fluoroquinolone prescriptions issued by primary care providers in the outpatient setting at the CMCVAMC. Patients enrolled in specialty clinics or services, such as urology, renal clinic, and home-based primary care, will be excluded. Collected data will be analyzed for inappropriate use of fluoroquinolones based on current treatment guidelines. Phase two of the project will provide education and feedback to primary care providers. This intervention will be conducted through targeted emails and a live presentation. The proportion of inappropriate fluoroquinolone use will be compared before and after intervention. Subgroup analyses will include the following: empiric versus definitive therapy, and lower UTI only versus UTI with systemic illness. In those receiving definitive therapy, the urine culture results will also be reviewed. 95% confidence intervals will be used for all point estimates. The rate of fluoroquinolone use in UTI treatment per patient visits will be compared before and after
intervention. Additionally, the proportion of fluoroquinolone use in UTI will be compared to fluoroquinolone use as a whole. Data will be collected and analyzed from outpatient primary care clinics over the course of several months with an anticipated completion date by the end of April 2017.

**Poster Title:** Appropriateness of broad spectrum antipseudomonal agents seventy-two hours after initiation

**Primary Author:** Ivan Puskovic, Corporal Michael J. Cresenz Veterans Affairs Medical Center, PA; Email: ivan.puskovic@va.gov

**Additional Author (s):**
Brooke Klenosky
Darren Linkin

**Purpose:** De-escalation of broad spectrum antibiotics in cases where they are no longer needed is a necessity in not only preventing the side effects associated with these agents, but helping stop the spread of antimicrobial resistance. The recently updated Joint Commission antimicrobial stewardship guideline published a list of core elements that an antimicrobial stewardship program must have, including the need for having a systemic evaluation of ongoing antibiotic therapy. This project aims to evaluate the appropriateness of antipseudomonal therapy after 72 hours of initial empiric treatment and to intervene with recommendations to providers when a change in therapy may be indicated.

**Methods:** This project was approved by the Institutional Review Board as a quality improvement project. Using Theradoc, an electronic clinical surveillance software that is incorporated into the hospital’s electronic medical record, all acute care inpatients admitted to the Corporal Michael J. Cresenz Veterans Affairs Medical Center on broad-spectrum antipseudomonal therapy greater than 72 hours will be identified. All data collected will be stored within Theradoc. An initial assessment will be made to see if treatment continuation is appropriate, like in documented Pseudomonas aeruginosa infections. If treatment is not appropriate, or appropriateness is uncertain, contact will be made to the appropriate pharmacist on the floors to discuss de-escalation of therapy with the medical team. Follow-up on the medical team’s decision to either continue treatment or to de-escalate treatment will then be made by said pharmacist to the investigator, who will document the intervention. Additional data to be collected includes: initial antipseudomonal agent and what it was de-escalated to, time it took to de-escalation, and percentage of cases where cultures were not obtained in the initial 72-hour treatment window.

Poster Title: Implementation of diabetes education classes utilizing clinical video telehealth

Primary Author: Morgan Peterman, Lebanon VA Medical Center, PA; Email: morgan.peterman@va.gov

Additional Author(s):
Heather Ulrich
Kevin Koons

Purpose: Currently, diabetes education classes are only available at the medical center’s main campus. Clinical pharmacy specialists and registered dieticians lead the three-class series consisting of diabetes basics, healthy eating, and risk reduction. Veterans receiving care through community-based outpatient clinics (CBOC) must commute to the main campus for the series. The goal of this project is to increase Veterans’ access to diabetes education classes through the use of real time, clinic-based video telehealth (CVT) technologies. By utilizing CVT, this series would be available to a greater number of Veterans with pre-diabetes or newly diagnosed type-2 diabetes mellitus (T2DM) within our facility.

Methods: This project was reviewed and approved in accordance with local policy and procedure for quality improvement projects. Currently, providers place a consult for diabetes education classes, which lists the main campus as the only location for group classes. Once the consult is placed, the Veteran is then scheduled for the series, three consecutive Monday afternoons in the designated month. This project will designate a single CBOC to serve as the pilot program and utilize CVT technologies for class facilitation. The clinical pharmacy specialists will work with the nutrition department to combine efforts for live CVT classes from the main campus to the pilot CBOC. The diabetes educators will also collaborate with CVT coordinators at the designated pilot CBOC to define program structure. Clinic grids and schedules will need to be established to coincide with the main campus. Additionally, education on the consult and series will be given to ancillary staff, primary care providers, and CVT coordinators at the pilot CBOC prior to implementation.
The current consult will be updated to include the pilot CBOC as a second location option. If the pilot CBOC is selected on the consult, the Veteran will then be scheduled for the live group education classes via CVT. Following the pilot program period, strengths and weaknesses of the program will be assessed before consideration of expansion to additional CBOCs.

Poster Title: Defining the role of the patient aligned care team (PACT) pharmacist

Primary Author: Kelcymarie Bye, Lebanon VA Medical Center, PA; Email: kbye@umaryland.edu

Additional Author(s):
Michele Margut

Purpose: Patient-centered medical homes (PCMHs) have become a foundation for primary care, involving a team of healthcare professionals working together with the patient as the focus. At the Department of Veterans Affairs (VA), primary care is structured as PCMHs that are known as Patient Aligned Care Teams (PACTs). These teams include pharmacists, but the concept of a pharmacist in primary care is relatively new. The objective of the project is to define the role of the PACT pharmacist at this facility.

Methods: This will be a quality improvement project. The plan will be to first assess the current responsibilities of the PACT pharmacist. Then, the structure of PACT pharmacy services, including communication methods, procedures for documentation, referral services, and appointment schedules, will also be reviewed. After defining the structure and responsibilities, a process to educate providers and patients on the role of the PACT pharmacist will be developed. This will provide a clear guideline to have consistency between the PACT pharmacists and to distinguish the roles of the PACT pharmacist from other clinical pharmacy specialists.

**Poster Title:** Impact of a transitions of care pharmacist at discharge and follow-up after total hip or knee arthroplasty

**Primary Author:** Chelsea Reed, Lebanon VA Medical Center, PA; **Email:** chelsea.reed2@va.gov

**Additional Author(s):**
Ashley Kelley

**Purpose:** Pharmacists are well-suited to assist in transitions of care (TOC) processes among patients at a high risk of hospital readmission. Patients undergoing elective knee or hip arthroplasty are at risk of complications or readmission, and the Centers of Medicare & Medicaid Services (CMS) has added the 30-day all-cause readmission rate for this population to the quality measures that they monitor. The objective of this project is to assess the impact of pharmacist-led medication reconciliation and education at discharge after total hip or knee arthroplasty on 30-day all-cause readmission rate.

**Methods:** This project has been approved by the pharmacy excellence committee. Patients undergoing an elective total knee or hip arthroplasty will be identified prior to discharge and will receive the following TOC services: discharge medication reconciliation, medication counseling, and a printed copy of the discharge medication list. Patients will be excluded if they are discharged to a long term care or assisted living facility, transitioning to another service in the hospital, or discharged to a nursing home. Patients will be offered a follow-up telephone call within five days of discharge to address any questions or concerns. Additionally, if the patient receives care from a non-VA primary care physician, an offer will be made to forward the discharge medication list to that provider. Baseline demographics will be collected and the primary outcome will be to assess the impact of pharmacist TOC services on 30-day all-cause readmission rate. Data collected will be compared with baseline data from patients undergoing hip or knee replacement prior to implementation of the above TOC services. The findings from the project may be used as evidence of the benefits of having a pharmacist providing these services in the future.

Poster Title: Implementation of a pharmacist managed electronic consult service for perioperative anticoagulation management

Primary Author: Christine Trusky, Lebanon VA Medical Center, PA; Email: christine.trusky@va.gov

Additional Author(s):
Ashley Kelley
Kevin Koons
Amanda Sturges

Purpose: Currently no standardized practice exists for perioperative anticoagulation management at this VA Medical Center. The objective of this project is to develop a pharmacist managed electronic consult (e-consult) service in order to provide a centralized process for perioperative anticoagulation management.

Methods: Current perioperative anticoagulation management at this institution will be reviewed. The following data from the electronic medical record will be collected: duration of anticoagulant interruption, documentation of instructions provided to patient, documentation of enoxaparin counseling, procedural delays related to anticoagulation management, and appropriateness of enoxaparin dosing. Education will be provided to primary care physicians (PCPs) and surgeons regarding the current evidence and recommendations for perioperative anticoagulation management. Additionally, a pharmacist managed e-consult service will be implemented. This consult service will provide recommendations for patients requiring perioperative anticoagulant management in a standardized template.

**Session-Board Number:** 1-311

**Poster Title:** The impact of a clinical reminder in prescription patterns of Nonsteroidal Anti-inflammatory Drugs, in patients with oral anticoagulant therapy among VA Caribbean Healthcare System providers

**Primary Author:** Vanessa Estrada-Rodríguez, VA Caribbean Healthcare System, PR; **Email:** vanessa.estrada@upr.edu

**Additional Author(s):**
Giselle Rivera

**Purpose:** Administration of NSAIDs and anticoagulants concomitantly can significantly increase the risk of a hemorrhagic event. Recent studies have proved that NSAIDs double bleeding risk with anticoagulants for DVT/PE, even when the treatment is just for a few days. Providers are used to prescribe these two medications concomitantly. Computerized Patient Record System (CPRS) clinical reminder will help the provider identify the risks of these interactions and as a result it will be expected to decrease concomitant administration of anticoagulants and NSAIDs. The purpose of this study is to know if this clinical reminder will have an impact in physicians prescription patterns.

**Methods:** We will be identifying patients with concomitant therapy of oral anticoagulants and NSAIDs in the time frame of October 2015 – August 2016 (Fiscal Year 16) thru a report. We will review the medical records of the identified patients for any signs or symptoms of bleeding during the concomitant use of the two drugs. After the assessment of incidence of bleeding we are going to implement a clinical reminder for providers prescribing NSAIDs about the risk of the interaction with a chronic treatment of oral anticoagulants. After 3 months post implementation we will identify patients with concomitant therapy of oral anticoagulants and NSAIDs again. And then with these results present the difference if any of the prescribing patterns after the implementation of the clinical reminder, comparing the rates of concomitant prescribing of NSAIDs and oral anticoagulants before and after the implementation of the reminder.

**Session-Board Number:** 1-312

**Poster Title:** Use of sodium-glucose co-transporter 2 inhibitors in patients at VA Caribbean Healthcare System (VACHS)

**Primary Author:** Karla Jimenez-Rodriguez, VA Caribbean Healthcare System, PR; **Email:** kj532@nova.edu

**Additional Author (s):**
Glendaly De Jesus-Cruz

**Purpose:** Recent studies have demonstrated the effectiveness of sodium-glucose co-transporter 2 inhibitors (SGLT-2) in patients with type 2 diabetes and cardiovascular disease. These are the newest class of oral anti-diabetic drugs on the market. Within the VA Healthcare System two of the three medications in this class are available: canagliflozin and empagliflozin. The rationale for performing this project as a Medication Use Evaluation is to determine the appropriateness and safety of the class of sodium-glucose co-transporter 2 inhibitors (SGLT-2) in the VA population selected.

**Methods:** This medication use evaluation of the SGLT-2 inhibitors class will include patients from the VA Caribbean Healthcare System. Also, patients with cardiovascular conditions who are currently on other medication than empagliflozin within the class of SGLT2 inhibitors will be switched to the VHA preferred therapy of empagliflozin. Inclusion criteria for this switch in therapy is as described in VA PBM Criteria for use of empagliflozin. Patients who do not have concomitant cardiovascular disease will be excluded from the group of patients that will be switched to empagliflozin. The project will be carried out by reviewing the medical charts of the patients. A time period will be selected from the date in which the patient started taking the medication until at least six months of therapy. Since VA has predetermined criteria for use for SGLT-2 inhibitors, each criterion will be evaluated to determine if patients meet each and every one of the required criteria. In terms of clinical outcomes, the following will be described in a retrospective manner by reviewing medical charts: Hemoglobin A1c, fasting glucose, blood pressure, weight, serum creatinine and estimated glomerular filtration rate. The appropriateness of this class of medication will be measured in terms criteria for use met in each patient. Safety analysis will be described according to the adverse effects of the class, tolerability and/or discontinuation of the medication.

Poster Title: Pharmacist-led interdisciplinary initiative to decrease benzodiazepine use in geriatric population of VACHS

Primary Author: Krissa Funes, VA Caribbean Healthcare System, PR; Email: krissa.funes@va.gov

Additional Author (s):
Lucia Garcia-Carmona

Purpose: The Beers Criteria published in 2015 by the American Geriatrics Society strongly recommends benzodiazepines be avoided in the elderly for the treatment of insomnia, agitation, or delirium. Benzodiazepines increase the risk of cognitive impairment, delirium, falls, and fractures. The goal of this activity is to minimize the exposure of elderly patients to side effects and adverse events associated with use of benzodiazepines.

Methods: In 2013, the Psychotropic Drug Safety Initiative (PDSI) dashboard was launched nationwide, in each VHA facility to foster the highest quality of treatment. The goal of this Veterans Health Administration (VHA) initiative is to help improve psychotropic drug prescribing by identifying patients who may benefit from a more thorough clinical review of current treatment, such as benzodiazepine drug utilization review in geriatric populations. The PDSI dashboard will be used to identify patients that are 75 years of age or older who are taking benzodiazepines. Patients will be selected from the outpatient setting, specifically those followed by the Geriatric Patient Aligned Care Team (PACT) clinic. PACT clinics are organized into interdisciplinary teams with the goal to improve clinical continuity, coordination, and patient-centeredness. Patients taking benzodiazepines for seizure disorder or under hospice care will be excluded from the activity. Patient will be contacted by team pharmacists via telephone to discuss potential side effects and adverse events of benzodiazepine use and patient willingness for discontinuation. Primary care provider (PCP) will be informed of patient interest to discontinue use of benzodiazepine. PCP will determine if discontinuation is appropriate, in which case an electronic consult will be generated for psychiatry for guidance in benzodiazepine taper. Patients will be followed up by the pharmacist to ascertain appropriate discontinuation taper of the benzodiazepine.

Poster Title: Use of Erythropoietin in Oncology Patients at VA Caribbean Healthcare System in San Juan, Puerto Rico (VACHS)

Primary Author: Sara Thompson, VA Caribbean Healthcare System, PR; Email: sara.thompson16@va.gov

Additional Author(s):
Lymaris Cruz-Diaz

Purpose: To describe the use of erythropoietin in the oncology patient population at VACHS. Current guidelines at the VA align with the ESA REMS program and state that the use of erythropoietin should be limited to those undergoing at least two planned rounds of palliative chemotherapy and who suffer anemia defined as a hemoglobin <=11mg/dL with symptoms or <=10mg/dL without symptoms. It is also recommended that the patient’s hemoglobin be monitored every 4 weeks. The project will assess the appropriateness of oncology patients selected for erythropoietin, their monitoring, and, if applicable, the conditions under which therapy was discontinued.

Methods: Our study will be a retrospective chart review. Patients will be selected from the APPRISE REMS program enrollment forms as these are individuals who have received erythropoietin for purposes of supportive care of anemia in the oncology setting. Approximately 80 patients spanning from 2011 to present are available to collect the following information from the medical record: Initial dose of erythropoietin, frequency of administration, dosage adjustments, number of doses received, hemoglobin levels, serum ferritin, folate, TSH, vitamin B12, planned duration of chemotherapy, intent of chemotherapy (curative or palliative), date of discontinuation of erythropoietin, reason for discontinuation, and adverse drug reactions documented. All patient information will be maintained in a secure and locked area at all times. Our goal is to collect parameters that describe the current practice of erythropoietin use in the oncology population at this institution.

Poster Title: Initiating direct oral anticoagulants through the use of clinical video teleconference software at the Providence VA Medical Center (PVAMC) – a new clinic startup.

Primary Author: Christopher Goncalo, Providence VA Medical Center, RI; Email: christopher.goncalo@gmail.com

Additional Author(s):
Carlos Freitas
Carol Botelho

Purpose: Warfarin is one of the most widely used anticoagulants today; however its use is slowly falling out of favorability since the release of the Direct Oral Acting Anticoagulants (DOAC). DOACs require less monitoring, but still have a high bleeding risk. At the PVAMC, initiation of a DOAC requires an appointment with a Clinical Pharmacy Specialist to discuss risks, and assess adherence. For select patients, a major barrier to patient care may include lack of long distance transportation, subsequently disqualifying eligible candidates to be converted. This study aims to eliminate that disparity and allow patients to be seen, regardless of distance.

Methods: This study will be submitted to the Institutional Review Board for prior approval. A new clinic will be introduced utilizing clinical video teleconference, or CVT, that will connect to three community based outpatient clinics, or CBOCs. The Computerized Patient Record System (CPRS) will identify patients who currently are on warfarin, their location, and use of a CBOC as their primary location of care. Additionally, the Anticoagulation Sharepoint Dashboard will identify patients who have a time in therapeutic range, or TTR, less than 50%. Those who meet both criteria will be offered an appointment to be seen for conversion. At the end of the appointment, the patient will be given a survey of their experience and satisfaction with their CVT appointment. In addition to the patients being selected due to low TTR, consults will be available for provider entry on patients with new indications for anticoagulation and not eligible for warfarin therapy. The following data will be collected from all patients seen in clinic: patient age, height, weight, gender, ethnicity, current warfarin dosing, warfarin refill history, current TTR, LFTs, total bilirubin, serum creatinine, patient satisfaction, and provider satisfaction. Primary outcomes will look at compliance ratio prior to initiating a DOAC, number of patients
converted to a DOAC, indications prohibiting conversion, and patient satisfaction. Secondary outcomes will look at patient conversion from consults and provider satisfaction.

Poster Title: Antipsychotic use as a risk factor for first episode venous thromboembolism (VTE): A case-control study

Primary Author: Amanda Eloma, Providence VA Medical Center, RI; Email: amanda_eloma@my.uri.edu

Additional Author(s):
Robert Dufresne
Cristofer Price

Purpose: There have been numerous case reports of venous thromboembolism (VTE) in patients receiving antipsychotic (AP) treatment. Although some literature suggests a probable association, more studies are needed to determine the comparative risk. Clozapine remains the most extensively reported AP associated with VTE. Data comparing the VTE risk potential of various antipsychotics subtypes and prescribing patterns is sparse. Some suggest VTE risk is dependent on type, potency, and agent, however other parameters (i.e., dose, duration of treatment) were not addressed. Our objective is to evaluate if AP use may be associated with the development of first episode VTE.

Methods: This retrospective case-control study will compare Veterans’ diagnosed with first episode VTE from August 1st, 2014 to July 31st, 2015 with matched controls (by age and sex). Frequency of active AP prescriptions at the time of VTE diagnosis will be determined for each group. We will review the use of AP and determine if there is a higher incidence of AP use in the VTE Case Group. Inclusion criterion includes patients greater than 18 years of age. Exclusion criteria includes malignancy, surgery/trauma in last 3 months, pregnancy, use of oral contraceptives, immobilization, history of VTE, atrial fibrillation, hormone replacement therapy, antiphospholipid syndrome, factor V Leiden deficiency, and prescribed any anticoagulants. The following data will be collected: demographics (age, sex, race, BMI), VTE ICD-9 /ICD-10 codes, antipsychotic parameters (name, dose, start date, date of most recent fill), and VTE risk factors such as smoking status.

The primary outcome is to determine AP risk of VTE. Secondary outcomes include analyzing which AP subtype, dosage, or usage pattern may place patients at higher risk of VTE. This study is pending Institutional Review Board approval.

Poster Title: Effect of lifestyle modification services on glycosylated hemoglobin in new onset type 2 diabetes mellitus: a pilot study

Primary Author: Jessica Lau, Providence Veterans Affairs Medical Center, RI; Email: lau.j@husky.neu.edu

Additional Author (s):
Carol Botelho

Purpose: The American Diabetes Association recommends lifestyle modifications, including diet and physical activity, as the cornerstone of diabetes management. The Providence Veterans Affairs Medical Center (PVAMC) offers services that target lifestyle changes to benefit glucose control, including nutrition, exercise programs, and diabetes education. However, a comprehensive diabetes service for patients with new onset type 2 diabetes mellitus (T2DM) is lacking. The objective of this study is to determine the change in glycosylated hemoglobin (HbA1c) in patients with new onset T2DM who are referred for, and enroll in, lifestyle modification services relative to patients who do not receive services.

Methods: This study will be submitted to the Institutional Review Board for approval. A retrospective electronic chart review will be conducted to identify patients with at least two consecutive HbA1c values between 6.5 and 8.0 percent. Patients with type 1 diabetes mellitus and patients on insulin therapy during screening will be excluded from the study. Patients with HbA1c between 6.5 to 8.0 percent will be further classified into two groups based on if the patient was referred to, and enrolled in, lifestyle modification services at the PVAMC. Subsequent changes in HbA1c will be assessed at 6, 12, and 24 months. At each interval, the difference in HbA1c between groups will be compared to characterize the effect of lifestyle modification services on diabetes control. Other data that will be collected include: patient age, gender, ethnicity, baseline body mass index, and medication list. No patient identifiers will be collected to maintain patient confidentiality.

Poster Title: Impact of medication reviews and interventions conducted by pharmacy representatives on frequency of falls

Primary Author: Chelsea Sampadian, Providence Veterans Affairs Medical Center, RI; Email: chelsea.sampadian@gmail.com

Additional Author (s):
Carol Botelho

Purpose: Falls are associated with increased morbidity, mortality, and direct medical costs. While generally multifactorial in nature, most falls are preventable, with medications being a common modifiable risk factor. Pharmacists maintain a crucial role in identifying medications that increase fall risk and performing applicable interventions. The primary objective of this study is to determine the impact of medication reviews and interventions conducted by a pharmacy representative on the frequency of falls in a home based, primary care patient population.

Methods: This study has been submitted to the Institutional Review Board for approval. A retrospective electronic chart review will be executed for patients enrolled in home based primary care between September 1, 2010 to September 1, 2015, who experienced at least one documented fall that was subsequently evaluated by a pharmacy representative (clinical pharmacist, pharmacy resident, or pharmacy student) for medication-related risk factors. Medical records that do not include at least one subsequent medication review and intervention recommended by the pharmacy representative will be excluded from the study. The primary endpoint is the difference in frequency of falls between the accepted pharmacy intervention group compared to the rejected pharmacy intervention group. Secondary endpoints include the most prevalent medication classes intervened upon by the pharmacy representative, as well as by the prescriber, and medication classes most often associated with a reduction in fall frequency. Baseline characteristics include age, sex, race, weight, height, body mass index, co-morbidities, as well as baseline medications and specific baseline laboratory values. All data will be collected via a standardized data collection form and void of any patient identifiers to maintain confidentiality.

**Poster Title:** Evaluation of the association between chronic proton pump inhibitor use and dementia at the Providence Veterans Affairs Medical Center

**Primary Author:** Alissa Scalise, Providence Veterans Affairs Medical Center, RI; Email: alissa.scalise@gmail.com

**Additional Author (s):**
Carol Botelho

**Purpose:** Proton pump inhibitors (PPIs) have been associated with an increased risk of incident dementia in recent studies. PPIs have been shown to decrease vitamin B12 levels with long term use which can be associated with decreased cognitive functioning. Additionally, PPIs were observed to enhance beta-amyloid levels in the brains of mice. The primary objective of this study is to determine if there is an association between chronic PPI use and incident dementia exists at the Providence Veterans Affairs Medical Center. A secondary objective will be completed to assess whether each patient had other known risk factors for cognitive decline.

**Methods:** This study will be submitted to the Institutional Review Board for approval. A retrospective electronic chart review will be conducted. Patients ≥ 65 years old who have been prescribed a 90-day supply of a PPI (omeprazole, esomeprazole, lansoprazole, pantoprazole and/or rabeprazole) at least one time from September 2014 to September 2016 will be included. The following data will be collected: patient age, gender, medical conditions, and medication list. If available, vitamin B12 and vitamin D levels will be collected. All data will be recorded without patient identifiers and maintained confidentiality. Patients found to meet these criteria will be separated into two groups, patients with a dementia diagnosis and patients without a dementia diagnosis. These groups will then be reviewed and further separated into patients with chronic PPI use, and short-term PPI use. Chronic PPI use will be defined as at least 1 prescription for a PPI filled per quarter for at least 1 year during the study period. For patients with a current diagnosis of dementia, the reviewers will determine if a dementia diagnosis was made after the initiation of chronic PPI use. The percent of the chronic PPI users diagnosed with dementia after initiating PPI use will be calculated.

**Poster Title:** Efficacy and Safety of Tacrolimus Three Times Daily Dosing in Pediatric Kidney Transplantation  

**Primary Author:** Zinah Alabdulkaim, King Faisal Specialist Hospital and Research Centre, Saudi Arabia; Email: zalabdulkarim99@kfshrc.edu.sa  

**Additional Author (s):**  
Ahmed Aljedai  
Dalal Alkortas  

**Purpose:** The aim of this study is to compare the efficacy and safety of three times daily (TID) to twice a day (BID) dosing of tacrolimus in pediatric kidney transplant patients, at King Faisal Specialist Hospital and Research Centre (KFSH&RC), Riyadh, Saudi Arabia.  

**Methods:** This is a retrospective, single center, comparative cohort study. All pediatric kidney transplant patients who aged less than or equal to 18 years were included. We excluded patients who received enzyme inhibitors and/or enzyme inducers in the first 14 days and who received tacrolimus BID dosing and reached therapeutic level with dose of less than 0.2 mg/kg/day. The primary endpoints were the percentage of patient who achieved therapeutic tacrolimus concentration at 5 days and median time to reach therapeutic tacrolimus concentration. The secondary endpoints were adverse events, patient and graft survival and biopsy proven acute rejection at 12 months. All patients who met the inclusion criteria were included. The study was approved by the Institutional Review Board (IRB).  

**Results:** A total of 86 patients were included in the study; 47 patients received tacrolimus BID and 39 patients received tacrolimus TID. The percentage of patients who achieved therapeutic levels with tacrolimus TID, did not significantly differ from those who received BID regimen at day 5 (48.7% TID vs. 61.7% BID; P=0.227). The median time to reach therapeutic level was three days for both groups. Adverse events were similar between the groups, however, elevated serum creatinine (57.44% vs. 30.77%; P=0.013) and hypomagnesemia (97.87% vs. 84.61%; P=0.025) were significantly more prevalent in the BID group. No significant difference in the patient survival (100% TID vs. 100% BID), graft survival (97.43% TID vs. 100% BID; P=0.269) and
biopsy proven acute rejection (15.38% TID vs. 14.89% BID, P=0.95) were seen between two groups.

**Conclusion:** No significant difference was observed between tacrolimus BID and TID dosing in either the percentage of patients who achieved therapeutic levels or the time to reach therapeutic level.

Poster Title: Antibiotic stewardship intervention package for the outpatient treatment of urinary tract infections: A provider-feedback based approach

Primary Author: Marisa Sauer, Ralph H. Johnson VA Medical Center, SC; Email: marisa.l.sauer@gmail.com

Additional Author(s):
Katherine Pleasants

Purpose: The National Action Plan for Combating Antibiotic-Resistant Bacteria issued by the White House in March 2015 recommends establishment of Antimicrobial Stewardship Programs (ASPs) in all outpatient settings by year 2020. Urinary tract infections (UTIs) are the most common indication for antimicrobial prescriptions in the outpatient setting, thus are an ideal target for outpatient ASP intervention. The purpose of this project is to determine if ASP intervention with education and provider-specific feedback can increase appropriate outpatient antimicrobial prescribing for UTIs.

Methods: This project consists of a pre-intervention phase from October 2015 through December 2015 and an intervention phase from October 2016 through December 2016. Eligible patients are those seen in the Charleston and Goose Creek primary care clinics within the Ralph H. Johnson VA Medical Center; have had a documented diagnosis of UTI, cystitis, or asymptomatic bacteriuria; and have been concomitantly prescribed an oral antibiotic associated with UTI treatment, such as penicillins, cephalosporins, fluoroquinolones, sulfamethoxazole-trimethoprim, and nitrofurantoin. The primary aim is to increase appropriate antibiotic usage for the outpatient treatment of UTIs. The following interventions will be routinely performed: patient and prescriber education, provider-specific feedback, one-on-one provider visits by regional VA pharmacy educators, UTI order set, and modification of antibiotic availability in clinic. Patient education will consist of educational posters and fliers in the waiting areas. Provider education will consist of monthly didactic presentations. Provider-specific feedback will consist of de-identified monthly report cards. Secondary aims include reducing inappropriate fluoroquinolone usage for outpatient UTI treatment, reducing inappropriate ordering of urine cultures for outpatient evaluation of UTIs, and assessing for UTI treatment failures.

**Poster Title:** Secondary prevention of atherosclerosis and cardiovascular disease with statin therapy in the elderly population in a veterans affairs community

**Primary Author:** Frances Ripepi, William Jennings Bryan Dorn VA Medical Center, SC; Email: frances.ripepi@va.gov

**Additional Author (s):**
Jared Wonders
Lauren Hundley
Kevin Brittain

**Purpose:** There is limited data to determine optimal use of statin therapy in the elderly population. The overall purpose of this study is to evaluate the efficacy and safety of statin therapy for secondary atherosclerotic cardiovascular disease (ASCVD) prevention in an elderly Veterans Affairs population. The primary outcome will be a comparison of the number of major ASCVD events between the statin and non-statin groups. The secondary outcome will assess discontinuation of statin therapy.

**Methods:** The following single-center, retrospective, observational study was approved by the institutional review board (IRB) to evaluate the safety and efficacious use of statins for secondary ASCVD prevention. The computerized patient record system (CPRS) will be utilized to identify patients 75 years or older with an international classification of diseases (ICD9) diagnosis code of clinical ASCVD, including myocardial infarction (MI), stroke, coronary artery disease, transient ischemic attack, peripheral vascular disease, angina, and coronary artery revascularization at the WJB Dorn VA Medical Center. Patients with familial hypercholesterolemia and those using non-statin lipid lowering therapies will be excluded. The study period will be October 1, 2010 to October 1, 2015. The following data will be collected: demographics, aspirin use, statin use prior to study, pertinent co-morbidities, statin regimen, adverse events, and major ASCVD events (non-fatal MI, cardiovascular heart disease death, non-fatal and fatal stroke) occurring during the study period. Baseline basic metabolic panel, cholesterol panel, and liver function tests will also be obtained. Charts will be reviewed for tobacco use, adherence to statin regimen, and cognitive function test scores, if available. The primary outcome will assess efficacy by comparing the combined endpoint of death due to
coronary heart disease, non-fatal MI, and fatal or non-fatal stroke between the statin and non-statin groups. Safety will be evaluated as the secondary endpoint using discontinuation rate and documented reasoning for discontinuation.

Poster Title: Assessment of glycemic outcomes in patients with type 2 diabetes infected with hepatitis C who achieved a sustained viral response with a direct-acting antiviral

Primary Author: Shannon Bear, William Jennings Bryan Dorn Veterans Affairs Medical Center, SC; Email: shannon.bear@va.gov

Additional Author (s):
Anne Bailey
Alexander Corboy
Kevin Brittain

Purpose: The purpose of this study is to evaluate potential changes in glycemic control in patients with type 2 diabetes with concomitant hepatitis C (HCV) infection treated with ledipasvir/sofosbuvir, ombitasvir/paritaprevir/ritonavir/dasabuvir, or elbasvir/grazoprevir, to determine the impact of direct-acting antiviral (DAA) therapy on glycemic control. The primary outcome of the study is change in A1c from baseline following DAA treatment course in patients achieving a sustained viral response at 12 weeks or longer (SVR12). Additionally, the study evaluates the effect of DAA therapy on cholesterol and BMI.

Methods: This study has been approved by the Institutional Review Board. The electronic medical record will be used to identify patients with type 2 diabetes and HCV genotype 1 who were treated with ledipasvir/sofosbuvir, ombitasvir/paritaprevir/ritonavir/dasabuvir, or elbasvir/grazoprevir and achieved SVR12 between January 1, 2015, and October 1, 2016. The study will include only those patients at least 18 years of age with an A1c checked within 4 months of HCV treatment initiation and within 4 months of achieving SVR12. Patients with a baseline A1c of less than 6.5% will not be included in the study, nor will patients using insulin pumps or those with a history of liver transplant. Data collected from the medical record will include demographic information, such as height, weight, sex, race, and age; HCV genotype; HCV viral load at baseline and SVR12; A1c, total cholesterol, LDL, HDL, non-HDL cholesterol, triglycerides, BMI, and total daily insulin dose at baseline and SVR12; and whether each patient had previously been treated with ribavirin prior to initiation of DAA therapy. The research analysis will be conducted via retrospective chart review. All data will be maintained
confidentially. Patient characteristics will be assessed using descriptive statistics, and the change in A1c from baseline will be assessed using paired t-test.

**Poster Title:** Utilization of a risk-prediction model to predict heart failure 30-day readmissions in the Department of Veteran Affairs  

**Primary Author:** Alexander Corboy, William Jennings Bryan Dorn Veterans Affairs Medical Center, SC; **Email:** alexander.corboy@va.gov  

**Additional Author(s):**  
Kevin Brittain  
Aaron Sloan  
Patrick Cogan  

**Purpose:** Unplanned hospital readmissions within 30 days are often preventable and are readily becoming a measure of healthcare quality. Additionally, preventable readmissions incur a large and unnecessary fiscal cost to the healthcare system. In particular, readmissions within 30 days are disproportionately high amongst patients with heart failure. Identifying heart failure patients at high risk for readmission in advance would empower healthcare facilities to target patients in need of more comprehensive care. This study aims to develop and validate a 30-day congestive heart failure readmission risk-prediction model from readily accessible health information data at the Department of Veteran Affairs.  

**Methods:** A retrospective cohort will be studied to create a 30-day readmission risk prediction model for patients with heart failure within our facility. The primary outcome will be hospital readmission(s) associated with heart failure, defined as any admission or transfer to our facility within 30 days of a previous discharge where the discharging diagnosis is heart failure. Risk factors will be identified utilizing data from the Veterans Health Administration corporate database from fiscal years 2010 to 2015. Significant univariate variables will be used in a multivariate logistic regression model to establish 30-day readmission risk factors. In turn, these risk factors will be utilized to develop a risk-prediction model for 30-day congestive heart failure readmission. This model will be compared to other commonly utilized risk models (LACE, HOSPITAL) evaluating the same observational cohort. The C-statistic will be utilized to assess the accuracy of the various models.

Poster Title: Direct oral anticoagulant event rates in obesity

Primary Author: Jabe Weaver, William Jennings Bryan Dorn Veterans Affairs Medical Center, SC; Email: jabewea@gmail.com

Additional Author(s):
Aubrey Cartwright
Heather Tanner
Kevin Brittain

Purpose: Direct-acting oral anticoagulants (DOACs) are approved for the treatment and prevention of venous thromboembolism (VTE) and ischemic stroke prevention in non-valvular atrial fibrillation (AF). Compared to warfarin, these agents have more ideal qualities due to their quick time-to-peak effects, lack of routine monitoring, and limited food interactions. According to each DOAC’s package insert, no dose adjustment is necessary for obese patients; however, data is insufficient in regards to the efficacy and safety in these populations. The objective of this study is to evaluate the bleeding and thrombotic rates of obese patients managed on DOACs under their approved indications.

Methods: The institutional review board approved this single center, retrospective, observational study. Using the computerized patient record system (CPRS), all veterans who began DOAC therapy between October 1, 2013 and August 1, 2016 for approved indications will be included. All veterans who received less than one week of anticoagulation with DOACs or diagnosed with a VTE not confirmed by imaging will be excluded. The following data will be collected: demographics, DOAC used, dose, and if followed by a pharmacist, verapamil, diltiazem, or amiodarone use, fill history, proton pump inhibitor use, presence of disease states such as congestive heart failure, hypertension, diabetes, stroke, alcoholism, cirrhosis, and history of bleeding, and baseline and event hemoglobin, platelets, renal function, liver function tests, and INR. All associated patient information will be de-identified and maintained confidentially. Primary outcomes will include comparison of all bleeding and thrombotic rates of obese (body mass index [BMI] greater than 30) versus non-obese patients taking DOACs. Secondary outcomes will include bleeding and thrombotic rates of obese (BMI 30 to 40), severely obese (BMI greater than 40) and non-obese patients taking DOACs for approved
indications, event rates for patients followed by a pharmacist, compliance in patients followed by a pharmacist and number of events occurring in first 3 months of therapy versus after 3 months of therapy.

Poster Title: Effect of a Focused Antibiotic Stewardship Pilot Program at an Ambulatory Care Facility

Primary Author: Brian Thomas, Rapid City Sioux San IHS Hospital, SD; Email: brian.thomas@ihs.gov

Additional Author(s):
Jason Kinyon
Tasha Standing Soldier

Purpose: The purpose of this study is to evaluate the effect of a focused antibiotic stewardship program on the prescribing practices and appropriateness of treatment of infectious diseases at Rapid City Service Unit (RCSU). The central hypothesis is that the retrospective chart review will reveal that prescribing practices, dosing, and duration of therapy vary greatly and often deviate from both IHS and IDSA guidelines without apparent or documented reasons. The implementation of this program will increase the appropriateness of treatment regimens, decrease reoccurrence rates, and improve resistance patterns, benefiting our patients and the public health of our community.

Methods: This study protocol is being submitted for approval by the Great Plains Area Indian Health Service IRB. In this retrospective chart review, the electronic health record will be used to identify all patients age 18 and older who were diagnosed with one of the three most prevalent infectious diseases and received their first dose of antibiotics during January 1, 2016 through March 31, 2016, and January 1, 2017 and March 31, 2017 at Rapid City Service Unit. Patients will be excluded if they received antibiotics for one of the three identified infectious diseases while also being treated for a concomitant infectious disease that is not part of the pilot program. The information collected will include patient demographics (age, gender, body weight, and height, etc.), chief complaint, diagnosis, type of infection, microbiology data from site of infection, serum creatinine, BUN, WBC count, AST and ALT, concomitant antibiotics, whether source control procedures were performed, return to clinic within 30 day, and adverse drug events.

Poster Title: Integrating the “Annie” mobile application into pharmacy medication management clinic to improve patient care and healthcare access.

Primary Author: Mark Myers, VA Black Hills Health Care System, SD; Email: myersmj@gmail.com

Additional Author(s):
William Hayes
Michael Lemon
Krista Sarvis

Purpose: Medication management clinic appointments are opportunities for clinical pharmacists to evaluate and modify patient medication regimens. Effective evaluation is typically dependent upon patient submission of home testing data (e.g., blood pressure measurements, blood glucose measurements). The Veterans Administration (VA) is developing a mobile phone application (“Annie”) that prompts patients to submit daily home testing data via text message to a web-based portal accessible by both patients and providers. The objective of this project is to improve the efficiency of medication management clinic by using Annie to streamline home testing data submission and review.

Methods: Following Pharmacy & Therapeutics Committee approval, patients already enrolled in pharmacy medication management clinic for uncontrolled hypertension and diabetes will be offered the opportunity to trial the Annie mobile application in accordance with ongoing therapy. Patients desiring to trial the application will undergo orientation, which will include assistance in downloading the application, logging in and setting up of preferences, education on its capabilities, and minimum expectations of patients using the application. At the same time, clinic providers will be educated on how to access the application and search for specific patient data. Patient consent to trial Annie will be documented in each patient’s progress note so that subsequent clinicians will know to access Annie during follow-on appointments. Once Annie access is established for patients and providers, patients will continue being seen in clinic according to pre-existing clinic standards of practice. At the end of the project period, patient records will be reviewed to determine average participation (number of Annie app submissions per day enrolled). Average number of medication changes per patient will be calculated and
compared to clinic averages. Finally, both patients and providers will be offered the opportunity to provide feedback on the application, specifically regarding ease of use, enjoyment of use, aspects of the application that were particularly beneficial or problematic, and recommendations for improvement.

**Poster Title:** Improving home naloxone rescue kit availability and education  
**Primary Author:** Rose Fitzgerald, VA Black Hills Health Care System, SD; **Email:** rose.fitzgerald2@va.gov  
**Additional Author(s):**  
Wendy Brink  
Lynn Hickox  

**Purpose:** The primary objective of this quality improvement project is to improve patient access to home naloxone rescue kits. In 2014, there were 18,000 deaths reported from prescription opioid overdose. Increased access to naloxone in the community has the potential to save many lives. This project involves assessing current practices for identifying candidates for the rescue kits through the VA Opioid Overdose Education and Naloxone Distribution (OEND) initiative and finding ways to increase utilization at VA Black Hills Health Care System (VA BHHCS). Secondary objectives include providing provider and patient education on proper and safe use of naloxone rescue kits.  

**Methods:** This quality improvement project will include patients at VA BHHCS with documented opioid dependence and who are using opioid medications chronically, which puts them at a high risk for opioid overdose. The project will be conducted consistent to current standards of the OEND program. Primary interventions include assessing strengths and limitations of current naloxone prescribing practices and providing practitioners with resources to help identify patients at risk for opioid overdose. Initially, baseline OEND utilization reports will be assessed and data on appropriate candidates for naloxone rescue kits will be collected. Prescribers will be provided information on home naloxone use as well as a list of qualifying patients on their service. Secondary interventions include providing patients and caregivers with educational materials upon initial naloxone fill and assessing patient understanding of appropriate use. If the prescriber would like to provide naloxone, pharmacy will fill the prescription and provide written educational materials to the patient. Patients will be contacted via phone call to ensure receipt of the aforementioned and to answer any questions. VA BHHCS OEND utilization will be reviewed to assess impact of the interventions.

Poster Title: Compliance with Oryx performance measures: improving assessment and continuity of care for cessation in tobacco users using Lean methodology

Primary Author: Ashley Pederson, VA Black Hills Healthcare System, SD; Email: ashley.pederson@jacks.sdstate.edu

Additional Author (s):
Jessica Mitchell
Amy Doten

Purpose: It is widely regarded that smoking cessation greatly reduces the risk of many serious health problems. The benefits of quitting may be greater in younger populations, but benefits of quitting may be seen at any age. Oryx performance measures are set by the Joint Commission to support organizations in quality improvement efforts. Oryx measures for tobacco cessation evaluation and follow-up at discharge have been identified as areas for improvement. The objective of this quality improvement project is to identify applicable inpatients, connect them with appropriate avenues for cessation help upon discharge if appropriate, and thus comply with the aforementioned measures.

Methods: Lean methodology will be used to develop an efficient process to assist with tobacco cessation upon inpatient discharge. This will be done by eliminating waste while creating a culture of continuous improvement. The types of waste outlined in Lean are represented by the acronym DOWNTIME: defects, overproduction, waiting, not using human potential, transportation, inventory, motion, and extra processing. Value stream mapping will be employed to identify services involved and outline goals to design the process. Other important steps to include in value mapping are current processes, delays, sources of overburden, and information flows. Services involved will receive education on the new process, tobacco cessation methods, and assistance programs available. The target patient population is inpatients who have used tobacco products within the last thirty days. The five A’s of smoking cessation (ask, advise, assess, assist, arrange) will be employed upon patient discharge. Patients will be asked about tobacco status, advised to quit, assessed if they are willing to quit at that time, assisted in the quit attempt by arranging a consult to respiratory therapy or an available cessation program, and then it will be ensured that the patient has an outpatient follow-up
appointment scheduled to increase chances of cessation. After this process is implemented, a further assessment process will begin to identify sources of waste, inefficiency and chances for improvement.

**Poster Title:** Value of Pharmacists’ Interventions in the Emergency Department: two different points of view

**Primary Author:** Paula Pena Villanueva, Hospital de Cabueñes, Spain; **Email:** penavpaula@gmail.com

**Additional Author (s):**
- Alba León Barbosa
- Rubén Pampín Sánchez
- Ana Lozano Blázquez

**Purpose:** To evaluate pharmacists interventions (PI) made in the Emergency Department (ED) focusing on the prevalence and severity of the prescription errors detected. To compare the clinical value of these interventions assessed from the point of view of a physicians and a pharmacist.

**Methods:** Prospective study conducted from January to February 2016 in an ED where there is a pharmaceutical resident physically for 2 months a year. Along this period, the pharmacist validated all the prescriptions of patients who were in the ER, taking into account blood tests, current situation and chronic treatment. A prescription error (PE) is any discrepancy in pharmacotherapy. The PE were classified by the pharmacist according to their severity using the Overhage’s method: potentially lethal, serious, significant, minor and no error. The PI were classified by the pharmacist into 5 categories: start medication, discontinue medication, change medication, dosage adjustment and drug information. The PI value was established in triplicate (one clinical pharmacist and two physicians from the ED) according to the Overhage’s classification: extremely significant, very significant, significant, somewhat significant, not significance and adverse significance. Finally, the two physician agreed on their assessments until they achieved a single classification. The physician-pharmaceutical valuations were compared statistically by Chi square test. Age, gender, drug (according to Anatomical, Therapeutic, Chemical classification system), PE description and its severity, PI category and its clinical value were recorded.
Results: Three hundred and five patients were reviewed along the study period. Their median age was 75 years [18-97 years]. 54% of them were women.

A total of 149 PI were performed in 84 patients (1.8 PI / patient). This means that there was a prevalence of 27%.

The EP severity rating was: potentially lethal (0,7%), serious (5,4%), significant (67,5%), minor (15,5%) and no error (10,8%).

The PI were classified as starting medication (39%), discontinuing medication (14%), change medication (17%), dosage adjustment (16%) and drug information (14%).

The main drugs involved were of the groups C (28%), N (22%), A (11%) and B (9%).

The clinical value of the PI according to physician criteria was: extremely significant (1%), very significant (3%), significant (29%), somewhat significant (36%), not significance (30%) and adverse significance (0%).

The clinical value of the PI according pharmacist criteria was: extremely significant (1%), very significant (11%), significant (51%), somewhat significant (15%), not significance (22%) and adverse significance (0%).

The assessments made by the pharmacist and the physicians were significantly different (Chi square = 31.4, p < 0.001).

Conclusion: The PE prevalence detected was similar to described in literature and its severity was significant in a high percentage.

However the physician rated the value of pharmacist interventions significantly lower than their pharmacist counterparts. This may be due to different visions on patient management. Therefore it’s very important to have a full-time clinical pharmacist integrated in the multidisciplinary team of the Emergency Department all year long.

Session-Board Number: 1-331

Poster Title: Use of Aflibercept in refractory patients to other anti-angiogenic treatments.

Primary Author: Rubén Pampín Sánchez, Hospital Universitario de Cabueñes (Gijón), Spain; Email: pampin_3@hotmail.com

Additional Author(s):
Paula Pena Villanueva
Yoar Labeaga Beramendi
Ana Lozano Blázquez
Aitor Ayastuy Ruiz

Purpose: Anti-angiogenic drugs are those that inhibit the production of new blood vessels getting delayed or stabilizing the progression of certain eye diseases. Despite their proven effectiveness, a significant number of patients treated for a long period of time develops resistance with progressive loss of response. The aim of the study is to evaluate the efficacy of intravitreal administration of Aflibercept in refractory patients that have used other anti-angiogenic drugs.

Methods: Retrospective observational study of eleven months (05/15 to 04/16). We studied patients who have been refractory to previous antiangiogenic treatments (Ranibizumab and/or Bevacizumab) and have received at least three monthly administrations of Aflibercept. Use of Aflibercept was authorized by the Medical Director in these patients. Data collection was performed using computer applications Oncofarm®, Selene® (electronic medical record review) and retinal optical coherence tomography (OCT). Sex, age, diagnosis, number of antiangiogenic previous administrations, Best-corrected visual acuity (BCVA by ETDRS system), retinal thickness (OCT measured in microns) and changes in subretinal fluid (SRF) were recorded. The change in BCVA, as well as change in retinal thickness and presence of LSR between the first visit and at the end of the third dose were the efficacy variables assessed in the study. It was felt that the treatment was effective against the following criteria: loss < 15 letters in BCVA (visual results) and reduced > 10 % in retinal thickness as well as visual impairment of SRF (anatomical results).
Results: A total of 19 eyes corresponding to 14 patients (12 women and 2 men) were evaluated, with a mean age of 72.7 years (37-91). While 17 eyes (89.5 %) were diagnosed with wet age-related macular degeneration (ARMD) only two eyes (10.5 %) were diabetic macular edema (DME). 11 eyes (8 patients) were refractory to Ranibizumab while 8 eyes (6 patients) were refractory to Ranibizumab and Bevacizumab. The average number of injections received was 5.4 and 5.5 / 3.6 respectively. As for the evolution of BCVA, 18 eyes (13 patients) maintained their visual acuity (VA) (loss of < 15 letters) after three months of treatment (Mean: 29.5 ± 13.9; p: 0.45). Of the 18 eyes that kept AV, 5 eyes gained visual acuity (> 5 letters). In 11 eyes, the mean macular thickness on OCT decreased from 367.2 to 262.2 microns decreasing by 27.8 % (Mean: 320.4 ± 127.2; p: 0.04). A correlation between the decrease in SRF and macular thickness reduction was observed.

Conclusion: Despite the low number of patients in the study, Aflibercept is shown to be an effective treatment in a significant number of patients resistant to treatment with other anti-angiogenic drugs. Larger studies are needed to evaluate the long-term efficacy.

Poster Title: Effectiveness and safety of romiplostim after eltrombopag in idiopathic thrombocytopenia purpura.

Primary Author: Inmaculada Reyes-Torres, Hospital Universitario Reina Sofía (Córdoba) Spain, Spain; Email: inma_reyes_87@hotmail.com

Additional Author(s):
Manuel Cárdenas
Pablo Montejano-Hervás
Julia Lopez-Santamaria
Teresa López-Vinau

Purpose: Idiopathic thrombocytopenic purpura (ITP) is an autoimmune disease caused by antibody-mediated platelet destruction. First-line treatment consists of corticosteroids, intravenous immune globulin or splenectomy. Novel thrombopoietin receptor agonist (TRAs), eltrombopag and romiplostim, stimulate platelet proliferation and differentiation. Although TRAs are highly effective and well tolerated for patients with ITP refractory to first-line treatments, the cross-resistance of these TRAs is still unknown. This report describes the effectiveness and safety of therapy with romiplostim in two patients with IPT refractory to previous treatments, including eltrombopag.

Methods: Patient and disease characteristics, including age, sex, months since diagnosis, type of therapies prior to starting romiplostim, platelet counts, dose and duration of treatment and adverse events were collected through medical records.
Subcutaneous administration 1 µg/kg/week of romiplostim was begun. The dose of romiplostim was gradually increased by 1µg/kg every week until the target platelet count of 50x10^9/L to 200x10^9/L was reached, without exceeding the maximum dose (10µg/kg/week). Romiplostim dose was reduced according to increase platelet count during treatment.
Complete response (CR) and partial response (PR) were defined as any platelet count ≥100x10^9/L and of 30-100x10^9/L respectively, in absence of bleeding. Non-response (NR) was defined as any platelet count < 30x10^9/L or bleeding. In addition, adverse events during treatment were recorded.
Results: Patient 1 is a 32-year-old female with acute ITP for 2 months, nonsplenectomized and had received corticosteroid and immunoglobulin without increasing platelet count. Eltrombopag was discontinued by no response and two bleeding events and rituximab was not effective. Her platelet count previous romiplostim treatment was 1x10^9/L. After 8, 12, 16, 20, 24 and 30 weeks of treatment, platelet count increased to 147x10^9/L, 437x10^9/L, 123x10^9/L, 191x10^9/L, 238x10^9/L and 185x10^9/L, respectively. In this patient dose of romiplostim was 8µg/kg at week 8 and was reduced to 3-4µg/kg/week according to increased platelet count. Patient discontinued romiplostim after 31 weeks with platelet count 194x10^9/L, absence of bleeding and was splenectomized. Nowadays her median platelet count is 260x10^9/L, untreated. Romiplostim was well tolerated.

Patient 2 is a 79-year-old men with chronic ITP for 5 years, nonsplenectomized and had received corticosteroid and immunoglobulin without improvement in platelet count. Eltrombopag was discontinued by severe erythema and rituximab did not increase platelet count. Platelet count previous romiplostim treatment was 17x10^9/L. Eight weeks after starting treatment romiplostim was increased to 8µg/kg/week, after 9 weeks there was no response and romiplostim was discontinued, with platelet count of 8x10^9/L and significant erythema in inferior members, similar to occurred with eltrombopag.

Conclusion: Patient 1 was refractory to eltrombopag and had complete response to romiplostim, without adverse events. Patients 2 had ITP refractory to eltrombopag and romiplostim, and adverse effects were similar with both TRAs. The cross-resistance of these two TRAs is still unknown, although the failure of treatment with eltrombopag does not imply the absence of response with romiplostim. In selected patient, still unknown, romiplostim can improve thrombocytopenia safe and effectively, allowing to perform splenectomy.

Poster Title: Autologous serum eye drops (20%) for the treatment of ocular surface disorders.

Primary Author: Estela García Martín, not applicable, Spain; Email: egarciamartin@salud.madrid.org

Additional Author(s):
M. Sagrario Pernia Lopez
Rosa Romero Jimenez
Carmen Rodriguez Gonzalez

Purpose: Serum and other bodily fluids have been used as natural tear substitutes. The aim of this study is to investigate the use of autologous serum (AS) eye drops (20%) in outpatients with ocular surface disorders who were refractory to conventional treatments.

Methods: AS eye drops were elaborated under aseptic conditions, the blood samples were collected in sterile tubes without anticoagulants. The containers were left standing for 2 hours at room temperature in an upright position. The blood was centrifuged at 4800rpm for 8 minutes. In a laminar flow hood, one milliliter serum was taken and deposited into sterile dropper bottles with 4 ml physiologic serum for a final concentration of 20 percent. The eye drops’ stability was three months frozen and five days after opening stored in fridge.

A retrospective cohort study was conducted at a tertiary care center. We included patients who picked up AS eye drops at outpatients department of the hospital pharmacy from December 2006 to January 2016. We created a database that included sociodemographic (age and sex) and pharmacotherapeutical variables (indication, number of dispensing medication, length of treatment, dosage, number of eyes in treatment and the use of others eye drops which were elaborated and dispensed at the hospital pharmacy). We reviewed electronic prescriptions (Prescriplant®) and clinical histories of the patients included in the study. The efficacy of the treatment was evaluated subjectively (patient’s opinion at the doctor visit about the improvement of their subjective symptoms) and adverse effects was a measurement of the safety.
**Results:** A total of 173 patients were considered for the study, 78.03% of females. Their mean age was 63.87 years (SD 16.69). The use of AS eye drops was indicated for several diseases: corneal diseases (corneal ulcer or corneal persistent epithelial defects) (34.32%); Sjögren syndrome (17.16%); dry eye resulting for autoimmune disease (15.38%); blepharitis or blepharospasm (12.43%); palpebral disorder (4.73%); others syndromes (Cogan syndrome, Fuchs’ dystrophy, Terrien degeneration, Posner Schlossman syndrome or Charles bonnet syndrome) (4.14%); graft-versus-host disease (GVHD) (2.96%); radiotherapy treatment (2.96%); conjunctive disorders (2.37%); laser assisted in situ keratomileusis (LASIK) (2.37%); corneal burns (1.18%).

The habitual dosage was every 3 or 4 hours (40.46%). 21.97% patients used the AS only in one eye. The length of treatment was for a long period in 94.22% of the patients. All patients, except one (this patient experimented a sticky sensation with minimal eye discomfort), improved their symptoms with the treatment and no one suffered harmful effects. Patients went to the hospital pharmacy to pick up AS eye drops every 75.89 days (RIC 60.33; 90.88). Other eye drops elaborated and dispensed at hospital pharmacy before or as the same time as AS were; before the use of AS (23.12%): cyclosporine 0.05% (60.00%), ceftazidime and tobramycin (15.00%), cyclosporine 1% (15.00%), acetylcysteine 10% (5.00%), cyclosporine 2% (2.50%), mytomycin 0.02% (2.50%); concomitant treatment (30.06%): cyclosporine 0.05% (80.77%), cyclosporine 1% (7.69%), acetylcysteine 10% (5.77%), tobramycin (3.85%), vancomycin (1.92%).

**Conclusion:** Indications for AS therapy were mostly; corneal diseases (corneal ulcer or corneal persistent epithelial defects), Sjögren syndrome, dry eye resulting for autoimmune disease and blepharitis or blepharospasm. Patients went to the hospital pharmacy to pick up AS eye drops before 90 days, it ensures the stability of eye drops. Habitual dosage was every 3 or 4 hours in both eyes.

The efficacy of the treatment was evaluated subjectively, it is the main limitation of the study. In spite of this, we can consider AS treatment as a chronical therapy. It is an effectiveness, safety and well tolerated treatment.
**Purpose:** Hospital readmission after a myocardial infarction (MI) is costly to the healthcare system, a frequent occurrence, and often preventable. Studies have previously shown that certain hospital and patient factors are known to influence readmission rates. The purpose of this study is to determine if hospital factors and time of discharge are associated with prescribing a comprehensive medication regimen in post-MI patients.

**Methods:** This retrospective review will examine data from January 1, 1999 through October 30, 2015 from the National Veterans Affairs Health Care System. Inpatients experiencing a ST-segment elevation MI (STEMI) or non-ST-segment elevation MI (NSTEMI) with a discharge date between January 1, 2005 and September 30, 2015 will be evaluated to determine if they were prescribed a comprehensive evidence-based medication regimen at discharge. Optimal therapy is defined as one or more medications from each of the STEMI or NSTEMI categories prescribed or on-hand 3 days after discharge. Optimal post-STEMI therapy will include 1) an angiotensin converting enzyme inhibitor (ACE-I) or alternately an angiotensin receptor blocker (ARB), 2) an antithrombotic agent, 3) a beta-blocker, and 4) a statin. Optimal post-NSTEMI therapy will include 1) an ACE-I or alternately an ARB, 2) an antithrombotic, 3) a beta-blocker, 4) a statin, and 5) a short-acting nitrate. Hospital factors and other variables to be studied include complexity and rurality of the VA facility, number of hospital beds, hospital bed occupancy rate, time of discharge, day of the week of discharge (weekday/weekend), and month of discharge. A subgroup analysis will be conducted to determine if there is a difference in the prescribing
pattern at discharge of first occurrence of MI compared to any recurrence of MI during the study timeframe.

**Poster Title:** Determining risk of sudden death with common antibiotics and combined angiotensin converting enzyme inhibitor or angiotensin (II) receptor blocker

**Primary Author:** Matthew Hollifield, James H. Quillen VA Medical Center, TN; **Email:** matthew_hollifield@charter.net

**Additional Author(s):**
David Burke
Robyn McKeller
Paul Laucka
Christian Thomas

**Purpose:** The purpose of this study is to determine if there is any risk of sudden death associated with combining the frequently prescribed antihypertensive drug classes known as angiotensin converting enzyme inhibitors (ACEI) and angiotensin (II) receptor blockers (ARB) with commonly prescribed antibiotics. It will also aim to assess the effect of these combinations on hospitalizations and emergency department visits and assess potential cardiac risk factors that could contribute to sudden cardiac death in this patient population.

**Methods:** This is a retrospective, population-based cohort study of adult patients (age greater than or equal to 18) in the United States Veterans Affairs Health Care System designed to assess the risk of sudden death in Veterans who are on chronic ACEI or ARB therapy and who, while taking the ACEI or ARB, filled a prescription in the outpatient setting for one of the top five most prescribed antibiotics in the VA system (azithromycin, amoxicillin, doxycycline, trimethoprim-sulfamethoxazole, and cephalexin) at any point between January 1, 2000, and December 31, 2014. Patients will be allowed to re-enter the study if they receive multiple study antibiotics, so long as prescriptions are separated by at least 15 days. Patients will be excluded if they receive any antibiotic simultaneously with the study antibiotic or if there are active prescriptions for an ACEI and an ARB simultaneously.

The primary outcome of sudden death will be defined as mortality that occurs within 14 days of initiation of a study antibiotic. Secondary outcomes include hospitalizations and emergency department visits within 14 days. An additional exploratory outcome will assess potassium
levels and hyperkalemia as a possible mechanism behind sudden death in patients who received a potassium level within 14 days of initiation of study antibiotic.

**Results:** TBD

**Conclusion:** TBD
Purpose: This study is being conducted to determine if herpes zoster (HZ) vaccination administered after the first episode of HZ provides secondary prophylaxis of HZ, defined as decreased risk of having a second episode. Secondarily, this study will investigate HZ vaccination efficacy for secondary prevention when accounting for age and certain immunocompromising disease states (diabetes, inflammatory bowel disease, rheumatoid arthritis, human immunodeficiency virus, multiple sclerosis, and systemic lupus erythematosus).

Methods: This study is a retrospective review examining data from January 1, 1999 through August 1, 2016. This study will include patients greater than or equal to 60 years old and diagnosed with herpes zoster (HZ) between January 1, 2008 and February 1, 2015 who had at least 6 months of follow-up. Patients will be excluded if they had an episode of HZ prior to January 1, 2008, were HZ vaccinated prior to their first episode of HZ, or had an active diagnosis of leukemia, lymphoma, or bone malignancy at any time from one year prior to first HZ infection through the end of follow-up. Patients will be categorized into two cohorts: vaccinated at study exit and unvaccinated at study exit. The primary outcome will be incidence of secondary HZ. Subgroup analyses will determine the incidence of secondary HZ infection in each cohort by age and in those diagnosed with immunocompromising disease states. The outcome will also be assessed for association with time to vaccination in the vaccinated cohort.

**Poster Title:** Comparison of long-acting, short-acting, and combination opioid therapy on all-cause mortality in Veterans using opioids for non-malignant pain

**Primary Author:** Christopher Blackburn, James H. Quillen VA Medical Center, TN; **Email:** zcab42@goldmail.etsu.edu

**Additional Author (s):**
Rebecca Spivey
Kellie Rose
Robyn McKeller
David Burke

**Purpose:** The purpose of this study is to determine if there is a difference in all-cause mortality in opioid users using long-acting opioid monotherapy, short-acting opioid monotherapy, or a combination of both. The results of this study will help direct future research and inform clinicians regarding the safety of opioid prescribing practices.

**Methods:** This population-based, retrospective cohort study will examine data for opioids prescribed between January 1, 2003 and July 31, 2015 within the United States Veterans Affairs Health Care System. Participants will be excluded if they had any diagnosis of malignancy, an indication of terminal illness, active enrollment in a palliative care or hospice program, or any history of a suicide attempt or self-inflicted injury. Study drugs will fall into two categories – long-acting and short-acting opioids. Participants will be allocated to one of three groups: long-acting opioid monotherapy, short-acting opioid monotherapy, or combination opioid therapy. All opioid medications will be standardized to morphine equivalent daily doses (MEDD) to facilitate analysis. Data will be tracked by total time spent within a group in person-years, and participants may switch groups indefinitely based on concurrent medications prescribed. The primary endpoint of all-cause mortality will be compared between the three groups. Analysis of secondary endpoints will include stratification of all-cause mortality by age, MEDD, and a composite of substance use disorder and pulmonary dysfunction.

Poster Title: Evaluating a CIWA-Ar Driven Benzodiazepine Loading Protocol for Alcohol Withdrawal in Medical and Psychiatric Patients at a Dual-Campus Veterans Hospital

Primary Author: Uyen Smyth, TVHS, TN; Email: uyen.m.le@gmail.com

Additional Author(s):

Purpose: The main goal of alcohol withdrawal syndrome (AWS) treatment is to prevent the development of severe symptoms such as seizure, delirium, and death, and to improve patient’s quality of life. Symptom-triggered and loading protocols utilizing Benzodiazepines (BZDs) are first-line in the treatment of AWS; however, execution of these protocols varies greatly across practice. The purpose of this study is to assess incidence of adverse outcomes associated with using a benzodiazepine loading protocol for alcohol withdrawal management in medical and psychiatric inpatient at a dual-campus veteran’s hospital and to identify potential variables associated with negative outcomes to aid in quality improvement.

Methods: This study will be submitted to the Institutional Review Board for approval. Data will be extracted from computerized patient records system. Patients included are those ≥18 years of age admitted to medical inpatient or psychiatric inpatient between December 1, 2015 and May 31, 2016 who were treated for alcohol withdrawal. Patients who will be excluded are those with epilepsy, received BZD outpatient for the treatment of AWS at home, and those who were transferred to higher level of care for reasons other than complications of AWS. Baseline demographic data extracted will include age, race, gender. Other demographic data that will be extracted manually will include: number of hours/days since the last drink, drinks per day, history of alcohol withdrawal seizures or delirium, and whether they were loaded with BZD upon admission. Benzodiazepine specific data will be extracted to include initial and total BZD dose per patient, use of scheduled BZD, duration of treatment with BZD, length of stay, number of patients who received ≥ 1 dose of BZD, and whether patients completed BZD load. Composite adverse outcomes will include number of patients who experienced seizures, delirium, or those transferred to higher level of care.

Poster Title: Assessing pharmacists' influence in ensuring appropriate transitions of care: a focus on anticoagulation

Primary Author: Candace Bryant, VA Tennessee Valley Healthcare System, TN; Email: candace.bryant@va.gov

Additional Author(s):
Bliss McMichael
Jennifer Baker
Bishoy Ragheb
Jessica Wallace

Purpose: Transitions of care between different healthcare settings can increase the risk of medication errors, possibly resulting in adverse drug events, increased hospital stays, and hospital readmissions. In 2015, the Food and Drug Administration received 34,765 adverse drug event reports for oral anticoagulants. Due to the complexities and risks of anticoagulants, ensuring appropriate transitions of care is essential to provide safe, effective therapy. Pharmacists’ unique knowledge of pharmacology, pharmacokinetics, and drug interactions makes them well-suited to ensure that transitions of care are optimized. This study will evaluate the impact of clinical pharmacists’ on the management of anticoagulants within transitions of care.

Methods: This will be a single-center, retrospective, observational analysis of veterans at the Veterans Affairs Tennessee Valley Healthcare System (TVHS) Nashville campus from July 1, 2011 to June 30, 2016. Patients who received rivaroxaban, apixaban, dabigatran, warfarin, fondaparinux, or enoxaparin at discharge from an inpatient setting or the emergency department who also received follow-up care in an outpatient clinic will be evaluated. Patients will be excluded if their primary care or anticoagulation is managed outside TVHS or if they are discharged to a long-term care facility or short-term rehabilitation facility. The primary objective of this study is to evaluate the percentage of patients who received appropriate anticoagulation at time of discharge before and after the implementation of decentralized clinical pharmacists. Secondary endpoints include assessing the number of pharmacists’ interventions, whether patient education was provided prior to discharge, and time to
outpatient follow-up for anticoagulation management. The following data will be collected: age, gender, race, weight, serum creatinine, and prescription information for anticoagulants and interacting medications. Manual chart review will be used to determine appropriate anticoagulation based on dosing, indication, renal function, weight, and the presence of major drug-drug interactions.

**Poster Title:** Evaluation of pneumococcal vaccination among veterans: A look at inpatient utilization of pneumococcal vaccines

**Primary Author:** Jakob Fann, VA Tennessee Valley Healthcare System, TN; **Email:** jakob.fann@va.gov

**Additional Author(s):**
Torrey Smith

**Purpose:** In the Veterans Affairs healthcare system 55 percent of dollars spent on community acquired pneumonia are in patients 65 years or older. There are currently two vaccines approved for use in prevention of pneumococcal diseases in this patient population, pneumococcal conjugate vaccine 13 and pneumococcal polysaccharide vaccine 23. To increase pneumococcal vaccination rates, facilities have implemented various interventions such as physician reminder notifications. This study will evaluate the utilization of both previously mentioned pneumococcal vaccines in hospitalized patients greater than or equal to 65 years of age, following the implementation of a reminder tool within the electronic medical record.

**Methods:** This is a single center, retrospective, observational analysis of two, three month time periods, both prior to and following reminder tool implementation. Patients will be included if they are 65 years and older with an index hospitalization greater than 72 hours, excluding patients with an allergy to the vaccines or any of the components, and those with disease states with an indication for alternative administration schedules per current Advisory Committee on Immunization Practices recommendations. In order to detect a 10 percent change in vaccine utilization, we will require 270 patients in each study period to achieve 80 percent power. The primary objective of this study is to evaluate the change in rate of inpatient utilization of pneumococcal conjugate vaccine 13 and pneumococcal polysaccharide vaccine 23 before and after the implementation of an electronic reminder tool within the electronic medical record. The secondary objective of this study is to evaluate the appropriateness of pneumococcal conjugate 13 and pneumococcal polysaccharide 23 vaccines, both administered and omitted, per current Advisory Committee on Immunization Practices recommendations, specifically in regards to choice, scheduling and timing of vaccines, along with the cost associated with vaccines administered inappropriately, according to the aforementioned recommendations.

**Session-Board Number:** 1-341

**Poster Title:** Comparison of gabapentin and pregabalin: measuring clinical impact of time to therapeutic dosing among patients achieving therapeutic dosing for pain

**Primary Author:** Mena Raouf, VA Tennessee Valley Healthcare System, TN; **Email:** menaraouf92@gmail.com

**Additional Author (s):**
Meredith Crumb
Jennifer Baker
Janet Bramell
Timothy Atkinson

**Purpose:** Gabapentin and pregabalin are commonly prescribed first-line agents for neuropathic pain, but a head-to-head comparison is lacking. Therapeutic dose targets for neuropathic pain have been established for in patients with normal renal function (gabapentin 1800-3600mg/day; pregabalin: 150-600 mg/day). There is no data available on the therapeutic impact or consequences for patients when selecting one medication over another. There would be ethical and pharmacoeconomic considerations if one were shown to improve long-term outcomes. The study purpose is to evaluate the clinical impact of agent selection measured by percentage of patients achieving therapeutic dose, time to therapeutic dose, and percentage continuing therapy.

**Methods:** This study is a retrospective observational analysis in a single healthcare system. Data will be pulled from the Veterans Integrated Service Network 9 data warehouse identifying all veterans with new start prescriptions for either gabapentin or pregabalin between January 1st, 2011 and December 31st, 2015. The following data will be extracted: age, weight, gender, height, race, comorbidities, prescriber, and concomitant analgesics at the date of initiation. Participants with outpatient initiations of gabapentin or pregabalin with a documented indication for pain will be included in the study. Participants will be excluded if they have a creatinine clearance less than 60 ml/minute at the time of initiation or prescribed gabapentin or pregabalin for a non-pain related condition. Manual chart reviews will be conducted to identify eligible participants based on the aforementioned criteria. The primary endpoints are percentage of patients achieving therapeutic dosing, time to therapeutic dosing, and
percentage of patients continuing on therapy. The secondary endpoints will include discontinuation rates, documented causes of discontinuation, and whether a relationship between titration rate and discontinuation exists.

Poster Title: Evaluation of a pharmacist-led clinical video telehealth (CVT) group for opioid overdose prevention and naloxone education

Primary Author: Aimee Patterson, VA Tennessee Valley Healthcare System, TN; Email: anp0017@auburn.edu

Additional Author (s):
Candace Beam
Jennifer Easterling
Amber Rieselman
Jennifer Bean

Purpose: Veterans are almost twice as likely to have accidental overdose compared to the U.S. population. In response to the increasing number of overdose deaths, opioid overdose education and naloxone distribution (OEND) programs were established. Currently, no published literature has evaluated OEND programs in the setting of a pharmacist-led telehealth clinic. Telehealth allows for pharmacists to reach Veterans outside of VA locations, and provide a level of comfort for patients who have concerns surrounding stigma. This project will evaluate the effectiveness of a pharmacist-led CVT clinic on the distribution of naloxone for Veterans who are at high risk of opioid overdose.

Methods: This project is a single-center, retrospective, observational analysis of adult Veterans at both campuses and two community-based outpatient clinics of the VA Tennessee Valley Healthcare System from January 1, 2016 through December 31, 2016. All patients who have had one fill of naloxone during the pre-specified time frame will be included in this study. Any patient who is receiving hospice care, palliative care, or living in the VA TVHS community living centers will be excluded from the project. The primary objective will be to assess how the development and implementation of a pharmacist-led CVT clinic affects naloxone distribution rates in patients who are considered at high risk for an opioid overdose. Secondary objectives include Stratification Tool for Opioid Risk Mitigation (STORM) and Risk Index for Overdose or Serious Opioid-induced Respiratory (RIOSORD) scores, percentage of naloxone distributed, and naloxone prescribed in the CVT
Resident Poster Abstracts

clinic vs other locations. Additional objectives include number of patients referred by a physician vs identified as eligible by a pharmacist.
This project will be submitted to the Institutional Review Board for approval. Patients identified through PDSI as meeting inclusion/exclusion criteria will have the following data collected: age, gender, race, comorbidities, prescriber, and concomitant benzodiazepine therapy. Manual data collection will be done utilizing the Computerized Patient Record System (CPRS). All data will be recorded without patient identifiers and maintained confidentially.

**Poster Title:** Impact of Provider Education and Implementation of Symptom-triggered Therapy, on Outcomes, for Patients with Alcohol Withdrawal.

**Primary Author:** Steven Braun, Central Texas Veterans Health Care System, TX; **Email:** u2steven8600@gmail.com

**Additional Author(s):**
Archana Banerjee
Brendon Hogan

**Purpose:** Previous, published studies have shown that for patient’s undergoing alcohol withdrawal, symptom-triggered benzodiazepine therapy based upon CIWA-Ar (Clinical Institute Withdrawal Assessment for Alcohol Scale) led to decreased total benzodiazepine use compared to fixed-dose therapy. The objective of this project is to determine whether provider education and the implementation of a symptom-triggered benzodiazepine therapy option in a currently existing order set containing only a fixed-dosing therapy option, would aid in decreasing cumulative benzodiazepine use within this population.

**Methods:** Quality improvement project will utilize a retrospective chart review of the computerized database, where patients will be selected based on a diagnostic code of alcohol withdrawal in addition to receiving at least one dose of a benzodiazepine while inpatient. The project time frame will be 6 months prior and 6 months after the new symptom-triggered option is added to the alcohol withdrawal medication order set. Current providers will be educated on the new option and will have the opportunity to ask questions regarding the details of the new symptom-triggered option. Patient’s clinical and baseline data will be collected in this study, which will include the patient’s age, gender, race, past medical history, and outpatient medication records. Other clinical data will include the inpatient medication record (including benzodiazepine usage), CIWA-Ar scores, recorded days of hospitalization, ADRs, vitals, and pertinent lab values. All data including PHI will be stored on an encrypted drive and destroyed after data analysis is complete. Data collected regarding the cumulative amount of benzodiazepine use will be compared between the already in place fixed-dosing protocol and the new option of symptom-triggered treatment based on CIWA-Ar scores. The comparison will be analyzed to determine if the new therapy option reduced benzodiazepine use and length of
stay in this population. Project has been submitted for determination of exemption from human subjects research.

**Poster Title:** Double the Fun: Psychiatric Exacerbations in Veterans Receiving Concomitant Oral Antipsychotics and Long-Acting Injectable Antipsychotics

**Primary Author:** Diana Loffgren, Central Texas Veterans Health Care System, TX; **Email:** diana.loffgren@utexas.edu

**Additional Author (s):**
Leah Rickert
Justin Benzer

**Purpose:** Concomitant use of long-acting injectable antipsychotics (LAIs) and oral antipsychotics beyond initiation phase for schizophrenia is not supported by evidence nor recommended by LAI manufacturers. This study is a continuation of a previous study that demonstrated concomitant use of LAIs and oral antipsychotics are used in a significant portion of schizophrenic patients. The primary objective of this study is to evaluate differences in patient severity between patients receiving concomitant LAI and oral antipsychotic medications as compared to those receiving only LAIs as recommended. A secondary objective is to compare antipsychotic related adverse events between the populations.

**Methods:** This study has been submitted to the Institutional Review Board for approval as an extension to a previously approved study. This will involve a retrospective chart review at three outpatient mental health clinics within a Veterans healthcare system in the Southwestern United States. The subjects will be the same as those utilized in the first portion of this study; patients were randomly selected from patients who were diagnosed with schizophrenia or schizoaffective disorder and received a second generation (SGA) LAI as an outpatient. Subjects are separated into two groups, (1) those receiving LAI SGA monotherapy and (2) those receiving both LAI SGAs and oral antipsychotics. Data collected in the first phase of the study include: patient age, gender, race, diagnosis, type of LAI, type of oral agent. The following data will be collected: emergency room visits, number of inpatient psychiatric admissions, days of inpatient psychiatric admission, reported adverse medication events. All data will be recorded without patient identifiers and maintained confidentiality. A student t-test or Wilcoxon rank-sum will be used to compare the number of emergency department visits and inpatient psychiatric admissions between groups. Chi-squared tests will be used to compare occurrence of adverse
drug effects related to antipsychotic medications. ADEs will be categorized as mild, moderate, or severe as defined in the Veterans Affairs Adverse Drug Event Reporting System.

**Poster Title:** Differences in outcomes of pharmacist-provided versus student pharmacist-provided medication counseling on transitions of care in patients in the Central Texas Veterans Healthcare System

**Primary Author:** Erin Pilcher, Central Texas Veterans Health Care System, TX; **Email:** erinpilcher@utexas.edu

**Additional Author(s):**

**Purpose:** The objective of this quality improvement project is to review the local impact on transitions of care by pharmacist and student pharmacist patient counseling on medication therapy. The aims of the study are (1) to determine the number of patients who currently receive discharge counseling from a pharmacy professional (2) to determine if there is a difference in the number of patients that experience improved health outcomes, such as fewer medication discrepancies noted at follow-up, improved medication adherence, decreased readmissions, and increased time to readmission, after pharmacist intervention.

**Methods:** Retrospective chart reviews will be performed on all patients who had inpatient stays on the Med/Surg telemetry and general medicine floors of the Olin E. Teague Veterans Hospital from July 1, 2015 to July 1, 2016. Patients who received pharmacist counseling will then be identified by Clinical Pharmacist Notes or Student Progress Notes in their electronic medical chart. Data from patients who received pharmacist counseling will be compared to patients who received resident or student pharmacist counseling. Outcomes will be compared between the two groups. The following data will be collected: Disease state related to chief complaint, if said disease state is new or preexisting, medications prescribed or discontinued during hospitalization, age, gender, ethnicity, chronic comorbidities, anticoagulation states and medication used for anticoagulation, refill history 4-months post-discharge, readmissions for the same disease state within 30 days due to medication non-compliance or medication errors, and time to readmission. All data will be recorded without patient identifying information and presented using descriptive statistics. This protocol has been submitted to the IRB for determination of exemption from classification as human subjects research.

Poster Title: Effect of standardization of vancomycin infusion rates on red man syndrome

Primary Author: Sarah Cho, Central Texas Veterans Health Care System, TX; Email: sscho1021@gmail.com

Additional Author(s):
Nathan Fewel
Amanda Trimm
Eileen Stock

Purpose: Red man syndrome (RMS), a rate-dependent infusion reaction, is a characteristic adverse reaction to vancomycin. While manufacturers recommend no greater than 10mg/min, the 2009 vancomycin guidelines suggest that faster infusion rates may be appropriate, up to 30 minutes for every 500 mg administered. The purpose of this quality improvement project is to explore if an increase in the incidence of red man syndrome has occurred following an increase in vancomycin infusion rates at our health system, which previously ranged from 11 to 14mg/min to the current standardized rate of 16.7mg/min (15 minutes for 250mg given).

Methods: This retrospective, observational quality improvement project will be conducted at a single Veterans Affairs hospital in the Southwestern region of the United States. Medical charts will be reviewed by searching for key words such as “red man syndrome,” “vancomycin,” and “rash.” Hospitalized patients who received at least one dose of parenteral vancomycin will be included. Patients will be excluded if they initiated vancomycin preoperatively, received systemic steroids or antihistamines during vancomycin therapy, or received an extremely low outlier rate of 500mg over 60 minutes. The project will aim to include about 400 patients prior to implementation (from July to November, 2015), and about 400 patients after the standardization (from January to May, 2016). A statistician will use relative risk and confidence interval to compare the risk associated with the increased infusion rates.

**Session-Board Number:** 1-347  
**Poster Title:** Evaluating the impact of an academic interdisciplinary patient aligned care team on patients and trainees within a veterans affairs academic medical center  
**Primary Author:** Ashley Adams, Michael E. DeBakey VA Medical Center, TX; **Email:** ashley.adams3@va.gov  
**Additional Author (s):**  
Richard Cadle  
Catherine Hatfield  
Julianna Fernandez  
Christina Pereira  

**Purpose:** The Office of Academic Affiliations, associated with the Veterans Healthcare Administration, has implemented a pilot project called the Centers of Excellence (COE) in Primary Care Education. This project will focus on implementation of an interprofessional Academic Patient Aligned Care Team (iAPACT) within the primary care setting to incorporate the framework of the patient-centered medical home to optimize clinical services provided to Veterans by medical trainees. The purpose of this research investigation is to evaluate pharmacy’s involvement within the iAPACT based on feedback from patients, other medical trainees, and pharmacy residents through surveys and semi-structured interviews.  

**Methods:** The design will be multifaceted to objectively capture the role of pharmacists within the iAPACT team. The study will be evaluating the primary objective of patient perceptions of the iAPACT team with the secondary objectives of medical trainees’ and pharmacy residents’ perceptions of being involved in an interprofessional training program within the COE. This project will utilize a retrospective pre- and post-implementation survey design to assess the primary objective of patient satisfaction with iAPACT and the perceived benefits. The survey will be disseminated in January and February of 2016 (3 months after pharmacy involvement begins).  
To measure secondary outcomes, a survey will measure medical trainees' experiences of interprofessional education and a semi-structured interview will assess pharmacy residents' experiences. The survey evaluating medical trainees’ perceptions will be completed before beginning their COE rotation and then at times as designated by the trainee’s length of time in
the program. Disciplines included are: medicine, nursing, physician assistants, pharmacy, and mental health. In addition to the surveys, a semi-structured interview will be completed with the pharmacy residents who participate in COE at the end of each resident’s one month rotation. All data from the surveys and questionnaires will be gathered until February 2016 for analysis. Information gathered will be assessed using appropriate statistics based on the qualitative and quantitative data collected.

Poster Title: Optimization of bulk medication utilization to improve patient care and decrease missing dose requests, while decreasing pharmacy expenditures in a large academic teaching facility

Primary Author: Marcy Pilate, Michael E. DeBakey Veteran Affairs Medical Center, TX; Email: marcy.pilate2@va.gov

Additional Author (s):
Vy Nguyen
Sima Desai
Christina Pereira

Purpose: The primary objective of this project is to determine an effective method to transfer bulk medications between nursing units for patients during their hospital admission. The secondary objective is to reduce the amount of nursing time spent on missing medication dose requests for bulk products, decrease the amount of medication waste, decrease unnecessary pharmacy spending, and improve patient care while preventing delays, by providing medications at the point of care.

Methods: Bulk medications returned to the inpatient pharmacy will be collected for a period of three months and sorted based on dosage form and drug name. A cost benefit analysis will be conducted to compare the amount of medication requests to the amount of medications returned to the pharmacy. The analysis will focus on bulk medications returned from the third floor medicine unit. After medication is collected and a cost benefit analysis is performed, nurses on each shift of a medicine unit will be asked to follow a specific standard of practice for three months to help with the transferring of medications. Upon transfer, the nursing staff will be required to document the transfer of all bulk medications not provided in the automated dispensing cabinets to the accepting nurse on the transfer unit. A section for medication transfers will be added to the nursing transfer summary sheet template in the electronic health record.

Patients included in this study must be admitted to the hospital for a minimum of three days, and prescribed at least one bulk medication. The patient must be admitted to the third floor medicine unit initially upon admission into the hospital. Patients excluded from the study are
patients not admitted to the third floor medicine unit, and patients with a hospital length of stay less than three days.

Poster Title: Incidence of delirium and evaluation of risk factors in a critically-ill Veteran population

Primary Author: Elisabeth Sulaica, Michael E. DeBakey Veterans Affairs Medical Center, TX; Email: elisabeth.sulaica@gmail.com

Additional Author (s):
Shazia Raheem
Stephanie Bird
Uma Ayyala
Charlie Lan

Purpose: Delirium is estimated to occur in up to 80% of critically ill patients and is associated with an increased risk of mortality, more ventilator days and a longer hospital length of stay. The identification and treatment of modifiable risk factors has been shown to decrease negative outcomes, however, there is limited data for intensive care unit (ICU) delirium in veterans. The purpose of this quality improvement project is to identify risk factors associated with development of delirium in critically-ill veterans.

Methods: A retrospective, observational chart review will be conducted on all adult patients admitted to the medical intensive care unit (MICU) and the surgical intensive care unit (SICU) at the Michael E. DeBakey Veterans Affairs Medical Center between October 1, 2016 and February 28, 2017. Confusion Assessment Method for the ICU (CAM-ICU) will be completed on all MICU and SICU patients by the bedside nurse at least twice daily. All patients admitted to the ICU during this time frame will be included in the study. Exclusion criteria include: patients admitted for less than 48 hours and patients who are unable to participate in CAM-ICU (Richmond Agitation-Sedation Scale score of -4 to -5, hearing impairment, cognitive deficits, and inability to understand English). The primary objective of this quality improvement project is to determine the incidence and identify risk factors associated with development of delirium in critically-ill veterans. Secondary objectives include all-cause mortality, mechanical ventilator days and ICU and hospital lengths of stay. The primary objective and baseline characteristics will be analyzed using chi-squared or Fischer’s exact test as appropriate; a p-value of less than 0.05 will be considered significant. Secondary objectives will be analyzed using chi-square for categorical
variables and Student’s t-test for continuous variables. Univariate and multivariate analysis will be conducted to evaluate risk factor variables in relation to patient delirium status.

**Poster Title:** Evaluation of statin therapy in liver disease  
**Primary Author:** Emily Van Klompenburg, Michael E. DeBakey Veterans Affairs Medical Center, TX; **Email:** emily.vanklompenburg@gmail.com  
**Additional Author(s):**  
Kathleen Morneau  
Yamini Natarajan  
Sonya Wilmer  

**Purpose:** Patients with liver disease are at higher risk of cardiovascular events compared to the general population. The objective of this study is to evaluate statin therapy prescribing patterns and compliance to the 2013 American College of Cardiology/American Heart Association Blood Cholesterol guideline recommendations in a liver disease population at the Michael. E. DeBakey Veterans Affairs Medical Center (MEDVAMC).  

**Methods:** A retrospective chart review of statin use in adult patients with stable liver disease will be conducted. Patients will be identified via hepatology clinic records and assessed for a two year timeframe following the initial clinic visit. Using the computerized patient record system, appropriate statin therapy will be determined in accordance with the 2013 American College of Cardiology/American Heart Association guidelines. Patients included are those age >18 years old with stable liver disease who received care at the MEDVAMC hepatology clinic from May 1, 2014 through August 31, 2014. Exclusion criteria include decompensated liver disease in the previous 90 days, documented history of allergy to statin or statin-induced rhabdomyolysis prior to study start, adults >76 years old, absence of lab work within prior two years, and acute liver failure. Mortality, cardiovascular, and liver outcomes will also be assessed. Data collected will include patient characteristics, comorbidities, hospitalizations, LFTs, INR, albumin, bilirubin, lipid panels, etiology of liver disease, statin therapy, escalation of liver disease treatment, liver disease decompensation, and MELD scores. Statistical analysis will include descriptive statistics and univariate and multivariate logistic regressions. All data will be collected without patient identifiers and maintained confidentially. This study will be submitted to the Institutional Review Board for approval.

Poster Title: Rates of Clostridium difficile infections associated with the frequency-adjusted use of antibiotic agents in an academic Veterans Affairs Medical Center

Primary Author: Anne Gonzales-Luna, Michael E. DeBakey Veterans Affairs Medical Center, TX; Email: annejones@utexas.edu

Additional Author(s): Daniel Mushar
Andrew Hunter
Richard Cadle

Purpose: Although use of any antibiotic agent has been established as a major risk factor for Clostridium difficile infections (CDI), there has been ongoing debate about which specific agents are most commonly implicated. Various studies have demonstrated an increase in CDI resulting from use of 3rd generation cephalosporins, clindamycin, and fluoroquinolones, but few have adjusted for the frequency with which these antibiotics are used in the patient population under study. Both the increasing use of antibiotics in the U.S. and the increasing incidence of hospital and community-acquired CDI indicate a need for further elucidation into factors predisposing to CDI.

Methods: A retrospective study will be conducted on data from July 2011-June 2016. Patients with a positive C. difficile fecal PCR assay who have previously received >=2 days of treatment with clindamycin, a fluoroquinolone, or a third-generation cephalosporin will be identified with the institution’s antibiotic surveillance software. Patients included in the study must have received treatment with clindamycin, a fluoroquinolone, or a third-generation cephalosporin as monotherapy or in pre-specified combination therapy in the 30 days preceding the positive assay. Patients will be excluded if they received any antibiotic agent in addition to the pre-specified antibiotic combinations, or if they have had a positive fecal PCR assay for C. difficile in the preceding 12 weeks. The institution’s pharmacy information technology software will be used to gather the number of prescriptions dispensed for all antibiotic agents over the same time period. Odds ratios will be calculated and analyzed for inpatients and outpatients receiving clindamycin, a fluoroquinolone, or a third-generation cephalosporin. Other data collected for
secondary outcomes will include use of a proton-pump inhibitor or histamine 2-receptor antagonist at time of positive C. difficile fecal PCR and age.

Poster Title: Assessment of asymptomatic bacteriuria and urinary tract infection treatment in the emergency department

Primary Author: Jessica Guastadisegni, Michael E. DeBakey Veterans Affairs Medical Center, TX; Email: jessica@hallockfamily.com

Additional Author(s):
Andrew Hunter
Caroline Pham
Sania Sultan
Richard Cadle

Purpose: Asymptomatic bacteriuria is defined as the isolation of bacteria from the urine without associated urinary symptoms. The Infectious Diseases Society of America advocates against screening for and treatment of asymptomatic bacteriuria in most populations. Despite these recommendations, patients often receive antimicrobials in the emergency department based on urinalysis results or non-urinary symptoms. The primary objective of this study is to assess the appropriateness of empiric management of asymptomatic bacteriuria and urinary tract infections in the emergency department of a Veteran Affairs Medical Center.

Methods: This study will be submitted to the Institutional Review Board for approval. This single-center retrospective cohort study will include all adult patients 18 years or older who have urine cultures collected in the emergency department with a positive result from July 2015 through June 2016. Pregnant patients and patients subsequently admitted to the hospital from the emergency department will be excluded. The research population will be identified using a clinical surveillance system and the electronic medical record system, and the following data will be collected: age, race, gender, height, weight, previous antibiotics within 30 days, antibiotic allergies, past medical history, urinary symptoms, systemic infection symptoms, documented urine collection method, urinalysis results, urine culture results, study determined infection result, initial antimicrobial prescribed, uropathogen susceptibility, antimicrobial changes within 30 days, and 30-day emergency department, hospital admission, or subsequent clinic appointment with report of urinary symptoms or adverse drug reactions related to
antimicrobial(s). Descriptive statistics will be utilized to analyze patient characteristics and outcomes.

**Poster Title**: Clinical outcomes of acute osteomyelitis in spinal cord injury patients at a Veteran’s Affairs teaching hospital

**Primary Author**: Cristian Mendez-Sepulveda, Michael E. DeBakey Veterans Affairs Medical Center, TX; Email: cristian.mendez-sepulveda@va.gov

**Additional Author(s)**:
Feibi Chi
Regina Issac
Richard Cadle
Rabih Darouiche

**Purpose**: A common complication of an ineffectively treated pressure ulcer in spinal cord injury (SCI) patients is contiguous osteomyelitis. However, studies providing information about the etiology of osteomyelitis as well as effectiveness of the current standard of care in this patient population are very limited. This study aims to evaluate the clinical outcomes and etiologic characteristics of SCI patients in the treatment of osteomyelitis at the Michael E. DeBakey Veterans Affairs Medical Center (MEDVAMC).

**Methods**: A retrospective chart review will be conducted using TheraDoc® and Computerized Patient Record System (CPRS) to search from January 1st, 2013 to July 1st, 2016. Patients who are at least 18 years of age, diagnosed with acute pelvic and/or vertebral osteomyelitis with a positive bone culture and received antibiotic treatment at the MEDVAMC will be included in the study. Patients with osteomyelitis of other sites or with palliative care will be excluded. The patients’ demographic data, location of osteomyelitis, type of surgical intervention for management of the infection, laboratory values, vitals, comorbidities, concomitant infections, microbiologic results, antimicrobial drug regimen and antibiotic drug levels will be recorded. The primary objective of this study is clinical cure at the end of 6 weeks of treatment or at the earliest visit after the completion of treatment. Secondary objectives include comparing clinical cure of osteomyelitis caused by gram positive bacteria, gram negative bacteria and combination of both, appropriateness of antimicrobial dosing based on the minimum inhibitory concentration and reinfection rates at 6 months post-treatment or next earliest visit. Poster Title: Analysis of referrals and interventions implemented by pharmacy practice residents within the Primary Care Center of Excellence at a Veterans Affairs (VA) teaching hospital

Primary Author: Kathleen Athern, Michael E. DeBakey Veterans Affairs Medical Center, TX; Email: kathleen.athern@va.gov

Additional Author(s):
Richard Cadle
Sonya Wilmer

Purpose: The Center of Excellence in Primary Care Education (CoEPCE) is an innovative clinic present in several Veterans Affairs hospitals currently. By incorporating trainees from several backgrounds of health care, the CoEPCE aims to expand the presence of interprofessional education into post-graduate training. While the CoEPCE is present at several hospitals, incorporation of pharmacy practice residents within this clinic has varied between locations. The goal of this project is to qualify the impact of pharmacy practice residents at the Micheal E. DeBakey VA CoEPCE and to draw conclusions from the results for effective utilization of the residents in the future.

Methods: A quality improvement study will be completed to analyze referrals to and subsequent interventions initiated by pharmacy practice residents within the CoEPCE from October 2016 to March 2017. Using the electronic record system within the VA (CPRS) and the pharmacist intervention tracking tool (PhARMD), a retrospective chart review will be completed focusing on the patients seen by pharmacy practice residents and the interventions initiated thereafter. The primary outcome of this project is the analysis of interventions implemented which includes identifying the initiation or discontinuation of pharmacotherapy, adjustment of medication doses, and initiation of non-pharmacological lifestyle interventions. Secondary outcomes will include the type of follow-up completed by the resident, the number of follow-up interactions with the patient, number of interventions initiated for disease states that were not the primary reason for referral, time to goal of therapy, and identification of the referral requestor. In addition, a cost-reduction analysis will be completed and the outcomes will be
assessed using descriptive analysis. Following the identification of this information, conclusions will be drawn on the proper utilization of the pharmacy practice resident within the CoEPCE.

Session-Board Number: 1-355

Poster Title: Buprenorphine for the treatment of Post-Traumatic Stress Disorder

Primary Author: Elizabeth Lake, Michael E. DeBakey Veterans Affairs Medical Center, TX; Email: elizabeth.lake8@va.gov

Additional Author(s):
Brian Mitchell
Thomas Kosten
Daryl Shorter
Coreen Domingo

Purpose: The core treatment of Post-Traumatic Stress Disorder (PTSD) is selective serotonin reuptake inhibitors (SSRIs) for negative mood/thoughts, although remission is only around 30% with them. Many patients will self-treat with opiates, but there is perhaps a deeper underlying mechanism for improvement of PTSD symptoms. Because of its involvement in dysphoric mood and anxiety/stress responses, it is likely that antagonism of the kappa opioid receptor (KOR) system represents a potential target for the treatment of PTSD. The aim of this study is to compare the response of PTSD symptoms when antagonizing KOR via buprenorphine/naloxone compared to SSRIs or opioid therapy.

Methods: A retrospective chart review of adult patients in the MEDVAMC between the dates of June 1, 2013 and June 30, 2016 will be conducted. Inclusion criteria include patients with a documented diagnosis of PTSD from either primary care or mental health clinics during the study timeframe with at least two (2) documented PTSD scores (either PCLC or PC-PTSD). Exclusion criteria include patients not prescribed at least one of the study medications (i.e., buprenorphine, an SSRI, or an opiate for chronic pain), as well as patients not on the study medication for at least thirty (30) days. For the primary outcome, the average standardized PTSD score for each group will be compared using a one-way analysis of variance (ANOVA). For the secondary outcome, the average change in first and last standardized PTSD scores (adjusted to a per diem basis) will be compared, again using a one-way ANOVA. Descriptive statistics will be used to report patient characteristics data. It was determined that a sample size of N=165 would ensure that a two-sided test with α =0.05 would have 80% power to detect a 1 point
difference in PTSD scores. The sample size needed is 165 patients across all treatment arms, with 55 patients per treatment arm utilizing 1:1:1 randomization.

**Poster Title:** Evaluating the impact of a pharmacy resident driven CoEPCE care plus outpatient clinic at the Michael E. DeBakey VA Medical Center

**Primary Author:** Amanda Shigle, Michael E. DeBakey Veterans Affairs Medical Center, TX;  
**Email:** a-shigle@onu.edu

**Additional Author (s):**  
Richard Cadle  
Sonya Wilmer

**Purpose:** The Center of Excellence in Primary Care Education (CoEPCE) is a pilot project within the Department of Veterans Affairs that is aimed to optimize interdisciplinary care provided by healthcare trainees. As part of the CoEPCE project, a care plus clinic will be established with the goal of providing a same day walk-in service that offers the opportunity to consult pharmacists without the need for a scheduled appointment. The purpose of this project is to evaluate the impact of pharmacists within a primary care clinic aimed to improve accessibility for time sensitive medical conditions or for additional pharmacologic education and management.

**Methods:** A quality improvement (QI) study will be completed to assess the effectiveness of a same day walk-in clinic within the CoEPCE. Data will be collected from October 1, 2016-February 28, 2017. The primary objective is to investigate the impact of pharmacy residents in the CoEPCE care plus clinic by assessing the type and average number of interventions per patient. The secondary objectives include the following: the primary reason for the walk in visit, the disease states managed, the average time of each visit, and patient characteristics, as well as, a cost prevention analysis. This QI project is a retrospective review that will utilize the VA electronic medical database (CPRS) and the VA outpatient intervention capturing tool (the PhARMD Tool) to investigate the specified objectives. Information collected will be assessed using appropriate statistics based on the descriptive data collected.

Poster Title: Reducing readmissions through transitions of care for heart failure patients: a retrospective quality improvement and program evaluation

Primary Author: Amber Gossett, South Texas Veterans Health Care System, TX; Email: angossett@gmail.com

Additional Author(s):
Jeffrey Larsen
Ashley Rogers
Tera Moore
Jordan Nelson

Purpose: The purpose of this retrospective review was to analyze the efficacy of intensive follow-up care post-discharge for a heart failure admission and the implementation of a quick order set to schedule follow-up prior to discharge. Compliance with scheduling and attendance of post-discharge follow-up appointments, as well as a comparison among the different providers—Primary Care Physician, Patient Aligned Care Team Clinical Pharmacy Specialist (PACT CPS), and Cardiology, was evaluated. Characteristics of patients with a congestive heart failure readmission within 30 days were assessed in order to provide further direction and potential areas of improvement.

Methods: Patients were included for review if a hospitalization with a primary diagnosis of congestive heart failure occurred between May 2012 and December 2015. Information was collected in three incremental date ranges to evaluate data at baseline and each intervention. Baseline characteristics extracted from a pre-existing quality management database for analysis. Data such as average total daily doses of cardiovascular medications, utilization of the quick order set, and ejection fraction were collected retrospectively. Patients were considered readmitted if the next admission date for any cause was within 30 days of the previous post-discharge date. Additional hospitalizations occurring within the 30day post-discharge timeframe were not counted as additional admissions per Centers for Medicaid and Medicare Services (CMS). Analysis included 30 day all-cause readmission rates and the percentage of visits scheduled and attended. Patients were excluded if they were on hospice or observation, expired prior to discharge, left AMA, or transferred to an acute/long term care facility.
**Results:** Data analysis included 1263 admissions with 348 meeting exclusion criteria. Of the patients evaluated, 96% were male with an average age of 70 years. A total of 204 all-cause 30 day readmissions occurred during the study period. The percentage of patients readmitted within 30 days post-discharge per CMS criteria at baseline, and following intervention one and two were 25%, 23%, and 20%, respectively. The 30 day mortality rate at the end of the study period was 7.16%. Percentage of patients scheduled for all four follow-up visits post-discharge at baseline and following intervention one and two were 1%, 12% and 28%, respectively. Of those with all four follow-up appointments scheduled, no patients attended all four visits at baseline and 9% and 30% of patients attended all four visits following intervention one and two, respectively.

**Conclusion:** Patients with heart failure are at increased risk for hospital readmission compared to the general population. This patient population uses a substantial amount of health care resources and new methods are needed to increase access to care while reducing costs. Utilizing a quick order set to ensure post-discharge appointments are scheduled prior to discharge plays a critical role in increasing attendance to follow-up care. Intensive follow-up with higher attendance rates post-discharge for heart failure patients is essential to improving 30 day readmission rates and mortality.

**Submission Type:** Evaluative Study

**Session-Board Number:** 1-358

**Poster Title:** Implementation and outcomes of opioid-related electronic consults (e-consults) by a clinical pharmacy specialist in a Veterans Affairs health care system

**Primary Author:** Christina Dorman, South Texas Veterans Health Care System, TX; **Email:** tinabherbert@gmail.com

**Additional Author (s):**
Amber Gossett
Tera Moore
Carrie Gonzalez

**Purpose:** The focus of chronic pain management has shifted to decreasing, or avoiding, chronic opioids in non-cancer patients due to known risks and lack of benefit of long-term opioid use in most patients. Electronic consults (e-consults) provide an outlet for providers to obtain evidence-based recommendations for tapering and discontinuing opioids. A clinical pharmacy specialist (CPS) trained in pain management conducts a thorough patient history review and provides recommendations to requesting providers. This project was conducted to evaluate the percentage of implemented recommendations, complete or partial, and if morphine equivalents per day (MED) decreased with these recommendations.

**Methods:** This review was conducted with approval from the Institutional Review Board. Information was collected through a retrospective chart review of South Texas Veterans Health Care System (STVHCS) veterans. The initial study population included any patient with a note titled “PharmD Opioid E-consult Results Note” entered from February 2015 through June 2016. To be included in the analysis, e-consults must have been placed primarily for opioid recommendations and patients had to have documented follow-up and receive pain medications through STVHCS. For patients with repeat consults, the more recent recommendations were included, but total MED from initial consult through the present time were used for complete data analysis. Data collected included specialty of the providers who placed the consult, consult submission and completion dates, reason for the consult, a summary of the recommendation, and MED at baseline, 3, 6, and 9 months along with “current” MED at the time of data collection. Concomitant benzodiazepine use and naloxone kit recommendations with notation of subsequent provision to patients were also collected.
Recommendation implementation was categorized as complete (full taper to no or low MED as recommended in consult response), partial (MED reduction to intermediate dose), minimal, or none.

**Results:** A total of 105 consults were submitted for 99 unique patients during the review period, with the majority (90%) placed by primary care providers, most often requesting recommendations regarding opioid taper or discontinuation. Nine consults were excluded because the primary consult reason was not for opioid taper or discontinuation, leaving 96 consults for 91 unique patients. Seventy-seven unique patients were included in the analyses after excluding patients no longer receiving care at STVHCS, including one who had passed away and another who was active military, or not receiving pain medications at STVHCS. E-consults took an average of 1.7 days to complete and recommendations were completely and partially accepted in 51% (39/77) and 35% (27/77) of e-consults, respectively. Thirty-three patients had data through all analyzed time periods. Twelve percent of recommendations were not accepted at all. The greatest MED reduction was seen from baseline to 3 months (49%), with subsequent reductions of 0.1%, 4%, and 26% at 6 and 9 months and to current dose, respectively. Concomitant benzodiazepine use was documented in 14% of patients and naloxone kits were recommended in 16%, only one of which was received by the patient.

**Conclusion:** The CPS-managed opioid e-consult service positively impacts health care and patient safety by supporting evidence-based management, often with taper or discontinuation, of chronic opioid therapy, helping reduce opioid misuse and overdose. Healthcare providers, but particularly CPSs, can play a critical role in reducing misuse of opioid medications. The opioid e-consult service evaluated in this review presents a way to recommend safe, evidence-based schedules for tapering off of these medications. With the utilization of the e-consult service, majority of these cases can be handled within primary care, but they require a strong alliance between pharmacist, provider and patient to achieve success.

Poster Title: Implementation of a standardized admission insulin order set in a veterans hospital

Primary Author: Erin Yeung, South Texas Veterans Health Care System, TX; Email: erinkyeung@gmail.com

Additional Author(s):
Mark Wong
Dana Wong

Purpose: Hyperglycemia in hospitalized patients with or without diabetes mellitus is associated with greater adverse outcomes and increased lengths of stay. Current guidelines recommend basal-bolus correction insulin regimens for inpatient glycemic control, but consensus for optimal insulin protocol design remains unclear. At our institution, admission order sets with sliding scale insulin were previously used. Recent implementation of a basal-bolus insulin order set has yet to be evaluated for efficacy. The purpose of this study is to determine the efficacy of a newly implemented admission insulin order set for hyperglycemia management as compared to hyperglycemia management before implementation.

Methods: This is a retrospective, single-center, pre-post study conducted at the South Texas Veterans Health Care System. Patients will be included if admitted to a general medicine ward and have a diagnosis of type 2 diabetes mellitus or admission blood glucose greater than 180 mg/dL. Data will be collected from an electronic health record from August 1, 2015 to October 31, 2015 and August 1, 2016 to October 31, 2016 to evaluate data pre- and post-implementation of the admission insulin order set. From the collected data, demographic information, patient diagnoses, hospitalization course, discharge data, length of stay, and medication history will be evaluated. The primary endpoint of mean blood glucose levels (before and after order set implementation) throughout hospitalization will be compared. Secondary endpoints include: percent of patients with average hospitalization blood glucose less than 180 mg/dL, percent of patients utilizing basal insulin, percent of patients utilizing sliding scale only, 30-day mortality, length of stay, and occurrence of hypoglycemia episodes. This data will be used to determine whether implementation of the admission insulin order set is associated with improved inpatient glycemic control.

**Poster Title:** Reducing concurrent prescribing of benzodiazepines and opioids

**Primary Author:** Chelsea Minor, South Texas Veteran's Health Care System, TX; **Email:** chelsea.minor@va.gov

**Additional Author (s):**
Jana Shults

**Purpose:** The concurrent use of opioids and benzodiazepines may put patients at greater risk for fatal overdose as both depress the central nervous system and can decrease respiratory drive. Due to an increased risk of falls, respiratory depression, overdose, cognitive problems and death in patients receiving benzodiazepines and opioids, concomitant use is not advised. In the 2014-2015 fiscal year, 6.3% of pharmacy patients were on combined opioid and benzodiazepine therapy in the South Texas Veteran's Health Care System. In line with current best practices, strategies are needed to reduce the rates of concurrent prescribing and improve patient care.

**Methods:** Patients who had an active prescription for a benzodiazepine and an active prescription for an opioid medication as of February 23, 2016 were included, unless the days supply of medication was less than 14 days or the quantity was less than the days supply (e.g. 15 tablets for 30 day supply). The electronic medical record was reviewed for each patient who met criteria for evaluation. Various patient factors and characteristics were extracted for analysis. An alert was completed by a mental health clinical pharmacy specialist (MH CPS) and sent to the prescribing physician. If medications were prescribed by more than one provider, both the prescriber of the opioid and the benzodiazepine were alerted. After ten days, the charts of patients whose prescriber had been alerted, were reviewed. Analysis includes percentage of responses received and medication changes.

**Results:** A total of 83 patients were included in the final analysis. Characteristics associated with an increased risk of overdose including morphine equivalent dose ≥ 100 mg, obstructive sleep apnea, and post-traumatic stress disorder were present in 13.3% (11/83), 28.9% (24/83), and 28.9% (24/83) respectively. Provider response with within the ten day follow up period was 46.9% (39/83). Overall, 28.9% (24/83) of provider responses indicated that patients would
either be initiated or continued on a benzodiazepine taper. This number encompasses the 12% (10/83) of providers who initiated a benzodiazepine taper within the 10 day follow up period, 9.6% (8/83) of providers that indicated that they would discuss or implement a taper at the patient’s next scheduled appointment, and 7.2% (6/83) of providers that agreed to continue a previously initiated a benzodiazepine taper. A portion of providers 7.2%, (6/83) opted to continue current therapy with caution. The MH CPS recommended a benzodiazepine taper in 68 patients, of which 26.5% (18/68) of providers either implemented or indicated they would consider a future change, 7.0% (6/88) providers indicated they would continue therapy with caution, and (44/68) providers did not respond within the 10 day follow up period.

**Conclusion:** The MH CPS led alert provided an effective means to reduce the amount of inappropriate prescribing of concurrent benzodiazepine and opioid therapy. This analysis was limited by the short follow-up period measured and the inability to capture non-VA prescriptions. Alternative strategies must be used to target providers who did not respond to the alert. Future efforts should be focused on preventing initiation of combination therapy when alternatives exist.

**Poster Title:** Effects of tapering high-dose opioid therapy on health care utilization in Veterans on chronic opioid therapy

**Primary Author:** Natalie Savona, VISN 17 Pharmacy Benefits Management Central Texas Veterans Health Care System, TX; **Email:** natalie.savona@va.gov

**Additional Author(s):**
Terri Hahn
Jennifer Gunter

**Purpose:** Chronic opioid use has a high prevalence within the Veterans Health Administration (VHA). It is well established that patients on high-dose opioids experience more overdoses, are more likely to have alcohol or drug-related healthcare encounters, and may experience opioid induced hyperalgesia. In June 2014 regional Academic Detailing Services with the Opioid Safety Workgroup began an educational campaign aimed at realigning opioid prescribing culture with the best evidence-based practices. This study’s purpose is to evaluate the impact of an opioid safety initiative (OSI) on the health care utilization of veterans on high-dose opioid therapy within a veterans integrated services network (VISN).

**Methods:** This quality assurance project is a retrospective analysis of prescription and patient encounter data for the specified cohort for two distinct time periods from a VHA regional data warehouse. The patient cohort will be identified by filled prescriptions for chronic high-dose opioid analgesics (i.e. 90 milligram morphine equivalent dose (MED) daily or greater, receiving a 90 day’s supply within 180 days) during fiscal year 2013. The OSI timeframe is defined as fiscal years 2014 and 2015 and follow-up analysis period is fiscal year 2016. Outcomes will be compared between the baseline data and the follow-up data for the identified cohort. Subject exclusion criteria includes: death during the baseline time period or OSI implementation period, although these numbers will be reported. Primary objective data includes: pain score, MED, prescription, and healthcare encounters. Additional demographic information will include: age, gender, concomitant benzodiazepine or sedative, and high risk comorbidities based on at least two encounter diagnoses within the baseline study period (i.e. post-traumatic stress disorder, major depressive disorder, substance use disorder, other mental health diagnosis, obstructive sleep apnea, and chronic obstructive pulmonary disease). The data query will be limited to VISN.
sites with available data for the evaluation timeframes, and will be executed using Toad for Structured Query Language (SQL) Server Management software. Microsoft Excel and other appropriate software will be used for data organization and statistical analysis.

**Poster Title:** Impact of clinical pharmacy case management on time to treatment for diagnosed Hepatitis C patients

**Primary Author:** Mertessa Espejo, West Texas VA Health Care System, TX; **Email:** mertessa.espejo@va.gov

**Additional Author(s):**
Tyson Kubena
Chantal Kneifel
Wendy Brown

**Purpose:** Advances in Hepatitis C therapy with direct-acting antivirals (DAAs) afford a curative goal contingent upon timely and sustained access to care. The clinical pharmacy Hepatitis C clinic at the West Texas VA Health Care System (WTVAHCS) was developed to meet the needs of evolving practice to improve linkage to care. The purpose of this review is to evaluate the impact that the clinical pharmacy Hepatitis C clinic has had on time to treatment for WTVAHCS Hepatitis C patients and compare the rates of sustained virologic response (SVR) achieved between Hepatitis C case management modalities.

**Methods:** This quality improvement project was approved by the WTVAHCS pharmacy and therapeutics committee. Retrospective analysis will evaluate time from initial Hepatitis C consult to receipt of DAA therapy for WTVAHCS Hepatitis C patients. A Computerized Patient Record System (CPRS) medication record review will identify WTVAHCS Hepatitis C patients who received DAA from the onsite pharmacy. The timeframe evaluated for comparison will include two years prior to the opening of the Hepatitis C clinic (April 1, 2014 – April 1, 2016) through the opening of the Hepatitis C clinic (April 1, 2016 – July 31, 2016). Time to treatment achieved by the Hepatitis C clinic will be compared to that of prior case management modalities. Data collection for the primary analysis will include the date of Hepatitis C CPRS consult and the date of written prescription for Hepatitis C DAA. Secondary analysis will evaluate Hepatitis C viral load after 12 and/or 24 weeks of treatment, Hepatitis C genotype, reported adverse medication related effects and distance from patient’s primary Community Based Outpatient Clinic (CBOC) location to the WTVAHCS site. Time to treatment will be
calculated based on the date of CPRS Hepatitis C consult entry and the date of the first Hepatitis C DAA prescription fill. SVR will be determined based on Hepatitis C viral load after prescribed duration of therapy (12 or 24 weeks).

**Poster Title:** Evaluating the change in unnecessary benzodiazepine use in veterans on both an opioid and benzodiazepine or a benzodiazepine alone after sending an educational self-taper letter  

**Primary Author:** Cynthia Bartha, West Texas Veterans Affairs Healthcare System, TX; **Email:** cynthiabartha@yahoo.com  

**Additional Author (s):**  
John Hoyng  
Tyson Kubena  

**Purpose:** Concomitant opioid and benzodiazepine use have been associated with an increase in the risk of death and severe adverse events. The EMPOWER study has shown a decrease in benzodiazepine use when patients are mailed a letter containing information describing benzodiazepines and strategies for discontinuation. The primary objective of this quality improvement project is to evaluate the change in benzodiazepine use in veterans on both an opioid and benzodiazepine or a benzodiazepine alone after receiving an educational letter covering benzodiazepines. The secondary objectives are to determine the most commonly prescribed benzodiazepine, diazepam equivalents prescribed, and indication for use.  

**Methods:** The Pharmacy and Therapeutics committee approved a retrospective review of patients on both opioids and benzodiazepines or benzodiazepines alone to determine if there was a change in benzodiazepine use after an educational letter containing information for benzodiazepines on self-tapering was sent. Data will be accessed through a structured query language (SQL) report for those patients who were sent the letter. The SQL report will access data on the last fill date of the benzodiazepine, the last day supply of benzodiazepine filled, the benzodiazepine prescribed, benzodiazepine dose, patient age, and indication for use. A benzodiazepine taper will be deemed complete if the benzodiazepine has not been filled within six months from the letter being sent. A decrease in benzodiazepine use will then be measured by the total number of patients on benzodiazepines before and after the letter as a percentage of the total population.

Poster Title: Direct acting oral anticoagulants in patients of extreme weights

Primary Author: Taylor Alford, Salt Lake City Veterans Affairs Health Care System, UT; Email: taylor.alford@ucdenver.edu

Additional Author(s):
Arthur Allen
Donald Miller

Purpose: A 2016 ISTH/SCC guidance document recommends that direct acting oral anticoagulants (DOAC) not be used in patients with body mass indexes (BMI) greater than 40 or weight greater than 120 kilograms (kg). This recommendation is based on the lack of representation of these groups in clinical trials and based on pharmacokinetic data, suggesting decreased drug exposures, reduced peak concentrations and shorter half-lives in these groups. The objective of this study is to identify efficacy outcomes to further guide DOAC treatment decisions.

Methods: This retrospective study will identify all Veterans Affairs (VA) patients prescribed a DOAC with a BMI greater than 40 or weight greater than 120kg. The following data will be collected from the electronic medical record utilizing ICD9 codes: DOAC indication (non-valvular atrial fibrillation (NVAF) or venous thromboembolism (VTE) treatment), specific DOAC (rivaroxaban, dabigatran, apixaban, edoxaban), DOAC dose and frequency of administration, thrombotic history while on a DOAC, duration on a DOAC, renal function (serum creatinine, creatinine clearance, eGFR), and CHADS2-VASc score for NVAF patients. All data will be managed by a SQL database and collected without patient identifiers. Treatment failures, defined as a thrombotic event while receiving a DOAC, will be compared between patients of various BMI and weight categories.

Poster Title: Medication use evaluation of intramuscular naltrexone for alcohol and opioid use disorder

Primary Author: Devin Livesay, VA Salt Lake City Health Care System, UT; Email: devin.livesay@va.gov

Additional Author(s): Jeffrey Gower

Purpose: This medication use evaluation aims to identify any deficiencies in patient follow-up for veterans prescribed intramuscular (IM) naltrexone with the goal of designing an intervention or protocol to improve compliance for follow-up injections.

Methods: Using the data warehouse, a list of all patients prescribed IM naltrexone between July 1, 2015 and July 1, 2016 will be collected. By way of chart review, when and why naltrexone was initiated and discontinued will be identified. In addition, demographics including age, sex, diagnoses, and start/stop dates will be collected. The number of hospitalizations related to disorders treated with naltrexone will also be collected. Cost analysis will be included as part of this project including potential cost savings through proposed interventions.

Poster Title: Medication use evaluation of medication assisted treatment for alcohol use disorder

Primary Author: Natalie Valentino, VA Salt Lake City Health Care System, UT; Email: valentinonatalie@gmail.com

Additional Author (s):
Sadie Roestenburg
David Denio

Purpose: The purpose of this medication utilization evaluation (MUE) is to determine the number of patients who are potential candidates for medication assisted treatment (MAT) for alcohol use disorder (AUD), as well as examine their characteristics, including the number of recent alcohol-related admissions and where they are currently accessing care. This information will be used to better direct our efforts in prescribing MAT and connecting patients with AUD to appropriate care based on patient preference and clinical necessity.

Methods: This MUE will be conducted as a retrospective chart review of patients with documentation of AUD or alcohol dependence in the electronic medical record. Patients with International Code of Diseases, Ninth or Tenth revision (ICD-9 and ICD-10) codes for 303, alcohol dependence syndrome, or F10, alcohol related disorders, will be included in chart review. Data will be collected on patients who have not filled an outpatient prescription for naltrexone, acamprosate, or disulfiram between 09/01/2015 – 09/01/2016. The following data points will be collected: demographics, including age, sex and alcohol related diagnosis; primary care provider (PCP) information, including PCP name, clinic location and date of last visit with PCP; mental health (MH) provider information, including MH provider name, clinic location and date of last visit with MH provider; and hospitalizations and emergency department (ED) visits, including dates and admission diagnoses. The primary endpoint is the number of patients with documented alcohol dependence who are not prescribed MAT, with secondary endpoints including the number of alcohol-related admissions/ED visits in the past year, percentage of patients with a PCP or MH provider visit in the past year, percentage of patients without a MH provider and location of PCP. Descriptive statistics will be used to evaluate primary and secondary outcomes.

**Session-Board Number:** 1-367  

**Poster Title:** Skin and soft tissue infection (SSTI) treatment evaluation at the Salt Lake VA Medical Center  

**Primary Author:** Jonathan Redd, VA Salt Lake City Health Care System, UT; **Email:** jwredd@gmail.com  

**Additional Author (s):**  
Jesse Sutton  
Peter Yarbrough  
Emily Spivak  

**Purpose:** Evaluations of SSTI treatment in other health systems have identified opportunities for reducing unnecessary antimicrobial exposure and diagnostic testing. The objective of this project is to evaluate the treatment of SSTIs at the Salt Lake VA Medical Center to identify opportunities for improvement of prescribing practices in the ambulatory care, inpatient and emergency department settings. The results of the evaluation will guide development of a facility-specific treatment pathway adapted from the Infectious Disease Society of America (IDSA) guideline for treatment of SSTIs.  

**Methods:** Patients with SSTIs from January 1, 2015 through July 31, 2016 will be identified using relevant SSTI Internal Classification of Diseases codes. Approximately 200 patients will be selected for manual chart review. Criteria for exclusion are diabetic foot infections, post-operative infections, osteomyelitis, joint infections, orofacial infections, perianal infections and coexisting non-SSTI infections. The following data will be collected from the medical record: demographics, medication allergies, relevant comorbidities, vital signs, relevant laboratory values, type of imaging used, location of infection, classification of SSTI as purulent or nonpurulent, culture results, antibiotic(s), duration of treatment, SSTI retreatment, Clostridium difficile infections within 1 month post-treatment, hospitalization and length of stay. The primary treatment evaluation objective is to assess the proportion of veterans whose antibiotic regimen met criteria for potentially avoidable exposure. Potentially avoidable exposures will be defined as use of a broad spectrum antibiotic for any SSTI, use of an anti-MRSA antibiotic for nonpurulent SSTI, or treating any SSTI for greater than 7 days.

Poster Title: Metformin use in patients with type 2 diabetes mellitus and renal dysfunction

Primary Author: Carolyn Garland, VA Salt Lake City Healthcare System, UT; Email: cmgarland2@gmail.com

Additional Author(s):
Dat Auduong
Elisabeth Birdsall

Purpose: In April 2016, the U.S. Food and Drug Administration (FDA) revised their recommendation regarding use of metformin in individuals with renal dysfunction. This update was based on a review of evidence showing safety in patients with an eGFR as low as 30 mL/min, and recommended that eGFR, not SCr, be used as a measure of renal function. The objective of this analysis is to determine if there are patients within a regional healthcare system who were not previously started on metformin due to elevated SCr, but would now be eligible for this therapy based on eGFR.

Methods: The electronic medical record will be used to identify patients with a diagnosis of type 2 diabetes mellitus according to ICD-9 or ICD-10 code, and moderate renal dysfunction, defined as eGFR greater than 45 mL/min, who do not have an active prescription for metformin or a documented adverse reaction to this agent. Patients will be included if they are male with an average SCr greater than 1.5 mg/dL, or female with an average SCr greater than 1.4 mg/dL. These laboratory findings may have contributed to avoidance of metformin based on previous guidance concerning increased risk of lactic acidosis. The following data will be collected: age, average HgbA1c, most recent HgbA1c, measure of renal function using average and most recent SCr and eGFR values, and other anti-hyperglycemic prescriptions. All average values will be based on labs measured between April 2015 and April 2016. A protocol will be developed to initiate metformin therapy in collaboration with primary care providers in patients considered clinically appropriate for therapy. A cost-savings analysis will be completed to determine the potential financial benefit to the institution if patients were able to transition to metformin from an alternative agent.

Poster Title: Medication utilization evaluation of lithium monitoring at the Veteran's Affairs Salt Lake City Health Care System (VASLCHCS)

Primary Author: Jenni-lyn Ladutko, VA Salt lake City Healthcare System, UT; Email: jenni-ly.ladutko@va.gov

Additional Author (s):
David Denio

Purpose: Ensuring appropriate monitoring in veterans maintained on lithium is a national Veteran's Affairs (VA) initiative. Lithium has a narrow therapeutic index and small changes in serum levels can result in therapeutic inefficacy or toxicity. To monitor safety, the VA/Department of Defense (DOD) guidelines recommend to check lithium serum levels every 4-14 days following initiation, titration, or a change in risk factors, and every six months in stable patients on a maintenance dose. The objective of this study is to evaluate serum lithium level monitoring at the VASLCHCS and identify strategies to improve lithium safety.

Methods: This evaluation will be a quality improvement project at the VASLCHCS, and has been exempt from Institutional Review Board review. Retrospective, local data will be pulled and charts will be reviewed for patients on lithium between June 2015-June 2016. Veterans will be included in the review if they are older than 18 years, receive care at the VASLCHCS or surrounding community based outpatient clinics (CBOCs), and have an active prescription for a lithium product on local VA formulary. Only those who receive their primary mental health care or draw labs outside of the VASLCHCS will be excluded. The following data will be collected and maintained confidentially: age, sex, weight, lithium dose/formulation, date of last lithium serum lab, identification of mental health provider/lithium prescriber, concomitant medications, and the date of the most recent TSH, Scr, CrCl, CBC labs. Based on this local data review, the local rates of lithium serum monitoring will be evaluated and compared to the VA national averages using descriptive statistics. Additionally, patient factors and lab monitoring trends will be evaluated, to identify the patients who may be due for monitoring, and to highlight areas where local processes can be improved.

**Session-Board Number:** 1-370  

**Poster Title:** Effect on prescribing patterns after implementation of a risk assessment tool in patients receiving co-prescribed benzodiazepines and opioids  

**Primary Author:** Jamie Cook, Hampton VA Medical Center, VA; **Email:** jamie.cook@va.gov  

**Additional Author(s):**  
Jennifer Gray  
Jessica Southward  
Natasha Harrigan  
Maninder Singh  

**Purpose:** The 2016 Centers for Disease Control and Prevention Guideline for Prescribing Opioids for Chronic Pain state that co-prescribing of opioids and benzodiazepines should be avoided whenever possible due to increased risk of morbidity and mortality. The purpose of this study is to determine if incorporating a risk assessment tool into provider’s assessment of patients co-prescribed benzodiazepines and opioids affects prescribing patterns. The ultimate goal is to improve patient safety and prevent adverse events.  

**Methods:**  
This is a prospective cohort study involving veterans currently co-prescribed long-term benzodiazepine and opioid therapy. It will be submitted to the Institutional Review Board for approval. All patients co-prescribed long-term benzodiazepine and opioid therapy will be identified using the outpatient pharmacy medication record. Using the patient’s electronic medical record, the following baseline data will be collected: patient age, gender, race/ethnicity, opioid prescribed and dose, benzodiazepine prescribed and dose, diagnosis for opioid and benzodiazepine use, if a naloxone kit has been prescribed, if urine drug testing is utilized, and whether or not the patient has a history of substance abuse. After receiving education on the risk assessment tool through the Veterans Affairs Academic Detailing Service, it will be distributed to the prescriber of the benzodiazepine. Prescribers will incorporate the risk assessment tool into follow-up appointments and document their assessment and plan in the patient’s medical record. After 6 months of tool implementation, data will be collected to determine the effects of the risk assessment tool. Primary outcomes include: change in number...
of patients co-prescribed benzodiazepines and opioids and the change in daily dose of benzodiazepine and/or opioid.

**Conclusion:** N/A
Poster Title: Impact of Pharmacist Administered Discharge Counseling on Veteran Transitions from a Long-Term Care Facility (Project IMPACT)

Primary Author: Allison French, Salem VA Medical Center, VA; Email: frenchak@vcu.edu

Additional Author(s): Rita Spencer

Purpose: Pharmacist interventions at hospital discharge have been associated with a decrease in preventable adverse drug events and hospital readmissions. The benefit of pharmacist involvement in the discharge process from long-term care facilities has not yet been determined. The purpose of this study is to evaluate the effect of pharmacist-led discharge medication counseling on 60-day unplanned hospital readmission rates of Veterans following discharge from a long-term care facility.

Methods: This study is designed as a retrospective matched cohort analysis using electronic chart review. Data will be extracted from the Computerized Patient Records System (CPRS) of patients discharged from a long-term care facility post-rehab/skilled care from 8/1/2013 to 8/1/2014. Data will also be extracted for patients discharged post-rehab/skilled care from 8/1/2015 to 8/1/2016 who received a pharmacist-led discharge medication counseling service. Adults (18 years or older) discharged from either skilled care or rehab treatment specialties will be included in the study. Exclusion criteria include patients with a length of stay greater than 90 days and those discharged to a long-term care facility, hospital, or emergency department. Patients designated as palliative/hospice, respite, or long-stay continuous care will also be excluded. The primary outcome is 60-day unplanned hospital readmission rates. The primary outcome will be determined based on records review and presence or absence of acute admission as a result of emergency department visit without scheduled appointment for admission. Secondary outcomes will include number of medication changes upon discharge and occurrence of successful primary care follow-up following discharge. Successful primary care follow-up includes patients reached by primary care or patients who contacted primary care within the first month of discharge.

**Poster Title:** Impact of a clinical pharmacist in the management of drug-drug interactions in HIV infected veterans

**Primary Author:** Leslie Perry, Salem VA Medical Center, VA; **Email:** lesliemwalters@gmail.com

**Additional Author(s):**
Katherine Jamison

**Purpose:** ASHP released guidelines in April 2016 advocating the involvement of pharmacists in HIV care. This study will evaluate the additional value of a Clinical Pharmacy Specialist (CPS) as part of an interdisciplinay care team in an outpatient Immunodeficiency Clinic at the Salem VA Medical Center (SVAMC) with regard to the treatment of HIV as measured by the change in the number of drug-drug interactions before and after CPS involvement, in addition to changes in viral load, CD4 cell absolute count and percentage, Hemoglobin A1c, low density lipoprotein levels, medication interventions, and number of patients on a one-pill-per-day regimen.

**Methods:** This study has been submitted to the Institutional Review Board for approval. The Clinical Case Registry and Computerized Patient Record System will identify patients seen by any infectious disease provider or trainee at the SVAMC between 1/1/1992 and 11/30/2011 as well as between 1/1/2012 and 10/1/2016, the dates marking introduction of a CPS or pharmacy trainee, precepted by a CPS, as part of standardized HIV care. Data analysis will include medications prescribed, progress notes, vaccination history, labs, and demographics. Patient identifiers will be removed and codes maintained in a password-protected spreadsheet with access limited to study personnel. Drug interactions will be classified by severity using the University of Liverpool’s Drug Interaction Checker (www.hiv-druginteractions.com). Only de-identified information will be put into the online drug interaction checker. CPS interventions that will be analyzed include concomitant medications, including dose changes, administration time changes, medication changes, recommendations, and vaccinations.

**Results:** To be determined

**Conclusion:** To be determined.

**Poster Title:** Use of U-500 Insulin in Veterans with Type 2 Diabetes  
**Primary Author:** Jenna St. Pierre, Salem Veterans Affairs Medical Center, VA; **Email:** jenna.st.pierre@va.gov  
**Additional Author(s):**  
John Minchak  
James Bozard  

**Purpose:** Many patients with type 2 diabetes mellitus (T2DM) require high doses of insulin that may be problematic to administer via traditional insulin formulations. To meet these high dose requirements with traditional insulin preparations requires a large injection volume multiple injections per day or both; this can potentially lead to patient discomfort, decreased adherence, unpredictable insulin absorption and leakage. U-500 insulin is five times more concentrated than traditional insulin and as such may alleviate some of these administration issues. The objective of this study is to evaluate the use of U-500 insulin at our institution for efficacy, safety and cost effectiveness.  

**Methods:** This study will be performed as a retrospective chart review. Data will be pulled from our institution’s data warehouse and electronic medical record system for patients with an active prescription for U-500 insulin over the last 24 months. For inclusion in the study, patients must have at least one A1C documented prior to the initiation of U-500 and at least one additional A1C documented afterwards. Patients with a lack of follow-up after initiation of U-500 and patients with Type 1 Diabetes will be excluded. Baseline characteristics will be gathered on all patients examined by the study in order to create an accurate clinical picture of each patient; this will include patient age, sex, ethnicity, weight, years with T2DM, and lipid profile. The primary outcome of this study is A1C reduction. Secondary outcomes will include change in body weight, change in total insulin dose, number of injections per day, and incidences of hypoglycemia that require emergency medical services. Additionally, we will compare the costs of utilizing U-500 to that of traditional U-100 insulin once data has been collected. Cost analysis will evaluate not only the acquisition cost of the insulin products, but also the costs of associated injection supplies based on the number of injections per day as well as the costs associated with emergency department utilization.

**Poster Title:** Assessing the sustained virologic response at 12 weeks (SVR12) for different treatment durations using sofosbuvir/ledipasvir for chronic hepatitis C in an African American Veteran population  

**Primary Author:** Chelsie Morrison, DC Veterans Affairs Medical Center, WA; **Email:** chelsie.morrison@va.gov  

**Additional Author (s):**  
Ivan Cephas  

**Purpose:** Hepatitis C treatment response is defined by sustained virological response (SVR) frequently indicated by an undetectable HCV RNA 12 weeks after the end of treatment (SVR12). Traditionally, genotype 1 has been harder to treat and the treatment duration efficacy between 8 vs. 12 weeks to achieve SVR12 is often conflicting. Although, African Americans have an increased risk of hepatitis C prevalence they are underrepresented in hepatitis C clinical trials. The aim of this retrospective study is to compare the SVR rate for 8 vs. 12 week use of ledipasvir/sofosbuvir in an African American compared to a non-African American Veteran Population.  

**Methods:** This is a retrospective cohort study, that will be submitted under the Institutional Review Board approved DC VAMC hepatitis C protocol. We will evaluate the outpatient prescription data for sofosbuvir and ledipasvir from the Veterans Health Information Systems and Technology Architecture (VistA). Additional outcomes will be evaluated utilizing Computerized Patient Record System (CPRS). All HCV-positive patients who have been treated with the combination Sofosbuvir and Ledipasvir at the Veteran Affairs Medical Center in Washington DC from November 2013 to July 2016 will be included. The clinical data for each patient will be abstracted and maintained in a password encrypted Excel spreadsheet, no patient identifiers will be used. Upon receipt of the patient information list, patients will be randomized using a list randomizer, then de-identified, and maintained confidentially. Subjects will be divided into two groups African Americans and Non-African Americans, all of which will be taking the combination Sofosbuvir and Ledipasvir, but may have different treatment durations. The following data will be collected: patient age, gender, ethnicity, prescription history for sofosbuvir and ledipasvir, SVR, viral load, substance abuse, use of mental health
provider, and substance abuse recovery program (SARP) enrollment. Refill history of sofosbuvir and ledipasvir will be recorded and analyzed for adherence. The SVR rate will be assessed 12 weeks after treatment for both the 8 and 12 week treatment groups.

**Poster Title:** Pharmacy-led implementation of angiotensin-converting enzyme inhibitor or angiotensin receptor blocker therapy in Veterans at high risk of kidney disease progression identified through a diabetes registry

**Primary Author:** Julia DiNardo, VA Puget Sound Health Care System, WA; **Email:** julia.dinardo@va.gov

**Additional Author(s):**
Katherine Wakefield
Bridget Kaufmann

**Purpose:** This project aims to assess, and implement a process to improve, our institution’s adherence to local and national guidelines regarding the use of angiotensin-converting enzyme inhibitors and angiotensin receptor blockers in patients with diabetes, hypertension, and albuminuria. Secondly, this project will evaluate whether pharmacist intervention is successful at initiating therapy and following outcomes compared to primarily physician-led management of therapy, which is current standard of practice. Results will also be used to determine whether implementation of a renal disease registry would be beneficial to capture a wider scope of patients in need of similar intervention.

**Methods:** Patients will be identified through the Veterans Affairs Diabetes Registry beginning October 2016. Inclusion criteria will entail enrollment in a primary care clinic at our institution, uncontrolled blood pressure of greater than 140/90 mmHg, history of macro/microalbuminuria greater than 30 mg/dL, and no current prescription for an angiotensin-converting enzyme inhibitor or angiotensin receptor blocker within the Veterans Affairs Healthcare system. Patients enrolled in a similar, physician-led investigation at a separate division of our institution will be excluded. After identification, a pharmacist will conduct a chart review to determine clinical appropriateness of initiating an angiotensin-converting enzyme inhibitor or angiotensin receptor blocker based on history and physical data. If a patient is deemed a candidate, he or she will be enrolled in his or her respective Patient Aligned Care Team pharmacist’s clinic for follow-up and management. The pharmacist will order any necessary baseline labs at that time for proper monitoring in order to facilitate patient care. Investigators will measure, as markers of success, number of patients enrolled in a Patient Aligned Care Team pharmacist’s clinic,
number of prescriptions for angiotensin-converting enzyme inhibitors or angiotensin receptor blockers generated, laboratory tests ordered, number of clinic visits, and rate of therapy continuation and discontinuation. Therapy outcomes measured will include change in blood pressure and microalbumin excretion ratios. This project has been submitted to the Institutional Review Board.

Poster Title: Pharmacist led management of immunizations in post-hematopoietic stem cell transplant patients within the VA Puget Sound Health Care System (VAPSHCS)

Primary Author: Czarina Franco, VA Puget Sound Health Care System, WA; Email: cz.franco@gmail.com

Additional Author (s):
Craig O’Brien

Purpose: Hematopoietic stem cell transplantation (HSCT) recipients are at risk of vaccine-preventable diseases secondary to immunosuppression involved in transplantation. To prevent these diseases, immunizations are given at specific time intervals following transplantation. Currently, Marrow Transplant Unit (MTU) pharmacists are not utilizing their designated scope of practice, which grants them the authority to order and administer vaccines as necessary. The purpose of this project is to implement a pharmacist-led process for administering post-HSCT vaccinations at this institution. If this newly developed process leads to a more systematic process and increased protocol adherence, then it may be adopted.

Methods: The primary objective of this project is to develop pharmacist led processes and procedures for the management of immunizations in post-HSCT patients within this institution. This project will be submitted to the Institutional Review Board. The results of this project are intended to be used for quality improvement purposes at this institution only. All protected health information will be kept confidential. This institution utilizes the Seattle Cancer Care Alliance (SCCA) treatment and study protocols and follows their post-HSCT vaccination schema, which is based on the Center for International Blood and Marrow Transplant Research guidelines. An immunization order set that reflects this schema exists within the Computerized Patient Record System (CPRS). Using this order set, MTU pharmacists will perform chart reviews to determine when local HSCT patients are to receive immunizations, and will facilitate the ordering and administration of vaccines. Prior to implementation, specific details will be addressed, including criteria for when to give vaccines, procedures for ordering and administrating vaccines, protocol for checking titers after administration, staff and patient education, and proper documentation. Chart review will be performed prior to initiation to determine patients’ baseline adherence to current vaccination schema, and again after three
months to determine if protocol adherence increases. If successful, the pharmacist led program will be adopted at this institution.

Poster Title: Implementation of an interprofessional polypharmacy consult service for medication deprescribing

Primary Author: Katherine Zimny, VA Puget Sound Health Care System, WA; Email: katherine.zimny2@va.gov

Additional Author (s):
Anne Lee
Cassandra Song

Purpose: The purpose of this project is to introduce an interprofessional polypharmacy consult service to the primary care team, with the goal of deprescribing unnecessary medications, improving medication adherence, and simplifying complex medication regimens in older adults.

Methods: Nurse practitioner residents practicing in primary care will identify patients over the age of sixty-five years who are taking greater than five medications and may benefit from medication deprescribing. Baseline patient characteristics will be collected, including age, gender, comorbidities, and number of medications. The nurse practitioner will refer the identified patients to the pharmacist for polypharmacy review. The pharmacist will perform a chart review and in-depth information gathering through an interview with the patient to identify potentially inappropriate medication use. During the pharmacist interview, patients will be asked about adherence, medication side effects, and perception of their general health. The pharmacist will then compile a written recommendation to the nurse practitioner resident who referred the patient. The type and number of medication intervention recommendations made by the pharmacist will be assessed. Potential pharmacist interventions include deprescribing, dosage changes, and reduction in medication administration times per day. Additional information will be collected, including health care provider workload, class of medications deprescribed, and number of interventions accepted by the provider.

**Poster Title:** Evaluation of phenobarbital as an adjunct to benzodiazepines for the treatment of severe alcohol withdrawal syndrome at a Veterans Affairs Medical Center

**Primary Author:** Heather Hresko, VA Puget Sound Health Care System, WA; **Email:** hhresko@gmail.com

**Additional Author(s):**
Stephanie Long
Brian Gulley

**Purpose:** Alcohol withdrawal syndrome (AWS) involves down-regulation of inhibitory GABA-A receptors and up-regulation of excitatory glutamate receptors in the brain. Benzodiazepines, the mainstay of treatment, suppress withdrawal symptoms by increasing the frequency of chloride channel openings at GABA-A. In contrast, phenobarbital reduces glutaminergic activity and enhances GABA-A effects by prolonging the open-channel state. This dual mechanism theoretically makes phenobarbital an ideal agent for synergistic use with benzodiazepines. Recent literature suggests benefits of phenobarbital for benzodiazepine resistant patients. This evaluation will assess phenobarbital use practices and examine the future role of phenobarbital in AWS at the VA Puget Sound Health Care System.

**Methods:** This study was submitted to the local Institutional Review Board for evaluation. Upon approval, a retrospective chart review of the VA Puget Sound Computerized Patient Record System (CPRS) will be conducted to identify all patients who received oral or intravenous phenobarbital from January 1, 2013 to October 1, 2016. Patients who received phenobarbital for indications other than AWS will be excluded. The following data will be collected: blood alcohol level on admission, phenobarbital prescribing pattern (dose, route, and frequency), benzodiazepine dose pre- and post-phenobarbital administration, Clinical Institute Withdrawal Assessment score, time to AWS resolution, length of hospital stay, use of escalation therapy (lorazepam, propofol, or dexmedetomidine continuous infusions), occurrence of seizures, respiratory depression (respiratory rate less than 12 breaths per minute), hypotension (blood pressure less than 90/60 mmHg), and use of mechanical ventilation. These data will be analyzed to determine the need for a systematic, standardized approach to phenobarbital administration for severe alcohol withdrawal at the VA Puget Sound. Subsequent policy development may
include criteria for phenobarbital use, identification of benzodiazepine-resistant AWS, standardization of phenobarbital dosing based on current literature, and development of an order set for CPRS.

**Poster Title:** Effect of adjunct subcutaneous insulin aspart on hyperglycemic control and variability in post-cardiothoracic surgery patients on an insulin infusion

**Primary Author:** Jenny Luu, VA Puget Sound Health Care System, WA; **Email:** jennybnluu@gmail.com

**Additional Author(s):**
Susan Lee
Anne Baciewicz
Melanie Cohen
Mimi Ho

**Purpose:** In cardiothoracic surgery (CTS) patients, post-operative hyperglycemia and glycemic variability is associated with increased morbidity and mortality. Until now, the Veterans Affairs Puget Sound Health Care System (VAPSHCS), has utilized a consolidated insulin infusion protocol (IIP) to manage all post-operative patients with solely an insulin infusion. Recently, VAPSHCS created an IIP specific to CTS patients which includes subcutaneous insulin aspart meal coverage for patients on an oral diet, in addition to an insulin infusion. This project will evaluate whether this new regimen maintains euglycemia and reduces blood glucose fluctuations in comparison to using an insulin infusion alone.

**Methods:** This study was submitted to the local Institutional Review Board for review. Electronic medical records will be queried for post-cardiac surgery patients who resumed an oral diet and were initiated on an IIP within 48 hours from date of cardiac surgery at the VAPSHC Seattle Division. Two study populations will be investigated. The first population will be selected from a retrospective chart review between January 1, 2016 to September 30, 2016. The second study group will be selected by chart review after implementation of the CTS IIP between October 1, 2016 to April 30, 2017. Patients 18 years of age and older will be included if they had documentation of cardiothoracic surgery and subsequent postoperative hyperglycemia managed by either the consolidated or CTS IIP, and resumed an oral diet within the first 48 hours of surgery. Patients will be excluded if they were less than 18 years of age, did not undergo cardiac surgery, were NPO, or were intubated during the first 48 hours post-surgery. Medical records will be reviewed in order to collect data on demographic, laboratory,
and clinical variables. Clinical variables will include factors that increase risk of hyperglycemia such as weight, body mass index, diabetes history, and other comorbidities. Data prior to and after the implementation of the new CTS IIP will be evaluated and compared to the consolidated IIP.

**Poster Title:** Implementation of a pharmacist led transitions of care program in the VA Puget Sound’s emergency department

**Primary Author:** Rakia Nasir, VA Puget Sound Health Care System, WA; **Email:** rakia1090@gmail.com

**Additional Author(s):**
Jeremy Smart
Bridget Kauffman

**Purpose:** Transitions of care (TOC) services such as medication management and education provided by pharmacists has proven beneficial both in the inpatient and outpatient settings. However, this has not been extensively studied in our emergency department (ED) which has grown in size and volume over the recent years. This study aims to evaluate whether TOC services such as comprehensive medication reconciliation, discharge counseling, 3-day patient follow-up phone calls and referrals to primary care pharmacists are associated with lower 30-day readmission rates, reduction in barriers of access to care for veterans, and increases in primary care pharmacist utilization.

**Methods:** This prospective analysis will evaluate adult patients presenting to the ED from January 1, 2017 to May 1, 2017. The primary objective of this study is to assess whether comprehensive medication reconciliation, discharge counseling, 3-day patient follow-up phone calls and referrals to primary care pharmacists is associated with a lower 30-day readmission rate. All subjects included in the study must be non-pregnant adults who have a preexisting diagnosis of congestive heart failure (CHF), chronic obstructive pulmonary disorder (COPD) or asthma and on a complex medication regimen defined as 6 or more scheduled drugs. All subjects with no prior diagnosis of CHF, COPD or asthma, admitted to inpatient setting, have significant communication barrier or lack of translator will be excluded. After the appropriate subjects are identified and services are provided, documentation will be done by completing a TOC note in the computer system highlighting the pharmacist and patient interaction. The primary care and specialty clinicians and pharmacists will be electronically alerted to the note. Results will be collected and analyzed in Microsoft® Office Excel. The outcome data will be analyzed against the historical 30-day readmission rates. Additionally, the use and intervention
data will be compared to historical data to assess the utility and cost effectiveness of the process.

Poster Title: Retrospective analysis of antimicrobial utilization in patients admitted with a beta-lactam allergy to determine candidacy for penicillin skin testing

Primary Author: Jennesa Sokol, VA Puget Sound Health Care System, WA; Email: jennesasokol@gmail.com

Additional Author (s):
Jonathan Casavant

Purpose: Currently, up to 10 percent of patients have a reported penicillin or beta-lactam allergy. Self-reported allergies are often not immune-mediated reactions and up to 80 percent of patients with true penicillin allergies lose sensitivity after 10 years. Beta-lactam allergies can cause deviations from standard of care treatments. A commercially available penicillin skin test (Pre-Pen) is a safe and effective method used to identify a true penicillin allergy. The objective of this study is to analyze current antimicrobial utilization in this institution’s patients with beta-lactam allergies and to identify candidates for a penicillin skin testing clinic.

Methods: This quality assurance/quality improvement project will be conducted through an electronic medical record chart review. The review will include patients admitted between September 26, 2015 to May 13, 2016 with a listed beta-lactam allergy that received either a fluoroquinolone or vancomycin. Selection of fluoroquinolone and vancomycin use was chosen to concentrate the data on the more frequently prescribed beta-lactam alternatives. The following data will be collected: medication allergy listed, type of reaction, number of hospital admissions with antibiotics administered, antibiotics used, prior beta-lactam use, type of infection treated, culture and sensitivity of isolated organism if available, comorbidities and 30 day readmission/reinfection rate. The results of this study will determine the potential benefit and identify patients for a pharmacist managed penicillin skin testing clinic. A penicillin skin testing clinic could reduce the use of costly and potentially clinically inappropriate antibiotics, and aid in achieving this institution’s antimicrobial stewardship goals.

**Session-Board Number:** 1-382  

**Poster Title:** Panel management to identify veterans who will benefit from opioid overdose education and naloxone distribution by pharmacists in the primary care clinic  

**Primary Author:** Cassandra Song, VA Puget Sound Health Care System, WA; **Email:** cassandra.song@va.gov  

**Additional Author (s):**  
Christopher Hoey  

**Purpose:** Veterans are twice as likely to die from accidental opioid overdose compared to the non-veteran population. Though naloxone is readily available at VA Puget Sound Health Care System, a large number of high risk veterans have not yet received naloxone kits or naloxone education. The purpose of this project is to utilize panel management in a targeted approach to identify veterans who will benefit from a naloxone kit and education. This study will determine the effectiveness of this pharmacist led initiative to disseminate naloxone kits and education, as well as evaluate veteran specific perceptions about opioid reversal.  

**Methods:** Pharmacists, pharmacy residents, and participating primary care providers will conduct panel management in order to identify veterans at high risk for opioid overdose. Through this targeted approach, the pharmacist and primary care provider will identify veterans on greater than fifty morphine equivalent daily dose (MEDD), on concomitant opioid and benzodiazepine therapy, or classified as a Risk Index for Overdose or Serious Opioid-Induced Respiratory Depression (RIOSORD) risk class of greater than eight. Veteran information including demographics, medication information, history of mental health disorders, history of emergency room visits, and comorbidities will be collected through chart review of the electronic health record system. Identified veterans will then be contacted by a pharmacist who will schedule agreeable veterans to an in-clinic visit for comprehensive naloxone and opioid overdose education as well as naloxone dispensing. After the clinic visit, the veteran will be asked to fill out a questionnaire regarding their perceptions about opioid reversal after receiving education. The primary outcome of this study is the number of veterans reached, educated, and dispensed naloxone as a result of this pharmacist led initiative. Additionally, the responses of patient questionnaires will be evaluated to determine the ability of the pharmacist to effectively educate veterans and disseminate unbiased information about naloxone.

**Poster Title:** Implementation of antifactor-Xa (anti-Xa) monitoring for weight based heparin protocols

**Primary Author:** Adam McCarthy, Clement J Zablocki VA Medical Center, WI; **Email:** adam.mccarthy@va.gov

**Additional Author(s):**
Carrie Lewandowski
Jennifer Koch
William Blaser

**Purpose:** American College of Chest Physicians recommends activated partial thromboplastin time (aPTT) or anti-Xa level for monitoring unfractionated heparin (UFH). Data suggests aPTT monitoring varies depending on reagent used and patient-specific factors, thus making anti-Xa level monitoring more advantageous in certain patients. Compared to anti-Xa monitoring, aPTT monitoring takes longer to reach therapeutic range, requires more lab draws, and results in less time in therapeutic range. The objective is to identify patients who may benefit from for anti-Xa level monitoring, and develop an anti-Xa monitoring protocol.

**Methods:** This is a single-center, retrospective chart review and quality improvement project that is exempt from the Institutional Review Board. Patients treated with high-intensity heparin protocol between August 31st, 2014 to August 31st, 2016 will be randomly selected until at least one hundred patients are identified. Using an electronic medical record the following data will be collected: weight, age, baseline aPTT, number of aPTT draws before reaching a therapeutic aPTT, baseline platelet count, baseline INR, indication for heparin and therapeutic heparin infusion rate. Outcomes: Data will be analyzed for the percentage of patients with a baseline aPTT greater than 40 seconds, percentage of patients that required three or more aPTT draws to reach a therapeutic aPTT and percentage of patients that require a heparin dose of 25 units/kg/hr or greater.

**Results:** N/A

Session-Board Number: 1-384

Poster Title: Implementation of a pharmacy service for assessing and managing patients on concomitant opioids and benzodiazepines

Primary Author: Erin McAllister, Clement J. Zablocki VA, WI; Email: erin.e.mcallister@gmail.com

Additional Author(s):

Purpose: In August 2016, the FDA added a black box warning to the prescription labeling of both opioid and benzodiazepine medications, advising against the use of these medications in combination due to increased risk for additive adverse effects, accidents, falls, and cumulative respiratory depression that may result in unintentional overdose or death. The purpose of this project is to reduce the number of patients prescribed concomitant opioid and benzodiazepine therapy by implementing a pharmacy service to assist primary care providers with the assessment and management of patients on this regimen.

Methods: Baseline data will be collected for patients taking concomitant opioids and benzodiazepines who are seen in one of the primary care clinics at the Clement J. Zablocki VA Medical Center in Milwaukee, WI. Patients who are taking opioids for palliative care and cancer-related pain will be excluded from this study. The pharmacist will review the patient’s medical record and the state prescription drug monitoring program and document relevant findings. Documentation will include prescribers, indications, daily doses, date and results of most recent urine drug screens, and patient-specific contraindications for both opioids and benzodiazepines. Recommendations will be made in the electronic health record regarding opioid and/or benzodiazepine taper plans per guidelines, alternative therapies for analgesia, anxiety, or insomnia, prescriptions for naloxone kits, and urine drug screens.

Data will be analyzed before and after pharmacist intervention. The primary outcome is the reduction in the number of patients who are prescribed concomitant opioid and benzodiazepine therapy. Additional measures include the percent of patients with a prescription for a naloxone kit, the percent of patients with a urine drug screen in the past year, the average daily doses of benzodiazepines and opioids, and the number of patients with relative or absolute contraindications to benzodiazepines or opioid medications.
Results: N/A

**Poster Title:** Dose-dependent differences in safety and efficacy of quetiapine for improvement of intensive care unit (ICU) delirium

**Primary Author:** Anna Jozefiak, Clement J. Zablocki VA Medical Center, WI; **Email:** anna.jozefiak2@va.gov

**Additional Author (s):**
- Mary Ellis
- Carrie Lewandowski
- Andreea Anton
- William Blaser

**Purpose:** Delirium in ICU patients is associated with poor outcomes. Current guidelines for the management of pain, agitation, and delirium emphasize limited evidence for the use of atypical antipsychotics in these patients. Despite lack of evidence, use of quetiapine for treatment of delirium has become a common practice. The goals are to assess current trends of quetiapine utilization for the treatment of ICU delirium, including dosing, efficacy, and length of stay and to provide a quetiapine dosing recommendation in order to standardize prescribing practices for ICU delirium.

**Methods:** A retrospective analysis of quetiapine use for ICU delirium will be performed. Utilizing data from July 1, 2014 to June 30, 2016, patients who were prescribed at least one dose of quetiapine for delirium will be included in the analysis. Exclusion criteria include patients with an active outpatient quetiapine prescription at the time of admission. Confusion Assessment Method for the ICU (CAM-ICU) scores will be assessed to confirm the diagnosis of delirium. The length of time from delirium diagnosis to first dose of quetiapine (less than or greater than 24 hours) and appropriate discontinuation will be recorded to assess current prescribing practices of quetiapine. The efficacy of quetiapine dosing will be determined by analyzing the time to resolution (in days) of delirium based on improvement of CAM-ICU scores. The safety will be assessed by recording QTc (if available) and reviewing the chart for possible adverse effects. Quetiapine dosing will be measured as a total daily dose divided into three groups: less than or equal to 25mg, 26 to 50mg, or greater than 50mg. Using this data, a
quetiapine dosing recommendation will be made to assist ICU providers with safe and effective prescribing practices in the event of ICU delirium.

**Poster Title:** Evaluation of prescribing direct oral anticoagulants (DOACs) in the setting of new onset venous thromboembolism (VTE): Increasing provider education and use of direct oral anticoagulants

**Primary Author:** Erin Kohl, Clement J. Zablocki Veteran Affairs Medical Center, WI; Email: Erin.kohl@va.gov

**Additional Author (s):**
Amy Van Ermen
Angela Green
Daisy Peterson
April Rogers

**Purpose:** New onset venous thromboembolism (VTE) treated with warfarin for at least three months requires a significant amount of time and resources for both inpatient and outpatient management. Inpatient length of stay, bridging requirements, frequent outpatient lab draws and follow-up appointments all affect patient and provider satisfaction. A 2016 update to the CHEST guidelines suggests direct oral anticoagulants (DOACs) over warfarin for treatment of VTE for non-cancer patients based on similar efficacy, less bleeding, and greater convenience for patients and health care providers. Utilizing DOACs instead of warfarin may reduce burden on providers, pharmacists, and patients.

**Methods:** A retrospective chart review will be conducted to determine the percentage of patients with new onset VTE who qualified for a DOAC that were actually treated with a DOAC (versus warfarin and/or low molecular weight heparin). Patients deemed appropriate for a DOAC include those who do not have any the following: a documented adverse drug reaction to the DOAC in consideration, active cancer, history of non-compliance, concurrent indication for mechanical valve replacement, estimated creatinine clearance less than 30ml/min or on dialysis. This project will include all patients in 2015 that were evaluated in the emergency department or admitted to the medicine floor with a diagnosis of new deep vein thrombosis and/or pulmonary embolism; outcomes during their first three months of anticoagulation will be reviewed. The project will implement a “DOAC friendly” decision tree for VTE treatment on the medical center’s computerized order set to help guide providers in the appropriate choice.
of anticoagulant. Additionally, education will be provided to prescribing providers and pharmacists on the clinical significance and logistics of the decision tree. The primary outcome is to determine the percentage of appropriate DOACs prescribed for new onset VTE. Secondary outcomes include hospital length of stay, length of bridging, number of outpatient lab draws, length of time of follow-up appointments with the pharmacist, and medication cost.

**Session-Board Number:** 1-387  

**Poster Title:** Appropriateness and improvement of pharmacologic venous thromboembolism prophylaxis in medically-ill hospitalized veteran patients  

**Primary Author:** Heather Powell, Clement J. Zablocki Veterans Affairs Medical Center, WI;  
**Email:** heather.powell3@va.gov  

**Additional Author (s):**  
Jennifer Koch  

**Purpose:** The Clement J. Zablocki Veterans Affairs Medical Center currently does not require providers to assess venous thromboembolism (VTE) risk using a risk assessment model (RAM) when medically-ill patients are admitted to the inpatient hospital, although external links to such tools are available. The objective of this project is to assess the appropriateness of current pharmacologic VTE prophylaxis prescribing and improve utilization of best-practice VTE RAMs in medically-ill hospitalized patients admitted to the general medicine and hospitalist services through anticoagulation order set improvement.  

**Methods:** This quality assurance project will utilize an electronic medical record to identify inpatient medically-ill veterans admitted to the general medicine and hospitalist services between September 1 and September 30, 2016 for an initial assessment of appropriate pharmacologic VTE prophylaxis prescribing practices and December 1 through December 31, 2016 for appropriateness assessment following implementation of an updated anticoagulation order set. Appropriateness of pharmacologic VTE prophylaxis prescribing practices will be assessed using the Padua Prediction score with inappropriate prescribing categorized into one of two categories: 1) Does not meet risk criteria to qualify for VTE prophylaxis or has contraindication to anticoagulation although prophylaxis is prescribed; or 2) Meets risk criteria to qualify for VTE prophylaxis although prophylaxis is not currently prescribed. The updated anticoagulation order set will require calculation of a Padua Prediction score greater than or equal to 4 (high risk) prior to allowing the physician to proceed to the pharmacologic VTE prophylaxis ordering menu. The investigators will analyze data for a difference in appropriate pharmacologic VTE prescribing practices between the two review periods.

Session-Board Number: 1-388

Poster Title: Implementation of an extended-infusion beta-lactam automatic interchange procedure and evaluation of related clinical outcomes

Primary Author: Jeremiah Barnes, Clement J. Zablocki Veterans Affairs Medical Center, WI; Email: jeremiah.barnes@va.gov

Additional Author(s):
Claire Dysart

Purpose: Current literature supports the use of extended-infusion beta-lactam antibiotics over short-infusion. The amount of time which the free drug concentration exceeds the minimum inhibitory concentration (MIC) of the pathogen is the best predictor of bactericidal activity for beta-lactams. This pharmacokinetic principle is supported by patient outcomes data from large clinical trials demonstrating improvements in mortality, survival, length of stay, and treatment success favoring extended-infusions over intermittent dosing. The purpose of this project is to implement an extended-infusion beta-lactam ordering menu and automatic interchange procedure, provide administration guidelines at a medical center level, and assess the potential impact on patient outcomes.

Methods: This study is a retrospective, electronic chart review comparing efficacy outcomes of extended-infusion and short-infusion beta-lactams from July 1, 2016 to January 1, 2017. The primary efficacy outcomes analyzed in this study are intensive care unit (ICU) and total hospital length of stay. Secondary outcomes include: time to de-escalation of antibiotics, treatment success rate, medication error rate, and cost of antibiotic therapy. Provider documentation in electronic health records, available microbiological cultures, electronic reports of patient’s time to floor transfer or discharge, data from error reporting software, and real time medical center cost data will be collected for the evaluation of these primary and secondary outcomes. This project will assess the implementation of the following antibiotics as extended infusions: piperacillin/tazobactam, cefepime, and meropenem.

Poster Title: Assessment and removal of inappropriately documented penicillin allergies at a Veterans Affairs medical center

Primary Author: Clayton Patros, Clement J. Zablocki Veterans Affairs Medical Center, WI; Email: clayton.patros@va.gov

Additional Author (s):
Claire Dysart
Asriani Chiu Chiu
Sheran Mahatme

Purpose: Beta-lactam antibiotics are commonly associated with immediate hypersensitivity reactions. On average, 10 percent of the general population have a reported history of a penicillin allergy, yet only 10 percent of those individuals are estimated to be truly allergic. Assessing these patients’ allergies is critical, especially for those with serious infections for which beta-lactams are the treatment of choice. For these patients, a detailed medication and allergy history may lead to the decision of a graded- or full-dose challenge or an allergist consult as a means to remove inappropriately documented allergies and safely administer beta-lactams in the future.

Methods: Patients with documented allergic reactions to penicillins will be screened through a pharmacist chart review and will be contacted to set up a phone or in person medication and allergy history. An algorithm will be created for patients with documented penicillin allergies in order to assess the appropriate next steps of management based on patient information. A note template will also be created within the electronic medical record in order to document pertinent medical and allergy information obtained from the initial chart review and interview and will then provide recommendations based on the algorithm and patient information. This note will be alerted to the primary provider, who will have the option to order a graded- or full-dose challenge of a beta-lactam, order an allergist consult, or perform no further action if the allergy is deemed to be appropriately documented. The primary outcome will be the number of patients that are able to safely receive beta-lactams after the above screening process and the total number of patients assessed. Secondary outcomes will include the number and type of infections for which alternatives to beta-lactams are used due to a documented allergy, number
and type of antibiotics used as alternatives to beta-lactams due to a documented allergy, and any adverse reactions from dose challenges.

Submission Type: Research-in-Progress

Session-Board Number: 1-390

Poster Title: Direct oral anticoagulant (DOAC) adherence and the risk of stroke among patients with atrial fibrillation

Primary Author: Jisha Jacob, Milo C. Huempfner VA Clinic, WI; Email: jisha.jacob@va.gov

Additional Author(s):
Frederick Dunkerson
Shannon Pace

Purpose: Unlike warfarin, direct oral anticoagulants (DOACs) have fewer drug-drug and drug-food interactions and do not require frequent laboratory monitoring. However, given the short half-lives of direct oral anticoagulants (DOACs), a high degree of medication adherence is crucial for reducing the risk of thrombotic events in patients with atrial fibrillation. The lack of need for frequent monitoring and close follow-ups may limit opportunities for early detection of medication non-adherence. The objectives of this retrospective analysis are to characterize adherence patterns of DOACs among patients with atrial fibrillation and analyze their association with long-term patient outcomes.

Methods: This will be a retrospective analysis of patients with atrial fibrillation who were initiated on dabigatran, rivaroxaban, or apixaban within the last 3 years. Given the retrospective nature of this analysis, it will be exempt from institutional review board approval. Patient records will be obtained from the Veterans Affairs Corporate Data Warehouse (VA CDW). Data collected and analyzed will include patient demographics, CHADS2 score, HAS-BLED score, and Charlson-Deyo comorbidity index. Measure of adherence will be determined by calculating ‘Proportion of Days Covered’ (PDC) based on fill dates and days supply. Additional calculations include gaps in therapy based on days not covered by anticoagulation therapy due to non-adherence. Primary end points of this study include stroke and all-cause mortality with a secondary end point of bleeding events. Comparisons between adherent and non-adherent groups will be assessed using chi-square test for categorical variables and independent samples t-test for continuous variables with normal distribution. Kaplan-Meier analysis will be used to determine the association between DOAC non-adherence and endpoints. Findings of this study will be used to identify patients who have PDC < 80% and alert providers for closer follow-up and intensive counseling about the risks associated with DOAC non-adherence.

**Session-Board Number:** 1-391  

**Poster Title:** Implementing a work-flow redesign at a VA Medical Center for Patient Aligned Care Team PharmD services in order to increase access to care.  

**Primary Author:** Monica Somerfelt, The Clement J. Zablocki VA Medical Center, WI; **Email:** monica.somerfelt@va.gov  

**Additional Author (s):**  
Angela Green  
Mike Grunske  
Michael Schmidt  
Casie Walsh  

**Purpose:** In 2015, the Madison VA Hospital streamlined their primary care services to better utilize all healthcare professionals within the PACT (Patient Aligned Care Team) model. Their initiative transitioned 27% of all primary care appointments away from primary care providers. This resulted in 850 new provider appointments per quarter at the Madison VA. The purpose of this project is to help redesign work-flow for PharmDs at a different VA Medical Center to increase PharmD disease state management and achieve increased access to both PharmD and primary care provider appointments for veterans.  

**Methods:** This project will work towards work-flow redesign of current PACT PharmD services to allow for increased access to care. The success of the work-flow redesign will be evaluated by measuring the number of appointments PharmDs provide that reduce workload for primary care providers (PCPs). The number of additional appointments PCPs can take on per quarter as a result of increased PACT PharmD access will also be evaluated. Pre and post surveys will be utilized to determine patient, PharmD and other PACT members’ satisfaction with the work-flow redesign.  

**Results:** Data collection is currently in progress.  

**Conclusion:** Final results and conclusions will be presented at the Great Lakes Pharmacy Residency Conference.
**Submission Category:** Ambulatory Care

**Session-Board Number:** 1-392  
**Poster Title:** Assessing anticholinergic burden and medication interventions based on tele-neuropsychological assessments in a rural geriatric Veteran population  
**Primary Author:** Daniel Langenburg, William S. Middleton Memorial Veterans Hospital, WI;  
**Email:** daniel.langenburg@va.gov  
**Additional Author(s):**  
Lauren Welch  
Christopher Nicholas  

**Purpose:** The Geriatrics Research Education and Clinical Center (GRECC)-Connect Program offers care and recommendations through telehealth consults to patients residing in rural areas with limited geriatric specialty services. A neuropsychologist was added to this interdisciplinary service to address the mental and cognitive concerns of these patients. Administration of a full battery of neuropsychological tests is a key component of the service, however assessment of anticholinergic risk and medication intervention recommendations as they relate to these tests has not been evaluated. The purpose of this study is to determine the correlation between neuropsychological assessment results and anticholinergic burden in this patient population.

**Methods:** A retrospective chart review was completed for all patients referred to the GRECC-Connect service for tele-neuropsychological testing between March 2014 and January 2016. Standard baseline data were collected, including patient age, gender, race, marital status, highest level of education, service connection, time period of service, and total number of medications. The primary objective of this study was to correlate the patient’s Anticholinergic Risk Scale (ARS) scores with their neuropsychological assessment results. These tests assess memory, executive functioning, verbal ability, attention, visuospatial functioning, and depression severity. Secondary objectives included evaluating medication interventions recommended by the interdisciplinary team following neuropsychological testing. Medications assessed included anticholinergics, dementia medications, and antidepressants.

**Results:** Forty-five patient met the criteria to be included in analysis. The average age of those included was 76.6 years and 48.8% were taking ≥1 anticholinergic medication. Significant positive correlations were detected between ARS scores and four specific subset scores of the
RBANS test and MMSE scores. No significant negative correlations were observed. 14 recommendations were made regarding anticholinergic medications, 8 regarding antidepressants, and 20 regarding memory medications.

**Conclusion:** No significant negative correlation was observed between neuropsychological assessments results and ARS scores. Significant positive correlations seen were likely due to the large age distribution skewing test results. Medication recommendations made by the interdisciplinary team appropriately matched neuropsychological assessments and subsequent dementia diagnoses.

**Poster Title:** Evaluation of pharmacy-led inpatient tobacco treatment intervention

**Primary Author:** Rebecca Wenzel, William S. Middleton Memorial Veterans Hospital, WI; **Email:** rebeccarwenzel@gmail.com

**Additional Author(s):**
Megan Heim

**Purpose:** Purpose: A pharmacy-led inpatient tobacco treatment service was implemented in an effort to improve tobacco treatment in the hospital setting while adhering to the Joint Commission measures, which include tobacco use screening, treatment, outpatient referral, and post-discharge assessment. The purpose of this retrospective chart review was to evaluate clinical outcomes after implementation of this pharmacy-led inpatient tobacco treatment service. The service includes pharmacy technicians and students completing tobacco use screenings during hospital admission and providing counseling and referral to outpatient tobacco treatment clinic for patients interested in tobacco cessation. Inpatient pharmacists then order tobacco treatment medications.

**Methods:** Methods: A retrospective chart review was performed for 301 patients who screened positive for tobacco use during hospital admission starting November 4, 2015 through February 4, 2016. The primary outcome includes tobacco quit rates one month post-intervention. Secondary outcomes include proportion of patients accepting tobacco treatment medication, counseling, and/or outpatient tobacco treatment clinic referral. Additional data collected includes tobacco treatment medication type, prescriber, and presence of order at discharge. Data collected for tobacco treatment outpatient referral will include the type of referral, type of provider ordering the referral, and status of tobacco treatment clinic consult post-discharge. Descriptive statistics were used to analyze baseline characteristics. Paired categorical variables were analyzed using McNemar test.

**Results:** Results: Of the approximately 1284 patients screened for tobacco, 25% were tobacco users. The one-month quit rate was 31% (n=51). The proportion of patients accepting medication, counseling, and/or outpatient tobacco treatment clinic referral were 41%, 42%, and 19%, respectively (n=301).
**Conclusion:** Conclusion: Hospitalization represents a unique time for tobacco intervention. Pharmacy-led tobacco treatment service is an effective mechanism for tobacco intervention. The tobacco quit rate was found to be similar to the national average, and there was a high acceptance of tobacco intervention during hospitalization.

**Poster Title:** Pharmacist adherence to an extended interval of International Normalized Ratio (INR) follow-up protocol at twelve months

**Primary Author:** Michael Nagy, William S. Middleton VA Medical Center, WI; **Email:** nagyx025@gmail.com

**Additional Author (s):**
Rebecca Schoen
Amanda Margolis
Andrea Porter

**Purpose:** The 2012 American College of Chest Physician guidelines suggests an INR monitoring interval of up to twelve weeks in patients on stable doses of warfarin. The William S. Middleton Memorial Veterans Hospital implemented a research protocol to determine the feasibility and safety of extending the INR follow-up interval to twelve weeks in patients with long-term stability on warfarin. The protocol includes a progressively extended follow-up time frame, addresses procedures for adverse events, and covers necessary regulatory procedures. A previous quality assurance evaluation documented high fidelity to the protocol after six months. This evaluation aims to confirm continued high pharmacist fidelity.

**Methods:** A retrospective chart review was conducted to audit pharmacist adherence to the study protocol from months six to twelve following enrollment for all enrolled participants. Key factors evaluating pharmacist adherence to the protocol procedures include: (1) correctly planned follow-up duration for participants while on the extended interval follow-up protocol, (2) participant follow-ups with shorter than indicated durations, (3) participant follow ups with longer than indicated durations, (4) participants correctly removed or restarted on the extended interval follow-up protocol, (5) pharmacists correctly notifying study staff to a bleeding event, thromboembolic event, or serious adverse events, (6) pharmacists obtaining thorough assessment from participants at each visit. These outcomes will be assessed using descriptive statistics to determine the percentage of time each of the above events occurred. The study was approved by the University of Wisconsin-Madison Health Sciences Institutional Review Board and the Veteran Affairs Research and Development committee.

**Primary Author:** Jinhee Park, William S. Middleton VA Medical Center, WI; **Email:** jinhee.park.29@gmail.com

**Additional Author (s):**
Berook Addisu
Megan Heim

**Purpose:** The purpose of this process implementation was to encourage tobacco treatment in patients admitted to the hospital while ensuring adherence to Joint Commission measures.

**Methods:** Process change was implemented in November 2015. The primary outcome of the study was to review adherence to three Joint Commission measures: percentage of patients admitted that are screened for tobacco use, percentage of patients offered counseling and U.S. Food and Drug Administration (FDA) approved tobacco cessation medications, and percentage of patients who accepted counseling and received FDA approved tobacco cessation medications. Secondary outcomes included a pharmacy technician motivational interviewing time study, comparison of motivational interviewing outcomes for pharmacy technicians versus pharmacists, and employee perception.

**Results:** October 2015 data collected by the Joint Commission Third Party was used as baseline prior to process implementation. The tobacco screening measure post implementation remained unchanged at one and three months (p=1.0) as it was one measure our facility had been meeting at baseline. At one month post process implementation in November 2015, 33% of patients who screened positive for tobacco use and were evaluated by the third party were offered counseling and medications, and was not significantly different compared to baseline(p=0.23). 17% of patients evaluated accepted tobacco counseling and treatment in November 2015, not significantly different from baseline (p=0.32). At four months, 100% of patients were offered counseling and treatment (p < 0.01) and 50% of these patients accepted counseling and treatment (p < 0.05), both significantly different from baseline.
Conclusion: There was a significant increase in adherence to Joint Commission measures at most recent assessment in January 2016.

Poster Title: Evaluation of hepatitis C cure on patients at the Huntington, West Virginia Veterans Affairs Medical Center

Primary Author: Leah Michael, Huntington Veterans Affairs Medical Center, WV; Email: leah.michael3@va.gov

Additional Author(s):
Kaitlin Harrison
Jerrica Parsley
Ashley Dodson

Purpose: The recent development of direct-acting antiviral agents have tremendously changed hepatitis C virus treatment. Direct-acting antivirals have made a substantial impact on clinical cure rates. The purpose of this study is to evaluate the impact of sustained virologic response following treatment with direct-acting antivirals on extrahepatic manifestations of hepatitis C such as, blood pressure, total cholesterol, low-density lipoprotein, aspartate aminotransferase, alanine aminotransferase, glycosylated hemoglobin, international normalized ratio, platelets, mortality, medication changes, and reported adverse drug events.

Methods: A retrospective chart review will be conducted on patients who have obtained clinical hepatitis C cure evaluating the impact of sustained virologic response on extrahepatic manifestations (listed above) and adverse drug reactions during Hepatitis C treatment. Results and conclusions pending and will be presented at ASHP Midyear Clinical Meeting.

Results: Results and conclusions pending and will be presented at ASHP Midyear Clinical Meeting.

Conclusion: Results and conclusions pending and will be presented at ASHP Midyear Clinical Meeting.

Poster Title: Drug use evaluation of proton pump inhibitor prescribing in the elderly at a Veterans Affairs Medical Center

Primary Author: Aleta Smithbauer, Louis A Johnson Veterans Affairs Medical Center, WV; Email: aleta.smithbauer@va.gov

Additional Author (s):
Nathan Stemple

Purpose: The American Geriatric Society 2015 Updated Beers Criteria recommends avoiding the use of proton pump inhibitors for greater than eight weeks due to an increased risk of Clostridium difficile infection, bone loss, and fractures. Indications for long-term use include high-risk patients such as those taking corticosteroids or non-steroidal anti-inflammatory drugs, patients with erosive esophagitis, Barrett’s esophagitis, pathological hypersecretory conditions, or those who have demonstrated a need for continued therapy such as discontinuation failure or histamine-2 blocker failure. The purpose of this project is to evaluate the appropriateness of proton pump inhibitor prescribing in a sample of elderly Veterans Affairs patients.

Methods: A retrospective chart review study has been submitted and approved by the Institutional Review Board and the local Research and Development Committee. The computerized patient record system will be used to identify patients 65 years or older who were prescribed omeprazole or pantoprazole for at least a 60 day supply between the dates of March 1, 2016 and May 31, 2016. Patients will be randomly selected for inclusion in the study up to a maximum sample size of 150 patients. Data collected will include age, medication, duration of therapy, and indication for use. Each proton pump inhibitor prescription will then be assessed for appropriate prescribing based on the American Geriatric Society 2015 Updated Beers criteria recommendations. Data will be reported without patient identifiers in order to maintain confidentiality. Collected data will be analyzed and reported as total number or percentage and compared for patterns and trends. Data analysis will allow determination of appropriate or inappropriate prescribing of omeprazole and pantoprazole among geriatric patients.

Poster Title: Integration of direct oral anticoagulant monitoring into an established pharmacist-managed anticoagulation clinic at the Louis A. Johnson Veterans Affairs Medical Center

Primary Author: Sara Stover, Louis A. Johnson VA Medical Center, WV; Email: sdstover@mix.wvu.edu

Additional Author(s):
Melissa Murray

Purpose: Direct Oral Anticoagulants (DOACs) (dabigatran, rivaroxaban, apixaban, and edoxaban) are listed on the national formulary and are increasingly being prescribed instead of warfarin. Evidence for the optimal management and follow-up of patients receiving DOACs is currently lacking. The VA Pharmacy Benefit Management Services recommends follow-up monitoring of renal function and complete blood count with platelets annually or more frequently in patients with increased bleeding risk, renal impairment, or those 75 years or older. The purpose of this project is to create a systematic process for ongoing monitoring of patients receiving DOACs to ensure their safe use and appropriate prescribing.

Methods: This quality improvement project has been declared not human subject research by the Institutional Review Board and approved by the local Research and Development Committee. Based on monitoring practices at other VA anticoagulation clinics, patients will be scheduled into the pharmacy anticoagulation clinic at six month intervals for monitoring of renal function and complete blood count with platelets, as well as assessment of adherence and any anticoagulation related complications. Patients with significant renal dysfunction will be scheduled more often, as clinically appropriate. To improve adherence with monitoring requirements, prescriptions for DOACs will be limited to a 90-day supply with one refill, as this practice has been effective in ensuring follow-up for patients on warfarin therapy. A policy will be developed outlining clinic and patient responsibilities and will be incorporated into the clinic’s existing standard of practice. The medical center memorandum (MCM) 119-32, which includes policies and responsibilities of the facility’s anticoagulation management program, will be revised to include DOAC monitoring. The revised MCM will also address management of patients who require discontinuation of DOAC therapy due to renal function decline; primary care will be responsible for determining if anticoagulation should be discontinued or if the
patient is a suitable candidate for warfarin. A letter will be created to notify all patients receiving DOAC therapy of the change in monitoring requirements.

Poster Title: Impact of ICU settings and environment factors on delirium within a Veterans Affairs Medical Center

Primary Author: Jalyn Robinson, Martinsburg VA Medical Center, WV; Email: jrobinso4@su.edu

Additional Author(s):
Trisha Exline

Purpose: Delirium is a debilitating syndrome for patients, families, and healthcare providers among acute care settings. The influence on delirium incidence is multifactorial with the acknowledgement that the environment for care impacts development and outcomes. However, the extent of this environmental impact among intensive care unit (ICU) patients has not been fully recognized. The purpose of this study is to assess the incidences of delirium within differing ICU settings by taking advantage of a unique occurrence within a Veterans Affairs Medical Center in which the ICU was renovated and changed locations for a period of time.

Methods: This study is pending approval from the Institutional Review Board and Office of Research and Development. Three distinct ICU settings—pre-renovation fourth floor ICU, temporary second floor ICU, and post-renovation fourth floor ICU—will be assessed for delirium incidence among patients during the pre-specified time periods from November 2015 through March 2016. Patients admitted to one of the ICU settings for at least 24 hours will be included if exclusion criteria is not met (unresponsiveness throughout admission; diagnosis of alcohol/substance withdrawal; pre-existing history of dementia, cognitive impairment, Alzheimer’s disease, or traumatic brain injury; delirium, altered mental status, altered cognition, or confusion at admission). Primary endpoint of delirium incidence will be determined through fulfillment of at least one of three criteria via electronic medical record assessment: (1) subjective/objective documentation meeting DSM-5 delirium diagnostic criteria, (2) positive CAM-ICU documentation, (3) documented administration of “as-needed” typical/atypical antipsychotics. Secondary endpoints will include the time to delirium onset, cumulative delirium duration, and mortality during ICU admission. Confounding variables also to be assessed will include: age; gender; benzodiazepine, opioid, diphenhydramine, zolpidem, or eszopiclone administration during ICU admission; intubation at any point during ICU
admission; ICU length of stay; illness severity at ICU admission assessed by APACHE II score; and co-morbidities assessed by CCI score.

**Poster Title:** Impact of secure messaging on glycemic control in patients with uncontrolled diabetes

**Primary Author:** Jason Abraham, Veterans Affairs Medical Center, Martinsburg, WV; **Email:** abrahamjason92@gmail.com

**Additional Author(s):**
Adam Gold

**Purpose:** There is a high incidence of diabetes among the Veteran population. It requires continuous care and support. However, there are obstacles to patients’ care including lack of transportation, inconvenient appointment times, and lengthy waiting room times. Secure messaging attempts to resolve these issues by facilitating remote communication between the provider and the patient through an encrypted channel to monitor blood glucose levels and manage medications. The purpose of this study is to discern the effectiveness of utilizing secure messaging in reducing HbA1C values, compare HbA1C reduction between different pharmacotherapy regimens, and analyze potential risks associated with secure messaging.

**Methods:** This is a single-center, retrospective, chart review of the electronic medical records of patients seen by a Clinical Pharmacy Specialist in an outpatient clinic, which is currently pending Institutional Review Board and Research and Development Committee approval. The charts of approximately 150 veterans diagnosed with diabetes and seen by the provider via secure messaging or clinical visits will be reviewed over a one year time period between November 2015 and October 2016. The case group consists of patients who had at least two secure messaging interactions with the provider, while the control group has patients with less than two interactions. Patients in the case group and the control group have a baseline measure prior to the intervention and two HbA1C values collected or estimated using ancillary blood glucose values within six and twelve months after the intervention for comparison. Patients’ pharmacotherapy regimens will be collected in both groups to analyze differences in HbA1C reduction across patients who use insulin versus those who only use oral medications. Acute hypoglycemic, hyperglycemic, and diabetic ketoacidosis incidences that led to emergency room visits and inpatient admissions between November 2015 and October 2016 will also be collected and recorded for all patients.

Poster Title: Retrospective analysis of treatment outcomes in patients with comorbid attention deficit hyperactivity disorder (ADHD) and bipolar disorder at a Veterans Affairs mental health clinic

Primary Author: Shawn Kohlhaas, Veterans Affairs Medical Center, Martinsburg, WV; Email: shawn.kohlhaas@va.gov

Additional Author(s):

Purpose: Bipolar disorder proves to be one of the more difficult psychiatric disorders to manage for the US healthcare system and poses one of the biggest clinical risk factors for suicidality in front of schizophrenia and depression. A paucity of data exists showing the effects of co-morbid substance abuse disorder and general anxiety disorder on bipolar treatment outcomes. In a few of these studies, ADHD had the biggest impact on suicidality and had shorter remission periods when compared to other comorbidities. The purpose of this study is to determine the effects that ADHD may have when diagnosed concurrently with bipolar disorder.

Methods: This study has been approved by the Washington DC VAMC institutional review board. Final approval by DC VAMC research and development is pending. A VAMC database search will be conducted utilizing ICD-9, ICD-10, and SNOMED codes to determine the number of patients with diagnosis of both ADHD/ADD and bipolar disorder along with patients without ADHD co-diagnosis. Demographic data along with reported suicide attempts, incidence of manic and depressive episodes, number of acute psychiatric admission, and the average number of psychiatric medications. Bipolar patients with co-morbid ADHD will be matched 1:1 with bipolar subjects without co-morbid ADHD diagnosis.

**Poster Title:** Pharmacist led new transition clinic: Pilot program in primary care

**Primary Author:** Roxanne Finn, Cheyenne VA Medical Center, WY; **Email:** roxanne.finn@va.gov

**Additional Author (s):**

**Purpose:** As Veterans continue to transition from various outside health-care systems into the Veteran Affairs Medical Center (VAMC), they often bring medications not in line with the Veteran Affairs (VA) national or local formulary. In prescribing any non-formulary medication within a VAMC, there is a Prior Authorization Drug Review (PADR) process that often causes increases to provider work load. The average number of PADRs avoided after conversion from non-formulary to VA formulary will be evaluated. The objective of this study is to improve patient care by streamlining and improving formulary compliance.

**Methods:** Single pharmacist led clinic, will identify new Veterans that are transitioning care from outside health care providers to the Veteran Affairs Medical Center or those Veterans returning to the VA after leaving for one year or greater. This quality improvement study will obtain a patient list derived from a Saturday provider clinic using an electronic medical record system. The following data will be assessed through phone interview: all current medications and their formulary status, over-the-counter herbals and supplements, patient’s date of birth, age, allergies and disease states. The results will address the average number of PADRs avoided by pharmacy staff, average number of therapeutic interchanges accepted by the primary care provider, percent improvement in medication appropriateness and if available, the average cost avoidance of intervention to pharmacy. All data will be recorded in a patient/control database for further analysis. Per VA Handbook 1058.05 and 1200.19, this study is exempt from review by an Institutional Review Board (IRB) because the study is defined as quality improvement and aims to improve patient care within the VA

**Results:** N/A

**Conclusion:** N/A
Submission Category: Quality Assurance/ Medication Safety

Submission Type: Research-in-Progress

Poster Title: Pharmacist led benzodiazepine taper clinic: Impact on benzodiazepine use in primary care

Primary Author: Leah Arnbrecht, Cheyenne Veteran Affairs Medical Center, WY; Email: leah.arnbrecht@va.gov

Additional Author(s):

Purpose: Long-term benzodiazepine use is associated with numerous adverse drug events including dependency, withdrawal, addiction, and cognitive impairment. The objective of this study is to compare benzodiazepine use in primary care before and after initiation of a pharmacist led clinic including patient outreach, education, and a step-wise benzodiazepine taper.

Methods: This quality improvement study will be submitted to the local Pharmacy and Therapeutics Committee for approval. Veterans receiving one or more benzodiazepine, on a scheduled basis, for more than 190 days, and prescribed by a primary care physician will be identified in the medical record. With consent from primary care, veterans will receive information about the risks of long-term benzodiazepine use, the risks of benzodiazepine use over the age of 65, and/ or the risks of benzodiazepine use in combination with an opioid analgesic. If the veteran is interested in discontinuing the benzodiazepine, a recommendation will be included in the medical record incorporating a step-wise benzodiazepine taper. With approval from the provider, veterans will have the opportunity to come into clinic or receive the benzodiazepine taper via mail. Contact information will be provided to the veteran for follow-up. Age, benzodiazepine, strength, dose, directions, provider, and indication will be recorded and maintained confidentially. All benzodiazepines will be converted to diazepam equivalents. The total amount of diazepam equivalents prescribed by primary care providers will be averaged into a total daily dose. The change in total average daily dose of diazepam equivalents before and after initiation of pharmacist led interventions will be compared to determine the impact of benzodiazepine use in primary care.

Poster Title: Assessment of primary care access and blood pressure control in a pharmacist managed hypertension clinic: A rural Veterans Affairs quality improvement project

Primary Author: Pace Owens, Sheridan VA Health Care System, WY; Email: Pace.Owens@va.gov

Additional Author (s):
Shawn Dalton
Kelly Moran
Bernadeane Roth
Brien Thompson

Purpose: Access to quality primary care for rural veterans continues to be a focus for the Department of Veterans Affairs. Currently, 3.7 thousand veterans with hypertension seek primary care within this rural health care system, and 36% have blood pressures greater than 140/90 mmHg. The pharmacy department offers a consultative service for primary care conditions, but their services are underutilized. The goal of this hypertension focused quality improvement project is to improve access to quality care and increase achievement of blood pressure goals.

Methods: Prior to initiation, this quality improvement project was reviewed and approved by the local Pharmacy and Therapeutics Committee. Patients diagnosed with essential hypertension with the highest recent blood pressure values, will be considered for enrollment into the Pharmacotherapy Clinic. Patients with a hospice or palliative care diagnosis, non-hypertension related medical instability, or those without chronic hypertension will be excluded from this project. Consults for enrollment into clinic will be generated for primary care providers to sign as appropriate per their clinical discretion. Providers and patients will be allowed to opt out of clinic at any time if they so choose. From October through March, patients will be evaluated and treated according to evidence-based literature and clinical practice guidelines. The primary outcome of blood pressure treatment will be assessed by measuring the percentage of patients reaching individualized blood pressure goals; utilizing both descriptive and inferential statistics. All other data collected will be assessed using descriptive statistics. In order to assess primary care access, the number and frequency of pre-
enrollment provider visits that addressed hypertension over the previous year will be compared to post-enrollment number and frequency of visits.

Poster Title: Implementation of a pharmacy led pain clinic focusing on high-risk opioid patients: A resident-driven quality improvement project
Primary Author: Megan Ziegler, Sheridan VA Health Care System, WY; Email: megan.ziegler@va.gov
Additional Author(s):
Shawn Dalton
David Dixon
James McDonald

Purpose: In the last 15 years the number of opioid overdoses in the United States has quadrupled. The recently released CDC opioid guidelines focus on decreasing opioid dosages while optimizing non-opioid therapy. The primary objective of this quality improvement project is to optimize pain management regimens while utilizing risk evaluation and mitigation strategies. This includes improving safety and decreasing risk through reductions in opioid dosages, the use of non-pharmacologic measures, and the use of non-opioid medications.

Methods: Prior to beginning, this quality improvement project was approved at this VA facility’s Pharmacy and Therapeutics Committee. The two weeks directly following clinic approval will be focused on identifying the appropriate patients for the pharmacy led pain clinic. Patients will be excluded if the patient refuses, is hospice or palliative care, has active cancer, or the primary care provider chooses not to sign the consult. The pharmacy led pain clinic is targeting the most high-risk patients receiving opioids at this VA facility, including patients on greater than or equal to 100 daily morphine milligram equivalents (MME). After identifying appropriate patients, the pharmacist will enter consults and perform a chart review on patients prior to seeing them in clinic. From October through March, patients enrolled in clinic will be evaluated and managed by the pharmacist for safety and optimization of their pain management regimen. Patients will be required to complete the Brief Pain Inventory at first and last clinic visits. A repeat chart review will be completed at the last patient visit. Descriptive statistics will be utilized to assess change in total daily MME dose and change in Brief Pain Inventory metrics. Secondary outcomes include number of patients prescribed naloxone, number of patients with a urine
drug screen in the last year, and number of patients with Prescription Drug Monitoring Program checked in the last year.

Poster Title: Retrospective evaluation of opiate discharge prescriptions from the emergency department

Primary Author: Madison Schwartz, Baptist Health Medical Center - Little Rock, AR; Email: madison.schwartz@baptist-health.org

Additional Author(s):
Cody Null
Hyejin Son
Stefanie Reid

Purpose: Acute pain is the most common reason patients come into the Emergency Department (ED), and these patients are often discharged with prescriptions for opiate analgesics. Long-term opioid use often begins with treatment of acute pain, and prescribing practices over the years have led to a nation-wide opiate epidemic. Various organizations including the Centers for Disease Control and Prevention have published guidelines for prescribing opioids. This retrospective review is an evaluation of discharge opiate prescribing patterns from the ED of a non-for-profit community hospital. The purpose of this study is to compare institution’s prescribing patterns to the current guideline-recommended practices.

Methods: Data will be collected retrospectively by a pharmacy resident from patient electronic medical records. The patient population will include all patients discharged from the Emergency Department of a single non-for-profit community hospital from June through August 2016. Patient data will be recorded and analyzed on a Microsoft Excel® spreadsheet. The primary composite outcome is the percentage of discharge opiate prescriptions that followed guideline and hospital policy recommendations in regards to duration of prescribed therapy (≥ 3 days), total quantity of opiate pills prescribed (≥ 30 pills), and prescriptions for long-acting opiate formulations (including, but not limited to, fentanyl patches, methadone, long-acting oxycodone). Secondary endpoints include the separate components of the primary composite outcome, patient demographic data, primary diagnosis, chief complaint, opiate(s) prescribed at ED discharge, maximum opiate dose per day and total opiate dose prescribed (in oral morphine equivalents), utilization of opioid and non-opioid analgesic therapies in the ED, and patient-reported pain levels before and after analgesics were provided (when available), and any noted
analgesic-related side effects. Continuous data will be presented as mean±standard deviation for normally distributed data and as median (interquartile range) for non-normally distributed data. Statistical methods for analysis of the primary endpoint and secondary endpoints will be determined once data collection is complete.

**Poster Title:** Impact of a clinical pharmacist driven sexually transmitted disease treatment protocol in the emergency department  

**Primary Author:** Sarah-Catherine Formiller, Baptist Health Medical Center - North Little Rock, AR; **Email:** sarah.formiller@baptist-health.org  

**Additional Author(s):**  
Olivia Turansky  
Kevin Robertson  
Natalie Ohrenberger  

**Purpose:** In the emergency department, patients are screened for chlamydia and gonorrhea, but are often discharged before the results are finalized. In 2015, clinical pharmacy was granted the autonomy to initiate a sexually transmitted disease treatment protocol. The clinical pharmacist documents the results, notifies and counsels the patient and prescribes appropriate therapy if it was not received in the emergency department. The purpose of this review was to assess the impact of a clinical pharmacist driven protocol to screen, communicate and effectively treat patients who have been evaluated for sexually transmitted diseases within the emergency department of a regional referral hospital.  

**Methods:** To evaluate the impact of this clinical pharmacist led protocol in the emergency department, the following were reviewed: the rates of patients who screened positive for either chlamydia or gonorrhea, the rates of patients with appropriate antimicrobial therapy and the rates of patients who received initiation or modification of antimicrobial therapy by a clinical pharmacist. To evaluate the impact of follow-up by a clinical pharmacist, the rate of success of contacting and counseling patients by phone who screened positive for chlamydia or gonorrhea was reviewed.  

**Results:** Of the five hundred and forty-two patients who were screened in the emergency department, ninety-two of those patients were positive for either chlamydia or gonorrhea. Seventy-five percent of patients who screened positive for either chlamydia or gonorrhea were given empiric antimicrobial therapy while in the emergency department. Only twenty-six
percent of chlamydia or gonorrhea positive patients received the appropriate antimicrobial therapy per the Centers for Disease Control and Prevention treatment guidelines. Clinical pharmacists were able to contact and counsel seventy-four percent of patients who screened positive for either chlamydia or gonorrhea. Initiation or modification of antimicrobial therapy was made in forty-one percent of patients by clinical pharmacists based on the treatment algorithm recommended by the Centers for Disease Control and Prevention treatment guidelines.

**Conclusion:** Clinical pharmacists played a critical role in contacting and counseling patients by phone for either chlamydia or gonorrhea. Clinical pharmacists had a positive impact on patients with chlamydia or gonorrhea by having the autonomy to initiate or modify antimicrobial therapy per a collaborative practice agreement. There is potential to expand the clinical pharmacist’s impact for the treatment of patients with sexually transmitted diseases by developing an expedited partner therapy protocol in the future. Expedited partner therapy is permissible in forty states and is strongly recommended by the Centers for Disease Control and Prevention treatment guidelines.

Poster Title: Evaluation of fluoroquinolone use and resistance in urinary tract infections at a community hospital

Primary Author: Olivia Turansky, Baptist Health Medical Center - North Little Rock, AR; Email: olivia.turansky@baptist-health.org

Additional Author (s):
Clare Carter
Natalie Ohrenberger
Shawn Turner
Megan Patch

Purpose: In May 2016, the Food and Drug Administration (FDA) issued a safety announcement warning providers that the risks generally outweigh the benefits for use of fluoroquinolones (FQs) in patients with less serious infections including uncomplicated urinary tract infections (UTIs). Fluoroquinolone use in UTIs should be reserved for patients lacking alternative treatment options. Additionally, resistance to fluoroquinolones in common urinary pathogens is steadily increasing and prior FQ exposure may contribute to this resistance. This retrospective chart review assesses the prescribing rates and the rate of resistance of FQs in patients treated for uncomplicated urinary tract infections at a community hospital.

Methods: This retrospective chart review included patients 18 years of age and older admitted to our institution with a positive urine culture from April 1, 2016 – July 31, 2016. Patients with multiple sources of infection (i.e. pneumonia and UTI), those who were not treated with antibiotics, culture contamination, and those with only fungal isolates were excluded from this study. Isolates with less than 10,000 colony-forming units per milliliter (cfu/mL) were also excluded. Only the first culture for each patient within the study period was included. Patients were evaluated for FQ-sparing treatment options as well as FQ resistance within the culture and sensitivity reports. Microbial isolates, antimicrobial therapy for UTI, and fluoroquinolone use within the three months and year prior to urine collection were also collected.

Poster Title: Retrospective assessment of stress ulcer prophylaxis medication therapy in intensive care unit patients

Primary Author: Morgan Ramey, Baptist Health Medical Center-Little Rock, AR; Email: morgan.ramey@baptist-health.org

Additional Author(s):

Purpose: Critically ill patients are at an increased risk for developing stress-related mucosal disease and its complications such as bleeding. Risk factors for stress-related mucosal bleeding (SRMB) includes prolonged mechanical ventilation, coagulopathy, sepsis, head injuries, and organ failures. To reduce incidence of SRMB, physicians often prescribe acid suppression therapy with proton pump inhibitor (PPI) or histamine H2 receptor antagonist (H2RA). However, patients are often continued on the acid suppression therapy when they are no longer at risk for SRMB. The purpose of this study is to assess the appropriateness of stress ulcer prophylaxis initiation and continuation at a not-for-profit community hospital.

Methods: Data will be collected retrospectively by a pharmacy resident from patient electronic medical records. Criteria for stress ulcer prophylaxis (SUP) therapy will be determined through a literature review. The patients who will be assessed will include all intensive care unit (ICU) patients who are on a PPI or H2RA for SUP. Patients who are on PPI or H2RA prior to admission for predefined appropriate indications, or patients who have Barrett’s Esophagus, acute Helicobacter pylori, acute gastrointestinal bleeding, or Zollinger-Ellison will be excluded from this evaluation. The primary endpoint will be percent of patients appropriately on a PPI or H2RA in ICU based on the predetermined criteria. Secondary endpoints will include percent of patients appropriately on PPIs or H2RAs following ICU discharge, cost of SUP therapy, and incidence of SRMB.

Poster Title: Evaluating the patient-perceived impact of outpatient clinical services offered by on-site outpatient community pharmacists in the District of Columbia

Primary Author: LaToya Benjamin, ASHP Accreditation-Pending, DC; Email: latoya.benjamin@walgreens.com

Additional Author(s):
Tamara McCants
Laly Havern

Purpose: The innovative services offered in the outpatient community pharmacy model may include bedside medication delivery, patient counseling, medication reconciliation, medication therapy management, disease state management, and medication adherence assistance program. Within the District of Columbia, there are 14 hospitals; five have an on-site outpatient community pharmacy. To evaluate the patient-perceived impact and value of outpatient clinical services offered by on-site community pharmacists, a 16-item survey was developed to measure the patient’s feelings about outpatient clinical services.

Methods: A cross-sectional survey was designed and is currently undergoing approval by the institutional research review board. A Likert Three-Point Scale will be utilized to assist with assessing the patient-perceived value and likelihood to participate in clinical services offered by on-site outpatient community pharmacists. Once approved, student pharmacist volunteers and pharmacy staff from outpatient pharmacies will assist with survey distribution and collection. Surveys will be distributed to one hundred patients who previously received or did not receive clinical services from one of the five identified outpatient pharmacies in the District of Columbia. Participating patients will be asked to complete a paper survey, which will be collected by research volunteers and by using an on-site data collection box at each of the participating outpatient clinics. Participants will be instructed to select choices by indicating the best possible answer. Data will be collected for four months from institutional research board approval. The survey results will be evaluated utilizing SPSS Statistical Software. Descriptive analyses will be used to identify patient demographics, knowledge of offered clinical services, and the patient-perceived value of services provided.

**Poster Title:** Comparison of time to intubation between rocuronium vs. succinylcholine for pediatric patients undergoing rapid sequence intubation

**Primary Author:** Boh Song, Children's National Health System, DC; **Email:** bsong2@childrensnational.org

**Additional Author (s):**
Josh Heffren

**Purpose:** At Children’s National Health System, succinylcholine has been favored for emergent airway management in the Emergency Department due to its rapid onset, dependable effect, and short duration of action during intubation. In the pediatric intensive care unit, rocuronium has been favored for its dependable duration of action and minimal adverse effect profile. This retrospective study will compare the mean time to intubation for the neuromuscular blocking agents (NMBA) administered for rapid sequence intubation in the emergency department. Analysis of data collected from this study may facilitate standardization of care for rapid sequence intubation across various units within our institution.

**Methods:** This study is pending IRB approval. Study will be a retrospective chart review evaluating patients receiving succinylcholine or rocuronium in the ED for RSI between January 1, 2012 and July 1, 2016. All patients greater than 30 days of age and less than or equal to 18 years of age receiving succinylcholine or rocuronium in the emergency department for rapid sequence intubation will be included. Data to be collected includes: patient demographics, reason for rapid sequence intubation, NMBA and dose, time to intubation, and vital signs with laboratory values to measure successful intubation or adverse events. Primary end point will be the mean time to intubation between rocuronium or succinylcholine administration, defined as the time to post-intubation oxygen saturation greater than baseline, end tidal CO2 35-45 mmHg, or perceived successful intubation as documented in the chart.

Poster Title: Comparison of Fixed versus Traditional Weight Based Dosing of Rasburicase in a Pediatric Population

Primary Author: Dimitrios Savva, Children's National Health System, DC; Email: dsavva2@childrensnational.org

Additional Author (s): Radha Rohatgi

Purpose: The American Society of Clinical Oncology guidelines recommend rasburicase for the treatment of pediatric patients with hyperuricemia at risk of tumor lysis syndrome using a weight based dose of 0.1-0.2mg/kg once daily for 1-7 days. However, there has been a trend in practice due to recent data showing benefit using a fixed dose approach. Based on these studies for adolescent or adult sized children, Children's National Hospital System providers started prescribing rasburicase 0.15-0.2mg/kg [max 6 mg]. The purpose of this study is to evaluate the efficacy and safety between fixed and weight based dosing of rasburicase in a pediatric population.

Methods: This study, following the approval of the Institutional Review Boards, will be a retrospective cohort chart review of oncology patients receiving rasburicase for the management of hyperuricemia from January 1st, 2007 to August 31st, 2016. Patients less than 18 years old with a documented diagnosis of a hematological malignancy and baseline uric acid level will be included in this study; patients less than 30 kilograms will be excluded. The primary endpoint of this study is time to treatment success of normalization of uric acid level, as defined per age group. The secondary endpoints of this study include percentage of patients with uric acid normalization at 24 hours, percent reduction of uric acid level at 24 hours, total number of doses given to achieve a normal uric acid level, incidence of GI related toxicities, and acute kidney injury. Patients will be identified by electronic medical record numbers. Data will be collected on demographic information, baseline electrolytes and white blood cells, serum creatinine, and uric acid level at baseline and at time of rasburicase discontinuation, other therapies used for hyperuricemia management, number of rasburicase doses received, number of rasburicase vials used, reports of nausea, vomiting, and abdominal pain, patient tumor lysis
risk category, and patient’s presentation of either laboratory tumor lysis syndrome or clinical tumor lysis syndrome.

Poster Title: Evaluation of foscarnet dosing efficacy in pediatric stem cell transplant patients

Primary Author: Ashley Cherian, Children's National Health System, DC; Email: acherian@childrensnational.org

Additional Author (s):
Devona Williams

Purpose: Cytomegalovirus infection is associated with significant mortality and morbidity. Foscarnet is second line therapy for ganciclovir-resistant infection. Foscarnet has been shown to be as effective as ganciclovir in treating cytomegalovirus. A few studies have been conducted, but an effective dosing regimen of foscarnet in pediatric stem cell transplant patients for induction therapy has not been established. The purpose of this study is to evaluate the foscarnet dosing regimens to result in cytomegalovirus viral clearance, defined as undetectable blood polymerase chain reaction viral levels by day 28 of treatment, in pediatric stem cell transplant patients diagnosed with cytomegalovirus positive antigenemia.

Methods: This study will be a historical cohort chart review evaluating pediatric stem cell transplant patients who received foscarnet therapy for cytomegalovirus from January 1, 2007-February 1, 2016 at Children’s National Health System, following the approval of the Institutional Review Board. Patients will be identified using a Cerner Discern Analytics report to include hematopoietic stem cell transplant patients, age 0-18 years old with cytomegalovirus blood polymerase chain reaction levels greater than or equal to 1,000 copies/mL. Patient data will be evaluated to assess the primary and secondary endpoints. The primary endpoint is to determine the percent of patients achieving cytomegalovirus viral clearance, defined as undetectable cytomegalovirus blood polymerase chain reaction levels less than 1,000 copies/mL by day 28 of treatment. Secondary endpoints include: the percent of patients achieving undetectable cytomegalovirus viral levels by day 14 of treatment, median time in days on foscarnet to undetectable cytomegalovirus blood levels, dosing regimen of foscarnet used to achieve undetectable viral load, percent of patients experiencing Grade 3 or Grade 4 nephrotoxicity defined by the National Cancer Institute’s Common Terminology for Adverse Events criteria, percent of patients requiring dose adjustment for renal impairment, percent of patients requiring a change in therapy from foscarnet to another agent, cytomegalovirus
recurrence within 180 days of undetectable cytomegalovirus blood levels, and mortality 6 months after first positive cytomegalovirus blood level and cause of death.

Poster Title: Barriers to hepatitis C cascade of care in an urban hospital in Washington, D.C.

Primary Author: Lindsy Liu, Howard University Hospital, DC; Email: lindsyliu@gmail.com

Additional Author(s):
Monika Daftary
Mary Maneno

Purpose: The purpose of this study is to determine what barriers to treatment exist in the Hepatitis C care cascade in an urban hospital in Washington, D.C. using a retrospective chart review.

Methods: A retrospective chart review of all hepatitis C positive patients, with an ICD 9/10 code of HCV, above the age of 18, who had at least one admission to the hospital or its ancillary services between 8/1/2015-8/1/2016. Data regarding patient demographics (race, gender, age, weight), baseline liver laboratory values, insurance type, co-infection, comorbid conditions, allergies, current medications, past medications, presence of HCV risk factors, the date of HCV diagnosis, referrals, HCV RNA, MetaVir score, FibroSURE results, HCV genotype, number of treatment attempts, barriers to care, date treatment was initiated, reasons for no treatment, SVR, response to treatment, compliance, reason for discontinuing treatment, and time from diagnosis to treatment will be collected from patient charts. The data will be collected in a data abstraction tool specifically created for this project and will be used to assess barriers to care. All results will be analyzed using SPSS with appropriate statistics.

Poster Title: The incidence of electronic medical record medication errors in a family medicine outpatient clinic at a teaching hospital in Washington, D.C.

Primary Author: Aulia Shariat, Howard University Hospital, DC; Email: ashariat@huhospt.org

Additional Author(s):
Monika Daftary
Mary Maneno

Purpose: The use of electronic medical records in clinical practice has helped to improve the quality of patient care by reducing the likelihood of medication errors. Medication errors continue to persist in spite of this, and further study of existing electronic medical records needs to be completed to quantify the number and types of medication errors that exist. This study will identify the types of medication errors in a family medicine outpatient clinic electronic medical record to determine the need for a clinical pharmacist on site to provide routine medication reconciliation and therapeutic interventions during clinic visits.

Methods: This study will be submitted to the Institutional Review Board for approval. This is a retrospective study, which will be conducted on all patients who have been seen at least once at the Family Medicine Outpatient Clinic at Howard University Hospital from September 1, 2015 through August 31, 2016. The following data will be collected from the electronic medical record: patient demographics such as age, gender, date of birth, race, weight, and height. Allergies, renal function, liver function tests (AST, ALT, T. Bili, and Alk Phos), date of visit, physician name and practice category (attending, resident, or fellow), comorbidities, current medications, medication error types identified, and dates of medication reconciliations (if documented). Medication error types include: incorrect dosing, renal adjustment, hepatic adjustment, duplication of therapy, incorrect frequency, drug-drug interaction, contraindication, allergy, or no indication. Information regarding the prescribers will be used to determine patterns of prescribing errors among attendings, residents, and fellows. All data will be secured under lock and key and/or encrypted by password to prevent an unintended misuse of data and will be analyzed using SPSS with appropriate statistics.

**Poster Title:** Evaluation of vancomycin dosing and monitoring at an urban, community hospital in Washington, D.C.: A pre- and post- intervention study

**Primary Author:** Adetokunbo Adedokun, Howard University Hospital, DC; **Email:** aadedokun@huhosp.org

**Additional Author (s):**
Maritsa Serlemitos-Day

**Purpose:** Vancomycin is used to treat a number of serious bacterial infections, including methicillin-resistant staphylococcus aureus (MRSA) infections and sepsis. There are a number of dosing and monitoring problems that may arise when vancomycin is ordered. These include: initial dosing and frequency errors, incorrectly timed troughs, and non-deescalation of therapy when appropriate. This is a drug use evaluation of vancomycin, performed pre- and post-intervention. The primary objective of this research is to optimize vancomycin administration at an urban, community hospital in Washington, D.C.

**Methods:** This study will be submitted to the Institutional Review Board for approval. This is a full drug use evaluation of vancomycin with two phases: pre- and post-intervention. Intravenous vancomycin orders for adult patients between 07/17/2016-09/23/2016 (pre-intervention) and 11/27/2016-01/29/2017 (post-intervention) will be identified using the electronic medical records system. Data regarding patient demographics, diagnosis, microbiology report, renal function, vancomycin dosing regimen, and therapeutic drug monitoring will be collected. Recorded information with patient identifiers will be kept confidential and discarded at appropriately at the conclusion of the study. The collected data will be used to evaluate for appropriateness of vancomycin dosing and monitoring, pre- and post-intervention. Interventions will include: (1) update to the vancomycin protocol at the hospital, (2) education to practitioners via grand rounds and in-service presentations. The primary outcome of this research is the frequency of appropriate initial vancomycin dose and interval. The secondary outcomes are (1) frequency of appropriately timed troughs and (2) frequency of vancomycin de-escalation. The data will be analyzed using SPSS with appropriate statistics.

**Poster Title:** Pharmacogenomics and Diabetes: The relationship between mood disorders and treatment outcomes.

**Primary Author:** Meighan LeGrand, Howard University Hospital, DC; **Email:** mlegrand@huhosp.org

**Additional Author (s):**
Earl Ettienne
Adaku Ofoegbu

**Purpose:** To determine the relationship between mood disorders (depression, anxiety, post-traumatic stress disorder, and bipolar disorder) and hemoglobin A1c (HbA1c) in patients with Type 2 Diabetes at the Howard University Hospital Diabetes Treatment Center.

**Methods:** This prospective cohort study will include patients randomly selected from the Howard University Hospital Diabetes Treatment Center. Patients with Type 2 Diabetes between the ages of 18-65 will be included in the study. Patients with Type 1 Diabetes or Gestational Diabetes will be excluded. Each study visit will take approximately 20 minutes and will occur during scheduled diabetes follow-up appointments. The Patient Health Questionnaire (PHQ-9) will be used to screen for depression and the My Mood Monitor (M3) screening tool will be used to screen for depression, anxiety, post-traumatic stress disorder (PTSD), and bipolar disorder. PHQ-9 and M3 Scores, as well as HbA1c levels will be collected for each patient. Other data to be collected includes patient age, gender, ethnicity, previous HbA1c values, and current medications. All patient data will be de-identified and maintained confidentially. Univariate statistical analyses will be conducted on patient demographic data. Regression analyses will be conducted to determine whether PHQ-9 and M3 scores are predictive of HbA1c levels. The study proposal will be submitted to the Howard University Institutional Review Board for approval. Genetic material will be collected for pharmacogenomic testing via buccal swab and sent to a third party genomics company for analysis. A pharmacogenomic testing report will be generated for each patient and used for the development of future point-of-care pharmacogenomic testing algorithms for patients with Type 2 Diabetes.

**Poster Title:** Developing an electronic pharmacy application to streamline delivery of information at a large tertiary care hospital

**Primary Author:** Parker Brumfield, Medstar Washington Hospital Center, DC; **Email:** brumfield.29@osu.edu

**Additional Author(s):**
Anil Kishore

**Purpose:** In today’s age, we have a vast array of information at our fingertips. However, it can become overwhelming to find the most current information in a timely manner. Pharmacists play a crucial role in providing medication related information accurately at a rapid pace in our dynamic world of health care. Electronic applications are becoming a staple in everyday life, readily accessible from computers to handheld devices. The objective of this project is to create, develop, and implement an application which consolidates various pertinent resources into an accessible and convenient application.

**Methods:** This project will describe how we will create, develop, and implement an electronic application to ease access to pharmacy information at a large tertiary care hospital. It will be submitted to our Institutional Review Board for approval. The application will be developed through a website using currently available technology. Our aim is to make the application easily accessible to our associates from various electronic devices. The application will include clinical practice guidelines, therapeutic interchanges, drug monographs, educational materials, residency documents, policies and procedures, pharmacy department orientation, and links to drug information resources. It is a goal to link this application to our facility’s current nursing application resulting in an all inclusive databank. A group of pharmacists will test the application and assist with content and functionality. The plan is to launch the application by April, 2017.

**Poster Title:** Benefits of a specialty hepatitis C pharmacy within a hospital ambulatory clinic

**Primary Author:** Joanne-Ritzelle Woskov, MedStar Washington Hospital Center, DC; **Email:** jwoskov@gmail.com

**Additional Author(s):** Jennifer Brandt

**Purpose:** Hepatitis C (HCV) is a chronic disease state that, under proper management and patient compliance, is treatable in an outpatient setting. Pharmacists have a unique ability to enhance patient care and treatment outcomes through oversight of medication regimens, insurance approval, direct dispensing of specialty medications, patient education, and medication compliance programs. Additionally, dispensing of specialty medications provides a significant source for revenue. The objective of this descriptive report is to describe the protocol and processes employed to incorporate a clinical pharmacist into specialty pharmacy operations.

**Methods:** This is a descriptive report of specialty pharmacy operations within a hospital ambulatory care clinic, to include both protocol and process development. It will be conducted in a large, tertiary, academic medical center. Institutional Review Board approval is pending. The electronic medical record system and provider documentation will be used to identify patients ≥ 18 years who have been diagnosed with and treated for HCV at the ambulatory specialty clinic between January 2016 and September 2016. The following patient data will be collected: medication regimen, length of therapy, number of prescriptions filled, medication insurance, outpatient pharmacy, and completion of therapy. All data will be recorded with patient identifiers removed and will be maintained confidentially. The primary outcome measures will be (1) the number of patients treated by the specialty pharmacy and (2) the revenue generated through direct medication dispensing operations.

Poster Title: Evaluation of cangrelor use in a large tertiary care hospital

Primary Author: Lyly Doan, MedStar Washington Hospital Center, DC; Email: lylytdoan@gmail.com

Additional Author(s):
Jennifer Brandt

Purpose: Cangrelor is indicated as an adjunct to percutaneous coronary intervention (PCI) to reduce the risk of periprocedural myocardial infarction (MI), repeat coronary revascularization, and stent thrombosis (ST) in patients who have not been treated with a P2Y12 platelet inhibitor and are not being given a glycoprotein IIb/IIIa inhibitor. Due to its high cost, the use of cangrelor at this large, tertiary care hospital is restricted to patients presenting with high-risk STEMI's, or not appropriately pre-loaded or adequately controlled by an oral P2Y12 agent. The objective of this study is to assess for the appropriate use of cangrelor at this institution.

Methods: This study will be submitted to the Institutional Review Board and conducted in the form of a retrospective drug utilization evaluation. A drug inquiry report will be generated to produce a list of patients who have received cangrelor from March 1, 2016 to October 1, 2016. Eligibility criteria will include patients who are 18 years of age and older and have received cangrelor during their hospitalization. The electronic medical record will be used to collect patient information, which will include: demographics (e.g. age, sex, height, weight), past medical history, medications prior to and during hospitalization, incidence of bleeding, additional procedures during the stay, and the total dose and indication for cangrelor use. The primary outcome of this study will assess the percentage of appropriate indications for the use of cangrelor according to this hospital’s clinical practice guidelines, and identify opportunities for cost-savings in a large tertiary care teaching hospital. Using an outcomes database, this study also aims to compare the clinical outcomes of cangrelor use in our patient population, to clinical outcomes before its addition to formulary, in order to identify potential opportunities to improve patient care.

**Poster Title:** Benefits of a clinical pharmacist in outpatient diabetes disease state management

**Primary Author:** Rola Halabi, MedStar Washington Hospital Center, DC; **Email:** rola.a.halabi@medstar.net

**Additional Author(s):**
Wafaa Abou-Zeineddine

**Purpose:** Diabetes is a chronic disease state that has significant impact on patients. Pharmacists can have an integral role on a healthcare team providing patients with knowledge, resources, and support in the treatment of diabetes. Pharmacists have the unique ability to educate patients regarding proper use of their medications, self testing supplies, insulin administration, screen for drug interactions and make recommendations for lifestyle improvements, so that complications from diabetes can be delayed. The purpose of this study will be to evaluate the impact of pharmacist involvement in diabetes management in an ambulatory clinic, where there previously has been no pharmacist participation.

**Methods:** This study will be submitted to the Institutional Review Board and conducted in conjunction with the Endocrinology group in an outpatient clinic of a large tertiary care hospital. Patients will be identified through the electronic medical record system, referrals from outside clinics, and those referred from inpatient admissions for diabetic complications, to be seen for follow-up in an ambulatory outpatient diabetes clinic. The following data will be collected: age, gender, diagnosis, Hgb A1C, diagnostic lab results, medication regimens, compliance, physical exam findings, past medical history and readmission for complications of diabetes. Provider documentation from previous encounters will be reviewed to determine reasons for non-compliance, complications, and/or target A1C goals being missed. Medication regimens will be optimized; techniques for insulin administration and lifestyle modifications will be discussed. Patients will be educated on proper self-monitoring techniques and set up so their health care provider can electronically monitor their test results. Patients will be followed in an ambulatory clinic for 12 weeks by physicians, nurse practitioners, certified diabetic educators (CDE) and/or a pharmacist. The primary outcome measures will be (1) reduction of Hgb A1C and (2) reduction in hospital readmissions for diabetic complications. This study also aims to compare the clinical outcomes of diabetes management by a pharmacist compared to
outcomes before pharmacist involvement in order to identify the impact that can be made in improving patient care.

**Poster Title:** Pharmacist-driven monitoring and education program for advanced breast cancer patients receiving palbociclib  

**Primary Author:** Sorana Pisano, Sibley Memorial Hospital- Johns Hopkins Medicine, DC; **Email:** spisano1@jhmi.edu  

**Additional Author (s):**  
Karen Smith  
John Grouse  
Eleni Yeatras  

**Purpose:** Oral anti-cancer therapies are becoming increasingly common. Despite ease of administration in the outpatient setting, these agents are associated with potential toxicities and close monitoring is often required. A multi-disciplinary approach, which includes pharmacists in the care team for patients receiving oral anti-cancer therapy, may enhance adherence to therapy and its attendant recommended monitoring, and, ultimately, improve patient safety. The purpose of this pilot study is to evaluate the feasibility of a pharmacist-driven education and monitoring program for patients with advanced breast cancer receiving palbociclib along with endocrine therapy.

**Methods:** This is a single center, one arm, pilot study which will prospectively evaluate a pharmacist-driven education and monitoring program over approximately 6 months. Patients eligible to participate are those initiating or continuing treatment for locally advanced or metastatic breast cancer with palbociclib and endocrine therapy through the medical oncology clinic at the Johns Hopkins Kimmel Cancer Center at Sibley Memorial Hospital. Patients who provide consent may enroll after the study opens and prior to May 30, 2017. The institutional review board will review this study. A pharmacist will educate patients about potential palbociclib-associated toxicities and required laboratory monitoring while on treatment with palbociclib. The pharmacist will provide each patient with a specific treatment and laboratory calendar, follow-up on laboratory test results, and recommend dose adjustments in accordance with standard palbociclib treatment guidelines. Pharmacist recommendations will be based upon hematologic toxicity. Patients will complete a post-study satisfaction survey. The primary objective will be to evaluate patient adherence to pharmacist-recommended laboratory
monitoring. Secondary objectives will be to evaluate adherence to the pharmacist-recommended palbociclib schedule and to evaluate adherence to pharmacist-recommended palbociclib dose. Exploratory objectives will be to describe adherence to concomitant aromatase inhibitor or fulvestrant therapy, to evaluate patient satisfaction, to identify patient specific factors associated with adherence, and to describe the correlation between pharmacist-recommended and provider-recommended palbociclib dosing.

Poster Title: Evaluation of the pharmacist’s role in the management of drug-induced QTc prolongation in the inpatient setting at a community hospital

Primary Author: Uzoma Obi, Sibley Memorial Hospital-Johns Hopkins Medicine, DC; Email: uobi1@jhmi.edu

Additional Author (s):
Afua Addo-Abedi
Benjamin Miles
Shahnaz Milani

Purpose: Delay in cardiac repolarization, (QTc prolongation) is a cause for concern in clinical practice, which untreated, can lead to the life-threatening occurrence of polymorphic ventricular tachyarrhythmia, also known as torsades de pointes (Tdp). Many medications have the potential to cause prolongation of the QTc interval, and even so combination of two or more QTc prolonging drugs have the potential to increase this risk even further. The objective of this study is to examine the opportunities for improving pharmacist monitoring of drug-induced QTc prolongation in an inpatient setting.

Methods: The electronic medical record system will be used to identify patients on four nursing units within the hospital that had high and or contraindicated drug-drug interaction QTc prolongation alerts, whether any interventions were made by the pharmacist due to those alerts and whether the alerts were overridden by the ordering physician. The following data will be collected: gender, patient age, patient nursing unit, prior to admission and inpatient medications, comorbidity status, laboratory data which will include potassium and magnesium levels, renal function and initial heart rate level. If available, results of baseline EKG status, and readings of QTc interval greater than 450 millisecond in men and QTc interval greater than 470 millisecond in women will be collected. Physician and pharmacist documentation will be reviewed to determine which interventions were made on the alerts and whether the alerts were overridden. The data will be recorded without patient identifiers. Data from patients with documented QTc interval greater than 450 millisecond in men and QTc interval greater than 470 millisecond in women will be reviewed to identify hemodynamic changes.

Poster Title: Development of a pharmacy department standard operating procedure for intravenous to oral administration conversion of antimicrobial agents at a health maintenance organization hospital

Primary Author: Eric Tsuji, Kaiser Foundation Health Plan, Inc. - Hawaii, HI; Email: eric.r.tsuji@kp.org

Additional Author (s):
Cynthia Yeh

Purpose: The intravenous (IV) route provides many benefits for medication administration but also has many drawbacks such as increasing risk of nosocomial infection, preparation and administration time, and cost (administration supplies and medications). Therefore, medications administered IV should be assessed and changed to oral (PO) administration as soon as clinically appropriate. This is especially true for antimicrobial agents, where IV to PO conversion is the simplest form of de-escalation. In addition, antimicrobial stewardship will soon be mandated by the Joint Commission and IV to PO conversion of antimicrobial agents is the first step to establishing a standard, hospital wide program.

Methods: Developing a standardized process for clinical pharmacists to convert antimicrobial agents from IV to PO began by reviewing current protocols and literature. Protocols from several other hospitals were reviewed to understand the necessary components of an IV to PO conversion protocol and the clinical pharmacist’s role. A literature search was performed to identify inclusion and exclusion criteria of eligible and non-eligible patients. Pharmacokinetic information of formulary antimicrobial agents were also collected from the prescribing information of each medication. Antimicrobial agents were included if they were available in both IV and PO formulations, were on the hospital formulary, and had sufficient oral bioavailability. The identified patient criteria, convertible agents, and a proposed workflow were then formulated into a protocol describing the automatic conversion of IV to PO administration by clinical pharmacists. We solicited input from Infectious Disease physicians and other clinical pharmacists to further refine the protocol. After finalizing the protocol, it was submitted for review by the institution’s Pharmacy Practice Committee (PPC), which decided
that the protocol should be implemented as a standard operating procedure (SOP) in lieu of a protocol.

**Results:** The protocol identifies inclusion and exclusion criteria of which patients qualify for IV to PO conversion. Patients ≥ 18 years of age who have a functioning GI tract, are hemodynamically stable, and are showing clinical signs of improvement are eligible for conversion. Patients unable to swallow or refuse anything PO, are not tolerating tube feedings, nothing by mouth (NPO) status, have malabsorption abnormalities, or are immunocompromised are not eligible for conversion. The formulary antimicrobial agents, eligible for conversion, and have sufficient oral bioavailability include azithromycin, ciprofloxacin, clindamycin, doxycycline, fluconazole, levofloxacin, linezolid, metronidazole, and moxifloxacin. Additional criteria to assess if a patient is declining or not responding to the PO therapy were also added for safety including increasing temperature and or white blood cell (WBC) count, becoming hemodynamically unstable, worsening signs or symptoms of infection, or unable to take medications PO. The PPC decided that the IV to PO conversion should be implemented as a SOP because the agreed upon workflow requires the pharmacist to first obtain permission from the supervising practitioner before proceeding with the conversion. Development of the protocol took approximately one month from inception to finalization of the SOP.

**Conclusion:** The resulting SOP for converting antimicrobial agents from IV to PO was the result of extensive literature review and input from multiple disciplines within the hospital. It will serve as a stepping stone for achieving the new antimicrobial stewardship standard by the Joint Commission and broaden the impact of clinical pharmacists in the hospital. This protocol will be implemented by the end of the year and the results of its impact will be presented at the Western States Conference for Pharmacy Residents.

Poster Title: Evaluating the use of ambulatory care clinical pharmacists (ACCPs) in assisting primary care providers (PCPs) with authorizing refill authorization requests (RARs) for chronic disease states

Primary Author: Minhhang Mui, Kaiser Foundation Health Plan, Inc. - Hawaii, HI; Email: minhhangmui@gmail.com

Additional Author(s):
Michelle Kunita
Crystal Tsuda
Shelley Nakasone

Purpose: Primary care physicians (PCPs) are continuously interrupted by medication refill requests throughout the day with limited time to perform a comprehensive review before approving such requests. Many institutions and pharmacies have implemented refill clinics or collaborative protocols managed by nurses and/or community pharmacists with a primary goal of reducing physician workload. The refill authorization request (RAR) pilot program was designed to alleviate the burden on PCPs as well as address care caps by allowing ambulatory care clinical pharmacists (ACCPs) to review and authorize refill requests for anti-hypertensive, anti-hyperlipidemia, chronic gout, and anti-diabetic medications and supplies.

Methods: Primary care ACCPs were each assigned to a group of PCPs from 18 clinics under a collaborative protocol to assist in approving RARs for anti-hypertensive, anti-hyperlipidemia, chronic gout, and anti-diabetic medications and supplies in patients 18 years and older. A total of 139 physicians signed the protocol. In addition to assessing the clinical appropriateness of a RAR, ACCPs also addressed the need for an annual office visit, blood pressure check, and appropriate laboratory work. ACCPs made clinical and pharmacy related interventions. The primary outcome was a composite of care gap closures, which included completion of the annual office visit, blood pressure check, and laboratory work, both jointly and separately. Secondary outcomes included number of clinical interventions, pharmacy related interventions, average time taken to approve a RAR, and average time saved for the PCP. The program was initiated in April 2016 with full implementation to all clinics by August 2016. Data will be collected from January to December 2016 to capture the impact of this program.

**Poster Title:** Drug utilization of intravenous acetaminophen in post operative patients

**Primary Author:** Brandi Semien, Lafayette General Health System, LA; **Email:** brsemien@lgh.org

**Additional Author (s):**
James Murungi
Shane Domingue
Caleb Stephenson
Wesley Turner

**Purpose:** Intravenous acetaminophen is currently used for the management of acute postoperative pain in patients unable to take oral or enteral analgesics or injectable ketorolac. Intravenous acetaminophen should be restricted to post operative use up to 24 hours with dosage regimens for every-6-hour intervals in adults and children. The objective of this study is to determine whether patients who are given intravenous acetaminophen require less opiate medications and/or intravenous morphine usage.

**Methods:** A retrospective, observational study was performed via electronic chart review on post operative patients at Lafayette General Medical Center from July 1, 2015 to July 1, 2016 initiated on intravenous acetaminophen pre-operatively and/or post operatively. Concurrent opioid analgesic therapy was also documented from the medication administration record, if any, for these patients. A selected group of 30 patients that received only intravenous acetaminophen served as the control group for the medication utilization evaluation. The drug, strength, route of administration, and time of administration were all documented for each analgesic medication. In addition, the total amount of acetaminophen per day was calculated and documented. Also noted was length of stay, gender, age, ethnicity, and procedure for the total of 60 patients included in the medication utilization evaluation. An F-test and T-test was performed on select data for the medication utilization evaluation. This study will be submitted to the Institutional Review Board for approval.

**Poster Title:** Evaluation of argatroban use at a tertiary hospital

**Primary Author:** Stephanie Youssef, Ochsner Clinic Foundation (Ochsner Medical Center), LA; Email: stephanie.youssef@ochsner.org

**Additional Author(s):**
Yana Bukovskaya
Katherine Jennings
Ngoc Vu

**Purpose:** Argatroban is a direct thrombin inhibitor indicated for the treatment and prophylaxis of thrombosis in patients with suspected or confirmed heparin induced thrombocytopenia (HIT). Argatroban dosing is weight-based, with initial doses of 2 micrograms/kilogram/minute, and requires strict monitoring to achieve therapeutic efficacy and avoid bleeding. Studies have shown that critically ill patients and those with liver or multi-organ dysfunction require much lower initial doses ranging from 0.5-1.2 micrograms/kilogram/minute. The purpose of this study is to evaluate the safety, as well as the appropriateness of dosing and monitoring of argatroban at our institution.

**Methods:** This is a single center, retrospective, drug-use evaluation study approved by the Institutional Review Board. Patients aged 18 years or older with a diagnosis of suspected or confirmed heparin-induced thrombocytopenia with or without thrombosis, treated with argatroban for at least 24 hours, and admitted to hospital for at least 24 hours were included. Data will be collected from the electronic medical record. Data collection will include patient baseline characteristics, admission location (intensive care unit (ICU) versus non-ICU units), liver and multi-organ dysfunction, indication for argatroban, appropriate diagnosis of HIT, initial argatroban infusion dose, duration of argatroban therapy, and adherence to the institution’s nomogram. The primary outcome is maintenance argatroban dose to achieve two consecutive therapeutic partial thromboplastin times (aPTT). Secondary outcomes include: time to achieve therapeutic aPTT, percent of subtherapeutic and supratherapeutic aPTTs, bleeding events, and thrombosis events.

Poster Title: Use of erythropoietin in kidney or liver transplant recipients

Primary Author: Jeffrey Quach, Ochsner Clinic Foundation (Ochsner Medical Center), LA; Email: jeff.quach.01@gmail.com

Additional Author(s):
Shelbie Ralph
Marissa Janusek

Purpose: The use of erythropoietin is common in chronic renal failure patients; however, there is a lack of data to support its place in therapy for patients after receiving a kidney or liver transplant. Currently, at our institution there is no standard protocol to administering erythropoietin to solid organ transplant patients in both the inpatient and outpatient setting. This study intends to describe the use of erythropoietin over two years in order to assess the necessity of a protocol for erythropoietin use in solid organ transplant.

Methods: This is a single center, retrospective descriptive study including patients greater than 18 years of age who received erythropoietin from July 1, 2014 to July 1, 2016 with a history of a kidney, liver, or combined kidney-liver transplant. Currently, there is no specific protocol that our institution uses to determine how to administer erythropoietin for patients with post-transplant anemia. Data will be collected from the electronic medical record. The primary outcome is to determine the number of patients who appropriately received erythropoietin at the correct dose. Secondary outcomes include determining patients who received oral iron therapy, thromboembolic events at any point post erythropoietin dose, blood pressure monitored pre-dose and held if patient is hypertensive, blood pressure monitored post dose, mortality, blood transfusions, cardiovascular events, and duration of erythropoietin administration. Appropriate use of erythropoietin was defined as pre-dose blood pressure that would not contraindicate administration in addition to the correct dose based on body weight. Hypertension pre-dose requiring dose to be held was defined as systolic blood pressure greater than 170 mmHg or diastolic blood pressure greater than 90 mmHg. Anemia was defined as a hemoglobin level less than 10 grams per deciliter or symptomatic requiring blood transfusions.

Poster Title: Comparison of outcomes with vancomycin or metronidazole for Clostridium difficile associated diarrhea among solid organ transplant recipients

Primary Author: Katherine Frieling, Ochsner Clinic Foundation (Ochsner Medical Center), LA;
Email: katherine.frieling@ochsner.org

Additional Author (s):
Sara Lott
Julius Li
Jonathan Hand
Cynthia Nguyen

Purpose: Clostridium difficile associated diarrhea (CDAD) is a rising nosocomial infection associated with increased morbidity and mortality. Solid organ transplant (SOT) recipients have been observed to have both higher rates and worse outcomes of CDAD compared with the general population. Currently, the standard of care for mild to moderate CDAD in the general population is metronidazole. However, literature among the SOT population is limited. The objective of the study is to assess efficacy outcomes comparing metronidazole or oral vancomycin therapy in adult SOT recipients with mild to moderate CDAD.

Methods: This is a retrospective cohort study of adult SOT patients diagnosed with their first occurrence or first recurrence of mild to moderate CDAD between June 1, 2012 and May 31, 2016 and received at least 48 – 72 hours of metronidazole or oral vancomycin therapy. Patients who initially received combination oral vancomycin and oral/intravenous metronidazole or those who died within 48 hours of the positive C. difficile result will be excluded. The primary outcome is the rate of treatment failure in patients receiving metronidazole compared to those receiving oral vancomycin. Treatment failure is defined as no resolution or improvement in baseline diarrhea by day three or change off of therapy due to worsening diarrhea. The secondary outcomes are the rate of all-cause mortality, recurrence within 30 days and 90 days, vancomycin-resistant enterococci (VRE) positive results within 90 days of positive C. difficile test, and CDAD complications. A subgroup analysis will be performed for secondary outcomes in patients who received at least 70 percent of their treatment with metronidazole compared to oral vancomycin.

**Poster Title:** Effect of a pharmacist-led medication discharge education program on the 30-day readmission rate of indigent patients undergoing coronary artery bypass graft or valve replacement surgery

**Primary Author:** Laura Carrell, Our Lady of the Lake Regional Medical Center, LA; **Email:** laura.carrell@ololrmc.com

**Additional Author (s):**
Katie Ducote
Ryan Landry

**Purpose:** Transitioning between health care settings is associated with increased medication errors and adverse drug events. Previous studies have demonstrated that discharge education can reduce medication errors and readmission rates in hospitalized patients. Because indigent patients have a higher risk of readmission and cardiac surgery patients are often initiated on many new medications, this population is a particularly important target for a discharge education program. The primary objective of this study is to compare 30-day all cause readmission rates in indigent patients undergoing cardiac surgery who received discharge medication education versus patients who did not receive discharge medication education.

**Methods:** This single center, retrospective chart review of patients admitted to Our Lady of the Lake Regional Medical Center from June 2016 to December 2016 will compare the 30-day readmission rates for the 3 months prior to re-initiation of a discharge education program to the 3 months after. Patients will be identified through the Society of Thoracic Surgeons (STS) database information collected by the hospital and subsequently stratified into two groups based on initial admission date. Inclusion criteria include self-pay and Medicaid patients undergoing coronary artery bypass graft or valve replacement surgery. All information will be collected using the STS database and the hospital’s electronic health record. Information to be collected includes patient demographic information, relevant past medical history, payor status, type of surgery, date of admission, hospital readmission date and reason (if applicable), and discharge medication list. Data will be de-identified and maintained confidentially. Results of this study will be summarized using descriptive statistics. This study will be submitted to the Institutional Review Board for approval.

Poster Title: Does low dose vecuronium provide adequate paralysis without the need for re-dosing in pediatric patients undergoing RSI compared to high dose vecuronium?

Primary Author: Danielle Thomas, Our Lady of the Lake Regional Medical Center, LA; Email: danielle.thomas@ololrmc.com

Additional Author(s):
Rachel Mathews

Purpose: Vecuronium is a neuromuscular blocking agent commonly used in rapid sequence intubation (RSI). While not considered a first line agent, it has been shown to be safe and effective. In contrast to other agents, vecuronium is devoid of cardiovascular side effects making it a favorable option. Unfortunately, there no widely accepted guidelines and the dose of vecuronium used during RSI can range from 0.1 to 0.4mg/kg. The purpose of this study is to determine if low dose vecuronium, 0.1mg/kg, provides adequate paralysis without the need for re-dosing in pediatric patients undergoing RSI compared to high dose vecuronium, 0.2mg/kg.

Methods: This retrospective review will be submitted to the Institution Review Board for approval. The electronic medical record system will identify pediatric patients who underwent RSI and received vecuronium as the neuromuscular blocking agent. The study will evaluate whether low dose vecuronium provides adequate paralysis without the need for re-dosing compared to high dose vecuronium. The following data will be collected: patient age, gender, indication for RSI, type of physician providing intubation, past medical history, current medications, vecuronium dose, the number of doses given, and intubating outcomes. If available, blood pressure and heart rate prior to and after intubation will be collected. The dose of vecuronium will be calculated using the patient’s actual body weight. Patient’s electronic medical record will be evaluated from the date of admission to discharge and all data will be recorded without patient identifiers and maintained confidentially.

Poster Title: Impact of alvimopan with or without liposomal bupivacaine on length of stay and opioid utilization in colorectal surgery patients

Primary Author: Kristin Howell, Our Lady of the Lake Regional Medical Center in Louisiana, LA;

Email: Kristin.howell@ololrmc.com

Additional Author (s):

Carli Nesheiwat
Brandi LaFrance

Purpose: Opioid utilization postoperatively for colorectal surgery provides acute pain relief, but is associated with complications such as postoperative ileus (POI). Alvimopan, a mu-opioid receptor antagonist, works to prevent POI by blocking opioid gastrointestinal effects, without antagonizing central analgesia. Liposomal bupivacaine (LB), indicated for single-dose administration into the surgical site after the procedure, provides local postoperative analgesia. Alvimopan alone has been studied in colorectal patients, however the impact of alvimopan with LB is unknown at our institution. The purpose of this study is to evaluate alvimopan with or without LB on postoperative outcomes of colorectal surgery.

Methods: This retrospective, single-center study will compare the impact of alvimopan with and without liposomal bupivacaine on postoperative outcomes, including postoperative length of stay, total hospitalization costs, and opioid consumption. Patients will be identified by generating a financial report with specific diagnosis-related group (DRG) codes who received alvimopan in 2013-2016. DRG codes 329, 330, and 331 will be included to cover all major small and large bowel procedures with and without comorbid complications. Analysis will be limited to colorectal procedures by previously identified surgeons. Adult patients shall not be included in the study more than once. Charts with incomplete information will be excluded. Included patients will be divided into DRG code and then further into treatment groups. The primary outcome is to determine the difference in postoperative length of stay, rounded up in days. Postoperative opioid use will be converted to morphine equivalents using a standard opioid
equianalgesic chart. Opioid charges will be obtained through a financial report. Findings will assist in order set and formulary management.

**Poster Title:** Development of a comparative HIV community viral load map for the Greater New Orleans area  

**Primary Author:** Victoria Nguyen, PGY 1 Internal Medicine and Acute Care Pharmacy Practice Resident, Xavier University of New Orleans College of Pharmacy and University Medical Center, LA; **Email:** vnguye26@xula.edu  

**Additional Author(s):**  
Lori Gordon  
Jeffrey Percak  
Christopher Gillard  
Kendra Bryant Burks  

**Purpose:** Louisiana has the second highest rate of HIV diagnoses, with New Orleans accounting for a significant portion of this burden. Achieving viral suppression in HIV-positive patients has been shown to significantly reduce transmission. The website, www.AIDSVu.org has developed an interactive map of HIV incidence in the United States. Thus, our primary outcome is to determine if a correlation exists between HIV community viral load and HIV incidence in the Greater New Orleans area. We will also seek to compare the HIV community viral load according to: retention-in-care, age, gender identity, and race/ethnicity.  

**Methods:** This study has been submitted to the Xavier University of Louisiana Institutional Review Board for approval. This is a multi-center geo-mapping study. Using geographic information system (GIS) technology, we will generate a HIV community viral load map, by zip code. This map utilize data collected from the electronic health records (EHRs) of Ryan White HIV clinics in the Greater New Orleans area between January 1, 2015 and December 31, 2015. Analytic dataset derived from EHRs will be stripped of all personal identifiers to ensure confidentiality. The study sample will be divided into two groups: retention in-care patients (defined as a patient who is in continuous care for at least two visits, at least three months apart, within a twelve-month period) versus non-retention in-care patients. The primary outcome measure will be the latest HIV viral load. Patient’s zip code will be the primary exposure factor. Other exposure or confounding factors are: all viral loads of 2015, age, gender identity and race/ethnicity. Descriptive statistics will be performed to describe sample
characteristics. The relation between HIV viral load and incidence will be determined using correlation analysis. Two sample independent t-tests or analysis of variance (depending on the level of categorization of independent variables) will performed to assess differences in viral load relative to the exposure factors. Statistical tests will be performed at 0.05 significance level using SAS 9.4.1.

Afaf Abdulbaki

**Purpose:** To compare median number of days to engraftment with changes in granulocyte-colony stimulating factor medication and start date of granulocyte-colony stimulating factor based on changes in standard operating procedures (SOP).

**Methods:** This is a retrospective chart review of approximately 75 patients. Adult patients 18 years of age and older and 79 years of age or less who received an autologous stem cell transplant with stem cell engraftment therapy between January 1, 2015 and December 31, 2016 at University Health System will be included. Patient information will be assessed to determine conditioning regimen, stem cell dose and how many days it took to collect stem cells, plerixafor use, stem cell engraftment therapy, dose and number of granulocyte colony stimulating factor received, how many days it takes until the absolute neutrophil count stays above 500 for 3 days and 1500 for 2 days, if granulocyte colony stimulating factor was restarted, any fever, intravenous antibiotic use and duration of use. The length of hospital stay, and intensive care unit stays will also be collected.

Poster Title: Effect of appropriate weight based vancomycin dosing in the emergency department on time to therapeutic trough

Primary Author: Katherine Weigart, University Health Shreveport, LA; Email: katie.weigart@uhsystem.com

Additional Author(s):
Kathryn Astle
Amanda Storer
Ashley Sadowy

Purpose: Current vancomycin guidelines recommend administering a weight based loading dose (25-30 mg/kg) followed by a maintenance dose (15-20 mg/kg) for critically ill patients to provide therapeutic trough levels between 15-20 mg/L. Patients with vancomycin trough less than 10 are at increased risk of their bacterial infection becoming resistant to vancomycin. In the emergency department initial vancomycin dosing is often not the recommended 15-20 mg/kg. This study will evaluate the time to therapeutic trough and hospital length of stay for critically ill patients initiated on doses greater than or equal to 15 mg/kg and those who were not.

Methods: This study is approved by the Institutional Review Board. Patients included are those that received vancomycin in the emergency department for suspected bacteremia, meningitis, pneumonia, or skin soft tissue infection (excluding cellulitis). Data collection will include: age, gender, weight, height, BMI, serum creatinine, baseline calculated creatinine clearance, diagnosis/suspected infection, initial weight based vancomycin dose, first vancomycin trough, hospital length of stay, admission unit, administration and trough times of vancomycin, adverse outcomes such as death, kidney failure/dialysis, and acute kidney injury, and other potentially intravenous nephrotoxic medications administered including piperacillin-tazobactam, amphotericin, IV contrast, and acyclovir. Descriptive statistics will be used to compare baseline patient variables. Chi-squared testing will be used for nominal data, and student’s t-test will be used to measure continuous data.

Poster Title: A standardized vancomycin dosing protocol in a neonatal intensive care unit
Primary Author: Ashley Trojcak, University Health Shreveport, LA; Email: ashley.trojcak@uhsystem.com
Additional Author(s):
Hilary Tice
Kelsey Trimble
Edward Martel

Purpose: Standardized dosing of vancomycin in neonatal patients is limited by differences in pharmacokinetics and possibility of nephrotoxicity. The objective of this study is to determine whether a vancomycin dosing protocol implemented in a neonatal intensive care unit was effective to achieve target vancomycin trough concentrations. Secondary endpoints include the time it took to achieve target concentrations from the first dose given, area-under-the-curve per 24 hours, and whether nephrotoxicity occurred.

Methods: This study has been submitted for Institutional Review Board approval. This is a retrospective review of patient charts between January 2013, when the vancomycin dosing protocol was implemented, and July 2016. Charts reviewed include patients admitted to the neonatal intensive care unit who received vancomycin intravenously and had a level obtained for monitoring. Those excluded include patients receiving vancomycin without a corresponding vancomycin level and those on extracorporeal membrane oxygenation. The following data will be collected: medical record number, age, height/length, weight, diagnosis, cultures with sensitivities, serum creatinine, urine output, vancomycin dose, vancomycin dosing interval, time of vancomycin dose, vancomycin trough levels, time vancomycin trough level was taken, and medications that could potentially cause nephrotoxicity. Data collected will be used to determine whether target trough was achieved, the time to target trough in hours, and the average area-under-the-curve per 24 hours of the doses used. For safety, serum creatinine and urine output will be evaluated to determine if nephrotoxicity changed with the protocol.

Poster Title: Evaluating and assessing readmission rates among pediatric patients in an academic medical center

Primary Author: Stephanie Hatten, University Health Shreveport, LA; Email: stephanie.hatten@uhsystem.com

Additional Author (s):
Sabeen Habib
Elizabeth Lafitte
Christopher Selby
Kelsey Trimble

Purpose: The objective of this study is to determine parallels among pediatric patients who are readmitted to the hospital. Using information gathered through comparing patients with frequent readmissions, including disease state, mismanagement of medications by the caregiver, and infection at the time of admission, high risk populations that may benefit most from pharmacist education prior to discharge or in the outpatient setting will be identified.

Methods: This study has been approved by the Institutional Review Board. Patients eligible for retrospective chart review will meet the following criteria: age 0-18, admitted January 1, 2013 to January 1, 2015. Patient data will be collected via the electronic medical record system. The following data will be collected for each patient meeting inclusion criteria: patient medical record number, age, reason for readmission, initial admission date, admitting diagnosis, payor status, number of clinic visits, number of readmissions within one year of admission date, length of stay, and pertinent labs. The patient’s outpatient medication history including the use of compounded versus manufactured medication and where the patient normally fills their outpatient prescriptions will also be collected. Readmission types will be stratified into the following categories: (1) general disease state exacerbation, (2) infection, (3) medication induced illness/exacerbation. All collected data will be maintained confidentially.

Poster Title: Comparison of Posaconazole vs. Voriconazole in the Induction of Acute Myeloid Leukemia: Impact on Cost, Safety, and Efficacy

Primary Author: Olivia Antosz, University Health Shreveport, LA; Email: olivia.antosz@uhsystem.com

Additional Author (s):
Breanne Peyton-Thomas
Caitlin Shamroe
Christopher Selby

Purpose: University Health Shreveport switched from using posaconazole to voriconazole for the prevention of invasive fungal infections in patients with acute myeloid leukemia (AML) undergoing intensive chemotherapy in February 2016. Currently, there are no studies comparing the cost effectiveness of posaconazole to voriconazole in reducing invasive fungal infections in this patient population. Therefore, the purpose of this study is to compare the cost of posaconazole to voriconazole in patients with AML undergoing intensive chemotherapy, in addition to the incidence of adverse effects and reduction of invasive fungal infections.

Methods: This is a single-center, retrospective chart review of patients with AML receiving voriconazole or posaconazole for prevention of invasive fungal infections. Quality improvement status was granted by the Institutional Review Board prior to data collection. Patients with AML will be included if undergoing intensive induction chemotherapy and received voriconazole or posaconazole as the primary antifungal prophylactic agent. Medical record numbers of patients with AML who underwent intensive induction chemotherapy from February 2015 to February 2017 will be obtained. The following data will be collected from the patient’s chart: age, gender, admission date, inpatient length of stay in days, prescribed inpatient antifungal, dose, route, frequency, dosage form, duration, chemotherapy regimen initiated, liver function tests, serum creatinine, signs and symptoms of visual disturbances, EKG readings, electrolytes including potassium, magnesium and calcium, fungal cultures or suspected fungal infection, death and if so, cause. The cost of medication therapy will be determined in US dollars by the acquisition cost at the time of purchase of voriconazole and posaconazole. Statistical analyses will be completed for all objectives using descriptive statistics.

Poster Title: An evaluation of the accuracy of allergy assessments in the inpatient setting

Primary Author: Alyssa Simpson, University Health Shreveport, LA; Email: alyssa.simpson@uhsystem.com

Additional Author (s):
Victoria Miller
Ashley Sadowy
Kathryn Astle

Purpose: This purpose of this project is to investigate the high number of penicillin allergies lacking reaction descriptions. The primary objective of this study is to evaluate the accuracy of a non-pharmacist provider obtained allergy history. The secondary objectives are to determine the number of clarifications made due to the allergy and the average time spent by a pharmacist clarifying the allergy.

Methods: This is a single-center, prospective quality improvement study. The electronic health record will be used to identify patients age 18 to 89 years admitted to University Health Shreveport between September 1, 2016 –June 30, 2017 with a reported penicillin allergy. Patients who have more than five allergies listed in the health record or an allergy assessment already completed by a pharmacist will be excluded. Prisoners, children, pregnant women, and patients who cannot verbally provide an allergy history will also be excluded. Patients meeting the criteria will have an allergy assessment completed by a pharmacist. A questionnaire will be utilized to help standardize the assessment process, and answers to the questionnaire will be recorded into a password-protected spreadsheet to organize the data collected from the patients. This allergy assessment will be updated in the patients’ electronic health record and compared to the documented history currently on file. The following data will be collected: patient medical record number, age, gender, date allergy entered, medication causing reaction, reaction description, reaction onset, other beta-lactams taken, allergy category, number of previous l-vents related to this allergy, time spent clarifying, and other antibiotics used. The data will be analyzed using descriptive statistics.

**Poster Title:** Factors associated with early discontinuation of long-acting reversible contraceptives in a community teaching facility

**Primary Author:** Emily Allen-Vieira, Woman’s Hospital, LA; **Email:** emilyallenvieira@gmail.com

**Additional Author(s):**
Fancy Manton

**Purpose:** Long-acting reversible contraceptives (LARCs) are highly recommended by The American College of Obstetrics and Gynecology for most women. The Contraceptive CHOICE Project reports that compared to other methods, these devices have a high satisfaction rate and are associated with decreased unintended pregnancies. Occasionally, however, patients may request early removal of these devices. The goal of this study is to identify factors affecting early discontinuation of LARCs in the local community.

**Methods:** This study will be submitted to the Institutional Review Board for approval. To determine study population, the electronic medical record will be accessed using ICD 9 and 10 codes for intrauterine device and implant (i.e. LARC) removals at Woman’s Hospital. We will further condense the data to identify early removal of LARCs, defined as removal less than one year after insertion not related to expulsion. Once these patients are identified, charts will be thoroughly reviewed and the following will be recorded: reason for removal, product name, and timing of insertion from delivery (if applicable.) Additional information regarding patient demographics, number of pregnancies, educational level, etc. will be collected to determine influence on removal rates. All data will be recorded without patient identifiers and maintained confidentially. This information will be thoroughly analyzed by a team of clinicians including pharmacists, physicians, and a statistician to determine discontinuation rates and factors associated with early removal of LARCs.

Poster Title: Patients’ perspective on pharmacists’ role as a sexually transmitted infection provider for gonorrhea, chlamydia, and trichomoniasis in an ambulatory care setting

Primary Author: Esther Okoro, Xavier University of Louisiana, LA; Email: eokoro@xula.edu

Additional Author (s):
LaKeisha Williams
Daniel Sarpong
Kristi Rapp

Purpose: Although preventable, sexually transmitted infections (STIs) affect one million people daily. The highest prevalence rates among STIs, gonorrhea, chlamydia, and trichomoniasis, affect over 300 million people annually. While studies demonstrate effective pharmacist-led management of chronic diseases, it is unclear how patients perceive pharmacists beyond being viewed as “drug experts”. Based on a need for more innovative STIs prevention strategies, limited data showing the benefits of pharmacists providing sexual health education in STIs, and pharmacists’ effectiveness in managing chronic diseases; this study is designed to assess and understand patients’ views on pharmacists serving as STI providers for gonorrhea, chlamydia, and trichomoniasis.

Methods: This prospective mixed method study will be submitted to the Institutional Review Board for approval. Fifty patients will be recruited from targeted medically underserved Federally Qualified Health Centers. Inclusion criteria: sexually active adults, ages 18 to 50 years, obtain informed consent. Phase I (Quantitative Study) will include the administration of a survey which will identify patients’ knowledge on pharmacists as healthcare providers, views on pharmacists as sexual health STI providers, patients’ sexual history (i.e. diagnosis of gonorrhea, chlamydia, and trichomoniasis), and patients’ knowledge on STIs. The survey instrument is an adaptation of sexual risk of patients and instruments that measures perception of pharmacists viewed as healthcare and STI providers. Phase II (Qualitative Study) will involve focus groups to ascertain context to the pattern of perception of the study sample relative to pharmacists serving as providers in sexual health management and education of STIs. The focus group data will be audio-recorded and transcribed. All data collected will be confidential and will not provide patient identifiers. Descriptive statistics, t tests, chi square tests, analysis of variance.
and regression analysis will be performed. All statistical tests will be performed at 0.05 significance level using SAS 9.4.1. Content analysis of the qualitative data will be performed to ascertain emerging themes relative to the role of pharmacists as STI providers.

Poster Title: Estimates and Determinants of cure rates of sofosbuvir and ribavirin (SOF/RBV) in patients with Hepatitis C (HCV) genotype 2 & 3

Primary Author: Paa Kwesi Yanful, Xavier University of Louisiana, LA; Email: pyanful@xula.edu

Additional Author(s):
Lori Gordon
Daniel Sarpong
Cassandra Youmans
Kristi Rapp

Purpose: Until July 2016, SOF/RBV remained acceptable for treating HCV genotype 2 and 3, based on demonstrated clinical trial cure rates (sustained virologic response [SVR12]) of 56-97%. However, the diversity in populations represented in these trials has been limited. Additionally, previous investigations have not explored the potential impact of baseline depression on SVR12 in patients treated with SOF/RBV. Thus, the objective of this study is to compare the SVR12 of genotype 2 versus genotype 3 patients treated with SOF/RBV at the University Medical Center New Orleans Hepatitis Clinic and to determine if depression, race and insurance status are correlates of SVR12.

Methods: This single-center, retrospective analytic study has been submitted to the Xavier University of Louisiana Institutional Review Board for approval. The study sample will include all genotype 2 and 3 HCV patients treated with SOF/RBV at the clinic. The primary outcome measure is sustained virologic response at 12 week (SVR12). This measure will be determined by HCV viral load < 25 IU/mL at ≥12 weeks following completion of treatment. Exposure measures will include age, race, gender, insurance type, baseline depression assessed using either patient health questionnaire (PHQ-2) score, ICD-9/10 codes for depression (as applicable) or concomitant antidepressant therapy. The abstracted analytic dataset will be stripped of all personal identifiers to ensure confidentiality. Descriptive statistics will be used to describe baseline characteristics and to estimate SVR12 rates of genotype 2 and 3 patients. The study estimated SVR12 rates will be compared to SVR12 rates estimated from clinical trials using a z-test. Two-sample t-tests or chi-square tests will be used to compare selected exposure variables.
(baseline depression, race, and insurance status) and SVR12 rates between genotype 2 and 3 patients. All statistical tests will be performed at a significance level of 0.05 using SAS 9.4.1.

Poster Title: Implementation of the proposed Medicare diabetes prevention program: a retrospective analysis of revenue increase based on pharmacist-led interventions

Primary Author: Erica Watson, Xavier University of Louisiana College of Pharmacy, LA; Email: ericawatson16@gmail.com

Additional Author(s): Sarah Amering
Kristi Rapp

Purpose: Diabetes is growing at an exponential rate in both the United States and Louisiana. Individuals with prediabetes are at higher risk for the development of diabetes, resulting in poor health outcomes and increased healthcare costs. Studies have shown that implementation of the Medicare diabetes prevention program (MDPP) has resulted in the delayed development of diabetes and led to the adoption of a new provider payment scheme. Our primary objective is to assess the revenue generated from pharmacist-led interventions upon implementation of the MDPP. The study will also assess the development of diabetes in high-risk individuals who are receiving pharmacist-led care.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify prediabetic patients that are receiving pharmacist-led care. Prediabetes will be defined as a hemoglobin A1C test with a value between 5.7% and 6.4%, or fasting plasma glucose of 100-125 mg/dL, or a 2-hour post glucose challenge of 140-199 mg/dL (oral glucose tolerance test). The following data will be collected: age, gender, race/ethnicity, body mass index (BMI), weight, blood pressure, hemoglobin A1C, current medications, average adherence to clinic visits/number of visits attended, and co-morbid conditions. If available, occupation and educational level will also be obtained. All data collected will be over an 18-month time period, from initial referral to pharmacist. All data will be recorded without patient identifiers and maintained confidentially. The data will then be evaluated to determine those individuals who have attended the appropriate number of sessions and achieved at least 5% body weight loss. Estimated revenue will be determined utilizing the Centers for Medicare & Medicaid Services reimbursement rates. The primary outcome measure is cost in dollars. The data for all patients regardless of weight loss or
sessions attended will be assessed to determine if they developed diabetes while receiving pharmacist-led care.

Poster Title: Assessing patients’ improvement in diabetes numeracy skills after one pharmacist-led educational session

Primary Author: Rose Duchane, Xavier University of Louisiana College of Pharmacy, LA; Email: rduchane@xula.edu

Additional Author(s):
Janel Bailey-Wheeler
Daniel Sarpong
Martha Harris
Tammy Hart

Purpose: Numeracy is an important element of literacy and is defined as the ability to understand and use numbers in everyday life. Having adequate numeracy skills is crucial in diabetic patients to interpret glucometer results, properly administer medications, and adhere to diabetic diet; and pharmacists can intervene in these three areas. Previous studies assessed numeracy skills of patients enrolled in a long-term diabetes program and showed that patients with higher numeracy scores tend to have better glycemic control. The objective of this study is to determine if one educational session with the pharmacist will improve numeracy skills.

Methods: This single-center, prospective, pre-and post-intervention study will be submitted to the Institutional Review Board for approval and will be conducted in a community setting. The study sample will include patients at least 18 years old with Type 1 or 2 diabetes who take at least one diabetic medication. Patients who have a corrected visual acuity of 20/50 or greater as determined using Rosenbaum pocket screener will be excluded. The validated Diabetes Numeracy Test-5 (DNT-5) is a 5-item survey that assesses nutrition, exercise, blood glucose monitoring, and medication use. Study participants, at baseline, will be administered the DNT-5 survey. In addition to the DNT-5, the following data will be ascertained: age, gender, race/ethnicity, income, comorbid conditions, duration of diabetes, previous diabetes education, and list of medications. Patients will participate in an education session that covers modules from the Diabetes Literacy and Numeracy Toolkit corresponding to the DNT-5. Patients will retake the DNT-5 as a post-test. All data will be recorded without patient identifiers and maintained confidentially. Paired T-test will be used to assess changes in DNT-5 scores pre- and
post-intervention. Analysis of Variance will be used to compare DNT-5 scores adjusted for factors mentioned above. All statistical tests will be performed at a significance level of 0.05 using SAS 9.4.1.

**Poster Title:** Describing and quantifying opioid prescribing patterns in acute respiratory distress syndrome patients

**Primary Author:** Casey Payne, Xavier University of Louisiana College of Pharmacy/Louisiana State University Health Sciences Center, LA; **Email:** cpayne4@xula.edu

**Additional Author(s):**
- Jessica Johnson
- Daniel Sarpong
- Christopher Gillard
- Kendrea Bryant-Burks

**Purpose:** Acute respiratory distress syndrome often requires prolonged sedation, intubation, and intensive care hospitalization. It is associated with high mortality and morbidity, and patients may endure chronic pain that persists long after hospital discharge. Opioid overdose is an epidemic, with the majority of overdose-related deaths involving prescribed opioids in the United States. There is limited information available that describes opioid use in these patients during and after their acute critical illness. The objective of this study is to describe the patterns of opioid use in acute respiratory distress syndrome patients.

**Methods:** Prior to the start of this study, the study protocol will be submitted to both the Xavier University College of Pharmacy Institutional Review Board and the Research Review Committee for approval. This is a single-center, retrospective, chart review, descriptive study. This study will include all patients meeting the inclusion criteria who are on the University Medical Center New Orleans’ electronic medical record from July 2015 through December 2016. Included patients are those who are 18 years of age or older, admitted in the ICU and diagnosed with acute respiratory distress syndrome (ARDS) with the ICD9 diagnosis code of 518.82 or the ICD10 diagnosis code of J80, and received opioids during their encounter. The primary outcome of this study is to describe opioid requirements and prescribing patterns in patients with ARDS across their transitions between various levels of care. The secondary outcome of this study is to describe the number and characteristics of patients discharged with prescriptions for outpatient opioid use.

Poster Title: Discharge prescribing trends of benzodiazepines for anxiety in emergency departments in the United States.

Primary Author: Catherine Olson, Essentia Health St. Mary's Medical Center, MN; Email: caolson@westmont.edu

Additional Author(s):
Montana Hemling
Amber Soukkala
Kevin Heald
Brittany Raymond

Purpose: Anxiety disorders are the most common class of mental health conditions in the United States (US) with an estimated lifetime prevalence of 18 percent. In the US approximately 26 percent of mental health cases seen in emergency departments (EDs) are related to anxiety disorders. While benzodiazepines are not recommended as first line treatment for anxiety, their use has been increasing with an estimated 1 in 20 US adults in 2008 filling a benzodiazepine prescription. There is little research on management of anxiety at ED discharge. This study’s purpose was to assess prescribing trends of benzodiazepines for anxiety upon ED discharge.

Methods: To answer the research question, 2011 National Hospital Ambulatory Medical Care Survey (NHAMCS) data were examined using bivariate and multivariate techniques. NHAMCS is designed to collect data on the utilization and provision of ambulatory care services in hospital EDs from a national sample of ED visits. The survey instrument is the Patient Record form. ED staff is instructed to complete Patient Record forms for a systematic random sample of patient visits during a randomly assigned 4-week reporting period. Data are obtained on demographic characteristics of patients, expected source(s) of payment, patients' complaints, diagnoses, diagnostic/screening services, procedures, medication therapy, disposition, types of providers seen, causes of injury, and certain characteristics of the facility, such as geographic region and metropolitan status. The study population included US male and female adults 18-80 years of age presenting to the ED with the diagnosis of anxiety (ICD-9 Code 300.0 and 300.02). The dependent variable was receipt of benzodiazepine prescription on discharge. The covariates or
Independent variables were: geographic locale, patient sex, race/ethnicity, patient residence, visit disposition, and health insurance status. Statistical Package for Social Scientists (SPSS, IBM, Chicago, version 24.0) was used to conduct the analyses. The Institutional Review Board (IRB) at the researchers’ institution does not require human subject’s oversight for the analysis of de-identified data.

Poster Title: Intentional opiate overdose: a population based cross-sectional study of disparities in patients presenting to an emergency department in the United States

Primary Author: Amber Soukkala, Essentia Health-St Mary's Medical Center, MN; Email: amber.soukkala2@essentiahealth.org

Additional Author (s):
Kevin Heald
Brittany Raymond
Lauren Hanson
Mary Heiken

Purpose: The National Center for Health Statistics (NCHS) reported that the rate of deaths involving opioid analgesics in the United States (US) increased from 1.5 per 100,000 in 2000 to 5.9 per 100,000 in 2014. This increase is coupled with the fact that 40 percent of all drug-poisoning deaths involved opioid analgesics, equating to 18,893 deaths in the US. Little research has been conducted examining intentional overdoses involving opiates. The aim of this study was to ascertain if population disparities exist for patients who present to emergency departments (ED) due to intentional opiate overdose.

Methods: To answer the research question, 2011 National Hospital Ambulatory Medical Care Survey (NHAMCS) data were examined using bivariate and multivariate techniques. NHAMCS is designed to collect data on the utilization and provision of ambulatory care services in hospital EDs. Data are collected from a national sample of ED visits. ED staff is instructed to complete Patient Record forms for a systematic random sample of patient visits during a randomly assigned 4-week reporting period. Data are obtained on demographic characteristics of patients, expected source(s) of payment, patients' complaints, diagnoses, diagnostic/screening services, procedures, medication therapy, disposition, types of providers seen, causes of injury, and certain characteristics of the facility, such as geographic region and metropolitan status. The study population for this research was male and female adults aged 18 to 80 years presenting to an ED for overdose of opiate and/or related narcotics (ICD-9 Code 965.09). Opiate and/or related narcotic overdose was the dependent variable for this research study. The covariates or independent variables were: geographic locale, patient sex, race/ethnicity, patient
residence and health insurance status. Statistical Package for Social Scientists (SPSS, IBM, Chicago, version 24.0) was used to conduct the analyses. For all analyses' alpha was set at less than or equal to 0.05. The Institutional Review Board at the researchers’ institution does not require human subject’s oversight for analysis of de-identified data.

Poster Title: Are there population disparities in the receipt of tissue plasminogen activator (tPA) among adults presenting to an emergency department (ED) with acute ischemic stroke?

Primary Author: Montana Hemling, Essentia Health-St. Joseph's Medical Center, MN; Email: montana.hemling@essentiahealth.org

Additional Author(s):
Amber Soukkala
Kevin Heald
Brittany Raymond
Lauren Hanson

Purpose: Stroke is the leading cause of long-term adult disability. The first line of therapy for acute ischemic stroke treatment is tissue plasminogen activator (tPA) to resolve the thrombus and restore blood flow. Those who receive treatment within 60 minutes of presentation are more likely to avoid the disabling effects of stroke and have decreased mortality. A recent study suggested that only an estimated 27 percent of stroke victims receive tPA within 60 minutes. Our research question is: Are there population-related disparities in receipt of tPA in the United States (US) among adults presenting to an ED with acute ischemic stroke?

Methods: To answer the research question, 2011 National Hospital Ambulatory Medical Care Survey (NHAMCS) data were examined using bivariate and multivariate techniques. NHAMCS is designed to collect data on the utilization and provision of ambulatory care services in hospital EDs. Data are collected from a national sample of ED visits. The survey instrument is the Patient Record form. ED staff is instructed to complete Patient Record forms for a systematic random sample of patient visits during a randomly assigned 4-week reporting period. Data are obtained on demographic characteristics of patients, expected source(s) of payment, patients' complaints, diagnoses, diagnostic/screening services, procedures, medication therapy, disposition, types of providers seen, causes of injury, and certain characteristics of the facility, such as geographic region and metropolitan status.

The study population for this research was US male and female adults 18 to 80 years of age presenting to an ED with acute ischemic stroke (ICD-9 434.91). The dependent variable for the analyses was receipt of tPA (NHAMCS drug codes: 01032, 03371, 00486). The covariates or
independent variables for this research study were: geographic locale (rural/non-rural), patient sex, race/ethnicity (Caucasian/non-Caucasian), and health insurance status (insured/noninsured). Statistical Package for Social Scientists (SPSS, IBM, Chicago, version 24.0) was used to conduct the analyses. The Institutional Review Board (IRB) at the researchers’ institution does not require human subject’s oversight for the analysis of de-identified data.

Poster Title: Are patients presenting to emergency departments with ST Elevated Myocardial Infarctions (STEMI) in the United States receiving heparin before admittance to a hospital unit?

Primary Author: Kevin Heald, Essentia Health-St. Joseph's Medical Center, MN; Email: kevin.heald@essentiahealth.org

Additional Author (s):
Brittany Raymond
Lauren Hanson
Mary Heiken
Catherine Olson

Purpose: Approximately 735,000 heart attacks occur every year in the United States (US). About 70 percent of these are ST Elevated Myocardial Infarctions (STEMI) which occurs when one of the major arteries that supply oxygen to the heart becomes completely occluded leading to heart muscle death. The sooner the occlusion can be fixed, the less heart muscle will die with possible better outcomes for the patient. Current guidelines suggest giving heparin products in the emergency department (ED) before hospital admission. The purpose of this research was to assess adherence to STEMI guidelines.

Methods: To answer the research question, 2011 National Hospital Ambulatory Medical Care Survey (NHAMCS) data were examined using bivariate and multivariate techniques. NHAMCS is designed to collect data on the utilization and provision of ambulatory care services in hospital EDs. Data are collected from a national sample of ED visits. The survey instrument is the Patient Record form. ED staff is instructed to complete Patient Record forms for a systematic random sample of patient visits during a randomly assigned 4-week reporting period. Data are obtained on demographic characteristics of patients, expected source(s) of payment, patients' complaints, diagnoses, diagnostic/screening services, procedures, medication therapy, disposition, types of providers seen, causes of injury, and certain characteristics of the facility, such as geographic region and metropolitan status. The population studied was those 18 to 80 years old presenting to the emergency department with a STEMI. The dependent variable was receipt of heparin the emergency department. The covariates or independent variables were: geographic locale (rural/non-rural), patient sex, race/ethnicity (Caucasian/non-Caucasian),...
patient residence (nursing home, homeless, private residence, other), provider type (physician, nurse practitioner, physician assistant), and health insurance status (insured/noninsured).

Statistical Package for Social Scientists (SPSS, IBM, Chicago, version 24.0) was used to conduct the analyses. The Institutional Review Board (IRB) at the researchers’ institution does not require human subject’s oversight for the analysis of de-identified data.

Poster Title: Alcohol and illegal drug use in US high school aged youth: Impact on safety, violence-related behaviors and suicide ideation

Primary Author: Mary Heiken, Essentia Health-St. Mary’s Medical Center, MN; Email: mary.heiken@essentiahealth.org

Additional Author(s):
Catherine Olson
Montana Hemling
Amber Soukkala
Kevin Heald

Purpose: The United States (US) Healthy People 2020 objectives call for the reduction of alcohol consumption, illegal drug use and improvements in mental health. Substance abuse is well-established as a major cause of long-term morbidity and mortality, but its impact on concerns of safety and violence in high school youth is less clear. Suicide, often linked to drug abuse, is the second leading cause of death among youths aged 10-24. The purpose of this study was to determine if alcohol and illegal drug use in US high school aged youth were associated with safety, physical violence, and suicide ideation.

Methods: 2013 Youth Risk Behavior Survey (YRBS) data was analyzed for this research study. YRBS is a national school-based survey conducted by the Centers for Disease Control and Prevention (CDC) and state, territorial, and tribal governments. YRBS is designed to collect data on a wide range of health-risk behaviors that contribute to the leading causes of death, disability and social problems among representative samples of high school students across the US. The 2013 YRBS data were used for this study because they were the most recently available data. Bivariate and multivariate analyses was performed on the data. There were three dependent variables for this study: suicide ideation, violence and safety. Violence and safety were computed variables. The independent variables were: alcohol use, substances abuse (cocaine, ecstasy, hallucinogens, heroin, glue/inhalants, synthetic marijuana, methamphetamines, steroids and prescription drugs without a prescription), age (14-18 years), sex, grade (9th-12th grade, ungraded or other grade), race/ethnicity (Hispanic, African American, Caucasian, or Other). The three dependent variables were used to test three logistic
regression models examining their association with the independent variables. Statistical Package for Social Scientists (SPSS, IBM, Chicago, version 24.0) was used to conduct the analyses. For all analyses alpha was set at less than or equal to 0.05. The Institutional Review Board (IRB) at the researchers’ institution does not require human subject’s oversight for the analysis of de-identified data.

Poster Title: Incidence of dermatologic side effects in patients using epidermal growth factor receptor (EGFR) inhibitors at a large urban safety net hospital

Primary Author: Aimee Cooke, Hennepin County Medical Center, MN; Email: aimee.cooke@hcmed.org

Additional Author(s):
Lynn Weber
George Konstantinides
Shannon Reidt

Purpose: To determine the time to and rate of cutaneous reactions in oncology patients using epidermal growth factor receptor (EGFR) inhibitors. Secondary measures to include dose reductions, therapy discontinuation, and an evaluation of treatment for cutaneous reactions.

Methods: This a retrospective chart review of oncology patients seen in the Hennepin County Medical Center outpatient Cancer Clinic on EGFR inhibitors. These patients will be stratified into three groups for cutaneous reaction presentation: early presenters (less than two weeks into therapy), late presenters (between 2 and four weeks into therapy) and delayed presenters (greater than 4 weeks into therapy). Patients will be evaluated based off of their severity of reaction and placed into four groups as seen in the categorization of the Multinational Association of Supportive Care in Center (MASCC) guidelines (grade one through four). The following data will be collected: patient age, gender, ethnicity, smoking history, days on EGFR inhibitor, cancer diagnosis, complete chemotherapy regimen, reported adverse reactions, and time to incidence. Providers’ notes will be reviewed to determine the severity of reaction, duration of reaction, and the treatment regimen for the cutaneous reaction (antibiotics, topical creams), including any dose reduction in the EGFR inhibitor or medication discontinuation. Treatment given for cutaneous reactions will be compared to the MASCC guidelines to compare both time to treatment and the appropriateness of the treatment given. This study has been submitted to the Minneapolis Medical Research Foundation Institutional Review Board for approval.

Poster Title: Evaluating the incidence of leukopenia and neutropenia in renal transplant patients after replacement of cyclosporine with tacrolimus in immunosuppression protocol

Primary Author: Kassandra Fabbri, Hennepin County Medical Center, MN; Email: kassandra.fabbri@hcmed.org

Additional Author (s):
Tracy Anderson-Haag
Anne Spenningsby
George Konstantinides
Shannon Reidt

Purpose: Medications used in solid organ transplant may cause bone marrow suppression which often leads to dose reductions of immunosuppression or antiinfective prophylaxis, potentially predisposing kidney transplant recipients (KTRs) to rejection or infection. Evidence demonstrating prolonged graft survival and decreased rejection with tacrolimus over cyclosporine prompted a shift in the transplant immunosuppression protocol at a large safety net hospital. The risk of bone marrow suppression with tacrolimus versus cyclosporine in combination with guideline-recommended immunosuppression is unclear. This study will compare incidences of leukopenia and neutropenia in KTRs treated according to the retired cyclosporine-based protocol versus the tacrolimus-based protocol.

Methods: This study is pending Institutional Review Board approval. A retrospective review of two groups of adult KTRs - one cohort treated according to the previous cyclosporine-based immunosuppression protocol and one cohort treated according to the current tacrolimus-based protocol - will be conducted to compare rates of incident leukopenia (white blood cells less than 4000 cells per microliter) and neutropenia (neutrophils less than 1500 cells per microliter) within the first 12 months post-transplant. White blood cell and neutrophil counts will be collected at time of transplant, then according to the post-transplant follow-up timeline: two weeks, four weeks, three months, six months, nine months, and one year post-transplant. Additional data to be collected includes: comorbidities, serum creatinine, induction and maintenance immunosuppression, drug monitoring levels, donor and recipient viral status, transplant rejection incidence, and rate of infection. Compensatory dose reductions or
filgrastim administrations will be recorded for each leukopenic and neutropenic event. Reviewers will evaluate provider notes to determine temporal associations of medication changes, rejection episodes, or infections with leukopenia or neutropenia.

**Poster Title:** Evaluation of asthma medications for a large urban, safety net health-system formulary

**Primary Author:** Jill Spitzmueller, Hennepin County Medical Center, MN; **Email:** jill.spitzmueller@hcmed.org

**Additional Author (s):**
Mark Holtan
Shannon Reidt

**Purpose:** The healthcare system's mission is to ensure access to healthcare for patients regardless of their socioeconomic status. Patients without commercial insurance or who do not qualify for state insurance plans are eligible for the Hennepin County Discount plan, a program designed to reduce healthcare costs and cost to the patient, including medications. The Hennepin County Discount plan is in the early stages of formulary development based on cost and effectiveness of medications. The objective of this study is to evaluate the cost and effectiveness of asthma medications to identify those most appropriate for formulary inclusion at this 340B health system.

**Methods:** This project has been submitted to the Institutional Review Board. Patients who are currently enrolled in the Hennepin County Discount plan and have a prescription for a long-acting beta agonist and/or active corticosteroid inhaler will be included in the study. Electronic health records will be reviewed for each patient to evaluate efficacy of asthma medications. Efficacy will be determined by number of emergency department visits related to asthma within the past year, asthma control test scores, asthma medication refill history, and number of prednisone courses for asthma exacerbations within the past year. The cost of the asthma medications will be determined by reviewing drug prices available through the hospital’s supplier. After the data has been collected, asthma experts will be consulted to review data and offer their clinical perspective based on expertise and literature.

**Results:** N/A

**Conclusion:** N/A
Purpose: The Comprehensive Addiction and Recovery Act calls for the development of methods to monitor opioids due to an increase in related addiction and fatalities. Differences in potency make it difficult to monitor patients on more than one opioid concurrently. Using morphine equivalents (ME) could standardize monitoring of these patients. However, there are a lack of techniques to incorporate this information into large datasets. This study mapped ME to the national drug specific terminology, RxNorm. A dataset of outpatient opioid prescriptions from orthopedic surgery visits was tested to demonstrate the validity of using RxNorm to incorporate ME into monitoring projects.

Methods: A dataset of outpatient opioid prescriptions containing drug name, quantity dispensed, frequency, and dose was queried for 7290 orthopedic surgery visits from 05/01/2015 to 05/31/2016 across 12 Minnesota hospitals via an enterprise data warehouse. The drug name for each prescription was sent to RxNorm’s RESTFUL RX API using the jsonlite package in R statistical software. Analysis of the approximate match values and common term types (TTY) for the top four RxNorm concept unique identifiers (RXCUI) returned for each drug name was performed. This allowed us to establish rules for string manipulation and supplementation of required information from the dataset. The Centers for Disease Control and Prevention (CDC) opioid conversion factors were then mapped to the identified RXCUIs based on ingredient and route. The dataset of outpatient opioid prescriptions was queried through RxNorm and ME were calculated for each prescription. Validation of ME was performed on 100 randomly selected prescriptions from the dataset and compared against manual ME calculations. This study was reviewed by Allina Health’s institutional review board.

**Poster Title:** Designing a heparin dosing protocol in ventricular assist device patients

**Primary Author:** David Green, Mercy and Unity Hospitals, MN; **Email:** david.green2@allina.com

**Additional Author (s):**
Jessica Swearingen
Ashley Philibert
Chris Davison

**Purpose:** Since their development in the early 1990’s, ventricular assist devices (VADs) have fast become a standard practice for use in patients who require hemodynamic support for conditions such as end-stage heart failure or cardiogenic shock. Due to an increased risk of thrombosis during the time a patient has a VAD implanted, the manufacturer recommends systemic anticoagulation with heparin. However, there are currently no standard dosing protocols or policies to follow when determining anticoagulation for VAD patients which can make managing anticoagulation difficult. This study will help guide pharmacists in determining appropriate anticoagulation for patients with VADs.

**Methods:** The study will be submitted to the Allina Health Institutional Review Board for review. The electronic medical record system will be used to identify patients at Mercy Hospital that have had a VAD implanted between January 2013 and August 2016. Patient charts will be reviewed for heparin doses, aPTT levels, evidence of adverse events (e.g. bleeding), and evidence of thromboses during their hospital stay. Recent literature evaluating anticoagulation in patients with a VAD will be reviewed to determine optimal heparin dosing. Our internal practices will be compared to the literature to characterize opportunities for improvement and guide future heparin dosing in patients with ventricular assist devices.

Poster Title: Ketamine use in a community hospital: Dosage and safety evaluation

Primary Author: Rebecca Wienbar, Mercy Hospital, part of Allina Health, MN; Email: rebecca.wienbar@allina.com

Additional Author(s):
Justin Hora
Jenna Phelps
Jessica Tonder
Jessica Swearingen

Purpose: Ketamine is an FDA approved anesthetic agent and is classified as a high-risk medication by the Institute for Safe Medication Practices (ISMP). Ketamine is also used off-label for indications including analgesia (acute/chronic pain), procedural sedation/analgesia, and depression. A lack of optimal dosing guidelines for off-label indications, in addition to potential safety concerns, may lead to underutilization and/or sub-therapeutic dosing. The objective of this study is to evaluate current prescribing patterns of ketamine, as well as to evaluate patient safety outcomes, at a community hospital. This study will help guide ketamine dosing, administration, and monitoring for physicians, nurses, and pharmacists.

Methods: The study will be submitted to the Institutional Review Board for review. The electronic medical record system will be used to identify patients on two campuses of a community hospital who received intravenous or intramuscular ketamine during their admission from August 1, 2015 to July 31, 2016. Patient charts will then be reviewed, and the following data will be collected: ketamine dosage, route of administration, dosing frequency, indication for use, patient care area, premedication use, concomitant pain medication use, pain scores, and patient age. Safety outcomes will be assessed by reviewing patient charts for vital signs (blood pressure, heart rate, respiratory rate, oxygen saturation) prior to administration, 30 minutes after administration, and 4 hours after administration. Patient charts will also be reviewed for mention of significant psychotomimetic effects (hallucinations, bad dreams), sedation/RASS scores, and any other notable tolerability issues. This data will be analyzed and compared with current literature.

Poster Title: Empiric antibiotic therapy selection in penicillin-allergic patients presenting with sepsis: a quality improvement needs assessment

Primary Author: Benjamin Yun, Methodist Hospital - Park Nicollet Health Services, MN; Email: benjamin.yun@parknicollet.com

Additional Author (s):
Galina Shteyman
Anne Schullo-Feulner

Purpose: Penicillin is one of the most commonly reported medication allergies, but only a small percentage of patients will truly develop a life-threatening hypersensitivity reaction. A noted penicillin allergy results in limited treatment options and increases the utilization of broad-spectrum antibiotics such as carbapenems. Overuse of such agents is concerning due to growing rates of bacterial resistance and the associated higher rates of mortality. The aim of this project is to assess the appropriateness of antibiotic selection based on allergy documentation, identify areas for improvement, and examine opportunities available to further promote antimicrobial stewardship.

Methods: Park Nicollet Methodist Hospital, part of Health Partners, is a 426-bed community hospital located in Saint Louis Park, Minnesota. A retrospective chart review will be performed using Methodist Hospital’s electronic medical record. Patients will be identified for potential inclusion if admitted to the hospital between March 1st, 2016 and August 31st, 2016 with a diagnosis of sepsis using the 10th revision of International Classification of Diseases (ICD-10) codes. Search codes will include sepsis (A41.50, A41.59, A41.9, R65.20) and bacteremia (R78.81, R78.89). Patients will be included if they are 18 years or older, have a documented penicillin allergy, and were prescribed meropenem or ceftazidime. Patients will be excluded if they did not provide consent for use of medical records for research projects, are pregnant, or were admitted to the intensive care unit. The following information will be gathered: gender, age, diagnosis, days of therapy, reported penicillin reaction or intolerance, date of noted penicillin allergy, history of prior beta-lactam use, indications for use, emergency department admission, primary service/medical unit (i.e., clinical team caring for the patient), additional/changes in antibiotics given after antibiotic therapy was initiated, culture results and sensitivities.
Appropriateness of antibiotic selection will be based on the documented allergic reaction, severity of hypersensitivity, and prior history of antibiotic use. This needs assessment evaluation is pending approval from Health Partners Institutional Review Board.

Poster Title: Development and feasibility of a pharmacist-hospitalist collaboration to improve medication utilization at a community hospital: a medication safety improvement pilot.

Primary Author: Chrissy Czychalla, Methodist Hospital - Park Nicollet Health Services, MN; Email: cpflugi@umn.edu

Additional Author (s):
Anne Schullo-Feulner
Abby Von Ruden

Purpose: The purpose of this quality improvement project is to develop, pilot and evaluate a pharmacist-hospitalist collaboration intended to improve safe medication utilization at a community hospital. The hospitalist department has advocated for additional pharmacist support, however, the responsibilities and feasibility of this role have not been established. This project will define the scope and focus of a pharmacist-hospitalist collaboration resulting in standardized work approved by both pharmacy and hospitalist department leaders. The resulting role will be piloted for feasibility and efficacy.

Methods: The methods for this project will follow the ‘Plan-Do-Study-Act’ model for quality improvement. In the initial ‘Plan’ phase, both pharmacists and hospitalists will be asked to voluntarily complete needs-assessment surveys regarding desired clinical interventions. The ‘Do’ phase will consist of drafting standard work that defines the scope and focus of a pharmacist-hospitalist collaboration based on compiled survey results data. The drafted standard work will be revised and approved by both pharmacy and hospitalist department leadership. During the ‘Study’ phase, the finalized standard work will be trialed by a pharmacist in a 4-week feasibility pilot. The feasibility pilot will include: implementing processes, documenting clinical interventions, and tracking allocation of time. Documentation of pharmacist time and clinical interventions will be done through iVent messages in the hospital’s electronic medical record. Clinical interventions will include the following standard of care practices: medication reconciliations, corrections to prior to admission medication lists, patient education, referrals to medication therapy management services, recommendations for medication therapy optimization, corrections to patients’ discharge after visit summary, and additional needs identified from the survey results data. The project will conclude with the ‘Act’
phase, during which feasibility pilot data will be assessed and opportunities for process improvement will be identified. The project will result in revised standard work for a pharmacist-hospitalist collaboration intended to improve safe medication utilization at a community hospital.

**Poster Title:** Utilizing rapid pathogen identification technology and a standardized clinical decision algorithm for antimicrobial stewardship decisions in patients with bacteremia  

**Primary Author:** Natalie Kravchenko, North Memorial Health Care, MN; **Email:** natalie.kravchenko@northmemorial.com  

**Additional Author(s):**  
R. Todd Burkhardt  
Emily Herstine  

**Purpose:** The FDA approved the multiplex, automated, molecular diagnostic test Verigene, which identifies twelve Gram-positive (GP) organisms, eight Gram-negative (GN) organisms, and nine associated resistance markers from positive blood cultures, with a turnaround time of approximately three hours. The utility and cost-effectiveness of such testing depends on time to physician action on reported results. The objective of this study was to evaluate the combined impact of rapid diagnostic testing and real-time antimicrobial stewardship interventions guided by a clinical decision algorithm outlining the most appropriate treatment choices for isolated pathogens in the management of patients with bacteremia.  

**Methods:** The study was prospectively conducted between February 1, 2016, and March 31, 2016. All patients ages 18 and older who had positive blood cultures with GP or GN microorganisms identified by Verigene were included in the intervention group. Per study protocol, all positive Verigene results were phoned in to pharmacists, who then notified physicians of the blood culture results and provided antibiotic recommendations based on the clinical decision algorithm approved by the hospital’s antimicrobial stewardship team. The primary outcome was the average time to targeted antimicrobial therapy. Secondary outcomes were lengths of hospital and intensive care unit (ICU) stays. Outcome results were compared to a historical control group of patients hospitalized at our facility between February 1, 2014, and March 31, 2014, with GP and GN positive blood culture isolates identified by conventional methods. It was determined that a sample size of 70 patients (35 patients in each group) would allow to detect an average 12-hour reduction to targeted antibiotic therapy with a power of 80 percent and an alpha value of 0.05, utilizing a two-sample t-test. The study protocol was granted exempt status by the institutional review board.
**Results:** The control group and intervention group consisted of 70 and 81 patients, respectively. Forty four patients (62.9 percent) in the control group and 50 patients (61.7 percent) in the intervention group had their antimicrobial therapy adjusted based on the blood culture results and continued on targeted therapy. These patients were included in the primary and secondary outcome analysis. Patients who continued on the same antimicrobial therapy (21.8 percent in control group and 22.9 percent in intervention group) or required broadened coverage after initial de-escalation (7.1 percent in control group and 9.9 percent in intervention group) were included in the ICU length and hospital length of stay analysis, but not in the primary outcome. Average time to targeted antimicrobial therapy was significantly reduced in the intervention group (45.67 vs. 20.8 hrs; p less than 0.001). There was not a statistically significant difference between the control and the intervention group in length of stay in the ICU or hospital. Mortality was similar between groups (7.1 percent vs 8.6 percent, p equals 0.916).

**Conclusion:** Our study demonstrated that rapid pathogen identification and real-time pharmacist intervention guided by the clinical decision algorithm can significantly reduce time to targeted therapy in the majority of patients without negatively affecting clinical outcomes.

Poster Title: Delirium in the Intensive Care Unit (ICU): A Healthcare Team Collaboration for Prevention and Management

Primary Author: Carrie Spindler, North Memorial Health Care, MN; Email: carrie.l.spindler@gmail.com

Additional Author(s):
Maggie Yurek
Mary Foss

Purpose: Medications known to cause delirium or that are associated with delirium development will be identified and tracked to determine opportunities to improve patient care in the ICU. The objective of this study, in collaboration with an interdisciplinary team, is to develop a proactive, pharmacy-driven approach to prevent and manage delirium in the ICU.

Methods: This is a single-center pilot project looking at patients in the cardiovascular and medical intensive care units. This project will consist of three phases: pre-consult, pharmacy delirium consult, post-consult. The primary efficacy outcome will be delirium free days, defined as the number of days in hospital without a CAM-ICU positive score. The secondary outcomes will include ICU length of stay, hospital length of stay, duration of mechanical ventilation, and falls. The data from the pre-consult and post-consult phase will be compared and analyzed. Pre-consult: ICU patients eligible for inclusion in the study would have a retrospective chart review done to gather data for analysis. Pharmacy delirium consult: ICU patients eligible for inclusion in the study will have a medication history review of both inpatient and pre-hospital medications, as well as compliance assessment. A progress note will be completed with any discrepancies and medication changes will be recommended that may decrease the incidence of delirium or shorten the duration if delirium has already occurred. Post-consult: The post-consult phase would include a retrospective chart review on the patients that received the delirium consult, once discharged.

Poster Title: Review of treatment selection and duration of therapy for Clostridium difficile at a community level one trauma center

Primary Author: Nicole Buuck, North Memorial Medical Center, MN; Email: nicole.buuck@northmemorial.com

Additional Author(s):
Emily Herstine

Purpose: In 2011, Clostridium difficile infection (CDI) was estimated to cause at least half a million infections in the United States. Of those that develop CDI, there were 83,000 patients that experience at least one recurrence. The Infectious Disease Society of America (IDSA) guidelines for CDI provide treatment recommendations based on severity of disease, initial occurrence and recurrence of infection. The purpose of this review of treatment selection and duration of therapy for patients with CDI is to assess the adherence to the IDSA guidelines.

Methods: A literature review and medication use evaluation will be used to assess the treatment selection and duration of therapy for patients with CDI in accordance with the IDSA guidelines. A sampling of data will be reviewed from a medication use evaluation from April 1st, 2016 through June 30th, 2016. Patients > 18 years of age, admitted to the hospital and diagnosed with CDI will be included in this review. A diagnosis of CDI will be tied to ICD-10 code of A04.7. Patients will be excluded if they have an allergy or other contraindication(s) to the recommended treatment per the IDSA guidelines. Parameters for adherence assessment will include white blood cell count (wbc), serum creatinine (Scr), timing of symptom onset, initial episode versus recurrent episode of CDI, severity of disease defined by leukocytosis with a wbc ≥ 15,000 cells/mL or Scr level ≥1.5 times the premorbid level, Clostridium difficile toxin polymerase chain reaction (PCR) result, treatment selection, duration of therapy, and prior antibiotic use within 28 days. Additionally, a CDI order-set will be developed and implemented for these patients, which will include pharmacist-led education to provider groups on current IDSA guidelines and order-set utilization. An evaluation will be conducted after implementation of the CDI order-set and education to providers to assess for changes in adherence to the IDSA guidelines in order to optimize CDI treatment.

Poster Title: Tranexamic Acid Protocol Completion Rates of Trauma Patients Presenting by Emergency Medical Services to a Community Level-One Trauma Center

Primary Author: Emily Grgic, North Memorial Medical Center, MN; Email: emily.grgic@northmemorial.com

Additional Author(s):
John Lyng
Mary Foss

Purpose: Current evidence suggests that tranexamic acid (TXA) confers a mortality benefit in adult patients with acute trauma and significant hemorrhage if given within three hours of injury. Studied dosing protocols include two-part dosing algorithm. This study is intended to determine the rate of protocol completion for patients in whom a TXA protocol is initiated by Emergency Medical Services and continued following arrival at a Level I Trauma Center.

Methods: This is a retrospective review of all patients transported by a single ambulance service to a single Level I Trauma center and who received tranexamic acid in the EMS and hospital settings. The following data points were abstracted from EMS and hospital charts: patient demographics, mechanism of injury, vital signs, time of injury, and timing of TXA dosing. The primary endpoint was completion of the entire TXA protocol. Secondary endpoints included occurrence of vascular occlusive events and. The study period spanned from December 2014 to September 2016. This was IRB-approved.

Poster Title: A Case Series of Ketamine as an Analgesia Adjuvant in Trauma ICU Patients

Primary Author: Mary Walters, North Memorial Medical Center, MN; Email: walte305@umn.edu

Additional Author(s):
James Bischoff
Cory Evans
Mary Foss

Purpose: Ketamine, an N-methyl-D aspartate (NMDA) receptor antagonist, has been explored by the North Memorial Trauma Service as an analgesic adjuvant at low “sub-anesthetic” doses (0.1 mg/kg/hr continuous IV infusion) in pain management of Trauma ICU patients. Based on limited data, ketamine is thought to have opioid-sparing and favorable hemodynamic properties compared to some traditional pain management modalities and represents a promising therapy in this patient population. This case series highlights our experience with ketamine thus far.

Patient 1 was a victim of a motor vehicle crash with closed fractures of the sternum, transverse lumbar vertebrae 2 and 3, and bilateral ribs 3-5. His pain management consisted of acetaminophen, oxycodone, and hydromorphone PCA. Despite these interventions, the patient’s pain was uncontrolled with a mean 24-hour Numeric Pain Scale (NRS) Score of 6.5 and worst reported pain of 8. Ketamine continuous infusion at sub-anesthetic doses listed earlier was initiated, and the patient’s mean reported NRS decreased to 4.33 with a worst reported pain of 6. Total 24-hour opioid consumption also decreased from 230 mg to 160 mg morphine equivalents. Richmond Agitation-Sedation Scale (RASS) scores, heart rate, respiratory rate, and blood pressure were unchanged after initiation of ketamine. The patient’s supplemental oxygen requirement, however, decreased from 10 L/hr via an oxymizer to 4L/hr via nasal cannula.

Another victim of a motor vehicle accident, Patient 2 had multiple fractures of the ribs, thoracic and lumbar spine, and facial bones and a subdural hematoma. Ketamine continuous infusion was started shortly after patient had been extubated to manage rib pain with a mean NRS of 4. Pain management prior to ketamine included: acetaminophen, hydromorphone, and a lidocaine patch. Mean NRS remained unchanged, but 24 hour opioid utilization decreased from 15 mg to 4 mg morphine equivalents. Blood pressure, RASS score, and heart rate, similarly,
remained unchanged after the initiation of the NMDA antagonist. Oxygen demands, however, increased due to the development of tension pneumothorax secondary to the patient’s trauma. Ketamine was discontinued in pursuit of comfort care. Even though intracranial pressures (ICP) were not measured while on ketamine, the patient exhibited no signs or symptoms elevated ICP (i.e. headache, nausea, vomiting, altered mental status, vision changes, etc.) while on or shortly after therapy.

Patient 3 suffered a traumatic brain injury, open nasal bone and vertebral fractures after an unhelmeted motorcycle crash. He was intubated and sedated on a midazolam drip due to aspiration, respiratory failure, and agitation. While weaning off the benzodiazepine, the patient remained distressed, and thus ketamine continuous infusion was started to aid in pain management and reduce agitation. Again, vitals remained stable and unchanged after the intervention, but the patient became even more agitated with average RASS scores increasing from +1 to +3. Ketamine was subsequently discontinued along with midazolam and the patient was switched to propofol. Mean 24-hr Behavioral Pain Scores (BPS) were similar before and during the ketamine infusion, but 24-hour morphine equivalent utilization decreased from 22 mg to 9 mg. Again, ICP was not measured, but the patient exhibited no concerning symptoms of this potential risk with ketamine use in head trauma patients. Although further study is required to elucidate the utility of ketamine as an analgesic, these cases demonstrate promise for the NMDA antagonist as an adjuvant in pain management in Trauma ICU patients to reduce opioid utilization without altering cardiopulmonary function.

**Poster Title:** Establishing a creatinine clearance cutoff guideline for sucrose-containing intravenous immune globulin through medication use evaluation and retrospective chart review  

**Primary Author:** Brittany Hawke, Unity Hospital – Allina Health, MN; **Email:** brittany.hawke@allina.com  

**Additional Author(s):**  
Ross Fishman  
Jessica Swearingen  
Ashley Philibert  

**Purpose:** Intravenous immune globulin (IVIG) products are manufactured with varying sources of sugar stabilizers. Those manufactured with sucrose have been shown to contribute to acute renal failure, renal dysfunction, and osmotic nephrosis in patients susceptible to these adverse effects. Products produced without sucrose are available, but at an increased cost. In a time of exponential drug-expenditure growth, treatment costs must be minimized while maintaining patient safety. This study will determine the impact of sucrose-containing IVIG on patients developing acute kidney injury (AKI). This data will be used to create creatinine clearance (CrCl) cutoff guidelines for sucrose-containing IVIG.  

**Methods:** The study will be submitted to the Institutional Review Board for review. The electronic medical record system will be used to identify patients in four metro hospitals of one health-system who received sucrose-containing IVIG as inpatients between August 1, 2015 and July 31, 2016. Patients with a baseline serum creatinine (sCr) level obtained within 30 days prior to and within 72 hours after IVIG administration will be included in this retrospective study. Acute kidney injury will be defined as a sCr increase of 0.3 mg/dL or greater within 48 hours, or an increase in sCr of at least 1.5 times baseline within a seven day period. Baseline CrCl will be calculated for all subjects using the Cockcroft-Gault equation. Subjects will be divided into two categories: those who developed AKI while on IVIG, and those who did not. Baseline CrCl of these two groups will be compared to identify if there is a correlation between baseline CrCl and AKI development. In addition, chart review will be performed for subjects in the AKI group to identify possible risk factors that may have contributed to AKI development.

**Poster Title:** Are there population related disparities in patients who have attended outpatient rehabilitation after a heart attack or stroke?

**Primary Author:** Brittany Raymond, University of Minnesota College of Pharmacy, MN; **Email:** stevensb1213@gmail.com

**Additional Author(s):**
Lauren Hanson
Mary Heiken
Catherine Olson
Montana Hemling

**Purpose:** An estimated 935,000 US adults experience a cardiovascular event annually, and approximately 30 percent will experience a second one. Cardiac rehabilitation programs can reduce mortality, improve functional capacity, improve quality of life, and decrease the incidence of re-hospitalization for cardiac complications and overall medical costs. Despite the known benefits of cardiac rehabilitation, less than 30 percent of eligible patients participate in a cardiac rehabilitation program after a cardiovascular event. This research sought to answer the question: Are there population-related disparities in patients who have attended outpatient rehabilitation after a heart attack or stroke?

**Methods:** Using bivariate and multivariate techniques, a cross-sectional analysis of the 2013 Behavioral Risk Factor Surveillance Survey (BRFSS) data was performed. BRFSS data are collected using a random-digit dial telephone survey targeting adults 18-97 years of age. All BRFSS data are self-reported responses to mostly forced-choice questions. All analyses conducted for this study using BRFSS data were performed on weighted data. The weighting provides a stratified representation of the US adult non-institutionalized population and conforms to census data patterns. BRFSS includes both core modules and optional modules in the survey. In 2013, 17 states chose to collect data using the optional Cardiovascular Disease (CVD) prevention module. From the CVD prevention module, we were interested in data generated by questions regarding participation in cardiac rehabilitation. Inclusion criteria for the population examined were: male and female adults 18 years of age and older who had experienced either a heart attack or stroke. The dependent variable for this study was
participation in a cardiac rehabilitation program. The study covariates were: sex, age range, race/ethnicity, annual household income, education attained, health insurance status, and geographic location (rural/non-rural). Statistical Package for Social Scientists (SPSS, IBM, Chicago, version 24.0) was used to conduct analyses. The Institutional Review Board (IRB) at the researchers’ institution does not require human subject’s oversight for analysis of de-identified data.

Poster Title: Population level factors impacting appropriate monitoring of fasting plasma glucose in patients receiving second-generation antipsychotic medications

Primary Author: Lauren Hanson, University of Minnesota College of Pharmacy, MN; Email: ljhanson2@uwalumni.com

Additional Author (s):
Mary Heiken
Catherine Olson
Montana Hemling
Amber Soukkala

Purpose: Second-generation antipsychotics have been linked to metabolic syndrome or an increased risk of heart disease and diabetes mediated via risk factors including elevated blood sugar. The American Diabetes Association and American Psychiatric Association made specific monitoring recommendations with the use of second-generation antipsychotics, including a recommendation to annually monitor fasting plasma glucose in these patients. Research has shown limited application of this recommendation in practice, and to our knowledge, population factors impacting this choice have not been examined. We sought to discern what population-related factors played a role in the patient receiving the recommended annual fasting plasma glucose screening.

Methods: To answer the research question, 2012 National Ambulatory Medical Care Survey (NAMCS) data were analyzed. NAMCS collects data on the utilization and provision of ambulatory care services nationwide. These data are collected from a national sample of ambulatory care visits in primary care offices. The 2012 NAMCS data were used for this study because they were the most recently available data. These data were weighted to be nationally representative of patient health records. Bivariate and multivariate analyses were performed on the data. The study population was male and female adults 18 years of age and older who had been prescribed a second-generation antipsychotic medication (clozapine, olanzapine, risperidone, quetiapine, aripiprazole, ziprasidone). A multivariate logistic regression model was tested using had fasting plasma glucose screening in the past twelve months as the dependent
variable. The independent variables included in the model were: sex, race/ethnicity, payer source, provider type, and geographic locale (rural/urban) of the provider.

Poster Title: Identification of Naloxone Candidates through Concurrent Opioid and Benzodiazepine Use

Primary Author: Landon Weaver, University of Minnesota College of Pharmacy CentraCare Health - St. Cloud, MN; Email: landon.weaver@centracare.com

Additional Author(s):
Michael Akers
Keith Karsky
Sarah Weyer
Jessica Lind

Purpose: On March 18, 2016, the Centers for Disease Control (CDC) recommended clinicians consider offering naloxone when factors that increase risk for opioid overdose, such as history of overdose, history of substance abuse, disorder, higher opioid dosages, or concurrent benzodiazepine use, are present. Furthermore, the CDC recommended clinicians avoid prescribing opioids and benzodiazepines together whenever possible. The aim of this medication use evaluation is to determine the number of patients with an indication for naloxone based on concurrent opioid and benzodiazepine use at a family medicine clinic.

Methods: This study will be submitted to the Institutional Review Board for approval. Patients to be included will meet the following criteria: (1) receive primary care at the family medicine clinic between September 1, 2015 and August 31, 2016 and (2) have active prescriptions for both an opioid analgesic and a benzodiazepine. Electronic medical records will be analyzed to determine the number of patients with an indication for a naloxone prescription based upon their concurrent opioid and benzodiazepine use.

**Poster Title:** Improving transitions of care management (TCM) in a family medicine residency teaching clinic

**Primary Author:** Lara Kerwin, University of Minnesota College of Pharmacy PGY-1 Pharmacy Residency Program, MN; **Email:** lkerwin@umn.edu

**Additional Author (s):**
Chrystian Pereira

**Purpose:** Medication management is a key driver to prevent hospital readmissions. As medication experts of the healthcare team, pharmacists position themselves to identify, resolve, and prevent drug-therapy problems (DTPs) leading to hospital readmissions. However, there are many more drivers to TCM, including inpatient and patient-specific drivers. The Institute for Healthcare Improvement (IHI) Model for Improvement is a framework to identify and study these drivers. This project aimed to test how pharmacists apply this model and collaborate with other members of the TCM team to reduce 30-day hospital readmissions and reduce drug-therapy problems (DTPs) related for the reason to readmission over time.

**Methods:** Over a nine-month span of time, the aim of this continuous quality improvement initiative was to:
1) reduce 30-day hospital readmissions by 25%, and
2) reduce number of DTPs (per month) related to admission from baseline (since February 2016) by 75%.

The project took place in an urban family medicine residency-teaching clinic located in south Minneapolis, Minnesota. Patients included in the project were any patient discharged from any hospital and referred to clinic for a TCM visit from August 1, 2015 to April 30, 2016. A TCM visit consisted of a 20-minute medication therapy management (MTM) visit with a pharmacist and a 20-minute visit with a provider. MTM pharmacists (2) documented each patient encounter in RedCapTM, which detailed the number and severity of drug-therapy problems assessed and the interventions recommended or made during the MTM visit.

The IHI Model for Improvement served as the framework for which the project was organized. With stakeholders identified, a driver diagram was created to map the clinic’s existing TCM process. Subsequently, small tests of change on various drivers of TCM were initiated,
performed, and evaluated using “Plan-Do-Study-Act” (PDSA) cycles. The three main drivers tested were those of 1) MTM pharmacist availability, 2) patient understanding of care primary care plan, and 3) medication management prior to discharge.

**Results:** Over the nine-month study, MTM clinic pharmacists saw 143 patients for TCM visits. An average of two DTPs was found per visit with 295 DTPs found in total. Sixty-two percent (n=183) of all DTPs found required a healthcare professional intervention to resolve. Of patients scheduled for a TCM visit when an MTM pharmacist was not available, telephone contact with a pharmacist identified an average of 2.25 DTPs per patient. When a pharmacist called and spoke to patients (n=21) two weeks after the clinic TCM visit, an average of 1.71 DTPs remained; 58.3% of the DTPs found during these phone calls related to re-admission. Lastly, inpatient pharmacy teams were reluctant to begin TCM quality improvement initiatives due to staffing and budgetary constraints.

When compared to readmission data from the year prior to the study period, there was a 48.1% reduction in 30-day readmissions; this was found to be statistically significant (p < 0.0045). Forty-four percent of the total DTPs found were related to the reason for admission, with chronic conditions of asthma (6%), heart failure (5%), diabetes (5%), and COPD/pneumonia (15%) among the conditions with most admission-related DTPs. Identification of DTPs related to readmission increased over the course of the study period.

**Conclusion:** While a statistically significant reduction in 30-day readmissions was found, a cause-and-effect association between this finding and pharmacist interventions in this study cannot be made conclusively. However, patients appeared to benefit from contact with a pharmacist. A positive trend in data suggests that phone calls by a pharmacist placed two weeks after the clinic TCM visit reduced hospital readmissions for those patients. The success of this initiative identifies a valuable role that pharmacists can play in TCM processes to improve patient outcomes.
**Purpose:** Medications are often restricted to outpatient use when indicated for chronically managed conditions. These medications are infrequently utilized in the acute setting, but, if inappropriately administered, can incur significant and unnecessary financial burden. Limiting prescriptive authority of such medications can decrease incidence of inappropriate administration as well as lower unnecessary inpatient expenses. The purpose of this study is to evaluate appropriateness and financial impact of administering restricted outpatient medications before and after the implementation of a novel order policy.

**Methods:** The institutional review board approved this retrospective chart review analysis of subjects who received restricted outpatient medications while being managed on inpatient units. Subjects were identified through electronic medical record reporting for patients hospitalized at Morristown Medical Center and Overlook Medical Center. Baseline patient-related data collected includes age, gender, patient care unit, and time of discharge. Baseline treatment-related data collected includes the name, dose, route, and frequency of the restricted medication, time of administration, indication for treatment, cost of treatment, and if initiation or continuation of therapy. The primary outcome measures are time from administration to discharge and cost of therapy.

Poster Title: Evaluation of parenteral nutrition indications and adverse events in adult patients in two community teaching hospitals

Primary Author: Sonia Kothari, Atlantic Health System, NJ; Email: sonia.kothari@atlantichealth.org

Additional Author(s):
Timothy Lise
Frank Diaz
Douglas Bloomstein

Purpose: Nutrition support in adults is a complex and crucial aspect of patient care. Current guidelines recommend specialized nutrition support with enteral (EN) or parenteral nutrition (PN) for patients with inadequate oral intake for seven to fourteen days. PN has traditionally been indicated if EN is not feasible or will not provide adequate nutrition within seven days following admission. Initiation of PN is an invasive, multifactorial decision requiring assessment of the potential benefit prior to initiation. The purpose of this study is to evaluate PN indications and to assess glycemic variability, central line days and incidence of bloodstream infections in adults.

Methods: A retrospective chart review identifying hospitalized patients from January 2016 to August 2016 will be conducted in patients greater than or equal to 18 years of age receiving PN. Patients will be identified via the internal PN system at Morristown Medical Center and Overlook Medical Center. Patients will be excluded if they did not receive the ordered PN. The primary outcome is the number of days of inappropriate PN as defined by registered dietician assessment or the ability to receive or meet caloric goals with EN. Secondary outcomes include nutritional risk screening (NRS) score, total days of PN therapy, central line days, insulin requirements, and bloodstream infections. Baseline demographics will be evaluated as well as history of gastrointestinal or pancreatic disease, albumin, prealbumin, admission to the intensive care unit (ICU), and cost. This retrospective chart review was approved by the institutional review board.

Poster Title: Evaluating the appropriateness of tbo-filgrastim use in oncology patients in two community teaching hospitals: A retrospective review.

Primary Author: Tressa Joseph, Atlantic Health System, NJ; Email: treesa.joseph@atlantichealth.org

Additional Author(s):
Patrick Curtin
Timothy Lise

Purpose: Febrile neutropenia, a dose limiting toxicity of chemotherapy is a major complication associated with myelosuppressive therapy. National Comprehensive Cancer Network (NCCN) and American Society of Clinical Oncology (ASCO) guidelines recommend the use of granulocyte- colony stimulating factors (G-CSFs) to reduce the risk, severity and duration of febrile neutropenia. Inappropriate or prolonged use of G-CSFs may result in increased cost and adverse events such as bone pain, musculoskeletal pain, and flulike symptoms. The objective of this study is to evaluate the appropriateness of tbo-filgrastim use for the treatment or prophylaxis of febrile neutropenia within two medical centers.

Methods: A retrospective chart review will be conducted on 100 randomly selected hospitalized patients, greater than or equal to 18 years of age, receiving tbo-filgrastim from March to September 2016. Patients with an oncology related disease, receiving chemotherapy within 7 days, or with febrile neutropenia will be included. Patients receiving tbo-filgrastim for severe chronic neutropenia will be excluded. The primary endpoint is the percentage of patients receiving tbo-filgrastim for an appropriate indication. ASCO defines appropriate indications as prophylaxis of neutropenia in patients undergoing chemotherapy or treatment of febrile neutropenia defined as a neutrophil count less than 1,000 neutrophils/mcl with a temperature of greater than 38.3°C. The secondary endpoint is the percentage of patients in whom tbo-filgrastim therapy was appropriately discontinued. Additionally, the cost incurred from inappropriate therapy will be analyzed. All appropriate demographic data along with temperature, ANC, documented indication for use, type and date of chemotherapy, number of doses of tbo-filgrastim received, and strength of therapy will be collected. Descriptive statistics
will be used to summarize the results. This study has been approved by the institutional review board.

Poster Title: Clinical evaluation of ceftazidime-avibactam use in a community teaching hospital

Primary Author: Larissa Woloszczuk, Atlanticare Regional Medical Center, NJ; Email: larissa.woloszczuk@atlanticare.org

Additional Author(s):
Rebecca LaSpada
Nissy Varughese
Dominique Fields
Gemma Downham

Purpose: Ceftazidime-avibactam (CAZ-AVI) is approved for the treatment of complicated urinary tract infections (cUTI), including pyelonephritis, and when used in combination with metronidazole is also approved for the treatment of complicated intra-abdominal infections (cIAI). At Atlanticare Regional Medical Center (ARMC), CAZ-AVI use is restricted and requires an infectious disease (ID) consultation. The antibiotic is reserved for multidrug-resistant (MDR) infections, including carbapenem-resistant Enterobacteriaceae (CRE). The objective of this evaluation is to assess each case for appropriate antibiotic utilization, as well as clinical and microbiologic outcomes as a function of our antimicrobial stewardship program.

Methods: Institutional Review Board approval was obtained from ARMC prior to data collection. Patients were identified via a report from Discern Analytics in Cerner. All patients who received one or more doses of CAZ-AVI from July 2015 through June 2016 were included in this medication use evaluation. Nineteen patients were identified for evaluation. Each patient’s electronic medical record will be reviewed and data will be collected including patient demographics, pertinent past medical history, immune status, source of infection, culture and susceptibilities, concurrent infections, level of care, and length of stay. Appropriateness of use will be evaluated by assessing CAZ-AVI dosing regimens, duration of therapy, and reassessment of dosing throughout treatment duration. Patient outcomes will be evaluated for clinical and microbiological cures. Clinical cure will be defined by a resolution or improvement of infection, based on clinical variables, determined by the investigator on a case by case basis. Microbiologic cure will be defined as subsequent negative cultures when available. Thirty day readmission rates will be reported, particularly evaluating source of infection and culture
results. The results of this study will be used to assess the appropriateness of CAZ-AVI prescribing and efficacy of treatment.

**Poster Title:** Clinical and economic evaluation of intravenous ethacrynic acid utilization in a community teaching hospital  

**Primary Author:** Anhh Vo, Atlanticare Regional Medical Center, NJ; **Email:** anhh.vo@atlanticare.org  

**Additional Author (s):**  
Christopher Becker  
Kennara Sok-Vuong  
Ethan Nhan  
Joseph Reilly

**Purpose:** Patient allergies to sulfonamide antibiotics may lead to avoidance of non-antibiotic sulfonamides despite limited evidence for cross reactivity. Ethacrynic acid is a diuretic that does not contain the sulfonamide moiety, and is often used for patients with a sulfonamide allergy instead of loop diuretics, thiazides, or acetazolamide. The acquisition cost for intravenous (IV) ethacrynic acid increased, necessitating the need for stringent utilization. The objective of this study is to evaluate the use of IV ethacrynic acid in patients with documented sulfonamide allergies and the impact of pharmacy managed restrictions and education on ethacrynic acid at a community teaching hospital.

**Methods:** All admitted patients who received at least one dose of IV ethacrynic acid at our hospital from January 1, 2015 to August 31, 2016 were included in our evaluation. Patients were identified through a report generated from Discern Analytics in Cerner. Data collection included the nature of each patient’s sulfonamide allergy and date of allergy documentation, the specific drug causing the allergic reaction, and reaction severity. Patients were considered to have a severe reaction if they had one or more of the following: respiratory depression, urticaria, anaphylactic shock, edema, laryngeal spasm, upper respiratory tract hypersensitivity reactions, and angioedema. The ethacrynic acid dose and duration was recorded, as well as indication. Ethacrynic acid was removed from our computerized physician order entry system, requiring the provider to contact pharmacy to order the drug. A clinical pharmacist would then evaluate the order and assess for appropriateness prior to dispensing the medication. Costs of therapy will be evaluated, specifically before and after hospital staff education and ordering.
restrictions were implemented. The Institutional Review Board at Atlanticare Regional Medical Center granted approval for this project.

**Poster Title:** Clinical and financial evaluation of a 750 mg ceiling-dose telavancin regimen in obese patients

**Primary Author:** Brent Jenkins, Atlanticare Regional Medical Center, NJ; **Email:** brent.jenkins@atlanticare.org

**Additional Author (s):**
Shela DelosReyes
Emily Lanza
Joseph Reilly
Manish Trivedi

**Purpose:** Telavancin is a lipoglycopeptide antibiotic used for the treatment of gram-positive bacterial infections. Based on pharmacokinetic studies, obese patients achieve higher exposures of telavancin compared to non-obese patients, and target tissue drug levels exceed the minimum inhibitory concentration for gram-positive organisms several-fold throughout the dosing interval. Standard telavancin dosing is 10 mg per kg once daily. A maximum daily dose of 750 mg was employed at our community hospital to minimize toxicity without compromising the efficacy. The purpose of this study is to assess patient outcomes and financial impact of a maximum 750 mg telavancin dose in obese patients.

**Methods:** This retrospective evaluation included all patients with a body mass index (BMI) greater than or equal to 30 kg per meter squared, defined as obese, and a weight of 80 kg or greater, who had received at least one dose of intravenous telavancin 750 mg between June 2015 and July 2016. Patients were identified using a generated report from Cerner Discern Analytics. Medical records were reviewed for data including pertinent past medical history, indication for telavancin, level of acuity, length of stay (LOS), culture and susceptibilities, and concurrent infections. Previous antibiotic use, immune status, and adverse drug events were recorded. Both clinical and microbiologic outcomes were assessed. Clinical cure was defined as documented infection improvement based on clinical findings and investigator determination. Microbiologic cure was defined as subsequent negative cultures in evaluable patients. Cost savings were determined based on the cost difference between our capped 750 mg doses and a
10 mg per kg dose for each patient. The institutional review board at Atlanticare Regional Medical Center granted approval for this evaluation.

**Results:** Four patients with an average age of 57 years were evaluated. The average patient weight was 96 kg (range 81 to 116) and average BMI was 34 (range 30 to 41). All patients were treated on the general medical unit for indications including osteomyelitis, pneumonia, central line-associated bloodstream infection (CLABSI), and bacteremia. The average telavancin dose based on weight was 8 mg per kg (range 6.6 to 9.3). Patients remained on telavancin for an average duration of 8 inpatient days. One patient with methicillin-resistant Staphylococcus aureus (MRSA) osteomyelitis had a 74 day LOS until transferred to another hospital while on telavancin day 11, and subsequently lost to follow up. The average LOS for the 3 remaining patients was 17 days (range 9 to 28). Infections included methicillin-susceptible Staphylococcus aureus pneumonia, methicillin-resistant Staphylococcus epidermidis CLABSI, and MRSA bacteremia. No adverse effects were reported with telavancin administration. Clinical cure was achieved in all 3 evaluable patients. Microbiological cure was only evaluable in the CLABSI and bacteremia patients, with both having sterile blood cultures while receiving telavancin. The use of a 750 mg telavancin ceiling-dose resulted in a cost saving of 3,024 dollars for all 4 patients.

**Conclusion:** Utilizing a maximum daily 750 mg telavancin dose appears to be an effective and cost saving option in this retrospective evaluation of obese patients. Doses of telavancin lower than the standard dose of 10 mg per kg may be sufficient for some patients without compromising efficacy. Additional pharmacokinetic and clinical studies are warranted in obese patients weighing over 80 kg to further support the results of this small retrospective evaluation.

**Poster Title:** Impact of pharmacogenetic testing on reducing trial-and-error prescribing in a psychiatric patient population

**Primary Author:** Lauren Stummer, Barnabas Behavioral Health, NJ; **Email:** lauren.stummer@rwjbh.org

**Additional Author (s):**
Kim Walsh
Henry Leach

**Purpose:** Pharmacogenetic testing examines inherited gene variations that dictate drug response and explores ways that these variations can be used to predict whether a patient will have a good, bad, or no response to a medication. It is estimated that genetic factors contribute to 20-40% of differences in drug metabolism and response between patients. The goals of pharmacogenetic testing are to identify these factors and develop optimized treatment strategies to improve efficacy, while reducing adverse reactions. The purpose of this study is to quantify the significance and reliability of pharmacogenetic testing in an outpatient psychiatric population.

**Methods:** This study will be submitted to the Institutional Review Board for approval. Patients included in this study must be greater than 18 years of age and participate in outpatient psychiatric services provided through Barnabas Behavioral Health. Pharmacogenetic testing will be offered and administered based on prescriber recommendation. Samples obtained by the prescriber along with documentation of current medications will be sent by the pharmacy department to a third party laboratory for testing. Results will be available within two business days. Result reports will contain information regarding patient specific metabolism on current medications and multiple psychiatric medications. Medications will be categorized as low, moderate, or high genetic impact based on each patient’s gene variations. Interpretation of the results will ultimately be left to the prescriber's clinical judgment. Outcomes that will be measured are frequency of medication changes, severity of side effects, and rate of readmission. Results of patients participating in pharmacogenetic testing will be compared to a control group of patients not participating with similar baseline characteristics. Chart reviews will be completed to obtain data to measure outcomes. Investigators will rate severity of side
effects using the Monitoring of Side Effects Scale (MOSES). The fisher exact test will be used for the statistical analysis of medications changes. The two-sample t-test will be used to assess the frequency and severity of side effects and rate of re-admission.

Poster Title: Impact of a pharmacy monitoring service on glycemic control in patients with diabetes and mental health disorders

Primary Author: Stepan Uhlyar, Barnabas Health Behavioral Health Center, NJ; Email: uhlyar@nova.edu

Additional Author(s):

Purpose: Diabetes mellitus is the seventh leading cause of death in the United States and a major contributor of cardiovascular mortality. Diabetic patients with mental health disorders are at a higher risk for progressive complication due to the nature of their illness, poor adherence, metabolic effects of psychotropics, and barriers to healthcare. Medication optimization and control of glycated hemoglobin (HbA1C) have been shown to reduce microvascular complications of diabetes. The objective of this initiative was to assess the impact of pharmacy intervention on glycemic control in diabetic patients with comorbid mental health disorders in an acute psychiatric setting.

Methods: A pharmacy quality improvement initiative was approved by the institutional review board and implemented within an acute care inpatient psychiatric hospital. The pharmacy intervention consisted of the pharmacy resident or another clinical pharmacist providing daily patient monitoring and identifying optimization opportunities. Utilizing a real-time clinical surveillance program, 136 patients were identified and monitored between October 2015 and March 2016. The inclusion criteria consisted of patients aged 18 to 85 with at least one of the following: a diabetes diagnosis, concurrent anti-hyperglycemic medication or insulin, fasting blood glucose greater than 126 mg/dL, or HbA1C greater than 6.5 percent. During the statistical analysis, patients with less than 2 blood glucose readings were excluded. Current hospital practice served as the standard control for assessing the impact of the intervention. Primary outcome assessed glycemic control via the incidence of hyperglycemic events, defined as blood glucose readings greater than 200 mg/dL. Secondary outcome assessed the appropriateness of HbA1C monitoring and the incidence of hypoglycemia, defined as blood glucose readings less than 70 mg/dL. Chi square testing was utilized to assess the nominal data and unpaired 2-tailed student t-test was used for continuous data.
**Results:** A total of 137 patients were included in this analysis; control group (n equals 71) and pharmacy intervention group (n equals 66). Males consisted of 55 percent of the population, mean age was 60 years old, mean weight was 87 kg, 88 percent of the patients were diagnosed with type 2 diabetes, mean HbA1C was 7.8 mg/dL, and the most prevalent psychiatric comorbidities were schizophrenia, depression, and dementia. Twelve patients were excluded from statistical analysis due to a lack of more than one recorded blood glucose reading. In the primary outcome, the pharmacy intervention group had a statistically significantly reduction in the occurrence of hyperglycemic events versus control, 23.5 to 33.8 percent (p less than 0.005). Furthermore, the pharmacy intervention group demonstrated an absolute reduction in hyperglycemic events by 10.3 percent and a relative risk reduction of 31.1 percent. In the secondary outcome, HbA1C monitoring compliance had a statistically significant increase from 39.5 to 69.1 percent, (p less than 0.05) between the control and pharmacy intervention group, respectfully. There was no observed difference in the incidence of hypoglycemia between the two groups.

**Conclusion:** Implementation of a pharmacy intervention initiative reduced the number of hyperglycemic events and improved HbA1C monitoring compliance. The addition of a pharmacy-driven diabetes monitoring service may improve patient outcomes and bridge the gap between health disparities in patients with mental health disorders.

Poster Title: Impact of implementing an antimicrobial stewardship program in a community hospital

Primary Author: Casey Anzulavich, Cape Regional Medical Center, NJ; Email: casey.anzulavich@wilkes.edu

Additional Author(s):
Michael Brocco
Lauren McCarthy

Purpose: The Joint Commission has mandated antimicrobial stewardship standards with a focus on streamlining therapy and reducing antimicrobial resistance. This is in an effort to reduce inappropriate antimicrobial prescribing and preserve the utility of our current antibiotics. The purpose of this study was to determine the impact of the addition of an antimicrobial stewardship pharmacist to a community hospital. The primary objectives of this study were to compare time to initiation of appropriate antibiotics and time to de-escalation of therapy. The secondary objectives were to compare length of stay, antimicrobial cost, and renal dosage adjustments.

Methods: This retrospective chart review, approved by the ethics committee, included inpatients admitted from July 1, 2015 to September 30, 2015 and July 1, 2016 to September 30, 2016 with a diagnosis of urinary tract infection or bacteremia who received concomitant antibiotics. Patients were excluded if they were less than 18 years of age, length of stay less than 48 hours, or pregnant. The following baseline demographic information will be collected: age, gender, height, weight, serum creatinine, and admission diagnosis. The following inpatient data will be collected: antibiotic dose and duration, time from diagnosis to appropriate antibiotic administration, renal dose adjustments, urine and blood cultures, temperature, white blood cell count, and length of stay. Descriptive statistics will be used to analyze demographic data. Student’s t-test will be used to analyze total daily antibiotic cost, time from diagnosis to appropriate antibiotic therapy, time to appropriate de-escalation, and length of stay. Chi-square test will be used to analyze number of renal dosage adjustments.

Poster Title: Evaluation of phenytoin and fosphenytoin loading dose appropriateness in a community teaching hospital

Primary Author: Jenny Oh, Capital Health Regional Medical Center, NJ; Email: joh@capitalhealth.org

Additional Author (s):
Natalie Gofman
Daniel Abazia
Kim To
Chester Lau

Purpose: Phenytoin and fosphenytoin are hydantoin anticonvulsants used for partial and generalized tonic-clonic seizures. These antiepileptics present dosing challenges due to weight-based dosing, drug levels that are highly dependent on albumin, and Michaelis-Menten saturable kinetics. These complexities are often apparent in obese patients, who may receive loading doses of 1500 mg or greater, but the added effectiveness of doses over 1500 mg is questionable. Hypoalbuminemia can also present complicated dosing challenges. The objective of this study is to evaluate the appropriateness of phenytoin and fosphenytoin loading doses, with subgroup analyses focused on obese and hypoalbuminemic patients.

Methods: This retrospective, observational, single-center study has been submitted to the hospital institutional review board for exempt approval. Patients will be included in the study if they were (1) admitted as inpatient, (2) 18 years of age or older, (3) administered phenytoin or fosphenytoin loading doses between March 1, 2015 and February 29, 2016, and (4) had free phenytoin levels drawn, or total phenytoin levels with albumin levels drawn within 24 hours of the total phenytoin level. Total phenytoin levels will be adjusted based on the Sheiner-Tozer equation if free phenytoin levels are unavailable. De-identified data to be collected includes: demographic information, actual body weight, height, past medical history, concomitant medications, phenytoin and fosphenytoin doses and dosage forms, total and free phenytoin levels, albumin levels, and reports of seizure activity or adverse effects, if available. The primary objective of the study is to evaluate the appropriateness of phenytoin and fosphenytoin loading...
doses based on available drug levels, with a subgroup analyses focused on obese and hypoalbuminemic patients. The secondary objectives are to analyze the frequency of seizure episodes and adverse drug events related to phenytoin doses and levels. Categorical data will be reported as percentages and continuous data will utilize means, medians, and standard deviations.

Poster Title: Effect of midodrine on intravenous vasopressor usage in a community teaching hospital

Primary Author: Raj Kalaria, Capital Health Regional Medical Center, NJ; Email: rkalaria@capitalhealth.org

Additional Author (s):
Natalie Gofman
Doug St. John
Theresa Catalano-Christou
Michelle Drzewiecka

Purpose: Intravenous vasopressors are used to treat hypotensive patients who have not adequately responded to fluid resuscitation. Intravenous vasopressor doses are adjusted according to the patients’ hemodynamic stability. Midodrine is an alpha-1-agonist increasing arterial and venous tone. Its use may potentially decrease intravenous vasopressor requirements. Literature has suggested that midodrine can decrease intravenous vasopressor requirements in surgical intensive care patients and in the recovery phase of septic shock. The purpose of this study is to determine if midodrine use results in a decrease in the dose of intravenous vasopressors in our medical intensive care unit.

Methods: This retrospective observational cohort study was submitted to the hospitals’ institutional review board for exempt approval. Eligible patients, greater than or equal to eighteen years of age, using intravenous vasopressors (epinephrine, norepinephrine, phenylephrine, vasopressin, milrinone, dopamine, and dobutamine) and midodrine for hypotension in the intensive care unit will be identified by querying our electronic clinical information system from August 2015 to August 2016. Patients that did not receive midodrine for at least twenty-four hours will be excluded from the study. Information collected will include: patient age, gender, diagnosis, intravenous vasopressor(s) used, dosage of vasopressor given, duration of vasopressor therapy, dosage regimen of midodrine administered, duration of midodrine therapy, length of intensive care unit stay, and the length of hospital stay. The rate of the vasopressor infusion prior to midodrine administration will be compared to the rate of infusion twenty-four hours post midodrine initiation. Patient identifiers will not be recorded
and data will be stored in a secure and confidential manner on a password-protected computer.

**Poster Title:** Retrospective evaluation of deep vein thrombosis management in the emergency department

**Primary Author:** Liu Peng, Clara Maass Medical Center, NJ; **Email:** liujia.peng@rwjbh.org

**Additional Author(s):**
Mitesh Patel
Jennifer Sternbach
Mona Philips

**Purpose:** Deep vein thrombosis was traditionally managed in the inpatient setting but outpatient management is becoming a more preferred therapy option with the availability of direct oral anticoagulants. The recent 2016 therapy guidelines recommend outpatient deep vein thrombosis management over inpatient management when possible due to the fact that outpatient management does not increase the risk of bleeding, mortality, or recurrent venous thromboembolism. The purpose of this study is to analyze retrospective data to determine the number of patients admitted to the hospital for deep vein thrombosis treatment that were eligible for outpatient management.

**Methods:** This IRB approved study will involve a retrospective chart review of all the patients treated for deep vein thrombosis from September 2015 to September 2016. Patient charts will be pulled using ICD-9 and ICD-10 codes for types of uncomplicated deep vein thrombosis. These charts will be reviewed to determine if patients were potential candidates for outpatient deep vein thrombosis management. Pre-specified inclusion and exclusion criteria will be used to assess eligibility. Some specific exclusion criteria include, but are not limited to, presenting with co-existing illness requiring hospitalization, risk/history/current bleed, immobilization, contraindications to anticoagulation, and renal dysfunction. Patients who exhibited at least one of the exclusion criteria were not be eligible for outpatient management. The following data will be collected: length of stay, anticoagulant agent received, history of bleed/clot events, previous DVT, specific labs, age, sex, weight, liver disease, and deep vein thrombosis location. All data will be recorded without patient identifiers and maintained confidentially.

**Results:** Pending
Conclusion: Pending

Poster Title: Evaluating therapeutic appropriateness and safety of benzodiazepines on a geriatric unit of a community hospital

Primary Author: Priyanka Kelshikar, Clara Maass Medical Center, NJ; Email: priyanka.kelshikar@rwjbh.org

Additional Author (s):
Scott Price
Jennifer Sternbach
Mona Philips

Purpose: Benzodiazepine use has been frequently associated with a potential increase in adverse events in the elderly. Many geriatric patients receive similar drug therapy to younger counterparts creating potential risk for adverse events, particularly falls. Sites with nurses improving care for health-system elderly (NICHE) hospital status strive to address these issues and improve geriatric care. The objective of this study is to evaluate the current use of benzodiazepines in a geriatric unit of a NICHE recognized hospital and determine if there are areas for improvement of care in this population.

Methods: In order to assess the appropriateness of benzodiazepine use, a retrospective chart review will be done utilizing the medication appropriateness index, a 10-item validated tool for measuring therapeutic appropriateness of a specific drug regimen. In this IRB approved study, the chart review will be conducted on patients 65 and older who were prescribed benzodiazepines from November 30th 2015 through April 31st 2016. Each patient’s chart will be reviewed for medication appropriateness index score, length of stay, and adverse drug events to help identify key areas where pharmacy intervention will be most beneficial to improve and impact patient care.

Poster Title: Analysis of fidaxomicin use and clinical outcomes in the treatment of recurrent Clostridium difficile infection

Primary Author: Tara Hathaway, Community Medical Center, NJ; Email: tara.hathaway@rwjbh.org

Additional Author(s):
Nicole East
Jesse Sullivan
Jessica Nodzon
Joseph Cavanaugh

Purpose: The incidence and severity of recurrent Clostridium difficile infection (RCDI) has become increasingly challenging to prevent and manage. Because the pathological process of RCDI is complex and involves altered intestinal flora, toxin production, and weakened host immunity, there is no consistent reliable data to suggest effective therapy or firm consensus on optimal treatment. The objective of this study is to analyze the appropriateness and clinical outcomes of fidaxomicin versus the typical standard of care (metronidazole and/or vancomycin) in patients treated for recurrent C. difficile infection.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will be used to retrieve necessary information from all patients who had a positive stool toxin PCR assay and recurrent C. difficile infection from October 2012 to June 2016. The following data will be collected: patient age, gender, ethnicity, length of stay, location prior to admission, date of CDI diagnosis, antibiotic regimen, cost per case, broad-spectrum antibiotic use, anti-spasmodic use, anti-diarrheal use, and readmission for RCDI after completion of antibiotic regimen. Nurse and provider documentation will be reviewed to determine clinical and global cure. All data will be recorded into a standardized excel spreadsheet for analysis without patient identifiers and maintained confidentiality.

Poster Title: Formal Massive Hemorrhage Protocol Implementation and Associated Patient Care Outcomes

Primary Author: Matthew Fagnan, Englewood Hospital and Medical Center, NJ; Email: mfagnan@usj.edu

Additional Author(s):
Joseph Cruz
Jeff Nemeth
Aryeh Shander
Rina Ivanova

Purpose: Patients who present with a massive hemorrhage can develop complications that may worsen their prognosis, and have an increased risk of mortality. The objective of this study is to evaluate outcomes before and after implementation of a formalized massive hemorrhage protocol at a 520 bed community hospital.

Methods: Patients will be identified and reviewed using the McKesson® electronic medical system. Massive hemorrhage bleed for the purpose of this study is defined as when a patient is given 8-10 units of blood within 24 hours or 4-5 units of blood within 1 hour. All patient’s information will be kept confidential and no patient identifiers will be recorded during data collection. The primary endpoint will be 30 day inpatient mortality and the primary safety endpoint will assess late complications defined as respiratory failure, sepsis, thrombotic complications, and iron overloaded with the needed of a chelator. Chi square analysis will be used to compared the primary endpoint and if the number of patients studied is less than predicted than the fisher exact test will be used instead.

*Poster Title:* Impact of pharmacist-guided infliximab dose rounding in an outpatient infusion center  
*Primary Author:* Jiyeon Park, Englewood Hospital and Medical Center, NJ; Email: jiyeonpark1214@gmail.com  
*Additional Author(s):*  
Lauren Boutillier  
Joseph Cruz  
GaEun Joung  
Jeffrey Nemeth  

**Purpose:** Infliximab dose rounding is a commonly accepted practice across many institutions for cost containment. There is currently limited data on clinical and safety outcomes of this practice. The objective of this study is to determine whether pharmacist-guided infliximab dose rounding is clinically comparable to using exact dose in patients receiving infliximab for ulcerative colitis or Crohn’s disease and to identify the cost difference between the two dosing methods in an outpatient infusion center at a community hospital.  

**Methods:** A retrospective electronic chart review will be conducted to identify patients who received infliximab for ulcerative colitis or Crohn’s disease over a six-month period. The following data will be collected for analysis: age, gender, height, weight, vitals, dosage and frequency of infliximab, use of medications for infusion reaction or hypersensitivity, and reported adverse medication events. All data will be handled with confidentiality. The primary outcome will be increase in dose or decrease in dosing frequency as a surrogate marker for inadequate response to therapy. The co-primary outcome will be cost difference between dose-rounded and exactly-dosed infliximab. The secondary outcome will be time to dose increase or decrease in frequency. Safety analysis will include use of medications for hypersensitivity or other adverse effects. Descriptive statistics will be used to summarize the findings of the study. Chi-square test will be used for analysis of nominal data and a student t-test will be used for analysis of continuous data with parametric distribution. The study will be submitted to the Institutional Review Board for approval.

**Poster Title:** Assessment of susceptibility patterns of pathogens causing urinary tract infections in kidney transplant recipients

**Primary Author:** Terry Pak, Hackensack University Medical Center, NJ; Email: terry.pak@hackensackmeridian.org

**Additional Author (s):**
Michael Wynd

**Purpose:** Urinary tract infections (UTIs) are the most common bacterial infection in kidney transplant recipients (KTRs) during the first year post-transplant. Management of UTIs in KTRs is challenging due to their immunocompromised status, possibility of drug-resistant pathogens, and exposure to routine post-operative antimicrobial prophylaxis. The primary objective of this study is to identify the incidence of UTIs in KTRs within the first year after transplant and evaluate the susceptibility patterns observed.

**Methods:** This study will be submitted to the Institutional Review Board for approval. The electronic medical record will be used to identify adult KTRs who develop UTI within the first year post-transplant from May 1st 2013 to April 1st 2016. Data collected will include patient demographics, laboratory data, history of UTI and bladder dysfunction prior to transplant, immunosuppression (induction and maintenance), duration of indwelling catheter, presence of ureteral stent, date of UTI post-transplant, susceptibility pattern of isolated organism, antimicrobial prophylaxis empiric/definitive antibiotic treatment and duration, occurrence of delayed graft function, and patient and allograft outcomes. Data will be recorded and maintained in a protected database without patient identifiers. The primary endpoint is to identify the incidence of UTIs in KTRs within the first year after transplant and evaluate the susceptibility patterns observed. Secondary endpoints include patient and graft survival one-year post transplant. Data will be assessed with descriptive statistics.

Poster Title: Risk factors for vancomycin-induced nephrotoxicity in pediatric patients

Primary Author: Jennifer Cheng, Hackensack University Medical Center, NJ; Email: jennifer.cheng@hackensackmeridian.org

Additional Author(s):
Katelin Kimler
Pooja Shah

Purpose: Nephrotoxicity is a known complication of vancomycin therapy in the pediatric patient population. In several studies, the incidence of vancomycin-induced nephrotoxicity (VIN) has shown to increase with higher total daily doses and higher trough concentrations. In our institution, there is hesitancy to increase daily doses above 100 mg/kg/day or 4-grams daily in adults. There is also apprehension surrounding the use of every 6 hour dosing intervals in adolescent patients due to nephrotoxicity concerns. The objective of this study is to determine the incidence of VIN and evaluate potential risk factors for nephrotoxicity in the neonatal and pediatric patient populations.

Methods: This retrospective chart review will be submitted to the Institutional Review Board for approval. Electronic medical records will be used to identify pediatric inpatients less than 18 years of age who received at least 48 hours of vancomycin therapy. Patients will be excluded if their baseline serum creatinine (SCr) is above the normal level for their age group or lack initial and/or at least one follow-up SCr level. Data such as patient demographics, underlying illnesses, concurrent medications and vancomycin regimens will be collected. This study will analyze the rates of vancomycin-induced nephrotoxicity in the pediatric and neonatal patient populations. For pediatric patients, nephrotoxicity will be defined as an increase greater than or equal to 0.5 mg/dL in SCr values or 50 percent over baseline values, persisting for at least 48 hours. In neonates, nephrotoxicity will be defined as an increase in SCr greater than or equal to 0.3 mg/dL or 50 percent over baseline values continuing at least 48 hours. Secondary objectives will evaluate risk factors for nephrotoxicity including age groups, dosing intervals, underlying comorbidities, and rate of early versus late nephrotoxicity in the pediatric and neonatal cohorts. Rate of return of baseline renal function will also be evaluated.

Poster Title: Safety and efficacy of direct oral anticoaguants in multiple myeloma patients

Primary Author: Sheryl Mathew, Hackensack University Medical Center, NJ; Email: sheryl.mathew@hackensackmeridian.org

Additional Author(s):
Christina Howlett
Ruchi Jain
Joshua Richter

Purpose: Multiple myeloma patients are at high risk of venous thromboembolism (VTE) as well as bleeding complications, due to disease-related factors and chemotherapy agents. Direct oral anticoagulants (DOACs), which include rivaroxaban, apixaban, edoxaban, and dabigatran, are treatment options for VTE. However, current treatment guidelines do not support the routine use of DOACs in oncology patients because there is limited evidence. Nevertheless, DOACs are frequently prescribed in patients with multiple myeloma due to ease of dosing and administration and lack of routine monitoring. The objective of this study is to assess the safety and efficacy of DOACs in multiple myeloma patients.

Methods: We are conducting a retrospective chart review using the electronic medical record to identify multiple myeloma patients who received DOACs from June 2015 to June 2016. Prior to initiation, this study will be submitted to the Institutional Review Board for approval. Patients will be included if they are greater than or equal to 18 years old, have a diagnosis of multiple myeloma, and have been treated with a DOAC. Patients will be excluded if their sole indication for a DOAC is atrial fibrillation or if they received hemodialysis. The following data will be collected: patient’s age, sex, height, weight, serum creatinine, coagulation parameters, DOAC agent and dosing, multiple myeloma therapy, concomitant anticoagulant or antiplatelet agents, concomitant medications with potential drug-drug interactions with DOACs, incidence of VTE, and incidence of major and minor bleeding. All data will be recorded without patient identifiers and will be maintained in a password-protected database. Primary outcome will be incidence of bleeding (major and minor), and secondary outcome will be incidence of VTE. Descriptive statistics will be used to describe study results.

Poster Title: Evaluation of pain management prescribing patterns in a community teaching hospital

Primary Author: Nainy Kathuria, Hunterdon Medical Center, NJ; Email: nkathuria@hhsnj.org

Additional Author(s):
Ashmi Philips
Mini Varghese
Thom Nguyen
Navin Philips

Purpose: Pain management is a complex health care challenge. Prescription opioids have been a necessary part of pain management in hospitals however, these drugs also carry serious potential for misuse, addiction, overdose, and death. Despite many advances in pain treatment, opioids remain the mainstay therapy in relieving most types of pain with no associated organ toxicity when used appropriately. The purpose of the study is to evaluate pain management prescribing in an acute care community teaching hospital.

Methods: This is a retrospective study that will be conducted from June to September 2016. The patient population will include patients greater than 18 years of age, admitted to the general medicine floors, who received at least one dose of an oral or intravenous opioid medication. Exclusion criteria include patients admitted to the intensive care, behavioral health, or maternity units, post-surgical patients, patients on a patient controlled analgesia pump or on palliative care service. The primary outcome of the study is to evaluate the number of initial pain medication orders that include mild, moderate, and severe orders in hospitalized patients. The secondary outcomes are documented opioid status, types of pain medications, medication to pain score correlation, and interventions made by pharmacists. A data collection sheet will be utilized to collect patient demographics, pain scores, past medical history, and home and inpatient medications related to pain management.

**Poster Title:** New analysis of pharmacist renal dosing interventions (NEPHRI) study

**Primary Author:** Michael Casias, Hunterdon Medical Center, NJ; **Email:** mcasias@hhsnj.org

**Additional Author (s):**
Rani Madduri
Ashmi Philips
Mini Varghese
Thom Nguyen

**Purpose:** There are a myriad of medications that require dose adjustments in patients with renal insufficiency to prevent accumulation, which could lead to serious adverse events. Pharmacists play a vital role to ensure dosing of medications are appropriate based on indication and the patients clinical status. Institutions have therefore implemented policies for pharmacists to automatically adjust selected medications based on their current renal function. The purpose of this study is to evaluate pharmacist interventions on medications requiring dose adjustments for renal impairment.

**Methods:** This is a retrospective study that will be conducted from April to September 2016. The primary outcome is to assess the number of interventions pertaining to renal dose adjustments made by profiling pharmacists for select medications. Secondary outcomes include the number of follow-up interventions by pharmacists upon improvement in renal function and reasons for rejection of pharmacist recommendations by prescribers. Patients in the study will include those 18 years of age and older who received one of the following medications: meropenem, famotidine, ciprofloxacin, piperacillin/tazobactam, and ampicillin/sulbactam in the study time frame. Patients will be excluded if they have end-stage renal disease on dialysis, receive one-time study medication orders, or if they are admitted to behavioral health, maternity, or pediatrics. The hospital’s electronic medical record will be utilized to collect the following data: age, gender, height, weight, past medical history, serum creatinine, and blood urea nitrogen. Renal function will be calculated using the Cockcroft-Gault equation unless the patient is experiencing an acute kidney injury in which the modification of diet in renal disease equation will be used to assess renal function.

**Poster Title:** Evaluation of antibiotic de-escalation and ordering practices in a community teaching hospital  

**Primary Author:** Daniel Fitzgerald, Hunterdon Medical Center, NJ; **Email:** dfitzgerald@hhsnj.org  

**Additional Author(s):**  
Ashmi Philips  
Rani Madduri  
Navin Philips  
Thom Nguyen  

**Purpose:** Antibiotic stewardship encompasses a variety of initiatives to judiciously utilize antimicrobial agents. Practices such as prospective review after two to three days of admission serve to evaluate the need for broad-spectrum agents and provides opportunity to de-escalate therapy. At our institution, we have implemented a three day stop order for all intravenous antibiotics to help prompt re-evaluation of treatment options. The purpose of this study is to evaluate adherence to this initiative.  

**Methods:** This is a retrospective chart review of patients who received intravenous antibiotics from July to September 2016. The primary outcome is to determine how frequently antibiotics are being de-escalated on day three of therapy. The secondary outcome is to determine the frequency of the three-day duration of therapy leading to missed doses. Patients will be included if they are 18 years of age or older and received empiric intravenous antibiotics for three days. Patients will be excluded if they are pregnant or admitted to behavioral health or maternity units. The patient’s electronic medical record will be utilized to collect the following data: age, gender, renal function (creatinine clearance using Cockcroft-Gault equation), site of infection, culture and sensitivity results, and antibiotics administered. De-escalation will be identified by collecting data on duration of antimicrobial therapy, appropriateness of therapy based on cultures and sensitivities, and change in antibiotic, noting the day of antibiotic therapy that the change was made.

Poster Title: Novel oral anticoagulants (NOACs) in post-operative atrial fibrillation (POAF) following coronary artery bypass graft (CABG) surgery

Primary Author: Ammie Patel, Jersey Shore University Medical Center, NJ; Email: ammie.patel15@gmail.com

Additional Author(s):
Rachael Durie
Michelle Kohute
Patricia Greenberg

Purpose: POAF occurs in approximately one third of patients after CABG surgery. For risk reduction of stroke in patients with atrial fibrillation, guidelines recommend the use of oral anticoagulation. Patients with planned major surgery however, were excluded from clinical trials of the NOACs. The use of dabigatran, rivaroxaban, and apixaban for POAF is therefore controversial, but may offer significant advantages over warfarin including rapid onset and potential for earlier discharge, fewer drug interactions, and no coagulation monitoring requirement. The purpose of this study is to retrospectively evaluate the safety and efficacy of the NOACs in new onset POAF following CABG surgery.

Methods: This study is undergoing review for Institutional Review Board approval. A report will be obtained by retrospective chart review of CABG cases in which patients developed POAF following surgery. All charts from the two year study period will be accessed through the institution’s electronic medical record system and will be recorded without patient identifiers. The study population will only include cases of elective, isolated CABG surgery. Data collected will include baseline patient demographics, surgery and discharge dates, past medical history of myocardial infarction, stroke, hypertension, chronic kidney disease, diabetes mellitus, pre-operative history of atrial fibrillation, and occurrence of thrombotic or bleeding events. Patients who have an active hemorrhage or gastrointestinal ulcer immediately prior to surgery will be excluded. Anticoagulant related data to be collected includes post-operative start date, agent prescribed, NOAC dosing regimen, and bridging with parenteral anticoagulant. The primary endpoints of the study are stroke, systemic emboli, and bleeding events. Secondary endpoints are hospital length of stay following CABG surgery and 30-day readmission to any of the seven
hospitals in this health system. The authors hypothesize that there will be no difference in thrombotic events or major bleeding when comparing NOACs and warfarin, thus demonstrating efficacy and safety against the standard of care and offering more options for the anticoagulation treatment of POAF after CABG surgery.

Session-Board Number: 8-087

Poster Title: Dexmedetomidine at high doses for long-term continuous infusion in the pediatric intensive care setting

Primary Author: Jaclyn Palumbo, Jersey Shore University Medical Center, NJ; Email: jaclyn.palumbo@hackensackmeridian.org

Additional Author(s):
Anita Siu
Lisa Degnan
Patricia Greenberg
Yen-Hong Kuo

Purpose: Dexmedetomidine is a selective alpha-adrenergic agonist with sedative, anxiolytic and analgesic properties. Currently, it is FDA indicated for sedation for intubation, mechanical ventilation, and procedural sedation in non-intubated patients. Dexmedetomidine has a favorable side effect profile compared to other sedatives; however its use is only approved for no more than 24 hours. Several adult studies have demonstrated the safety and efficacy of dexmedetomidine for greater than 24 hours, but there is limited pediatric literature. This study was designed to determine the safety of dexmedetomidine at doses higher than 0.7 mcg/kg/hour for greater than 24 hours in critically ill pediatric patients.

Methods: The institutional review board will review this retrospective chart review for approval. The primary outcome includes the overall safety of high-dose dexmedetomidine continuous infusion in pediatric patients for greater than 24 hours. Safety will be characterized by both the value and time of changes in blood pressure or heart rate which are not within the normal range. Normal ranges will be based on the patients’ stature and weight-per-age percentiles as defined by the Centers for Disease Control and Prevention (CDC). Secondary outcomes will include: adverse events, need for drug discontinuation, and drug withdrawal symptoms. The following data will be collected: age, gender, height, weight, admission diagnosis, initial dose, maintenance and maximum dose of dexmedetomidine. Duration, method (wean or abrupt), reason for discontinuation, adverse events, blood pressure, heart rate and withdrawal symptoms will also be collected. The data will be analyzed to determine any observable decrease in blood pressure and heart rate with high doses of dexmedetomidine.
Continuous variables, such as blood pressure and heart rate will be evaluated using the Shapiro-Wilk test, and categorical variables, such as gender and adverse events will be tested using the Chi-square test.

Poster Title: Outcome Data for the Treatment of Klebsiella Pneumoniae Carbapenamase Urinary Tract Infections with Fosfomycin

Primary Author: Gregory Cabanas, Jersey Shore University Medical Center, NJ; Email: g.cabanas10@gmail.com

Additional Author(s):
Saira Chaudhry
Janine Louie
Marcus Flores
Patricia Greenberg

Purpose: Klebsiella pneumoniae carbapenemase (KPC) producing organisms are becoming increasingly prevalent, particularly as a cause of urinary tract infections (UTIs). These bacteria have limited treatment options and require the use of less conventional antibiotics, such as polymyxin. Fosfomycin, an antibiotic discovered over 40 years ago, has recently made a comeback as a treatment option for KPC UTIs. Fosfomycin has shown great in-vitro potential in treating KPC UTIs; however, in-vivo data is lacking. Therefore, this study would be one of the first to observe clinical outcomes in patients with KPC UTIs treated with fosfomycin.

Methods: The institutional review board will approve this retrospective observational study. Adults admitted to our institution with a KPC UTI (as verified by the modified Hodge test) and treated with fosfomycin from January 1, 2006 to July 1, 2016 will be included in the study. Patients will be excluded if they presented with KPC bacteremia from any pathogenic source. The primary endpoint is to verify the resolution of symptoms from a KPC UTI after initiation of therapy in the inpatient setting. Secondary endpoints include rate of discontinuation of fosfomycin therapy, rate of readmission for a KPC UTI within 60 days from beginning fosfomycin therapy, and number of days from the start of fosfomycin to resolution of symptoms. Evaluation of antibiotic therapy and resolution of symptoms will be performed by retrospective review of the patient chart and discharge medication history. Clinical outcomes of this study will be based on the resolution of symptoms and/or failure of therapy. Patients will be considered treatment failures if they had to be switched to a different antibiotic to treat the KPC or were readmitted to our institution for a KPC UTI within 60 days of the start of their
fosfomycin treatment. Patient data that will be collected includes but is not limited to patient demographics, medication history, and medications administered throughout the hospital course.

Poster Title: Evaluation of midodrine use on duration of vasopressor therapy and intensive care unit (ICU) length of stay in adult patients at a community hospital

Primary Author: Michael Ferenz, Kennedy University Hospitals, NJ; Email: m.ferenz@kennedyhealth.org

Additional Author(s):
Anthony Fryckberg

Purpose: Patients requiring ICU level of care are exposed to an environment with established elevated mortality risks inherent to the unit. Despite improvement, some patients remain in the ICU exclusively due to hemodynamic instability and require vasopressor support. Other patients may exhibit signs of vasopressor resistance prolonging their ICU stay. Midodrine is an oral alpha-1 agonist used at this institution to help wean patients off vasopressors and downgrade level of care. The purpose of this study is to determine if midodrine decreases both the duration of vasopressor therapy and ICU length of stay in patients requiring vasopressors.

Methods: This was an IRB approved retrospective chart review assessing the utilization of oral midodrine in ICU patients requiring vasopressors in a community hospital. Patients 18 years of age or older admitted to the ICU for more than 48 hours between October 1, 2015 and April 1, 2016, requiring vasopressors for more than 24 hours were included in the study. There were two comparator groups consisting of patients requiring vasopressors in the ICU who received at least three doses of scheduled midodrine, and patients requiring vasopressors who did not receive midodrine. Patients were excluded if they were taking midodrine prior to admission, received hemodialysis treatment of any kind, were taking any other oral vasopressor-like medication, or were ordered midodrine as needed. Information was collected from the electronic reporting system and included ICU time in, ICU time out, vasopressor start/stop times and dose, and midodrine start time, dose, and number of doses administered. Data was analyzed to determine number of vasopressor hours and length of ICU stay (days) based on the two comparator groups.

Poster Title: Comparison of ceftolozane/tazobactam to alternative therapy for treatment of multi-drug resistant Pseudomonas aeruginosa or extended-spectrum beta-lactamase infections.

Primary Author: Adam Penn, Kennedy University Hospitals, NJ; Email: a.penn@kennedyhealth.org

Additional Author(s):
Shereef Ali
Nikunj Vyas

Purpose: One of the largest challenges facing healthcare today is the evolution of multi-drug resistant (MDR) Gram-negative organisms such as Pseudomonas aeruginosa (PSA). Ceftolozane/tazobactam (CTZ) is a broad-spectrum cephalosporin antibiotic with activity against MDR PSA as well as extended-spectrum beta-lactamase (ESBL) Enterobacteriaceae. In March 2016, CTZ was added to the formulary at our institution to treat MDR organisms including MDR PSA. The purpose of this study is to evaluate the appropriateness and effectiveness of ceftolozane/tazobactam compared to alternative therapy in treating MDR PSA or ESBL infections.

Methods: This study is an Institutional Review Board approved retrospective evaluation of patients receiving ceftolozane/tazobactam for MDR PSA or ESBL infections. Inclusion criteria are patients admitted with age 18 years or older with documented PSA or ESBL infections receiving CTZ. These patients are matched based on age, sex, renal function and type of infection with patients who received alternative therapy. Patients are excluded if they are immunocompromised, pregnant, or had any previous exposure to CTZ. The primary outcome of the study is to evaluate appropriate therapy utilization of CTZ, which is achieved if institutional criteria and protocol are followed in prescribing CTZ. Subgroup analysis is conducted to evaluate clinical cure, length of therapy, and length of stay in lower respiratory tract infections. Clinical cure is defined as resolution of signs and symptoms with radiographic improvement or microbiological cure at the end of therapy. The secondary outcome of the study is in-hospital mortality and 30 day readmission. A pharmacoeconomic analysis is performed evaluating cost-comparison between the treatment groups.

**Poster Title:** Medication use evaluation of paliperidone palmitate intramuscular injection in a health system

**Primary Author:** David Lanza, Kennedy University Hospitals, NJ; **Email:** d.lanza@kennedyhealth.org

**Additional Author(s):**
Gregory Bogart

**Purpose:** The initiation of paliperidone palmitate intramuscular (IM) injection follows a specific protocol that is necessary to ensure the efficacy of the drug. The objective of this evaluation is to determine adherence to the institution’s approved initiation protocol of paliperidone palmitate IM injection.

**Methods:** This is an IRB approved retrospective chart review that will be conducted with patients admitted to our health system, who received paliperidone palmitate 234 mg and 156 mg IM injections, between October 1, 2014 and September 30, 2016. Medical record numbers of patients will be identified through the health system’s electronic reporting system. The following data will be collected: diagnosis at time of initiation, creatinine clearance (calculated via the Cockcroft-Gault equation), documentation of previous tolerability test with oral risperidone or paliperidone, patient’s insurance plan, administration date and time of both injections, location of the injection site, use of other antipsychotics concurrently with this drug (excluding as needed medications), ordering physician/service, and if the oral overlapping therapy was discontinued. All data will be recorded without patient identifiers and maintained confidentially. For each parameter, data will be sorted to determine the percent compliance with established medication use evaluation (MUE) criteria in accordance to the pharmacy and therapeutics committee approved protocol. Analysis and discussion to follow.

Poster Title: Evaluating the appropriateness of direct oral anticoagulants in patients with atrial fibrillation

Primary Author: Sajani Patel, Monmouth Medical Center, NJ; Email: sajani.patel@rwjbh.org

Additional Author(s):
Michelle Gardiner

Purpose: Direct oral anticoagulants (DOACs) are indicated for the management of non-valvular atrial fibrillation (NVAF) for patients with a CHA2DS2-VASc score of one or more. However, there are patients who are not treated or are prescribed incorrect dose of these agents leading to adverse effects. The objective of this study is to determine if patients with NVAF are on an appropriate anticoagulant and dose based on patient specific factors.

Methods: This retrospective study has been submitted to the Institutional Review Board and is awaiting approval. MedeAnalytics will be used with the electronic medical records to identify patients with a diagnosis of NVAF from June 2016 to August 2016. Data collected for each patient will include age, gender, weight, serum creatinine, and a CHA2DS2-VASc score. Electronic medical charts and medication administration records will be reviewed to evaluate if patients were treated with a DOAC during their hospitalization. The primary endpoint is to determine if these patients were on an appropriate dose of an anticoagulant and if they were appropriately treated based on the CHA2DS2-VASc score. To determine if patients were correctly treated, the data collected, documented medical notes for or against the use of anticoagulation, and the 2014 AHA/ACC/HRS Guideline for the Management of Patients with Atrial Fibrillation will be taken into consideration. The secondary endpoint is to look for evidence of treatment failure in these patients such as documented symptoms of stroke, gastrointestinal bleeds, or venous thromboembolisms to evaluate the appropriateness of their anticoagulant therapy. Descriptive statistics will be used to analyze the data.

Poster Title: Retrospective comparison of rapid loading of diazepam versus a lorazepam infusion for the management of severe alcohol withdrawal

Primary Author: Tulsi Shah, Monmouth Medical Center, NJ; Email: tulishah92@gmail.com

Additional Author(s):
Julie Saleh

Purpose: Benzodiazepines are the mainstay of treatment for alcohol withdrawal syndrome (AWS), however there are no set guidelines dictating a standardized treatment regimen. This study aims to compare two methods of managing severe alcohol withdrawal syndrome in critically ill patients: a lorazepam infusion versus rapid loading of escalating doses of diazepam.

Methods: This study has received IRB approval. A retrospective chart review will be conducted to collect data for patients at least 18 years of age who were admitted into the intensive care unit (ICU) for AWS and were managed on either a lorazepam infusion or rapid loading of escalating doses of diazepam. Data will be collected from medical records, medication administration records, progress notes, laboratory data, and discharge notes. The primary endpoint will be the ICU length of stay. The secondary outcomes include the total amount (mg) of each drug used, evidence of adverse drug reactions (changes in serum creatinine, increases in serum osmolality, decreases in serum bicarbonate level), and the use of adjuvant agents for management. Patient identifiers will be removed from collected data and limited to demographic qualifiers.

Poster Title: Impact of a pharmacist-managed antimicrobial stewardship initiative for intravenous to oral conversion at a large teaching institution

Primary Author: Seumsack Somtakoune, Newark Beth Israel Medical Center, NJ; Email: seumsack.somtakoune@rwjbh.org

Additional Author(s):
Kayla Torppey
Sheetal Patel

Purpose: Major regulatory agencies recently enacted conditions of participation requiring healthcare institutions to take an active role in antimicrobial stewardship. Although stewardship programs are comprised of several aspects, conversion of intravenous (IV) medications to the oral (PO) route is beneficial in reducing costs, increasing workflow, decreasing risk of line infections, and reducing discomfort. While our institution grants pharmacy the privilege to automatically convert certain agents from IV to PO, the documented activities performed remain few. The objective of this study is to evaluate the impact of targeted education on staff clinical pharmacists to convert eligible intravenous antimicrobials to equivalent oral formulations.

Methods: This study has been submitted to the Institutional Review Board for approval. In this single-center prospective review, all orders for IV formulations of azithromycin, doxycycline, fluconazole, levofloxacin, linezolid, and metronidazole for patients admitted to an adult inpatient service will be identified using a web-based, real-time clinical surveillance tool. Orders will be reviewed for automatic IV to PO conversion eligibility using inclusion and exclusion criteria set forth by a policy approved by the institution’s Pharmacy and Therapeutics Committee. A targeted one-on-one education will be provided to staff clinical pharmacists on evaluation of eligibility requirements, the mechanics around IV to PO conversions, and documentation of activities. Additionally, a pre- and post-education questionnaire will evaluate the pharmacist’s knowledge of the IV to PO policy and their satisfaction with the education provided. Post-education, staff clinical pharmacists will be performing IV to PO conversions daily for an allotted time. Two conversion activities per pharmacist per week will be evaluated, and feedback will be provided to ensure quality. Additionally, median time to conversion to oral
formulation and total cost savings will be evaluated. Data will be collected into spreadsheets and outcomes analyzed using descriptive statistics.

Poster Title: Evaluation of an educational intervention on adherence to the American College of Chest Physicians (ACCP) recommendations for initiation of anticoagulants in post-surgical patients

Primary Author: David Nardo, Newark Beth Israel Medical Center, NJ; Email: david.nardo@rwjbh.org

Additional Author(s):
Leena Kansagra
Sheetal Patel

Purpose: ACCP highlights the need to initiate anticoagulation in post-surgical patients who warrant therapy. Despite publication of guidelines and pressure from accrediting bodies to administer anticoagulation to surgical patients on the appropriate day, many institutions continue to display suboptimal compliance with ACCP recommendations. The purpose of this study is to evaluate the impact of pharmacist education on physician compliance with ACCP recommendations for initiation of anticoagulation in post-surgical patients and assess incidence of venous thromboembolism events and bleeding pre- and post-intervention.

Methods: This single centered educational study will include hospitalized surgical patients who are 18 or older, unless they are actively bleeding, pregnant, receiving palliative care, in a hypercoagulable state, undergoing transplant, on extracorporeal membrane oxygenation, have an implanted device, or length of stay less than 2 days. The following information will be collected from their electronic medical records (EMRs): demographics, length of stay, renal function, oncologic diagnoses, procedure, platelets, anticoagulant regimen and documentation of new VTE and bleeding following surgery. For the pre-education phase, 125 hospitalized surgical patients meeting the above criteria will be chosen randomly from a list of inpatient surgeries from October 15 to December 15, 2016. From December 15, 2016 to January 31, 2017 a brief educational session will be provided to physicians, supplemented by an anticoagulation pocket card. During the last two weeks of the educational phase, physicians will be contacted with therapeutic recommendations if discrepancies are found in anticoagulant orders for post-surgical patients. For the post-educational phase 125 hospitalized surgical patients meeting the above criteria will be chosen randomly from a list of inpatient surgeries from February 1 to April
30, 2017. Compliance rates with ACCP guidelines, appropriateness of anticoagulant regimen, and VTE/bleeding incidence will be compared before and after the intervention. This study has been submitted for review to the Institutional Review Board.

Poster Title: Impact of multidisciplinary antimicrobial stewardship intervention on appropriate discontinuation of antibiotics for early onset sepsis in the neonatal intensive care unit

Primary Author: Vaibhavi Bhavsar, Robert Wood Johnson University Hospital, NJ; Email: vaibhibhav@gmail.com

Additional Author(s):
Jessica Lise
Navaneeth Narayanan
David Sorrentino
Kaavya Rao

Purpose: Early onset sepsis occurs within the first 72 hours of life. Empiric antibiotic therapy commonly consists of ampicillin and gentamicin. In certain clinical situations, a third generation cephalosporin may be substituted. The American Academy of Pediatrics recommends discontinuation of antibiotics after 48 hours if the probability of sepsis is low. Prolonged antibiotic use in neonates is associated with an increased risk of late onset sepsis, necrotizing enterocolitis, and mortality. The purpose of this research is to assess the impact of the intervention on duration of empiric antibiotic therapy for early onset sepsis in the neonatal intensive care unit (NICU).

Methods: IRB submission is in progress for this before-and-after observational study. All NICU patients who received antibiotics for empiric therapy of early onset sepsis will be included. Baseline characteristics will be collected, including but not limited to: age, duration of antibiotics, culture results at 48 hours, and demographic data. A multidisciplinary approach will be utilized to create a protocol to guide decisions for discontinuation of antibiotics. The pre-intervention group, which will serve as a historical control, will include patients who received antibiotics prior to protocol implementation. The consecutive sample population following protocol implementation will be the post-intervention group. Post-intervention data will be collected and compared to the baseline data. This study will evaluate the impact of the intervention on the rate of appropriate discontinuation of antibiotics.

Poster Title: Clinical outcomes in patients with Staphylococcus aureus bacteremia and a blinded vancomycin minimum inhibitory concentration (MIC)

Primary Author: Shaili Adani, Robert Wood Johnson University Hospital, NJ; Email: shaili.adani@rwjbh.org

Additional Author (s):
Navaneeth Narayanan
Tanaya Bhowmick

Purpose: Recently, there have been several inconsistent analyses on the relationship between vancomycin MIC and clinical outcomes including treatment failure and mortality. Some claim higher rates of vancomycin treatment failure with methicillin-resistant Staphylococcus aureus (MRSA) infections despite the organism being fully susceptible, which is denoted by a vancomycin MIC less than or equal to 2, whereas others show no such association. The objective of this study is to determine if treatment with vancomycin is associated with inferior clinical outcomes in patients with MRSA bacteremia with a vancomycin MIC equal to 2.

Methods: This study will be submitted to the Institutional Review Board for approval. This will be a retrospective, observational cohort study of patients with MRSA bacteremia treated with vancomycin from January 2013 to August 2016. There will be two study arms, with the control arm having MRSA isolates with a vancomycin MIC less than 2 and the active arm having an MIC equal to 2. The inclusion criteria will entail patients with MRSA bacteremia and those that have been treated with vancomycin for greater than or equal to 7 days. The exclusion criteria will entail patients with an age less than or equal to 18 years, with an index blood culture from an outside hospital, with a polymicrobial bacteremia, and died, were discharged, or sent to hospice within 24 hours. Analysis of baseline characteristics will include demographics (age, gender, weight), the Charlson comorbidity index, the Pitt bacteremia score, potential sources of infection, presence of endocarditis, and intensive care unit admission date when applicable. The primary outcome will be mortality within 30 days. Secondary outcomes include microbiologic data including time to clearance of organism from blood cultures when applicable, recurrence within 30 days from completion of therapy, length of stay from index blood culture, and re-hospitalization within 30 days.

Poster Title: Evaluation of the impact of levetiracetam therapeutic drug monitoring on dosing adjustments

Primary Author: Rajeev Shah, Robert Wood Johnson University Hospital Somerset, NJ; Email: rajeev.shah@rwjbh.org

Additional Author(s):
Fatema Dhanaliwala
Luigi Brunetti
Christopher Adams

Purpose: The advent of therapeutic drug monitoring lead to advances in managing anti-epileptic therapy by creating well-defined reference ranges for the first generation anti-epileptic drugs. Levetiracetam, a second generation agent, does not require routine therapeutic monitoring because it lacks the well-defined reference ranges of its predecessors. There is little literature to support the correlation between serum concentration and efficacy or toxicity. Therefore, the utility of therapeutic drug monitoring is limited to assessing adherence. The objective of this study is to examine the effect of therapeutic drug monitoring on the frequency of dosing changes in hospital inpatients with known adherence.

Methods: This study was approved by the Institutional Review Board. A retrospective chart review of randomly selected patients who received levetiracetam therapy from January 2013 to January 2016 will be performed. The study group will consist of subjects in whom a levetiracetam serum concentration was obtained, and the control group subjects will be those without a serum drug concentration. The incidence of inappropriate dosing changes will be compared between the two groups. An inappropriate dosing change will be defined as a change without clinical rationale or without a documented incidence of a breakthrough seizure. Adult subjects with a history of seizure disorders who received any formulation of levetiracetam for greater than 48 hours will be included. Because levetiracetam is renally dose adjusted, those with unstable renal function as defined by doubling of serum creatinine, absolute increase in serum creatinine of 0.5 mg/dL, or documented urine output of less than 0.5 mL/kg/hour will be excluded. A total of 250 patients will be enrolled with 125 in each arm of the study. The data will be summarized using descriptive statistics. The categorical data will be analyzed using an
uncorrected Chi squared test. Continuous data will be analyzed with an independent sample t-test. We will also construct a logistic regression to identify predictors of levetiracetam levels.

**Poster Title:** Evaluation of running a decision support alert in test mode to determine opportunities to reduce supratherapeutic acetaminophen dosing in the inpatient setting

**Primary Author:** Juanqin Wei, Robert Wood Johnson University Hospital Somerset, NJ; **Email:** stephanie.wei@rwjbh.org

**Additional Author (s):**
Melissa Crossen

**Purpose:** Acetaminophen is a widely used medication available in numerous formulations and combinations. Supratherapeutic doses can cause serious adverse events including coagulopathy, hepatic encephalopathy, and liver failure. Decision support alerts are commonly used to prevent dosing errors. However, reliance on these alerts has led to alert fatigue among health care professionals. The objective of this study is to examine the effect of running a decision support alert in the background to determine and correct root causes of supratherapeutic dosing to reduce incidence proactively, rather than reactively.

**Methods:** This is a retrospective cohort study examining supratherapeutic acetaminophen dosing among inpatients at the Robert Wood Johnson University Hospital Somerset facility. A decision support alert was run in test mode in July 2014 to observe the incidence of supratherapeutic dosing and used to determine and address root causes. This study will examine all patients who received a total daily acetaminophen dose of greater than 4 grams before and after running the decision support alert in test mode during the time periods of January 1, 2014 to June 4, 2014 and January, 2015 to June 4, 2015. Data from both time periods will be analyzed and compared to determine the impact from running the decision support alert in test mode. Patients were identified using the hospital electronic medical record and discharge database. Combination acetaminophen medications, standing orders of acetaminophen, and as-needed orders of acetaminophen were all included. The proportion of patients on multiple acetaminophen-containing medications and the type of medication order will also be examined. Results will be stratified by patient age and liver disease.

**Results:** N/A
Conclusion: N/A
Purpose: This case highlights the potential hazard of using atherosclerotic cardiovascular disease (ASCVD) risk calculators without employing clinical judgment in patients who present to their primary care physicians. The patient is a healthy male with no history of coronary artery disease, hypertension, diabetes, smoking, or family history of premature ASCVD. In 2009, statin therapy was initiated, but it was recently questioned whether this patient was an appropriate candidate for statin therapy based on his laboratory values and past medical history. The patient is 74 years old with a systolic blood pressure of 115 mmHg, an LDL of 115 mg/dL, a total cholesterol of 234 mg/dL, and an HDL of 99 mg/dL. Using the American Heart Association ASCVD risk calculator, his 10-year ASCVD risk was calculated to be 16.5%. This was indication for at least moderate-intensity statin therapy according to the American College of Cardiology/American Heart Association guidelines, despite his being healthy and having no clinical ASCVD risk factors. If his parameters were “optimized” to the risk calculator recommended levels of total cholesterol of 170 mg/dL, HDL of 50 mg/dL, and systolic blood pressure of 110 mmHg, his ASCVD risk would increase to 17.4%. Similarly, using the Framingham Coronary Heart Disease Risk Score, his 10-year risk of heart attack or death with his existing risk parameters is 7.9%; however, once “optimized” to the recommended levels, his risk increases to 13%. This case report demonstrates both the variability and lack of accuracy of risk calculators in stratifying certain patients for statin therapy. Healthcare providers can utilize these tools to help guide treatment, but must recognize that clinical judgment is key to making appropriate decisions regarding patient pharmacotherapy.

**Poster Title:** Darbepoetin as a substitute for epoetin alfa: Developing a hospital-based protocol for patients requiring bloodless surgery.

**Primary Author:** Vatche Demirjian, Rutgers, NJ; Email: vatche.demirjian91@gmail.com

**Additional Author (s):**
Mary Bridgeman
Jaimini Amin
Evelyn Hermes-DeSantis

**Purpose:** Based on the significant risk of blood loss associated with certain surgical procedures, assuring that adequate hemoglobin levels are achieved preoperatively is critical to reduce adverse outcomes. Some patients will not accept certain blood products according to religious beliefs. Utilizing erythropoietin stimulating agents (ESAs), is one option in managing patients with moral objection to receipt of human blood product derivatives. Epoetin alfa is commonly used in preparation for bloodless surgical procedures; however, it does contain albumin, a minor blood fraction. Darbepoetin does not contain albumin, making it a potential treatment option for patients with moral objections to epoetin alfa therapy.

**Methods:** During July 2016, our institution experienced three emergency cardiac intervention cases requiring bloodless surgery whereby the patients requested the use of darbepoetin in lieu of epoetin alfa. A search of the medical literature, utilizing Medline, PubMed, and Google Scholar was performed to identify available literature concerning the management in bloodless medical and surgical procedures. Meetings with the physician team responsible for bloodless surgery were held for input and evaluation. Based on the literature and physician experiences, a hospital protocol will be developed. Once an appropriate dosing regimen of epoetin alfa is agreed upon, an equivalent darbepoetin dose will be derived. In the absence of clinical data to support use of darbepoetin in bloodless surgery patients, we will be applying the dosing regimen suggested in the package insert, identifying the appropriate equivalent dose of darbepoetin as compared to epoetin alfa. The protocol will stratify patients based on time prior to surgery and baseline hemoglobin level to identify the proper epoetin alfa dose. Other auxiliary medications needed to be utilized in conjunction with the ESA will be included, such as iron supplementation, vitamin B12, and folic acid.

Poster Title: Stevens-Johnson syndrome associated with chlordiazepoxide

Primary Author: Tara Jawaro, Rutgers University/Robert Wood Johnson University Hospital Emergency Medicine Pharmacy Residency, NJ; Email: tara.jawaro@rwjbh.org

Additional Author(s):
Deepali Dixit
Oleksandr Pistun

Purpose: Stevens-Johnson syndrome (SJS) is a rare but severe skin reaction resulting from drug exposure or infection. Classic drugs with the risk to induce SJS include anticonvulsants, oxicam type nonsteroidal anti-inflammatory agents, and anti-infective sulfonamides. We describe a case of chlordiazepoxide associated SJS. This case provides insight into a serious adverse drug reaction secondary to a drug not commonly associated with SJS.

**Primary Author:** Jenny Liu, Saint Barnabas Medical Center, NJ; **Email:** jenny.liu@rwjh.org  
**Additional Author (s):**  
Rachel Meyers  
Uzma Hasan  

**Purpose:** Assess appropriate utilization of clindamycin in the pediatric population due to the increasing resistance of Staphylococcus aureus.

**Methods:** In this IRB approved retrospective chart review from July 1, 2015 to June 30, 2016, we will evaluate antibiotic prescribing practices for pediatric patients from 1 month of age to 18 years old with a skin and soft-tissue infection (SSTIs) treated at Saint Barnabas Medical Center. Patients will be excluded if they had diabetes, a perirectal abscess, decubitus ulcer, or pharyngeal abscess. The primary end point is to evaluate the percentage of cultures growing community acquired methicillin-resistant Staphylococcus aureus (CA-MRSA) that are resistant or have inducible-resistance to clindamycin. Secondary endpoints are to determine the percentage of SSTI cultures that are MRSA (versus other causative pathogens) and whether de-escalation or antibiotic adjustments were made. Descriptive statistics will be used for all data collected in this study.

**Results:** Research is currently under review.

**Conclusion:** Non-applicable.

Poster Title: Implementation of a medication review service for patients with enteral tubes in a community teaching hospital

Primary Author: Olawonuola Abiona, Saint Barnabas Medical Center, NJ; Email: olawonuola.abiona@gmail.com

Additional Author(s):
Alison Eisenhart
Jennifer Costello

Purpose: Inappropriate enteral tube administration of medications can result in occluded tubes, altered clinical response, and an increase in adverse effects. An internal retrospective chart review was performed showing that 43% of patients on enteral tubes received ≥1 medication that should not be crushed. The objective of this study is to implement a hospital-wide medication review service for patients with enteral tubes to improve their safety.

Methods: This study, approved by the Saint Barnabas Medical Center IRB, is designed to implement and assess the progress of our new crushed medication consult service. Implementation started with education to pharmacists, prescribers, and nurses, reviewing the new program. A list of medications that should not be crushed was developed based upon guidance from the Institute for Safe Medication Practice. An automatic substitution list of medications was created and approved by the Pharmacy and Therapeutics Committee that would allow pharmacists to interchange medications to liquid or crushable formulations. An electronic task list was also created to alert pharmacists about patients who had an enteral tube placed requiring medication review and potential substitution. In addition, the list also identifies patients whose tubes were removed in order to place them back on their original medications. Study participants are patients at our institution who had and enteral tube placed during the pilot portion of the program. They will be monitored to identify if their medications were changed to the proper doses and/or dosage forms as defined by our protocol. Data will also be analyzed to assess if the pharmacist compliance with the program.

Poster Title: Evaluation of diuretics in admitted congestive heart failure patients

Primary Author: Dimple Patel, Saint Barnabas Medical Center, NJ; Email: dimpleppatel8@gmail.com

Additional Author(s):
Yekaterina Opsha
Rebeca Kane

Purpose: Appropriate diuresis in congestive heart failure patients is important for overall outcome of the disease. The most frequent cause of hospitalizations is due to congestion, which can be alleviated by the use of diuretics if started at an appropriate time. Failure to do so can increase cost, length of stay, and morbidity. The primary objective of this study is to determine whether the first dose of diuretic was ordered and administered timely in the emergency department. The secondary objective is to assess the total urine output in the first twelve hours and its effects on cost and length of stay.

Methods: This Institutional Review Board approved retrospective chart review will be conducted using patients with the diagnosis of congestive heart failure from January 1, 2016 to July 31, 2016. Patients 18 years of age or older, male or female, and who have been given a diuretic within the first 24 hours of admission will be evaluated. The electronic medical record system will be used to collect the following data: patient age, gender, length of stay, home diuretic dose, past medical history, time of emergency department arrival, diuretic ordered, time ordered and administered, and time to diuresis. All data will be de-identified and remain confidential. Timing of when diuretic was ordered and administered, time to diuresis and amount of diuresis (in mL) will be assessed as final outcomes. Descriptive statistics will be used to analyze all data collected in this study.

**Poster Title:** Review of pharmacological venous thromboembolism (VTE) prophylaxis in post-operative renal transplant patients

**Primary Author:** Nalinoe Kernizan, Saint Barnabas Medical Center, NJ; **Email:** kernizan.nalinoe@gmail.com

**Additional Author(s):**
Alison Eisenhart

**Purpose:** Venous thromboembolism is a potential complication of any surgical procedure, and new kidney transplant recipients are at a moderate risk for developing a clot after surgery. The objective of this study is to determine the rate of adherence to our hospital venous thromboembolism prophylaxis protocol in post-operative kidney transplant patients and determine the rate of venous thromboembolism within 3 months of the surgery.

**Methods:** This retrospective study was approved by the Institutional Review Board at Saint Barnabas Medical Center. Adult patients who have received a living or cadaveric kidney from October 1, 2015 to March 31, 2016 will be identified, and their post-operative course will be reviewed in our electronic medical record. The following data will be collected: age, sex, height, weight, serum creatinine, venous thromboembolism risk per screening protocol, modality of prophylaxis, prescribed anticoagulant, and time to its initiation. Additional data include documentation of venous thromboembolism or bleeding event, readmission rate due to these events, and requirement of therapeutic anticoagulation. The primary outcome is the adherence to the hospital venous thromboembolism event prophylaxis protocol in patients who have received a kidney transplant. Secondary outcomes will be to identify the incidence of thromboembolic and bleeding events within 3 months of kidney transplant. Patients with a prior history of venous thromboembolism or indication for chronic anticoagulant or antiplatelet use will be excluded. Data will be analyzed using descriptive statistics to quantify protocol compliance and venous thromboembolism and bleeding rates. Results of the study will be used as a quality assurance measure as well as to enhance future staff education.

**Poster Title:** Integration of pharmacists into a code blue team: An educational program

**Primary Author:** Xiao Ma, Saint Peter's University Hospital, NJ; Email: xma@saintpetersuh.com

**Additional Author (s):**
Maria Cardinale
Avni Desai

**Purpose:** The involvement of a pharmacist in Code Blue teams has been shown to improve survival, reduce medication errors, and enhance compliance to the Advanced Cardiac Life Support (ACLS) algorithms. At Saint Peter’s University Hospital (SPUH), a site-specific Code Blue training program was developed to facilitate the integration of pharmacists into the team. The purpose of this study is to assess the effectiveness of the Code Blue training program by evaluating the pharmacists’ competency and readiness to participate in Code Blue response.

**Methods:** This study is a prospective evaluation of 10-20 SPUH pharmacists participating in a training program designed by pharmacists with ACLS certification. Pharmacists will be included in the study if they are able to provide written informed consent. The training consists of a three to four hour didactic training session, and a 90-minute interactive session that includes hands-on training in medication preparation. Prior to training, participants will be given a twenty-item competency exam. Upon completion of the training, the following will be assessed: improvement in pharmacists’ competency via an exam identical to the pre-test, and a four-item post-training survey assessing readiness to participate in codes. Finally, two follow-up competency exams will be provided in person to participants at 7 and 30 days after training to assess continued competency. The study will take place between October 2016 and November 2016. The Student t-test, Mann Whitney U test, McNemar’s test, and Fisher’s Exactor Chi-Squared test will be used to analyze the results, as appropriate. The methodology of this study was submitted to the Institutional Review Board for expedited review.

**Poster Title:** Establishment of an interdisciplinary glycemic stewardship committee at a community hospital

**Primary Author:** Diana Solomon, Shore Medical Center, NJ; **Email:** dsolomon@shoremedicalcenter.org

**Additional Author(s):**
Mathew Piskun
A. Maggie Randazzo

**Purpose:** Hospitalized patients with frequent hyperglycemia and hypoglycemia are at an increased risk for adverse outcomes, including death. Additionally, patients with diabetes are more likely to be hospitalized and have longer lengths of stay. Appropriate glycemic control in the hospital is essential to promote medication safety, minimize costs, and improve patient outcomes. This project was designed to develop a glycemic control stewardship committee, and report its impact on a community hospital’s glycemic management.

**Methods:** The institutional review board determined that this study did not require their approval. Baseline institutional glycemic control was analyzed through retrospective review of all patients who received insulin in the past month. After analysis of hyperglycemia and hypoglycemia rates it was determined that glycemic management in its entirety needed to be addressed. The baseline state of institutional glycemic control was brought to the attention of the pharmacy and therapeutics committee. The formation of a sub-committee to address glycemic management in the hospital, deemed the glycemic control stewardship committee, was approved by the pharmacy and therapeutics committee. Investigators will move forward to assemble an interdisciplinary team and develop protocols to improve glycemic management throughout the hospital. Glycemic control will be measured at baseline and after protocol implementation by percent of glucose values within the therapeutic range. The primary endpoint of this study is a comparison of the percent of glucose values within the target therapeutic range at baseline versus after protocol implementation. Secondary outcomes will include mortality and length of stay.

**Results:** N/A
Conclusion: N/A

Poster Title: Vancomycin drug utilization evaluation: a review of a community hospital’s therapeutic monitoring protocol

Primary Author: Tea Cadenovic, Shore Medical Center, NJ; Email: tcadenovic@shoremedicalcenter.org

Additional Author(s):

Purpose: The Infectious Disease Society of America (IDSA) recommends vancomycin as a first-line agent for methicillin-resistant Staphylococcus aureus (MRSA) coverage in complicated skin and skin structure infection (cSSSI), healthcare-associated pneumonia (HCAP) and osteomyelitis. Vancomycin is frequently ordered for the listed indications and all orders are automatically substituted to the pharmacy’s dosing and monitoring protocol. The objective of this study is to retrospectively review the ability of the hospital’s vancomycin protocol to achieve optimal therapeutic levels while minimizing adverse effects such as acute kidney injury.

Methods: The Institutional Review Board reviewed this project and determined that approval was not necessary. Data from the second quarter will be extracted anonymously from electronic health records. Patient demographics such as age, weight, co-morbidities, renal risk factors, baseline laboratory values and temperature will be collected. The therapeutic monitoring data will consist of culture results, administered doses, length of therapy, trough values, time spent in therapeutic range, and discontinuation rates. The safety monitoring will be assessed through reports of infusion related reactions, allergic reactions, and acute kidney injury. Acute kidney injury will be staged according to the Kidney Disease: Improving Global Outcomes (KDIGO) guideline. The primary endpoints evaluated will be percentage of patients obtaining a therapeutic concentration on the first and second trough and percentage of treatment duration spent in therapeutic range. Secondary outcomes will focus on appropriateness based on organism cultured and minimum inhibitory concentrations to vancomycin, dose adjustments required to reach trough, reasons for discontinuation, and patient outcomes.

**Poster Title:** Assessment and implementation of a protocol for direct oral anticoagulant use in the outpatient management of thromboembolism in eligible low-risk patients

**Primary Author:** David Yang, St. Joseph’s Regional Medical Center, NJ; **Email:** r_yangdavid@sjhmc.org

**Additional Author (s):**
Steven Nerenberg

**Purpose:** While outpatient management of deep vein thrombosis (DVT) has been the standard of care, patients with pulmonary embolism (PE) have historically been treated inpatient due to the possibility of rapid cardiovascular compromise. Recent trials have demonstrated outpatient PE management in low-risk patients is safe, effective and cost-saving. Therefore, some patients with venous thromboembolism (VTE) may be unnecessarily admitted. Our institution has developed criteria to discharge patients with VTE at low-risk for complications. The purpose of this study is to retrospectively identify the percentage of patients admitted for VTE who would have been eligible for outpatient management based on predefined criteria.

**Methods:** This study is a retrospective chart review conducted at St. Joseph’s Regional Medical Center to evaluate VTE management in emergency department patients from mid-March to mid-September 2016. A report will be generated identifying patients ≥18 years of age with radiologic confirmed diagnosis of DVT or PE. PE patients without shock, BNP ≥ 90pg/mL, troponin-I ≥0.05 ng/mL, or sPESI score ≥1 will be considered eligible for outpatient management. DVT patients without proximal end of clot not visualized on ultrasound, phlegmasia, documented iliac component of DVT, or oxygen saturation < 93% on room air will be considered eligible for outpatient management. Additionally, having pre-specified risk factors for complications with direct oral anticoagulant therapy will exclude outpatient eligibility, including clinical evidence of active bleeding, pregnancy, CrCl < 30 mL/min, platelets < 50,000 cells/mm3, therapeutic on anticoagulation, malignancy with active treatment, severe liver impairment, surgery in last 2 weeks or neurosurgery in last 4 weeks, social factors prohibiting outpatient treatment or other significant comorbidities requiring hospitalization >24 hours. Data on all risk factors will be collected. The primary endpoint will be the percentage of admitted patients during this time period that would have been eligible for outpatient
management based on the developed criteria. Secondary outcomes will be potential cost avoidance and safety measures, including hospital acquired complications, significant bleeding, and fatalities.

**Poster Title:** Prescriber perceptions on the use of oral anticoagulants in the treatment of venous thromboembolism and non-valvular atrial fibrillation

**Primary Author:** Christopher Yap, St. Joseph’s Regional Medical Center, NJ; Email: chris.a.yap@gmail.com

**Additional Author(s):**
Christopher Malabanan
Mohamed Fouad
Radhika Pisupati

**Purpose:** Initiation of direct oral anticoagulants (DOACs) compared to warfarin has been associated with a statistically significant decreased length of stay at our organization, as seen in a previous evaluation. As a result, a pharmacy-led protocol to identify and recommend DOACs for eligible patients was approved in April 2016 by the P and T committee. Successful implementation of the protocol requires understanding how prescribers choose oral anticoagulants (OACs) for their patients. Currently, the amount of published literature surveying prescriber opinions of DOACs is limited. The purpose of this study is to survey prescribers regarding their experiences and perceptions with OACs.

**Methods:** This study will be submitted to the Institutional Review Board for approval. An online survey will be distributed through e-mail to prescribers at our institution on the use of OACs for treatment of venous thromboembolism (VTE) and non-valvular atrial fibrillation (NVAF). The survey will consist of questions regarding demographic information (prescriber’s credentials, practice area, and level of professional experience), frequency of ordering OACs, potential concerns for prescribing a DOAC over warfarin, types of DOAC-specific education completed, influence of patient’s prescription coverage on choice of OAC, and awareness of DOAC-specific medication access programs. Prescribers who participate in the study will remain anonymous. Descriptive statistics will be used to analyze the responses.

Submission Category: Ambulatory Care

Submission Type: Research-in-Progress

Session-Board Number: 8-112

Poster Title: Evaluation of diabetes-related health outcomes in patients managed by the ambulatory care pharmacist

Primary Author: Kayla Natali, St. Joseph's Regional Medical Center, NJ; Email: r_natalikayla@sjhmc.org

Additional Author(s):
Mohamed Fouad
Radhika Pisupati

Purpose: Diabetes is a chronic illness affecting millions of Americans and it is estimated that 33-49% of patients do not meet his/her target glycemic goal which results in increased health care costs and poor health outcomes. Recently, an ambulatory care pharmacist started performing clinical interventions on patients with type 2 diabetes mellitus (T2DM) at an adult medicine clinic associated with the institution. The objective of this retrospective study is to evaluate the impact of the ambulatory care pharmacist on hemoglobin A1c (HbA1c), the number and type of interventions made, and the number of diabetes-related hospitalizations and/or emergency department (ED) visits.

Methods: This study has been submitted to the Institutional Review Board for approval. It is a retrospective chart review conducted at a tertiary teaching hospital and an adult medicine clinic. A list of eligible patients will be identified through medical charts. Eligible patients include those who are 18 years of age or older, have been diagnosed with T2DM, and are managed by the ambulatory care pharmacist. The following data will be collected: patient age, gender, height, weight, past medical history, medications at initial visit, baseline HbA1c, serum creatinine, blood urea nitrogen, albumin to creatinine ratio, and fasting lipid panel, HbA1c 3 months after the pharmacist has initiated anti-diabetic pharmacologic therapy and/or resolved any medication access issues, a second HbA1c taken by the pharmacist, hospital admissions and ED visits, dose adjustments, appropriate drug therapy added, and inappropriate drug therapy discontinued by the pharmacist, basic diabetes teaching provided including disease state education, sick day management, hypoglycemia and hyperglycemia management, self-monitoring of blood glucose, and teaching and/or assessment of subcutaneous insulin injection technique, and labs obtained by the pharmacist including HbA1c, fasting lipid panels, and
comprehensive metabolic panels. All patient identifiers will be de-identified using a numerical coding system, stored in a password protected computer, and the coding system will be destroyed upon completion. The reviewers will use the data to analyze diabetes-related outcomes pre and post pharmacist management.

Poster Title: Evaluation of drug therapy for Clostridium difficile infection in a tertiary health system

Primary Author: Xing Tan, St. Joseph's Regional Medical Center, NJ; Email: r_tanxingf@sjhmc.org

Additional Author(s):
Dorothy McCoy
Lynette Richards

Purpose: The Infectious Disease Society of America/Society of Hospital Epidemiologists of America (IDSA/SHEA) and the American College of Gastroenterology (ACG) guidelines currently recommend drug therapy for Clostridium difficile infection (CDI) in adults to be guided by the severity of disease. The objective of this study is to evaluate whether the therapy of CDI matches disease severity within a health system.

Methods: This study has been submitted to the Institutional Review Board for approval. A computerized report will identify patients between January 1, 2016 – July 31, 2016 with C. difficile by a positive glutamate dehydrogenase (GDH) antigen test, C. difficile toxin, and/or a positive PCR test. The following data will be collected from the CDI admission: patient age, gender, length of stay, use of antibiotics, chemotherapy, or other immunosuppressive therapy prior to onset of CDI, medications for CDI treatment, and concurrent medications used during the hospital stay (other antibiotics used for treatment of other bacterial infections, acid-reducing agents, probiotics, laxatives, antidiarrheal agents, bile acid sequestrants, chemotherapy, immunosuppressive agents). Data pertinent to staging of CDI severity and clinical resolution will also be collected from day of admission, day of diagnosis, day 7 of treatment, last day of treatment, and day of discharge, including: mean number of bowel movements per day, maximum temperature, maximum WBC, serum creatinine, albumin, serum lactate, and blood pressure. In addition, admission to ICU, use of vasopressors in the ICU, and presence of colitis on CT scan will be recorded. The data will be reviewed for appropriateness of drug therapy according to IDSA/SHEA and ACG for each patient. Clinical outcomes, prescribing practices of each level of health care professional, and potential predisposing factors for CDI will also be evaluated.

Poster Title: Benefits of having a pharmacist-led medication reconciliation program for admitted patients in an emergency care setting
Primary Author: Saloni Shah, The Valley Hospital, NJ; Email: sshah7@valleyhealth.com
Additional Author(s):
Veronica Feltrin
Marian Gergis
Christine Park

Purpose: Through previous research at The Valley Hospital, it was found that medication reconciliation performed by a pharmacist in the emergency department, resulted in a total of 4,531 medication discrepancies among 1,600 patients over a four month period. This data showed potential cost savings of approximately $159,048 along with favorable patient outcomes. The purpose of this study is to evaluate the use of a standardized medication reconciliation process in order to optimize patient safety and circumvent medication related complications.

Methods: A teaching tool was created by the current emergency department pharmacist and was approved by the Quality and Patient Safety Clinical Support Services, as well as the pharmacy director and manager. The tool was created in collaboration with other pharmacists in order to gain consistency among colleagues when performing patient interviews. In addition, the tool summarized a step-wise approach to determine which patients presented with a time sensitive priority for medication reconciliation. This tool served as a training instrument for pharmacists in their medication reconciliation role. For two consecutive weeks, medication reconciliation was performed, by either one or two pharmacists, using the approved tool. From April 21, 2016 to May 2, 2016, excluding weekends, one medication reconciliation pharmacist was dedicated to the emergency department for an 8-hour shift. The following week, May 4, 2016 to May 13, 2016, excluding weekends, two medication reconciliation pharmacists were dedicated to the emergency department for a total of 15 hours.

Results: During the week of April 21, 2016 to May 2, 2016, 59 percent of admissions came through the emergency department. Of the 59 percent, 45 percent of patients received
medication reconciliation from the emergency department pharmacist. During the following week, May 4, 2016 to May 13, 2016, 55 percent of admissions came through the emergency department. Of the 55 percent, 70 percent of patients received medication reconciliation from one of the emergency department pharmacists. Furthermore, by expanding the medication reconciliation hours, the percentage of medication reconciliations performed for emergency department admissions, increased by 11 percent.

**Conclusion:** With the start of the medication reconciliation program, only three full-time pharmacists (5 percent) were trained in the process of medication reconciliation. As of now, seventeen (29 percent) of pharmacists employed at The Valley Hospital are thoroughly trained in conducting medication reconciliation. The goal is for all pharmacists to be properly trained in medication reconciliation and to expand the program hours into a seven day operation.

Poster Title: Post-discharge pain level in patients undergoing total knee replacement (TKR), based on choice of local/regional pain control

Primary Author: Matthew Young, University Medical Center of Princeton at Plainsboro, NJ; Email: matthew.young03@gmail.com

Additional Author (s):
Jayanti Ingle
Whitney Hung
Antora Banerjee
Philip Coco

Purpose: The duration of stay for patients who receive a unilateral total knee replacement is variable. One of the factors that determine length of stay is a patient’s functional status which is measured by the distance the patient can walk after surgery. Optimal pain control plays a major role in patient recovery and quality of life. The objective of this study is to determine the impact, if any, of the choice of local/regional pain management agents on inpatient narcotic usage, functional status, as well as post-discharge pain scores.

Methods: The Investigational Review Board approved this single center, retrospective chart review. Adult patients who received a unilateral total knee replacement from April 18, 2016 to July 18, 2016 at University Medical Center of Princeton at Plainsboro and were discharged to home after hospital stay were included in this study. Patients who received a bilateral or partial knee replacement were excluded. The standard multimodal pain control regimen included a long acting narcotic with as needed doses immediate-release narcotics for breakthrough pain, around the clock acetaminophen, and ketorolac as needed. The patients that are eligible to be included in the study were split into 2 groups that compared the standard post-operative pain control to the standard plus a continuous infusion of ropivacaine into the adductor canal. Physical therapists work with the patients after surgery to get the patients home or to a rehabilitation facility more quickly. Type of anesthesia, time in surgery/post anesthesia recovery, length of stay, narcotic usage, other pain medication use, distance walked after surgery, and pain scores was retrospectively evaluated for patients in both categories. The t-
test and chi-square will be used to detect any significant differences in pain scores and narcotic usage per hour between the two groups.

Poster Title: Evaluating current practice of using local sensitivities to determine the treatment option for patients without risk of healthcare-associated infection

Primary Author: Toral Patel, University Medical Center of Princeton in Plainsboro, NJ; Email: tpatel@princetonhcs.org

Additional Author(s):
Whitney Hung

Purpose: The Infectious Disease Society of America (IDSA) guidelines for acute uncomplicated cystitis and pyelonephritis recommend that patients should receive treatment based on local sensitivities. There is no known community antibiogram available for central New Jersey. Institutions may utilize the results of emergency department antibiogram to determine the treatment options for patients coming from community. However, studies have shown that many patients coming into the emergency department have risk factors for healthcare-associated infections. The purpose of this study is to assess the rationale for empiric treatment based on current practice through surveillance data.

Methods: The Department of Pharmacy at the University Medical Center of Princeton in Plainsboro approved this observational study. Individuals enlisted in the American Society of Healthsystem Pharmacists (ASHP) new practitioner form will be sent a survey via email. The survey will ask questions related to their institution’s use of an antibiogram. Questions will ask individuals how frequently does their institution update their antibiogram, if they only include isolates obtained from hospital setting, if they have separate antibiograms for clinic and/or emergency room, if they have a separate community antibiogram, and whether or not they feel there is benefit in having an antibiogram for individuals without healthcare associated infection. Individuals will answer the survey anonymously. Descriptive analysis will be used to summarize the results.

**Poster Title:** Dexmedetomidine versus propofol or benzodiazepines in mechanically ventilated adult patients in the intensive care unit

**Primary Author:** Duy Nguyen, Virtua Memorial Hospital of Burlington County, Inc., NJ; **Email:** 1nguyed@gmail.com

**Additional Author (s):**
Kavitha Dalal

**Purpose:** Dexmedetomidine has been shown in randomized controlled trials as an effective sedative in mechanically ventilated patients when compared to propofol or midazolam. It is one of the recommended sedatives in the 2013 Clinical Practice Guidelines for the Management of Pain, Agitation, and Delirium to improve clinical outcomes. Recently, dexmedetomidine has been approved at Virtua Health in addition to propofol and benzodiazepines as standard sedatives used for mechanically ventilated patients in intensive care unit (ICU). The purpose of this study is to investigate how dexmedetomidine will affect clinical and safety outcomes in mechanically ventilated adult ICU patients at Virtua Health.

**Methods:** This study will be submitted to the Institutional Review Board for approval. A retrospective chart review will be performed on adult ICU patients who required mechanical ventilation and had received at least once dose of dexmedetomidine. ICU length of stay, days on mechanical ventilation, incidence of breakthrough agitation, and pertinent safety data will be assessed. Clinical outcomes will be compared to a historical control group of matching criteria who received either propofol or benzodiazepines. All medical charts will be obtained from Virtua’s medical record system, with data collection period covering at least 3 months in order to achieve 25 patients within each cohort. For the purpose of maintaining confidentiality, all patient identifying information will not be included in this study.

**Poster Title:** Impact of in-patient pharmacist directed management of anticoagulation bridging from parenteral to oral therapy

**Primary Author:** Amanda Yu, Virtua Memorial Hospital of Burlington County, Inc., NJ; **Email:** ayu@virtua.org

**Additional Author (s):**
Carolyn Orendorff
Kavitha Dalal

**Purpose:** Despite its wide use, anticoagulants are still considered one of the most common drug classes involved in medication errors. Recommendations for safe practices require multiple elements of performance, including utilization and evaluation of approved protocols for the management of anticoagulation. Studies have shown an overall improvement in quality of care with the involvement of a pharmacist. Virtua Memorial Hospital will implement a pharmacist directed practice to provide drug and dose recommendations to prescribers. The objective is to evaluate the provision of pharmacist recommendations for appropriate bridging on length of stay and time to therapeutic international normalized ratio (INR).

**Methods:** Adult patients, admitted to Virtua Memorial Hospital, who were initiated on therapeutic enoxaparin or heparin infusion with the intent of bridging to warfarin will be included in this study. Patients will also be evaluated to determine if they are candidates for the novel oral anticoagulants (NOAC). Prescribers will then be notified to determine if a NOAC agent is preferred over warfarin. This study will include both newly indicated patients and patients who are restarted due to an interruption of therapy. Time to first therapeutic INR, length of stay, whether or not recommendation was accepted and safety data will be collected and assessed. The first fifty patients who meet requirement will be evaluated daily, Monday through Friday. Data collected from these patients will be deemed the intervention group. Retrospective chart review will be performed for the most recent fifty patients prior to implementation, of pharmacist directed management, to establish the control group data. The data collected prior to implementation will be compared to the data extracted following implementation using the Pearson’s Chi-Square test with an a priori significance level of 0.05. This study will be submitted for approval from the Institutional Review Board.

Poster Title: Outcomes and cost analysis of poractant alfa versus calfactant treatment in neonates with respiratory distress syndrome

Primary Author: Abigail Bertonazzi, Virtua Memorial Hospital of Burlington County, Inc., NJ; Email: abertonazzi@virtua.org

Additional Author (s):
Jessica Hunt
Barbara Zambon

Purpose: Respiratory distress syndrome in neonates is generally caused by surfactant deficiency. Surfactant deficiency can lead to poor lung expansion, inadequate gas exchange, and a gradual collapse of the lungs. Poractant alfa and calfactant are surfactants that help compensate for this deficiency in neonates with respiratory distress syndrome and restore surface activity to the lungs. The objective of this study is to assess the safety, effectiveness, and cost of poractant alfa when compared to calfactant in neonates with respiratory distress syndrome.

Methods: This is an observational, retrospective chart review conducted at a community hospital that will be submitted to the Institutional Review Board for approval. Previously, calfactant was the formulary surfactant used at the hospital, but poractant alfa has now been added to the formulary. Data will be collected through an electronic medical record system post-discharge for all neonates who received calfactant for six months prior to the conversion to poractant alfa and those that received poractant alfa for six months after the conversion. The following outcomes will be statistically evaluated and compared: patient demographics (gestational age, postnatal age, weight, comorbid conditions), cost (direct drug cost, ventilator hours, cost of hospital stay), redosing rates, ventilator hours, total days on respiratory support, length of hospital stay, accurate dose and frequency, use of appropriate vial sizes based on dose rounding, endotracheal tube obstruction, bradycardia, oxygen desaturation, and overall survival at fourteen days. There will be no risk to patients because the research does not involve direct patient contact and data will be collected retrospectively after the patient is discharged. All data collected will be stored in a secure pharmacy folder accessible only by the study investigators in order to protect health information and minimize improper disclosure.

Poster Title: Preventing admissions to intensive care unit due to delirium tremens

Primary Author: David Adams, Abington Hospital - Jefferson Health, PA; Email: david.t.adams@jefferson.edu

Additional Author(s):
Danielle Schulingkamp
Corrine Young

Purpose: Delirium tremens (DT) are a severe complication of alcohol withdrawal that can increase both length of stay in an intensive care unit (ICU) and overall morbidity and mortality. Early identification and rapid treatment is vital to stabilizing the patient and reducing the risk of mortality. Our aim is to evaluate the effectiveness of a newly implemented DT protocol at a 660 bed community teaching hospital for use by rapid response teams. By allowing rapid response to treat DTs we can provide timely medication management, thereby curbing the progression of both the withdrawal syndrome and the patient’s transfer to the ICU.

Methods: This study has been submitted to the Institutional Review Board for approval. Patients will be included if they are considered to be at risk of DTs based upon a Clinical Institute Withdrawal Assessment of Alcohol Scale, Revised (CIWA-Ar) monitoring score of 20 or higher during admission. Patients will be excluded if they present to the emergency trauma center (ETC) with active alcohol withdrawal DTs present. In our institution, patients determined to have alcohol withdrawal and have two or more consecutive CIWA-Ar scores of 20 or higher will result in a rapid response code call. Upon the team’s arrival, the DT protocol will be followed while patient’s vital signs are monitored continuously. Our DT protocol utilizes evidence from previous trials establishing benzodiazepines as the first-line therapy for alcohol withdrawal and delivers high dose lorazepam intravenous (IV) pushes at a high frequency over a short duration. Prospective evaluation following protocol implementation will be compared to retrospective data prior to implementation to establish differences in the following endpoints: the number of transfers to the ICU, number of patients converted to lorazepam IV continuous infusions, and number of ICU related complications or deaths.

**Poster Title:** Primary care pharmacy: a novel pharmacy model

**Primary Author:** Frederick DiPasquale, Abington Hospital - Jefferson Health, PA; **Email:** frederick.dipasquale@jefferson.edu

**Additional Author (s):** Sandeep Bains

**Purpose:** A novel pharmacy model will be implemented, embedding a clinical pharmacist in a primary care practice, including acute care for patients while in the hospital and during all transitions of care. This model will incorporate the pharmacist throughout the complete continuity of care rather than operating in separate clinical silos. This novel model is expected to result in improved outcomes while minimizing costs. The objective of this pilot program is to assess the impact of a primary care pharmacist on hospital readmission rates, among other quality measures.

**Methods:** This ten-week pilot will embed a pharmacist as a member of the primary care team following patients in the primary care office, within the hospital, and across all transitions. The pharmacist will follow the same patients within all settings rather than seeing a multitude of varying patients. Within the primary care office, the pharmacist will be an accessible drug information resource for the practitioners and patients, improve patient access to medications and implement several strategies focused on improving quality outcomes. In the acute care setting, the pharmacist will focus on minimizing cost to the health system, reducing length of stay, and improving patient outcomes via several clinical strategies including antimicrobial stewardship, anticoagulation stewardship, and increasing core measure compliance. Within the transition phases, the pharmacist will function both as a clinician and as a care navigator by working closely with an interdisciplinary team to help fill any gaps in care. The primary outcome will be thirty day hospital readmission rate. The major secondary endpoints may include core measure compliance, the length of hospital stay, the cost of care, and physician satisfaction. The other endpoints include the number of drug information questions answered, and various safety endpoints, including avoided adverse events.

**Poster Title:** Effect of implementing a proton pump inhibitor restriction at a community teaching hospital

**Primary Author:** Helen Phu, Abington Hospital - Jefferson Health, PA; **Email:** hxp018@jefferson.edu

**Additional Author (s):**
Anna Drapkin
Maria Foy

**Purpose:** Proton pump inhibitors (PPIs) suppress gastric acid production by irreversibly binding to H+/K+ ATPases on parietal cells, thereby inhibiting acid secretion by proton pumps. Indications for PPI use include gastroesophageal reflux disease, nonsteroidal anti-inflammatory-induced gastropathy, peptic ulcer disease and stress ulcer prophylaxis. Long-term use of PPIs has been associated with increased risk of hip fracture, pneumonia, and Clostridium difficile infection. The purpose of this study is to evaluate the impact of a PPI restriction on utilization at a community teaching hospital.

**Methods:** Following investigational review board approval, all patients on general medicine and medical-surgical units who received a PPI for two or more days will be included in this study. Data will be collected one month prior to restriction implementation via retrospective chart review. Once the PPI restriction is in place, data will be collected prospectively for a period of one month. PPIs will be restricted to patients who are being treated for an upper gastrointestinal bleed, Helicobacter pylori infection, peptic ulcer disease, erosive esophagitis as well as those who have gastroesophageal reflux disease or Zollinger-Ellison syndrome. Additionally, PPIs may also be utilized for stress ulcer prophylaxis in patients who meet restriction criteria. A PPI order set will be created containing these indications, which will serve as a guide for appropriate PPI utilization through forced indication selection. The order set will also aide the pharmacist in determining appropriateness based on indication. A pharmacist will then prospectively review orders for appropriateness of indication as well as restriction adherence and make interventions as necessary. The primary endpoint of this study will be to evaluate the effect of implementing a PPI restriction on the rate of inappropriate PPI prescribing at a community teaching hospital.

Poster Title: A retrospective evaluation of ordering and administration practices of vasopressin in the medical intensive care unit

Primary Author: Alexandra McPherson, Albert Einstein Medical Center, PA; Email: mcphersa@einstein.edu

Additional Author(s):
Bliss Masiarczyk
Sandra Aguero

Purpose: After being rebranded in 2014, the acquisition cost of vasopressin (Vasostrict®) increased by approximately 10-fold. In addition, the reformulated product has a shorter compounded stability which results in the need to replace stock more frequently. These two factors have led to the need to reassess our utilization of vasopressin. In August 2016, the Department of Pharmacy spent approximately $41,000 on vasopressin, which is an increase in expenditure when compared with historical spending patterns. The objective of this project, therefore, is to evaluate current vasopressin administration practices in the medical intensive care unit (MICU) at an academic medical center.

Methods: This study will include four weeks of retrospective data. This data will be isolated through use of a Crimson drug and indication specific report, and will be collected for patients identified as having an ICD-9 coded diagnosis of “sepsis,” “severe sepsis,” or “septic shock” receiving vasopressin in the MICU. We will evaluate how often vasopressin was ordered and compounded by pharmacy, but then subsequently wasted. The number of vasopressin doses wasted will include those which are not administered within the expiration time or discontinued prior to administration. The findings from this study will be used to identify opportunities for education on appropriate vasopressin prescribing and administration practices, which in turn, will potentially lead to decreased waste and cost savings.

Poster Title: Evaluation of a pharmacist-run outpatient anticoagulation management service in durable mechanical support devices

Primary Author: Brittany Rosenfeld, Allegheny General Hospital, PA; Email: brittany.rosenfeld@ahn.org

Additional Author(s):
Sarah Winter
Abby Bauer
Edward Horn
Paula Horn

Purpose: Outpatient anticoagulation and/or antiplatelet therapy are central components of management for left ventricular assist device (LVAD) patients but must be carefully balanced with a high bleeding risk. Allegheny General Hospital pharmacist-run Anticoagulation Service has been managing outpatient anticoagulation in LVAD patients since March 2010 through telephone or face-to-face encounters. In 2012, publications showing an increase in pump thrombosis in HeartMate II® devices led to a shift in implant paradigms and anticoagulation practices at Allegheny General Hospital. This study is aimed to show the efficacy of the pharmacist-run Anticoagulation Clinic in managing LVAD patients with growing patient population and complexity.

Methods: The study was approved as an IRB exempt review. A retrospective chart review was performed on patients enrolled in the anticoagulation clinic during a twenty four-month period. The electronic health record was used to identify patients with a LVAD and at least two documented international normalized ratios (INRs). Results gathered were compared to an internal audit of the clinic performance that took place in 2010 in this patient population. Endpoints assessed included calculation of time in therapeutic range based upon patients’ INR goal and individual INRs during the time period. Clinical outcomes were evaluated through collection of bleeding and thrombotic events, death during the time period, and frequency of INR evaluations.

Results: Not applicable.
Conclusion: Not applicable

Poster Title: HMG-CoA Reductase Inhibitors in Patients after Heart Transplantation

Primary Author: Kelsey Moss, Allegheny General HOspital, PA; Email: kelsey.moss@ahn.org

Additional Author(s):
Edward Horn
Claire Walter
Nathan Verlinden

Purpose: HMG-CoA reductase inhibitors (statins) are recommended for patients after heart transplant; however the current prescribing practices for patients being managed at a tertiary care facility are unclear. Describing the percentage of patients on statin therapy and meeting low density lipoprotein (LDL) goal levels, and uncovering the barriers to statin maintenance can assist in understanding these practices. These data are crucial in determining whether a change in clinic practice is warranted to ensure continuity of patient care.

Methods: This retrospective observational study will be submitted to the Institutional Review Board for approval as quality improvement/quality assurance and is designed to describe the current prescribing practices for statin therapy in heart transplant patients at a tertiary care facility. Electronic medical record documentation will be reviewed for patients listed in the active heart transplant patient database aged 18 – 89 years who had undergone a heart transplant from 01/01/2011 to 06/01/2016. Patients will be grouped based on whether their medication list currently includes a statin medication. For all patients, baseline characteristics and pertinent donor characteristics will be collected. For patients on statin therapy, LDL level, name and dose of statin, and coronary allograft vasculopathy (CAV) will be collected. If applicable, reason for not reaching LDL goal will also be collected. For patients not on statin therapy, preclusions to statin therapy and CAV will be collected. The primary endpoint is the percentage of heart transplant patients on statin therapy. The percentage of these patients who also meet target LDL levels, the barriers to achieving target LDL levels, preclusions to statin therapy, and the percentage of patients with diagnosed CAV in statin-treated compared to non-statin treated patients will also be analyzed. Quantitative and qualitative results will be reported using descriptive statistics and chi-square tests where appropriate.
Results: Data collection is currently ongoing.

Conclusion: N/A - Research in progress.

Session-Board Number: 8-126

Poster Title: Impact of frequency of tele-monitoring interactions on time in therapeutic range for patients on warfarin performing self-testing of international normalized ratios (INRs).

Primary Author: Cynthia Kuntz, Allegheny General Hospital, PA; Email: cynthia.kuntz@ahn.org

Additional Author(s):
Paula Biscup-Horn
Sarah Winter
Angela Raymond

Purpose: Monitoring warfarin therapy by means of patient self-testing (PST) utilizing frequent (up to weekly) fingerstick INRs at home has become an alternative to traditional INR testing methods. However, PST increases the volume of follow-up tele-monitoring interactions by clinicians compared to (up to monthly) interactions with traditional testing methods. To better allocate clinician resources, less frequent tele-monitoring interactions for PST was implemented. The objective of this quality assurance study is to determine the impact on time in therapeutic range (TTR) for patients using PST when follow-up phone calls are not provided for every therapeutic INR.

Methods: This study will be submitted to the Institutional Review Board for exempt review. Patient electronic medical records will be retrospectively reviewed for the pre- and post-study periods. Pre-study period is defined as June 1, 2016 to August 31, 2016 when patients using PST received a follow-up phone call for every INR result. Post-study period is defined as October 1, 2016 to December 31, 2016 when patients received a follow-up phone call at least monthly or when their INR is out of therapeutic range. The primary outcome will be average TTR during the pre- and post-study periods. Secondary outcomes will include individual TTR, number of bleeding and thrombotic events, and number of non-adherence and non-reporting events. Other patient variables that will be collected include age, sex, warfarin indication, INR goal, INR results, length of warfarin therapy, number of INR results and number of clinician interactions per month. All data will be recorded without patient identifiers and maintain confidentiality. No intervention will occur to patients as part of the data collection. Electronic health records from the Outpatient Anticoagulation Clinic at Allegheny General Hospital will be used to collect patient data. All PST patients managed by the clinic from May through December 2016 will be
included in the study. Major exclusion criteria will include patients with a ventricular assist device and those considered vulnerable for research.

**Poster Title:** Evaluation of UFH nomogram for safety and user compliance  

**Primary Author:** Chelsea Konopka, Allegheny General Hospital, PA; **Email:** chelsea.konopka@ahn.org  

**Additional Author (s):**  
Laura Brickett  
Edward Horn  
Claire Walter  
Nathan Verlinden  

**Purpose:** Intravenous unfractionated heparin (UFH) is commonly prescribed for the prevention and treatment of thromboembolic disorders and is monitored by the activated partial thromboplastin time (aPTT). The Joint Commission requires institution-approved protocols for dosing and laboratory monitoring due to the high risk nature of UFH. In our institution, therapeutic ranges for UFH monitoring via aPTT have recently changed due to use of a new reagent. Additionally, a new Electronic Health Record (EHR) was implemented, creating operational changes for all users. The purpose of this project is to evaluate the compliance with and safety of these nomograms given these updates.  

**Methods:** This project was approved by the institution’s IRB as a Quality Improvement initiative. A retrospective chart review was conducted on patients receiving an intravenous UFH infusion from May 1, 2016 – June 30, 2016. The first 72 hours of UFH therapy was evaluated. Patients were excluded from the analysis if they met any of the following criteria: age less than 18 years, UFH discontinued prior to therapeutic aPTT, change of nomogram during therapy, UFH initiated at an outside hospital, use of a physician defined nomogram, use of an anti-Xa level nomogram, patients on extracorporeal membrane oxygenation, pregnancy, and incarcerated patients. Safety was assessed by measuring the following: proportion of patients with subtherapeutic, therapeutic, or supratherapeutic initial aPTT’s; time to first and second therapeutic aPTT values; time to two consecutive aPTT values; and number of adjustments prior to attaining first therapeutic aPTT. Compliance was evaluated by determining user adherence to the nomogram regarding timing of aPTT monitoring; utilization of dose titrations,
bolus dosing, and dosing holds; and utilization of the UFH order sets in the EHR. Data were evaluated utilizing descriptive statistics.

Poster Title: Transitions of care: assessment of antiretroviral medication errors in an academic medical center

Primary Author: Carley Buchanan, Allegheny General Hospital, PA; Email: robert.sutton@ahn.org

Additional Author(s):
Robert Sutton
Colton Collier
Cindy Magrini
Noreen Chan-Tompkins

Purpose: Medication errors involving HIV-infected patients treated with antiretroviral therapy (ART) are frequent during transitions of care (TOC) including hospital admission and discharge. Consequences of omitting or altering ART may include antiretroviral resistance, toxicities, treatment failure, and increased cost. To reduce drug waste, our institution removed combination antiretroviral products from the inpatient formulary and built combination antiretroviral linked orders (from single-entity products) in the computerized prescriber order entry (CPOE) system. The primary objective was to assess the frequency of medication errors related to ART on admission. The secondary objective was to determine the percentage of patients discharged on appropriate ART.

Methods: Exempt review was granted by the Institutional Review Board for this quality improvement project. A computerized report was generated in the CPOE system for patients prescribed commercially available ART between March 1, 2016 and September 30, 2016. Inclusion criteria: age 18 years and older, HIV-infection, and taking ART as an outpatient. Exclusion criteria: new ART started during the current admission, acute kidney injury or fluctuating renal function necessitating dose adjustment during admission. A retrospective chart review of the electronic medical record will be conducted. Data collected will include: age, sex, ethnicity, outpatient ART, inpatient ART, whether the ART was a co-formulated product, modified ART during admission as applicable and discharged ART regimen. Confidentiality will be maintained and no patient identifiers will be collected. Outcome measures include inpatient
and outpatient TOC prescribing errors tabulated as wrong medication, wrong frequency, wrong dose, omission, or ART regimen not reordered.

Results: From March 1 to September, 30, 2016, 46 patients were ordered ART. Of 136 orders, 50(36.8%) were combination ART and 86(63.2%) were single-entity ART. Data collection is ongoing and data analysis will be conducted when data collection is complete.

**Poster Title:** Retrospective analysis of treatment practices for managing coagulopathies in critically ill patients with cirrhosis

**Primary Author:** Daniel Jenniches, Allegheny General Hospital, PA; **Email:** daniel.jenniches@ahn.org

**Additional Author (s):**
Lauren Finoli
Sarah Young

**Purpose:** Critically ill patients with cirrhosis often present with coagulopathies. There is debate about whether an elevated international normalized ratio (INR) in the setting of liver impairment demonstrates a hypocoagulable state or a rebalanced coagulation equilibrium. Currently, there is a lack of quality studies evaluating the utilization of vitamin K or fresh frozen plasma (FFP) to prevent bleeding in cirrhotic patients with coagulopathies. This study aims to characterize the current practice of managing coagulopathies in critically ill patients with cirrhosis in the absence of bleeding.

**Methods:** This is a single-center retrospective cohort study. Patients residing in the medical intensive care unit with cirrhosis and a coagulopathy will be included in the study. Coagulopathy is defined as an INR of 1.5 or greater on at least one day. Patients with bleeding on admission or those who received treatment dose anticoagulation will be excluded. The primary objective is to determine the percentage of the study population that received vitamin K, FFP, both, or neither. Multiple secondary objectives will also be evaluated, which include characterizing the prescribing practice of vitamin K and FFP, evaluating the efficacy of vitamin K and FFP in correcting coagulopathies, and evaluating the safety of receiving treatment. The prescribing practice will be characterized by evaluating the dose given and administration route, the median total number of administrations, the median total amount of therapy received, and the percentage of product administrations that were given prior to a procedure. Efficacy will be assessed by the median INR after product administration and the percentage of major bleeding events in patients who received treatment. Safety will be assessed by the
percentage of thrombosis, transfusion-related acute lung injury, and anaphylaxis in patients who received treatment.

Poster Title: Direct-acting oral anticoagulants (DOACs) versus low-molecular weight heparin (LMWH) for the prevention of venous thromboembolism (VTE) recurrence in patients with malignancy

Primary Author: Jennifer Zhao, Conemaugh Memorial Medical Center, PA; Email: jzhao@conemaugh.org

Additional Author (s):
Sierra Roberts

Purpose: The current standard of care for venous thromboembolism (VTE) prophylaxis and treatment in cancer patients is low molecular weight heparin (LMWH). Direct-acting oral anticoagulants (DOACs) are new options that may address limitations of LMWH such as injection pain, inconvenience, and cost. Currently, there are no head-to-head studies comparing the two. This is a retrospective cohort study that will analyze the efficacy and safety of DOACs compared to LMWH in cancer patients for the prevention of symptomatic recurrent VTE.

Methods: This study was submitted to the Institutional Review Board for approval. The health system’s billing records will be used to identify patients with International Classification of Disease (ICD)-10 codes in the past 3 years for both venous thromboembolism (deep vein thrombosis or pulmonary embolism) and any type of solid or hematologic malignancies. Electronic medical records will be used to review each patient and collect data including treatment regimen, indication, start date, duration, cancer diagnosis, diagnosis date, metastatic status, treatment status, venous thromboembolism history, and occurrence date. Patients who used thrombectomy, caval filter, fibrinolytic agents for treatment of venous thromboembolism, or used therapeutic doses of an anticoagulant other than low-molecular weight heparin or direct-acting oral anticoagulants are excluded. Primary objective is to determine the incidence rate of venous thromboembolism recurrence (efficacy) in cancer patients on prophylactic anticoagulation. Secondary objective is to determine the incidence rate of clinically significant bleeding (safety). Hypothesis is direct-acting oral anticoagulants will have equal or less incidence of recurrent venous thromboembolism and bleeding than low-molecular weight heparin in cancer patients. All data will be stored in secure, password protected Microsoft Excel documents. Only investigators involved with this study will have access to data.

Poster Title: Outpatient clinic naloxone kit protocol

Primary Author: Annie Tien, Conemaugh Memorial Medical Center, PA; Email: atien1540@gmail.com

Additional Author(s):

Purpose: Naloxone is an opioid antagonist used as an antidote during an emergency situation to treat known or suspected acute opioid overdose manifested by central nervous system and/or respiratory depression. The goal of this study is to establish a protocol to appropriately identify outpatient clinic patients on opioids and provide them a naloxone kit. Each patient and/or caregiver will be counseled and must successfully demonstrate proper administration of a naloxone kit.

Methods: This is a prospective study of outpatients who are on opioids at the Family Medical Center, an outpatient clinic at Conemaugh Memorial Medical Center. Subjects less than eighteen years of age, pregnant women, patients who are incarcerated, or patients receiving opioids for an acute issue for less than a month will be excluded from the study. Recommendations for a naloxone kit will be made to physicians for patients on high doses of opioids equal to 100 milligrams or more of morphine equivalence per day, prescribed both opioids and benzodiazepines, or suspected of or known to have nonmedical use of opioids. Prescriptions for naloxone kits will be accompanied by standard counseling to the patients and/or caregivers on prevention, identification, and response to an opioid overdose.

Poster Title: Hepatitis C virus surveillance: Implementing a screening initiative in a family medicine clinic

Primary Author: Rebecca Morcheid, Conemaugh Memorial Medical Center, PA; Email: rmorchei@conemaugh.org

Additional Author(s):
Stephanie Thomas
Jeanne Spencer

Purpose: Hepatitis C Virus (HCV) affects approximately three million people in America and half of these infected patients are unaware. Due to the routes of transmission of the infection, patients with a history of intravenous drug use (IVDU), HIV, and patients born between the years of 1945 to 1965 are at an increased risk for contracting the infection. The objective of this study is to observe an increase in rate of patients screened for HCV in a family medicine clinic after implementation of a screening initiative which includes patient education and Pennsylvania state law requirements.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record will identify patients who have received an HCV screening or diagnostic test. The data collected for the purposes of this study will include: total number of patients who seek care in a family medicine clinic, patients who received an HCV screen, the high-risk category in which the patient was flagged for an HCV screen (IVDU, HIV, high-risk age range), results of the screen, if the infected patient received treatment, and if the infection was eradicated after completed medication therapy. Pharmacists and physicians will identify high-risk patients. The state of Pennsylvania will require a one-time offer of an HCV screen to patients born between the years of 1945 to 1965 beginning September 18th, 2016. The screening initiative will also include patient education delivered by healthcare providers and informational handouts. The primary outcome of this study will measure screening rates after the implementation of the screening initiative and compare them to previously reported screening rates. Secondary outcomes will measure the prevalence of positive screens in each high-risk category, the number of patients who received treatment, and the number of
infections that were successfully eradicated. After completion of data collection by the principal investigator and co-investigators, all patient identifiers will be erased.

Poster Title: Pharmacy-driven discharge antibiotic counseling for patients on oral or intravenous antibiotic therapy for osteomyelitis, endocarditis, or bacteremia

Primary Author: Paige Coleman, Conemaugh Memorial Medical Center, PA; Email: pcoleman@conemaugh.org

Additional Author(s):
Bret Chapman

Purpose: The Joint Commission released a new antimicrobial stewardship medication management standard for hospitals and nursing care centers that will go into effect on January 1, 2017. This new standard will include implementing new policies and practices to increase antibiotic education for patients and ensure proper use of antibiotics. The objective of this project is to create a protocol that will involve the completion of an antibiotic review for inpatients requiring long-term antibiotic therapy post-discharge, increase the patient’s understanding of their post-discharge antibiotic regimen, and improve overall patient satisfaction.

Methods: This quality improvement project will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients with a diagnosis code of osteomyelitis, endocarditis, and/or bacteremia. The following data will be collected: diagnosis, prescribed antibiotic (including strength and frequency), and duration of antibiotic therapy. An antibiotic review will be done to ensure the patient is on appropriate therapy. Patients will then be counseled on their antibiotic(s) prior to discharge and will receive a follow-up phone call one-week post-discharge and again at the end of antibiotic treatment. During the first follow-up phone call, the pharmacist will assess adherence, tolerability to medication, and the patient’s overall understanding of their antibiotic treatment. The second phone survey will be given at the end of treatment and will evaluate if the patient’s comfort level with their antibiotic regimen increased after counseling, if their overall care was improved due to the antibiotic counseling, and if it impacted their adherence to their medication therapy. The patient will also be asked if they missed any treatment doses and this will be recorded. All collected data will be de-identified after the completion of the project.

Poster Title: Transitions to Discharge: Evaluation of Pharmacist-Involvement in Discharge Planning

Primary Author: Kimberly Grant, Duquesne University Mylan School of Pharmacy/St. Barnabas, PA; Email: grantk@duq.edu

Additional Author (s):
Christine O'Neil

Purpose: Pharmacist involvement in the skilled nursing facility (SNF) has historically been limited to chart review. Today, shorter hospital length of stay and more acute patients contribute to the many challenges skilled nursing facilities face. The objective of this study is to investigate the effect of a pharmacist-run transitions of care model in a skilled nursing facility with a focus on discharge preparation. Primary outcomes will include re-hospitalization, emergency department visits, and readmission to SNF within 30 days of discharge.

Methods: This study will be submitted to the Institutional Review Board for approval. Patients admitted for skilled nursing stays beginning July 1, 2016 will be included. Admissions relating to respite stay, hospice care or long term care will be excluded. Sample size is projected to be 50-100 patients. These patients will be reviewed by a clinical pharmacist upon admission, three times weekly and on the day prior to discharge to ensure any medication-related problems are addressed prior to discharge home. Interventions will be documented as either relating to indication, adherence, effectiveness or safety. In addition, high risk diagnoses of acute pain, diabetes and congestive heart failure will prompt additional monitoring as outlined in the study protocol. Both descriptive data and outcomes data will be collected from this group and a comparator group at another skilled nursing facility within the health system.

Poster Title: Economic impact of patient centered pharmacy services in long term care.

Primary Author: Teresina Imbrogno, Duquesne University Mylan School of Pharmacy/St. Barnabas, PA; Email: imbrognot@duq.edu

Additional Author(s):
Christine O'Neil
Khalid Kamal

Purpose: The purpose of this study is to evaluate pharmacy services provided, specifically looking at types of recommendations, acceptance rates, and outcomes of recommendations made for medication related problems, in order to identify the clinical and economic impact of patient-centered pharmacy services in a skilled nursing facility.

Methods: Retrospective data will be collected at St. Barnabas’s Skilled Nursing Facility through an electronic charting system based on past pharmacy recommendations to improve and resolve medication related problems from June 2015 to June 2016. Data collected will include patient demographics, what the recommendation was, outcome of recommendation and the pharmacy service the recommendation was made through. Acceptance rate for each type of patient-centered pharmacy service provided, including medication reconciliation upon admission, anticoagulation monitoring, antibiotic monitoring, requested review, and falls, will be analyzed for clinical impact. Economic impact of pharmacy services at St. Barnabas will then be determined using cost-benefit analysis methodology.

**Poster Title:** Analysis of increased 4-factor prothrombin complex concentrate waste at an academic medical center

**Primary Author:** Demi Lenox, Einstein Healthcare Network, PA; **Email:** dlenox@mail.usciences.edu

**Additional Author (s):**
Leila Forouzan

**Purpose:** The FDA has only approved 4-Factor Prothrombin Complex Concentrate (Kcentra®) for acute major bleeding or urgent surgery in patients who are taking a vitamin K antagonist. Kcentra® is a costly medication and it has been speculated that in some cases doses are being ordered, but then subsequently not administered. Once prepared, the drug must be used within four hours or the dose is wasted. This six month retrospective chart review in an academic medical center aims to analyze the cost incurred by the wasting of this drug and to evaluate cases associated with discontinuation of 4-Factor Prothrombin Complex Concentrate.

**Methods:** A retrospective drug utilization review is being performed on 23 patients who had an order for 4-Factor Prothrombin Complex Concentrate within the past eight months. This is a single-center, hospital-based chart review where the variables of interest are physician and department placing the order, patient’s home anticoagulation, indication for order, INR before and after 4-Factor Prothrombin Complex Concentrate administration, proportion of ordered doses that were subsequently administered, and reason for discontinuation of the order. Analysis of appropriateness of the dose ordered for the patient will also be conducted. Lastly, calculation of the cost of therapy, or in some cases, the cost of the therapy that was never given will be calculated in order to try to minimize wasting of 4-Factor Prothrombin Complex Concentrate.

Poster Title: Assessment of the prescribing patterns for the management of carbapenem-resistant Enterobacteriaceae infections at an academic medical center

Primary Author: Rachel Lynch, Einstein Medical Center, PA; Email: lynchrac@einstein.edu

Additional Author(s):
Seung Ha

Purpose: Infections due to multi-drug resistant gram negative organisms are a growing issue within healthcare. In particular, carbapenem-resistant Enterobacteriaceae present clinicians with the challenge of determining antimicrobial regimens due to the lack of treatment guidelines. Treatment of these serious infections usually involves combination therapy with antimicrobials, including high-dose carbapenems, ceftazidime-avibactam, colistimethate sodium and other alternative agents. Many of these antimicrobials have limitations to therapy, including side effects, inadequate concentrations at the infection site, development of resistance, and lack of availability. This research will provide an analysis of prescribing patterns of clinicians at an academic medical center when treating these infections.

Methods: A retrospective chart review will be conducted to collect information on the prescribing patterns of clinicians when treating carbapenem-resistant Enterobacteriaceae infections. The site of infection, organism isolated, and antibiogram of the organism will be documented. Patient factors that could influence which regimen is selected will also be collected. These factors include baseline creatinine clearance, incidence of acute kidney injury, allergies, and their residence prior to admission or recent hospitalization. Antimicrobial agents, doses, frequency of administration, duration of treatment and rate of infusion will then be collected. We will evaluate if the regimens vary based on prescriber and if the antimicrobials are ordered appropriately. We will calculate the frequency of regimens selected and determine if there is a consistent prescribing pattern that is seen at this institution. We will also analyze if varying patient factors impacted the choice to order the selected regimen.

Poster Title: Assessment of Prescribing and Monitoring Habits for Patients Taking an Antiarrhythmic and a Concomitant QTc-prolonging Antibiotic

Primary Author: Kelsey Noss, Einstein Medical Center, PA; Email: nosskels@einstein.edu

Additional Author(s):
Travis Reinaker

Purpose: The QTc interval on an electrocardiogram (EKG) represents depolarization and repolarization of cardiac ventricles. QTc-prolongation (>450 milliseconds in males, and >470 milliseconds in females) can predispose patients to life-threatening ventricular arrhythmias. QTc-prolongation occurs in 1-10% of patients taking QTc-prolonging antiarrhythmics, and < 1% of patients taking macrolide or fluoroquinolone antibiotics. The concomitant use of ≥2 QTc-prolonging medications increases this risk. However, it is unknown if EKGs alter prescribing and monitoring habits when these medications are combined. This project will observe prescribing and monitoring habits for patients taking an antiarrhythmic and a concomitant QTc-prolonging antibiotic at an academic medical center.

Methods: This retrospective chart review, determined to be exempt from IRB-approval, included patients admitted to an academic medical center from October 1, 2015 to September 30, 2016. Patients were identified based upon an electronic report identifying drug interaction alerts advising both prescribers and pharmacists of an increased risk of a QTc-prolonging effect. Patients taking either amiodarone or sotalol and had ciprofloxacin, moxifloxacin, or azithromycin added to their treatment regimen during admission were included. Data collection included patient age and gender, inpatient medical service, initial and additional QTc-prolonging agent, the presence or absence of baseline and follow-up EKGs, QTc interval measurement, pharmacist interventions, and physician therapy modifications. Descriptive statistics will be used to analyze patient demographics, prescribing, and monitoring data.

Poster Title: Monitoring and Management of Trastuzumab-Induced Cardiotoxicity at an Outpatient Cancer Center

Primary Author: Anupama Divakaruni, Geisinger Medical Center, PA; Email: a.divakaruni@gmail.com

Additional Author(s):
Lori Stopper
Samuel Eckel
Victor Vogel

Purpose: Trastuzumab is a monoclonal antibody that is indicated for treatment of HER2 positive adjuvant or metastatic breast cancer and gastric cancers. Cardiomyopathy is one of the many toxicities associated with trastuzumab. The prescribing information suggests monitoring the left ventricular ejection fraction (LVEF) at baseline and every three months during therapy. It also discusses the course of therapy when a decrease in LVEF occurs. The administration of many chemotherapy agents, including trastuzumab, occurs in an outpatient setting. While the monitoring and management of cardiotoxicity has been studied in clinical trials and institutional settings, the consistency in an outpatient setting is unknown.

Methods: In this retrospective cohort study, we seek to analyze the records of patients who initiated therapy with trastuzumab between January 1, 2014 and July 31, 2015 in the Geisinger Health System to better characterize the extent of cardiac monitoring and interruptions in therapy. The primary endpoints include the number of patients during this time period that were monitored and had interruptions in therapy as outlined in the package insert while taking trastuzumab. The secondary endpoints include the number of patients that discontinued therapy as a result of cardiac dysfunction, the number of patients that resumed therapy and the dose at resumption after recovery of cardiac function, the number of patients that reported symptoms of CHF, whether patients had an ECHO or MUGA scan to determine cardiac function, the number of patients that were started on cardio-protective medications, and the number of patients receiving trastuzumab for adjuvant versus metastatic breast cancer.
**Results:** Between January 1, 2014 to July 31, 2015, there were approximately 40 patients within the Geisinger Health System (GHS) that were treated with trastuzumab. Data collection is in progress.

**Conclusion:** Conclusions will be made after completion of data collection and analysis.

Poster Title: Risk of hospital-acquired Clostridium difficile enterocolitis following treatment with cefepime or piperacillin/tazobactam: A retrospective chart review

Primary Author: Bradley Lauver, Geisinger Medical Center, PA; Email: belauver@geisinger.edu

Additional Author(s):
Ricky Rampulla
Sally Tice

Purpose: Clostridium difficile (C. diff) enterocolitis is associated with significant morbidity and mortality as well as direct and indirect costs of around $1 billion per year in the United States, according to the Centers for Disease Control and Prevention (CDC). C. diff enterocolitis is also a well-recognized risk of antibiotic use and both cefepime and piperacillin/tazobactam are frequently used broad-spectrum, empiric antibiotics. The objective of this study is to determine the relative risk of developing C. diff enterocolitis after a course of either cefepime or piperacillin/tazobactam.

Methods: The Institutional Review Board approved this retrospective chart review. The electronic health record system will identify hospitalized patients aged 18 and older who received two or more consecutive doses of cefepime and/or piperacillin/tazobactam. The following data will be collected: patient medical record number, age, gender, ethnicity, comorbidities (i.e. obesity, renal dysfunction, hepatic dysfunction, cardiac dysfunction, history of C. diff enterocolitis), prior to admission and inpatient medications, date of admission and discharge, date of birth and death (if applicable), and ICD9 and ICD10 diagnostic codes for C. diff enterocolitis. All electronic study data will be encrypted and stored confidentially. Relative risk of patients developing C. diff enterocolitis within eight weeks of receiving either cefepime or piperacillin/tazobactam will be calculated. Mortality during hospitalization, hospital length of stay, and readmission rates in patients who developed C. diff enterocolitis attributed to either antibiotic will also be reviewed.

Poster Title: Utilization of four-factor prothrombin complex concentrate (PCC): A drug-use evaluation

Primary Author: Lauren Para, Geisinger Medical Center, PA; Email: lmpara@geisinger.edu

Additional Author(s):
Sarah Hale
Melissa Millo

Purpose: Four-factor prothrombin complex concentrate (PCC, Kcentra) is approved in the health system's anticoagulation guidelines to be used for the reversal of warfarin and factor Xa inhibitors in patients with severe or life-threatening bleeding or an urgent surgery or procedure. However, it is often used for non-approved indications. With the high cost and increased risk of thromboembolic complications associated with its use, it is essential to optimize the utilization of four-factor PCC and reserve for patients in which the benefits outweigh the risks. The objective of this evaluation is to determine whether four-factor PCC is used appropriately within the health system.

Methods: The electronic health record system will identify patients 18 years of age or older who were admitted to a hospital within the health system and had four-factor PCC ordered between March 1, 2016 and August 31, 2016. The following data will be collected: patient medical record number, weight, prior to admission anticoagulant, international normalized ratio (INR) prior to administration, indication for four-factor PCC use, dose, number of doses given, number of patients with recent thromboembolic events (within 3 months), dose and route of phytonadione if used, pharmacist interventions, attending provider and service that ordered four-factor PCC, and whether the appropriate order set was used. All data will be maintained confidentially and presented without patient identifiers.

**Poster Title:** Medication usage evaluation of chemotherapy dose rounding at Geisinger Medical Center

**Primary Author:** Tristan Maiers, Geisinger Medical Center, PA; **Email:** tamaiers@geisinger.edu

**Additional Author(s):**
Jenna Carmichael  
David Klinger

**Purpose:** Due to increasing patient volumes and decreasing reimbursement, hospitals are tasked with finding ways to meet the demands of its patients without increasing costs. Antineoplastic chemotherapy costs have risen significantly over the years and accounts for a large portion of a pharmacy budget. One approach to decrease costs and reduce waste includes dose rounding, a technique that reduces waste and cost without decreasing efficacy or increasing toxicities. The objective of this study is to quantify and evaluate the inventory and financial benefits of dose rounding by analyzing pharmacist interventions completed through the electronic medical record.

**Methods:** The electronic medical record system will identify oncology patients 18 years of age and older who have received single-dose vial intravenous chemotherapy at Geisinger Medical Center or Geisinger Wyoming Valley who got their chemotherapy dose rounded per protocol. Chemotherapy agents used for investigational purposes will be excluded from analysis. The following data will be analyzed from October 2014 through July 2016: order identification number, patient's medical record number, medication name, intervention classification, and intervention documentation. Intervention documentation includes pharmacist's name, time of intervention creation, original ordered chemotherapy dose, chemotherapy dose administered to patient, and facility where chemotherapy was administered. All data will be maintained confidentially. The reviewer will also appraise a subset of interventions to verify if the dose rounding policy was appropriately followed per protocol.

**Poster Title:** Validating a standardized weight-based vancomycin dosing protocol in end stage renal disease patients on intermittent hemodialysis

**Primary Author:** Mandana Naderi, Geisinger Wyoming Valley Medical Center, PA; **Email:** mnaderi@geisinger.edu

**Additional Author(s):**
Scott Harley
Jamie Kerestes

**Purpose:** No guidelines currently exist for optimal vancomycin dosing and monitoring strategies in end-stage renal disease patients on intermittent hemodialysis. The purpose of this study is to validate a standardized weight-based vancomycin dosing protocol in hospitalized patients on intermittent hemodialysis.

**Methods:** This retrospective study will determine if a standardized weight-based vancomycin dosing protocol leads to consistent vancomycin trough levels between 15-25 mg/L. End stage renal disease patients were deemed eligible for this study if they were prescribed IV vancomycin and received intermittent hemodialysis 3 times/week during their hospitalization (e.g. Monday, Wednesday, December 7, Friday) from January 1, 2015 to December 31, 2016. All patients received a loading dose of 20 mg/kg, then a 10 mg/kg vancomycin dose after each of their hemodialysis sessions. A pre-dialysis vancomycin trough level was obtained after a loading dose was given but before their first hemodialysis session. If patients' first vancomycin level was therapeutic between 15-25 mg/L, then their level was checked only once a week during their hospitalization. If patients had a supratherapeutic initial trough level that was >25 mg/L, then more levels were obtained during the week as appropriate. The vancomycin dosing and monitoring data will be pulled from our electronic medical record system. Any data obtained will not include any patient identifiers and will be kept confidential. This study will be submitted to the Institutional Review Board for approval.

**Results:** N/A

**Conclusion:** N/A

**Poster Title:** Effectiveness of a modified vancomycin dosing protocol developed for obese patients

**Primary Author:** Matthew Hadginske, Geisinger Wyoming Valley Medical Center, PA; **Email:** matthew.hadginske@wilkes.edu

**Additional Author(s):**
Michelle Budzyn
Sarah Miller

**Purpose:** Intravenous vancomycin is indicated for the treatment of severe infections caused by susceptible gram-positive microorganisms. Significant adverse effects including nephrotoxicity and ototoxicity necessitate therapeutic monitoring of vancomycin levels. Dosing is initially based on a patient’s actual body weight and renal function. However, current weight-based dosing recommendations may result in higher trough concentrations in obese patients compared with non-obese patients. The objective of this study is to compare the effectiveness of an original (15 mg/kg/dose) and a modified (10 mg/kg/dose) dosing protocol in attaining goal trough concentrations in the obese patient population, as well as to compare the incidence of nephrotoxicity.

**Methods:** This retrospective study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients greater than or equal to 120 kg with a baseline serum creatinine less than or equal to 1.3 mg/dL, who have received two or more doses of vancomycin with at least one subsequent vancomycin trough. The following data will be collected: patient age, gender, height, weight, indication for vancomycin use, serum creatinine, BUN, vancomycin doses, vancomycin troughs, and concurrent nephrotoxic medications. Patients weighing greater than or equal to 120 kg and greater than or equal to 140 percent of their ideal body weight who received a 20-25 mg/kg (3 g maximum) loading dose of vancomycin will be included. Patients will be divided into two groups based upon the initial maintenance dose administered. The original protocol group will include patients who received maintenance doses of 15 mg/kg/dose, while the modified protocol group will include patients who received maintenance doses of 10 mg/kg/dose. All vancomycin dosing is based on the patient’s actual body weight. Vancomycin trough concentrations of 15-20 mcg/mL will be
considered therapeutic. Trough concentrations less than 15 mcg/mL will be considered below goal, while troughs greater than 20 mcg/mL will be deemed above goal. Nephrotoxicity will be defined as an increase in serum creatinine greater than or equal to 0.3 mg/dL within 48 hours.

**Poster Title:** Incidence of acute kidney injury among patients initiated on vancomycin and piperacillin/tazobactam versus vancomycin and cefepime

**Primary Author:** Megha Shah, Hahnemann University Hospital, PA; **Email:** megha.shah@tenethealth.com

**Additional Author(s):**
Jay Patel
Suraj Rajasimhan
Tiffany Bias

**Purpose:** Broad spectrum antibiotics are routinely initiated in hospitalized patients to provide empiric coverage of suspected pathogens. Clinicians often utilize vancomycin and beta-lactams for such regimens until susceptibilities are available. Recent literature has associated concomitant vancomycin and beta lactam antibiotics with nephrotoxicity, particularly, piperacillin/tazobactam. The objective of this study is to evaluate the incidence of acute kidney injury among patients receiving vancomycin and piperacillin/tazobactam versus vancomycin and cefepime combination therapies.

**Methods:** This study is a retrospective, observational, cohort analysis performed at Hahnemann University Hospital, a 496-bed teaching hospital in Philadelphia, Pennsylvania. Patients who received vancomycin with piperacillin/tazobactam or cefepime for at least 48 hours will be included in the study. Patients will be excluded if they had baseline chronic kidney disease or on any form of continuous renal replacement therapy. The following data will be collected: demographics, renal function, antibiotic dosages, total duration of combination therapy, number of concomitant nephrotoxic agents, and initial and maximum vancomycin trough levels. The primary outcome will be the incidence of acute kidney injury defined as an increase in serum creatinine by two times from baseline according to the Risk Injury Failure End Stage Renal Disease criteria and the Acute Kidney Injury Network criteria. Secondary outcomes will include total length of hospital stay and length of intensive care unit stay. All continuous data will be analyzed using the Student’s t-test or Mann-Whitney U test and all categorical data will be analyzed using the Chi Squared test. Baseline characteristics will be analyzed using means and standard deviations. For all analyses, alpha will be set at 0.05.

Poster Title: Efficacy and nephrotoxicity associated with colistin use in the treatment of multi-drug resistant (MDR) infections

Primary Author: Aiman Bandali, Hahnemann University Hospital, PA; Email: aiman.bandali@tenethealth.com

Additional Author(s):
Tiffany Bias

Purpose: In light of carbapenem resistance and limited antimicrobial armamentarium, colistimethate sodium has become a competing option for MDR infections. Its use has been precluded given the disparity that exists in reported rates of nephrotoxicity with intravenous administration between old and recent studies; older studies reporting rates upward of 65%, with more recent reporting 8-19%. These differences are attributed to pharmacokinetic data derived from prodrug rather than active metabolite studies. The objective of this study is to evaluate colistin associated nephrotoxicity according to a standardized definition of acute kidney injury (AKI) and assess clinical outcomes in patients with documented MDR infections.

Methods: This retrospective study will be conducted at Hahnemann University Hospital, a 496-bed tertiary hospital located in Philadelphia, PA, upon Institutional Review Board approval. Patients who have received at least 48 hours of colistin treatment with documented MDR infections will be included for further analysis. The following data will be collected: patient demographics; creatinine clearance, glomerular filtration rate (GFR); comorbidities; albumin; vital signs; colistin dose, frequency, and duration; concomitant nephrotoxins; and culture data. The primary outcome is the rate of AKI according to the Risk, Injury, Failure, Loss and End stage renal disease (RIFLE) criteria. Secondary endpoints include clinical cure, infection related mortality, 30 day mortality, and length of stay. A univariate analysis will be conducted to assess risk factors associated with AKI. Baseline characteristics will be evaluated via means and standard deviations. Categorical variables will be compared using the Chi square or Fisher’s exact, where appropriate. The Student paired t or Mann Whitney U test will be used to assess continuous variables.

Poster Title: Incidence and risk factors associated with tacrolimus-induced posterior reversible encephalopathy syndrome in allogeneic hematopoietic cell transplant recipients

Purpose: The incidence and risk factors associated with tacrolimus-induced posterior reversible encephalopathy syndrome (PRES) in hematopoietic cell transplant (HCT) recipients remains poorly characterized. The objective of this study is to define the incidence and risk factors associated with PRES following HCT.

Methods: This study will be submitted to the University of Pennsylvania Institutional Review Board for approval. This is a retrospective case-control study that will include HCT recipients receiving tacrolimus-based graft-versus-host disease (GVHD) prophylaxis. Patients will be excluded if they are not receiving tacrolimus, < 18 years old, or possess other possible PRES induced etiologies (such as infection, metabolic disturbances, thrombotic thrombocytopenic purpura and structural neurological lesions). The following data points will be collected: patient age, weight, sex, past medical history (hypertension and chronic kidney disease), conditioning intensity, graft source, conditioning regimen, diagnosis of GVHD, GVHD prophylaxis regimen, day of PRES onset (following HCT), tacrolimus dose and levels 24 and 48 hours prior to PRES onset, tacrolimus levels on the day of PRES onset, pertinent laboratory parameters (serum creatinine, magnesium, blood pressure liver function tests), diagnosis of PRES (clinical findings or objective radiographic imaging). All data will be recorded without patient identifiers and maintained confidentially. The primary endpoint is to identify risk factors associated with PRES in HCT recipients.

Poster Title: Implementation of reminder software in the operating room and its effect on the appropriate re-dosing of intra-operative antimicrobials

Primary Author: Stephen Saw, Hospital of the University of Pennsylvania, PA; Email: tsalovin@gmail.com

Additional Author (s):
Tyler Salovin
Daniel Timko
Shawn Binkley
Keith Hamilton

Purpose: In order to maintain adequate serum concentrations, certain antimicrobials should be re-dosed during surgery in the setting of a prolonged procedure or large volumes of blood loss. Examples of these antimicrobials include ampicillin/sulbactam, aztreonam, cefazolin, cefepime, penicillin, and clindamycin. In April 2015, reminder software was implemented into EPIC OPTIME to alert anesthesiologists to re-dose these antimicrobials based on procedure length and blood loss. The objective of this study will be to determine the effect of this software on the appropriate re-dosing of intra-operative antimicrobials and the incidence of CDC reported surgical site infections.

Methods: A retrospective, single-center, quasi-experimental study of approximately 200 patients who have undergone a surgical procedure between April 2014 and June 2016 at the Hospital of the University of Pennsylvania will be included. Patients who underwent surgery for < 3 hours, surgery with no or minimal blood loss recorded, and patients with previously identified infections prior to surgery will be excluded. Patients will be assessed one year prior to and after implementation of this reminder software. Data variables that will be collected include patient, surgery, and infection demographics. An interrupted time series analysis will be performed to assess the impact of implementing a reminder alert software on the appropriate re-dosing of intra-operative antimicrobials and descriptive statistics will be used to analyze demographic variables.

**Poster Title:** Use of granulocyte colony-stimulating factor (G-CSF) in leukopenic patients post-kidney transplantation

**Primary Author:** Vicky Kuo, Hospital of the University of Pennsylvania, PA; **Email:** stephanie.hamel@uphs.upenn.edu

**Additional Author (s):**
Stephanie Hamel
Michael Moranville
David Johnson
Jennifer Trofe-Clark

**Purpose:** Leukopenia is a frequent complication following kidney transplantation, which can significantly increase a patient’s risk of viral and bacterial infection. In addition to reducing medications that may cause leukopenia, colony stimulating factors (CSFs) have been employed to more quickly achieve white blood cell (WBC) count recovery. However, in the solid organ transplant population, guideline recommendations regarding the use of CSFs are lacking and clinical experience is limited. The objective of this study is to describe the use of granulocyte colony-stimulating factor (G-CSF) when prescribed to help achieve WBC count recovery in kidney transplant recipients with leukopenia.

**Methods:** This study will be conducted at our post-renal transplant clinic and has been approved by the Institutional Review Board. The electronic medical record will be used to retrospectively identify kidney transplant recipients who were prescribed at least one dose of G-CSF between January 1, 2013 and June 30, 2016. For the purpose of data analysis, we will define clinical leukopenia as WBC less than 3000 cells/mm3 based on previous literature. The following baseline data will be collected at the time of leukopenia: patient demographics, indication for kidney transplantation, type of kidney transplantation, donor and recipient cytomegalovirus (CMV) status, induction and maintenance immunosuppression regimen, opportunistic infection prophylaxis regimen, serum creatinine, and CMV polymerase chain reaction (PCR). WBC, absolute neutrophil count (ANC), and transplant medication regimen will be collected at the following time points: 1-2 weeks prior to leukopenia, at the time of leukopenia, and at 1 week, 1 month, and 3 months after leukopenia. Provider documentation
and laboratory data will be reviewed to evaluate the following: time from transplant to leukopenia, G-CSF dose prescribed, number of G-CSF doses administered, days to WBC count recovery, changes in immunosuppression and opportunistic infection prophylaxis regimens due to leukopenia, biopsy-proven acute rejection within 3 months, and opportunistic infection or infection requiring hospitalization within 3 months.

Poster Title: Cisatracurium dose finding in medical intensive care unit patients with acute respiratory distress syndrome

Primary Author: Alison Merkel, Hospital of the University of Pennsylvania, PA; Email: alison.merkel@uphs.upenn.edu

Additional Author(s):
Kyle Massey
Christina Candeloro
Cassandra Bellamy
Barry Fuchs

Purpose: Neuromuscular blockade with cisatracurium has been shown to improve mortality in the acute respiratory distress syndrome (ARDS) population. Train-of-four (TOF) monitoring is a commonly used method for determining depth of neuromuscular blockade, however correlation between dose and train-of-four response in ARDS patients is not well elucidated. Alterations in factors affecting the pharmacokinetics and pharmacodynamics of cisatracurium may impact the dose required to achieve adequate TOF response. The objectives of this study are to determine the average steady-state dose of cisatracurium required to elicit adequate neuromuscular blockade measured by TOF and to determine what factors impact the dose.

Methods: This is a single-center, retrospective cohort study pending approval by the Institutional Review Board at the Hospital. All patients receiving cisatracurium infusion without interruption for at least 12 hours between 7/1/11 and 6/31/16 will be cross referenced with medical intensive care unit admissions and the internal ARDS database to target an estimated inclusion of 250 patients. Provider documentation will be reviewed to confirm the diagnosis of ARDS. Patients will be excluded if they are receiving cisatracurium for indications other than ARDS, do not have a TOF documented at baseline or during treatment, have a history of neuromuscular disease, or are pregnant. The following data will be collected at baseline: age, gender, race, weight, serum creatinine, PaO2:FiO2 ratio, Simplified Acute Physiology Score II (SAPS II), and body mass index (BMI). Adequate neuromuscular blockade is defined as a TOF response of one to two. Steady state dose will be defined as two consecutive TOF measurements of one to two recorded at least three but no more than six hours apart.
Temperature and pH will be captured during steady state and analyzed as secondary outcomes with a priori identified predictors of dose including age, BMI, and presence of acute kidney injury. Dose findings will be described using measurements of central tendency. Secondary outcome measurements will be evaluated using multivariable logistic regression.

Poster Title: Evaluation of the use of benzodiazepines in elderly patients who are taking opioid medications

Primary Author: Sebastian Choi, Lake Erie College of Osteopathic Medicine/Millcreek Community Hospital, PA; Email: sebastianchoi28@gmail.com

Additional Author(s):
Abbey Krysiak

Purpose: The US Food and Drug Administration recently added a boxed warning on the opioid and benzodiazepine labeling about serious risks and death when combining opioid pain or cough medications with benzodiazepines. The objective of this study is to evaluate the use of benzodiazepines in elderly patients who are also taking opioid medications in a sub-acute rehab/long-term care facility.

Methods: This is a medication use evaluation conducted at the LECOM Senior Living Center in Erie, PA. This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will be used to identify patients who are on opioids and benzodiazepines, opioids alone, or benzodiazepines alone. The data that will be collected includes patient’s age, opioid or benzodiazepine agents given, indications for such medications, directions of use (scheduled versus as needed), history of as needed administration, duration of combined use, and changes in doses (such as gradual dose reductions). Provider documentation will also reviewed for identifying reasons for continued use or decreased doses. If available, pain scale ratings, before and after opioid administration, will be obtained. All data will be recorded without patient identifiers and maintained confidentially in a secure location within the institution. Collected information as well as providers’ medication prescribing and discontinuing habits will be reviewed and analyzed using descriptive statistics.

Poster Title: Retrospective review of an ambulatory clinical pharmacist’s interventions within a primary care ambulatory collaborative care team

Primary Author: Chelsea Evry, Lancaster General Health/ Penn Medicine, PA; Email: cevry2@lghealth.org

Additional Author(s):
Nafisa Khan
Adrienne Jantzi

Purpose: The patient centered medical home (PCMH) model is designed to improve the quality, efficacy and safety of primary care by providing the individual patient comprehensive and integrated healthcare through multidisciplinary care. Lancaster General implemented an ambulatory collaborative care team within each PCMH. The team consists of a care manager, social worker, community health worker and ambulatory pharmacist. One goal of this team is to assist patients that have complex diseases, multiple chronic illnesses, frequent hospitalizations and/or psychosocial barriers. The purpose of this study is to review the role of the ambulatory pharmacist within this specific type of team.

Methods: This is a single center, retrospective, observational study. One-hundred and twenty-five adults (age greater than or equal to 18 years) with an institution specific, general risk score of greater than 10 seen by an ambulatory care multidisciplinary team from October 1, 2015 to November 30, 2016 will be retrospectively entered into a database. The general risk score is calculated by factors including: patient disease state, social and behavioral determinants, number of emergency department visits and number of hospital admissions. The primary objective is number of interventions made by a clinical ambulatory care pharmacist. Secondary objectives include type of interventions made by the clinical ambulatory care pharmacist, medication adherence of patients seen by the team, identification of potential interventions in patients not referred to the clinical ambulatory care pharmacist, and type of medication errors identified by the clinical ambulatory care pharmacist. Data collected includes: demographic information, serum creatinine, estimated glomerular filtration rate, glycosylated hemoglobin A1c, low density lipoprotein, serum blood glucose, serum potassium and blood pressure.

**Poster Title:** Impact of pharmacist-driven management on compliance to an institution-specific perioperative bridging algorithm versus standard of care  

**Primary Author:** Katlyn Combs, Lancaster General Health/ Penn Medicine, PA; **Email:** kcombs2@lghealth.org  

**Additional Author (s):**  
Jennifer Walls  
Greta Kemmer  

**Purpose:** Perioperative bridging management remains an ongoing topic of interest for surgeons, primary care providers and pharmacists. Limited evidence is available on provider compliance to institution-specific perioperative anticoagulation bridging algorithms and whether compliance has an effect on patient-oriented outcomes. This study was designed to determine whether pharmacist-driven management of a perioperative bridging anticoagulation protocol improves compliance to an institution-specific perioperative bridging algorithm.  

**Methods:** This study is a retrospective cohort at Penn Medicine Lancaster General Health and has been submitted to the Institutional Review Board for approval. A report will be generated to identify those patients who had an “active anticoagulation episode” and underwent a procedure or surgery at Penn Medicine Lancaster General Hospital between October 1, 2016 and December 31, 2016. A password-protected, HIPAA-compliant software program will be designed to randomly choose a total of 50 patients for each group who meet the inclusion and exclusion criteria. The study will compare compliance to a perioperative anticoagulation bridging algorithm between Group A (Pharmacist-Driven Management; those patients whose perioperative bridging anticoagulation plan was managed by a pharmacist) and Group B (Standard of Care; those patients whose perioperative bridging anticoagulation plan was not managed by a pharmacist). Secondary outcomes will include individual components of compliance, acceptance rate of pharmacist bridging recommendations, thromboembolic and major bleeding events within 30 days of procedure, readmissions related to thromboembolism or bleeding and death due to thromboembolism or bleeding.

**Poster Title:** Is there a difference between high dose 3-factor and 4-factor prothrombin complex concentrate for emergent warfarin reversal?

**Primary Author:** Joel Musser, Lancaster General Health/Penn Medicine, PA; Email: jmusser2@lghealth.org

**Additional Author(s):**
- Jennifer Costello
- Daniel Wu

**Purpose:** There are limited data comparing 4-factor prothrombin complex concentrate (PCC) to high dose 3-factor PCC in regards to efficacy and safety when utilized for emergent warfarin reversal. The purpose of this study is to compare the effect on INR of 3-factor and 4-factor PCC in patients receiving warfarin in need of emergent reversal due to a bleeding event or surgical procedure.

**Methods:** This study will be submitted to the Institutional Review Board for approval. The proposed investigation is a single-center retrospective analysis at a community teaching hospital that will be conducted by pharmacist evaluation of any inpatient who meets the criteria for inclusion. All patients who were taking warfarin and in need of emergent reversal of their INR for which either high dose 3-factor (35 units/kg) or 4-factor PCC were ordered will be identified using the institution’s electronic health record. The projected number of patients to be included in the study is approximately 100, with an estimated number of 50 patients receiving 4-factor PCC, and 50 patients receiving 3-factor PCC. The demographic data that will be collected includes: sex, age, actual body weight, ideal body weight, indication for PCC, baseline INR, INR following PCC administration, PCC dose, Vitamin K administration and dose, fresh frozen plasma administration and dose, hemoglobin and hematocrit, platelet count, blood pressure upon admission, antiplatelet use, warfarin indication, and renal function. For assessment of the occurrence of adverse effects, progress notes, doppler and computerized tomography scans will be evaluated for evidence of any thrombosis.

Poster Title: Time to first antibiotic administration in adult oncology patients with fever who present to the emergency department and infusion centers

Primary Author: Breana Goscicki, Lehigh Valley Health Network, PA; Email: breanagoscicki@gmail.com

Additional Author (s):
Janine Barnaby

Purpose: Febrile neutropenia (FN) is a complication that occurs in 10-30% of oncology patients receiving chemotherapy and is deemed a medical emergency. Due to the likelihood of quick progression of infection and the significant mortality associated with FN, it is recommended that patients receive timely empirical antibiotic therapy upon presentation. The purpose of this retrospective study is to assess the time to first antibiotic administration (TTA) in adult oncology patients presenting with fever to the emergency department (ED) and infusion centers as well as summarize the antibiotic regimens patients received.

Methods: This study will be submitted to the Institutional Review Board for approval. Emergency department records, adult oncology infusion center records, and admission records will be used to generate a list of patients that presented and were assigned a diagnosis of malignancy and fever or neutropenic fever between June 1, 2013 and September 30, 2016. Patients will only be included if they received chemotherapy in the 30 days prior to presentation. Patient data to be collected includes: medical record number, age, gender, height, weight, race, date and location of presentation, date of last chemotherapy treatment, temperature, absolute neutrophil count (ANC), cancer type, patient allergies, time of registration, time of blood culture order release, time blood culture drawn, intravenous line status, time of first antibiotic order, time of first antibiotic order verification, time of first antibiotic administration (TTA), and antibiotic regimens (drug, dose, route). Additional data to be collected for patients presenting to the emergency department include: acuity description assigned at presentation, admission status, time of admission (if applicable), sepsis alert status, and time of sepsis alert (if applicable). The percentage of patients that receive antibiotics within 60 minutes of presentation will be calculated, as well as the average and median TTA. Depending on the sample size, subgroup analyses may also be conducted.

Poster Title: Determination of secondary encounter rates for urinary tract infections in patients treated with cephalexin

Primary Author: Aubrey Goertel, Lehigh Valley Health Network, PA; Email: aubrey.goertel@lvhn.org

Additional Author(s):
Jarrod Kile

Purpose: Fluoroquinolones historically been the agents of choice for treatment of urinary tract infections. Increasing resistance rates paired with their propensity for adverse effects led to the preferential use of alternative agents for treatment. First-generation cephalosporins have become popular agents for treatment of urinary tract infections due to their narrow antimicrobial spectrum, limited adverse effect profile, and retained susceptibility. The purpose of this retrospective chart review is to evaluate the rate of return within 30 days for patients admitted for a urinary tract infection and received a prescription for cephalexin upon discharge.

Methods: This study will be submitted to the Institutional Review Board for approval. Electronic medical records will be used to identify patients 18 years of age and older, admitted to an adult unit for urinary tract infection and discharged with a cephalexin prescription between December 1, 2015 – June 30, 2016. Patient and clinical data to be collected will include: medical record number, date of birth, age, gender, pregnancy status (ICD-10 code Z33.1) at time of admission, history of diabetes (ICD-10 code E10.9 or E11.9) at time of admission, hospital length of stay, intensive care unit admission, intensive care unit length of stay, cephalexin regimen (dose, frequency and duration), microbial organism obtained from urine culture, and susceptibility of uropathogen(s) to levofloxacin/ciprofloxacin, cefazolin and trimethoprim/sulfamethoxazole. Rate of return encounters to an urgent care, doctor’s office, emergency room or hospital within 30 days for a urinary tract infection that have received additional antibiotics will be calculated. Clinical risk factors will be assessed to identify independent predictors for return. Cephalexin dose, frequency and duration will also be characterized. Patients that will be excluded from this study include patients with genitourinary
abnormalities and patients with a urinary tract infection within the previous 30 days of admission.

Poster Title: Determining the effect a pharmacist has on pneumococcal vaccination rates in the primary care setting

Primary Author: Katie Schumacher, Millcreek Community Hospital/Lake Erie College of Osteopathic Medicine, PA; Email: katie.schumacher@rx.lecom.edu

Additional Author(s):
Sarah Dombrowski
Kristen Gawronski

Purpose: For pneumococcal vaccination, the Advisory Committee on Immunization Practices (ACIP) recommends all patients receive the Prevnar 13 vaccine at age 65 or older with a Pneumovax 23 vaccine administered at least one year later. The Office of Disease Prevention and Health Promotion (DPHP) reports that in 2008, only 60% of patients over 65 had their pneumococcal vaccine. The healthy people 2020 goal from the DPHP is that 90% of adults over 65 are vaccinated. The purpose of this medication use evaluation is to determine the impact an ambulatory care pharmacist has on pneumococcal vaccination rates in the primary care setting.

Methods: This medication use evaluation is being submitted to the Institutional Review Board for exempt review. The electronic medical record system will be used to identify patients 65 years and older in primary care offices with a pharmacist and without a pharmacist within one health system. A review of each patient 65 years and older will be completed to determine whether they have received a Prevnar 13, Pneumovax 23, neither vaccine or both vaccines. The pneumococcal vaccine administration rates of the two subject groups will be compared. A secondary analysis will be completed in the groups of patients who received both vaccines to assess the average amount of time between the Prevnar 13 and the Pneumovax 23, the appropriateness of the time interval between vaccines, and identify any inappropriate vaccinations such as duplicate vaccine administration. The data will be analyzed and statistical significance will be determined.

**Poster Title:** Accuracy of a standardized vancomycin dosing calculator  
**Primary Author:** Ian Hatlee, Millcreek Community Hospital/Lake Erie College of Osteopathic Medicine, PA; Email: ian.hatlee@rx.lecom.edu  
**Additional Author(s):**  
Erica Pascale  

**Purpose:** A 2009 consensus review by the American Society of Health-System Pharmacists, Infectious Disease Society of America, and Society of Infectious Disease Pharmacists provides recommendations for therapeutic monitoring of vancomycin, including individual pharmacokinetic dosing adjustments and verification of serum trough achievement. A vancomycin dosing calculator was developed based on patient-specific data, pharmacokinetic dosing equations and a standard volume of distribution (Vd) of 0.7 L/kg. The primary objective of this study is to determine the accuracy of this standardized vancomycin dosing calculator in achieving a target trough concentration.  

**Methods:** This study is a retrospective review and will be submitted the Institutional Review Board for approval. A reporting function in the electronic medical record will be utilized to identify patients who both received vancomycin and had a serum trough concentration drawn at our facility between March 1, 2016 and August 31, 2016. The ideal body weight (IBW), adjusted body weight (AdjBW), creatinine clearance, estimated vancomycin volume of distribution, elimination rate constant (ke), half-life, and dosing regimen for each patient was determined using the calculator. Pharmacist and nursing documentation will be reviewed to determine if the serum trough concentration was ordered and drawn at an appropriate time (i.e., 30 minutes before a dose at steady state). The percentage of patients attaining a serum trough concentration within goal range will be evaluated to determine the accuracy of the initial dosing regimen. A subgroup analysis will also be performed in both underweight (actual body weight < IBW) and obese (>130% IBW) patients.

**Poster Title:** Retrospective evaluation of vitamin K use in patients receiving warfarin

**Primary Author:** BreAnne DeMarco, Millcreek Community Hospital/LECOM, PA; **Email:** breanne.demarco@rx.lecom.edu

**Additional Author(s):**
Zachary Heeter

**Purpose:** Though several guidelines offer guidance for the use of warfarin reversal with vitamin K, the recommendations are not strong and may not be followed in clinical practice. The primary objective of this study is to evaluate the use of vitamin K to reverse warfarin anticoagulation in patients admitted to the hospital. Secondary outcomes will be the extent to which reversal complies with the guidelines and patient outcomes following reversal.

**Methods:** This study will be submitted to the Institutional Review Board for approval. The electronic medical record will identify patients who have received vitamin K to reverse anticoagulation with warfarin during a hospital stay in the last year. The following data will be collected: patient age, gender, initial international normalized ratio (INR), amount and route of vitamin K given, subsequent INR values, concomitant medications that could contribute to bleeding risk, renal and hepatic function if available, mortality, and readmission within 30 days. Provider documentation will be reviewed to determine the reason for reversal, the indication and home dose of warfarin, adverse events experienced, and the discharge plan for anticoagulation. All data will be recorded without patient identifiers and maintained confidentially. Data will be reviewed to assess compliance with guideline-directed therapy and patient outcomes. Statistical analysis will be done to evaluate actual use of vitamin K versus recommended use of vitamin K and to compare outcomes following reversal of anticoagulation.

**Poster Title:** Evaluation of Appropriate Proton Pump Inhibitor (PPI) Use in a Primary Care Physician Office

**Primary Author:** Diana Pak, Moses Taylor Hospital, PA; **Email:** diana.pak@wilkes.edu

**Additional Author (s):**
Thomas Franko

**Purpose:** PPIs are safe and effective options when used appropriately to treat various gastrointestinal disorders. However, persistent use in the absence of any indication or treatment beyond the recommended duration of therapy may place the patient at risk for several negative effects. These negative effects include Clostridium difficile infection, osteoporosis, bone fractures, hypomagnesemia, and community and hospital-acquired pneumonia. Furthermore recent studies have associated the use of PPIs with an increased risk for chronic kidney disease. The aim of this study is to determine appropriate PPI use in the primary care setting.

**Methods:** All patients diagnosed with having Helicobacter pylori (H. pylori), gastroesophageal reflux disease (GERD), ulcers, esophagitis, peptic ulcer disease, Zollinger-Ellison syndrome, or Barrett’s disease and all patients with an active PPI such as pantoprazole, lansoprazole, rabeprazole, omeprazole, esomeprazole, or dexlansoprazole seen between March 23, 2016 to September 23, 2016 were included in the study. Information was queried from an electronic health record for each patient. All information will be de-identified. The data will be analyzed to determine patients taking a PPI without an indication. Further analysis will be completed to determine patients taking a PPI with an indication but beyond the recommended duration of therapy.

**Poster Title:** Assessment of a pharmacist-driven initiative to reduce inpatient falls in a community hospital

**Primary Author:** Andrea Lordan, Paoli Hospital, PA; **Email:** lordan@mlhs.org

**Additional Author(s):**
Kelly Butler
Elizabeth Ferrigno

**Purpose:** Falls that occur in hospitalized patients are a prevalent patient safety problem. Morbidity and mortality resulting from inpatient falls place a substantial financial burden on the health care system, due to the need for additional treatment and prolonged hospital stays. Multiple factors have been associated with falls, including age, mental status, and illness severity. Although fall risk is multifactorial, medications that cause sedation, orthostatic hypotension, and cognitive impairment are also known to increase the risk of falls. The goal of this study is to implement a pharmacy-driven initiative to reduce the number of inpatient falls in a community hospital.

**Methods:** A medication-based screening tool will be developed to determine patients at a high risk of falls. Medications in high-risk classes will be assigned a point value based on their side effects and a medication-based fall risk score will be calculated. A 4-month retrospective review of inpatient falls occurring on a single unit of a community hospital will be conducted to determine how many of these patients would be identified as a fall risk using the new medication-based screening tool, compared to those identified using the current nursing assessment. A 4-month prospective phase of the study will review the medication profiles of patients on the same unit and determine a medication-based fall risk score for each patient. For patients determined to be at a high risk of falls, verbal medication education will be provided in order to review the side effects of medications which may increase the risk of falls. Patient counseling sessions will reinforce education provided by nursing, enabling an interdisciplinary approach to fall prevention. Recommendations regarding therapy adjustment will also be provided to physicians, based on the appropriateness of the medications and corresponding dose for each patient. The number of inpatient falls on this unit will be compared before and
after the implementation of this pharmacy-driven initiative in order to assess the impact of pharmacist involvement on inpatient falls.

**Poster Title:** Evaluation of pharmacists’ attendance during medical resuscitations in a community hospital

**Primary Author:** Marissa Cushing, Paoli Hospital, PA; **Email:** cushingma@mlhs.org

**Additional Author(s):**
Deena Rojek
Kiyo Yoda

**Purpose:** Pharmacists attending medical resuscitations have been shown to improve patient outcomes, decrease deviations from advanced cardiac life support (ACLS) guidelines, and is appreciated by other medical professionals. Currently, a 222 bed, level II trauma community hospital does not have pharmacists attending medical resuscitations outside the emergency department. This study will analyze the benefits to patient care from having trained pharmacists attend medical resuscitations throughout the entire community hospital. Additionally, this study will assess the perception of the health care resuscitation team towards pharmacists’ attendance during medical resuscitations.

**Methods:** This is a single center, retrospective review of medical resuscitations from January 2015-September 2016. Data will be collected regarding the patient’s location at the time of the arrest, the duration of the arrest, the patient’s outcome at the conclusion of the arrest, and whether ACLS guidelines were followed. If ACLS guidelines were not followed, the deviations will be reviewed. A survey will be distributed to the resuscitation team members in order to obtain their perspective of having pharmacists present at medical resuscitations. From October 1, 2016 to present, trained emergency department or resident pharmacists will attend medical resuscitations Monday through Friday 0800 to midnight. The pharmacists will assist with the appropriate selection and timing of medication administration, prepare medications for administration, confirm IV compatibilities, calculate infusion rates, and verify pump settings. Data will continue to be collected as before with the addition of noting if a pharmacist was present. The survey will be re-distributed to the resuscitation team members near the completion of the study. A comparison will be done between medical resuscitations with and without pharmacists present to see if pharmacists’ attendance improves patient outcomes and increases adherence to ACLS guidelines. The first survey will be compared with the second
survey to observe any changes in the resuscitations teams’ perspective on pharmacists’ attending medical resuscitations and if pharmacists’ attendance is preferred.

**Poster Title:** Development and implementation of a pharmacy driven long acting antipsychotic administration service in a community pharmacy: a feasibility study

**Primary Author:** Sarah Goldsborough, PennState Health St. Joseph, PA; **Email:** sgoldsborough@pennstatehealth.psu.edu

**Additional Author(s):**

**Purpose:** In the United States, greater than 2 million Americans have a diagnosis of schizophrenia. One major contributing factor for symptom relapse as well as hospitalization is non-adherence. Long acting antipsychotic injections can provide a valuable treatment option for this patient population. In the United States there are almost 300,000 pharmacists while there are only 50,000 psychiatrists. Pharmacists can play a crucial role in assisting patients with accessing and administering long acting antipsychotics. The objective of the study is to evaluate the feasibility of implementing a pharmacy driven long acting antipsychotic administration service in a community pharmacy setting.

**Methods:** This is an observational study with a run in period that includes meeting with local behavioral health providers to promote the new pharmacy service of administering long acting antipsychotics. Patients are included if they are above the age of 18, have a valid prescription for the long acting antipsychotic, the medication is acquired through a licensed wholesaler or other source where chain of custody can be validated, have received at least one dose of a long acting antipsychotic and have no contraindications to receive the prescribed medication. Patients are excluded if they refuse the injection. Data will be collected for all patients receiving a long acting antipsychotic on a standardized data collection form. Patients will be properly de-identified and confidentiality will be maintained. Descriptive statistics will be used to demonstrate the number of patients enrolled as well as adherence rate of long acting antipsychotic administration.

**Results:** N/A

**Conclusion:** N/A

Poster Title: Development of a pharmacy-driven penicillin skin testing program to optimize the selection of antibiotics in patients with self-reported penicillin allergy

Primary Author: Jacqueline Chirico, Pennsylvania Hospital, PA; Email: jacqueline.chirico@uphs.upenn.edu

Additional Author(s):
Lindsay McDonnell

Purpose: With the emergence of multidrug resistant pathogens, it is especially important to utilize current antibiotics correctly and when properly indicated. Penicillin skin tests exist as a way to potentially decrease the use of second-line antibiotics, while providing treatment with a preferred beta-lactam antibiotic. It is supported as an intervention to improve patient care by optimizing antibiotic utilization, which leads to improved efficacy, reduced resistance, and decreased cost. The purpose of this project is to develop a pharmacist-led penicillin skin testing program in order optimize antibiotic selection in patients who present with a self-reported penicillin allergy.

Methods: This study is undergoing Institutional Review Board evaluation for approval. Pending addition of PRE-PEN (benzylpenicilloyl polylysine) to inpatient formulary, a pharmacy-driven protocol for skin-testing in patients with a self-reported penicillin allergy will be developed in collaboration with an infectious disease physician. Both pharmacists and physicians will be trained on how to perform the skin test, including proper intradermal administration techniques, documentation requirements, and the proper procedures to follow if the patient has an anaphylactic reaction. Prior to testing, the pharmacist will screen patients for eligibility and obtain informed consent. Patients with a self-reported history of a penicillin allergy where penicillin or a beta-lactam antibiotic is the drug of choice for treatment will be considered eligible. While testing, the patient will be observed and ensure that every step is done according to the protocol. After testing, the pharmacist will document the results and may assist physicians in optimizing antibiotic selection if the allergy is proven to be negative. Following the implementation of this program, an evaluation will be conducted to compare the optimal beta-lactam antibiotic that was used to treat the patient with the alternative agent that was avoided due to the negative penicillin skin test. This evaluation will also compare cost
saved as a result of doses of alternative treatment avoided, while taking into account the cost to conduct the skin test itself.

Poster Title: Evaluation of outcomes in specialty pharmacy management of hepatitis C

Primary Author: Ta-Seti Donald, Pennsylvania Hospital, PA; Email: ta-seti.donald@uphs.upenn.edu

Additional Author(s):
Alyssa Vaysman
Lauren Long

Purpose: If left untreated, hepatitis C can lead to chronic liver disease, cirrhosis, and cancer. Direct acting antivirals carry a hefty price tag, insurance hurdles, multiple drug interactions and the potential for non-adherence. The Penn Specialty Pharmacy can ensure patients begin therapy by initiating prior authorizations and performing medication reconciliation. The specialty pharmacy is also equipped in patient education and stressing adherence to lab work/follow up. The primary purpose of this study is to evaluate the percentage of patients who achieved sustained virologic response (SVR) 12 weeks after completion of therapy in a pharmacy hepatitis C program in a gastroenterology clinic.

Methods: A retrospective chart review of patients who were initiated on direct acting antivirals at Penn Gastroenterology Clinic between January 1st, 2016 to August 31st, 2016. The primary endpoint is the percentage of patients who achieve SVR at 12 weeks post treatment determined by completed lab work. Secondary endpoints will include pharmacist interventions (drug interaction screens, treatment recommendations, dose adjustments), time to initiation of therapy, compliance with monthly lab work and adherence to treatment.

Poster Title: Clinical outcomes and costs associated with removing a combination long-acting beta-agonist and inhaled corticosteroid product from the formulary in managed care Medicaid plans

Primary Author: Erika Green, PerformRx, PA; Email: egreen@performrx.com

Additional Author(s):
Jamila Jorden
Lauren Megargell
Franmar Kopko
Daniel Gustafson

Purpose: Formulary management is a cornerstone of managed care practice. When properly utilized, it allows managed care organizations to promote the use of high quality, cost effective medications that improve patient outcomes. To further control medication costs, manufacturers’ rebates can be considered in formulary decisions when safety and efficacy are considered comparable. Even when additional savings are taken into account, it is not known if the total administrative and clinical expenditures due to a formulary change outweigh savings. The purpose of this study is to investigate the total clinical and financial impact of removing a combination inhaler product from the formulary.

Methods: The study is a retrospective, observational review; therefore, it will not require Institutional Review Board approval. Pharmacy databases will identify patients 12 years of age and older who have a diagnosis of asthma and had at least 2 fills of Advair during a one year period prior to formulary removal. These patients must have continuous enrollment in their health plan during the time period of the study defined by no more than 30 days of coverage lapse. The following data will be collected and analyzed: patient demographics; cost difference between Advair, Symbicort, and Dulera; cost of member outreach; call center and prior authorization volume; medication adherence; and emergency room visits, hospital admissions, and outpatient visits related to asthma. All data will be recorded without patient identifiers to maintain confidentially.

**Poster Title:** Analysis of tighter control of buprenorphine-containing products and its effect on utilization for a Medicaid plan

**Primary Author:** Edward Avanessians, PerformRx, PA; **Email:** eavanessians@performrx.com

**Additional Author(s):**
Calla Vodoor
Jamila Jorden
Franmar Kopko

**Purpose:** Opioid addiction and deaths from opioid use have grown into a troubling problem throughout the United States. While intended as treatment for patients with addiction to opioids and other licit and illicit drugs, buprenorphine-containing agents come with an element of risk with their long-term use. Buprenorphine-containing agents are increasingly associated with incidents of diversion and members can sometimes suffer from physical dependence, withdrawal symptoms, and psychological issues. The objective of this study is to determine how tighter regulation of prescribing criteria will impact the overall utilization of buprenorphine products.

**Methods:** The study is an observational review and will therefore not require Institutional Review Board approval. The effective date of the new criteria will occur on November 1, 2016. The study will be conducted over a six-month period and split into two three-month intervals. There will be an assessment of the pre- and post-implementation periods to evaluate the impact of more stringent prior authorization criteria. The following data will be collected and reviewed: change in call center volume, prior authorization metrics, total number of claims, and cost spent. Provider outreach will also be conducted to assess how prescribing patterns change with tighter criteria in place. All data will remain confidential and will not include any patient identifiers.

Poster Title: Impact of a pharmacy resident’s intervention(s) on blood pressure control in patients with diabetes and uncontrolled hypertension

Primary Author: Katelyn Simmons, Preferred Primary Care Physicians and Duquesne University, PA; Email: k-simmons.2@onu.edu

Additional Author (s):
Jamie McConaha
Khalid Kamal
Louis Civitarese
Nicole Handlow

Purpose: Despite a plethora of data supporting pharmacists’ positive impact on patient blood pressure (BP) control, no studies have specifically assessed similar interventions by a pharmacy resident within a primary care physician (PCP) office setting. This study will investigate the impact of pharmacy resident intervention on patients with comorbid type 2 diabetes (T2DM) and uncontrolled hypertension (HTN) in physician offices that are part of an Accountable Care Organization and Patient Centered Medical Home. Additionally, this study will evaluate the perception and satisfaction of physicians, physician assistants, and nurse practitioners regarding these pharmacy resident services.

Methods: Patients aged 18-75 years with comorbid T2DM and uncontrolled HTN, defined as systolic BP >139mmHg and/or diastolic BP >89mmHg, will be identified from the electronic medical record (EMR) of the resident’s PCP practice setting and sent a letter inviting them to enroll in the study. To qualify, patients must be on a minimum of seven medications including at least one anti-hypertensive. Upon receiving consent, enrolled participants will be randomly divided into intervention and control groups. The resident will individually meet with intervention group patients either telephonically or face-to-face to review medications, provide counseling, intervene with the physician, and offer follow-up. BP will be measured two months (+/- seven days) from the resident intervention. The control group will receive the standard of care from their PCP but will not meet individually with the pharmacy resident. Data collected from the EMR and intervention meeting will include, but is not limited to: patient age, gender, allergies, body mass index (BMI), BP, lifestyle factors, medications, medical history, and
resident intervention. Results in terms of BP control will be compared between the groups at the conclusion of the study. In addition, a final survey will be administered to physicians, physician assistants, and nurse practitioners to assess their perception of the role and effectiveness of the pharmacy resident interventions.

**Poster Title:** Assessing pharmacist impact on long-term use of proton pump inhibitors in an ambulatory clinic

**Primary Author:** Sandra Rumyantsev, Reading Hospital, PA; **Email:** sandra.rumyantsev@gmail.com

**Additional Author (s):**

James Helms

**Purpose:** The primary objective of this study is to assess pharmacist impact on reducing long-term proton pump inhibitor (PPI) therapy relative to treatment recommendations for specific indications. Evidence shows that prolonged PPI use is a risk factor for adverse effects including Clostridium difficile associated diarrhea, osteoporosis related fractures, pneumonia, and rebound acid hypersecretion. Limiting use in the outpatient setting can reduce the potential for adverse events and minimize health care burden.

**Methods:** A report will be obtained of clinic patients over 18 years of age who have been on PPI therapy for greater than 4 weeks. The need for continued treatment or alternative therapy will be considered. Pharmacologic recommendations will be communicated as a message to the provider via electronic medical record. Recommendations may include discontinuing/tapering PPIs or initiating alternative therapy. Non-pharmacologic recommendations may include dietary and lifestyle modifications. The provider may refer patients to the pharmacist for counseling. The following data will be collected: patient demographics, indication for PPI use, PPI regimen, concomitant interacting medications, adverse effects, number of patient charts evaluated, number of patients counseled by pharmacist, and number/type of recommendation made (pharmacologic vs. non-pharmacologic). The number of recommendations and rate of acceptance by the provider will be used to assess the impact of pharmacists in the ambulatory clinic.

**Results:** N/A

**Conclusion:** N/A

**Poster Title:** Evaluating the impact of pharmacist recommendations in patients with metabolic syndrome at an outpatient psychiatric clinic

**Primary Author:** Rimmel Khan, Reading Hospital, PA; **Email:** rimzahid@gmail.com

**Additional Author(s):**
Gina Ghoubrial-Waibel
Amit Neog
Jessica Plocher

**Purpose:** Second-generation antipsychotics (SGA) have shown significantly decreased extrapyramidal adverse effects as compared to first-generation antipsychotics. The majority of guidelines recommend SGAs as first-line therapy for schizophrenia. However, all SGAs have been associated with metabolic complications. The objective of this study is to assess the impact of pharmacist recommendations for patients with metabolic syndrome receiving SGAs at an outpatient psychiatric clinic.

**Methods:** Patients receiving oral SGAs at an outpatient psychiatric clinic who meet criteria for metabolic syndrome will be identified through an electronic medical record review. Patients’ pharmacologic therapy will be reviewed and patients will be offered counseling on management of weight gain, hyperglycemia, and hyperlipidemia. Pharmacologic recommendations will be made to the outpatient psychiatrist or nurse practitioner. These may include changes to existing therapy as well as initiation of new therapy. Non-pharmacologic recommendations may include dietary and lifestyle modifications. Data collected will include patient demographics, non-pharmacologic recommendations, patient’s history of SGA therapy, presence of concomitant disease states relating to metabolic syndrome, and number of recommendations made and accepted. The recommendations, as well as rates of acceptance, will be assessed to determine the need for future pharmacist review of patients with metabolic syndrome at this psychiatric clinic.

Session-Board Number: 8-171

Poster Title: Optimizing anticoagulation therapy for the treatment of deep vein thrombosis (DVT) and pulmonary embolism (PE) in a hospital based, pharmacist managed anticoagulation clinic.

Primary Author: Nissa Tasnim, Reading Hospital, PA; Email: nissa@temple.edu

Additional Author(s):
Daniel Forman
Joan Mege

Purpose: Warfarin has historically been the principle oral anticoagulant used in the treatment of DVT and PE. The narrow therapeutic window and pharmacokinetic profile of warfarin require significant healthcare resources for safe and effective management. Novel oral anticoagulants (NOAC) have been shown to be equally effective in the treatment of DVT and PE and require less frequent monitoring. The goal of this study is to evaluate warfarin managed patients and assess eligibility for transition to novel oral anticoagulant therapy.

Methods: Chart review from electronic medical record will be completed as part of the patient identification process and further evaluation of anticoagulation management. The collected data will include: patient demographics, thromboembolic history, duration of anticoagulant therapy, relevant medication, disease state history, and international normalized ratio results and frequency. Recommendations to the provider may include continuation of warfarin therapy, transition to NOAC therapy, or discontinuation of therapy if patient has completed the recommended treatment duration. The impact of pharmacist review will be quantified by measuring the rate of anticoagulant therapy changes.

**Session-Board Number:** 8-172

**Poster Title:** Impact of implementing an antibiotic time out on the time to de-escalation of broad spectrum antibiotics in a community teaching hospital.

**Primary Author:** Rafah Saad, Saint Joseph Medical Center, PA; **Email:** rsaad@pennstatehealth.psu.edu

**Additional Author(s):**

**Purpose:** An “antibiotic time out” is performed 48 to 72 hours after antibiotic initiation wherein the clinician should assess their need, if a narrower spectrum can be utilized, and if they are prescribed at the correct dose, route, and frequency. It should include streamlining or de-escalation of empirical antimicrobial therapy when culture results become available. De-escalation of antibiotic therapy to more targeted or narrow spectrum agents can prevent superinfections, decrease costs, bacterial resistance, and toxicities associated with broad spectrum agents. This study will determine whether implementing an antibiotic time out will reduce the time to de-escalation of empiric therapy.

**Methods:** This study was submitted to the Institutional Review Board at Penn State Health St. Joseph for approval. Phase I involved a retrospective chart review that included patients 18 years or older that had been hospitalized at least 72 hours with an active order for broad spectrum antibiotics (vancomycin, piperacillin/tazobactam, cefepime, ampicillin/sulbactam and levofoxacin). A computer generated medication utilization report was used to identify possible subjects. Each medical record was reviewed for baseline demographics, antibiotic use (indication, site of infection, start and stop date, therapy modification), culture data (culture results, sensitivity, presence of multi-drug resistant organisms), clinical symptoms and pertinent laboratory data. Time to de-escalation was assessed, where day 1 was the first day the broad spectrum empiric antibiotic was administered. De-escalation was characterized as the discontinuation, reduction in number, or the narrowing of spectrum of the initial empiric antibiotics. For Phase II, an antibiotic time out was implemented and time to de-escalation after implementation was analyzed. Descriptive statistics will be utilized to detect a difference between the time to de-escalation before and after antibiotic time-out implementation.

Poster Title: Assessment of monitoring and compliance of a deep vein thrombosis (DVT) prophylactic dosing protocol with enoxaparin and heparin in obese adult patients

Primary Author: Taylor Warmbrodt, Saint Vincent Hospital, PA; Email: twarmbrodt@svhs.org

Additional Author(s):
Rebecca Nick-Dart

Purpose: According to the National Institute of Health, 68.8 percent of adults are overweight or obese. With such a large percent of the population falling into this category, hospitals must often take weight into account when dosing medications. At our institution, an adult medication dosing in obesity protocol was implemented in May 2013 for select antibiotics, enoxaparin, and heparin. Pharmacy is automatically consulted for monitoring heparin and enoxaparin for patients weighing greater than 150 kg. The purpose of this study is to assess monitoring appropriateness, safety, and compliance with the protocol in regards to enoxaparin and heparin within our institution.

Methods: Patients who weighed greater than 150 kg and received either enoxaparin or heparin for deep vein thrombosis (DVT) prophylaxis were eligible for inclusion. Per the hospital policy, if a patient is ordered enoxaparin or heparin for DVT prophylaxis and weighs greater than 150 kg, their dose is adjusted and a clinical pharmacist is consulted to verify appropriateness of the dose as well as to monitor the patient via either an antifactor-Xa level for enoxaparin or an aPTT for heparin. A level is to be obtained if a patient remains on therapy for greater than 72 hours, and doses should be adjusted as necessary. Antifactor-Xa levels should be drawn four hours after an enoxaparin dose and should be between 0.2-0.5 IU/ml and aPTT levels should be drawn one hour after a heparin dose and should be less than 50 seconds. Data was collected for patients admitted between July 1, 2015 through June 30, 2016. Patients were identified from dispensing records and clinical pharmacy consults. Data collection included patient age, sex, weight, dose, number of doses received, whether a level was obtained, the level, timing between the dose and the level, and how many doses the patient received prior to the level.

Results: A total of 170 patients met inclusion criteria, however 159 patients received at least one dose of either enoxaparin or heparin. The average age was 51 years old (range 24-78 years)
and 64 percent of the patients were men. The average weight was 173 kg (range 150-263 kg), with 51 patients prescribed enoxaparin and 108 patients prescribed heparin. In total, 33 percent of patients (n=52) had at least one level drawn and a total of 61 levels were obtained. The level was drawn correctly 57 percent of the time, which was defined as within 180-300 minutes post enoxaparin dose or within 30-90 minutes post heparin dose. Of the levels that were obtained, 16 percent (n=10) were outside of the target range. When assessing compliance with the protocol, 80 percent of patients had a level obtained by 72 hours of therapy while 91 percent of patients had a level obtained by 96 hours of therapy.

**Conclusion:** Overall, one third of patients who received dose-adjusted heparin or enoxaparin were monitored while on therapy. Of patients monitored, the level was appropriate 84 percent of the time and the level was drawn appropriately greater than 50 percent of the time. Overall, the compliance rate was greater than 90 percent for patients who remained on therapy for at least 96 hours. In conclusion, compliance and monitoring of the obesity protocol are appropriate, however appropriateness of when the level is drawn could be improved.

**Submission Type:** Evaluative Study

**Session-Board Number:** 8-174

**Poster Title:** Impact of a procalcitonin algorithm on antibiotic duration in patients with lower respiratory tract infections

**Primary Author:** Daniel Nelson, Saint Vincent Hospital, PA; **Email:** danielnelson583@gmail.com

**Additional Author(s):**
Andrew Grimone
Justine Russell

**Purpose:** Approximately 37 percent of antibiotic use in hospitals may be inappropriate. Procalcitonin (PCT), a biomarker useful in identifying bacterial infections, has been shown to be effective in decreasing antimicrobial exposure in lower respiratory tract infections (LRTIs). Several randomized clinical trials have demonstrated effectiveness of PCT in the reduction of antibiotic duration. A PCT algorithm was implemented for patients presenting to the hospital diagnosed with a LRTI. The purpose of this evaluation was to analyze the impact of the algorithm on antibiotic duration in patients diagnosed with a LRTI by comparing results from before and after implementation of the PCT algorithm.

**Methods:** A retrospective chart review was performed on patients diagnosed with a LRTI before and after implementation of the PCT algorithm over two 3-month time frames. Patients with a primary discharge diagnosis of chronic obstructive pulmonary disease (COPD) exacerbation or pneumonia were identified using Internal Classification of Disease, 9th and 10th revision (ICD-9 and ICD-10) codes. Patients were also identified if a PCT was drawn upon admission. Patients were included if diagnosed with a LRTI and admitted to the hospital during the study periods. Patients were excluded if they were less than 18 years old, were not admitted to the hospital, or did not receive antibiotics during admission. Data collection was performed using patients’ medical records and included the following: patient demographics, past medical history, antibiotic regimens and duration, length of hospitalization, microbiologic data, imaging data, and 30-day readmission rates. Antibiotic duration was defined as antibiotics administered during the hospital stay plus oral antibiotics prescribed at discharge. The primary objective was antibiotic duration in patients diagnosed with a LRTI before and after implementation of the PCT algorithm. Secondary objectives included overall length of stay, average duration of antibiotics prescribed at discharge, Clostridium difficile infection rates, and 30-day readmission...
rates. Descriptive statistics were used to quantify results. A student’s t-test was used to compare the primary and secondary objectives from both study periods.

Results: A total of 356 patients were screened for inclusion in the baseline evaluation before the PCT algorithm was implemented, resulting in 179 patients in the final evaluation after accounting for exclusion criteria. There were 231 patients screened after the PCT algorithm was implemented, with 163 patients included in the final evaluation. The average antibiotic duration in the baseline evaluation was 5.7 days compared to 6.4 days after implementation of the PCT algorithm (p equals 0.002). Average length of stay was 5 days before PCT algorithm implementation compared to 3.7 days after algorithm implementation (p equals 0.393). The average duration of antibiotics prescribed at discharge was 2 days before PCT algorithm implementation compared to 3 days after algorithm implementation (p equals 0.001). There was only 1 documented Clostridium difficile infection from the baseline evaluation and no cases reported after implementation of the PCT algorithm. The 30-day readmission rates before and after implementation of the algorithm were 30 patients (16.8 percent) and 39 patients (17 percent), respectively.

Conclusion: The use of a PCT algorithm did not decrease antibiotic duration in patients diagnosed with a LRTI. However, there was a decrease in overall length of hospitalization in patients diagnosed with a LRTI after the PCT algorithm was implemented. The impact of a PCT algorithm on antibiotic duration in patients diagnosed with a LRTI may be apparent in larger and longer evaluations.

Poster Title: Evaluation of anticoagulant reversal agent use appropriateness in a tertiary care facility

Primary Author: Brandon Sing, Saint Vincent Hospital, PA; Email: bsing@svhs.org

Additional Author(s):
Jenna Young
Justine Russell

Purpose: Anticoagulant reversal agents can be invaluable and even life-saving when selected and administered appropriately. However, these agents can be both harmful to the patient and costly to the administering institution if improperly employed. Anticoagulant reversal agents are indicated only for severe active bleeding, urgent procedures, and supratherapeutic INR in some cases. One study reported appropriate use of phytonadione for warfarin reversal as low as 25 percent, while data regarding newer agents is lacking. The purpose of this study was to evaluate the use and appropriateness of anticoagulant reversal agents in a community hospital to identify potential areas for improvement.

Methods: A list of patients who were ordered an anticoagulant reversal agent, including phytonadione within the last two months or prothrombin complex concentrate (PCC), anti-inhibitor coagulant complex, or idarucizumab within the last year, was generated via a central pharmacy dispensing report. A retrospective electronic chart review was then performed to gather patient demographics, reason for admission, anticoagulant regimen, anticoagulation indication, reason for reversal (including bleeding stratification), reversal agent and dose used, ordering service, administration lag-time (time between reversal agent order and administration), and labs of interest (such as INR). Any patient dispensed one of the previously mentioned reversal agents was included in the chart review. Patients were excluded from data analysis if the reversal agent was not administered. Appropriateness of anticoagulant use and dosing was determined using institution-specific reversal guidelines within the Allegheny Health Network Antithrombotic Guide. The primary objective of this study was the composite of appropriate dosing and indication for anticoagulant reversal agents administered. Secondary objectives included appropriate dosing and indication, individually, administration lag-time, INR differences between pre- and post- reversal agent administration, proportion of concurrent
phytonadione and fresh frozen plasma administration with PCC, and rate of repeat lab appropriateness. Descriptive statistics were used to analyze all data.

**Results:** The study population had a mean age of 73.8 years and was 49.3 percent male. A total of 86 anticoagulant reversal agent administrations, given to 73 patients, were evaluated. Of these administrations were 47 oral phytonadione, 17 intravenous phytonadione, eight subcutaneous phytonadione, 12 PCC, two anti-inhibitor coagulant complex, and zero idarucizumab. Twelve patients received repeat phytonadione administrations. Anticoagulant reversal was performed due to urgent surgery/procedure in 23 patients, elevated INR in 21, major bleeding in 21, minor bleeding in six, and for other reasons in two. Reversal agents were both indicated and dosed appropriately in 53.5 percent of cases. Reversal of anticoagulation was indicated in 76.7 percent of cases, while dosing was appropriate in 69.7 percent of indicated uses. A mean administration lag-time of 68 minutes (standard deviation (SD): 64 minutes) and 94 minutes (SD: 81 minutes) was observed for intravenous and non-intravenous administrations, respectively. A mean difference between pre- and post- phytonadione and PCC administration of -2.5 (SD: 3.3) and -3.9 (SD: 5.0) was observed, respectively. PCC was administered with phytonadione in all cases. However, fresh frozen plasma was inappropriately administered in half the cases. Repeat labs were drawn appropriately in 78.6 percent of cases.

**Conclusion:** Anticoagulant reversal agent use at the institution was appropriate in 53.5 percent of cases, and a mean administration lag-time for intravenous agents of 86 minutes was observed. These results are suboptimal and indicate a need for additional physician education on appropriate use of anticoagulant reversal agents. Moreover, the observed administration lag-time suggests need for further intervention such as nursing and pharmacy education, improvement in communication, and streamlining of processes. Further study with larger patient sampling is recommended to verify and validate the results of this evaluation.

Poster Title: Evaluation of the use of codeine-containing products at a community teaching hospital

Primary Author: Jessah Villamor, St. Luke’s University Health Network, PA; Email: jessah.villamor@gmail.com

Additional Author(s):
Leslie Johnson

Purpose: Codeine-containing products are widely used for a variety of ailments and conditions. Codeine is associated with many adverse effects that can be intolerable. Studies show that a genetic polymorphism can cause individuals to rapidly metabolize codeine leading to supratherapeutic levels of morphine. Reports of deaths in pediatric ultra rapid metabolizers led to the addition of a boxed warning regarding codeine use in children under the age of 18. Despite the risks, codeine is continually prescribed by many practitioners. The purpose of this study is to evaluate the use of codeine-containing products at a community teaching hospital.

Methods: This study has been submitted for approval to the institutional review board at St. Luke’s University Health Network. The electronic medical record system will be used to identify all medication orders for a codeine-containing product during the study period. Data will be collected on the utilization of codeine-containing products throughout the network. All data will be recorded without patient identifiers and will be maintained confidentially. The following data will be collected: patient age, gender, admission diagnosis, codeine-containing product ordered, dosage, indication for use, ordering department, treatment duration of codeine-containing product, length of admission, patient-reported adverse effects (if any). Analyses will be conducted to evaluate the findings and identify any patterns of utilization.

Poster Title: Medication use evaluation of rapid infusion rituximab within St. Luke's University Health Network

Primary Author: Shari Williams, St. Luke's University Health Network, PA; Email: shari.williams@sluhn.org

Additional Author(s):

Purpose: Rituximab is a monoclonal antibody directed at CD20 antigen on B cells. It has utility in the treatment of a variety of conditions including malignancy and autoimmune conditions. In 2012, the administration of rituximab as a 90 minute infusion in patients that did not experience a Grade 3 or 4 toxicity with the initial rituximab infusion was added to the drug’s label. Many facilities, including this health-system adopted “Rapid Rituximab” infusion protocols as a result of this change. The purpose of this evaluation is to assess the adherence to institutional guidelines for the administration of accelerated rituximab.

Methods: This study will be submitted to the Institutional Review Board for approval. Electronic reports will be retrieved from Epic electronic medical record system to conduct a retrospective chart review assessing institutional adherence to the St. Luke’s University Health Network (SLUHN) Rapid Rituximab infusion protocol. The following data will be collected from patients receiving rapid infusion rituximab: patient age, gender, ethnicity, diagnosis related to rituximab use, documented steps taken before administering rapid infusion rituximab, and reported adverse events. Administration documentation will be reviewed to determine adherence to the SLUHN Rapid Rituximab protocol. Confidentially will be maintained and data will be recorded without patient identifiers. From the Epic reports obtained, documented components of the protocol followed will be assessed to rate compliance to the administration outlined in the protocol within the institution. Each report will be reviewed on a case by case basis and at the conclusion of its assessment will be rated as compliant or noncompliant. The rates at which documentation is deemed compliant or noncompliant will be calculated to determine adherence to the rapid infusion protocol at St. Luke’s University Health Network.

Poster Title: Effect of Pharmacy Lead Nursing Education on HCAHPS Scores and Nurses Perception of Knowledge

Primary Author: Bryan Klosky, Summit Health Systems, PA; Email: Bklosky@summithealth.org

Additional Author(s):

Purpose: The Hospital Consumer Assessment of Healthcare Providers and Systems, or HCAHPS, scores are designed to help consumers assess health systems and make an informed choice about their care. One of the elements HCAHPS scores measure is communication about medicine, specifically how well do healthcare professionals communicate to patients information about their new medications. While nurses do an exceptional job at communicating medication information to patients, there is room for improvement, which may be aided by increased nursing knowledge on medications. The objective of this study is to determine whether pharmacy lead nursing medication education can help to improve HCAHPS scores.

Methods: This study will be submitted to the Institutional Review Board for approval. The target of this study will be ICU/Critical Care nurses at Waynesboro Hospital. Prior to the education the nurses will be given a questionnaire to evaluate their knowledge on certain pharmacy related topics. The questionnaire will collect the following data, the unit they work on, years of experience as a nurse, and their perception of their knowledge on 5 pharmacy related topics. Their perception of knowledge on the subjects will be evaluated on a 5 point Likert Scale, from no knowledge about the subject, to extremely knowledgeable. The educational sessions will be spaced out every 2-3 weeks, and each session will be given at multiple times on multiple days to ensure it reaches as many nurses as possible. Once all the education is complete, the nurses will be given a similar questionnaire to the one they were given previously to rate their knowledge, with the addition of a question asking the nurses to rate the overall usefulness of the educational sessions. These results will be evaluated along with the changes in HCAHPS scores before and after the education, to evaluate if the education had any benefit.

**Poster Title:** Evaluation of risk factors for Clostridium difficile in hematopoietic stem cell transplant recipients

**Primary Author:** Sana Mandal, Temple University Health System, PA; **Email:** sanamandal@yahoo.com

**Additional Author (s):**
Brittany Cael

**Purpose:** Clostridium difficile infection (CDI) is the most common hospital-acquired infection in the United States and is associated with substantial mortality and healthcare burden. Hematopoietic stem cell transplant (HSCT) recipients are at elevated risk for the development of CDI due to numerous factors, including immunosuppression, broad-spectrum antibiotic exposure, and prolonged hospital stay. Additionally, the burden and severity of infection may be underestimated in this population due to abnormalities in traditional diagnostic laboratory markers. The primary purpose of this study is to identify CDI risk factors in HSCT recipients at our health system's bone marrow transplant program.

**Methods:** This retrospective case-control study is currently under expedited review by the institutional review board. Electronic medical records will be used to identify all HSCT recipients with a documented CDI diagnosis; this cohort will be matched with a subset of CDI-negative recipients. The following data will be recorded from both cohorts to ascertain risk factors: age, type of transplant (allogeneic versus autologous), type/severity of underlying malignancy, type of chemotherapy/conditioning regimen, antibiotic use (type, number, days), colonization with vancomycin-resistant enterococci, presence of graft-versus-host disease, mean length of hospital stay, prior CDI history, history of gastrointestinal surgery, white blood cell count, absolute neutrophil count, baseline serum creatinine level, use of proton pump inhibitors, and use of miscellaneous immunosuppressives (e.g. steroids, immunomodulators). All data will be collected without patient identifiers and maintained confidentially.

**Poster Title:** Adherence to quality of care indicators in the management of Staphylococcus aureus bacteremia  

**Primary Author:** Ann Marie Porreca, Temple University Hospital, PA; **Email:** ann.porreca@tuhs.temple.edu  

**Additional Author (s):**  
Kazumi Morita  

**Purpose:** Staphylococcus aureus bacteremia (SAB) is a common type of bacteremia associated with high mortality, longer hospital stays, and higher treatment cost. Adherence to quality-of-care indicators (QCI) for patients with SAB is associated with decrease in-hospital mortality and earlier discharge and is improved with an Infectious diseases (ID) consultation. The primary objective of this study is to determine adherence to QCIs for the management of SAB and its impact on patient outcomes. The secondary objectives include evaluation of the impact of ID consultation on the adherence to QCIs and outcomes and factors associated with hospital mortality for patients with SAB.  

**Methods:** This retrospective chart review was approved by the Institutional Review Board and includes adult inpatients with one documented positive blood culture growing Staphylococcus aureus. Exclusion criteria includes patients < 18 years old, who died, were initiated hospice care, transferred to another facility, or left against medical advice within 2 days of positive blood cultures, were transferred from another hospital, refused treatment, had a polymicrobial infection, and had missing data. Primary endpoints include percent adherence to QCIs and difference in outcomes based on the number of QCIs adhered. Secondary endpoints include difference in adherence to QCIs between patients that had an ID consult vs. no ID consult, and difference in hospital mortality, length of stay, and recurrence. QCIs assessed were empiric therapy initiated within 72 hours and definitive therapy initiated within 4 days of initial positive blood cultures, appropriate definitive therapy and duration of therapy, collection of blood cultures within 48-96 hours of therapy initiation, and completion of an echocardiography. Data that will be collected includes patients’ demographics, comorbidities, disease characteristics, labs, microbiological data, antibiotic therapy, documented ID consult, outcomes, and adherence to QCIs. Percent adherence will be calculated for QCIs. A logistic
regression analysis will determine the factors associated with increase mortality. Categorical data and continuous data will be analyzed using Fisher’s exact tests or Chi-square and Student’s t-test or Mann Whitney U tests, respectively.

**Poster Title:** Evaluation of pharmacological agents for sedation or analgesia in order to facilitate noninvasive positive pressure ventilation in the Emergency Department  

**Primary Author:** Sharmin Amjad, Temple University Hospital, PA; **Email:** sharmin.amjad@tuhs.temple.edu  

**Additional Author (s):**  
Matthew Hinton  
Kerry Mohrien  

**Purpose:** Noninvasive ventilation (NIV) is commonly utilized in the Emergency Department (ED) as a treatment for acute respiratory failure (ARF). Although efficacious, providing adequate ventilation with NIV can be difficult especially in the setting of patient intolerance. Failure to tolerate NIV can be multifactorial but may be associated with discomfort or agitation. Previous data has suggested that use of sedative/analgesic medications may improve tolerance; however clinicians may be hesitant to administer these agents due to deleterious effects on respiratory drive, mental status, or hemodynamics. The purpose of this study is to evaluate the safety and efficacy of sedatives/analgesics to facilitate NIV.  

**Methods:** This single center, retrospective chart review was approved by the Institutional Review Board at Temple University Hospital and includes adult patients admitted to the ED who received NIV for management of ARF. Patients will be included if they received sedative or analgesic medications for any reason during NIV treatment. Patients less than 18 years of age and those who had insufficient data documented were excluded. The primary objective is to identify the incidence of adverse events following administration of sedative or analgesic medications in patients receiving NIV in the ED. Secondary objectives include identification of risk factors associated with NIV treatment failure and to describe the incidence of NIV failure associated with individual sedative and analgesic agents. Adverse events will be evaluated as a composite definition consisting of the occurrence of one of the following: mean arterial pressure < 70 mmHg or systolic blood pressure < 100 mmHg within 2 hours of medication therapy, or need for endotracheal intubation.

**Poster Title:** Safety and efficacy of atypical antipsychotics as adjunct treatment for alcohol withdrawal in the surgical intensive care unit

**Primary Author:** Priya Bhimani, Temple University Hospital, PA; **Email:** priya.bhimani3@tuhs.temple.edu

**Additional Author (s):**
Kimberly Harris
Kerry Mohrien

**Purpose:** Benzodiazepines are recommended first line for the management of alcohol withdrawal syndrome (AWS). Typical antipsychotics have been used as adjunct agents for AWS patients exhibiting psychosis or delirium. Atypical antipsychotics are potentially equally efficacious with an enhanced safety profile, but there is minimal evidence supporting their use. This study will evaluate the safety and efficacy of atypical antipsychotics in addition to benzodiazepines for the management of AWS in the surgical intensive care unit (SICU). We hypothesize that patients who receive an adjunct atypical antipsychotic will spend more time at goal sedation levels than those who receive benzodiazepines alone.

**Methods:** This retrospective chart review was approved by the Institutional Review Board. Adult patients admitted to the SICU with a diagnosis code indicating AWS, and who were treated with benzodiazepines will be included. Exclusion criteria include traumatic brain injury, dementia, non-alcohol induced seizure disorder, patients requiring a Richmond Agitation and Sedation Scale (RASS) score less than -2, pregnancy, or a prolonged baseline QTc interval. The primary efficacy outcome is the percentage of time spent at a goal sedation level (RASS of 0 to -2), while secondary outcomes include the cumulative benzodiazepine dose during the SICU stay, duration of benzodiazepine use, and the percentage reduction in benzodiazepine requirements after addition of an atypical antipsychotic. Safety outcomes include the incidence of QTc prolongation and AWS induced seizures.

Poster Title: Impact of baseline characteristics on graft rejection after kidney transplantation

Primary Author: Ann Dao, Temple University Hospital, PA; Email: ann.dao@tuhs.temple.edu

Additional Author(s):
Adam Diamond
Christina Ruggia-Check

Purpose: Despite advances in treating acute rejection, graft loss after kidney transplant (KT) remains a significant challenge to clinicians. Limited data exists on demographic variations and the impact on the risk of rejection in the kidney transplant population. Recipient sociocultural variables such as African American race, gender, and age are the most studied variables on rejection risk. However, other baseline characteristics should be further evaluated to better construct individualized immunosuppressive regimens for transplant recipients. The objective of this study is to identify the impact of baseline characteristics on acute graft rejection within 12 months post-transplantation.

Methods: This single-centered retrospective chart review is currently under expedited review by the Temple University Hospital’s Institutional Review Board. Our electronic medical record will identify adult patients receiving a kidney transplant at Temple University Hospital’s Kidney Transplant Program, between January 1st, 2014 and April 1st, 2016. Subjects will be assigned an arbitrary study ID number, and all information from electronic medical records will be stored in a de-identified fashion. The primary outcome measure is the incidence of biopsy-proven acute rejection at 12 months. Secondary outcomes include incidence of graft loss and patient survival at 12 months. A multivariate logistic regression analysis will be performed in order to identify variables associated with graft rejection.

**Poster Title:** Impact of weight-based pembrolizumab exposure on safety and efficacy in advanced or metastatic melanoma patients

**Primary Author:** Lauren DeRespiris, The Hospital of the University of Pennsylvania, PA; **Email:** erin.brown2@uphs.upenn.edu

**Additional Author(s):**
Erin Brown
Ronac Mamtani
Christine Cambareri

**Purpose:** The FDA approved pembrolizumab in September 2014 for unresectable metastatic melanoma at a weight-based dose of 2mg/kg every three weeks. Due to the high cost of the medication, our institution implemented a dose rounding protocol, where patients’ weight-based doses were rounded to the nearest vial size (50mg). Studies have examined the cost impact of dose rounding monoclonal antibodies, including immune-checkpoint inhibitors, but have not evaluated safety or efficacy. The objective of our study is to examine the mg/kg pembrolizumab doses patients received due to rounding, and the impact of the mg/kg dose on safety and efficacy outcomes.

**Methods:** This descriptive study is a retrospective chart review of patients greater than or equal to 18 years old with advanced or metastatic melanoma treated with at least one dose of pembrolizumab between January 2015 and August 2016. The study will be submitted to the Institutional Review Board for approval. Patients who received prior immune therapy within 6 months or who had treatment delays greater than three weeks will be excluded. The primary outcome will be the occurrence of infusion-related reactions during pembrolizumab infusions based on mg/kg exposure. Secondary outcomes will include immune-mediated adverse effects (iMADEs) and efficacy of treatment up to one year after the initial pembrolizumab dose, also based on mg/kg exposure. The following data will be collected: patient age, gender, ethnicity, weight, height, ECOG performance status, prior therapies for melanoma, prior history of iMADEs, pembrolizumab dose received, number of doses received, physical examination findings, documented infusion reactions, documented iMADEs as defined by the Common Terminology Criteria for Adverse Events (CTCAE), and treatment efficacy as per Response
Evaluation Criteria In Solid Tumors (RECIST) via scans and provider documentation. The impact of iMADES on treatment delays, therapy discontinuation, or treatment with corticosteroids will also be assessed. The mg/kg pembrolizumab dose will be calculated using the patient’s weight on the day the dose was administered and received.

**Session-Board Number:** 8-185

**Poster Title:** Anticipating the clinical impact of a single-source discontinued product: A retrospective review of tromethamine injection for the management of metabolic acidosis

**Primary Author:** Anna Marie Morlino, Thomas Jefferson University Hospital, PA; **Email:** annamarie.morlino@jefferson.edu

**Additional Author(s):**
Cindy Wordell

**Purpose:** Tromethamine (Tham) injection is an alkalizing agent indicated for severe metabolic acidosis as an alternative to sodium bicarbonate. It is commonly utilized in patients that cannot tolerate sodium bicarbonate, due to the risk of hypernatremia and volume overload. In May 2016, the single manufacturer of Tham, Hospira, ceased production of the medication worldwide. Currently, there are no other manufacturers of Tham and no 503B sterile compounding facilities producing it. This drug use evaluation was completed to assess the frequency of requests for Tham to manage patients at Thomas Jefferson University Hospital and the clinical situations in which it is used.

**Methods:** This retrospective chart review was approved by the institutional review board. Through MacroHelix, a 340B management software system, patients that received Tham throughout the health-system within the last two years, according to charge data, were identified. Administration of Tham was confirmed through review of medication administration records (MAR) and/or anesthesia records within the patients’ medical records. The medical records were further reviewed for each patient to determine past medical history, history of present illness, and clinical status, including acid-base status and serum sodium, at the time of Tham administration. Serum pH was also determined after administration of Tham to determine its efficacy in treating metabolic acidosis in these patients.

**Results:** Between October 2014 and June 2016, there were 15 instances when 10 patients were charged for Tham. It was confirmed that 9 patients received 13 doses of Tham over the 20 month period. The majority of Tham doses (n equals 11, 84.6 percent) were administered to 8 patients while undergoing a surgical procedure. The most common type of surgical procedure was a liver transplant (n equals 5, 56 percent). Most patients received only 1 dose of Tham,
while some patients received 2 doses, and 1 patient received a continuous infusion. When Tham was dosed during surgery, patients had an average pH of 7.31 at the time it was administered. The average serum sodium at this time was 139.7 miliequivalents per liter. For Tham that was administered outside of the operating room, only one patient had a pH checked prior to administration (pH equals 7.21). The average serum sodium for these two patients at this time was 154 miliequivalents. All patients also received sodium bicarbonate for management of their metabolic acidosis, with approximately 80 percent of patients receiving it both prior to and after Tham. On average, Tham increased pH by 0.05 (range equals negative 0.06 to 0.2).

**Conclusion:** As the sole manufacturer of Tham has discontinued all production, and no 503B sterile compounding facilities are producing it, it will be important to continue to educate the physicians and other healthcare providers that it is unavailable once the current supply has been depleted. Based on the findings of this drug use evaluation, Tham was largely used in combination with sodium bicarbonate for management of metabolic acidosis. However, it will be important to seek alternatives for the select patients who truly cannot tolerate sodium bicarbonate due to its risk of hypernatremia and volume overload.

**Session-Board Number:** 8-186  

**Poster Title:** Outcomes analysis of an expanded pharmacy managed vancomycin dosing program  

**Primary Author:** Christopher Hvisdas, Thomas Jefferson University Hospital, PA; **Email:** christopher.hvisdas@jefferson.edu  

**Additional Author(s):**  
Omar Richardson  
Douglas Stickle  
Claudine El-Beyrouty  

**Purpose:** Thomas Jefferson University Hospital has offered a pharmacy managed aminoglycoside and vancomycin dosing program in two adult intensive care units (ICUs) for 10 years. In 2015, the pharmacy department expanded this service to the remaining adult ICU’s. The objective of this study is to analyze the impact of these expansions on vancomycin dosing and costs. This will be accomplished by retrospectively examining data for patients six months before and six months after the change in protocol.  

**Methods:** This study is a retrospective chart review that will analyze the electronic medical record for patients treated with vancomycin pre- and post-protocol change that allowed physicians the option to select dosing of vancomycin by pharmacy personnel in select ICU’s. The pre-protocol implementation study group will consist of patients dosed within three specific units (Cardiac Critical Care Unit (CCU), Neurological Intensive Care Units (NICU), and Jefferson Hospital of Neuroscience Neurological ICU) between November 2014 and April 2015. The post-protocol implementation study group will consist of data collected from patients in the same units from June 2015 to November 2015. Institutional Review Board (IRB) approval will be obtained before data collection. The following data will be collected: duration of therapy, vancomycin trough and random blood serum levels, goal target trough level, timing of antibiotic and associated trough levels, patient age and gender, antibiotic regimens, white blood cell counts, patient temperature, serum creatinine, body weight, height, creatinine clearance, urine output, and infection being treated. Patient information will be de-identified and maintained confidentially throughout the study. The primary outcome will be defined as percentage of vancomycin troughs in therapeutic range. Secondary outcomes will include: time
to therapeutic level, appropriately timed levels, length of stay, length of vancomycin therapy, and associated costs.

**Poster Title:** Rifampin cost savings for ventricular assist device (VAD) antimicrobial prophylaxis

**Primary Author:** Jennifer Hoh, Thomas Jefferson University Hospital, PA; **Email:** jennifer.hoh@jefferson.edu

**Additional Author(s):**
- Priya Panchal
- Cheryl Abbas
- Brian Roslund

**Purpose:** Ventricular assist devices (VAD) continue to improve survival and quality of life in patients with advanced heart failure. However, device-related infections contribute to significant morbidity and mortality. In 2012, Thomas Jefferson University Hospital (TJUH) adapted a perioperative antibiotic regimen suggested in the REMATCH trial, consisting of intravenous (IV) vancomycin, gentamicin, rifampin and oral fluconazole. One year later, IV rifampin was affected by a drug shortage. Thereafter, the VAD protocol was amended to reflect administration of oral rifampin. The purpose of this study is to determine whether use of the oral formulation has provided a significant cost reduction for TJUH.

**Methods:** A pharmacoeconomic analysis will be performed between oral and IV rifampin for preoperative antimicrobial VAD prophylaxis utilizing average wholesale price (AWP). Data extrapolated will be used towards future economic analyses.

**Results:** n/a

**Conclusion:** n/a
Purpose: Emergence of vancomycin-resistant enterococcus (VRE) species with decreased susceptibility to daptomycin has given rise to innovative treatment approaches to VRE bacteremia. Enterococcus species—E. faecium or E. faecalis can lead to a variety of infections including bacteremia. E. faecalis has a higher virulence and susceptibility to beta-lactam antibiotics than E. faecium. Therefore, fast identification of the specific species, antibiotic susceptibility, and source identification are crucial to successful treatment and eradication of the microorganism.

To help combat enterococcus resistance, beta-lactam antibiotics are emerging therapy as adjunctive therapy to daptomycin in the treatment of VRE bacteremia. This multi-modal approach to VRE treatment has shown promising results in combating daptomycin resistant and susceptible enterococcus. Ceftaroline is currently the only beta-lactam antibiotic that has exhibited synergy against VRE strains that are both susceptible and non-susceptible to daptomycin. It exhibits this synergistic effect by altering the structural and electrochemical components of the bacterial cell wall. This alteration in the cell membrane results in an increase in daptomycin’s cell surface binding ability and bactericidal effect. This novel treatment approach to VRE bacteremia will be reviewed and evaluated for a patient treated for recurrent VRE bacteremia.

A 42 year-old female with a complicated 15-week hospital stay (two separate admissions) was treated for respiratory failure requiring extracorporeal membrane oxygenation (ECMO), acute kidney injury, drug induced liver injury, anoxic brain injury, Escherichia coli urinary tract infection, and E. faecium bacteremia. On the fourth week of her hospitalization the patient developed a fever. Three blood cultures obtained at this time were positive (3/3) for E. faecium, resistant to vancomycin and ampicillin. This VRE strain was daptomycin susceptible, and she
was initiated on daptomycin for 14 days. On week 10 of her hospital stay, blood cultures grew VRE, which remained daptomycin susceptible. Daptomycin was restarted for an additional two-week, and ceftaroline synergy was added for a seven day course. Blood cultures obtained four days after initiation of ceftaroline were negative. A transesophageal echocardiogram (TEE) was performed in an attempt to diagnose endocarditis as the source of the VRE, which returned a negative result. Nine days later, the patient was discharged from the hospital to a rehabilitation facility. The source of the VRE could not be identified at the time of discharge. Seventeen days after being discharged to a rehabilitation facility, the patient was readmitted due to a fever, and worsening tachypnea. Additionally, a CT scan performed at the rehabilitation center showed a right groin hematoma. An unsuccessful attempt was made to drain the abscess, so a wash out was performed. Blood cultures obtained at the time of the wash-out grew VRE. Tracheal aspirate specimen grew Klebsiella oxytoca. Daptomycin and ceftaroline were discontinued and the patient was started on tigecycline and linezolid. Two days after initiation of tigecycline and linezolid cultures were negative. Due to concerns of linezolid-induced thrombocytopenia and the patient’s need for long term antibiotic therapy, linezolid and tigecycline were discontinued and daptomycin was reinitiated for a duration of 6 weeks.

**Poster Title:** Treatment of heartmate II left ventricular assist device associated refractory gastrointestinal bleeding with thalidomide: a case report

**Primary Author:** Catherine Chun, Thomas Jefferson University Hospital, PA; **Email:** chuncatherine@gmail.com

**Additional Author (s):**
Kody Merwine
Megha Patel
Cheryl Abbas

**Purpose:** Gastrointestinal bleeding (GIB) is a common complication of continuous-flow left ventricular assist devices (CF-LVADs), caused most frequently by gastrointestinal angiodysplasia (GIAD). Thalidomide, an angiogenesis inhibitor, has been used in the treatment of refractory gastrointestinal bleeding related to GIAD. This case report illustrates the potential use of thalidomide to treat refractory GIB in patients with CF-LVADs. LH is a 60 year old male, with a past medical history significant for systolic heart failure secondary to a non-ischemic cardiomyopathy, who received a HeartMate II CF-LVAD. Seventeen days post LVAD implantation, he presented with symptomatic anemia secondary to a GIB while on therapeutic anticoagulation. At that time, the patient was initiated on appropriate pharmacologic therapy to manage the GIB, and anticoagulation was held intermittently. The source of the bleed was identified as an arteriovenous malformation (AVM). Despite multiple surgical and medical interventions, the symptomatic anemia continued while therapeutic anticoagulation was attempted to be restarted. Due to the refractory bleed, he was started on thalidomide 50 mg daily at bedtime with parenteral anticoagulation. Six days after initiation of thalidomide, he was hemodynamically stable and was restarted on warfarin. Eventually, LH was discharged to a rehabilitation unit, while continuing thalidomide and therapeutic anticoagulation. He was later readmitted twice from May 2016 to October 2016 for symptomatic anemia. Thalidomide has been shown to be useful for refractory GIBs in patients with CF-LVADs based on previous published case reports. In this particular case, thalidomide was found to be beneficial at reducing the number of hospitalizations for this patient, who was unresponsive to conventional therapy. Future studies with larger cohorts would be beneficial to further evaluate the effectiveness of thalidomide for CF-LVAD related GIB.

Poster Title: Evaluation of the incidence of prescribed nonsteroidal anti-inflammatory drugs (NSAIDs) in alcohol and opioid detoxification patients with concomitant thrombocytopenia

Primary Author: Sheheryar Muhammad, University of Pittsburgh Medical Center - Mercy Hospital, PA; Email: muhmmads2@upmc.edu

Additional Author (s):
John Tomko
Laura Wilson

Purpose: At our institution, patients with thrombocytopenia related to alcoholism undergoing both alcohol and opioid detoxification are likely to be inadvertently ordered the NSAID ibuprofen, as it is an automatic standard order within the opioid withdrawal protocol. This unintentional combination of ibuprofen and thrombocytopenia may increase the risk for bleeding. Furthermore, these patients are at a heightened risk of falls in light that they are being administered clonidine, buprenorphine, or benzodiazepines, compounding the risk for bleeding. The purpose of this study is to evaluate the incidence of ibuprofen prescription in patients who are undergoing alcohol detoxification and have concomitant alcohol-induced thrombocytopenia.

Methods: This cross-sectional study will be submitted to the Institutional Review Board for approval. During the study period, a daily manual review of electronic health records will be conducted for patients in the Detoxification and Behavioral Health units of the hospital. Patients who are (1) age 18 years or more, (2) are ordered both alcohol and opioid detoxification protocols, and (3) have a platelet count of less than 150,000 will be included in the study. For each patient meeting the inclusion criteria, the following data will be collected: age, gender, actual body weight, platelet count, administration of any anticoagulant and/or anti-platelet medications (besides ibuprofen), an order for ibuprofen, and the number of doses of ibuprofen received, in any. Descriptive statistics will be used to express the data as frequency, percentage, and mean with standard deviation.

Poster Title: Evaluating the Frequency Delirium Medications are Discontinued Prior to Hospital Discharge

Primary Author: Tanya Mumau, UPMC Hamot, PA; Email: mumautc2@upmc.edu

Additional Author(s):
Maryann Scholl

Purpose: A previous study at this institution performed by a pharmacy resident revealed that 35 percent of patients initiated on medications for the purpose of delirium between August 22, 2014 and August 26, 2015 were discharged home on the medications. Education to the critical care physicians and staff about discontinuation of these medications was issued after the previous study was performed. Discussion during multidisciplinary rounds regarding delirium medications was encouraged. The purpose of this medication utilization evaluation is to determine if these efforts impacted the discontinuation frequency of delirium medications prior to patient discharge from the hospital.

Methods: All patients admitted to either the Medical Intensive Care Unit or the TraumaNeuro Intensive Care Unit treated for delirium with haloperidol, olanzapine, quetiapine, risperidone, or ziprasidone between January 2016 and July 2016 will be assessed for the frequency of discontinuation of these medications prior to discharge from the hospital. The patient must be greater than or equal to 18 years old and have an Intensive Care Delirium Score Checklist score of greater than or equal to 4 or have a diagnosis of delirium listed in a progress note. Patients will be excluded if the medication is being used for treatment indicated for a condition present at time of intensive care unit admission or if medications being used for delirium were appropriate at time of death in the intensive care unit. Data collection will take place during August and September of 2016. These results will be compared to the previous study to determine if improvements have occurred.

**Poster Title:** Evaluating the appropriate use of 24% sucrose in neonatal units in a community hospital

**Primary Author:** April Elling, UPMC Hamot, PA; **Email:** ellingaa2@upmc.edu

**Additional Author(s):**
Sarah Moffett

**Purpose:** Oral sucrose has commonly been utilized in the neonatal population as analgesia for painful procedures. In January 2016, The American Academy of Pediatrics Committee on Fetus and Newborn and Section on Anesthesiology and Pain Medicine published guidance on the management of procedural pain in the neonate recommending that oral sucrose be prescribed and tracked as a medication. Although prescribed, sucrose was not scanned at our institution until June 2016. The purpose of this medication use evaluation is to determine if sucrose is being used appropriately for painful procedures and being scanned into the electronic medication administration record.

**Methods:** Patients admitted to the newborn nursery and neonatal intensive care unit (NICU) with an order for sucrose will be reviewed daily to determine appropriate sucrose use. Criteria for appropriate use of sucrose is documentation of a painful procedure including a heel lance, lumbar puncture, venipuncture, intramuscular injection, ophthalmic examination, circumcision and intravenous line insertion. Stock counts will take place at least twice weekly to review the proper scanning of the medication. Data will be collected for a 1.5 month period.

**Poster Title:** Evaluation of pediatric inpatient influenza immunization at a tertiary care hospital

**Primary Author:** Sadaf Mahmood, UPMC Hamot, PA; **Email:** sadafm27@gmail.com

**Additional Author(s):**
Steve Saber

**Purpose:** The 2015 Joint Commission Annual Report listed influenza immunization as a measure with a target compliance rate of 95 percent or more. Our hospital's inpatient compliance rate exceeded that standard in the 2015-2016 flu season. However, since the pediatric population is a small subset of the total inpatient population, it is important to determine if the hospital's current protocol is sufficient in screening and vaccinating pediatric patients. The purpose of this study is to determine if the pediatric inpatients at our hospital are being appropriately screened and immunized for influenza, and to determine the pediatric inpatient influenza immunization compliance rate.

**Methods:** This retrospective analysis will evaluate the first 10 pediatric inpatients > 6 months of age discharged each month from a tertiary care hospital from October 2015 to March 2016. The patients will be assessed for appropriate screening and, if indicated, vaccination for influenza. The influenza immunization compliance rate will also be determined. Criteria for use of the influenza vaccine include all pediatric individuals 6 months of age and older and less than 18 years of age. The evaluation will assess for each patient whether or not, per protocol, the attending physician placed an order for the influenza vaccine if indicated. If an order was placed, it will be determined whether the vaccine was administered to the patient prior to discharge and, if not, the reason(s) why. The evaluation will assess if the patient received the vaccine prior to admission, if the patient had any contraindications to receiving the vaccine, and if the patient or their guardian(s) refused the influenza vaccine. The Joint Commission/CMS criteria will be used to determine if the hospital's pediatric population met or exceeded the 95 percent compliance rate for influenza immunization in the preceding year.

Poster Title: Cost-effectiveness of MRSA surveillance cultures in patients diagnosed with healthcare-associated pneumonia and treated with vancomycin

Primary Author: Ryan Steiner, UPMC Mercy, PA; Email: steinerr2@upmc.edu

Additional Author(s):
Christina Andrzejewski
Henry Freedy
Laura Wilson

Purpose: Updated IDSA Hospital-acquired and Ventilator-associated pneumonia guidelines have excluded the diagnosis of healthcare-associated pneumonia (HCAP). Recent evidence has shown no increased risk of multi-drug resistant organisms, including MRSA, in the HCAP population. At our institution, MRSA surveillance cultures have been performed on HCAP patients admitted to critical care units. The goal is to discontinue vancomycin if appropriate based on the culture results. This study will identify if implementation of MRSA surveillance cultures is a cost-effective strategy and if it would be a beneficial practice for all inpatients with a diagnosis of HCAP by eliminating unnecessary vancomycin use.

Methods: This study will be submitted to the Quality Improvement Committee for approval. The electronic medical record system will be used along with ICD 9 and 10 codes to identify HCAP patients treated with vancomycin in both critical care and non-critical care areas. Data collection will consist of retrospective chart review from September 1, 2015 to August 31, 2016. Cost of vancomycin therapy per day will be calculated by accounting for the cost of the medication, the cost of drug monitoring, and the cost associated with the pharmacy pharmacokinetic service for vancomycin dosing over the total duration of therapy. Average cost per day of vancomycin therapy will be used to estimate an average total therapy cost depending on the mean duration of therapy. The time associated with the pharmacokinetic service will be self-recorded by participating pharmacists over a one month period and averaged per day. The total cost of vancomycin therapy will be compared to the cost of one time surveillance cultures in the critical care units. The duration of therapy in the critical care units will be assessed from the time of vancomycin initiation to the discontinuation of therapy and compared to the duration of therapy in the non-critical care areas. The cost savings from
the implementation of MRSA surveillance will be assessed in both inpatient areas assess the
cost effectiveness of that practice.

Poster Title: Effectiveness of Phenobarbital Loading Doses in Alcohol Withdrawal Syndrome (AWS)

Primary Author: Jaclyn Niggemyer, UPMC Mercy, PA; Email: niggemyerjm@upmc.edu

Additional Author(s):
Steven Ganchuk
Laura Wilson

Purpose: Alcohol withdrawal syndrome is a life-threatening condition. Benzodiazepines are effective GABA stimulants and considered the medications of choice for treatment in this setting. Though evidence supporting the use of phenobarbital is limited, some studies suggest it is beneficial in this patient population. Like benzodiazepines, phenobarbital stimulates GABA receptors. Additionally, phenobarbital inhibits the activity of the excitatory neurotransmitter glutamate. Despite this potential pharmacologic advantage, data comparing phenobarbital with diazepam for the treatment of AWS is lacking. This study will investigate if loading doses of phenobarbital are more effective than loading doses of diazepam in the initial treatment of AWS.

Methods: This study will be submitted to the Institutional Review Board for approval. A retrospective list of patients that received a loading dose of phenobarbital (defined as > 130mg) or a loading dose of diazepam (defined as >40mg) for the treatment of alcohol withdrawal syndrome will be generated. Patients excluded from the study include those who did not receive standard therapy for alcohol withdrawal syndrome (defined as a phenobarbital taper with or without “as needed” benzodiazepines). Additionally, patients excluded include those who received mixed loading doses of phenobarbital and diazepam as well as those discharged within 12 hours of the loading dose. The following data will be recorded: base line withdrawal assessment score (WAS), withdrawal assessment score 12, 24, and 48 hours following the loading dose, patient age, gender, cumulative phenobarbital dose 12, 24, and 48 hours following the loading dose, cumulative benzodiazepine dose 12, 24, and 48 hours following the loading dose, location in which the patient was admitted, and length of hospital stay.

Poster Title: Incidence of myopathies in patients received cisatracurium alone versus cisatracurium in combination with low dose steroids
Primary Author: Seohyun Choi, UPMC Mercy, PA; Email: chois5@upmc.edu
Additional Author(s):
Steve Ganchuk
Laura Wilson

Purpose: Numerous studies have reported myopathies as an adverse effect of aminosteroidal neuromuscular agents, particularly when used in conjunction with high dose steroids. As a result, practitioners at our institution commonly avoid the combination of steroids and neuromuscular blocking agents. Myopathies associated with the combination of low dose steroids and cisatracurium, a neuromuscular blocking agent belong to the benzylisoquinolinium classification is not well established in the literature. We hypothesize that the incidence of myopathy in patients receiving the combination of cisatracurium and low dose steroids will be similar to those patients receiving cisatracurium alone due to mechanistic differences.

Methods: A list of patients who received cisatracurium from September 1, 2013 through September 1, 2016 will be generated from the hospital’s electronic medical record. A second list will be generated, identifying patients who received the combination of cisatracurium and low dose steroids (less than 1 g of methylprednisolone equivalent) from the same time period. A cohort from both groups will be randomly selected and a chart review will occur to collect data. Patients of any age, gender or ethnicity will be included. Exclusion criteria are patients who received high dose steroids defined as more than 1 g of methylprednisolone equivalent, or patients with underlying muscular diseases such as rheumatoid arthritis, fibromyalgia, multiple sclerosis, Parkinson’s disease, sarcoidosis, muscular dystrophies and myasthenia gravis. Using ICD-9 and ICD-10 codes that define myopathies, the difference in the proportion of patients with reported myopathy who received cisatracurium vs. patients who received cisatracurium plus low dose steroids will be analyzed. ICD codes that will be used to define myopathies include: acute necrotizing myopathy, quadriplegic myopathy, myositis, non-traumatic rupture of muscle, muscle weakness, rhabdomyolysis, progressive muscular atrophy, myoglobinuria,
drug induced myopathy and myalgia. In addition, intensive care unit length of stay, time on ventilator and need for rehabilitation will be assessed.

**Results:** N/A

**Conclusion:** N/A
Purpose: In June 2016, the FDA announced that patients with uncomplicated urinary tract infections (UTIs) should receive fluoroquinolones only if other treatment options are not available, due to disabling and potentially permanent adverse effects involving tendons, muscles, and the central nervous system. Despite FDA recommendations, fluoroquinolones are still frequently prescribed upon discharge as step-down therapy for uncomplicated UTIs following a course of IV antibiotics, when alternative agents exist. This quality improvement (QI) project is designed to evaluate the need for an antimicrobial stewardship program focusing on pharmacist intervention to avoid unnecessary fluoroquinolone prescribing in the setting of uncomplicated UTI upon discharge.

Methods: This QI project is a retrospective chart review of patients who were treated for uncomplicated cystitis and discharged from an academic medical center in Pittsburgh, PA. Patients who were discharged with a prescription for ciprofloxacin from October 2015 to September 2016 were identified utilizing discharge prescription records generated from the hospital’s electronic health record. Patients were cross-referenced with all patients with the ICD-10 diagnosis code for cystitis during the same time period. A chart review is to be conducted for patients who meet both criteria. Exclusion criteria will include patients that are less than 18 years of age, patients being treated for a UTI who have additional indications requiring antibiotics, and patients with allergies that would preclude the use of alternative agents. Data collection will include demographics, in-patient antibiotic regimen, discharge antibiotics, allergies, infecting organism [including minimum inhibitory concentrations (MICs) to ciprofloxacin, sulfamethoxazole/trimethoprim, and cefazolin], concomitant medication orders for warfarin and/or tizanidine, and disposition upon discharge.

Poster Title: Drug-associated acute kidney injury identified in the Food and Drug Administration Adverse Events Reporting System

Primary Author: Hanna Welch, UPMC Presbyterian Shadyside (Presbyterian Campus), PA; Email: welchhk@upmc.edu

Additional Author(s):
Sandra Kane-Gill

Purpose: Acute kidney injury (AKI) is a common condition associated with both short-term and long-term consequences including dialysis, development of chronic kidney disease, and mortality. Recognition of nephrotoxic medications is necessary to prevent AKI and AKI progression in patients at risk. The Food and Drug Administration Adverse Event Reporting System (FAERS) is a powerful tool to examine drug-associated events; however, no study to date has analyzed FAERS to identify the drugs most frequently reported with AKI. The objective of this study is to classify medications most frequently associated with AKI in FAERS and to identify new potential nephrotoxins for further study.

Methods: The publicly available FAERS database will be queried for reports of AKI. For each adverse event report retrieved, data collected will include patient demographics, drug identity, and adverse event characteristics. Extracted drugs will be assessed for known nephrotoxin status by consulting four authoritative references, and each drug will be classified as a known, potential, non-established, or new potential nephrotoxin. The most frequently reported drugs in each category will be identified, and the reporting odds ratio (ROR) will be calculated for each drug and for each category of drugs. The ROR of each new potential nephrotoxin will be compared with that of known nephrotoxins. Reporting frequencies over time will be examined for medications in each category. For new potential nephrotoxins identified in FAERS, previous literature reports of AKI will be discussed.

Poster Title: Risk factors in patients with thrombotic microangiopathy

Primary Author: Ting-Ting Wu, UPMC Presbyterian Shadyside (Presbyterian Campus), PA;
Email: wuxx0691@umn.edu

Additional Author(s):
Cody Moore
Carlo Iasella
Christopher Ensor

Purpose: Thrombotic microangiopathy (TMA) is a rare disorder after transplantation. TMA comprises a group of disorders including thrombocytopenic purpura, hemolytic uremic syndrome or the combination of two. The clinical course severely deteriorates and often leads to death once TMA occurs. It is a well-recognized complication of the allogeneic hematopoietic stem cell transplantation and renal transplantation. However, published data on risk factors in lung transplant recipients (LTRs) remains limited owing to the rarity in this population. The purpose of this study is to determine the prevalence and ascertain the risk factors for its occurrence that may be of influence on LTR outcome.

Methods: This study is submitted to the Institutional Review Board for approval. Data will be obtained from University of Pittsburgh Medical Center lung transplant database up to September 2016. Adult LTRs (18-80 years old) are included in the study. Patients who are pregnant, prisoners, or age less than 18 years old are excluded from the study, as well as patients with malignancy receiving allogeneic hematopoietic stem cell transplantation, chemotherapy, or radiation. The following data will be collected: Age, gender, race, indications for lung transplant, bilateral or single lung transplant, ADAMTS13 activity testing, platelet counts, haptoglobin level, lactate dehydrogenase, hemoglobin, creatinine, peripheral blood smear, Coombs test, un-conjugated bilirubin, HIV and other viral infections, CMV donor and recipient serotype, aspergillosis infection, and the use of other particular medications (ticlopidine, clopidogrel, quinine, oral contraceptives), systemic rheumatic disorders, pancreatitis, SBP>160, disseminated intravascular coagulation, and severe vitamin B12 deficiency. Chi-square test or Fischer’s exact test will be used for categorical variables. Normality of the data will be assessed with the Shapiro-Wilk test for continuous data. Student’s
T test or Wilcoxon’s rank-sum test will be used accordingly. Multivariate regression based on demographic variables and/or clinical variables will be used to evaluate the association of risk factors with the development of TMA.

Poster Title: Use of oritavancin in the emergency department as a hospital-avoidance tool in patients with complicated acute bacterial skin and skin structure infections (cABSSSI)

Primary Author: Alana Grabigel, UPMC Presbyterian Shadyside (Shadyside Campus), PA; Email: grabigela@upmc.edu

Additional Author(s):
Casey O'Brien
Louise-Marie Oleksiuk

Purpose: Oritavancin is a newly approved long-acting lipoglycopeptide that can be administered in a single dose when treating complicated acute bacterial skin and skin structure infections (cABSSSI). This dosing strategy creates the opportunity for treating such infections in outpatient settings, such as the emergency department (ED). The primary objective of this quality improvement initiative is to describe the utilization of oritavancin as a hospital-avoidance tool in patients with cABSSSI who present to the ED at a large academic medical center. This project also aims to quantify both hospital reimbursement for the medication and patient out-of-pocket costs.

Methods: A retrospective chart review of patients receiving oritavancin via an outpatient treatment pathway in the emergency department (ED) between June 2016 and March 2017 will be conducted. In order to be included, patients must receive oritavancin for treatment of cellulitis, a wound infection and/or major cutaneous abscess characterized by purulent drainage, erythema, flutuance, localized warmth, edema, pain or tenderness with or without leukocytosis, fever, or swollen lymph nodes. All patients will be evaluated for the presence of any exclusion criteria as outlined in the treatment pathway. The following data will be collected as a part of the retrospective chart review: hospital discharge within the previous 30 days, length of ED visit, time from ED admission to medication order entry, time from medication order entry to administration, 30-day ED visit, 30-day admission, outpatient follow-up and time to follow-up, hospital reimbursement and out-of-pocket cost to the patients. Approval through the quality improvement department will be obtained prior to data collection.

**Poster Title:** Impact of a geriatric pharmacist’s clinical and educational activities during weekly interprofessional team meetings

**Primary Author:** Kristin Hart, UPMC Presbyterian/Shadyside, PA; **Email:** kristin.m.hart1@gmail.com

**Additional Author(s):**
Christine Ruby

**Purpose:** The majority of adverse drug events occur in the elderly as a result of physiological changes, multiple co-morbidities, and polypharmacy. Several studies have demonstrated the improvement of medication use as a result of pharmacist-led medication reviews. The primary objective of this study is to describe the clinical interventions of a geriatric pharmacist during weekly interprofessional team meetings via retrospective analysis using a newly developed documentation template. Secondary objectives will be to enumerate the pharmacist’s education provided to the interprofessional team. A survey will also be administered to evaluate the team’s perception of the pharmacist’s effectiveness.

**Methods:** A retrospective chart review of the patients discussed on team meetings between October 1, 2016 and March 31, 2017 will be conducted. Patient cases are selected by the medical learners due to the complexity of their cases and to enrich interprofessional collaboration and learning between medicine, pharmacy, nursing, social work, nutrition, and physical and occupational therapy. A newly devised pharmacy template will be utilized and recorded in the electronic medical record. This template captures data from the geriatric pharmacist’s clinical activities as well as education provided to the patient, patient’s family, and team. Clinical activities such as the identification of medication discrepancies and drug-drug interactions, and the provision of recommendations for dosing changes, therapeutic alternatives and cost-savings, will be ascertained. Descriptive analyses will be conducted. Results from the survey will be used to enhance future educational endeavors provided by the pharmacist. Prior to initiation, this study will be submitted for approval by the Institutional Review Board at the University of Pittsburgh.

**Poster Title:** Pharmacist impact on improving inhaler technique retention in an outpatient primary care setting

**Primary Author:** Sheava Blackman, UPMC Presbyterian-Shadyside (Shadyside Campus), PA;
**Email:** blackmans2@upmc.edu

**Additional Author (s):**
Stephanie Ballard
Trisha Miller

**Purpose:** Chronic lower respiratory diseases such as Asthma and Chronic Obstructive Pulmonary Disease (COPD) are extremely common and carry with them a high burden of disease. A large percentage of these patients are prescribed inhaled medications to manage their symptoms. Improper inhaler technique can lead to poor patient outcomes resulting in multiple exacerbations, increased hospital admissions and consequently, increased cost to the healthcare system. The primary objective of this study is to determine the effectiveness of pharmacist provided inhaler technique on patient ability to independently and correctly use an inhaler. Other data regarding spacer distribution will also be collected.

**Methods:** This is a prospective observational study of outpatient adults with asthma and/or COPD presently using or newly prescribed at least one metered dose inhaler medication at study enrollment. Participants will be selected from two primary care clinics, which are both residency practice sites with integrated clinical pharmacists. Appropriate informed consent will be obtained prior to participant enrollment. The clinical pharmacists, pharmacy residents and/or pharmacy students at the specified locations will conduct training sessions as well as follow up between November 2016 and April 2017. Correctness of inhaler technique will be determined using a developed observational checklist at baseline. This will be followed immediately by inhaler education and participant demonstration. Participants who are initially unable to complete defined critical steps will be provided with spacers and subsequent instruction on use. An additional assessment post demonstration and provision of spacer device will be conducted. Information regarding the frequency that patients conducted critical faults resulting in spacer distribution will be reported. Participant’s ability to retain information will be evaluated via office appointment or telephone call four weeks after the initial educational
session. Participant’s perceived satisfaction with inhaler administration post pharmacist intervention will also be assessed via survey. This study will be submitted to the Institutional Review Board for approval prior to study commencement.

Poster Title: Cost of heparin versus enoxaparin for non–ST-elevation acute coronary syndromes (NSTE-ACS)

Primary Author: Chelsea Master, WellSpan York Hospital, PA; Email: chelseamaster41@gmail.com

Additional Author (s):
Geoffrey Arentz

Purpose: Unfractionated heparin (UFH) and low molecular weight heparins, such as enoxaparin, are both used in the initial treatment of NSTE-ACS. The ACC/AHA Guideline for the Management of Patients with NSTE-ACS recommends enoxaparin over unfractionated heparin. Because the initial drug cost of UFH is less expensive than enoxaparin, it is often preferred in the hospital even though its use is associated with more secondary costs including laboratory monitoring, infusion supplies and additional nursing time. With the recent approval of the first generic enoxaparin, an evaluation of direct and indirect costs is warranted.

Methods: This study is a retrospective chart review of adult inpatients who were initiated on WellSpan York Hospital’s Heparin Cardiac Nomogram from July 1, 2016 through September 30, 2016. Adult patients over 18 years of age who were admitted for medical management of NSTE-ACS and started on the Heparin Cardiac Nomogram within 24 hours of presentation will be included in the analysis. Patients admitted to an intensive care unit, who received percutaneous intervention (PCI) or who have end-stage renal disease will be excluded. The cost of treatment with UFH will include the drug procurement cost, laboratory cost of the activated partial thromboplastin time (aPTT), and an estimate of the nursing time required for initiation and rate adjustments per nursing policy. The cost of UFH will not include the infusion pump or the infusion lines. The cost of treatment with enoxaparin will only include the cost of the drug itself as it does not require laboratory monitoring. From the results of this study, the direct and indirect costs of UFH when used for NSTE-ACS will be determined. The potential cost difference will be evaluated if patients are transitioned to the ACC/AHA guideline recommendation of enoxaparin at this institution.

**Poster Title:** Evaluation of naloxone use at a community teaching hospital  

**Primary Author:** Brittany Thomas, WellSpan York Hospital, PA; Email: bthomas6@wellspan.org  

**Additional Author (s):**  
Kishan Patel  

**Purpose:** Naloxone is an opioid receptor antagonist indicated for reversal of opioid-induced respiratory depression. Hospitalized patients receive opioids for acute and chronic indications and inappropriate naloxone administration may increase discomfort and/or precipitate opioid withdrawal. At WellSpan York Hospital, naloxone is administered following a provider’s order or a nurse-driven protocol for opioid-induced respiratory depression. The primary objective of this study is to identify the appropriateness of the naloxone administration, defined as a respiratory rate less than 8 breaths per minute, prior to naloxone administration. Secondary objectives will assess resolution of respiratory depression and reported pain scores after naloxone administration.  

**Methods:** This study is an IRB-exempt retrospective chart review of patients at WellSpan York Hospital charged for naloxone between August 2015 and July 2016. These patient will be identified using the electronic medical record. Admitted adult patients administered naloxone for reversal of suspected opioid toxicity will be included. Patients will be excluded if naloxone was received for indications other than opioid reversal, were receiving methadone, or received naloxone in the emergency department or post-anesthesia care unit. The following patient demographic data will be collected confidentially and without patient identifiers: age, sex, weight, opioid history prior to admission, total opioids received in previous twenty-four hours converted to oral morphine milligram equivalents, location of patient and admitting service. The following data will also be collected: the dose and route of naloxone administered, the respiratory rate prior to and following the naloxone, the pain score before and after naloxone administration, the last opioid dose and route of administration, whether the opioid was scheduled or as needed. The initiating opioid order characteristics will be collected including if this order was initiated via a protocol and by a medicine or surgery provider.

Poster Title: Evaluating the use of dexmedetomidine to facilitate non-invasive ventilation (NIV) in progressive care units and intensive care units.

Primary Author: Daniel Smith, McLeod Regional Medical Center, SC; Email: connor.smith@mcleodhealth.org

Additional Author(s):
Bradley White
Megan Lail

Purpose: Non-invasive ventilation (NIV) is becoming more utilized for managing acute respiratory failure. NIV is associated with fewer complications than endotracheal intubation but patient compliance can be challenging. Commonly used agents for anxiety in this setting include benzodiazepines and opiates. These are associated with adverse events such as respiratory depression, hypotension, and excessive sedation. Dexmedetomidine exerts its effects through agonism of the alpha-2 adrenergic receptor. Unlike other sedatives, dexmedetomidine has sedative and anxiolytic properties without causing significant respiratory depression. This study aims to evaluate the efficacy and safety of dexmedetomidine for sedation in patients that require NIV.

Methods: All patients 18 years old or older, located in a progressive care unit (PCU) or intensive care unit (ICU), on NIV, and requiring dexmedetomidine will be included in this study. Dexmedetomidine use in these patients will be initiated and guided through a hospital approved protocol. Patients that are located in a PCU or ICU and on dexmedetomidine will be identified through a daily drug utilization report. Clinical pharmacists will determine the patients that meet the inclusion criteria through investigation of the EMR, paper-chart, and speaking with nurses/physicians caring for these patients.

Poster Title: Evaluation of Adjunct Dexmedetomidine in Benzodiazepine-Resistant Patients Exhibiting Alcohol Withdrawal Inpatient

Primary Author: Allie Curlin, McLeod Regional Medical Center, SC; Email: allie.curlin@mcleodhealth.org

Additional Author(s):
Megan Lail
Bradley White

Purpose: An estimated 17 million Americans have an alcohol use disorder. The risk of alcohol withdrawal syndrome (AWS) during acute care admissions is significant. Benzodiazepines (BZDs) provide inhibitory activity post alcohol discontinuation in AWS, however, BZD-resistance secondary to GABA receptor downregulation and conformation may develop. Dexmedetomidine (DEX) is an alpha-2-agonist, producing sedative and sympatholytic effects. DEX does not provide seizure control; however, it may have an adjunct role in reducing BZD use and resistance. The purpose of this analysis is to determine the efficacy and safety of adjunct dexmedetomidine for BZD-resistant patients in Progressive Care or Intensive Care Units exhibiting AWS.

Methods: This is a prospective observational study. For the purpose of this study, BZD resistant is defined as a Modified Severity Assessment Scale (MSAS) > 10 requiring scheduled lorazepam plus two consecutive PRN lorazepam doses or MSAS > 15. Patients will be included in this analysis if they have been diagnosed with alcohol withdrawal syndrome, transferred to an Intensive Care Unit (ICU) or Progressive Care Unit (PCU), and either meet the requirements for BZD resistance or have been initiated on DEX by an intensivist or pulmonologist. Patients will be excluded if they are less than 18 years of age, have been administered BZDs for purposes other than AWS, have had adverse reactions or have contraindications to DEX including: hypersensitivity, active myocardial ischemia, second-or third-degree heart block, hepatic impairment, severe ventricular dysfunction, pregnancy, bradycardia or hypotension. Primary endpoints will be the difference in MSAS scores prior to and post initiation of DEX and the number of patients transferred to the ICU. Secondary endpoints include ICU/PCU LOS and
hospital LOS. Secondary safety endpoints for DEX include maximum dose required to achieve a goal RASS score, hypotension (systolic blood pressure [SBP] < 90) and bradycardia (heart rate < 50 bpm). Secondary safety endpoints for BZDs include total daily dose of lorazepam prior to and post DEX initiation, administration of flumazenil, number of patients requiring intubation, and seizures.

Poster Title: Practice change from intermittent medication boluses to bolusing from a drip in pediatric critical care: a quality improvement project

Primary Author: Jessica Hochstetler, Medical University of South Carolina, SC; Email: hochstet@musc.edu

Additional Author(s):
A. Jill Thompson
Elizabeth Mack
Diana Nguyen

Purpose: Intermittent IV medications may be administered either as an individual dose, obtained from a pharmacy or an automated dispensing machine on the unit, or as a bolus from a drip if that same medication is being continuously infused (bolus from drip method). Bolus from drip method is standard of practice in many children’s hospitals across the country. MUSC Children’s Hospital implemented a practice change to bolus from drip in November 2015. The objective of this study is to determine the impact of this method on the quality of patient care and safety in pediatric intensive care units.

Methods: This study is evaluating patients < 18 years old in the MUSC pediatric cardiac and medical intensive care units receiving continuous infusions of midazolam, fentanyl, morphine, vecuronium, rocuronium, dexmedetomidine, pentobarbital, or cisatracurium between 5/1/2015 and 5/31/2016, with November being a washout period. The following was evaluated for patients receiving these drips: time between medication bolus need being identified to time to beginning of bolus administration, central line entries, nursing satisfaction, cost savings, unplanned extubations, patient safety events, and Alaris™ pump guardrail overrides. The time (seconds) between the point in which a bolus medication dose was deemed necessary by a bedside nurse until the medication administration began was collected by a group of volunteers and nurses. Central line entries were collected by nurses each time they accessed a patient’s line before and after the implementation of the bolus from drip method. A nursing satisfaction survey was administered before and after the process change. Cost savings are being evaluated through a retrospective chart review of the number of intermittent doses given from an automated dispensing machine (ADM) prior to the new process compared with the number
given as a bolus from a continuous infusion plus from an ADM after implementation. The data for unplanned extubations, patient safety events, and Alaris™ pump guardrail overrides were collected from an outside source and evaluated by reviewers.

Poster Title: Incidence of hypoglycemia in patients with renal dysfunction treated for hyperkalemic with regular insulin

Primary Author: Dannielle Brown, The Medical University of South Carolina, SC; Email: dannieller.brown@yahoo.com

Additional Author(s):
Chase Brown
Tracie Delay
Genevieve Hayes
Ruth Campbell

Purpose: Patients with hyperkalemia are often treated with regular insulin and dextrose to rapidly shift potassium intracellularly. While insulin has been shown to be an effective short-term therapeutic option, previous observational studies have reported increased hypoglycemic events in patients with end stage renal disease (ESRD) treated with insulin for hyperkalemia. Healthcare professionals at the Medical University of South Carolina (MUSC) treating such patients have made similar observations. This study aims to determine the incidence and risk factors for the development of hypoglycemia at MUSC in patients with chronic kidney disease (CKD) stages III-V or on dialysis with hyperkalemia treated with insulin.

Methods: A report was generated from the electronic health record of all patients with CKD stages III-V or on dialysis with a potassium level greater than 5.5 mg/dL treated with regular insulin. Patients treated between October 1st, 2015 and August 16th, 2016 were included in the analysis. The following data was collected: age, race, sex, body mass index, history of diabetes or oral antihyperglycemic medications, stage of CKD, inciting potassium level and time, regular insulin dose and time, blood glucose levels and time, and time to hypoglycemia. Exclusion criteria included patients less than 18 years old, those without a blood glucose reading within 24 hours before insulin administration, without a blood glucose reading within 24 hours after insulin administration, or blood glucose less than 70 mg/dL before insulin administration. Hypoglycemia was defined as blood glucose less than 70 mg/dL and severe hypoglycemia was defined as blood glucose less than 50 mg/dL. The primary outcome was incidence of hypoglycemia in patients with renal dysfunction that receive regular insulin. Secondary
outcomes included incidence of severe hypoglycemia, assessment of average time to onset of hypoglycemia, and identification of risk factors associated with hypoglycemia. Risk factor analysis included stratification by age, sex, race, diabetes history, body mass index, CKD stage, insulin dose, and initial blood glucose.

Poster Title: Implementation of pharmacogenetics service in an adult oncology outpatient chemotherapy infusion center.

Primary Author: Glenn Roma, Baptist Cancer Center, TN; Email: gwroma@gmail.com

Additional Author(s):
Alexander Quesenberry

Purpose: Both efficacy and toxicity of medication therapy varies among patients, largely due to genetic differences in the drug metabolizing enzymes and pathways. Identifying patients with these differences will provided safer and more effective therapy. Main objective: Identify patients at risk for increase adverse drug events (ADE) based upon pharmacogenetic testing, and provide drug specific recommendations to minimize ADEs. Primary objective: Demonstrate decrease in chemotherapy related ADEs in patients receiving fluoropyrimidine-based chemotherapy using preemptive dihydroxymidine-dehydrogenase (DPD) test results to guide initial dosing recommendations. Secondary objective: Provide medication therapy management services using pharmacogenetics testing results for non-antineoplastic medication therapies patients are prescribed.

Methods: Prior to the initiation of chemotherapy, 60 oncology patients prescribed fluoropyrimidine therapy will be consented for pharmacogenetics testing. The testing procedure includes an initial pharmacist-patient interaction to discuss the purpose of the testing and to perform an initial medication history evaluation. Buccal swabs will be collected and submitted for analysis of approximately 50 different drug metabolizing genes, including DPD. Based upon the results of the DPD genotyping, dosage recommendations will be made regarding the fluoropyrimidine portion of therapy. Recommendations for initial dosing will follow those proposed in by the Clinical Pharmacogenetics Implementation Consortium (CPIC) guidelines. Further dose adjustments will be made on a patient by patient basis secondary to tolerance of therapy. Rates and severity of adverse effects among the patients will be compared to historic rates among patients receiving fluoropyrimidine therapy between January 1, 2015 and December 31, 2015 based on chart review from the electronic health record, evaluating severity and frequency of ADRs, need for dose adjustments based on toxicities, and hospitalizations related to chemotherapy toxicity. Additionally, the pharmacist will evaluate the
patient’s pharmacogenetics results and the current medications to determine any other potential therapeutic concerns.

**Poster Title:** Evaluation of peri-operative bleeding and thrombosis in LVAD patients

**Primary Author:** Megan Gregory, Baptist Memorial Hospital - Memphis, TN; Email: gregorymegan59@gmail.com

**Additional Author(s):**
Dawn Waddell
Amy Brewster
Sarah Beth Moore

**Purpose:** In patients with heart failure and severely impaired ejection fraction, placement of a left ventricular assist device (LVAD) is often necessary. For patients receiving an LVAD, there is an increased risk of both thrombosis and bleeding. Studies evaluating the long-term risks of thromboembolism and bleeding have been previously published, but information on the peri-operative period is lacking. Therefore, the purpose of this study is to determine what factors may be associated with bleeding and/or thrombosis in the peri-operative period of LVAD placement.

**Methods:** This retrospective chart review was approved by the Baptist Memorial – Memphis Institutional Review Board. Patients 18 years of age or older who were admitted between March 1, 2014 and August 31, 2016 for LVAD placement will be included. The primary outcome is the incidence of thrombosis or clinically significant bleeding from time of admission to discharge. Key secondary endpoints include incidence of venous thromboembolism, ischemic stroke, hemorrhagic stroke, and in-hospital mortality. Data on the following patient characteristics will also be collected: blood pressure, body mass index (BMI), pre-operative antithrombotics and post-operative anticoagulation, type of LVAD placed, purpose and urgency of LVAD placement, length of stay from LVAD placement to discharge, and coagulation studies. All data will be recorded without patient identifiers and maintained confidentially.

**Poster Title:** Correlation of inappropriately dosed direct oral anticoagulants and incidence of readmissions due to thromboembolism or bleeding in atrial fibrillation patients

**Primary Author:** Sila Shalhoub, Baptist Memorial Hospital - Memphis, TN; **Email:** sshalhoub22@gmail.com

**Additional Author (s):**
Amy Brewster
Zachary Brent
Dawn Waddell
Ginger Burton

**Purpose:** Antithrombotic therapy is indicated for stroke prevention in patients with atrial fibrillation. Prescribing direct oral anticoagulants (DOACs) has increased due to limited monitoring, fewer drug/food interactions and support from recent national guidelines versus warfarin. Inappropriate doses, both above and below FDA approved doses, are being seen commonly in practice. Although current literature has studied the prevalence of inappropriate dosing, the outcomes associated with this trend are still unknown. The purpose of this study is to investigate the incidence of thromboembolism or bleeding in patients with atrial fibrillation who were discharged on recommended versus inappropriate doses of DOACs.

**Methods:** This single-center, retrospective chart review study was approved by Baptist Memorial Hospital Institutional Review Board. Data will be collected through the electronic medical record system for patients discharged on a direct oral anticoagulant from March 2014 to August 2016 for the indication of atrial fibrillation. The primary outcome is to identify and compare the prevalence of hospital readmissions due to venous thromboembolism, stroke, or bleeding in patients who were previously discharged on an appropriate versus inappropriate dose of DOAC. Demographic data as well as admission diagnosis, major surgeries during hospitalization, past medical history, and concomitant medications will be collected. Lab values including complete blood count and comprehensive metabolic panel will also be used to assess dose appropriateness. DOAC doses will be evaluated based on the manufacturer recommended dosages for patients with atrial fibrillation. Readmission diagnosis and the DOAC dose from the previous admission will be collected to assess for any correlation.

Amy Brewster

**Purpose:** Venous thromboembolism (VTE), which includes deep vein thrombosis (DVT) and pulmonary embolism (PE), contributes to approximately 200,000 deaths per year. Obesity has been identified as an independent risk factor for the development of VTE. Identification of an appropriate VTE prophylactic dose is necessary to reduce the risk of thrombosis in this population. The purpose of this study is to evaluate the use of prophylactic anticoagulation in hospital-acquired VTE, stratified by BMI, in order to assess if obese patients are at a higher risk of acquiring VTE during their hospital stay compared to non-obese patients.

**Methods:** This study is a single-center, retrospective chart review of patients admitted to Baptist Memorial Hospital – Memphis (BMHM) from March 11th 2014 to August 31st 2016 with a hospital-acquired VTE diagnosis. Patients were identified by ICD-9 and ICD-10 codes using the electronic medical records. The primary outcome of this study is the incidence of hospital-acquired VTE in non-obese vs. obese patients, defined as a BMI greater than 30 kg/m2. The secondary endpoints are to identify length of stay and bleeding risk, and to stratify incidence of VTE by BMI and VTE prophylactic therapy received. This study has been approved by the BMHM International Review Board (IRB). Patients were excluded if they had an admitting diagnosis of VTE or required a treatment dose of anticoagulation prior to admission. The following data will be collected: patient demographics (age, sex, race, weight, height, BMI), heparin allergy, inpatient VTE prophylaxis received (drug, dose), the day of hospital stay the VTE was identified, total length of hospital stay, a drop in hemoglobin greater than 2 g/dL during hospital admission, and hormone replacement therapy. A history of heart failure, liver failure, renal failure, cancer, or VTE will also be collected.

Poster Title: Evaluation of pain management in abdominal surgery patients

Primary Author: Ariel Dye, Baptist Memorial Hospital - Memphis, TN; Email: ariel.dye@bmhcc.org

Additional Author(s):
Kelsey Krushinski
Elizabeth Mills
Kristina Schatz

Purpose: Pain management is an important component in the care of surgical patients. Despite improvements in surgical pain control, many patients still experience postoperative pain. The traditional approach to pain control has been largely opioid-based despite their broad range of undesirable side effects. Studies evaluating multimodal pain management have shown benefits including superior pain control, decreased opioid requirements, fewer adverse effects, and shorter inpatient length of stay. The purpose of this study is to evaluate the status of postsurgical pain management at this institution by assessing the current techniques used.

Methods: This retrospective chart review has been approved by the Baptist Memorial Hospital – Memphis (BMHM) Institutional Review Board. Patients greater than 18 years of age who underwent either gastric abdominal or colon surgery at BMHM between September 1, 2014 and August 31, 2016 will be eligible for inclusion. Exclusion criteria include length of stay less than 24 hours post-surgery, history of drug or alcohol abuse, chronic opioid use at the time of surgery, and/or oncology patients. The primary outcome will evaluate 24-hour post-surgery opioid use. Secondary outcomes will include 24-hour post-operative pain scores, opioid-related side effects (nausea, vomiting, constipation), and length of stay. Data on the following patient characteristics will also be collected: pre, intra, and post-operative pain medications administered (NSAIDs, acetaminophen, gabapentin, and pregabalin), serum creatinine, and creatinine clearance. All data will be recorded without patient identifiers and maintained confidentially.

**Poster Title:** USP 800 Implementation in a community hospital

**Primary Author:** Joanna Kasper, Baptist Memorial Hospital - Memphis
PGY2 Health-System Pharmacy Administration, TN; **Email:** joanna.kasper@bmhcc.org

**Additional Author(s):**
Heather Griffin
Sarah Pauk
Dennis Roberts

**Purpose:** Hazardous drugs (HDs) affect many workers in healthcare. According to the Centers for Disease Control, each year approximately 8 million U.S. Healthcare workers are potentially exposed to HDs. The United States Pharmacopeia has finalized a new chapter to the National Formulary titled USP 800 Hazardous Drugs–Handling in Healthcare Settings. This chapter expands on the current 795 & 797 nonsterile & sterile compounding chapters with importance on ensuring hazardous drug exposure at as low a level as reasonably achievable. This implementation project aims to address all elements of USP 800 for safety and quality improvement at Baptist Memorial Hospital – Memphis.

**Methods:** This implementation project will begin with the identification and mapping of hazardous drugs (HDs) within Baptist Memorial Hospital – Memphis (BMH-M) based on the 2014 National Institute of Occupational Safety and Health (NIOSH) list. Once identified, requirements for receiving, storing, mixing, preparing, compounding, dispensing, administering, transporting, and disposing will be addressed for each medication. Also included will be creation of new policies and procedures, risk assessments, employee medical surveillance, and house-wide education modules. Annual education will include pharmacy, nursing, environmental services, transport, and maintenance, as these departments all may have contact with HDs. Once implementation is complete, assessment of knowledge will be gained using education modules within internal HealthStream system. This module will include a PowerPoint self-learning section followed by questionnaire. To complete the competency an 85% score will be required. The primary objective of this project is comprehensive implementation of all elements required by USP 800 Hazardous Drug standards to ensure patient safety, worker safety, and environmental protection.
Results: N/A

Conclusion: N/A
Purpose: Atrial fibrillation (AF) is an important and common complication following cardiac surgery. The incidence of postoperative atrial fibrillation (POAF) is approximately 30% following isolated coronary artery bypass graft (CABG) surgery, 40% after isolated valvular surgery, and 60% in combined CABG and valvular surgery. Increasing evidence suggest inflammation and oxidative stress may play a key role in the development of POAF. Statins have been studied for the prevention of the incidence of POAF with conflicting results. The aim of this study is to evaluate the effect of preoperative statin therapy on the incidence of POAF in patients who undergone cardiothoracic surgery.

Methods: This study is a retrospective analysis of computerized medical records of patients at Baptist Memorial Hospital – Memphis who underwent cardiothoracic surgery. ICD 9/10 diagnostic codes were used to identify patients who have undergone cardiac surgeries. Patients were included if they were greater than 18 years old and had undergone a CABG aortic valve replacement (AVR), mitral valve replacement (MVR) or combination of CABG and AVR between August 1, 2015 and August 31, 2016. Patients with a history of AF or prior cardiothoracic surgery were excluded. The primary outcome is the incidence of POAF following cardiac surgery documented within 5 days postoperatively. The secondary outcomes are the composite of myocardial infarction, ischemic stroke, length of hospital stay, length of ICU stay, and mortality 30 days postoperatively. Data collected will include patient demographics, past medical history, preoperative and postoperative medications, type of cardiac procedure, ICU length of stay, and hospital length of stay.

Poster Title: Evaluating inpatient usage of intravenous immune globulin at a large tertiary hospital

Primary Author: Gregory Kelly, Baptist Memorial Hospital-Memphis, TN; Email: gregoryfkelley@outlook.com

Additional Author(s):
Jillian Foster

Purpose: Intravenous immune globulin (IVIG) has been studied as a treatment option for various medical conditions. IVIG therapy may be considered for use in acute and chronic conditions. It is safely administered in inpatient and outpatient settings. Because of the high cost and limited availability associated with the procurement of IVIG, unnecessary use of IVIG is discouraged. Additionally, differences in medication reimbursement between inpatient and outpatient settings encourage administration of IVIG outpatient when appropriate. This project evaluates the appropriateness of inpatient IVIG usage at a large tertiary hospital with emphasis on identifying opportunities to relocate administration from inpatient to outpatient settings.

Methods: To assess the appropriateness of inpatient usage, IVIG orders from January 1 to March 31, 2016 were reviewed. Information regarding each IVIG order was extracted from the medical record to a standardized de-identified data collection sheet. To identify trends of usage within the hospital, ordering provider, location of use, as well as IVIG dosing were recorded. In order to assess necessity of inpatient administration, reason for admission, and indication for use were noted. Lastly, to consider the ability to relocate administration to outpatient settings, length of stay and proximity of IVIG administration to discharge were recorded. Using the collected information, each order of IVIG was evaluated for appropriateness with additional consideration given to patient clinical status at the time of IVIG administration.

Results: A total of 3517 grams of IVIG were ordered between January 1 and March 31, 2016. Of the 3517 grams, 1489 grams (43%) were administered inpatient and 2028 grams (57%) were administered outpatient. Inpatient orders were associated with 38 unique patient admissions and 22 ordering providers. IVIG was used primarily on medical oncology (28%) and myelosuppression (22%) units, with frequent use seen on internal medicine (13%), medial
intensive care (9%), and neurology units (7%). The most common indications for inpatient IVIG usage were: severe thrombocytopenia (24%), myelodysplastic syndromes (21%), chronic inflammatory demyelinating neuropathy (16%), myasthenia gravis exacerbation (13%), chemotherapy induced myelosuppression (11%), and hematopoietic stem cell transplant (11%). Of the 38 unique patient admissions, IVIG orders in 6 encounters were identified as potentially inappropriate (16%). Potentially inappropriate uses accounted for 975 grams (66%) of the 1489 grams of IVIG used between January 1 and March 31, 2016.

**Conclusion:** Administration of IVIG for chronic conditions such as stable chronic inflammatory demyelinating neuropathy and stable myasthenia gravis comprised the majority of inappropriate usage. In addition to administration for stable conditions, multiple instances of prolonged length of stay were observed in patients identified as ready for hospital discharge who remained inpatient to receive IVIG. A secondary finding of wide variations in IVIG dosing was observed between patients and indications. IVIG dosing also varied within indications with dosing varying from 0.4 gram per kilogram to 0.7 gram per kilogram and treatment durations from 3 to 7 days for the same indication.

Poster Title: Fluoroquinolone use in hospital-acquired pneumonia (HAP), healthcare-associated pneumonia (HCAP) and ventilator-associated pneumonia (VAP).

Primary Author: Benjamin Afoakwa, Baptist Memorial Hospital-Memphis, TN; Email: bafoakw1@gmail.com

Additional Author(s):
Athena Hobbs

Purpose: Empiric dual antipseudomonal therapy is a guideline recommendation for treatment of HAP/VAP in critically ill patients with risk factors for Pseudomonas aeruginosa. Guidelines also recommend taking local resistance into account when selecting a second agent. In November 2015, the Antimicrobial Stewardship Program (ASP) developed a combination antibiogram of beta-lactam resistant Pseudomonas isolates that found 13 percent sensitivity to levofloxacin versus 87 percent sensitivity to tobramycin. The ASP created a guideline describing when and which agents to use for dual Pseudomonas coverage for the treatment of HAP/HCAP/VAP. This retrospective cohort study aims to illustrate the impact of this protocol at BMH-Memphis.

Methods: This is a single center, retrospective study evaluating patients admitted to the BMH-Memphis medical intensive care unit (MICU) and surgical intensive care unit (SICU) who had a diagnosis related group (DRG) code for HAP, HCAP, or VAP from the period of 8/1/2014 through 8/31/2016. To achieve a power of 80 percent, 150 participants will be included in this study with 75 each in the pre and post implementation cohorts. The primary objective of this study is to compare levofloxacin days of therapy per 1000 patient days (DOT/1000 patient days) before and after implementation of the dual Pseudomonas antibiogram guideline at BMH-Memphis in patients diagnosed with HAP, HCAP, or VAP. Secondary objectives will include a comparison of the percentage of patients who received dual Pseudomonas coverage, 90 day Clostridium difficile rates, hospital length of stay, ICU length of stay, 30 day mortality, 30 day readmission rates, 90 day incidence of multi drug resistant organisms, and adverse events pre and post implementation of the guideline.

Poster Title: Clinical outcomes of mechanically ventilated patients based on choice of sedative

Primary Author: Bhavyata Parag, Baptist Memorial Hospital-Memphis, TN, TN; Email: bhavyata.parag@bmhcc.org

Additional Author(s):
Maria Zhorne
Sarah Moore
Margaret Beaugh

Purpose: The Society of Critical Care Medicine guidelines for management of pain, agitation, and delirium in the intensive care unit (2013) recommend the use of an analgosedation approach for the management of mechanically ventilated (MV) patients. Pain management and choice of pain and sedation agents in critically ill, MV patients has been shown to impact time on MV, incidence of delirium, length of intensive care unit (ICU) stay and length of hospital stay. The purpose of this study is to evaluate current sedation management in a medical ICU (MICU).

Methods: After obtaining approval from the Institutional Review Board (IRB), patients were identified as those who were MV in the MICU for greater than 24 hours. Patients were included if they received either continuous sedation with a benzodiazepine (midazolam or lorazepam), propofol, or dexmedetomidine or no sedation for greater than or equal to 80 percent of time while MV. Patients were excluded if they had a diagnosis of a neurologic disorder (traumatic brain injury, seizures or cerebrovascular accident) or acute respiratory distress syndrome, patients who transitioned to hospice or comfort care and pregnant or breastfeeding women. Baseline characteristics included age, weight, gender and significant past medical history (COPD, asthma, chronic opioid use, chronic alcohol consumption). Data collection included ICU and hospital length of stay, time on MV and sedation and analgesic agents utilized. The remaining data collected included Confusion Assessment Method for the ICU (CAM-ICU) scores, Richmond Agitation Sedation Score (RASS) scores, and the percent of time Critical Care Pain Observation Tool (CPOT) scores were greater than or equal to 3 and treated.

Poster Title: Pilot study to investigate cardiovascular adverse effects of a class of pain relievers

Primary Author: Regan Sevinsky, Bill Gatton College of Pharmacy, East Tennessee State University, TN; Email: sevinsky@etsu.edu

Additional Author (s):
David Stewart
Sam Harirforoosh
Fereshteh Gerayli
Christopher Bridges

Purpose: Nonsteroidal anti-inflammatory drugs (NSAIDs) are frequently prescribed for patients with arthritis. Research has demonstrated NSAIDs are associated with renal effects, including reduced sodium excretion, and higher rates of cardiovascular (CV) and cerebrovascular events. The goal of this study is to determine whether the degree of cardiorenal effects associated with the use of NSAIDs correlates with drug plasma levels.

Methods: This study will be reviewed by the local institutional review board. Four groups of six patients with osteoarthritis between ages 50 to 65, on total daily doses of celecoxib 200 mg, meloxicam 15 mg, naproxen 1,000-1,100 mg or placebo for at least one month will be included. Exclusion criteria are: KDOQI stage 3b, 4 or 5 renal failure, Child Pugh class B, C, or D liver failure, heart failure, stroke, myocardial infarction, or cardiac event within three months, patients taking: as needed NSAID, angiotensin converting enzyme inhibitors, angiotensin receptor blockers, any diuretics, immunosuppressant therapy, aspirin containing analgesics, any medication that may affect renal function at the discretion of two investigators and the more than two doses of over-the-counter or prescription NSAID within the previous two weeks or one dose within the previous 48 hours. Blood and urine samples will be collected. The following will be recorded: blood pressure; weight; plasma concentration of the NSAID; serum concentrations of potassium, sodium, creatinine, blood urea nitrogen, C-reactive protein, fibrinogen, troponin-T, n-terminal pro-brain natriuretic peptide, homocysteine, fasting lipid profile; and a 24-hour urine sample to measure the concentrations of sodium, potassium, creatinine, and urea. Data comparisons will be made among the groups with a two-way ANOVA
and linear regression analyses will be performed to examine the relationship between parameters.

Poster Title: Creation, evaluation, and implementation of a chemotherapy order review guide for use at a community hospital

Primary Author: Alexandra Punke, Blount Memorial Hospital, TN; Email: apunke@uthsc.edu

Additional Author(s):
James Waddell
Amy Porter
Robert Lucas
Jenna Parrett

Purpose: The proper evaluation of chemotherapy orders is necessary to ensure the safety and appropriate treatment of patients with cancer. A board certified oncology pharmacist is employed through a clinical services contract but is not always present to evaluate chemotherapy orders. While various policies have been adopted by the pharmacy department in an attempt to meet the need of chemotherapy order evaluation guidance, the topic evades capture in a policy because it is too broad in scope and depth. The primary objective is to create a step-by-step chemotherapy order evaluation guide and provide a detailed explanation for each step.

Methods: A step-by-step, one-page chemotherapy order evaluation guide with reference tables will be created based on an accepted method of chemotherapy order review consisting of the following eight steps: regimen verification, protocol verification, BSA calculation, dose calculation, laboratory values, emesis prophylaxis, adjunctive or supportive care drugs, and pharmacy labels. The intent of this guide is to provide non-oncology trained pharmacists with a concise, systematic process to be able to independently and efficiently review chemotherapy orders. A literature search will be performed for each of these eight steps, and the information will be compiled into a literature review providing a comprehensive explanation for each step. This component will serve as a resource to advance the understanding of chemotherapy principles beyond the step-by-step order review guide as time permits. The chemotherapy order evaluation guide will be tested on pharmacists without oncology training or experience using simulated chemotherapy orders. The effectiveness of the guide will be determined by
examining the pharmacists’ ability to correctly verify chemotherapy orders and the length of
time required to do so. Provided the guide is effective, a policy will be written and presented to
the appropriate committees for approval to implement the chemotherapy guide. The guide
would then be required to be used by pharmacists during evaluation of every chemotherapy
order regardless of indication.

**Poster Title:** Cockcroft-Gault equation accuracy compared to measured creatinine clearance in special patient populations

**Primary Author:** Meghan Garrett, Blount Memorial Hospital, TN; **Email:** meghanjgarrett@gmail.com

**Additional Author(s):**
- Brad Crane
- Susan Roberts
- Stephanie Grimes

**Purpose:** Studies have conflicting results regarding which body weight should be used in Cockcroft-Gault to best correlate with measured creatinine clearance (mCrCl) in obese patients. Similar discrepancies exist for using actual serum creatinine (SCr) or a rounded value in elderly and other patients with low SCr. Due to variability seen in the literature, there is a need to develop a standardized weight and SCr for CrCl estimate in the Cockcroft-Gault equation in these populations. The goal of this research is to determine which body weight and SCr best approximates mCrCl in special patient populations and to provide the best dosing recommendations.

**Methods:** Electronic medical records at a community hospital will be retrospectively reviewed for patients who had a 24-hour urine collection with mCrCl. Information to be collected includes: age, race, sex, height, weight, mCrCl, SCr, and past medical history (diabetes mellitus, nephrectomy, renal transplant, chronic kidney disease). This information will be used to perform up to thirteen Cockcroft-Gault calculations using four possible body weights (actual body weight [ABW], ideal body weight [IBW], 30% adjusted body weight and 40% adjusted body weight), three possible SCr values (actual SCr, SCr round to 0.8 and 1), and an equation without body weight. The estimated CrCl values obtained from the above calculations will be compared to mCrCl. A ranked list will determine which variables best approximate mCrCl. Metrics include ranking the weight of obese patients (greater than or equal to 120% of IBW) in the order that most accurately correlates with the mCrCl. In patients with SCr less than or equal to 0.79 mg/dL, determine if rounding the SCr to 0.8 mg/dL or 1.0 mg/dL is more likely to
correlate with a mCrCl. In elderly patients (greater than or equal to 65 years of age), determine which weight and SCr is most likely to correlate with a mCrCl.

**Poster Title:** Evaluation of sedation analgesia in rapid sequence intubation in a community hospital

**Primary Author:** Amanda Barnett, Blount Memorial Hospital, TN; **Email:** kacee.barnett@gmail.com

**Additional Author (s):**
Rachel Lazim
Jamie Chapman
Patrick Blankenship

**Purpose:** The purpose of this study is to evaluate the use of sedation and analgesia in rapid sequence intubation (RSI) at a community hospital. After an initial review, an education plan will be created to target physicians and nurses who are involved in RSI. A follow up review will be completed to assess for improvement. We will also be looking at the incidence of adverse effects related to inadequate sedation. In addition to evaluating the medication use, this study will look at the impact of pharmacist involvement during RSI.

**Methods:** Patients will be identified using RSI charge sheets between May 2016 and July 2016 for the pre-education phase, and November 2016 and January 2017 for the post-education phase. Information will then be gathered using the electronic medical record. The primary objectives are to assess whether or not patients are receiving adequate analgesia and sedation after RSI per the PAD guidelines, to determine the incidence of adverse effects related to inadequate analgesia and sedation, and to determine the impact of ED targeted education on post-intubation compliance. Secondary objectives are to determine whether or not pharmacist involvement during RSI impacts the time until post-intubation medications and to determine if physicians are using the sedation order set. Patients who are intubated outside the hospital, patients undergoing conscious or procedural sedation, and patients who died prior to administration of post-intubation medications will be excluded from this study.

Poster Title: Breathing better: Assessing the impact of a breathing care team on 30-day readmissions

Primary Author: Daniel Rose, Bristol Regional Medical Center, TN; Email: daniel.rose@wellmont.org

Additional Author(s):
Matthew Bledsoe
Abby Ricket

Purpose: Patients with COPD or pneumonia are at high risk for readmissions within 30 days of initial hospital discharge. This study will evaluate the impact of a breathing care team (including a respiratory therapist and pharmacist) on the number of 30 day all-cause readmissions.

Methods: Patients with traditional Medicare admitted to Bristol Regional Medical Center with a primary diagnosis of COPD or pneumonia will receive disease state education from a respiratory therapist (RT), discharge counseling from a pharmacist, and follow-up phone calls post-discharge day 3, 7, 14, and 21. Readmission rates in the study group will be compared to historical data. Information collected during the study will include: patient age, gender, ethnicity, number of chronic conditions, ICU transfer during admission, health literacy using the BRIEF assessment, number of medications at admission and discharge, time to first prescription fill, length of stay, and time spent per patient. Patients ineligible for the study include those discharged to a location other than home, hospice and palliative care patients, patients who are pregnant, non-English speaking patients, and patients with cognitive impairment.

Poster Title: Evaluation of penicillin allergy documentation and the effect of a penicillin allergy guideline on antibiotic selection

Primary Author: Hunter Perrin, Bristol Regional Medical Center, TN; Email: hunter.perrin@wellmont.org

Additional Author (s):
Candice Simpson
Rebecca Holt

Purpose: Patients with a documented penicillin allergy often receive alternative antimicrobials that are not considered first line agents. The literature suggests that significant allergic reactions to penicillin, as well as, the rates of cross reactivity among beta-lactam agents, are lower than expected. Negative patient and economic outcomes occur with the avoidance of penicillins in this patient population. The objective of this study is to determine whether complete penicillin allergy documentation and utilization of a penicillin allergy guideline will result in improved antibiotic selection and economic outcomes.

Methods: The antimicrobial stewardship team for this study will consist of the pharmacy resident, the infectious disease pharmacist, and an inpatient clinical pharmacist. The retrospective portion of the study will utilize the electronic medical record to identify patients with a documented penicillin allergy and an ordered antibiotic from November 2015 through January 2016. In these pre-intervention patients the following will be measured: the extent of penicillin allergy documentation, the antimicrobial agent(s) selected, and the average dollar cost per day of antibiotics. The prospective portion of the study will take place from November 2016 through January 2017 with the implementation of a penicillin allergy assessment questionnaire and a penicillin allergy guideline. The antimicrobial stewardship team will run a report using the electronic medical record Monday through Friday to identify patients with a documented penicillin allergy that have been ordered antibiotics. These patients will then be interviewed through the use of a standardized penicillin allergy assessment questionnaire. Patients’ allergy profiles will be updated based on this comprehensive assessment. Antibiotic selection for each patient will then be assessed through the use of a penicillin allergy guideline. If a patient is on an alternative antibiotic and a beta-lactam agent appears safe for use, the
prescriber will be contacted to discuss antibiotics and allergy assessment. Antimicrobial expenditures in these patients will be evaluated in these patients during their hospital stay.

Poster Title: Pharmacist-led intervention to prevent hospital admissions for stable venous thromboembolism from the emergency department

Primary Author: Justin Reinert, CHI Memorial, TN; Email: justin_reinert@memorial.org

Additional Author(s):
Rachel Kile

Purpose: The 2016 American College of Chest Physician (CHEST) guidelines for the management of venous thromboembolism (VTE) now recommend the utilization of a direct oral anticoagulant (DOAC) over traditional low molecular weight heparin (LMWH)/warfarin therapy for the management of select, stable patients with a VTE. The primary objective of this study is to promote guideline-directed outpatient treatment of emergency department (ED) patients with newly diagnosed clinically stable VTE. Cost-savings generated by preventing hospital admissions for a primary diagnosis of VTE will be calculated.

Methods: This study has been submitted to and approved by the Investigational Review Board. Patients with a primary diagnosis of VTE and who are considered stable, as defined by CHEST, will be included in this prospective cohort analysis: clinically stable with good cardiopulmonary reserve; no contraindications including recent bleeding, severe renal or hepatic disease or severe thrombocytopenia defined as a platelet count < 70,000/mm3; expected to be compliant with treatment; and the patient feels well enough to be treated at home. Patients < 18 years of age, those on anticoagulation before developing a VTE, and those with malignancy will be excluded. De-centralized pharmacists in the emergency department will screen patients on an individual basis and communicate with prescribers about the most appropriate DOAC. Accepted interventions will be documented based on two criteria: admission vs. discharge from the ED, and treatment with a DOAC vs. standard LMWH/warfarin therapy. Cost savings and expenditures will be calculated and reported based on medication selection and treatment disposition chosen by the prescriber.

Poster Title: Economic and clinical impact of a clinical pharmacist in a community hospital-affiliated patient-centered medical home

Primary Author: Meredith Tate, CHI Memorial, TN; Email: meredith_tate@memorial.org

Additional Author (s):
Sydney Hopper

Purpose: Some accountable care organizations (ACO) have included pharmacists as part of their coordinated care model in efforts to improve quality of care and reduce costs. The purpose of this study is to exhibit the economic and clinical value of pharmacist involvement by validating cost-savings and tracking clinical interventions. This study will also describe the methods used to establish successful integration of a clinical pharmacist into a collaborative relationship between a community hospital and patient-centered medical home (PCMH).

Methods: This is an observational prospective study. The pharmacist will collaborate with 3 providers within a community hospital-affiliated clinic. Services provided will be aligned with the goals of the ACO and will focus on high-risk patients, increasing generic utilization, and closing the transitions of care (TOC) gap. Additional services are to be provided through spontaneous consults. Specialized software will be used to identify high risk patients and opportunities for increasing generic utilization. The inclusion criteria consists of all patients under the care of the PCMH admitted to our hospital during the study period and those identified as high risk or eligible for conversion from a brand to less expensive generic drug. Patients not seen by a discharge pharmacist or who miss the TOC visit will be excluded. All patients included in the study will meet with the pharmacist prior to their TOC visit. The pharmacist will perform a medication reconciliation during this visit then address any issues with the provider. The TOC model includes medication reconciliation on admit and discharge by pharmacy technician and pharmacist, respectively, with follow-up in the PCMH. The primary endpoints assessed are quantity and associated cost-savings of generic utilization, number of spontaneous consults, total interventions, and actual patient cost per year. All data will be collected using secure software. Statistical analyses will be performed using descriptive statistics.

Poster Title: Evaluation of prescribing practices and glycemic management in a 365-bed community hospital

Primary Author: Ricky Church, CHI Memorial, TN; Email: ricky_church@memorial.org

Additional Author(s):
Darrin Majors
Patrick Ellis

Purpose: The purpose of this study is to objectively identify current prescribing practices and quantify the level of effectiveness of glycemic management at our institution. Following analysis, the goal is to implement a quality improvement strategy that will better optimize the glycemic management of our patients.

Methods: This is a single-center, retrospective, observational analysis of patients admitted to the hospital with an applicable ICD-10 code for type 1 or type 2 diabetes mellitus. Point-of-care testing devices will be utilized to gather capillary blood glucose measurements so that mean blood glucose levels may be assessed. The incidence of hyperglycemia and hypoglycemia will also be analyzed. Results from this analysis will be used to develop and implement targeted quality improvement strategies. Similar data collection and analysis is planned following strategy implementations so that the effectiveness of the quality improvement strategies may be evaluated. This study has been submitted and approved by the Institutional Review Board.

**Poster Title:** Impact of multiplex polymerase chain reaction technology with antimicrobial stewardship interventions in the management of patients with positive blood cultures  

**Primary Author:** Jenny Gibson, CHI Memorial, TN; Email: jenny_gibson@memorial.org  

**Additional Author(s):**  
Linda Johnson  
Camellia Davis  

**Purpose:** The delay that exists between patient presentation and traditional culture identification in patients with bloodstream infections may result in prolonged ineffective or broad-spectrum antimicrobial therapy. The objective of this study is to assess the impact of a rapid multiplex polymerase chain reaction (mPCR) blood culture identification (BCID) technology in conjunction with antimicrobial stewardship interventions in patients with positive blood cultures.  

**Methods:** This study will be submitted to the Institutional Review Board for approval. The mPCR BCID panel will be implemented in October 2016. All positive blood cultures will be run on the panel and results will be transmitted via pager to an on-call pharmacist. This pharmacist will review the patient’s profile and, if appropriate, contact the primary physician to make an antimicrobial recommendation based on an established protocol. Management of bacteremic and fungemic patients will be retrospectively compared pre- and post- intervention. Patients diagnosed with bacteremia or fungemia at an outside facility, neutropenic patients, patients who are discharged or expired less than 24 hours after admission, those with a polymicrobial source and patients with a suspected concomitant infection unrelated to the positive blood cultures will be excluded. The following data will be collected: baseline demographics, admitting infectious diagnosis, antimicrobials (empiric and final), stewardship intervention and relevant labs, mPCR and culture results. Primary endpoints include time to effective and de-escalated antimicrobial therapy pre- and post- mPCR BCID implementation. Secondary endpoints include length of stay (hospital and ICU), 30-day re-admission, all-cause mortality, Clostridium difficile PCR positive within 30 days of admission, and antimicrobial costs.

Poster Title: Evaluation of a medication history pharmacy technician

Primary Author: Laura Kroon, Community Health Systems Professional Services Corporation, TN; Email: laura_kroon@chs.net

Additional Author(s): Laura Crow
Trent Beach

Purpose: The purpose of this evaluation is to assess the effectiveness of a medication history pharmacy technician in the emergency department (ED) to help improve the medication reconciliation process at hospital admission. In addition to the potential avoided medication errors and associated complications arising from them, it is anticipated this will decrease readmissions, improve transitions of care, provide cost savings of over $75,000 in nursing labor costs and allow for reallocation of nursing time to “top of license” activities.

Methods: A medication history technician role was justified and proposed to work in the emergency department (ED) within this community hospital. Assessment of similar published research, internal ED visit volumes and flows including those that convert to inpatient admissions, as well as current work processes have been analyzed in preparing the proposed approach and its evaluation. A business proposal was developed for 1.75 full-time equivalent pharmacy technicians to provide service in ten-hour shifts on an alternating 7-on, 7-off schedule. The role will have the technician work with patients and families to compile and then document thorough medication histories in the electronic health record at admission. The medication history pharmacy technician will work to prevent reconciliation issues by collecting accurate patient home medication lists, compiling patient allergies/intolerances, effectively communicating with other healthcare professionals, completing unit inspections for all ED and diagnostic imaging areas and assisting with the care and maintenance of pharmacy-related ED department equipment, hardware, and supplies.

Poster Title: Bleeding risk stratification for anticoagulation selection in patients receiving percutaneous coronary intervention

Primary Author: Robley Bartholomew, Community Health Systems Professional Services Corporation, TN; Email: robley_bartholomewii@chs.net

Additional Author(s):
Richard Dion
Mike Farrell
Trent Beach

Purpose: The primary objective of this quality improvement project was to evaluate clinician adherence with the National Cardiovascular Data Registry (NCDR) Bleeding Risk Calculator by comparing the anticoagulant agent selected prior to percutaneous coronary intervention (PCI) with the recommended anticoagulant based on the calculated bleeding risk category. The HEAT-PPCI and MATRIX studies comparing unfractionated heparin and bivalirudin demonstrated no difference in all-cause mortality, cerebrovascular accident, re-infarction, or additional unplanned target lesion revascularization in low bleeding risk patients. Additionally, the 2013 AHA/ACC STEMI guidelines state that bivalirudin is preferred over unfractionated heparin with glycoprotein IIb/IIIa receptor antagonists in high bleeding risk patients.

Methods: This quality improvement project included one hospital facility utilizing the NCDR Bleeding Risk Calculator over a six week period from August 1, 2016 to September 14, 2016 and included all patients undergoing PCI in the cardiac catheterization lab for treatment of acute coronary syndromes or elective PCI procedures. Baseline bleeding risk, based on prescriber judgment, and anticoagulant selection data was collected one month prior to implementation of the bleeding risk calculator. The NCDR Bleeding Risk Calculator was provided to the facility in an electronic format and results were calculated and documented independently by the facility. The cardiac catheterization laboratory director facilitated data collection and was responsible for data management and reporting. A standardized bleeding risk documentation form was utilized at the facility to ensure consistent reporting with regards to the calculator classifications. Data collected included ST-elevated myocardial infarction vs. non-ST elevated myocardial infarction status, age, body mass index, prior PCI, chronic kidney disease, shock...
status, cardiac arrest within the last 24 hours, gender, hemoglobin levels, PCI status (elective, urgent, or emergency).

**Results:** Baseline bleeding risk and anticoagulant selection data for 30 patients was collected one month prior to implementation of the bleeding risk calculator. All 30 patients in the baseline group were assessed by the clinician prior to performing the PCI and were stratified into bleeding risk categories using prescriber judgment. In the baseline group, 5 patients were classified as low bleeding risk, 18 patients were classified as medium bleeding risk, and 7 patients were classified as high bleeding risk. All patients (n=30) included in the baseline data set received bivalirudin prior to PCI. A total of 49 patients in the post-calculator implementation group were stratified into low (n=7), medium (n=31) or high (n=11) bleeding risk categories prior to PCI based on the NCDR Bleeding Risk Calculator. Utilization of the NCDR bleeding risk calculator resulted in the recommended anticoagulant being selected in 91.8% (n=45) of the post-implementation cases. Further stratifying by bleeding risk category in the post-implementation group, the recommended anticoagulant was selected in 85.7% of the low risk patients, 96.7% of the medium risk patients, and 81.8% of the high risk patients.

**Conclusion:** The results of this quality improvement project demonstrated that the utilization of the NCDR Bleeding Risk Calculator provided an objective method for stratifying patients into the appropriate bleeding risk category. Additionally, the results of this quality improvement project demonstrated that utilization of the NCDR Bleeding Risk Calculator provided clinicians with an effective method for anticoagulant selection in patients undergoing PCI. Finally, there may be significant cost-saving opportunities associated with the utilization of the NCDR Bleeding Risk Calculator. By stratifying patients into the various bleeding risk categories, clinicians have the ability to reserve bivalirudin for patients considered to be a high bleeding risk.

Poster Title: Implementation of ambulatory care pharmacy services to reduce hospital readmission rates in a community hospital

Primary Author: Denise Bentley, Cookeville Regional Medical Center, TN; Email: dabentley@crmchealth.org

Additional Author(s):
Jason Hutchens

Purpose: Hospital readmission has been associated with poor quality of medical care. Recent additions to the Affordable Care Act now require Medicare payment reductions to hospitals with higher than predicted readmission rates. In response, several institutions have created transitional care programs in order to minimize penalties and improve patient outcomes. Our purpose is to create a pharmacist driven post discharge clinic at Cookeville Regional Medical Center (CRMC) targeting patients at high risk of readmission. Clinical pharmacist positions will also be established at a CRMC affiliated cardiology clinic to assess the impact of intensive patient medication counseling and pharmacist led pharmacotherapeutic intervention.

Methods: Patients will be targeted for the transitional care clinic by physician and pharmacist referral, as well as through the use of an automated risk index scoring tool. Clinic visits will occur three to five days post hospital discharge. Key objectives of the appointment are to ensure clear patient understanding and purpose of all medications, assess patient adherence to the prescribed regimen, and evaluate the need for any pharmacotherapeutic changes in order to achieve goals of therapy. The pharmacist will develop collaborative practice agreements granting the authority to initiate and deescalate agents, perform medication interchanges, and modify other aspects of medication management. In addition to establishing a transitional care program, pharmacists will be positioned in outpatient cardiology and pulmonology clinics. Pharmacist responsibilities are to complete any medication related tasks as requested by the physicians and nursing staff including but not limited to: providing extensive patient medication counseling, leading cardiac and pulmonary rehabilitation educational courses, answering drug information questions, and delivering new drug updates. Pharmacists will also perform thorough medication reviews and recommend pharmacologic modifications as clinically warranted. All encounters and interventions will be documented for review. Data on
myocardial infarction, heart failure, and chronic obstructive pulmonary disease hospitalizations and readmissions will be collected to measure impact of the new services.

Mark Pierce  
Stephanie Etter  

**Purpose:** Clostridium difficile (CDI) has been identity by the CDC as an urgent threat to public health, contributing to increased hospital stays, medical costs, and adverse patient outcomes. CRMC has one of the highest rates of CDI in Tennessee. The objective of this project is to reduce CDI via targeted, evidence-based interventions and treatments. This initiative intends to maximize positive patient outcomes and decrease medical costs by curbing unnecessary use of antimicrobials and laboratory tests.  

**Methods:** Based on the identified need for increased CDI control, an interprofessional team has been formed, consisting of an infectious disease physician, gastroenterologists, pharmacists, microbiology staff, quality control, and nursing staff members, in order to oversee implementation of new order sets. CDI order sets will be revised to include fecal microbiota transplant and criteria for use for restricted antimicrobials like fidaxomicin and nitazoxanide. The ultimate goal is to create a unified order set to be utilized by all providers in order to foster optimal and consistent outcomes. Pharmacists will review all patients receiving antimicrobial therapy and CDI treatment, follow up on cultures and susceptibilities, and assess appropriate dosing. With input from gastroenterologist, algorithms and protocols will be written regarding stress ulcer prophylaxis with appropriate use and duration of proton pump inhibitor and histamine-2 receptor antagonist therapy. Focus will be put on education of medical staff via lectures and print material on pathogenesis, epidemiology, prevention, diagnosis, and treatment. A clinical decision support system will be implemented in order to collect data and identify at-risk patient populations.

Poster Title: Implementation of a pharmacist-provided intensive education program for high-risk readmission patients in a regional medical center

Primary Author: Rhiannon Facchinei, Cookeville Regional Medical Center, TN; Email: rhiannon.facchinei@gmail.com

Additional Author(s):
Erin Tackett
Seth Tucker
Jason Hutchens

Purpose: The objective of this study is to implement and evaluate a pharmacist-driven patient education program based on identification of patient risk factors that could increase the likelihood of readmission due to disease-related complications. High-risk patient groups, including newly diagnosed, will be targeted for intensive education beyond established discharge counseling services. Disease states affected will include diabetes, anticoagulation, chronic obstructive pulmonary disease (COPD) and heart failure.

Methods: Patients with complex disease states and/or medication regimens are in need of extensive education in order to effectively achieve optimal outcomes. Clinical decision support systems will be utilized through mechanisms including, but not limited to: diagnoses of diabetic ketoacidosis (DKA), heart failure, chronic obstructive pulmonary disease (COPD), hemoglobin A1C values, pro B-type natriuretic peptide, medication combinations such as beta-blockers and diuretics, anticoagulant orders, and inhaled bronchodilator orders. Focused patient educational material will be created to educate on disease states and medication regimens. Initial pharmacist education will be documented at the conclusion of the hospitalization. After education sessions, follow-up visits will be scheduled with the transitional care ambulatory pharmacy clinic to complete the continuum of care. Outcomes to be measured include time spent with patients, HCAHPS scores, 30-day readmission rates, and compliance with follow-up evaluations.

Poster Title: Implementation of a medication stewardship program through collaborative practice with the hospitalist service in a community hospital.

Primary Author: Kinsi Tellep, Cookeville Regional Medical Center, TN; Email: kmtellep@crmchealth.org

Additional Author (s):
Erica Rawdon
Jonathan Mitchell
Jason Hutchens

Purpose: The team-based healthcare approach has provided opportunities for pharmacists to collaborate with providers to optimize patient care. The aim of this project is to develop a medication stewardship program through a collaborative practice agreement with hospitalists at a community hospital. The hospitalist services wishes to use the expertise of the pharmacists to streamline patient medication regimens and enhance patient outcomes.

Methods: The medication stewardship program will be structured by a modifiable collaborative practice agreement that grants pharmacists the ability to autonomously change patients’ medication regimens when appropriate. Initial target areas include, but are not limited to: antimicrobial stewardship, IV to PO conversions, anticoagulant dosing from prophylaxis to treatment, assessment of stress ulcer prophylaxis, therapeutic duplications, and dose optimization dependent upon disease state. The data from all interventions will be collected over a 3 month period at minimum with the goal of a 6 month evaluation period. This data will then be evaluated by the interprofessional team with the goal of credentialing and privileging of pharmacists as autonomous direct patient care providers within the facility.

Poster Title: Evidence-based heart failure management process implementation at a residency-teaching clinic

Primary Author: Elicia White, East Tennessee State University Bill Gatton College of Pharmacy, TN; Email: whiteen@etsu.edu

Additional Author(s):
Brandon Mizell
Jodi Polaha
Leigh Johnson
David Stewart

Purpose: The American College of Cardiology/American Heart Association/Heart Failure Society of America guidelines for management of heart failure were recently updated to included use of sacubitril/valsartan due to its proven ability to reduce mortality and hospitalizations over the current standard of therapy. With this guidance, a process was implemented to assist in appropriately screening patients for evidence-based pharmacotherapy. The objective of this study is to evaluate process implementation in a residency-teaching clinic. Implementation outcomes, such as pre- and post-provider knowledge of evidence-based pharmacotherapy, adoption of the new process, and its reach to patients with systolic heart failure will be assessed.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients who have heart failure. The following data will be collected: patient age, gender, ethnicity, ejection fraction, vital signs, serum creatinine, potassium, current medications, and reported adverse events. Providers will be educated on evidence-based medication management of systolic heart failure and will complete a pre- and post-education quiz. Providers will utilize a treatment algorithm to implement medication changes during patient appointments. This algorithm will include monitoring and follow-up recommendations. All data will be recorded without patient identifiers and maintained confidentially. Data from patients will be reviewed by the research team to rate compliance with evidence-based treatment guidelines. Additionally, providers will complete a post-process survey to rate the success of the implemented process.

**Poster Title:** Evaluation of current heparin-induced thrombocytopenia management in an academic teaching hospital and opportunities for improved utilization of argatroban

**Primary Author:** Bailey Bolten, Erlanger Health Systems, TN; **Email:** bcbolten@yahoo.com

**Additional Author(s):**
Brittany White
Lacie Bradford

**Purpose:** Heparin-induced thrombocytopenia (HIT) is often over-diagnosed. Inappropriate diagnosis and management of HIT can lead to unnecessary treatments, increased healthcare costs, and increased length of stay. Furthermore, the failure to properly document suspected HIT can increase anticoagulation expenses during future hospital admissions. Literature has shown that a protocol designed and directed by pharmacists can improve the management of HIT. The purpose of this study is to evaluate the use of argatroban at a large, academic teaching hospital and to utilize the data as a means of developing an improved, evidence-based protocol for the management of HIT.

**Methods:** In this retrospective study, drug codes were used to identify all patients who received argatroban at our institution from May 2015 through May 2016. Data will be collected on each patient who received argatroban to pinpoint admissions in which HIT was a suspected or confirmed diagnosis. Medical records will be reviewed to assess the management of actual or suspected HIT as defined by the American College of Chest Physicians guidelines. Discrepancies between current practice at the study hospital and evidence-based best practices will be used to develop a new protocol for the order and management of argatroban and HIT.

Poster Title: Use of a pharmacy based clostridium difficile risk tool in a community hospital

Primary Author: Sarah Wilson, Fort Sanders Regional Medical Center, TN; Email: swilso28@covhlth.com

Additional Author(s):
William Strozyk
Joel Morrison
Christopher Norris

Purpose: The recently implemented Affordable Care Act incentivizes hospitals to establish a Hospital-Acquired Condition (HAC) Reduction Program to decrease and prevent HACs, which includes clostridium difficile infection (CDI). Hospital acquired CDI increases hospital costs, puts those infected at risk for extending hospitalizations and readmissions, and has a resultant mortality of approximately 10%. Multiple studies have identified risk factors for CDI, however, data is lacking determining which risk factors will be present in each CDI case as well as a successful strategy to consistently prevent CDI. This study evaluates a recently implemented pharmacist initiative to help prevent CDI in a community hospital.

Methods: This study will be submitted to the Institutional Review Board for approval. High risk patients will be prospectively identified as defined by IDSA identified risk factors which include antimicrobial use, advanced age, gastrointestinal manipulation, chemotherapy, and immunosuppression on hospital units with patients at high risk for developing CDI (oncology, pulmonary, surgical) with the following information collected: antibiotics received prior to admission and during hospitalization, age, recent hospitalizations/long-term care stay, previous CDI, receipt of chemotherapy, use of proton pump inhibitors, Gl tract surgery, tube feeding, albumin < 2.5 g/dL, serum creatinine > 2 mg/dL, and immunosuppression. Pharmacists will evaluate and provide recommendations to reduce modifiable risk factors which may include antibiotic streamlining and/or discontinuation of acid suppression therapy. Number and type of recommendations, the acceptance rate of recommendations, the incidence of CDI, and risk factors associated with each CDI case will be collected.

**Poster Title:** Pharmacist driven order entry standards to improve compliance for “as needed” (PRN) pain medication orders

**Primary Author:** Casey Murray, Fort Sanders Regional Medical Center, TN; Email: cmurray1@covhlth.com

**Additional Author(s):**
Beth Field
Chris Norris
Pam Turner

**Purpose:** Computerized physician order entry (CPOE) has led to quicker order processing by pharmacy but may lead to overlooked details which may include duplication of therapy, orders without an indication, or for multiple indications. Implementation of an inpatient CPOE PRN order outline has allowed prescribers to quickly order medications based on severity rating (first line, second line, breakthrough agent). Despite order outlines, pharmacists must continue to ensure correct messaging from the pharmacy system into the nursing system for all PRN orders. The objective of this study is to identify opportunities to improve the order entry process to minimize PRN medication ambiguity.

**Methods:** This study is under review for IRB approval. A retrospective chart audit of PRN pain medication orders will be conducted to document indication, ordered medication, pharmacist interventions, and areas for improvement. Cardiovascular surgery, epidural or patient controlled analgesia use post-operatively, pregnant women, and children will be excluded. Based on the audit findings, the PRN medication policy will be reviewed for compliance and potential changes. Pharmacy staff will be educated on any changes to the order entry process. Following education, a follow-up audit will be performed. The data collected will be reviewed and compared with the preliminary audit to evaluate improvement.

**Poster Title:** Evaluation of an opioid taper protocol for patients at high risk of opioid related adverse events in a hospital setting.

**Primary Author:** Jeremiah Metzdorf, Fort Sanders Regional Medical Center, TN; **Email:** jeremiahmetzdorf@yahoo.com

**Additional Author (s):**
Traci Gilliland  
Chris Norris

**Purpose:** The 2016 Centers for Disease Control Guidelines for prescribing opioids for chronic pain recommend tapering or discontinuation of opioids when risks outweigh benefits of continued therapy for patients receiving treatment outside active cancer, palliative care, and end-of-life care. The objective of this study is to evaluate an opioid taper protocol at Fort Sanders Regional Medical Center in patients with chronic opioid use greater than or equal to 90 morphine milligram equivalents (MME) daily for indications other than active cancer, palliative care, end of-life-care, post-surgical pain, and at an elevated risk of opioid related adverse events.

**Methods:** This study will be submitted to the Institutional Review Board for approval. Patients will be identified by practitioners in which the risk of adverse effects with continued opioid use is greater than the benefits of opioid therapy. The protocol will require patients to have their opioid medications tapered while pain management will be augmented with non-opioid therapies. Prescription records will be validated using the Tennessee Controlled Substance Monitoring Database and patient electronic medical record system to determine baseline opioid usage. Patients will be converted to morphine sulfate sustained-release dosed twice daily with dose reductions occurring over 12 days. The taper schedule will reduce doses every 2 days until completion with an initial decrease of 25 percent from baseline, then additional 25 percent, 20 percent, 10 percent, and finally 10 percent to equal zero MME daily. The maximum initial dose will be 120mg by mouth twice daily to ensure safety. Patients will be followed throughout the taper process. The following data will be collected: patient age, gender, ethnicity, diagnoses, pain scale ratings, opioid usage, and Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey scores. The primary outcomes that will be
assessed are opioid usage prior to protocol initiation and at discharge, pain scale ratings, adverse events reported, adherence to the opioid taper protocol, and change in HCAHPS scores.

Poster Title: Evaluation of weight based dosing of gentamicin in pregnant patients with urinary source infections

Primary Author: Danielle Walker, Fort Sanders Regional Medical Center, TN; Email: dwalke11@covhlth.com

Additional Author (s):
Joel Morrison
Dana Walters

Purpose: Gentamicin is commonly used within the hospital setting for the treatment of urinary source infections in the pregnant population. In an effort to optimize dosing, this study seeks to retrospectively evaluate the gentamicin peak and trough levels from pregnant patients treated with gentamicin. This community hospital currently uses traditional weight-based dosing of 1-2 mg/kg of actual body weight (or ideal body weight if they are >120% of their ideal weight) and follows drug levels to assess efficacy and safety. This study will use this information to evaluate pharmacokinetic parameters, volume of distribution, and other specific dosing considerations for this population.

Methods: This study will include a retrospective chart review of pregnant patients over the last five years (2011-2016) to determine the dosing regimen and if those patients achieved goal peak levels in order to treat their urinary source infection. The review will exclude peri-operative or single dose orders and any regimen where a peak or trough level was not obtained. This information will then be extrapolated to determine trends, effects of weight, and variation of volume of distribution in this specific patient population for the dosing of gentamicin for the treatment of a urinary source infection.

Results: N/A

Conclusion: N/A
Purpose: The concern for methicillin-resistant Staphylococcus aureus results in high empiric usage of intravenous (IV) vancomycin therapy in the hospital setting. However, vancomycin treatment for methicillin-sensitive S. aureus bacteremia has been associated with poor clinical outcomes and increased morbidity and mortality compared to therapy with an anti-staphylococcal penicillin or a first-generation cephalosporin. One of the key principles in antimicrobial stewardship is culture-driven de-escalation of antibiotic therapy, which leads to reduced drug toxicities and a reduced risk of antimicrobial resistance. The objective of this study is to assess the timeliness of vancomycin de-escalation across a multi-hospital healthcare system.

Methods: This study will be a multi-center, retrospective, observational study, which will be submitted to the Institutional Review Board for approval. The real-time antimicrobial pharmacy alerts will be used to identify patients who received IV vancomycin during their hospitalization between September 1, 2015, and August 31, 2016. Patients who meet the following criteria will be excluded from the study: No cultures drawn prior to the initiation of antimicrobial therapy, absolute neutrophil count of less than 1,000, primary diagnosis of skin and soft tissue infection, or death before the culture(s) resulted. The following data will be collected: Patient age, gender, allergies, comorbidities, time of first pharmacy de-escalation alert, culture source, end-organism(s) identified, antimicrobial susceptibilities, duration of vancomycin and total antimicrobial therapy, length of hospital stay, in-hospital, all-cause mortality, and readmission rates at 30 and 90 days post discharge. The primary outcome of this study is the time from the
first real-time pharmacy alert to the time of IV vancomycin therapy de-escalation. Secondary outcomes include the percentage and rationale of alerts not intervened upon by the care team, in-hospital, all-cause mortality rate, 30- and 90-day post-discharge readmission rates, and the time to the acknowledgement of the real-time pharmacy de-escalation alerts.

**Poster Title:** Evaluation of medications for malignant melanoma in Medicare beneficiaries: A utilization review and cost analysis

**Primary Author:** Lauren Belemjian, HCA Management Services/University of Tennessee College of Pharmacy, TN; **Email:** lauren.belemjian@hcahealthcare.com

**Additional Author (s):**
Carol White
Sarah Fraker
Tracy McDowd

**Purpose:** Malignant melanoma, one of the most immunogenic types of solid tumors, is the most dangerous form of skin cancer with high risk of metastasis and genetic implications. In the United States, approximately 76,380 individuals will be diagnosed with melanoma in 2016, with 10,130 expected deaths. However, melanoma can be treated with immunotherapy or targeted therapy. The economic burden of these treatments is approximately $44.9 million in annual costs among Medicare patients. The purpose of this retrospective study is to evaluate resource utilization of Medicare Part B and Part D beneficiaries receiving oral and injectable medications for malignant melanoma.

**Methods:** Medicare beneficiaries who underwent pharmacological treatment for malignant melanoma between calendar years 2013 and 2014 will be included in this study. Medicare Provider Utilization Payment Data will be utilized including Part D Prescriber Public Use Files (PUF), Medicare Physician and Other Supplier Data, and Medicare Outpatient Prospective Payment System (OPPS) Means Files. Medications will be identified by drug name and Healthcare Common Procedure Coding System (HCPCS) code sets. Trends in Medicare spend for associated lab tests for BRAF mutations during the study period will be determined as well as baseline comparisons of guideline changes with advances in therapy. This study will be submitted for approval by the University of Tennessee Health Science Center (UTHSC) Institutional Review Board (IRB).

Poster Title: Evaluating the impact clinical variables have on reported positive Clostridium difficile infection rates

Primary Author: Troy Watson, HCA Management Services/University of Tennessee College of Pharmacy, TN; Email: troy.watson@hcahealthcare.com

Additional Author(s):
Karla Miller
Russell Poland
Jason Hickok
Ed Septimus

Purpose: The incidence of clostridium difficile infection (CDI) has become one of the most significant threats to hospitalized patients and represents an increasingly important issue in terms of morbidity and mortality. In addition, it is associated with extended hospital stay and increased resource utilization. According to a Healthcare Cost and Utilization Project report released in 2014, the incidence and projections of CDI are increasing. Healthcare facility-onset is defined as a positive specimen collected after the third day of admission to the facility. The purpose of this large, multicenter retrospective study is to evaluate the factors that influence CDI rates.

Methods: Adult patients with a positive lab value for CDI between October 1, 2015 and September 31, 2016 will be included in this study. Along with basic patient demographics, the following data related to CDI will be collected: risk factors for CDI (e.g., antibiotic exposure, gastrointestinal surgery, admission from a long term care facility), concomitant medications, the time the CDI test and/or repeat tests were collected, length of hospital stay, admission date and date of previous hospital admission. Data analyzed in this study will be collected from a centralized enterprise data warehouse. The electronic medical record system will be used to retrospectively review data from inpatient hospital facilities within a large health-system across the United States. All data will be recorded without patient identifiers and maintained confidentially. This study will be submitted for approval by the Institutional Review Board. Following data collection, the primary outcome to be evaluated will be rates of CDI per antibiotic class.

**Poster Title:** Retrospective analysis of glucose management following the resolution of diabetic ketoacidosis (DKA) within a community hospital

**Primary Author:** Victoria Gehrke, HCA Management Services/University of Tennessee College of Pharmacy, TN; **Email:** victoria.paine@hcahealthcare.com

**Additional Author(s):**
Alicia Perry
Carol White
Wendy Gay
Dana Woodall

**Purpose:** Diabetic ketoacidosis (DKA) is an acute complication of uncontrolled diabetes mellitus and has been associated with extended hospital stay, long-term mortality, and increased resource utilization. Treatment guidelines provide a stepwise approach to the management of DKA, which includes fluid, electrolyte, and intravenous insulin administration. Current recommendations promote the efficient transition of stabilized patients from intravenous insulin to subcutaneous insulin. The purpose of this retrospective study is to analyze the appropriateness of insulin transition following DKA at a community hospital.

**Methods:** Adult patients with a diagnosis of DKA admitted to the hospital between August 1, 2015 and July 31, 2016 will be included in this study. The following data will be collected: patient demographics, pertinent lab data, insulin regimen utilization, timing of insulin administration, length of stay, and other patient-specific parameters. Patient electronic medical records, including physician orders, progress notes, and the medication administration record, will be used to retrospectively review data. This study will be submitted for approval by the University of Tennessee Health Science Center (UTHSC) Institutional Review Board.

**Additional Author(s):**
Alicia Perry
Carol White
Wendy Gay
Dana Woodall

**Purpose:** Inpatient hyperglycemia is associated with poor outcomes and mortality. Available guidance defines inpatient hyperglycemia as persistently elevated blood glucose >140 mg/dL. Recommendations also include a threshold of 180 mg/dL for initiating insulin treatment, with a target range of 140-180 mg/dL, unless a range of 110-140 mg/dL can be achieved while minimizing hypoglycemia. The purpose of this retrospective study is to analyze RTCST activations and current glucose management protocols at a community hospital to define opportunities for practice change. The results of the analysis will be used to develop a hyperglycemia protocol and a pilot implementation strategy for a healthcare enterprise.

**Methods:** Adult patients with RTCST activations indicating initiation of insulin who were admitted to the hospital between March 1, 2016 and August 31, 2016 will be included in this evaluation. Patients receiving insulin therapy via intravenous infusion will be excluded; these patients will be evaluated in a related study. Basic patient demographics, patient lab data, insulin regimen utilized, timing of events, length of stay, admission date and time, as well as other patient specific parameters will be collected. Data will be collected from a centralized enterprise data warehouse and patient electronic medical records. All data will be de-identified to maintain confidentiality. This study will be submitted to the Institutional Review Board.

Poster Title: Evaluating bleeding risk using a point-of-care platelet function assay in cardiac surgery patients exposed to P2Y12 inhibitors

Primary Author: Jennifer Wood, HCA Tristar Centennial Medical Center/ University of Tennessee College of Pharmacy, TN; Email: jennifer.h.wood15@gmail.com

Additional Author(s):
Jonathan Bain

Purpose: The use of P2Y12 inhibitors in the perioperative period can increase the risk of bleeding. It is recommended to discontinue the use of these agents at least 5 days prior to surgery by the American College of Cardiology Foundation and American Heart Association. However, studies suggest that recovery of platelet function may occur earlier than the recommended 5 days. The Society of Thoracic Surgeons suggest that testing for platelet responsiveness can determine if patients qualify for earlier surgical intervention which can mean earlier cardiac revascularization and an decrease in hospital length of stay.

Methods: A retrospective cohort study will be performed reviewing electronic medical records. The primary objective of this study is to determine if there is a correlation of platelet reactivity using the VerifyNow® point-of-care platelet assay and bleeding post cardiac surgery. Secondary outcomes include time from discontinuation of P2Y12 inhibitor to surgery and hospital length of stay (LOS). Platelet reactivity will be assessed in P2Y12 Reactive Units (PRU) using the VerifyNow® P2Y12 assay. Bleeding will be measured by transfusion requirements, chest tube output, as well as the occurrence of perioperative intracranial bleeding and reoperation to control bleeding. PRU results and timing of P2Y12 inhibitor discontinuation and surgery start time will also be collected, along with hospital LOS.

Results: Results will be presented on difference in bleeding events for PRU ranges following cardiac surgery as well as length of time from P2Y12 inhibitor discontinuation to surgery and hospital LOS.

Conclusion: Data analysis pending, results to be presented.

**Poster Title:** Implementation of pharmacy-prepared prefilled anesthesia syringes in the operating rooms

**Primary Author:** Michael Massmann, HCA/UT College of Pharmacy, TN; **Email:** michael.massmann@hcahealthcare.com

**Additional Author(s):**
Michelle McMains
John Dalton

**Purpose:** Perioperative medication administration bypasses many of the checks and balances in place to prevent medication errors. In addition, medication preparation in the operating room (OR) setting can lead to unnecessary medication waste and increased costs. The use of prefilled syringes has demonstrated increased compliance with national recommendations. The purpose of this standardization project is to measure waste, compounding time, cost, and clinician satisfaction with pharmacy-prepared prefilled syringes.

**Methods:** In an attempt to create standardization of medication administration in the hospital OR setting, a pilot of five medications was selected to be drawn up in prefilled syringes by the pharmacy department for all OR suites at two facilities. Glycopyrrolate, neostigmine, succinylcholine, ephedrine, and phenylephrine were chosen after an evaluation of commonly used anesthesia-administered medications. Retrospective data gathered from the anesthesia team included doses administered during a three-month period. In collaboration with the anesthesia team, this data led to our standard syringe dose, volume, and concentration for each medication. A cost analysis was performed to identify additional labor required to implement the prefilled syringe process. Syringes are compounded using a pump promoting standardization of the process and increasing efficiency of preparation. The beyond use dating of the syringes will be determined by stability testing after the finalization of the preparation process. Following implementation of the prefilled syringe pilot, outcomes to be measured will include: waste, preparation efficiency, cost, and satisfaction of the anesthesia team. This study is seeking approval by the University of Tennessee Health Science Center Institutional Review Board.
Results: In progress.

Conclusion: In progress.

**Poster Title:** Inpatient hyperglycemia managed with basal and bolus or sliding scale insulin in the non-critically ill at a rural hospital: an observational study

**Primary Author:** Devin McKenzie, Henry County Medical Center, TN; Email: dmckenzie@mail.hcmc-tn.org

**Additional Author(s):**
Taiga Jolley
Lyte Parsons
Paula Bell

**Purpose:** Insulin is a mainstay of therapy in the treatment of inpatient hyperglycemia. Uncontrolled hyperglycemia in hospitalized patients is associated with poorer clinical outcomes, such as prolonged hospital stay, increased readmissions and urinary tract infections. Clinical literature supports improved outcomes in hyperglycemic patients when insulin therapy consists of basal and bolus regimens when compared to sliding scale insulin monotherapy. The primary purpose of this retrospective analysis is to evaluate the effectiveness of basal and bolus insulin as compared to sliding scale insulin in the treatment of inpatient hyperglycemia at a rural community hospital in non-critically ill inpatients.

**Methods:** This study will be submitted to the Medical Executive Committee for approval. It is designed to determine the overall effectiveness of two different insulin regimens to decrease length of stay in general ward patients. To evaluate this relationship, study authors will perform a retrospective chart review of non-critically ill patients admitted and insulin regimen used for the treatment of hyperglycemia. Patients will be placed into one of two groups: basal-bolus regimen and sliding-scale regimen. For purposes of this study, authors have defined hyperglycemia as any two-blood glucose readings of 180 mg/dl or greater with in a 24-hour period while hospitalized. Daily blood glucose levels in each group will be averaged over the period of each patient stay. Groups will be compared with a final statistical analysis to detect differences in patient outcome measures with the primary endpoint being the mean length of hospital stay. Secondary endpoints will include rates in hyperglycemia during treatment, new urinary tract infections, and readmissions between groups. A safety analysis will be performed...
regarding the incidence of hypoglycemia. Descriptive statistics will be used to analyze collection data.

**Results:** N/A

Poster Title: Impact of delayed prescription filling on 30-day readmission rate following hospital discharge for heart failure or chronic obstructive pulmonary disease

Primary Author: Aaron Kovacik, Henry County Medical Center, TN; Email: akovacik@hcmc-tn.org

Additional Author(s):
James Renfroe
Charles Dyer
Paula Bell
Amy Mallon

Purpose: The purpose of this retrospective study is to determine if a delay in prescription filling of greater than 48 hours following hospital discharge in patients with a primary diagnosis of heart failure or chronic obstructive pulmonary disease leads to an increase in 30-day readmission rate.

Methods: This study will be submitted to the Medical Executive Committee for approval. Utilizing the electronic medical record, researchers will identify those discharged home with a new prescription(s) related to a hospital admission secondary to an exacerbation of heart failure or chronic obstructive pulmonary disease. These patients’ primary outpatient pharmacy(ies) will be documented and contacted to determine the date and time of initial prescription fill following hospital discharge. Time of prescription fill will be compared to time of discharge and patients will be categorized into two comparative groups: prescriptions filled within 48 hours and prescriptions filled after 48 hours. Further review will be conducted to determine number of patients that were readmitted within 30 days of discharge. Additionally, electronic medical records will be reviewed to determine if pharmacist-led medication counseling prior to discharge was completed, per facility policy, to determine further impact on readmission rates.

**Poster Title:** Closing the Gaps on an Interprofessional Transitional Care Program: Evaluating the Impact of Pharmacist-Provided Discharge Counseling on 30-day Readmission Rates

**Primary Author:** Tyler Finocchio, Holston Valley Medical Center, TN; **Email:** tyler.finocchio@wellmont.org

**Additional Author(s):**
- Josh Whaley
- Brooke Stayer
- Ralph Lugo

**Purpose:** The Center for Medicare and Medicaid Services has instituted payment penalties for hospitals with high readmission rates for patients with specified diagnoses, which has led to an effort to decrease overall readmissions and thereby cut costs incurred by health systems. At Holston Valley Medical Center, the pharmacy department implemented a pilot program to provide discharge counseling to patients at high risk of readmission, on top of an existing nurse-driven protocol. The objective of this study is to evaluate the effect of pharmacist-provided services as part of an interprofessional team on 30-day readmission rates.

**Methods:** This retrospective analysis evaluates hospital readmissions between July 6, 2016 and January 6, 2016 and compares three months of a newly instituted nurse-driven protocol with the following three months after the addition of pharmacy services. Pharmacy services included: reviewing a list of admitted patients daily to identify those at highest risk of readmission and for whom discharge medication lists had been completed, discharge medication reconciliation, medication counseling, and the creation of a patient-friendly medication summary to clearly indicate medications to be discontinued, new medications to start, and ones that are being continued, with more specific instructions and guidance for the patient or caregiver. Patients age 18 years or older who had a high risk LACES readmission score are included. Exclusion criteria are: pregnancy, discharge within 24 hours, patient left against medical advice, discharge to a skilled nursing facility, discharge to hospice care, or death prior to discharge. The primary outcome is overall hospital readmission rate. Secondary outcomes are readmission rate for patients age 65 years or older and readmission rate for high risk patients. All outcome measures will be evaluated using chi-square test.

**Poster Title:** Evaluation of enoxaparin thromboprophylaxis in morbidly obese patients based on anti-Xa levels

**Primary Author:** Bradley Willis, Holston Valley Medical Center, TN; **Email:** bwillistn@gmail.com

**Additional Author(s):**
Rebekah Wilson
Brooke Stayer
Ralph Lugo

**Purpose:** Enoxaparin is approved for venous thromboembolism prophylaxis at the dose of 30 mg every 12 hours or 40 mg once daily in those with good renal function, regardless of patient size. A common measure of appropriate thromboprophylaxis is serum anti-Xa levels. Morbidly obese patients or those larger are often under-dosed and experience subtherapeutic anti-Xa levels. This retrospective study analyzes anti-Xa levels for morbidly obese patients (BMI of greater than or equal to 40) receiving enoxaparin 40 mg twice a day and those with a BMI of greater than or equal to 50, receiving 60 mg twice a day.

**Methods:** This study will be submitted to the Institutional Review Board for approval. Information is to be collected retrospectively from the electronic medical record using EPIC software on a standardized form under a non-identifying subject number. Data recorded will include: patient age, gender, weight, height, BMI, diagnoses, enoxaparin dose, anti-Xa level, creatinine clearance, and evidence of drug related events. Patients evaluated will be those greater than or equal to 18 years of age, have a BMI of greater than or equal to 40, and were given enoxaparin for thromboprophylaxis per protocol at Holston Valley Medical Center. The primary endpoint is to evaluate the achievement of target anti-Xa levels in the patient groups (BMI 40-49, greater than or equal to 40, greater than or equal to 50) comparative to the enoxaparin dose given. The secondary endpoints regard safety and evaluate: Rates of bleeding, thrombocytopenia (Platelets greater than or equal to 50 percent decrease from baseline or drop to less than 100,000/ microliter), and symptomatic venous thromboembolism. Data will be analyzed using Fisher’s Exact for categorical data, such as achievement of target anti-Xa, and t-test for continuous data such as average anti-Xa level achieved. The results of this analysis will be presented at the meeting.

**Poster Title:** Evaluation of the safety and efficacy of a standardized hypoglycemia protocol

**Primary Author:** Sarah Ayers, Jackson- Madison County General Hospital, TN; **Email:** sayers4904@bellsouth.net

**Additional Author(s):**
Dylan Wilson

**Purpose:** Due to the risk of hypoglycemia, The Joint Commission (TJC) and the Institute for Safe Medication Practice (ISMP) both recognize insulin products as high-alert medications. Acute hypoglycemic episodes in patients with diabetes can lead to complications including confusion, loss of consciousness, seizures, and even death. Due to the risks to patient safety posed by hypoglycemia and varying treatment practices, our institution developed a hypoglycemia treatment protocol designed to standardize the treatment of hypoglycemic events in the inpatient setting. The purpose of this medication use evaluation was to evaluate the safety and efficacy of this hypoglycemia protocol.

**Methods:** This medication use evaluation was exempt from institutional review board approval as it was deemed a quality improvement project. Patients who experienced at least one blood glucose level less than 70mg/dL during a specified period of time were selected for a retrospective chart review. Inclusion criteria include inpatients 18 years of age or older who experienced at least one measured hypoglycemic event. Exclusion criteria include patients with erroneous blood glucose measurements less than 70mg/dL as determined by a measured blood glucose level greater than 70mg/dL within 5 minutes of the initial hypoglycemic reading. The primary endpoint for this study was rate of adherence to our institution’s hypoglycemia protocol. Secondary endpoints included time to fist blood glucose measurement after administering treatment for hypoglycemia, percent of time treatment resulted in resolution of hypoglycemia, percent of time first treatment resulted in resolution, time to resolution of hypoglycemia, percent of patients experiencing recurrence of hypoglycemia after treatment, and percent of time treatment resulted in severe hyperglycemia as determined by blood glucose greater than 250mg/dL at measurement immediately following treatment.

Poster Title: Hydromorphone medication utilization evaluation: defining and capturing meaningful outcome and process measures

Primary Author: Sonia Pernia, Jackson-Madison County General Hospital, TN; Email: sonia.pernia@wth.org

Additional Author (s):
Andrew Martin

Purpose: The Institute for Safe Medication Practices recognizes opioids as high alert medications in the acute care setting. As such, The Joint Commission addressed patient safety regarding inpatient opioid use in a 2012 Sentinel Event Alert. This alert suggests actions to take to avoid opioid related adverse events, encouraging hospitals to “create and implement policies and procedures for tracking and analyzing opioid-related incidents.” With this medication use evaluation, we will define institution-specific outcome and process measures, identify data sources for capturing reliable data, establish a baseline description of hydromorphone use, and delineate a reproducible method for future monitoring of hydromorphone use.

Methods: Institutional Review Board approval was waived for this medication utilization evaluation as a quality improvement project. Patients with a hydromorphone order between July 11, 2016 and July 24, 2016 were selected for retrospective chart review. Automated dispensing cabinet data were also collected for each patient for the defined study period in order to assess hydromorphone removal on override as well as naloxone administration. A fourteen-day time period was chosen in order to mirror previous data collection periods. The Pennsylvania Patient Safety Authority’s “Hydromorphone Measures Worksheet” was used as a starting point to identify outcome and process measures for this project. Outcome measures that will be assessed include respiratory complications, central nervous system complications, and treatment for adverse events (naloxone or oxygen administration). Prescribing, dispensing, administration, and monitoring process measures that will be assessed include [Prescribing] incidence of non-protocol orders, doses greater than 1mg administered to opioid-naïve patients, and PCA basal doses in opioid-naïve patients; [Dispensing] pharmacist interventions on hydromorphone orders; [Administration] hydromorphone doses removed from automated dispensing cabinets without a pre-existing order; and [Monitoring] number of patients on
hydromorphone PCA without continuous pulse oximetry monitoring. Pharmacist interventions include dose corrections, instruction clarifications, and discontinuation of duplicate opioid medications orders for severe pain. All data points and sources will be defined to create a standardized tool that could be used for future monitoring.

Poster Title: Evaluation of overanticoagulation associated with concomitant warfarin and select antimicrobial therapy in the inpatient setting

Primary Author: Emily Gateley, Jackson-Madison County General Hospital, TN; Email: emily.gateley@wth.org

Additional Author (s):
Christy Waggoner

Purpose: The 2016 Joint Commission National Patient Safety Goal 03.05.01 states to “take extra care with patients who take medicines to thin their blood.” Warfarin, the most commonly prescribed anticoagulant, is highly susceptible to drug-drug interactions, with antimicrobial agents causing some of the more severe interactions. Initiating antimicrobial therapy in a patient receiving warfarin is associated with a 2-fold increased risk of bleeding. The purpose of this study is to evaluate the incidence of overanticoagulation associated with concomitant warfarin and select antimicrobial therapy in the inpatient setting.

Methods: This medication use evaluation is a quality improvement project and has been granted exemption from institutional review board approval. Electronic medical records will be used to identify patients who were prescribed at least one oral antimicrobial agent concomitantly with warfarin between January 2016 and June 2016. Inclusion criteria consist of patients over the age of 18 on warfarin therapy prior to hospitalization that were started on an antimicrobial agent deemed to cause a drug-drug interaction. The following classes of antimicrobial agents will be targeted: azole antifungals, macrolides, sulfonamides, penicillins, cephalosporins, tetracyclines, and metronidazole. Exclusion criteria will consist of new warfarin initiation, concomitant antimicrobial therapy duration of less than 3 days, argatroban therapy, documented liver dysfunction, and documented heart failure exacerbation. A standardized data collection sheet will be used for each patient that meets criteria. Data will be analyzed to determine the incidence and management of overanticoagulation associated with concomitant warfarin and select antimicrobial agents.

Poster Title: Impact of a rapid diagnostic blood culture identification panel on timing of appropriate antimicrobial therapy in patients with bloodstream infections.

Primary Author: Olivia Davis, Johnson City Medical Center, TN; Email: davisoa@msha.com

Additional Author(s):
Jennifer Tharp
Paul Lewis
David Jones

Purpose: Sepsis is the 10th leading cause of mortality in the United States and accounts for roughly 20 billion dollars of the United States healthcare budget. Delays in appropriate antimicrobial therapy leads to increase in mortality. Improvements in rapid diagnostics in microbiology have led to earlier identification of organisms, although the clinical significance is unknown. The purpose of this study is to assess the clinical impact of a rapid diagnostics blood culture panel on the timing of appropriate antimicrobial therapy prescribing.

Methods: This study will be submitted to the Institutional Review Board at East Tennessee State University for approval. Study design is a controlled before-and-after study. Similar time periods will be evaluated before and after the implementation of a rapid diagnostics blood culture panel, the FilmArray blood culture identification panel. Patients will be identified using Premier’s Safety Surveiller for the pre-implementation and internal microbiology reports for post-implementation. Inclusion criteria are patients 18 years or older with a positive blood culture. Patients will be excluded for blood cultures positive for coagulase negative staphylococci. Primary endpoint will be the time to appropriate antimicrobial therapy. Secondary endpoints include number of patients requiring escalation, number of patients requiring de-escalation, sepsis related-mortality rates, hospital length of stay and intensive care unit length of stay. Charlson Comorbidity Index will be calculated to compare severity between groups. Additional data points to be collected include patient age, sex, mortality, blood cultures, empiric antimicrobial therapy, time to organism identification, identification of organism, and final or targeted antibiotic. Appropriate therapy is defined as therapy covering organism and elimination of duplicate or unnecessary coverage (de-escalation). Continuous
variables will be compared using a student’s t-test and categorical variables will be compared using Chi squared or Fisher’s exact test.

Poster Title: Impact of a 72 hour automatic stop and pharmacist-led review on the empiric use of vancomycin

Primary Author: George Wohlford, Johnson City Medical Center, TN; Email: gfwohlford@gmail.com

Additional Author (s):
Paul Lewis
Jen Tharp
Jessica Burchette

Purpose: It has been estimated that up to 50 percent of antibiotics prescribed to humans are inappropriate, leading to an increase in drug resistance and adverse events. To combat this, many institutions develop global initiatives designed to reduce inappropriate prescribing. One strategy is the implementation of automatic stop dates when antibiotics are ordered empirically through an order set. Pharmacist-led review with prescriber callback is necessary to avoid interruptions in care when therapy is truly indicated. This study is designed to evaluate the impact of a 72 hour automatic stop with pharmacist-led review on empiric use of vancomycin.

Methods: This study will be submitted to the East Tennessee State University Institutional Review Board for approval. The study design will be a retrospective cohort review evaluating the impact of a 72 hour automatic stop date with pharmacist-led review implemented in October 2015 at the Johnson City Medical Center on empiric utilization of vancomycin. Patients will be included if they are 18 years of age or older, admitted to inpatient status, and started on vancomycin within 12 hours of admission via order set. Patients will be excluded if they have microbiological evidence for continuation of vancomycin, diagnosed with culture-negative endocarditis or osteomyelitis, vancomycin ordered for surgical prophylaxis or continuation from home or other facility, or are pregnant. The primary endpoint will be average length of therapy for vancomycin in each cohort. Secondary endpoints include overall days of therapy per 1000 patient days, rates of therapy continuing past 72 hours, average length of stay, rates of acute kidney injury, and rates of therapy interruption. Additional data points to be collected include vancomycin indication, pathway or order set from which vancomycin originated, age, sex,
weight, height, serum creatinine. Charlson Comorbidity Index will be calculated for each cohort. Continuous variables will be compared using student’s t-test. Categorical variables will be compared using Fisher’s exact or Chi-square test.

Poster Title: Clonidine for prevention of withdrawal after dexmedetomidine use in children

Primary Author: Alicia Sanchez, Le Bonheur Children's Hospital, TN; Email: alicia.sanchez@lebonheur.org

Additional Author(s):
Julie Croll
Andria Gonzales
Becky Landman
Rebecca Chhim

Purpose: Studies have reported withdrawal symptoms in patients who have received prolonged dexmedetomidine infusions. Based on its similar chemical structure and mechanism of action, clonidine is a logical agent for use in patients in whom there is a concern for withdrawal. The objective of this study is to assess the use of clonidine in pediatric patients who have received dexmedetomidine for sedation in an intensive care unit. Secondary analyses will aim to identify factors that may increase the risk of withdrawal.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record will be used to identify patients less than eighteen years of age who received a dexmedetomidine infusion and clonidine for prevention of withdrawal. Patients will be excluded if they received methadone or clonidine within 30 days prior to dexmedetomidine. Data collected will include each patient’s age, weight, sex, primary diagnosis, hospital unit, intensive care unit length of stay, ventilator days, hospital length of stay, use of other sedatives, dose and duration of dexmedetomidine, and duration of clonidine wean. Heart rate and blood pressure will also be collected for assessment of withdrawal. This information will be used to evaluate trends in clonidine weaning by assessing the duration of clonidine wean compared to the dose and duration of the dexmedetomidine infusion. For patients who had a documented clonidine wean, the percentage of patients who required an adjustment to the original wean will be determined. Additionally, factors that may increase the risk of dexmedetomidine withdrawal will be assessed.

Poster Title: Evaluation of the impact of antimicrobial stewardship on necrotizing enterocolitis outcomes

Primary Author: Nicole Palazzolo, Le Bonheur Children's Hospital and The University of Tennessee Health Science Center, TN; Email: nicole.palazzolo712@gmail.com

Additional Author(s):
Chasity Shelton
Kelley Lee
AJay Talati
Bindiya Bagga

Purpose: There exists a paucity of data guiding clinicians regarding antimicrobial selection and duration for patients diagnosed with necrotizing enterocolitis (NEC), potentially leading to broader spectrum antimicrobial coverage than may be clinically necessary. At Le Bonheur Children’s Hospital, Antimicrobial Stewardship Neonatal Intensive Care Unit (NICU) Guidelines were implemented to provide guidance regarding antimicrobial use. The purpose of this study is to evaluate the impact of this initiative on outcomes associated with NEC. Outcomes assessed pre- and post-implementation of the guidelines will include mortality, length of hospital stay, development of fungal sepsis, days until full enteral feeds and need for surgical intervention.

Methods: In this single center, retrospective, quality improvement study, a chart review of pediatric patients admitted from July 2010 through July 2016 with a documented diagnosis of NEC will be conducted. All patients included will be admitted to the NICU at Le Bonheur Children’s Hospital with a clinical and/or radiologic confirmed diagnosis of stage I, II or III NEC at any time during their admission. Patients will be excluded if there is poorly documented antimicrobial use information for patients transferred to Le Bonheur following their NEC diagnosis, or if antimicrobial agents were discontinued after less than 48-72 hours of therapy. Details of antimicrobial agent, dosing and duration will be collected. Additional data collected via chart review will include demographic information, comorbidities, duration of mechanical ventilation, culture results, days to full enteral feedings, requirement for surgery as well as other clinically relevant patient and laboratory findings.

**Poster Title:** Stigma Toward Antipsychotic Medication among Healthcare Clinicians  
**Primary Author:** Tyler Casey, Lipscomb University College of Pharmacy, TN; **Email:** tyler.casey@lipscomb.edu

**Additional Author(s):**

**Purpose:** Patients with mental illness have many barriers to receiving comprehensive and effective treatment. One barrier is the stigma associated with one of the most common classes of medications in mental health, antipsychotics. Although research has been conducted to investigate stigma from and directed toward patients, little has been done to look at stigma toward antipsychotic medications. This study seeks to assess and define how much of that stigma originates from healthcare professionals.

**Methods:** This study has been submitted and approved by the Lipscomb IRB committee. Data will be collected through the use of an extensive survey distributed online and via physical mail. The survey will be distributed to physicians, pharmacists, pharmacy students, nurses, physician assistants, and healthcare social workers. Types of questions in the survey include likert scale questions, semantic differential scale questions, and interval scale questions. Background data collected from participants will include practice setting, profession, specialty, years in practice, gender, ethnicity, age, and location. Questions in the survey will be centered around perceptions of antipsychotics, side effects of these medications, what types of patients take antipsychotics, risk/benefits of antipsychotics, what diagnoses antipsychotics should be used to treat, and so on. Once the data is collected, it will be analyzed for an overall level of stigma toward antipsychotic medication. Data will also be used to compare difference in responses from different professions, practice settings, and years in practice.

Poster Title: Retrospective review of a pharmacist managed diabetes clinic on hemoglobin a1c

Primary Author: Cindy Kaing, Lipscomb University College of Pharmacy, TN; Email: cindy.kaing@lipscomb.edu

Additional Author(s):
Benjamin Gross

Purpose: Over 29 million adults in the United States have diabetes. Many of those affected experience complications such as heart disease, retinopathy, kidney disease, and neuropathy. The healthcare cost associated with diabetes is astronomical, accounting for more than 20 percent of the total cost. From a financial and health standpoint, it is essential that providers and patients work together to optimize care. Clinical pharmacists specializing in diabetes management can provide focused care regarding non-pharmacological and pharmacological management of these patients. Our research will evaluate the impact a pharmacist can have on patients’ diabetes outcomes when in direct supervision of their care.

Methods: Our pharmacist-managed clinic functions as a referral system within a medical group for primary care related disease states. This study will include adult patients, 18 years of age or older, diagnosed with diabetes who have previously been or are currently under the care of the pharmacist. Patients who declined the referral or self-discontinued care with the pharmacist will be excluded. Once referred, the pharmacist will operate under a collaborative practice agreement to manage lifestyle and pharmacological changes specific to diabetes-related matters. Lifestyle management will focus on education regarding nutrition and physical activity, as well as goals of therapy. Scope of practice will also include making any necessary pharmacological changes such as medication adjustments (involving oral agents, injectables, and insulin pumps), initiation and adjustment of self-monitoring blood glucose practices, and implementation and interpretation of continuous glucose monitoring systems. We will monitor demographics, diagnosis information, time spent with the pharmacist, pertinent medications, and related laboratory parameters. Each patient’s progress will be measured by a laboratory test of hemoglobin a1c. Progress will be tracked at baseline, periodically at follow-up, and at discharge from the clinic for referral back to the primary provider, if applicable.

Poster Title: The incidence of high-risk patient readmission at a regional medical center following implementation of a transitions of care program by a community pharmacy

Primary Author: Jessica Lampley, Lipscomb University College of Pharmacy - Perkins Drugs, TN; Email: jllampley@lipscomb.edu

Additional Author (s):
Benjamin Gross

Purpose: Transitioning a patient from one setting is often complex. Factors include lack of communication between institutions, insufficient patient education and lack of knowledge about the patient’s resources outside of the facility. Patient’s lack of adequate medication education is a factor in patient’s nonadherence to their medication regimens resulting in readmissions within 30-days post-discharge. This study will aim to assess the role that community pharmacists can play in educating high-risk patients with newly prescribed medication and the transitions of care process. This study also aims to highlight the potential value of this initiative as a clinical service in the community pharmacy.

Methods: A risk stratification tool, the LACE index, will be utilized to determine which patients are at an increased risk of readmission and recruited to participate in the study. Patients with a LACE score > 8 as well as a diagnosis of CHF, pneumonia, COPD, DM, MI, total knee/hip replacement, cardiac disease, coronary artery bypass graft, orAfib will be consented. Participants will have to agree to having their medications delivered to their bedside upon discharge.

After a participant consents to have their medication delivered to their bedside upon discharge, the hospital will send electronic prescriptions to Perkins Drugs, along with, their consent and discharge information 30 minutes prior to discharge. This information will include new medications, instructions, diagnoses, labs, and follow-up appointments. Medications will be filled and delivered to patient’s bedside. The patient will be educated on each of the medications he or she is receiving and provided with an up-to-date medication list. The participant will agree to post discharge (within 48-72 hours) telecommunication, a one-on-one formal educational appointment with the investigator within 7-14 days post-discharge depending on their risk of readmission, and a final call at 25 days post-discharge.
Perkins drugs will also provide patient’s primary care provider, specialist, and facility care manager with documentation of the discharge process, follow-up information, and updated medication list.

Poster Title: Retrospective analysis of psychiatric emergency department visits and identifying opportunities for pharmacy involvement

Primary Author: Kayla Johnson, Maury Regional Medical Center, TN; Email: kayladjohnson42@gmail.com

Additional Author (s):
Jennifer Whittington
Erika Hasford

Purpose: Patients with psychiatric conditions are admitted to the emergency department (ED) for a variety of conditions, including altered mental status, lack of medication adherence, and disease state exacerbations. Often, these patients must be held in the ED or admitted to the floor until placement at a psychiatric facility can be obtained. Due to limited formulary options, many patients may not be treated appropriately during this time period which may further worsen their original admission diagnosis. As the number of ED visits continues to climb, so does the need for clinical pharmacists in the ED who are familiar with psychotropic medications.

Methods: This study has been submitted to the Institutional Review Board and received approval. An evaluation of psychiatric patient holds or admissions in the ED will be conducted through a retrospective chart review utilizing the International Classification of Diseases, 10th edition (ICD-10) diagnosis codes of F01-99 (mental, behavioral, and neurodevelopmental disorders), G20-26 (extrapyramidal and movement disorders), and T39-43 and T50 (poisoning by, adverse effect of, and under dosing of substances). The following data will be collected: age, gender, county of residence, admitting diagnosis, length of stay (including holding), transferring facility, resumption of home psychotropic medications, and days until next ED visit, if applicable. Data from identified patients will be reviewed with the purpose of identifying average length of stay (holding), resumption of home medications, counties with highest visitation rates, and areas in which clinical pharmacists can assist in providing more complete care.

Poster Title: Implementation of a pharmacist-led chronic obstructive pulmonary disease (COPD) medication management program in a rural community hospital

Primary Author: Shelby Hood, Maury Regional Medical Center, TN; Email: shelby.hood@pop.belmont.edu

Additional Author(s):
Jordan Robinson
Jennifer Whittington
Erika Hasford

Purpose: Chronic obstructive pulmonary disease (COPD) is a respiratory disease that is not fully reversible; however, symptoms associated with this disease can be treated and prevented if managed appropriately. Hospital thirty-day readmission rates for patients with chronic obstructive pulmonary disease are at an all-time high. These readmissions could potentially be prevented with proper lifestyle modifications and medication management. Pharmacists are in a unique position to provide services that help prevent these exacerbations. For this study an inpatient chronic obstructive pulmonary disease medication management program will be implemented by decentralized pharmacists to help reduce the recurrence of exacerbations and hospital readmissions.

Methods: This study has been submitted to the Institutional Review Board and received approval. A prospective cohort review will compare outcomes after the implementation of a pharmacist-led chronic obstructive pulmonary disease (COPD) medication management program. Pharmacists will perform patient interviews, full chart reviews, medication reconciliation, identify areas of need and barriers for individual patients, provide interventions, and make recommendations in collaboration with providers. Informed consent will be obtained by each patient prior to any involvement by the pharmacist. All patient identifiers will be excluded from the data presentation and only study investigators will have access to protected health information while on site at the hospital. The primary outcome will compare thirty-day hospital readmission rates for chronic obstructive pulmonary disease from the implementation of the program to before the program began. Secondary outcomes will include accepted recommendations by providers, potential cost savings, and length of hospital stay.

Poster Title: Evaluating the difference in heart failure readmission rates between the cardiac floor versus general medicine floors in a regional hospital

Primary Author: Cody Coulter, Maury Regional Medical Center, TN; Email: ccoulter@mauryregional.com

Additional Author(s):
Rebecca Sowell
Jennifer Whittington
Erika Hasford

Purpose: Heart failure is the leading cause of hospitalizations, readmissions, and hospital costs in the United States. To combat this increasingly prevalent statistic, Maury Regional Medical Center (MRMC) began a pharmacist-led education program for heart failure patients throughout the cardiovascular floor. However, not all heart failure patients are admitted to the cardiovascular floor, and therefore do not receive education. The objective of this study is to evaluate the difference in heart failure readmission rates between the cardiovascular floor and the general medicine floors. This comparison will assess the need for expansion of this program to all inpatient medicine patients throughout MRMC.

Methods: The institutional review board approved this retrospective chart analysis to examine heart failure exacerbation readmission rates at MRMC. Once this readmission data is gathered, the difference in readmission rates between the cardiovascular floor versus the general medicine floors will be calculated to assess the need for expansion of pharmacist-led heart failure education on all inpatient medicine floors at MRMC. Patients will be identified using heart failure specific ICD-9 and ICD-10 codes. Patients age 18 and older with either a primary or secondary diagnosis of heart failure and with a heart failure exacerbation as reason for readmission from October 1, 2015, to September 30, 2016 will be included in this study. Patient demographics, days to readmission from initial hospitalization, as well as length of stay with will be analyzed. Subgroup analysis will include estimated cost savings.

Poster Title: Neuroleptic malignant syndrome secondary to quetiapine

Primary Author: Amie Algrim, Methodist Healthcare - University Hospital, TN; Email: amie.algrim@mlh.org

Additional Author(s):

Purpose: A 34-year-old male was admitted to the hospital with status tonic-clonic seizure activities and was found to have a right middle cerebral artery stroke. During admission, quetiapine 25 mg was administered three times per day. After administering the quetiapine, the patient was noted to have changes in mental status, laboratory abnormalities, intermittent fever with tachycardia and tachypnea. The patient’s intermittent fever reached a maximum of 39.5 degrees Celsius with no definitive documented infection. The patient showed no response to three broad-spectrum antibiotics including vancomycin, meropenem, and linezolid. Multiple cultures from bronchoalvelar lavage, pleural fluid, sputum, urine and blood failed to reveal evidence for infection. Elevations of the serum creatinine kinase of 1361 IU/L due to rhabdomyolysis were also observed. The patient met diagnostic criteria for neuroleptic malignant syndrome. Quetiapine was immediately discontinued after twenty doses were given; intravenous hydration and supportive care were administered. The patient’s condition resolved after receiving one dose of intravenous dantrolene sodium followed by 4 days of oral dantrolene sodium given twice a day. After the initiation of dantrolene sodium, the patient’s cognitive impairment improved, along with his vital signs and laboratory abnormalities. As this case report suggests, the use of quetiapine has the potential to cause life-threatening neuroleptic malignant syndrome. Twenty cases of quetiapine-induced neuroleptic malignant syndrome have been reported. In the few cases where quetiapine was the single agent, the mean dose was 267 mg per day. The observed core signs of neuroleptic malignant syndrome were hyperthermia and autonomic dysfunction. This case should serve as a reminder that atypical antipsychotics can be a cause of neuroleptic malignant syndrome.

**Poster Title:** System-wide evaluation of sugammadex use

**Primary Author:** Ashley Holmes, Methodist Healthcare - University Hospital - Germantown, TN; Email: ashleykholmes16@gmail.com

**Additional Author(s):**
Joan Stumpe
Cortney Swiggart
Nicole Walker
Mary Yates

**Purpose:** Sugammadex, a selective relaxant agent that binds to unbound steroidal neuromuscular blockers to reverse neuromuscular blockade, was recently added to formulary at Methodist Le Bonheur Healthcare – Memphis Hospitals. The objective of this study is to conduct a medication use evaluation to characterize the use of sugammadex at Methodist, and to determine adherence to criteria and restrictions approved with the addition of sugammadex to formulary.

**Methods:** A Cerner PowerVision report will be utilized to identify adult patients who received sugammadex within the Methodist Le Bonheur Healthcare system. The following data will be collected: patient age, gender, weight, surgery type, pre-operative renal function, American Society of Anesthesiologists (ASA) physical status, use of hormonal contraception prior to surgery, neuromuscular blocker being reversed, time to extubation, post anesthesia care unit (PACU) time, and operating room (OR) time. Sugammadex dose and the use of other neuromuscular reversal agents including neostigmine and glycopyrrolate will be collected. Incidence of bradycardia, administration of blood products, administration of anti-emetics, and documentation of hypersensitivity to sugammadex will also be collected to evaluate the adverse effects associated with sugammadex use. All data will be recorded without patient identifiers and will be maintained confidentially.

**Results:** N/A

**Conclusion:** N/A
Purpose: Based on previous medication use evaluations (MUE), it was identified that indication specific order sentences may improve appropriate dosing at our healthcare facility. As a result, in August 2016, new ordering sentences for the direct oral anticoagulants (DOAC) were introduced to ensure correct dosing for each labeled indication and reduce prescribing errors. The objectives of this study are to characterize the current utilization of DOACs, evaluate appropriateness of dosing using pre-built orders based on indication and compare these results to previous MUEs. Additionally, this study will evaluate injectable anticoagulant use and ensure appropriate transitions and lack of concomitant use.

Methods: The electronic medical record system will be utilized to identify patients who have received a DOAC (apixaban, dabigatran, edoxaban, or rivaroxaban) during admission to a Methodist – Le Bonheur adult Hospital between October 1st and October 31st 2016. Up to 100 patients will be included in this analysis. The following data will be collected: patient demographics, serum creatinine and creatinine clearance, DOAC indication, dose and frequency, potential drug interactions documented in the medication administration record (MAR), and any heparin or low molecular weight heparin use during a 24 hour period before or during DOAC use. If a patient received more than one DOAC, the agent that the patient was prescribed on the day of discharge will be analyzed. Data will be reviewed to assess appropriate dosing of each agent based on renal function, age, weight, drug interactions, and indication. Records will also be reviewed to determine if the indication specific ordering sentence was used and if the documented indication noted in the history and physical or discharge summary.
matches the selected order. All data will be recorded without patient identifiers and maintained confidentially.

**Poster Title:** Lithium toxicity treatment: Analysis of adherence to proven therapeutic modalities

**Primary Author:** Hannah Hewgley, Methodist Healthcare-University Hospital, TN; **Email:** hannahhewgley@gmail.com

**Additional Author(s):**
Ana Negrete
Jessica Rivera

**Purpose:** Lithium is used to treat bipolar disorder and has a complex mechanism of action that is not fully understood. Lithium is a simple cation that is primarily excreted as unchanged drug in the urine and has a narrow therapeutic window. Lithium toxicity can be acute, acute-on-chronic, or chronic. Signs of lithium toxicity can vary and often present as gastrointestinal (GI) symptoms, neurologic manifestations, and even Diabetes Insipidus in chronic toxicity. Proven treatment modalities include IV fluids and dialysis. The purpose of this study is to determine the appropriateness of lithium toxicity treatment in one healthcare system.

**Methods:** This is a quality improvement project based on retrospective data from a single healthcare system. This study will be submitted to the appropriate Institutional Review Board for approval. Patients with supratherapeutic lithium levels (lithium levels > 1.5 mEq/L) will be identified by a report run in Cerner Millennium. Patient demographics that will be collected include age, gender, race, height, and weight. Toxicological data that will be collected include type of lithium taken (extended release versus immediate release), lithium dose (if known), and all serum lithium concentrations during the clinical encounter. Clinical laboratory data that will be collected include baseline serum creatinine, baseline blood urea nitrogen (BUN), baseline serum sodium, thyroid panels, and diabetes insipidus workup including urine osmoles. Finally, the following therapeutic data will be obtained: IV fluids given, IV fluid rate, time to IV fluids, time to nephrology consult (if consulted), if dialysis was done, time to dialysis, type of dialysis, and if repeat levels were obtained after dialysis. We will also collect the following signs and symptoms of lithium toxicity from provider documentation: altered mental status, gastrointestinal symptoms, abnormal vital signs, abnormal electrolytes, seizures, acute kidney injury, neuromuscular symptoms, slurred speech, and other. All data will be recorded without patient identifiers and maintained confidentially.

**Poster Title:** Assessing compliance with calcitonin restrictions

**Primary Author:** Samarth Shah, Methodist University Hospital, TN; **Email:** samarthpshah31@gmail.com

**Additional Author(s):**
Justin Usery

**Purpose:** At Methodist Healthcare, calcitonin injection is on formulary, but it is reserved for patients who have severe or symptomatic hypercalcemia. While calcitonin has a quicker onset of action, tachyphylaxis with calcitonin is a known phenomenon that has been described to occur after 48 hours of usage. Electronic prescribing restrictions through the auto-population of a form were employed in 2015 due to the substantial increase in price for calcitonin. This medication use evaluation will assess system–wide compliance of the calcitonin restrictions with regard to utilization, effectiveness, and cost.

**Methods:** A retrospective chart review of patients that received calcitonin intramuscularly or subcutaneously throughout our hospital system was performed. The methodology was approved by the University of Tennessee Institutional Review Board. The time frame for the two groups collected were January 1st 2015 to February 28th 2015 for Group A (2015) and January 1st 2016 to February 29th for Group B (2016). A total of 35 calcitonin orders were screened in 2015 with 30 total occurrences being included from our hospital system. Patients were excluded if calcitonin was ordered and not subsequently administered. A total of 30 calcitonin orders were screen in 2016 and all 30 occurrences were included for analysis. Calcitonin was restricted to patients with severe or symptomatic hypercalcemia. The definition of hypercalcemia for this evaluation was an ionized Ca of greater than 1.5 mmol/L or total/corrected Ca of greater than 13 mg/dL. Documentation of typical symptoms for hypercalcemia was utilized in this evaluation. Doses were restricted to 4 units/kg for two doses which necessitated a reassessment for the continued need for calcitonin. Patients could receive additional calcitonin at 4 units/kg for two more doses to allow for a maximum of four doses in 48 hours. Outcomes assessed were total vials that were used as well as differences in calcium reduction between the two groups.
Resident Poster Abstracts

Results: The recommended dosing for calcitonin is 4 units/kg every 12 hours. Based on the data provided, the average dose of calcitonin for 2015 and 2016 was 3.4 units/kg. Only 15 patients were started on the appropriate dose in 2015 with the patient number increasing to 19 patients in 2016. The average number of doses given per order was 6.3 in 2015 compared to 2.4 in 2016. There were 17 patients that received more than 4 doses before implementation of the form compared to 4 patients post-implementation. Clinical outcomes that were reviewed included concomitant therapy, average change in serum Ca, and length of stay. Similar rates of Ca reduction were seen between the various treatment modalities. The average serum Ca at the time of therapy initiation was 13.39 and was reduced by 1.48 in 2015. In 2016, the average serum Ca at the time of therapy initiation was 13.68 and was reduced by 1.24. The average length of stay was higher in the 2015 group, but was due to 3 patients having an extended length of stay.

Conclusion: Of the patients evaluated, 93 percent of patients met at least one of the criteria based on current prescribing restrictions compared to 90 percent in 2015. Through analyzing the documentation of prescribing restrictions in both groups, we were able to determine appropriate usage of calcitonin. The number of patients receiving calcitonin remained unchanged, but the number of doses administered per patient reduced substantially. Due to implementation of the form and prescribing restrictions, the number of units dispensed over a two month period decreased from 46,669 units to 20,267 units. This prescribing reduction led to a decrease in 63 vials between 2015 and 2016 during these 2–month time frames. Converting the decrease in vials used to dollars saved, this two month comparison saved our hospital system 135,000 dollars. Extrapolating this data over a 12 month period, we would be on track to save approximately 810,000 dollars.
**Submission Category:** Critical Care

**Submission Type:** Research-in-Progress

**Session-Board Number:** 8-270

**Poster Title:** Effect of tissue plasminogen activator administration on international normalized ratio (INR) in patients with acute ischemic stroke

**Primary Author:** Kimberly Davidson, Methodist University Hospital, TN; **Email:** erin.davidson2@mlh.org

**Additional Author(s):**
- John Haller
- Whitney Gross
- Samarth Shah
- G. Jones

**Purpose:** The most serious complication of tissue plasminogen activator (tPA) administration is symptomatic intracranial hemorrhage. Monitoring of coagulation factors before and after tPA administration is warranted to observe if patients are at higher risk of bleeding. However, tPA may falsely elevate the international normalized ratio (INR), making monitoring for increased risk of bleeds difficult. The purpose of this study is to determine the relationship between tPA administration and INR elevation within 24 hours of tPA.

**Methods:** This study will be submitted to the appropriate Institutional Review Board for approval. Patients who received tPA for acute ischemic stroke will be identified by a report run in Cerner Millennium. Subsequently, patients will be screened for baseline INR measurement and INR within 24 hours of tPA. The following other data will be collected: hospital arrival time, tPA dose and time, baseline INR, any follow up INR, fibrinogen levels and the times of these measurements. Past medical history including the use of aspirin and/or antiplatelets, tobacco use, atrial fibrillation, hypertension, diabetes mellitus, and liver disease will be collected. We will also collect baseline liver function tests and initial National Institutes of Health Stroke Scale (NIHSS) measurements, any neurological intervention performed, and adverse outcomes including symptomatic intracranial hemorrhage (sICH), or other bleeding complications. Finally, we will collect basic patient demographics, age, gender, race, height and weight. Patients will be excluded for missing baseline INR, missing follow up INR within 24 hours of tPA, known baseline liver disease or taking any medications that would otherwise elevate INR. Patients with
follow up INR’s within 24 hours of tPA will be analyzed to determine if there is an association of elevated INR with administration of tPA.

Poster Title: Evaluation of Alerts that Fire with Therapeutic Duplication Checking

Primary Author: Jared Heiles, Methodist University Hospital, TN; Email: jared.heiles@mlh.org

Additional Author (s):
Tiffany Derheimer
Lauchland Roberts
Jamie Johnson-Hardy
Cortney Swiggart

Purpose: Electronic health records with computerized provider order entry (CPOE) and clinical decision support have been adopted by many healthcare facilities. These systems have been shown to increase patient safety and decrease medication errors. However, increased duplicate order entry is an unintended consequence that has been well documented after implementation of CPOE. Therapeutic duplication checking is one strategy used to reduce duplicate medication orders. Therapeutic duplication checking in CPOE for select medication categories was implemented in 2016 at Methodist LeBonheur Healthcare. The purpose of this project is to evaluate therapeutic duplication checking alerts in our hospital system.

Methods: This study will evaluate alerts that fired upon order entry to healthcare providers for therapeutic duplication of medications. A report of all duplicate orders that triggered an alert to fire will be generated from the electronic medical record system and placed in an Excel spreadsheet. Alerts will be quantified for July and September 2016, and data from the report will include: duplicate medication order, medication that triggered the duplicate order, ordering personnel, override reason, medication therapy changes, and medication orders part of a Powerplan. This study will determine whether the duplicate alert prompted the prescriber to make a change in medication therapy. In addition, the following will be identified: medications that triggered the majority of duplicate alerts to fire, duplicate alerts that fired from medications that are part of a Powerplan, the top three medication categories that prompted prescribers to make a change in therapy, the most common reason indicated for overriding therapeutic duplication alerts, the percentage of alerts where no override reason was selected, and the top medication categories that would have fired if therapeutic
duplication checking was turned on for those categories. All data will be reported without patient identifiers and will maintain confidentiality.

**Poster Title:** Evaluation of the use and management of peripheral parenteral nutrition within a healthcare system

**Primary Author:** Samantha Ellingson, Methodist University Hospital, TN; **Email:** samantha.ellingson.se@gmail.com

**Additional Author (s):** Joyce Broyles  
Kaleb Brown

**Purpose:** Peripheral parenteral nutrition (PPN) is often used as an alternative to central parenteral nutrition, but there are fewer guidelines on proper administration and management. The purpose of this evaluation is to assess the appropriateness of PPN initiation and administration within a healthcare system.

**Methods:** A retrospective chart review of all adult patients who received PPN between January 1, 2016 and June 30, 2016 will be conducted. Patients eligible for study inclusion will encompass all adult hospitals within the healthcare system. Data points collected will include patient demographics such as age, height, weight, race and sex, along with the indication and duration of PPN therapy. Adverse events that may be attributable to the use of PPN, such as electrolyte disturbances, glucose abnormalities, or extravasation events, will also be documented. Data obtained from the medical record will be recorded on a standard data-collection form and encrypted using a randomly assigned patient number. During data analysis, these patient numbers will be dropped, ensuring the confidentiality of all subjects. Endpoints that will be assessed include appropriate initiation of therapy, adverse events that may be a result of PPN, and average length of hospital stay.

**Poster Title:** Mortality from a case of metformin associated lactic acidosis with a severely elevated metformin level

**Primary Author:** Heidi Riha, Methodist University Hospital, TN; **Email:** heidi.riha@mlh.org

**Additional Author(s):**
Jessica Rivera

**Purpose:** Metformin associated lactic acidosis (MALA) is characterized by acidosis (pH < 7.35) and elevated lactate (>5 mmol/L). It occurs in a small percentage of patients taking metformin (0.03 to 0.06 per 1,000 patient-years), however, is associated with a high mortality. This case illustrates a patient on chronic metformin therapy with a severely elevated metformin level and lactic acidosis who had rapid clinical deterioration despite aggressive supportive care which resulted in death. The patient was a 58 year old African American female who presented from an assisted living facility with altered mental status. The patient had a past medical history of polysubstance abuse, schizophrenia and diabetes mellitus. The facility stated that they provided a daily dose of her medications and there was nothing unusual in her possession. She had no visitors, had not gone anywhere, and was acting normal that morning except for her breathing was a little off and she exhibited vomiting and diarrhea for one day. The patient was taking tiotropium 18 mcg inhalation daily, omeprazole 20 mg by mouth (PO) daily, metformin 1000 mg PO twice daily, insulin glargine 10 units subcutaneously nightly, ibuprofen 600 mg PO three times daily as needed for pain, hydrochlorothiazide-lisinopril 12.5-10mg PO daily, fluphenazine 10 mg PO at bedtime, and benztrpine 1 mg PO twice daily. Upon arrival to the emergency department the patient was hyperventilating, cool to the touch, hypoglycemic (blood glucose 68 mg/dL), and hypotensive (blood pressure 64/43). Computed tomography without contrast of the head and chest x-ray were unremarkable. The patient was immediately intubated, and given 1 ampule of 50% dextrose intravenously (IV), normal saline 2 liters IV, vancomycin 1500 mg IV and piperacillin/tazobactam 3.375 g IV. Labs indicated the following were elevated: hemolysed potassium (5.7 mEq/L), blood urea nitrogen (93 mg/dL), creatinine (12.00 mg/dL), anion gap (38), ammonia (194 mcmol/L), beta-hydroxybutyrate (6.09 mmol), serum osmolality (363 mOsm/kg), lactate (16.6 mmol/L), white blood cell (29.00 thousand/microliter), and INR (1.7). She had severe hypobicarbonatemia (bicarbonate 3 mEq/L), and acidosis (pH 6.69). Lactated ringers 2 L IV was given and a norepinephrine infusion was initiated. Due to refractory
hypotension and acidosis, she was given the following throughout her 4.5 hour hospitalization: sodium bicarbonate 150 mEq IV push, a bicarbonate infusion, vasopressin 0.04 units/min, hydrocortisone 50 mg IV and an epinephrine infusion. Unfortunately, the patient’s condition worsened rapidly and underwent four rounds of cardiopulmonary resuscitation with return of spontaneous circulation each time. The patient was ultimately made a do not resuscitate due to poor prognosis and passed. A comprehensive toxicology urine drug screen was performed (through Quest Diagnostics) and was negative except for detection of cotinine (nicotine metabolite) and acetone 7 mg/dL. A metformin level was drawn in the early afternoon and sent out due to the possibility of MALA and resulted later as 35 mcg/mL (therapeutic level: 1-2 mcg/mL and levels associated with MALA >5 mcg/mL). The following laboratory parameters were checked and found to be non-contributory: thyroid stimulating hormone, creatinine kinase, salicylates, iron, ethylene glycol, methanol, and isopropanol. Urine and blood cultures had no growth to date. This patient had many causes of anion gap acidosis excluded, increasing the likelihood she had MALA. Additionally, she had a severely elevated metformin level from chronic metformin therapy with severe renal injury. Metformin levels in the literature are inconsistently reported. There is not a clear consensus on levels associated with MALA or mortality resulting from MALA. In this example, severely elevated metformin levels were associated with a MALA case which resulted in rapid deterioration despite supportive care and mortality.

**Session-Board Number:** 8-274

**Poster Title:** Rifaximin does not improve outcomes in cirrhotic patients with systemic inflammatory response syndrome

**Primary Author:** Katherine March, Methodist University Hospital University of Tennessee College of Pharmacy, TN; **Email:** katherine.march@mlh.org

**Additional Author(s):**
Jennifer Twilla
Joyce Broyles
Lydia Hutchinson

**Purpose:** Cirrhosis marks the final stage of chronic liver disease (CLD) and is accompanied by a host of serious complications. Evidence suggests that systemic inflammation and the activation of the systemic inflammatory response syndrome (SIRS) are independently associated with in-hospital mortality and portal hypertension-related complications (PHRC). Recent literature theorizes that rifaximin may alter the inflammatory process leading to these devastating consequences. The purpose of this study is to evaluate the impact of rifaximin on hospital outcomes in cirrhotic patients meeting SIRS criteria.

**Methods:** A retrospective review of patients admitted to Methodist LeBonheur Healthcare adult hospitals between 8/2008-8/2015 was conducted in reverse chronological order. Inclusion criteria: age > 18 years, ICD9-codes for CLD, and admission > 24 hours. Exclusion criteria: admission for liver transplant, hepatocellular carcinoma, transition to hospice, and incomplete data points. Patient groups: RP (rifaximin prior to hospitalization) or NRP (no rifaximin prior). The rate of in-hospital mortality based on grade of SIRS criteria (< 2 or ≥ 2 criteria) and MELD score as well as the development of PHRC were evaluated between the groups.

**Results:** Of the 715 patients screened, 305 met inclusion criteria (RP equals 100, NRP equals 205). Baseline characteristics were similar between the groups with the exception of MELD score. In patients that received rifaximin prior, a significant difference for in-hospital mortality was observed in patients with SIRS less than 2 (13 percent RP, 1 percent NRP; p equals 0.03),
SIRS greater than or equal to 2 (23 percent RP, 9 percent NRP; \( p \) equals 0.03), and in patients with a MELD score of greater than 18 (23 percent RP, 9 percent NRP; \( p \) equals 0.01). No significant difference of in-hospital mortality was identified in the MELD less than or equal to 18 group (3 percent RP, 4 percent NRP; \( p \) equals 1). There was a significant difference observed in the PHRC of hepatic encephalopathy in patients with SIRS less than 2 (54 percent RP, 8 percent NRP; \( p \) equals 0.0001) and SIRS less than or equal to 2 (41 percent RP, 13 percent NRP; \( p \) equals 0.0001) as well as a significant difference in the incidence of hepatorenal syndrome in the SIRS greater than or equal to 2 group (11 percent RP, 2 percent NRP; \( p \) equals 0.01).

**Conclusion:** In our study, administration of rifaximin prior to hospitalization did not improve in-hospital mortality or the development of PHRC in cirrhotic patients; however, this result may be biased by the acuity of illness seen in the RP group. Further studies examining the relationship between early initiation of rifaximin and the inflammatory process in cirrhosis are needed.

**Poster Title:** Medication adherence interventions to reduce readmission rates for patients with psychiatric diagnoses

**Primary Author:** Patrycia Leja, Parkridge Medical Center, TN; Email: patrycialeja@gmail.com

**Additional Author (s):**

**Purpose:** Research in the scope of medication compliance for the psychiatric patient population has proven to have many barriers. Current research has focused on team management, patient education, and supporting patients as they transition to outpatient care. Studies have found conflicting results on efficacy of these interventions. The aim of this study will be to evaluate the reduction of readmission rates for psychiatric patients with schizophrenia, bipolar or psychosis based on pharmacist interventions.

**Methods:** Patients will be interviewed at discharge and upon readmission to discuss ways to be successful with their antipsychotic medication regimens. These patients will be counseled on compliance strategies and how to overcome barriers. Insurance programs or vouchers will be found through the hospital's utilization review team to find the optimal program for patients. Additional resources will be given to indigent patients or those that require extra support. These interventions will be categorized to determine whether they are successful.

**Results:** Study in progress.

**Conclusion:** Study in progress.

Poster Title: Decreasing antibiotic time to administration through pharmacy interventions and hospital education

Primary Author: Priyanka Patel, Parkridge Medical Center, TN; Email: ph0003@auburn.edu

Additional Author(s):
Rebecca Horne

Purpose: Currently, literature shows that administering now doses of antibiotics improves patient outcomes in morbidity and mortality. However, due to various reasons, these doses are not always given on time, which may worsen patient health outcomes and prolong hospital stay. The primary aim of this study is to evaluate antibiotic time to administration before and after pharmacy intervention and hospital education.

Methods: A retrospective review will be conducted on the metrics that Hospital Corporation of America (HCA) headquarters maintains on antibiotic administration for our hospital. The retrospective review will be conducted prior to pharmacy interventions and hospital education. After pharmacy interventions have been implemented and education has been conducted, a prospective review of the metrics will be conducted to assess for a decrease in antibiotic time to administration. These metrics will assess for delays in antibiotic time to administration in specific areas of the hospital.

Poster Title: Evaluation of Computerized Physician Order Entry Alerts through a Medication Clinical Decision Support Committee to Counteract Alert Fatigue

Primary Author: Ryan O’Neal, PGY2 Health System Pharmacy Administration, TN; Email: ryan.oneal@mlh.org

Additional Author(s):
Tifany Derheimer
Jamie Johnson-Hardy

Purpose: Computerized physician order entry has made a significant impact on medication error reduction. Therapeutic duplication, drug-drug interaction, dose range checking, allergy, as well as other alerts have the ability to verify medication orders based on the patient’s medical record. As alert frequencies increase to the provider, the development of alert fatigue has the potential to lead to a medication error. One strategy to counteract the development of alert fatigue is to evaluate alerts for meaningfulness. Methodist LeBonheur Healthcare has developed a Medication Clinical Decision Support Committee to evaluate common alerts and requests by providers for modifications to alerts firing.

Methods: The Medication Clinical Decision Support Committee was created in July 2015 with membership of physicians, pharmacists, and information technology support. The committee is responsible for evaluating alerts that fire to providers upon medication ordering including alerts for therapeutic duplication, drug-allergy, drug-drug interaction, and dose range checking alerts. The committee reports to the System Medication Safety Committee at Methodist LeBonheur Healthcare, which reports their meeting minutes to the Methodist LeBonheur Healthcare Pharmacy and Therapeutic Committee monthly. Alerts are evaluated by the committee based on priority, request by physician, or frequency during a seven day period. A pharmacy representative provides a recommendation for each alert based on alert data built in computerized physician order entry and evidence-based practice. The Medication Clinical Decision Support Committee meets every other week to discuss alerts and recommendations. All recommendations approved through the committee are changed by the information technology support team and re-evaluated based on frequency. The meetings are held virtually using a webinar platform equipped with screen sharing and conference call capabilities. The
presentation consists of a review of previous meeting minutes, alert presentation and recommendation, and a pharmacy IT report. The pharmacy IT report provides the alert rates, alert rate trends, and top ten adult and pediatric alerts during a seven day period for dose range checking and duplication alerts.

**Results:** The Medication Clinical Decision Support Committee has met every two weeks since July 2015. Multiple improvements have been made to reduce the frequency of alerts, while maintaining the meaningfulness and safety of the alert. In December 2015, the committee acknowledged a 53% reduction in intravenous morphine alerts, a 95% reduction in intravenous diltiazem alerts, 82% reduction in epoetin alfa alerts, and 73% reduction in one-time intravenous levetiracetam alerts. In February 2016, the committee reduced intravenous vancomycin dose range checking alerts by 91%. The committee has reduced dose range checking alerts by half since July 2015. Based on successes from dose range checking additional alert actions were submitted for evaluation by the committee. In February 2016, dose range checking for the discharge prescription writing process and therapeutic duplication checking was implemented. The classes of medications activated for therapeutic duplication were anticoagulants, angiotensin-converting-enzyme inhibitors, angiotensin receptor blockers, statins, beta-blockers, and beta-lactam antibiotics. Other therapeutic duplication alerts for opioids, selective serotonin reuptake inhibitors, and tricyclic antidepressants have been implemented, in addition to clinical rules to help meet Leap Frog recommendations.

**Conclusion:** The Medication Clinical Decision Support Committee has been a vital group to tackle alert fatigue at Methodist LeBonheur Healthcare. The committee has made a significant impact on reducing alerts while maintaining patient safety. Due to the success of the committee, other provider alerts have been implemented to alert the provider in an effort to improve patient safety and comply with criteria for Leap Frog.

Poster Title: Identification of risk factors for venous thromboembolism (VTE) in patients with thermal and inhalation injury

Primary Author: Tracy Whitney Brown, Regional One Health, TN; Email: thandler@regionalonehealth.org

Additional Author (s):
David Hill
William Hickerson

Purpose: Critically ill patients are at a higher risk for developing venous thromboembolism (VTE). Thermal and inhalation injuries augment standard critical care risk with hypercoagulopathies, an overwhelming inflammatory response, and potential direct endothelial damage. It is unclear whether burn patients have higher rates of symptomatic VTE. Clarity is needed to determine if VTE incidence and associated complications balanced with bleeding necessitate initiation of chemoprophylaxis. Scoring systems for VTE risk in burn patients have been created based on national data. This study was conducted to determine incidence and identify potential risk factors for VTE in thermal and inhalation injury in our institution.

Methods: This study was performed in a single, southeastern United States burn center. It was an institutional review board approved, retrospective, observational study that utilized data collected from the institution’s electronic medical record. All patients admitted with a thermal injury or an inhalation injury from January 1, 2000 to July 31, 2015 were included. Patients were excluded if they were less than 18 years of age or had incomplete data. SigmaPlot 11.2 was used for data analysis. Univariate analysis was used to compare patients with and without VTE. Independent variables with a p ≤ 0.1 were included in a multivariable logistic regression. During regression modeling, p < 0.05 was considered significant. Nominal data were analyzed by chi-square test. Continuous variables were compared using either Mann-Whitney U test or t-test, depending on normal distribution. Shapiro-Wilk test was used to test for normal distribution.

Results: N/A
Conclusion: N/A

Poster Title: Development and implementation of an antibiotic prescribing pathway in the critically ill burn patient

Primary Author: Matthew Percy, Regional One Health, TN; Email: mpercy@regionalonehealth.org

Additional Author(s):
David Hill

Purpose: Infections are a frequent occurrence in patients with thermal injuries secondary to a compromised immunologic barrier. Timely and accurate diagnosis of infection in critically ill burn patients can be difficult as these patient have a hypermetabolic and proinflammatory presentation at baseline. Prompt evaluation and administration of appropriate antibiotics is necessary to reduce exposure, decrease resistance, and reduce mortality. The purpose of this process was to develop an antimicrobial prescribing pathway in the critically ill burn patient.

Methods: We developed a protocol for use in the Firefighters Burn Center that uses clinically accepted methods of diagnosis along with our local antibiograms to streamline the diagnosis of infection, collection of cultures, prescribing of empiric antibiotics, and early conversion to definitive antimicrobial therapy. This protocol is being implemented and evaluated to determine its effect on early and accurate diagnosis of infection and subsequent prescribing of antibiotics.

Results: N/A

**Poster Title:** Use of technology to assess the accuracy of anesthesia dosing and drug administration in the operating room

**Primary Author:** Megan Hicks, Regional One Health, TN; **Email:** drmeganhicks@gmail.com

**Additional Author(s):**
Marilyn Lee
Christopher Sharp
Kay Ryan
Raymond Cooper

**Purpose:** Historically, very little data has been reported regarding medication errors in the operating room. Operating rooms typically lack medication safety checks, such as barcoding or system double-check. High rates of perioperative medication errors have been reported, and adverse events attributed to perioperative medication errors have been shown to increase hospital costs and length of stay. New technology has recently been introduced to incorporate medication safety measures in the operating room and to assist anesthesia practitioners with the administration of medications. The objective of this study is to assess the accuracy of self-reported perioperative medication dosing errors utilizing advanced barcoding technology.

**Methods:** The study will be submitted to the Institutional Review Board for approval. The surgical patient information system will identify patients who receive medications during operating procedures in an outpatient surgery center. Data collected will include type of procedure performed, outpatient surgery clinic performing procedure, perioperative medication(s) given, medication doses given as reported by anesthesiology or nurse anesthetist, medication doses given as reported by advanced barcoding technology, and reported adverse drug events. All data will be recorded without patient identifiers and maintained confidentially. A medication error will be defined as a difference between self-reported medication doses and technologically-documented. The primary outcome of the study will be to compare incidences of self-reported medication errors and medication errors detected by technology.

**Results:** N/A
Conclusion: N/A

Poster Title: Use of Pharmacist-Assisted Health Regimen in Patients with Elevated HbA1c: Effectiveness on Decreasing Elevated HbA1c Percentages.

Primary Author: Krista King, South College School of Pharmacy, TN; Email: kingkm3@gmail.com

Additional Author(s):
Laura Schalliol
Denise Barker
Jeremy Crain

Purpose: The objective of this study is to evaluate the effectiveness of using of a standardized patient health regimen on patient HbA1c. This study will utilize a pharmacist-assisted diet and exercise regimen with company employees identified as having a baseline HbA1c greater than 6.5%, with a goal to reduce this number.

Methods: This is an exploratory pilot study. The participants of this study are employees of a national grocery chain with in-house pharmacy services who had a biometric screening performed between July 1st and September 30th, 2016. Screenings took place at one of the company’s pharmacy locations in the southeastern United States. The biometric screenings included blood glucose, blood pressure, body mass index, and total cholesterol. Patients with a HbA1c of greater than 6.5% will be offered a pharmacist-assisted patient health regimen. Collection of data will be obtained through the A1c Now™ point-of-care screening device for the pre- and post-HbA1c value at one of the company’s locations. The time interval between the pre and post screening will be 90 days. Additional data collection will be throughout the 90 days with a phone call or email to assess adherence to the regimen. The primary end point will be defined as a decrease in the post-HbA1c value from the pre-HbA1c value.

Results: N/A

Conclusion: Favorable results would indicate the benefit of further research into the utilization of this pharmacist-assisted approach to reducing overall HbA1c values and improving patient quality of life.
Expanding the role of a pharmacist within a patient-centered framework, pharmacists are able to partner with patients and aid in their decision making toward their healthcare goals.

Poster Title: Thiopurine methyltransferase genotyping compliance to guide thiopurine dosing and improve patient safety in acute lymphoblastic leukemia patients

Primary Author: Jennifer Hockings, St. Jude Children's Research Hospital, TN; Email: jennifer.hockings@stjude.org

Additional Author (s):
Cyrine Haidar
Kristine Crews
Mary Relling
James Hoffman

Purpose: Thiopurines are a main component of treatment in acute lymphoblastic leukemia (ALL) regimens. Thiopurine methyltransferase (TPMT) is an enzyme that methylates and inactivates thiopurines. Polymorphisms within TPMT result in a loss of enzymatic activity and have been associated with severe myelosuppression and thiopurine intolerance. Based on these data, the goal at St. Jude Children’s Research Hospital is to obtain a TPMT (3 variants) genotype on every patient with a diagnosis of ALL before thiopurine therapy is initiated as a method to maximize efficacy while minimizing adverse effects.

Methods: A retrospective review was conducted to determine the percentage of patients who had a TPMT genotype in the electronic health record (EHR) at the time a thiopurine order was placed. At St. Jude, most ALL therapy order sets include a TPMT genotype order in the first days of induction therapy in order to obtain the result in time to guide thiopurine dosing. In addition, pre-test clinical decision support (CDS) alerts have been created to recommend ordering a TPMT genotype in the event that a thiopurine is prescribed to a patient who has not been genotyped for TPMT, as well as post-test alerts that suggest thiopurine dose modifications in patients with a known high-risk TPMT phenotype. Patients were included if they were diagnosed with ALL, were thiopurine-naïve prior to treatment initiation at St. Jude, and received their first dose of thiopurine between October 2012 and December 2015. Patients were excluded if they had received an allogeneic hematopoietic stem cell transplant prior to starting the first dose of thiopurine. EHRs of patients who did not have a documented TPMT genotype prior to an initial thiopurine order were reviewed to determine potential reasons for
lack of TPMT genotyping compliance. Once routine data collection procedures are established, the percent of ALL patients genotyped for TPMT prior to initiating thiopurine therapy will be established as a routine medication safety metric.

**Results:** A total of 299 thiopurine-naïve patients with ALL were identified. A TPMT genotype was documented in the EHR prior to thiopurine initiation for 297 (99%) patients. Two patients did not have a documented TPMT genotype prior to the entry of thiopurine orders. The first patient was on an ALL protocol in which the dose of 6-mercaptopurine was low (25 mg/m2/day), and the clinician ordered a TPMT genotype on day 1 of 6-mercaptopurine therapy. The second patient received standard doses of thioguanine through a non-protocol treatment plan that did not include a TPMT genotype order in the order set. A TPMT genotype was obtained within the first 4 weeks of therapy initiation. Both instances prompted process changes to prevent such exceptions from happening in the future. Overall, 265 (88%) patients were predicted to be TPMT normal metabolizers, 32 (11%) patients were predicted to be TPMT intermediate metabolizers and 2 (1%) patients were predicted to be TPMT poor metabolizers in this cohort.

**Conclusion:** The use of both active CDS alerts and passive guidance through order sets ensures that the majority of patients at St. Jude have a documented TPMT genotype test result available to guide initial thiopurine dosing. In establishing TPMT genotyping as a medication safety metric, our goal was set to have 100% of thiopurine-naïve patients with ALL genotyped for TPMT prior to initiating thiopurine therapy and to use the result to help guide initial dosing, and we found 99% compliance. We will continue to monitor compliance with this metric on a quarterly basis through incorporation in our hospital’s medication safety scorecard.

**Poster Title:** Antimicrobial stewardship of nitrofurantoin in the geriatric population

**Primary Author:** Erin Todd, TriStar Centennial Hospital, TN; **Email:** erin.todd@hcahealthcare.com

**Additional Author (s):**
Mary Beth Brinkman

**Purpose:** The American Geriatrics Society’s Beers Criteria gives a strong recommendation to avoid nitrofurantoin in patients greater than 65 years of age with renal impairment. The objective of this drug-use evaluation is to determine if nitrofurantoin is appropriately prescribed to patients greater than 65 years old at a single, large acute care hospital facility.

**Methods:** This study has been submitted to the Institutional Review Board for approval. A drug-use evaluation study has been selected to improve antibiotic use and safety within the geriatric population, focusing on nitrofurantoin prescribing. In order to complete this study, the electronic medical record system will identify patients who are greater than 65 years old and received nitrofurantoin. The following data will be collected: patient age, urinary infection specific findings, renal function values, prescribed dose and duration of nitrofurantoin, days to re-admission, re-admission infection and signs of nitrofurantoin toxicity at re-admission, if applicable. Data will be recorded and analyzed without patient identifiers and maintained in a confidential manner. The data collected will be reviewed by a resident pharmacist and an infectious-disease clinical pharmacist. These investigators aim to identify opportunities to improve geriatric care and antimicrobial stewardship with the evaluation of nitrofurantoin’s prescribed use in the geriatric population. This evaluation will not only improve geriatric care within the facility, but contribute to the limited antimicrobial stewardship data available for the geriatric population.

Poster Title: Timing of first dose anti-infectives for patients in the emergency department

Primary Author: Erin Loncharic, TriStar Centennial Medical Center, TN; Email: erin.loncharic@hcahealthcare.com

Additional Author (s): Jennifer Sandi

Purpose: Timely administration of anti-infectives in the emergency department (ED) should be a priority for patient care in both septic and non-septic patients. Current sepsis guidelines and the Centers for Medicare and Medicaid Services (CMS) recommend broad spectrum antibiotics are administered to patients suspected of sepsis within three hours of presentation to ED triage. The objective of this study is to examine the process that occurs from when a prescriber orders an anti-infective in the emergency department to when it is administered to the patient in order to identify areas for improvement and optimization.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system and pharmacotherapy monitoring software will identify patients who presented to the ED and were administered an anti-infective. The following data will be collected: time of patient presentation/registration to the emergency department, time of anti-infective ordering by a prescriber, time of pharmacist order verification, time of medication delivery from pharmacy/time medication was removed from medication dispensing cabinet, and time of administration to patient. Additionally, if available in the patient’s medical record, the following will be collected: patient’s initial temperature, heart rate, respiratory rate, white blood cell count, if an initial lactate level was obtained, if blood cultures were obtained prior to anti-infective administration, and time of administration of crystalloid for fluid resuscitation (if given). Data collected will be reviewed to determine areas and procedures for improvement to minimize delay from patient presentation to anti-infective administration for both septic and non-septic patients.

**Poster Title:** Enoxaparin for thromboprophylaxis in obese and underweight patients

**Primary Author:** Sarah Mehringer, TriStar Centennial Medical Center, TN; **Email:** sarah.mehringer@hcahealthcare.com

**Additional Author (s):**
 Stephens Julie

**Purpose:** Inpatient deep vein thrombosis (DVT) prophylaxis is crucial to all patients because it prevents unnecessary complications, which are not reimbursed by third party payers. Enoxaparin is one of the most commonly used agents for pharmacological DVT prophylaxis. Enoxaparin must be adjusted for renal dysfunction, but limited data exists regarding the appropriate dosing of enoxaparin for DVT prophylaxis in both overweight and underweight patients. There is speculation that obese patients are often under-dosed, therefore posing a risk of thrombosis, while underweight patients may be over-dosed, posing a risk for bleeding.

**Methods:** We conducted a retrospective chart review including non-pregnant patients over 18 years old with a body mass index (BMI) greater than 40, greater than 120 kilograms, or less than 40 kilograms on enoxaparin for DVT prophylaxis. We excluded patients with renal dysfunction, cancer, atrial fibrillation, and clotting disorders. Our primary study endpoint is the occurrence of thromboembolic events or bleeding in patients treated with enoxaparin for DVT prophylaxis. Secondary endpoints included duration of therapy and length of stay. Data collection is currently in process, and will be completed prior to ASHP Mid-Year Clinical Meeting.

Poster Title: A Medication Use Evaluation of Argatroban

Primary Author: Michael Allen, TriStar Centennial Medical Center, TN; Email: mjallen6216@gmail.com

Additional Author(s):
Jonathan Bain

Purpose: Heparin-induced thrombocytopenia (HIT) is an antibody-mediated adverse reaction to heparin administration. Argatroban is a non-heparin anticoagulant indicated for treatment of thrombosis in adult patients with HIT. The primary objective of this study is to evaluate the effectiveness of argatroban dosing protocol for patients with HIT at a 650-bed community hospital. The primary endpoint of the study will be time within the therapeutic PTT range, which will be a surrogate indicator of effectiveness of the protocol. Secondary objectives will be assessment of the time to therapeutic PTT range, time above the therapeutic PTT range, and adverse effects experienced by patients.

Methods: A single-center, retrospective chart review will be conducted for patients who were admitted and received an order for argatroban infusion for HIT. This study is pending approval through the University of Tennessee Institution Review Board. Eligible patients will be limited to patients 18 years of age or older suspected to have HIT who received argatroban during a several month period.

Data for each patient will be extracted from the patients’ electronic health record (EHR) on a standardized data collection tool. Collected data will include age; gender; actual body weight; baseline PT/INR; baseline PTT; complete blood count (CBC); serum albumin; presence of ascites or hepatic encephalopathy; HIT antibody; serotonin release assay; blood pressure at initiation of infusion; medication orders for strong CYP3A4 inhibitors; status-post cardiac surgery; history of multi-organ failure; total bilirubin; initial rate of infusion; PTT results post infusion; and time of PTT results. From this data, we will then determine whether argatroban was initiated at the appropriate rate, whether PTT values were drawn at appropriate times, and the length of time the PTT was compliant with the goal range all defined by the hospital argatroban protocol.

**Poster Title:** Clinical pharmacist impact on the reduction of intensive care unit (ICU) delirium: Intervention and monitoring

**Primary Author:** Myaa Lightfoot, Tristar Skyline Medical Center, TN; **Email:** myaa.lightfoot@hcahealthcare.com

**Additional Author(s):**
Adam Sanders
Chris Burke
Jessica Patton

**Purpose:** To determine the impact of pharmacy intervention on clinical outcomes related to intensive care (ICU) delirium

**Methods:** Retrospective analysis will be conducted on patients who were admitted to the trauma ICU for >24 hours and were flagged using special rules with CDS, a unique intelligent software that can monitor patient data in real time. CDS rules will be implemented based on ICU delirium specific risk factors gathered from previous studies such as: age, unrelieved pain, continuous use of sedation medication, + CAM-ICU score and large amounts of benzodiazepines used in 24 hours. This will serve as the control group. Data that will be collected from the control: ICU length of stay, ICU delirium +/-, RASS score, CAM-ICU scores, ventilator days, the use of sedation medication and antipsychotic medication. Modifiable risk factors will be gathered from the control group. CDS rules will then be used to identify currently admitted patients in the trauma ICU that would benefit from pharmacy intervention in the prevention of ICU delirium. Clinical pharmacist will monitor the flagged at risk patients and provide intervention recommendations as the the standard of care to prevent the development of ICU delirium. Possible interventions will be: recommending to decrease benzodiazepine use, wean trials for patients on ventilators and controlling pain as recommended by the guidelines. Before and after data will be analyzed to see if there was a positive change made by pharmacy intervention.

**Results:** Primary: The frequency of ICU delirium and ICU length of stay
Secondary: Ventilator days and hospital length of stay, antipsychotic use
Conclusion: Tristar Skyline Medical Center currently does not have an ICU delirium protocol in place, which leaves patients vulnerable to the development of ICU delirium. Pharmacy has a unique clinical decision support (CDS) software, that allows us to create relevant rules to follow patients with specific characteristics that are of interest. With CDS clinical pharmacist can be alerted to a patient who meets specific risk factors for developing ICU delirium. These patients will be followed by a clinical pharmacist to make appropriate recommendations about the care of the patient to improve their clinical outcome.
**Submission Category:** Emergency Medicine/ Emergency Department/ Emergency Preparedness

**Submission Type:** Research-in-Progress

**Session-Board Number:** 8-288

**Poster Title:** Implementation of a pharmacy-led medication reconciliation program through pharmacy technicians in the emergency department

**Primary Author:** Mariah Durham, TriStar Skyline Medical Center, TN; **Email:** mariah.r.durham@gmail.com

**Additional Author(s):**
Deanna Pouliot
Kim Dang

**Purpose:** An accurate medication history upon arrival to a medical facility is essential for medication reconciliation to be completed by a patient’s medical team. The purpose of this study is to evaluate the implementation of a pharmacy-driven medication reconciliation program in the emergency department of a 230-bed, designated level II trauma center. Proposed benefits include improved accuracy of admission medication histories and enhanced transitions of care.

**Methods:** Pharmacy technicians will participate in interactive lectures on the importance of accurate medication histories, high risk medications, common errors in medication histories, communication with patients, and documentation in the medical record. Technicians will then receive training by the Emergency Medicine Clinical Pharmacist and PGY-1 Pharmacy Practice Resident through demonstration, direct observation, and teach-back methods. Trained pharmacy technicians will complete admission medication histories on patients seen in the emergency department of TriStar Skyline Medical Center. Technicians will interview patients regarding their home medications and then utilize a second reference such as a patient’s home pharmacy, physician office, nursing facility, etc. to verify accurate medication information. Technicians will document the final medication history into the electronic medical record for review by the supervising pharmacist. Data will be collected by comparing nursing-completed medication histories versus pharmacy technician-completed medication histories. The primary outcomes will be the number of errors and discrepancies discovered in the medication histories reviewed. Time required to complete an average medication history will also be recorded to evaluate cost effectiveness of pharmacy technician verses nursing-led medication histories.

**Poster Title:** Impact of a quetiapine tapering guideline following admission in an intensive care unit

**Primary Author:** Kent Wilin, University of Tennessee Medical Center, TN; **Email:** kwilin@utmck.edu

**Additional Author (s):**
Leslie Hamilton
Brian Daley
James Langdon
James McMillen

**Purpose:** Quetiapine, an atypical antipsychotic, has seen significant use in intensive care units (ICUs) following the publication of the 2013 guidelines on pain, agitation, and delirium from the Society of Critical Care Medicine. Several studies have since demonstrated that patients started on antipsychotics in the ICU are frequently and inappropriately continued on them at discharge. The purpose of this study is to assess the impact of a quetiapine tapering guideline on new quetiapine prescriptions at discharge.

**Methods:** This quasi-experimental study has been submitted to the Institutional Review Board for approval. All patients that received quetiapine during admission to the Trauma/Surgical Critical Care and Neurocritical Care services will be screened for inclusion in the study. Exclusions will be made for patients taking quetiapine prior to admission, orders for quetiapine from a psychiatric service, patients who died before discharge, patients with incomplete documentation of study variables, and patients not discharged by study end-date. The primary endpoint of this study will be the incidence of new quetiapine prescriptions at discharge. Data that will be collected from electronic medical records includes: baseline demographics, admission unit, admission reason, comorbid conditions, Glasgow Coma Score on admission, APACHE II Score, ICU length of stay, hospital length of stay, initial dose of quetiapine, dose of quetiapine at discharge, incidence of active quetiapine order at ICU discharge, duration of active quetiapine order during hospital stay, incidence of requiring taper vs. immediate discontinuation of quetiapine, use of other antipsychotics, and adverse drug events. Statistical
tests to be used for analysis include Chi Square Test, Mann-Whitney U Test, and Student’s t-test for nominal, ordinal, and normally distributed data respectively.

Poster Title: Impact of pharmacist-assisted automatic discontinuation of unnecessary stress ulcer prophylaxis in non-critically ill hospitalized patients

Primary Author: Nichole Szczerbowski, University of Tennessee Medical Center, TN; Email: nszczerbowski@utmck.edu

Additional Author(s):
John Yates
Jennifer Mendez

Purpose: Studies have shown that many patients are inappropriately initiated and continued on stress ulcer prophylaxis (SUP) when it is not indicated. The most recent SUP guidelines published in 1999 include criteria for SUP in critically ill patients and recommend against SUP in non-critically ill patients. Recent studies indicate that there are independent risk factors for stress ulcer development in non-critically ill patients which have been incorporated into a Stress Ulcer-Related Gastrointestinal Bleeding (SURGIB) risk score. The purpose of this study is to determine if a pharmacist-assisted, SURGIB-focused protocol will decrease the rate of unnecessary SUP use in non-critically ill patients.

Methods: This study is a single-center, retrospective cohort which evaluates the rate of unnecessary stress ulcer prophylaxis (SUP) in non-critically ill patients both pre- and post-pharmacist-assisted protocol implementation. Patients who are 18 years of age or older and are receiving a proton pump inhibitor (PPI), histamine-2 receptor antagonist (H2RA), or sucralfate will be included via lists generated from the pharmacy informatics department at University of Tennessee Medical Center. Exclusion criteria will include patients who are critically ill, taking SUP per gastroenterology recommendation, taking SUP as a home medication, receiving enteral feedings, taking scheduled non-steroidal anti-inflammatory medications, and/or being observed for chest pain. Bariatric surgery patients and patients with treatment indications for PPIs, H2RAs, or sucralfate will also be excluded. Data collection will include patient demographics, length of hospital stay, duration of SUP use, indications for SUP use, and use of specific SUP medications. The primary endpoint of this study will be the duration in days of unnecessary SUP use pre- and post-protocol implementation. Secondary endpoints will include the percentage of patients discharged on unnecessary SUP, prevalence of stress ulcers, prevalence of adverse
effects (pneumonia, Clostridium difficile infection), and cost associated with unnecessary SUP use.

**Results:** N/A

**Conclusion:** N/A
Purpose: Increased incidence and severity of Clostridium difficile infection (CDI) makes appropriate treatment crucial. Optimal dosing of enteral vancomycin in patients with severe, complicated CDI has not been specifically investigated. Both major American society guidelines recommend 500 mg of enteral vancomycin for the treatment of severe, complicated CDI. Despite this recommendation, evidence to support this dose is based on case reports and expert opinion. The objective of this study is to determine the most appropriate dose of enteral vancomycin (125, 250, or 500 mg four times a day) for the first occurrence of severe, complicated CDI.

Methods: Upon completion of Institutional Review Board approval, the electronic medical record will be utilized to identify patients who received enteral vancomycin for greater than or equal to 48 hours and had an ICD-9/ICD-10 diagnosis of CDI. Patients will be included if they are at least 18 years of age and meet the criteria for severe, complicated CDI. Severe, complicated CDI was defined according to Infectious Disease Society of America/Society for Healthcare Epidemiology of America guideline definitions, which include a white blood cell (WBC) count of at least 15,000 cells/µL or serum creatinine (Scr) of greater than or equal to 1.5 times the pre-morbid level or acute kidney injury plus any one of the following: hypotension, shock, ileus, or megacolon. Patients will be excluded if they have documented recurrent CDI or any baseline conditions that would influence the assessment of severe, complicated CDI criteria. The primary outcome being evaluated is time to clinical cure defined as the resolution of diarrhea (less than 3 unformed stools, 200mL of watery rectal bag output or 1 L of colostomy output in 24 hours). Secondary outcomes include 28 day mortality, recurrence and reinfection rates, readmission
rates, ICU and hospital LOS, discharge disposition, appropriateness of initial therapy based on CDI severity, and a composite endpoint of complications due to CDI.

**Results:** N/A

**Conclusion:** N/A
**Submission Category:** Critical Care

**Poster Title:** Initiation of a quetiapine taper order set for delirium in the intensive care unit (ICU)  

**Primary Author:** Stefanie Underwood, University of Tennessee Medical Center, TN; **Email:** underwood864@gmail.com  

**Additional Author (s):**  
Shauna Winters  
Danielle Dennis  
John Callison  
Chandler Dawn  

**Purpose:** Current literature cites the prevalence of an atypical antipsychotic initiated for the treatment of ICU delirium being continued at ICU discharge to be 47 - 84.2 percent and 21 - 33.9 percent at hospital discharge. A retrospective study conducted at the University of Tennessee Medical Center from July 1, 2011 through June 30, 2012 in the trauma-surgical and neurocritical care units showed that 21 percent of patients were discharged on quetiapine therapy. The purpose of this study is to determine if an ICU delirium quetiapine taper order set decreases the incidence of patients being continued on quetiapine at hospital discharge.

**Methods:** This is a single-center, retrospective cohort conducted at the University of Tennessee Medical Center, which will be submitted to the Institutional Review Board for approval. The electronic medical record system will be used to identify patients. Inclusion criteria consist of patients with diagnosis of delirium, admitted to the critical care medicine service who received quetiapine for treatment. Exclusion criteria include patients with quetiapine as a home medication, died during hospitalization, or quetiapine therapy initiated for another indication. Data collection will include patient demographics, length of stay, primary physician team at discharge, comorbidities, quetiapine dosing regimen, length of stay, sedation medications while in the ICU, incidence of prolonged QTc, haloperidol use, and APACHE II scores. The primary outcome of this study is to determine the incidence of patients discharged from the hospital on quetiapine. The study design consists of two parts. Part one is a cross-sectional study that will establish the prevalence of quetiapine discharge at our institution between June 1, 2013 to September 26, 2016. Part two consists of initiating a quetiapine taper order set for ICU
delirium, establishing incidence of patients discharged on quetiapine between September 27, 2016 to June 1, 2017 and comparing the results to part one of the study. Secondary outcomes include protocol utilization, duration of quetiapine use and number of patients discharged from the ICU on quetiapine.

Poster Title: Effect of a clinical decision support tool on outpatient antibiotic prescribing for uncomplicated urinary tract infections (UTIs) – Phase I

Primary Author: Alexandra Foster, University of Tennessee Medical Center, TN; Email: afoster@utmck.edu

Additional Author (s):
Andrea Franks
Shaunta' Chamberlin
Julie Jeter
Sarah Eudaley

Purpose: An update to the IDSA guidelines for treatment of acute uncomplicated UTIs was published in 2011. In light of increasing antimicrobial resistance, the FDA Drug Safety Communication in May 2016 on fluoroquinolone use in uncomplicated infections, and Tennessee Medicaid’s value-based reimbursement system, assessment of outpatient prescribing and implementation of interventions to guide empiric therapy for uncomplicated UTIs are imperative to optimize treatment success, patient safety, and cost-effectiveness. The objective of this study is to identify trends in outpatient antibiotic prescribing practices for uncomplicated UTIs in a family medicine clinic and to evaluate adherence to current clinical practice guidelines.

Methods: Phase I is a cross-sectional study of non-pregnant female patients aged 18 years and older diagnosed with an uncomplicated UTI at an outpatient family medicine clinic between July 1, 2011 and April 30, 2016. Patients excluded are those with complicated and/or recurrent UTIs, use of prophylactic antibiotics for UTIs, concurrent sexually transmitted diseases, and chronic immunosuppression. Data collected from eligible patients’ electronic medical records includes: date of visit, diagnosis, demographics, past medical history, allergies, presenting symptoms, renal function, urinalysis results, urine culture results, antibiotic prescribed, healthcare provider, insurance status, and re-presentation to an outpatient clinic or ED within 14 days of initial diagnosis. The primary endpoint is prescribing trends of antibiotics for uncomplicated UTIs. Secondary endpoints include the proportion of patients receiving appropriate empiric therapy, duration of therapy, and dose based on renal function; antibiotic
susceptibilities of uropathogens isolated from urine culture; prescribing trends of individual health care providers; and proportion of patients re-presenting to an outpatient clinic or ED within 14 days of diagnosis. Descriptive statistics will be utilized to describe the study population, as well as current prescribing rates of antibiotics for treatment of uncomplicated UTI. The Cochran Mantel-Haenszel Chi-square test will be utilized to assess trends in the prescribing of antibiotics between the different years. This study has been submitted to the Institutional Review Board for approval.

**Poster Title:** Impact of pharmacist involvement in the discharge medication reconciliation process for inpatient rounding teams at an academic medical center

**Primary Author:** Rachel Renwick, University of Tennessee Medical Center, TN; **Email:** rrenwick@utmck.edu

**Additional Author (s):**
Andrea Franks
Sarah Eudaley
Laura Bullock

**Purpose:** Discharge from the hospital is a complicated transition time and a time that is particularly susceptible to errors. Multiple observational studies have looked at the rate of discrepancies/errors in discharge medication reconciliation and found 20-50% of discharges may have some discrepancies. At our institution, pharmacists are involved in admission medication reconciliation and inpatient medication therapy but have no formal role in discharge medication reconciliation. The objective of this study is to determine impact of pharmacist involvement in the discharge medication reconciliation process for inpatient rounding teams at our academic medical center.

**Methods:** For this study, pharmacists rounding with the family medicine service will be directly contacted when the physician has completed a patient’s discharge medication reconciliation Monday-Friday 7am to 4pm. Physicians will contact the pharmacist directly by pager system or telephone. Pharmacists will review the medication list and contact the physician if there are any discrepancies. Pharmacists will review the discharge medication list to compare the medications a patient is prescribed with newly ordered medications. The comparison addresses duplications, omissions, and interactions, and the need to continue current medications. All patients whose discharge medication reconciliation is reviewed by a pharmacist will be included in the intervention group. The control group will comprise of patients discharged by the family medicine service outside of the study hours or whose discharge medication reconciliation was not reviewed by the team pharmacist. The primary endpoint will be the incidence of pharmacist interventions on discharge medication reconciliations. Secondary endpoints will include category and severity of discrepancies identified, readmission rates, emergency department
visits, time taken for pharmacist review, and number of medications patient is taking on admission and discharge. To determine potential high risk groups, patients with heart failure, COPD, and diabetes, as well as those taking anticoagulants, insulin, or opioids will be identified.

Poster Title: Effect of protocolized management of severe traumatic brain injuries on incidence of intracranial hypertension

Primary Author: Carly Stoneman, University of Tennessee Medical Center, TN; Email: carly.stoneman@gmail.com

Additional Author(s):
James McMillen
Heath Many
Christy Lawson

Purpose: Traumatic brain injuries (TBIs) cause over 50,000 deaths annually in the United States with a significant burden on our healthcare system. Increased intracranial pressures (ICPs) above 20 mmHg have been shown to increase risk of mortality. Even if elevated ICPs are decreased, TBI patients are 2.2 times more likely to die than those who consistently have normal ICPs. Our institution began utilizing a protocolized approach for treating TBIs in July 2016 with more emphasis on ICP monitoring for severe TBIs. The objective of this study is to determine if standardized treatment of severe TBIs decreases the incidence of intracranial hypertension.

Methods: This study will be submitted to the Institutional Review Board for approval. The trauma registry will identify patients who were admitted with a diagnosis of severe TBI (Glasgow Coma Scale of 8 or less) pre- and post-implementation of the TBI protocol at our institution. Patients treated prior to implementation of the protocolized approach to treatment of TBI will be matched to post-implementation patients based on Injury Severity Score (ISS) and mechanism of injury. Patients less than 18 years of age or those with severe TBIs who expired within 48 hours of hospital admission will be excluded. The following information will be collected: demographic information, incidences of elevated ICPs, cerebral perfusion pressure (CPP), use of hyperosmolar therapy, Glasgow Outcome Scale, and Sequential Organ Failure Assessment (SOFA) score. The primary outcome will be incidence of elevated ICPs. Secondary outcomes will include incidence of CPP < 60 mmHg, use of hyperosmolar therapy, ICU and hospital length of stay, in-hospital mortality, days of mechanical ventilation, time to DVT prophylaxis, Glasgow Outcome Scale, and compliance to the severe TBI pathway.

Poster Title: Evaluation of pharmacist assisted auto-substitution of long acting inhalers to nebulized medications

Primary Author: Emily Foster, University of Tennessee Medical Center, TN; Email: ekfoster@utmck.edu

Additional Author(s):
Laura Bullock
Danielle Dennis
Jennifer Mendez
Stacy Wells

Purpose: Novel inhalers for the management of pulmonary/respiratory diseases are gaining FDA approval rapidly. The large number of new inhalers has been challenging from a formulary management standpoint. Many institutions are transitioning from maintenance inhalers to comparable nebulized medications for hospitalized patients. Current data on auto-substitution to nebulizers has shown theoretical cost savings analysis, but is limited on effects on patient outcomes. Our objective is to implement a pharmacist initiated auto-substitution from long-acting inhalers to long-acting nebulized medications at our 609 bed academic medical center. Following the initiation process, we will compare patient outcomes as well as hospital cost data.

Methods: This study will be submitted to the Institutional Review Board for approval. Implementation of the pharmacist driven auto-substitution is anticipated to begin in January 2017. This pilot study will be conducted as a pre- and post-implementation, retrospective cohort. This study will include patients 18 year or older, admitted to select acute care floors, who have active orders for long-acting inhalers (excluding tiotropium or patients with trachs). The pre- and post-implementation groups will be identified via electronic medical record by active orders for long-acting controller inhalers and long-acting nebulized medications respectively. Our primary outcome will compare the two groups length of stay based on the month of admission (ex. January 2016 compared to January 2017). Secondary outcomes include: 30 day readmission, number of respiratory therapy administered treatments per
patient, duplicate inhaled therapies, transfers to critical care unit or higher level of care, the need for PRN inhalers and cost. Other data collection will include baseline demographics such as: age; sex; race; comorbidities; vital signs; primary diagnosis code; data to collect severity score.

Poster Title: Use of Diltiazem versus Amiodarone in patients with new onset atrial fibrillation/atrial flutter and a history of heart failure with reduced ejection fraction

Primary Author: Rachael Broscious, University of Tennessee Medical Center, TN; Email: rbroscious@utmck.edu

Additional Author(s):
Travis Fleming
Kimberly Keller

Purpose: Atrial fibrillation and heart failure, recently described as a dual epidemic, are two of the most common cardiovascular diseases and often concurrent comorbidities. The ACC/AHA atrial fibrillation guidelines recommend rate control strategies first line, but discourage the use of nondihydropyridine calcium channel blockers in patients with coexisting heart failure. Data evaluating their use in this population, however, is lacking. The primary aim of this research is to determine if diltiazem use in heart failure patients increases overall length of hospital stay. Secondary aims of this research are to evaluate treatment success, acute worsening of heart failure, and adverse drug reactions.

Methods: This study is designed as a retrospective chart review of approximately 300 patients with new onset atrial fibrillation/flutter and a history of heart failure with reduced ejection fraction. The sample size was determined to reach 80% power with an alpha of 0.05. The protocol will be submitted for Institutional Review Board approval. Data will be evaluated for all patients over 18 years old with new onset atrial arrhythmias and a history of heart failure with reduced ejection fraction who received either IV/PO diltiazem or amiodarone. Exclusion criteria will consist of patients with a history of atrial arrhythmias, heart failure with preserved ejection fraction, receipt of other rate or rhythm control agents first line, surgical or ablative procedure first line, contraindications to study medications, patients presenting with heart failure exacerbation, patients changing atrial fibrillation therapy within 12 hours of initiation, and cardiothoracic surgery patients. Demographic data will be collected including, but not limited to: comorbidities, QTc, LVEF and heart failure home medications. Data collected for the primary endpoint will include admitting diagnosis, admitting service, and length of hospital stay. Treatment success will be collected as a secondary outcome and measured by achievement of
average heart rate less than 80 beats per minute or return of normal sinus rhythm within 48 hours. Duration of treatment, diuretic use, inotrope initiation, and adverse drug reactions will also be evaluated.

Poster Title: Comparison of Intravenous and Oral Acetaminophen for Pain Reduction in Neurocritical Care Patients

Primary Author: Christopher McCown, University of Tennessee Medical Center, TN; Email: cmccown@utmck.edu

Additional Author(s):
Leslie Hamilton
Anthony Rowe
James McMillen

Purpose: Several studies have investigated differences between intravenous (IV) and oral (PO) acetaminophen administration in different patient populations with regard to analgesia, opioid use, and incidence of adverse effects. Most recently, a retrospective study of neurocritical care patients showed a significantly greater reduction in pain intensity 30 minutes after IV acetaminophen administration compared to PO. The purpose of this study is to prospectively examine the analgesic efficacy of IV versus PO acetaminophen in a neurocritical care population.

Methods: This is a single-center, prospective, double-dummy, randomized, placebo-controlled study to be conducted at a 609-bed academic medical center. Patients included in the study will be those presenting with a diagnosis of spontaneous intracranial hemorrhage (intracerebral hemorrhage, intraparenchymal hemorrhage, aneurysmal subarachnoid hemorrhage, intraventricular hemorrhage, subdural hematoma) enrolled within 12 hours of admission. Patients with no enteral access (PO or feeding tube), acetaminophen allergy, liver disease, and those weighing less than 50 kg will be excluded. Data collected will include age, gender, race, weight, intensive care unit (ICU) admitting diagnosis, pain scores before, 30 minutes after, and 24 hours after acetaminophen administration, opioid use and dose, and time to bowel movement. The primary endpoints of the study are the mean 24-hour Critical-Care Pain Observation (CPOT) score in intubated or sedated patients and the change in Visual Analog Scale (VIS) pain score 30 minutes after acetaminophen dose in non-intubated or non-sedated patients. Secondary endpoints include reduction in opioid equivalents, time to rescue analgesia,
time to bowel movement, adverse events, duration of mechanical ventilation, ICU length of stay, and hospital length of stay.

Poster Title: Impact of the sequence of norepinephrine and vasopressin discontinuation in patients recovering from septic shock

Primary Author: Benjamin Bredhold, University of Tennessee Medical Center, TN; Email: bbredhold@utmck.edu

Additional Author(s):
Shauna Winters
Leslie Hamilton
John Callison
Lauren Allen

Purpose: Although the 2012 Surviving Sepsis guidelines offer guidance on the initiation of norepinephrine and vasopressin in septic shock, they do not address the sequence of their discontinuation after patients have recovered from septic shock. The objective of this study is to assess the impact of the sequence of norepinephrine and vasopressin discontinuation on intensive care unit (ICU) length of stay.

Methods: This retrospective study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients with a diagnosis of sepsis and use of norepinephrine in combination with vasopressin. The following data will be collected: patient demographics, ICU length of stay, highest norepinephrine rate documented in each 24 hour period, total duration of norepinephrine, total duration of vasopressin, dose of norepinephrine when vasopressin was discontinued, dose of vasopressin when norepinephrine was discontinued, mean arterial pressure (MAP) at the time of norepinephrine discontinuation, MAP at the time of vasopressin discontinuation, lowest documented MAP within 24 hours after discontinuation of both agents, SOFA score, APACHE II score, and the use of corticosteroids. The primary endpoint will be to compare the ICU length of stay between patients in which norepinephrine or vasopressin was discontinued first, after combination of use in septic shock. Secondary endpoints include the dose of norepinephrine at which vasopressin was started, dose of norepinephrine at which vasopressin was stopped, incidence of hypotension within 24 hours upon discontinuation of the first agent, total vasoactive medication duration, and ICU mortality. Descriptive statistics will be used to analyze the data collected.

Poster Title: Antibiotic use in pediatric appendicitis

Primary Author: Amy DuPont, Williamson Medical Center, TN; Email: adupont@wmed.org

Additional Author(s):
Courtney Sutton
Deborah Armstrong

Purpose: Appendicitis is the most common surgical emergency in the pediatric population, with a high risk of infections and/or prolonged hospital stays if appropriate antibiotics are not utilized in the pre-operative and post-operative periods. The purpose of this study is to assess if the implementation of a pediatric-specific surgical order set increased the rate of appropriate antibiotic selection and weight-based dosing, decreased length of stay, and decreased occurrence of adverse outcomes in pediatric patients with appendicitis in a community hospital setting. The study will also evaluate the utilization of the surgical order set after implementation.

Methods: This retrospective chart review has been approved by the Institutional Review Board, and will evaluate patients 2 months to 17 years of age diagnosed with appendicitis and managed at WMC prior to and after implementation of a pediatric-specific order set. Patients will be identified through the electronic medical records via ICD 9 and 10 codes that reflect diagnosis of appendicitis. Data to be collected includes patient demographics, imaging results, initial laboratory values, perioperative antibiotic usage data, and adverse outcomes data, including surgical site infection, post-operative abscess formation, and post-operative small bowel obstruction. The study will compare the rate of appropriate antibiotic selection, rate of appropriate weight-based dosing, average length of stay, and rate of known surgical complications of the two study groups prior to and after implementation of the new order set. Appropriate antibiotic selection will be determined based on the current Pediatric Surgical Association guidelines. Appropriate weight-based dosing will be determined from tertiary pediatric dosing references.

**Poster Title:** Implementation of protocol-based sepsis therapy in a community hospital

**Primary Author:** Adrian Stephens, Williamson Medical Center, TN; **Email:** astephens@wmed.org

**Additional Author(s):**
Michael Wright
Deborah Armstrong

**Purpose:** Williamson Medical Center implemented a sepsis initiative in September 2015. The initiative included extensive nursing and provider education, nurse driven sepsis screening, and the development of order sets that reflect the recommendations of the Surviving Sepsis Campaign. The goal of this retrospective study is to evaluate the implementation of a guideline-based severe sepsis and septic shock treatment protocol. We will compare patient outcomes one year before and one year after implementation.

**Methods:** This retrospective chart review will evaluate patients 18 years and older who developed severe sepsis or septic shock. We will assess mortality, time to appropriate antibiotics, and total intravenous fluid volume received by patients treated after the implementation of a protocol-based sepsis order set compared to a historical control group of patients treated prior to implementation. Compliance with the order set will be evaluated and we will also compare the mortality rates of subgroups with a history of heart failure and chronic kidney disease due to their perceived risk for iatrogenic fluid overload. The intervention group will include patients treated one year post-implementation of the sepsis initiative (10/1/2015-9/30/2016) and the control group will include patients treated one year prior to implementation (10/1/2014-9/30/2015). ICD-9-CM and ICD-10-CM codes will be used to identify adult patients diagnosed with severe sepsis or septic shock in the Williamson Medical Center Electronic Health Record. This study was submitted to the Institutional Review Board for approval.

**Poster Title:** Impact on appropriate pneumococcal vaccine ordering following an enterprise-wide clinical decision support tool implementation

**Primary Author:** Erica Feinberg, HCA Management Services/University of Tennessee College of Pharmacy, TN
; Email: erica.feinberg@hcahealthcare.com

**Additional Author (s):**
Connie Saltsman
Jennifer Harris
Will Cooper

**Purpose:** The Advisory Committee on Immunization Practices (ACIP) provides recommendations for the use of pneumococcal vaccines. These recommendations have become more complicated in recent years based on patient characteristics. CDS tools provide clinicians with a knowledge base and support to make appropriate clinical decisions. At the Hospital Corporation of America (HCA), a clinical decision support (CDS) tool was developed to assist healthcare providers in ordering the appropriate pneumococcal vaccination for patients. The study objective is to determine change in percentage of patients ordered appropriate pneumococcal vaccine after new clinical decision support screens were implemented.

**Methods:** This study will be submitted to the Institutional Review Board for approval. A retrospective review will be conducted on patients who received screening for pneumococcal vaccination admitted to HCA facilities using Meditech 5.6. This study will exclude all pregnant patients. Data will be collected from both the electronic health record and the HCA data warehouse. As well as purchasing history for pneumococcal vaccinations. The following data will be collected including patient’s age, prior vaccination status, co-morbid conditions, vaccine contraindications, vaccination ordered, vaccine administered. Two groups will be compared to assess the appropriateness of the vaccine ordered. The first group will be assessed prior to updated CDS screens and the second group will be assessed after the implementation of the CDS screens.

**Session-Board Number:** 8-303  
**Poster Title:** Fluoroquinolone use after Antimicrobial Stewardship Program implementation  
**Primary Author:** Ashley Feik-Campbell, Baylor Scott & White All Saints Medical Center, TX;  
**Email:** ashley.feik@me.com  

**Additional Author(s):**  
Keri Simon  

**Purpose:** Resistance to fluoroquinolones is rising each year and their use is often associated with serious adverse events. In light of this, the FDA has issued a new black-box warning (BBW) regarding the use of fluoroquinolones and recommends using alternative agents for acute sinusitis, acute bronchitis and uncomplicated urinary tract infections (UTIs). Reducing the use of fluoroquinolones may limit the emergence of resistance and avoid associated adverse events. The purpose of this study is to determine if the implementation of an Antimicrobial Stewardship Program (ASP) will decrease the overall use of fluoroquinolones at a 574-bed community based hospital.  

**Methods:** This study will be submitted to the Institutional Review Board (IRB) for approval. An electronic medical record system will be used to identify patients who have been treated with a fluoroquinolone for a suspected or confirmed infection during the same 3-month time frame before and after the implementation of the ASP. The following data will be collected: patient demographics, allergies, length of stay, antibiotic start date, antibiotic stop date, and concomitant antibiotic use. If available, indication, specimen type, current and previous culture results, sensitivities, 30-day readmission and 30-day mortality data will also be collected. The electronic medical record will be reviewed, if necessary, to determine the type of suspected or confirmed infection, risk factors for resistant organisms, recent antibiotic therapy, and potentially associated adverse events. Intervention documentation will be reviewed to determine if pharmacist recommendations were accepted or denied and any therapeutic changes that resulted from this intervention. All data will be recorded without patient identifiers to maintain patient confidentiality. A comparison of overall fluoroquinolone use prior to and after implementation of an ASP will be compiled upon reviewing the number of patients treated with levofloxacin or ciprofloxacin, appropriateness of therapy, associated adverse events, days of fluoroquinolone therapy and days of total antibiotic therapy.

**Poster Title:** Clinical impact on empiric carbapenem use in the emergency department and intensive care units after implementation of antimicrobial stewardship and a clinical decision support tool

**Primary Author:** Brent Ottarski, Baylor Scott & White All Saints Medical Center - Fort Worth, TX; 
**Email:** brent.ottarski@bswhealth.org

**Additional Author (s):**
Sunaina Rao
Shelley Simon

**Purpose:** Increasing concern for resistance to carbapersens, particularly with carbapenem-resistant Enterobacteriaceae, drives the need to reevaluate carbapenem use. Effective January 1, 2017, The Joint Commission’s new Medication Management standard 09.01.01 requires antimicrobial stewardship in hospitals and it is expected that the Centers for Medicare and Medicaid Services will soon require the same as a condition of participation. This study aims to assess the clinical impact of an antimicrobial stewardship program and a clinical decision support tool on minimizing the empiric use of carbapenem in the emergency department and intensive care units at a 574-bed community hospital.

**Methods:** This study will be submitted to the Institutional Review Board for approval. First, the electronic medical record system will identify patients that were started empirically on any carbapenem in the emergency department or intensive care units from October 2015 to December 2015. The following data will be retrospectively collected: patient demographics, indication for carbapenem use, source or suspected source of infection, duration of carbapenem therapy, previous and concomitant antibiotic use, and documented allergies to beta lactams. If available, culture and susceptibility data, culture history, incidence of Clostridium difficile, 30-day readmission, and 30-day mortality data will be collected. Data will be collected for a duration of three months after the implementation of an antimicrobial stewardship program and a clinical decision support tool in September 2016. The primary outcome measure is duration of carbapenem therapy. Secondary outcomes measures will include C. difficile rates, lengths of stay, 30-day readmission rates, and 30-day mortality rates. All data will be recorded without patient identifiers to maintain confidentiality.

Poster Title: Evaluation of pharmacist involvement in Medicare Wellness Visits

Primary Author: Tram Tran, Baylor Scott & White Health, TX; Email: tramtran98@gmail.com

Additional Author(s):
Heather Miller

Purpose: The annual Medicare Wellness Visits (MWVs) are cost-covered visits for Medicare beneficiaries that focus on preventive health measures. Although medication reconciliation is a required component of the MWVs, pharmacists are rarely involved in conducting these visits. Furthermore, medication-related problems are frequently cited as a cause for increased morbidity in Medicare beneficiaries. As drug therapy experts, pharmacists can potentially help identify drug therapy problems to promote more safe and effective medication regimens. In order to advocate pharmacist involvement in MWVs, this study will be comparing drug therapy problems identified by pharmacists during MWVs compared to non-pharmacist providers.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients who are due for their MWVs. The patient will be seen by a pharmacist for medication reconciliation. The patient will be provided with medication counseling and drug therapy recommendations will be documented. The data to be collected will include number of drug therapy problems identified and categorized as indication, effectiveness, safety, and compliance. The number of drug therapy problems identified by the pharmacist will be then compared to those identified by a non-pharmacist provider conducting MWVs. All data will be recorded without patient identifiers and a consent form will be provided to all patients prior to each MWV led by pharmacist.

Poster Title: A system-based quality improvement focus on accurate patient weights

Primary Author: Alyssa Sinkov, Baylor Scott & White Health, TX; Email: megha.patel@irmc.cc

Additional Author(s):
Jason Trahan
Carp Daniel

Purpose: The Institute for Safe Medication Practices released the Targeted Medication Safety Best Practices for Hospitals in 2014 and a revision in 2016. The revision placed an emphasis upon the importance of measuring and documenting accurate patient weights to avoid significant medication errors. The best practice statement is two-fold. Patients should be weighed upon each encounter, avoiding the use of stated, estimated or historical weights. Second, patient weights should be measured and documented in metric units only. The objective of this study is to design, implement, and sustain such practices in a large, not-for-profit health system in Texas.

Methods: A representative sampling of operational, cultural, and practice data regarding the measurement and documentation of patient weights will be collected for departments and facilities throughout Baylor Scott & White Health System utilizing a standard survey tool. Upon the completion of data collection, an Ishikawa diagram will be utilized to identify factors contributing to errors involving inaccurate patient weights. A multidisciplinary focus team, including pharmacists, nurses, physicians, human factors engineers, biomedical engineers, and supply chain employees will be formed to prioritize changes to the current processes through the use of a failure modes and effect analysis (FMEA) matrix and assignment of risk priority numbers.

Joseph Cantey  

**Purpose:** There are a significant number of studies identifying the benefits of Antimicrobial Stewardship Programs (ASP) in adult hospitals, but considerably fewer are available for pediatric institutions. The purpose of this study is to evaluate the integration of MedMined® as a tool for improving the ASP of our clinical practice.

**Methods:** This study will be submitted to the IRB for approval. Prior to the evaluation of this tool, clinical pharmacists at Baylor Scott & White McLane Children’s Medical Center were re-educated on the appropriate use and documentation within MedMined. The MedMined program will be used to identify patients on greater than 48 hours of antimicrobial therapy and pharmacists will evaluate the drug therapy for appropriateness and document their interventions. The primary outcome is categorizing and quantifying interventions made through the MedMined alert system over a six month period. The secondary outcomes for this study are change in drug cost and length of therapy per 1000 patient days for vancomycin, ceftriaxone, and piperacillin-tazobactam. The drug cost and length of therapy will be compared to the preceding year when MedMined was not in use.

Poster Title: Impact of pharmacy residents and students on patient outcomes in a smoking cessation program at outpatient charity clinics: a retrospective study

Primary Author: Rolake Kuye, Baylor Scott and White, TX; Email: rolake.kuye@bswhealth.org

Additional Author(s):
Peterson Monestime
Amulya Tatachar
Kiara Thomas

Purpose: A continuous quality improvement study was conducted at Baylor Scott & White charity outpatient clinics to assess the impact of pharmacy-delivered smoking cessation services. Twenty-one percent of patients self-reported smoking cessation and 42 percent self-reported reduction in cigarette use. While outcomes were positive, the study identified inconsistent follow-up of smoking cessation consults due to high clinic workload and an understaffed pharmacy team. To address this, pharmacy residents and students were integrated into the smoking cessation workflow. The objective of this study is to examine the impact of smoking cessation services provided by preceptors, pharmacy residents and students.

Methods: Institutional Review Board approval pending. This retrospective chart review will be conducted from July 2016 to October 2016 on patients enrolled in the smoking cessation program at three outpatient clinics receiving the highest number of smoking cessation referrals. Initial smoking cessation consultation includes assessment of smoking status and readiness to quit, review of non-pharmacologic and pharmacologic therapies, and implementation of individualized smoking cessation treatment plans. Follow up calls allow for further counseling including relapse prevention strategies, discussion of medication use, and motivational interviewing. The following data will be collected: patient age, sex, ethnicity, race, self-reported smoking status, quit stage, self-reported smoking cessation status, pharmacologic therapy being used, and number of follow-up smoking cessation consultations. The primary outcome is self-reported smoking cessation rates. Secondary outcomes include number of follow-up visits and self-reported reduction in total number of cigarettes per day. Primary and secondary outcomes will be compared to pharmacist interventions on smoking cessation prior to integration of pharmacy residents and students in the smoking cessation program.

**Purpose:** The beneficial outcomes of anticoagulation therapy depend on achieving and maintaining optimal INR therapeutic range. There is growing evidence showing improvement in anticoagulation management by pharmacists as compared to usual care. The purpose of this study is to compare pharmacists’ impact on anticoagulation outcomes to standard of care.

**Methods:** Investigational IRB approval pending. This retrospective chart review study will be conducted from January 1, 2016 through August 31, 2016 at Baylor Scott & White charity anticoagulation clinics. In March 2016, clinical pharmacists shared responsibility with medical assistants and nurses for anticoagulation management. The following data will be collected: patients’ demographics, INR goal range, time in therapeutic range, pharmacist interventions, adverse events, hospital and emergency admission rates, and medication adherence. The primary outcome of the study is percentage of time patients’ INR was in therapeutic range (TTR). Secondary outcomes include frequency of adverse events, emergency room visits and hospitalizations related to anticoagulation, number of dose adjustments made, and adherence to warfarin therapy.

**Conclusion:** N/A
Purpose: Opportunistic infections by Clostridium difficile are the most common cause of nosocomial diarrhea. Per Infectious Diseases Society of America C. difficile guidelines, the severity of the disease and the initial treatment is based upon a collection of patient factors, one of which is an elevated white blood cell count. However, in neutropenic patients this risk factor cannot be utilized. The purpose of this evaluation is to examine what other criteria will be correlated to severe disease in neutropenic patients.

Methods: Once approved by the Institutional Review Board, this retrospective review will examine neutropenic cancer patients diagnosed with C. difficile associated diarrhea and use regression analysis to ascertain what patient characteristics are linked to severe outcomes. Primary endpoints defining severe disease include Pseudomembranous colitis, recurrence of C. difficile infection within 60 days, or any of the following in which C. difficile infection was the primary cause: death, colectomy, or admission to the intensive care unit. Inclusion criteria are: cancer patients who have received chemotherapy and within 30 days developed both an absolute neutrophil count less than 2000 cells per liter and C. difficile infection; or cancer patients who have an underlying neutropenia during an active C. difficile infection. Data points to be collected are as follows: malignancy, age, gender, history of COPD or diabetes, type of chemotherapy and antibiotic use in the past 30 days, albumin, lactate, creatinine, temperature, length of hospital stay prior to positive C. difficile PCR, date of last hospitalization, acid suppression therapy in the past 30 days systemic steroid use in the past 30 days, history of inflammatory bowel disease, and initial C. difficile therapy (drug, dose, frequency, duration).

Poster Title: Impact of pharmacists performing medication reviews during hospital discharge follow-up visits at a family medicine clinic

Primary Author: Vicente Aparicio, Baylor Scott and White PGY1 Community Pharmacy Residency, TX; Email: vicente.aparicio@bswhealth.org

Additional Author (s):
Delaney Ivy
Paul Godley

Purpose: Hospital discharge visits are an important part of the transitional care process where drug therapy problems can be addressed by pharmacists. Studies have shown that readmission rates for patients with medication discrepancies were twice as high as those observed in patients without medication discrepancies. The purpose of this study is to identify the average number of drug therapy problems a pharmacist can identify per patient during hospital discharge follow-up visits. The types of drug therapy interventions will also be analyzed. The secondary outcome will be the number of patients that were readmitted within 30 days of the hospital discharge visit.

Methods: This study will be submitted to the Baylor Scott & White Institutional Review Board for approval. Patients will be scheduled for a hospital discharge follow-up visit at a family medicine clinic. During the first 10 minutes of the visit, the pharmacist will perform a complete medication review to identify potential drug therapy problems and medication discrepancies, provide patient education, and make recommendations to the physician if drug therapy modification is needed. The pharmacist will document all interventions in the patient’s electronic medication record, and the data for these will be compiled for every patient. The following data will be collected: the number of interventions performed, the type of intervention that was performed (e.g. patient education on drug administration, incorrect drug, incorrect dose, therapeutic duplication, drug therapy needed and not provided), reason for hospitalization, patient age, gender, number of medications at hospital discharge, and the therapeutic class of the medications involved in discrepancies. The number of interventions performed during these visits during the study period will be counted, and they will be averaged over the number of patients that were seen. The study’s secondary outcome will be
the number of readmission rates among this group of patients. Furthermore, data collected from patients who are readmitted will be analyzed in order to find potential risk factors for hospital readmission.

**Poster Title**: Impact of pharmacist remote order verification in a quaternary academic medical center

**Primary Author**: Joshua Blackwell, Baylor St. Luke's Medical Center, TX; **Email**: joshuaabellblackwell@gmail.com

**Additional Author(s)**:
Divya Varkey
Trina La
Houng Pham
David Wallace

**Purpose**: According to American Society of Health System Pharmacy, pharmacy departments in comparison to other hospital departments have unique operational budgets with < 20% related to personnel expenses and >80% for medications and supplies. Rising medication costs require pharmacy leaders to be strategic in the delivery of patient care through their labor resources. Many rural hospital pharmacies implemented the labor cost-containment strategy of remote order verification (ROV) to provide 24/7 medication review; however, limited studies exist describing large academic medical centers using ROV. This study assesses ROV providing a standard of care within an academic medical center while improving pharmacy clinical services.

**Methods**: This is a quasi-experimental quality improvement study to determine the impact of remote order verification in a large academic medical center. Patients admitted during the study period will be divided into three groups: Group A (January 1 to February 28, 2016) – pre-implementation with all active clinical services; Group B (August 15 to October 15, 2016) – pre-implementation with suboptimal clinical services due to limited resources and no services in the outpatient heart failure clinic; and Group C (January 1, 2017 to February 28, 2017) – post-implementation with November being excluded as the washout period. Clinical services include rounding, warfarin and vancomycin consult services, patient profile reviews, and discharge counseling. To determine the pharmacist-led discharge counseling capture rate, interventions labeled as “discharge counseling” will be reviewed in the electronic health record (EHR). Also pharmacists’ interventions documented within the EHR will be quantified and evaluated throughout the study. The number of orders verified per pharmacist per hour will be assessed...
as a measure of productivity. The quality of ROV will be assessed and analyzed through reported medication errors within the EHR and internal medication reporting system. A survey containing items on a 10-point Likert scale will be used to measure nursing satisfaction with the pharmacy department (Groups B and C). All measurements will be compared between groups to analyze the impact of remote order verification.

**Poster Title:** Prescribing patterns of antipsychotics and associated outcomes in intensive care unit patients 65 years and older

**Primary Author:** Okikoluwa Arojo, Baylor St. Luke's Medical Center, TX; **Email:** oarojo2@stlukeshealth.org

**Additional Author (s):**
Kimberly Putney
Meghna Vallabh
Greg Laine

**Purpose:** In 2005, the FDA issued a notice alerting healthcare professionals to the increased risk of death in elderly patients who are 65 years or older with dementia-related psychosis treated with atypical antipsychotics. In 2008, the alert was updated to include conventional antipsychotics. Currently, there is a wide range of use of antipsychotics; however, when initiated in the intensive care unit (ICU), they are used to treat patients with delirium, agitation or insomnia. This study aims to assess the prescribing patterns of antipsychotics in elderly patients admitted to either the medical or neurology ICU at our institution and their outcomes.

**Methods:** A retrospective study will be performed to identify elderly patients who are 65 years or older admitted to the medical or neurology ICU at the study institution between January 2015 through December 2015 who received an antipsychotic. The antipsychotics in this study include aripiprazole, haloperidol, olanzapine, quetiapine, and ziprasidone. The following data will be collected: ICU admission and discharge date, age, weight, height, race, sex, drug, dosing, indication, ICU and hospital length of stay, and CAM-ICU documentation. In addition, patients’ home medication histories will be examined for prior antipsychotic exposure. If available, baseline and post-antipsychotic exposure electrocardiogram data will be collected to measure for QTc prolongation. The primary endpoint is all-cause mortality. Secondary endpoints include ICU and in-hospital length of stay, change in QTc from baseline, rates of CAM-ICU documentation, and continuation of antipsychotics after transfer of care or discharge. Prescribing patterns will be assessed using the above collected data. All identifiable patient data will be recorded and maintained confidentially.

**Poster Title:** Narrow spectrum empiric antimicrobial therapy for ventilator-associated pneumonia in critically ill trauma patients

**Primary Author:** Holly Krohn, Baylor University Medical Center, TX; **Email:** holly.krohn@bswhealth.org

**Additional Author (s):**
Jennifer Roth
Geoffrey Funk
Michael Foreman

**Purpose:** Ventilator-associated pneumonia is a common nosocomial infection. Empiric broad spectrum antimicrobials are frequently prescribed upon suspicion of pneumonia. However, recent evidence-based guidelines suggest that patients who develop pneumonia less than 5 days into hospitalization are at lower risk of multi-drug resistant organisms compared to those with onset of pneumonia greater than 5 days. Additionally, incidence of pneumonia due to multi-drug resistant pathogens has not been extensively studied in traumatically injured patients. This study aims to assess the efficacy of utilizing a protocol that promotes narrow spectrum empiric antimicrobials for early ventilator-associated pneumonia in critically ill trauma patients.

**Methods:** A single-center, retrospective, quality assurance analysis will compare pre- and post-protocol respiratory culture results of adult trauma patients with ventilator-associated pneumonia. Patients will be classified as early [hospital days 0 to 5] or late [hospital days 6 or more] onset of pneumonia. The primary outcome will be the appropriateness of initial antimicrobial therapy based on identified pathogens and susceptibilities on respiratory cultures. Secondary outcomes include length of stay in the intensive care unit, 30 day all-cause mortality, antibiotic days of therapy, antibiotic-free days, percentage of antimicrobials utilized with activity against pseudomonas and MRSA, and rates of clostridium difficile infection. All data will be analyzed for normality of distribution. Summary statistics will be reported using measures of central tendency and statistical significance will be determined using the appropriate parametric tests or their non-parametric analogs.

Poster Title: Empiric micafungin therapy and risk factors for candidemia

Primary Author: Amy Carr, Baylor University Medical Center, TX; Email: amy.carr@bswhealth.org

Additional Author(s):
Peter Colley
Mezgebe Berhe

Purpose: Currently, risk factors for candidemia are non-specific and qualify many patients for empiric antifungal therapy. Identification of more precise risk factors could promote more judicious use of empiric micafungin. Ultimately, this could decrease antifungal exposure, the development of resistant species, and associated costs. The objective of this study is to identify risk factors predicting candidemia in patients at Baylor University Medical Center in order to develop specific criteria to qualify patients for empiric micafungin therapy.

Methods: This retrospective case control will be submitted to the Institutional Review Board for approval. Using clinical surveillance software (MedMined, BD), patients with positive blood cultures for Candida species and patients on empiric micafungin for greater than 3 days will be identified. Patients with blood cultures positive for both Candida and bacteria will be excluded. Bone marrow transplant patients on prophylactic posaconazole will also be excluded. The electronic medical record will be used to collect the following data: age, gender, diabetes mellitus, cirrhosis, hemodialysis, immunosuppressant use, uncontrolled HIV/AIDS, central venous catheter, hospitalization within 90 days, antibiotic use within 30 days, antifungal exposure within 30 days, candidemia (organism, susceptibilities), total parenteral nutrition, recent surgery, multifocal Candida colonization, gastrointestinal perforation, severe sepsis, 1,3-beta-D-glucan result, duration of hospitalization prior to positive culture, culture collection site, length of stay, ICU length of stay, and 30-day mortality. Candida score will be calculated. All data will be analyzed for normality of distribution. Statistical significance will be determined using the appropriate parametric tests or non-parametric analogs. This data will be utilized to compare the two patient groups and identify which factors are the strongest predictors of candidemia.

Poster Title: Application of the 4T Score in patients receiving Extracorporeal Membrane Oxygenation (ECMO) with suspicion of Heparin Induced Thrombocytopenia (HIT)

Primary Author: Ellen Colman, Baylor University Medical Center, TX; Email: ellen.colman@bswhealth.org

Additional Author(s):
Kathryn Cox
Sharnae Stevens
Omar Hernandez
Gary Schwartz

Purpose: Anticoagulation is required for patients receiving extracorporeal membrane oxygenation (ECMO). Unfractionated heparin is the anticoagulant of choice with ECMO therapy. Thrombocytopenia may occur with heparin administration and/or ECMO. The 4T score is a strategy commonly used to predict probability of heparin induced thrombocytopenia (HIT). The 4T score has been reviewed in critically ill patients, but has never been looked at concomitantly in the ECMO population. The primary objective of this study is to determine the value of 4T scores in patients receiving ECMO, as it compares to 4T scoring in the critically ill.

Methods: This study will be submitted for Institutional Review Board approval. This retrospective chart review will include patients at Baylor University Medical Center in Dallas who were greater than 18 years old, who received ECMO, and had a HIT antibody assay sent from July 2012 through July 2016. We will gather our population from the current ECMO database which has 332 patients. The primary objective is to evaluate 4T scores in ECMO patients versus critically ill, non-ECMO, case matched patients. Secondary objectives will include mean 4T score and length of ECMO with patients having SRA positive versus SRA negative results. In addition, there will be an assessment of the positive and negative predictive value defined as the percentage of patients with HIT and a 4T score greater than or equal to six or less than or equal to 3 respectively. Data will be collected and recorded in a confidential manner, and clinical outcomes data will be summarized to mitigate patient identifiers. Data will include baseline demographics plus laboratory values including platelets, PT-INR, D-dimer, FDP, WBC, CRP, IL-6, and optical density.
The 4T score will be manually calculated. Summary statistics will be reported with the appropriate measures of central tendency. Appropriate parametric tests or non-parametric equivalent tests will be used. A P-value of less than 0.05 will indicate a statistically significant difference.

Poster Title: Effect of risk-stratified mycophenolate mofetil dosing in heart transplantation outcomes

Primary Author: Joanna Wu, Baylor University Medical Center, TX; Email: joanna.wu@bswhealth.org

Additional Author(s):
Teena Sam
Jose Mendez
Shelley Hall

Purpose: Mycophenolate mofetil (MMF) is considered the antimetabolite of choice after transplant; however, dosing can pose a therapeutic challenge. While the recommended dosage for MMF after heart transplant is 1.5 gram twice daily, in practice, dosing is commonly reduced due to intolerance. Safety and efficacy of reduced dose MMF regimens remains unclear. Due to increased infection with conventional MMF dosing, our center switched to a tailored approach based on age where low risk patients received 0.5 gram twice daily and high risk 1 gram twice daily. We sought to evaluate the impact of risk-stratified MMF dosing on outcomes after heart transplantation.

Methods: This study will be submitted to the Institutional Review Board for approval. Patients who received a heart transplant between January 2013 and January 2016 will be retrospectively reviewed. Demographic data including recipient age, gender, race and immunosuppressive regimen history will be collected. If available, cold ischemic time, human leukocyte antigen (HLA) mismatches and panel reactive antibody (PRA) levels will be collected. Exclusion criteria will include multi-organ transplant, ongoing active infection or history of extensive liver disease. The primary objectives are to assess rate of biopsy-proven acute rejection and mortality. Secondary objectives will assess adverse effects associated with MMF including neutropenia, thrombocytopenia, and opportunistic infection. Fisher’s exact or chi-squared test will be used to analyze nominal data. Continuous data will be analyzed using the student’s t-test or its non-parametric analog. All patient data will be de-identified to maintain confidentiality.

Poster Title: Clinical outcomes of analgesic-first sedation versus benzodiazepine-first sedation in mechanically ventilated patients

Primary Author: Rosemary Amponsaa-Korang, CHI St Luke's Health - The Woodlands Hospital, TX; Email: nansaa2@gmail.com

Additional Author(s):
Ran Xu
Hanh-Nhi Duong
Kayleigh Emerson
Elizabeth Lee

Purpose: Mechanically ventilated patients frequently experience pain and agitation, and require analgesics and sedatives for comfort, to mitigate stress and anxiety, and to improve compliance with mechanical ventilation. Studies, mostly from large tertiary institutions have shown that analgesic-based sedation is associated with shorter mechanical ventilation time and intensive care unit (ICU) length of stay compared with benzodiazepine-first sedation. The objective of this study is to evaluate and compare clinical outcomes in mechanically ventilated patients managed by analgesic-first sedation versus benzodiazepine-first sedation in an acute care community hospital.

Methods: This is a retrospective cohort study at an acute care community hospital. The inclusion criteria are adult patients admitted to the ICU from January 2016 to September 2016, mechanically ventilated for 48 hours or longer, and requiring continuous administration of analgesia and sedation. The exclusion criteria include pregnant or lactating women, patients who received neuromuscular or epidural blockade, history of opioid, sedative or alcohol abuse, major surgery within 3 days of ICU admission, metabolic encephalopathy, anticipated death during ICU stay, palliative care patients refraining from or refusing full life support, and induced hypothermia. The primary endpoint is duration of mechanical ventilation. The secondary endpoints are pain and sedation scores, and ICU and hospital length of stay (LOS). Data collected include demographic information, hospital LOS, duration of mechanical ventilation, daily doses of analgesics and benzodiazepines, and pain and sedation scores. Descriptive statistical analyses will be performed, and appropriate statistical testing will be applied to
compare the clinical outcomes of the analgesic-first sedation versus benzodiazepine-first sedation groups. The study has been submitted to Institutional Review Board for approval.

**Results:** N/A

**Conclusion:** N/A
Purpose: The most common manifestation of sickle cell disease and the reason for recurrent emergency department visits and hospital admissions is acute pain crisis, also known as vaso-occlusive crisis. Vaso-occlusive crisis will effect almost every patient with sickle cell disease during their life-time and usually presents as an abrupt onset of pain, varying from mild aches to debilitating pain. The purpose of this study is to evaluate intravenous fluid resuscitation and pain management for patients with sickle cell disease who present to the emergency department at a large academic medical center.

Methods: This study, which will be submitted to the Institutional Review Board for approval, is a single-center, retrospective chart review from September 1, 2015 to August 31, 2016 of all patients with any diagnosis of sickle cell type with suspected vaso-occlusive crisis upon presentation to the emergency department. The primary endpoint is the difference in emergency department length of stay in patients who were administered pain medication and intravenous fluids within one hour of emergency department registration versus patients who were not administered pain medication and intravenous fluids within one hour after emergency department registration. The secondary endpoints are the number of emergency department admissions for patients taking hydroxyurea versus patients not taking hydroxyurea, the number of hospital admissions in patients taking hydroxyurea versus patients not taking hydroxyurea, emergency department length of stay for patients who left the emergency department against medical advice versus patients discharged by the provider, and the number of patients admitted to the hospital versus patients discharged by the provider from the emergency department.

Poster Title: Assessment of the rate of rejection with brand Prograf versus generic tacrolimus

Primary Author: Oluwaseyi Fasiku, CHI St. Luke’s Health - Baylor St. Luke’s Medical Center, TX; Email: sfasiku@stlukeshealth.org

Additional Author(s):
Melissa Manson
Raymond Yau

Purpose: Immunosuppressants for the prevention and treatment of organ rejection have been fundamental in establishing solid organ transplantation as the treatment of choice for many patients with end-stage organ failure of vital organs, including the kidney, liver, heart, and lungs. The contribution of tacrolimus to effective immunosuppression in solid organ transplantation is well established. The use of generic tacrolimus has become widely available and represents a viable cost-saving opportunity in minimizing post-transplant expenses and increasing medication compliance. The objective of this study is to determine the difference in rejection rates immediately post-transplant in patients receiving brand Prograf or generic tacrolimus.

Methods: This will be a single-center retrospective, observational study and will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify organ transplant recipients that received brand Prograf® or generic tacrolimus immediately post-transplant at CHI St. Luke’s Health, Baylor St. Luke’s Medical Center between 01/2014 and 06/2016. Patients will be stratified based on the organ transplanted and time since transplant. Patients will be divided into two groups: those who received brand Prograf® and those who received generic tacrolimus. Data to be collected will include: patient age, gender, organ transplanted, PRA levels, Induction regimen, maintenance regimen, and biopsy proven rejection during the first 3 months of transplant. All data will be recorded without patient identifiers and maintained confidentially. Number of biopsy proven rejections will be calculated in each group. Study objectives will be answered using appropriate univariate and multivariate statistical techniques.

**Poster Title:** Evaluating the use of gastrointestinal prophylaxis in a liver transplant population  

**Primary Author:** Khuloud AlJoudi, CHI St. Luke’s Health - Baylor St. Luke’s Medical Center, TX;  
**Email:** khuloudaljoudi@gmail.com

**Additional Author(s):**  
Raymond Yau  
Mozhgon Moaddab

**Purpose:** Proton pump inhibitors (PPIs) or histamine-2 receptor blockers (H2RBs) are chosen for gastrointestinal ulcers prophylaxis in liver transplant patients. Previous studies suggested that H2RBs have similar efficacy and carry less infection-associated risks compared with PPIs. PPIs increase the risk of infection by altering gastric pH levels which allow bacteria to colonize in the gastrointestinal tract which can potentiate the risk of infection including Clostridium difficile and pneumonia. This study will be used to provide more data in terms of using PPIs compared to H2RBs in liver transplant population.

**Methods:** This is a retrospective, observational study evaluating liver transplant patients who were receiving PPIs or H2RBs at Baylor St. Luke’s Medical Center (from August 1, 2013 to August 1, 2016). The primary endpoint will evaluate the incidents of gastrointestinal bleeding and H2RBs tolerability. Secondary endpoints will assess infection rates including pneumonia and Clostridium difficile. Patient records from the hospital healthcare software “Epic”, will be reviewed following a data collection sheet. The data collection sheet will help us collect at least 100 liver transplant patients with 1:1 ratio in each study arm, using either PPIs or H2RBs. Individuals younger than 18 years old with recent or history of gastrointestinal bleeding with less than six months of treatment with PPIs are excluded from the study. The following data will be collected: patient age, gender, immunosuppressants, antibiotics used, comorbidities, and patients on mechanical ventilation. Other baseline data like white blood cell counts, maximum temperature, thrombocytopenia and imaging related to infection diagnosis will be involved. Data collected will be stored on a password protected Microsoft Office Excel 2007 spreadsheet and simple statistical method (mean, median) will be used in the analysis.

**Poster Title:** Assessing the Induction Immunosuppression Therapy at a Liver Transplant Center

**Primary Author:** Amal AlSomali, CHI St. Luke’s Health – Baylor St. Luke’s Medical Center, TX; Email: amal.a.alsomali@gmail.com

**Additional Author (s):**
Raymond Yau
Mozhgon Moaddab

**Purpose:** The aim of immunosuppression in liver transplantation is to balance the risk of organ rejection and drug toxicities. Patients generally receive potent and high intensity regimens intraoperatively and immediately post-transplant to prevent and minimize the risk of organ rejection. Therapies for immunosuppression consist of an induction and a maintenance phase. No guidelines have been set for induction therapy practices and the use of varies between different transplant centers. The aim of this project seeks to assess the safety and efficacy profile of induction agents, focusing on hydrocortisone compared to methylprednisolone.

**Methods:** This study will be submitted to Institutional Review Board for approval. This is a retrospective observational chart review of patients who received a liver transplant at CHI St. Luke’s Health – Baylor St. Luke’s Medical Center (BSLMC) from August 1, 2013 through August 31, 2016. A list of all patients receiving institution’s induction therapy with hydrocortisone or methylprednisolone who fit the inclusion and exclusion criteria was obtained from the electronic health record database. At BSLMC, patients can receive 1 gm of hydrocortisone intraoperatively at the anhepatic phase; however methylprednisolone has also been observed to be given in place of hydrocortisone. Information collected will include demographics (age, gender), indication for transplant, pertinent labs, induction agents and doses, adverse effects related to induction therapy, tacrolimus dose, time to therapeutic tacrolimus levels, and evidence of rejection.

**Poster Title:** Evaluation of warfarin dosing in patients with impaired renal function as compared to patients with normal renal function

**Primary Author:** Fahad AlDhahri, CHI St. Luke’s Health – Baylor St. Luke’s Medical Center, TX; Email: faldhahri@yahoo.com

**Additional Author (s):**
Ellen Yin
Maryam Bayat

**Purpose:** Warfarin remains the most widely used oral anticoagulant option for patients with end-stage renal disease (ESRD). Previous studies have shown that CKD and ESRD patients require an approximate dose reduction of 20% to maintain a therapeutic INR and may require less time to achieve a therapeutic INR compared to patients with normal kidney function. The objective of this study is to compare warfarin dosing requirements and time to reach therapeutic INR in patients with normal kidney function to patients with a creatinine clearance (CrCl) of < 30 mL/min (calculated via the Cockcroft-Gault equation) and/or patients on renal replacement therapy.

**Methods:** This study, which will be submitted to the Institutional Review Board for approval, is a single-center, retrospective, cohort observational study-evaluating patients who received warfarin therapy under pharmacy consulting services at CHI Baylor St. Luke’s Medical Center. All profiles of patients admitted between September 2013 and September 2016. The following data will be collected: Patient age, gender, actual weight, comorbidities diseases, drug interaction, indication, baseline lab data of hemoglobin, platelet, and INR, daily Warfarin dose, time to therapeutic INR, time to supratherapeutic INR and Is therapeutic INR keeping patient from discharge. All adult patients (≥18 years) hospitalized at CHI Baylor St. Luke’s Medical Center who received at least three days of warfarin therapy and followed by pharmacy consult service will be included. Exclusion criteria include patients with a baseline INR > 1.3, INR goal other than 2-3 and concurrent bivalirudin or argatroban therapy. The primary Endpoints: To compare the average daily dose of warfarin need to reach a therapeutic INR in patient with normal kidney function to that of patient with CKD or ESRD. Secondary Endpoints: To evaluate...
time needed to reach therapeutic INR, use of unfractionated heparin versus low-molecular weight heparin, number of patient with supra-therapeutic INRs, and bleeding events.

Purpose: The excessive use of antibiotics may increase patients’ exposure to potential adverse effects, affect bacterial resistance pattern, and contribute to increased healthcare cost. Previous studies demonstrate that procalcitonin (PCT)-based algorithm decreased antibiotic exposure in acutely-ill patients without adverse outcomes. However, evidence is unclear on how the utilization of PCT will impact clinicians’ decision to de-escalate or discontinue antibiotics. In this study, we aim to assess whether the guidance of PCT can reduce the length of antibiotic therapy in clinically stable patients with suspected sepsis and/or bacterial infection.

Methods: This is an observational study at a community acute care hospital from September 2016 to February 2017. Per medical staff approved protocol, PCT is ordered by clinicians for patients with suspected sepsis and/or bacterial infection in the emergency department, intensive care unit, and progressive care unit. Sepsis is defined by the 2012 International Guidelines for Management of Severe Sepsis and Septic Shock in this study. Inclusion criteria are non-pregnant patients 18 years or older with suspected sepsis and/or bacterial infection. Exclusion criteria include patients who have received antibiotics 24 hours prior to admission, presentation of severe cardiogenic shock, paraneoplastic syndromes, or viral/malarial infection. The primary endpoint is number of days exposed to antibiotics. The secondary endpoints are hospital length of stay, antibiotic-related adverse outcomes, and cost-benefit analysis. All outcomes are compared between patients with baseline PCT levels and historical control patients with similar characteristics, who were admitted without PCT levels. Data of eligible
patients are to be collected from Electronic Medical Records. Descriptive statistical analyses and appropriate statistical testing will be applied to determine significance. This study has been submitted to the Institutional Review Board for approval.

Poster Title: Prevalence of left atrial thrombus detection by transesophageal echocardiography in patients with atrial fibrillation/flutter undergoing catheter ablation: warfarin therapy versus target specific oral anticoagulants.

Primary Author: Priyam Patel, CHI St. Luke's Health - Baylor St. Luke's Medical Center, TX; Email: ppatel2@stlukeshealth.org

Additional Author(s):
Maryam Bayat
Ellen Yin

Purpose: Studies investigating the prevalence of a left atrial (LA) thrombus as detected by a transesophageal echocardiogram (TEE) in atrial fibrillation (AF)/atrial flutter undergoing catheter ablation (CA) are currently limited to patients taking warfarin. The primary purpose of this study is to compare the prevalence of a LA thrombus as detected by a TEE in AF/atrial flutter patients receiving warfarin versus TSOACs for at least three weeks prior to CA. Secondarily, this study will assess for the risk of bleeding, correlation of the CHA2DS2-VASC scores to reported bleeding and thrombotic complications, and all-cause mortality.

Methods: This study will be submitted to the Institutional Review Board for approval. This is a retrospective cohort study evaluating the presence of a LA thrombus in patients receiving warfarin versus TSOACs with a diagnosis of AF/atrial flutter undergoing a CA who were admitted between January 1, 2014 and August 31, 2016. Patients will be divided into two groups: those that took warfarin and those that took TSOACs. The following data will be collected for all patients: age; sex; race; documented past medical history; creatinine clearance; CHA2DS2-VASC score; HAS-BLED score and its parameters; AC regimen of either warfarin, apixaban, dabigatran, or rivaroxaban at home, prior to, and after CA; INR on day of TEE; duration of AC prior to admission; history of previous CA; and history of previous LA thrombi. Data from TTEs prior to CA will be reviewed for left ventricular size, LA size, LA volume, LA area, and presence of a LA thrombus. All documented complications will be collected. The primary objective is to assess for the prevalence of a LA thrombus as detected by a TEE in AF/atrial flutter patients on warfarin versus TSOAC patients undergoing a CA. The secondary objectives are to evaluate the incidence of bleeding among the warfarin group versus the TSOAC group,
correlate the calculated CHA2DS2-VASC scores to reported bleeding and thrombotic complications, and assess all-cause mortality.

Kimberly Putney

Purpose: Orthopedic surgeries, such as total hip arthroplasty (THA) and total knee arthroplasty (TKA), are associated with significant risk of venous thromboembolism (VTE). In 2011, the Food and Drug Administration approved rivaroxaban, a direct factor Xa inhibitor, to prevent VTE in adults undergoing THA or TKA. Although several trials have demonstrated superior efficacy of rivaroxaban against enoxaparin, a low-molecular-weight heparin, in preventing VTE, outcomes such as surgical site infection and reoperation remain inadequately studied. This study compares rates of surgical site infection within 30 days of THA or TKA in patients treated with rivaroxaban versus patients treated with other anticoagulants.

Methods: Prior to commencement, this study will be submitted to the Institutional Review Board for approval. Patients who underwent THA or TKA between September 2015 and September 2016 will be identified using ICD-9 codes in the Premier Hospital database. The electronic medical records of these patients will be retrospectively evaluated. Data collected will include: procedure and discharge date, surgeon name, procedure type, patient demographics, past medical history, and medications prior to surgery. Thromboprophylactic anticoagulation data including the agent used, dosing, timing of initiation and duration of therapy will be recorded. Additionally, the appropriateness of the thromboprophylaxis regimen will be determined based upon recommendations by the American College of Chest Physicians. Estimated blood loss during surgery, hematologic and coagulation data will be recorded at baseline, 24, 48, and 72 hours post-operation. Prophylactic antibiotic data including the agent used, dosing, timing of initiation and duration of therapy will be recorded. The appropriateness of antimicrobial prophylaxis will be determined based upon recommendations provided in the
Surgical Care Improvement Project guidelines. The primary endpoint is the occurrence of surgical site infection within 30 days of THA or TKA. The secondary endpoints are occurrence of deep venous thrombosis, pulmonary embolism, and major or minor bleeding.

Nicholas Beyda  
Hannah Russo

**Purpose:** Echinocandins are frequently recommended as first line treatment for most Candida species. However, controversy exists around the optimal antifungal choice for the treatment of C. parapsilosis infections, as this species exhibits innately higher MICs to echinocandins. Clinical evidence to support the use of one antifungal over another is lacking. The goals of this study are to assess the rates of antifungal susceptibility and describe the treatment patterns of C. parapsilosis candidemia at a large academic medical center. This study also aims to describe the clinical outcomes among patients treated with different antifungal agents, including azoles and echinocandins.

**Methods:** This is a retrospective cohort study evaluating patients with at least one positive blood culture for C. parapsilosis at CHI St. Luke’s Health Medical Center between December 2006 and January 2016. Patients with multiple Candida species in one culture will be excluded. Electronic medical records as well as the pharmacy and microbiology databases will be reviewed. The following data will be collected: demographics (age, sex, race, weight, height, past medical and surgical history), antifungal susceptibilities, antifungal treatment choices, antifungal dosing, microbiological clearance, laboratory data including white blood count and temperature, and mortality. Study objectives will be described using descriptive statistics.

**Purpose:** Blood and marrow transplant patients undergo hematopoietic stem cell (HSC) collection prior to autologous stem cell transplant. They often require proliferation and mobilization of their stem cells before this collection process. Proliferation is achieved through the use of granulocyte colony stimulating factors (G-CSF). However, after proliferation, stem cells are anchored in the bone marrow by a chemokine receptor interaction. Plerixafor (Mozobil®) disrupts the interaction and allows the stem cells to move into the blood stream so that successful collection can occur. Data for this medication in the pediatric population is limited although adult data shows good success. This case series illustrates the utilization of plerixafor in pediatric patients with metastatic neuroblastoma undergoing HSC mobilization. The purpose is to analyze the safety and efficacy of plerixafor in the retrospective analysis of 2 pediatric cases. Both received plerixafor after at least one previously failed HSC mobilization with filgrastim (Neupogen®). Mobilization failure is defined as a peripheral CD34 count of < 10 cells/µL after the first 4 days of filgrastim therapy. Mobilization with plerixafor is considered successful if peripheral blood CD34 count is >10 cells/µL prior to apheresis and collection results in > 2.5 x 10^6 CD34 cells/kg per transplant. The first case is a three year old male with a history of metastatic neuroblastoma. After initial treatment failure with four days of G-CSF alone, he received one dose of plerixafor prior to stem cell collection to enhance mobilization. The second case is a one year old female, also with a history of metastatic neuroblastoma. The patient has failed collection in the past with G-CSF alone and upon presentation it was determined that plerixafor along with high-dose G-CSF would be used to avoid another failure. In both patients, plerixafor resulted in successful HSC mobilization after one dose. Safety analysis was conducted using defined adverse effects of plerixafor from the manufacturer labeling. Neither patient experienced any adverse effects.

Poster Title: Retrospective study evaluating antimicrobial prophylaxis in pediatric spinal surgeries

Primary Author: Holly Lien, CHRISTUS Santa Rosa Healthcare: Children’s Hospital of San Antonio, TX; Email: holly.lien@christushealth.org

Additional Author(s):
Sarah Kubus
Jonathan Crews

Purpose: Surgical site infections after spinal surgeries result in increased morbidity, prolonged hospital stay, and increased health care costs. In an effort to decrease the number of surgical site infections (SSIs) after spinal surgeries at an academic pediatric institution, the infection control program designed an educational protocol card for surgeons to utilize perioperatively. The objective of this study is to compare adherence rates of using optimal antimicrobial prophylaxis before and after protocol implementation. The goal of this quality improvement study is to optimize antibiotic usage for surgical prophylaxis through identifying correlations between protocol adherence and appropriate antibiotic prescribing.

Methods: This is a retrospective, institutional review board approved, descriptive study based on a single center chart review. All patients with spinal surgeries with or without instrumentation from January 1, 2013 to September 1, 2016, regardless of whether or not they had post-operative surgical site infections, will be included in the study. Subjects will be excluded if they do not meet inclusion criteria, were on one or more antibiotics prior to surgery, or had a surgery performed at another hospital. Data of interest include patient specific characteristics, demographics, surgical antimicrobial prophylaxis regimen (including drug, dose, time of administration, and number of doses), and presence of surgical site infection. Descriptive statistics will be utilized to assess data for trends. Absolute occurrence will be used to determine average values across subject groups and relative percentage of patients that received antibiotic regimens adherent to the protocol. Rate of adherence to the protocol will be assessed over time, with the date of protocol implementation as the point of reference. The primary composite outcome is overall adherence to the protocol. A secondary aim is to identify correlations between protocol adherences to rates of infections.

**Poster Title:** Evaluation of pharmacist-managed insulin therapy using telehealth glucometer technology  

**Primary Author:** Stephen Liu, CHRISTUS Spohn Health System, TX; **Email:** stephen.liu@christushealth.org  

**Additional Author(s):**  
Karlye Trevino  
Rolando Gonzalez  

**Purpose:** Telehealth glucometer technology transmits home blood glucose readings to a web-based software that is accessed with an assigned username and password. This allows the provider to monitor patient blood glucose levels and titrate therapy on a more frequent basis; however, this technology is underutilized, as providers currently review the data just prior to clinic visits and not between them. The underutilization creates an opportunity for pharmacists to more closely monitor blood glucose levels and to optimize therapy. The objective is to compare the A1c prior to and after having a pharmacist titrate insulin therapy in-between provider visits.  

**Methods:** This prospective study will include patients who already use telehealth glucometer technology, follow with the CHRISTUS Spohn outpatient clinic for management of their diabetes, and have been admitted to the hospital within the past year with a primary diagnosis of uncontrolled diabetes. Patients who have consented will attend an initial clinic visit with the pharmacist to establish care. This will include an assessment of baseline glycemic control and explanation of the pharmacist’s role using the telehealth system. Thereafter, the pharmacist will schedule weekly telephone follow-up to review blood glucose levels, diet, and exercise, as well as implement any regimen changes. The primary endpoint will be the difference in A1c prior to and after pharmacist intervention. Secondary outcomes include the difference in mean fasting glucose between the first and last weeks in the study, incidence of readmission for uncontrolled diabetes, and patient compliance with glucometer use and appointments. All patient data will be stored on password-encrypted software and computers. This study is pending Institutional Review Board approval.

Poster Title: Efficacy of the 10-year ASCVD equation in risk classification in a cohort of Hispanic and non-Hispanic patients with first-occurrence MI

Primary Author: Lu Ge, CHRISTUS Trinity Mother Frances Health System, TX; Email: kimikolu_07@hotmail.com

Additional Author(s):
Jean Dib
Amy Martin

Purpose: The new atherosclerotic cardiovascular disease risk equation (ASCVD) is used to predict the 10-year risk of primary cardiovascular risk and potential benefit from statin therapy in patients who have never had a cardiovascular event. The equation, however, was developed with limited ethnic diversity. In fact, there are no studies that specifically look at the applicability and classification of the pooled cohort equation in the Hispanic population. In this study, we aim to evaluate the accuracy of the 10-year ASCVD equation in classifying and categorizing low-risk patients in Hispanic vs. non-Hispanic population.

Methods: This study will be submitted to Institutional Review Board (IRB) for approval before project initiation. Patients with first-occurrence myocardial infarction at CHRISTUS Trinity Mother Frances Health System-Tyler will be identified through electronic medical record databases (EPIC) and their 10-year ASCVD risk will be calculated. Pertinent data will be collected utilizing electronic medical record database including but not limited to patient demographics, labs, vital signs, comorbid conditions, statin use, ASCVD status, and social history. Patients' profiles of Hispanic and non-Hispanic descent will be randomly selected from a cohort group between December 2011 and September 2016. All data will be recorded and evaluated without patient identifiers to maintain confidentiality. Patient demographics, labs, and variables will be analyzed through descriptive statistics, and inferential statistical analyses will be utilized to assess the associations between outcome variables.

Poster Title: Impact of implementation of an automated dispensing cabinet (ADC) profile dispense configuration on potential medication errors in the emergency department

Primary Author: Britney Henning, CHRISTUS Trinity Mother Frances Health System, TX; Email: britney.henning@tmfhc.org

Additional Author (s):
Wyley McCoy
Amy Martin
Craig Cocchio
Justin Hooper

Purpose: The Joint Commission (TJC) and the Institute for Safe Medication Practices (ISMP) both support the prospective review of medication orders by pharmacists to optimize medication safety. This standard of care is not yet universally adopted in emergency departments across the nation. The purpose of this study is to determine if the implementation of an ADC profile dispense configuration, requiring prospective pharmacist medication order review, is associated with a change in potential medication errors, defined as the wrong medication warning event rate at the time of bedside medication barcode scanning.

Methods: This study has been submitted to the Institutional Review Board for approval. This is a study evaluating the impact of implementing a profile dispense configuration on the incidence of potential medication errors, as well as associated changes in the number of discontinued/expired order warnings and changes in barcode compliance. All information will be taken directly from reports generated monthly by the electronic medical record system (Epic©) that specifically track the number of wrong medication warnings, discontinued/expired order warnings, and rates of barcode compliance based on the total number of medication administrations per department.

Poster Title: Pharmacist driven discontinuation protocol for nonsteroidal anti-inflammatory drugs (NSAIDs) in heart failure patients

Primary Author: Erica Rath, Christus Trinity Mother Frances Hospital, TX; Email: erica.rath@tmfhc.org

Additional Author (s):
Amy Martin

Purpose: The FDA has recently strengthened the warning on non-steroidal anti-inflammatory drugs (NSAIDs) and their use in patients with cardiovascular disease, particularly in patients with heart failure (HF). NSAID use is particularly concerning in HF as observational data has linked NSAID use with an increase in morbidity and mortality in this subset of cardiovascular disease. The purpose of this study is to evaluate the effect of the decision support trigger tool with the pharmacist driven NSAID discontinuation protocol on patient outcomes as defined by the frequency of NSAID prescriptions on discharge and 90 day readmission rate within the HF population.

Methods: The electronic medical record system will identify patients with an admitting diagnosis of HF who also have orders for a scheduled NSAID. The following data will be collected: age, other cardiovascular diseases, physical exam findings, NSAID ordered, home NSAID use, physician action to clinical decision tool, pharmacist documentation, NSAID discontinuation, NSAID on discharge, readmission within 90-days of discharge. Provider documentation will be reviewed for compliance with trigger tool. All data will be recorded without patient identifiers and maintained confidentially. Pharmacist will be notified of scheduled NSAID order, in combination with HF admitting diagnosis. Pharmacist will review chart, discontinue the NSAID and counsel patient on NSAID use. Readmission data will be reviewed to evaluate HF patients continued on NSAIDs after discharge.

Poster Title: Systemic corticosteroids for exacerbation in Cystic Fibrosis patients without asthma: a single-center retrospective chart review

Primary Author: Lauren Duran, Cook Children's Medical Center, TX; Email: lauren.duran@cookchildrens.org

Additional Author(s):
Greg Wendel
Melissa Gervase
Karen Schultz
Tyler Hamby

Purpose: An important focus of the management of Cystic Fibrosis (CF) is treatment of exacerbations when they occur. Though guidelines do not recommend their use in CF patients without asthma, systemic corticosteroids may provide benefit in acute exacerbations in this population. The primary objective of this study is to evaluate the risks and benefits of systemic steroid use in CF exacerbations in patients without asthma. The secondary objective will quantify the use of systemic steroids in CF exacerbations in patients without asthma at our institution.

Methods: This study is a retrospective chart review of patients admitted to a single institution for a CF exacerbation between July 1, 2015 and June 30, 2016. Data will be collected using the electronic medical record. Patients will be included if they are 21 years of age or younger, have a diagnosis of CF, and are admitted to the hospital during the study period. Patients with a diagnosis of asthma will be excluded from this study. Data collected includes: age, gender, ethnicity, diagnosis code used for admission, systemic steroid administered (including dose, directions, and length of therapy), length of stay, pulmonary function tests, blood pressure, additional medication requirement for blood pressure control, blood glucose, and requirement for additional insulin therapy. Comparisons will be made between patients who received steroids and those who did not. All data will be stored in a secure database and only accessible to the research team. This study has been approved by the Institutional Review Board.

Poster Title: Assessment of empiric antimicrobial therapy choice in critically ill pediatric patients with sepsis

Primary Author: Matthew Nguyen, Cook Children's Medical Center, TX; Email: matthew.nguyen@cookchildrens.org

Additional Author (s):
Ean Miller
Lorrainea Williams
Tyler Hamby
Javier Gelvez

Purpose: At our institution, a sepsis screening tool embedded in the electronic healthcare record facilitates early identification and treatment of sepsis. Although the tool and associated processes have decreased time to antibiotic and fluid delivery, the coverage provided by initial empiric antimicrobial therapy has yet to be assessed. The purpose of this study is to determine adequacy of empiric antimicrobial therapy in a retrospective cohort of septic pediatric intensive care patients in a freestanding, tertiary care medical center.

Methods: A retrospective review of empiric antimicrobial therapy will be conducted for patients diagnosed with severe sepsis or septic shock and who were treated in the pediatric intensive care unit from October 1, 2012 through May 31, 2016. Inclusion criteria will include age of less than 18 years, initial emergency room visit with antimicrobial therapy initiated in the first twenty-four hours of presentation, and positive culture results. Demographic data will comprise of age, gender, weight, and co-morbidities. Treatment and outcome data will include infection source, mortality, length of hospitalization, total duration of antibiotic(s), cultured pathogens, susceptibility profiles, and antibiotics initiated within the first twenty-four hours. The primary objective, adequacy of empiric antimicrobial therapy, will be determined by the drug impact on the pathogen’s susceptibility profile. Results from the study will be used to identify potential improvement opportunities for empiric antimicrobial therapy selection. All collected data will be entered into a protected database created with Microsoft Excel 2016. Descriptive analyses, chi-square and logistic regression analyses, general linear model, and critical alpha level of 0.05 for inferential statistics will be used. Analyses will be performed with
Statistical Analysis System and Statistical Package for the Social Sciences. This study was exempted from the Institutional Review Board as quality improvement work product.

Poster Title: Development of an interactive pharmacy tracker with clinical guidance for outpatient oncology treatment

Primary Author: Bryan Donald, Corpus Christi Medical Center, TX; Email: bryan.donald@hcahealthcare.com

Additional Author (s):
George Udeani
Joseph High

Purpose: Computerized order entry (COE) has been demonstrated to improve medication safety, however, nationwide COE for chemotherapy has been implemented more slowly and reluctantly than non-chemotherapy orders. Implementation of COE for chemotherapy should be carefully considered and designed to improve medication safety for chemotherapy drugs, which are considered high-risk medications. This study will describe the development and implementation of a COE application for oncologists and pharmacists to order and track chemotherapy orders in a facility with a newly opened outpatient oncology treatment center.

Methods: This study will be submitted to the Institutional Review Board for approval. The COE application will be developed and stored on a secure, internal server and synchronized with the electronic medical record. During Phase I of implementation, oncologists will continue to issue paper orders, which will be entered into the COE application by oncology pharmacists. Phase II of implementation will include oncologists in the COE process. The application will require pharmacists to monitor critical information including vital signs, laboratory data, and medication regimens, doses and exposure before preparing chemotherapy for patients. Pharmacists are also required to double-check oncology orders and regimens against published literature for safety and accuracy and to document, discuss, and resolve deviations from sources with oncologists. Finally, a second pharmacist must double-check COE and verification of any oncology order. The application will track pharmacists’ monitoring, literature review, double-checks, and input, check, or monitoring errors. Information will be collected about input errors, adherence to pharmacist-led drug monitoring, adherence to pharmacist-led literature review, and conformity of ordered regimens to
literature and guidelines. Additionally, a survey will be distributed to personnel who interact with the application to assess perceptions of ease-of-use and patient safety. These results will be analyzed with descriptive statistics.

Poster Title: Utilization of chest radiographic imaging and clinical parameters to evaluate inappropriate use of antimicrobial therapy in patients with fluid overload and congestive heart failure

Primary Author: Uche Mbadugha, Corpus Christi Medical Center, TX; Email: utchay2@gmail.com

Additional Author (s): Micheal Bullen
Nana Akuffo
George Udeani

Purpose: Pneumonia can be a potentially life-threatening lung infection that is treated with antimicrobial therapy. Chest radiography is a noninvasive approach used to evaluate and diagnose pneumonia, fluid overload, and chronic lung diseases. Patients with radiographic evidence of fluid overload without typical clinical symptoms of pneumonia are often misdiagnosed and started on empiric antimicrobial therapy. This study will evaluate the inappropriate use of antimicrobial therapy in critically ill patients with fluid overload or congestive heart failure misdiagnosed with pneumonia. Inappropriate use of antimicrobial therapy in such clinical settings can lead to Clostridium difficile infection, antimicrobial resistance and prolonged hospitalization.

Methods: Study protocol will be submitted to the Institutional Review Board for approval. Electronic medical record (EMR) will be used to search for patients with radiologic evidence of fluid overload or congestive heart failure admitted into the intensive care units at a community teaching hospital. A retrospective chart review of this cohort will be conducted to identify patients with no clinical features of pneumonia that received empiric antimicrobial therapy. Patients will also be identified prospectively during antimicrobial stewardship rounds (ASP). Patients on antimicrobial therapy for concurrent infections other than pneumonia will be excluded. Demographic and clinical data collected will include past medical history, physical examination, home medications, laboratory and microbiology results, chest radiographs, medication orders, diagnoses, and discharge information. Data on physicians’ documentation and rationale for antimicrobial therapy based on results of chest radiographs will also be
collected. Patient information will be de-identified. The primary outcome is to determine number of cases with fluid overload or congestive heart failure with no radiologic or clinical evidence of pneumonia managed with antimicrobial therapy. Secondary outcomes will assess antimicrobial therapy associated complications, and number of cases with ASP recommendations as well as resulting outcomes. Investigators will evaluate antimicrobial therapy for appropriateness based on radiographic evidence and clinical presentation in accordance with current practice guidelines. Analysis of this study will elucidate the inappropriate use of antimicrobial therapy in this cohort.

**Session-Board Number:** 8-338

**Poster Title:** Evaluation of inter rater reliability of the ramsay sedation scale and its utility in dosing of sedatives in critically ill patients

**Primary Author:** Harmee Deol, Corpus Christi Medical Center, TX; **Email:** deol.pharmd@gmail.com

**Additional Author(s):**
Arash Minaie
Salim Surani
George Udeani

**Purpose:** Titratble palliative sedation (TPS) is defined as the use of sedative medications to relieve intolerable and refractory distress by the reduction in patient consciousness. TPS can be adjusted according to objective and subjective data, Ramsay Sedation Scale (RSS). Variability in clinician assessment or improper use of the RSS can contribute to poor patient outcomes. Inter-rater reliability (IRR) and its correlation to variations in dosing will be assessed to determine if there is a need for additional training of healthcare professionals in sedation scale assessment.

**Methods:** Institutional Review Board (IRB) exempt approval will be obtained. This will be a prospective data collection study. Patients will be identified with the assistance of the critical care team. Mechanically ventilated patients will be included in the study. Patients with neurogenic abnormalities will be excluded. Data will be collected from nursing charts and the electronic health record. Such data will include: demographics, past medical history, vitals, laboratory values and sedative medication dosage, along with interacting medications and adverse effects. Patient data will be de-identified and confidentiality will be maintained. The first part of the study will determine IRR. Two separate trained evaluators will prospectively assess patients’ sedation scales using the RSS; their assessments will then be compared to those determined by the nursing staff. Inter-rater reliability will be assessed via analysis of Fleiss’ Kappa statistics, from data collected. The kappa statistics will provide an indication for reliability of application of RSS in this facility. The second part of the study will correlate dosing administration with sedation assessments to identify institutional trends. This data will be stratified to determine if any observed time-related variances in sedative doses employed are
either physiological or a result of inter-rater variability. The results will also be stratified based on demographic characteristics.

Poster Title: Impact of an automated dispensing cabinet-regulated community insulin vial pilot program on inventory costs

Primary Author: Amanda Grego, Harris Health System, TX; Email: amanda.grego@harrishealth.org

Additional Author (s):
Jerry Wong
Ogechi Eshleman
Shaji Varghese

Purpose: Subcutaneous insulin injections are a commonly used treatment for glycemic control of patients in a hospital setting. Various studies have been conducted regarding the effect of switching from an insulin vial to an insulin pen in a hospital setting; however, few studies have been conducted regarding the impact of switching from a patient-specific insulin vial to a community insulin vial. The primary objective of this study is to assess the impact an automated dispensing cabinet-regulated community insulin vial pilot program on inventory costs.

Methods: This study will be submitted to the Harris Health System Institutional Review Board for approval. An automated dispensing cabinet-regulated community insulin vial pilot program will be implemented in two nursing units of Ben Taub Hospital. This pilot program will target regular insulin, NPH insulin, and insulin detemir in a designated surgical unit and a medical intensive care unit (MICU). Before implementation, nursing and pharmacy staff will receive education regarding the pilot program workflow. The primary endpoint of this study is the impact on inventory cost which will be calculated by multiplying insulin utilization before and after implementation by the institution’s acquisition cost. The secondary endpoints include the impact on the average number of insulin vials per patient, the average number of medication messages sent to pharmacy per insulin order, and the average employee satisfaction survey score for nursing and pharmacy. In order to measure employee satisfaction regarding the insulin administration and dispensing process, respective nursing and pharmacy staff will voluntarily complete anonymous pre- and post-implementation surveys using a 5-point Likert scale. All other metrics will be analyzed over a 3-month period before and after
implementation. The student’s t-test will be used to compare continuous data and the chi-square test will be used to compare categorical data.

**Results:** Pending implementation and data analysis

Poster Title: Evaluation of Clinical Outcomes in HIV/Hepatitis C co-infected patients treated with direct-acting antivirals (DAAs) for Hepatitis C in an Ambulatory Care setting

Primary Author: Sumanth Reddy, Harris Health System, TX; Email: sumanth.reddy2@harrishealth.org

Additional Author(s):
Teddy Zerai

Purpose: Hepatitis C is a bloodborne pathogen that can result in liver damage and cirrhosis if left untreated. Literature has revealed that co-infected patients were three times more likely than patients without HIV co-infection to develop decompensated liver disease and therefore more likely to experience adverse events related to treatment. Conventional Hepatitis C treatment included combination interferon and ribavirin. This regimen has poor efficacy and serious treatment-related side effects. The purpose of this study is to determine the real-world effectiveness of these newer direct acting Hepatitis C antivirals in HIV/Hepatitis C co-infected patients in an ambulatory care setting.

Methods: This study is a retrospective chart review that will be submitted to the Institutional Review Board for approval. A list of patients meeting the inclusion criteria will be generated by Harris Health’s Information Technology department for this study. All patient data will be de-identified and encrypted. Patients included in this study are over the age of 18, diagnosed with HIV/Hepatitis C, and completed treatment with one or more of the following medications: ledipasvir/sofosbuvir, elbasvir/grazoprevir, ombitasvir/paritaprevir/ritonavir/dasabuvir, sofosbuvir/velpatasvir, daclatasvir, PEG-interferon Alpha-2a, PEG-interferon Alpha-2b, and ribavirin. Approximately 100 patient charts in Harris Health’s electronic medical records system will be reviewed. Data obtained will include: patient demographics, degree of cirrhosis present, antivirals received, Hepatitis C genotype, prior Hepatitis C treatment, Hepatitis C RNA viral load, number of follow-up visits attended with a clinical pharmacist or primary care physician, patient compliance, reported adverse events related to Hepatitis C treatment (fatigue, diarrhea, nausea, liver function test elevations), and the source of funding for these newer direct acting antiviral medications. Patients will be stratified based on the degree of cirrhosis present (Metavir score). The primary outcome is the number of patients with sustained virological
response or undetectable Hepatitis C viral load at 12 and 24 weeks post-treatment. The secondary outcomes include treatment related adverse events, source of funding for medications, and relapses related to treatment.

Poster Title: Assessment of the feasibility in implementing a mail order prescription service for an indigent patient population within a community health system

Primary Author: LiChao Zhao, Harris Health System, TX; Email: lichao.zhao@harrishealth.org

Additional Author(s):
Leroy Perkins
Shawn Gautreaux

Purpose: Harris Health System is the third largest community health system in the United States with 15 outpatient pharmacies dispensing over 2.2 million prescriptions per year. The health system serves approximately 64 percent of uninsured and underinsured residents of Harris County. Currently, limited data is available regarding success of mail order prescription services within underserved communities and individuals with transient lifestyles. The purpose of this project is to assess the overall feasibility of providing mail order service within Harris Health System and consider potential benefits including patient satisfaction, medication compliance, and financial impact.

Methods: This multicenter prospective study has been deemed exempt from Harris Health System Institutional Review Board approval. An electronic medical record will be utilized to collect data and MyHealth enrollment information on patients who receive prescriptions at Harris Health System. Additionally, an electronic questionnaire will be sent to patients to determine interest in mail order services and assess the accuracy of patient details. Projected expenditures (automation, mailing providers) and return on investment (ROI) will be developed and presented for administrative approval.

**Poster Title:** Impact of switching patients with diabetes in the ambulatory care setting on insulin vial to insulin pen therapy within a county-owned healthcare system.

**Primary Author:** Rene Banzuelo, Harris Health System, TX; **Email:** rene.banzuelo2@harrishealth.org

**Additional Author(s):**
Jerry Wong
Monica Robinson Green
Cesar Munoz

**Purpose:** Diabetes mellitus (DM) is a chronic condition associated with high morbidity and mortality. Insulin vial therapy may present a compliance barrier to some patients. Insulin pens have been found to improve compliance while providing similar glycemic control to insulin vial therapy. Studies have been conducted converting patients with diabetes from insulin vials to insulin pens, but few have been conducted in the ambulatory care setting in a county-owned healthcare system. The primary objective of this study is to evaluate the clinical and economic impact of converting patients with diabetes in a county-owned healthcare system from insulin vials to insulin pens.

**Methods:** This study has been deemed exempt from the Institutional Review Board. This prospective, cohort study will focus on patients 18 years old or greater with a diagnosis of diabetes who used insulin vials between March 1, 2015 and March 1, 2016 and were then switched to insulin detemir pens after March 1, 2016. Pregnant patients will be excluded. A random sample of 200 patients converted to insulin detemir pen therapy from March 1, 2016 to September 1, 2016 will be analyzed. The following data will be collected: patient demographics, past medical history, medications related to diabetes, HbA1c, insulin fill history and patient satisfaction. A telephone survey will be used to assess patient satisfaction with insulin detemir pen therapy. Student t-test and chi-square test will be used to compare continuous data and categorical data respectively. Institutional costs comparing vial and pen therapy will be assessed based on estimated utilization. Secondary objectives are compliance and patient satisfaction.

**Poster Title:** Impact of rescheduling of hydrocodone combination products from schedule III to schedule II on patient pain management

**Primary Author:** Cindy Adibe, Harris Health System, TX; **Email:** cindy.adibe@harrishealth.org

**Additional Author(s):**
Jason Lionetti
Krupa Patel
Erika Bergeron

**Purpose:** Effective October 6, 2014, all hydrocodone combination products were rescheduled by the DEA from Schedule III to Schedule II in an effort to combat prescription drug abuse. These prescriptions must be written on a DPS official prescription form and no refills may be authorized. A previous study showed that this rescheduling decreased the hydrocodone prescribing habits of physicians at Harris Health System. More physicians are prescribing tramadol and acetaminophen-codeine no. 3 instead of hydrocodone for pain management. Given the change in prescribing habits, we are assessing the impact on patient pain management and the financial impact on the institution.

**Methods:** This study will be submitted to the Institutional Review Board (IRB) for approval. The monthly electronic medical record reports for outpatient controlled substance prescribing will be reviewed from October 2012 to December 2012 and October 2015 to December 2015. These two sets of data will be compared to ensure that the reports measure equal time periods before and after the rescheduling of hydrocodone. Patients will be included if they were discharged from Ben Taub or Lyndon B. Johnson Emergency Center during these time periods, and were prescribed at least one analgesic controlled substance in a solid oral dosage form (i.e. tablets, capsules). Patients will be excluded if they have a documented history of drug-seeking behavior. The following data will be collected and included in the analysis: patient age, gender, ethnicity, the prescribed analgesic and other current medications, the indication for the analgesic, and the number of pain-related primary care visits after the initial emergency center visit. All data will be used to assess the potential impact on patients’ pain control, evaluate the financial impact on the institution, and explore cost-savings pain management alternatives. The
measurable data will be categorized based on the number of pain-related visits and the cost to the institution.

**Poster Title:** Evaluation of fall risk in elderly patients taking antihypertensive medications concomitant with overactive bladder or benign prostatic hyperplasia medications

**Primary Author:** William Long, Hendrick Medical Center/ Texas Tech University Health Science Center School of Pharmacy/Abilene, TX; **Email:** william.g.long@ttuhsc.edu

**Additional Author(s):**
Pamella Ochoa
Jose Vega

**Purpose:** Medications used to treat hypertension, benign prostatic hyperplasia or overactive bladder share similar side effects that may have an association with increased fall risk in the elderly population. The purpose of this study is to investigate the combined effect of medications used in the treatment of hypertension, benign prostatic hyperplasia or overactive bladder on the risk of falls that necessitate hospitalization.

**Methods:** This study has been submitted to the Institutional Review Board for approval. Electronic medical records will be used to identify patients over the age of sixty-five who have been admitted to the hospital for injuries due to fall. Age, gender, body mass index, causative medications, dosage of medications being studied, average daily blood pressure, average daily heart rate, ambulatory status, diagnosis of fracture, and comorbidities will be recorded. All patient data will be recorded without patient identifiers and maintained confidentiality. Three categories of these patients will be analyzed: patients prescribed antihypertensive and benign prostatic hyperplasia or overactive bladder medications, patients prescribed antihypertensive medications without medications for benign prostatic hyperplasia or overactive bladder, and patients prescribed medications for benign prostatic hyperplasia or overactive bladder without the use of antihypertensive medications. The three groups will be matched based on gender, age, and comorbidities. Fall rates among the three groups will then be analyzed as the primary endpoint. The secondary endpoint will be fracture risk.

Poster Title: Evaluating antiretroviral therapy in hospitalized HIV-infected patients

Primary Author: Lynn Dang, Memorial Hermann Hospital System, TX; Email: lynn.dang@memorialhermann.org

Additional Author(s):
Christy Su
Amy Schilling

Purpose: Human Immunodeficiency Virus (HIV) related deaths have decreased significantly in the past decade. The decline in HIV-related deaths is in part due to advances in antiretroviral therapy (ART), which has led to improved tolerability and efficacy making HIV a more manageable chronic disease. Despite these improvements, there continues to be challenges with ART regimens due to adherence, drug interactions, and toxicity. These problems become more apparent when HIV patients are hospitalized. The purpose of this study is to quantify the number of ART regimens requiring optimization at three community hospitals within a large healthcare system in Houston, Texas.

Methods: This retrospective, multicenter chart review in HIV-infected patients who were hospitalized from January 2016 – June 2016 was determined exempt by the Institutional Review Board. Patients will be identified by a computer-generated report using ICD-9 diagnosis code 40 for HIV. Adult patients greater than 18 years old admitted with an existing diagnosis of HIV and have scheduled ART medication orders on the electronic medication administration record (eMAR) will be included in the study. Patients receiving ART for indications other than HIV and those who were newly diagnosed with HIV during hospitalization will be excluded. The primary outcome will be the number of ART regimens requiring optimization related to regimen selection, dosing, and drug interactions. In addition, secondary outcomes aim to assess whether ART compliance was evaluated prior to order entry, if the need for opportunistic infection prophylaxis was addressed, and the overall impact of an infectious diseases specialist on the interventions. The following data points will be collected: gender, age, race, height, weight, CD4 T-cell, HIV RNA (viral load), serum creatinine, creatinine clearance (estimated based on the Cockcroft–Gault equation), ART regimen ordered in the hospital as well as other scheduled medications. All data will be collected without patient identifiers and maintained confidentially.

Poster Title: Evaluation of blood glucose control using computer-based insulin protocol

Primary Author: Hongmei Wang, Memorial Hermann Hospital System, TX; Email: hongmei.wang@memorialhermann.org

Additional Author (s):
Julin Thomas

Purpose: Hyperglycemia is common in critically ill patients with or without diabetes. The occurrence of hyperglycemia, especially severe hyperglycemia, is a predictor of poor clinical outcome in variety of patients. Computer-based insulin infusion protocol has been shown to achieve stable blood glucose control without an increased risk of hyperglycemic and hypoglycemic events compared to paper-based protocol. The purpose of this study is to evaluate the efficacy and safety of a computer versus paper-based insulin infusion protocol on blood glucose control for adult intensive care units (ICU), intensive medicine units (IMU) and cardiovascular intensive care units (CVICU) patients.

Methods: The study is a retrospective, observational pre- and post- implementation study evaluating computer-based Atlanta Multiplier Insulin Protocol compare to paper-based Columnar Insulin Dosing Protocol at a single institution. Collection of data was performed in adult patients (greater or equal to 18 years old) admitted to ICU, IMU and CVICU treated with insulin infusion in Memorial Hermann Greater Heights Hospital. Patients who underwent diabetic ketoacidosis and hyperosmolar hyperglycemic syndrome treatment were excluded. The first co-primary endpoint was time to first blood glucose in target range (110 to 180 mg/dL). The second co-primary endpoint was the incidence of hypoglycemic events (less than or equal to 40 mg/dL and 40 to 60 mg/dL). The secondary endpoints were mean daily blood glucose level (24 hours), the incidence of hyperglycemia (greater or equal to 180 mg/dL), ICU length of stay and hospital length of stay. Normally distributed continuous variables were reported as mean and stand deviation and compared using t-tests. Non-normally distributed continuous variables were reported as median and interquartile range (IQR) and compared using the Mann-Whitney U test. Proportional differences in nominal variables between groups were compared using Fisher’s exact or Chi-squared tests. Statistical significance was defined with P value less than 0.05, and all results were 2-tailed.

Poster Title: Evaluation of antibiotic usage in patients with beta-lactam allergy in a community emergency department

Primary Author: Soyoon Lee, Memorial Hermann Hospital System, TX; Email: soyoon.lee@memorialhermann.org

Additional Author (s):
Dante Gravino

Purpose: Having a documented beta-lactam allergy can increase risk of harm, be treated with suboptimal antibiotics, and may contribute to emergence and spread of multi-drug resistant organisms. The Obama administration released a National Action Plan to combat antibiotic resistance by establishing antibiotic stewardship programs in all hospitals. The increased emergence of multi-drug resistant bacteria urges the hospital to ensure optimal antibiotic selection by limiting overuse and misuse of antibiotics. The objective of this study is to evaluate the antibiotic selection in patients with a reported beta-lactam allergy at Memorial Hermann The Woodlands Emergency Department (ED).

Methods: The study was submitted for approval to the Institutional Review Board. Data will be collected retrospectively from the Memorial Hermann Hospital System’s electronic medical record (EMR) from January 1, 2016 to June 30, 2016. Patients who were 18 years or older admitted to the ED with reported beta-lactam allergy and received at least a single dose of antibiotic that was ordered by the ED physician are included. Patients who had their beta-lactam allergy documented after antibiotic administration are excluded from the study. Data elements will include age, gender, pregnancy status, allergy and documented allergic reaction in the EMR upon ED admission, administered antibiotic, allergic reaction noted if beta-lactam antibiotic was administered, main infectious diagnosis, and infectious disease (ID) consultation. The primary endpoint is the number of each antibiotic administered. Secondary endpoints include the appropriateness of antibiotic, allergic reaction noted if patient was re-challenged, ID consultation, and prescribing ED physician. Descriptive statistical analysis will be used to analyze the data.

Poster Title: Safety and efficacy of varying doses of insulin for the treatment of hyperkalemia in patients with end stage renal disease

Primary Author: Trishna Kuber, Memorial Hermann Memorial City Medical Center, TX; Email: trishnakuber@gmail.com

Additional Author(s):
Terence Chau
Sapana Desai

Purpose: Patients with end stage renal disease on dialysis are at an increased risk of hyperkalemia. A common treatment to quickly shift potassium intracellularly is through the administration of insulin. The purpose of this study is to assess whether 5 units of insulin compared to 10 units of insulin decreases the incidence of hypoglycemia while effectively lowering serum potassium levels in patients with end stage renal disease requiring dialysis.

Methods: This study will be a retrospective, observational study that will be submitted to the Institutional Review Board for approval. Eligible patients will be identified via electronic medical records and will be included if they have end stage renal disease requiring dialysis, if they have a potassium level greater than 5.0 mEq/L and if they received an order for either 5 units or 10 units of insulin as treatment. Collected data includes: patient age, sex, height, weight, race, admitting diagnosis, home medications, episodes of cardiopulmonary arrest or rapid response records, mortality during hospital admission, pre-treatment and post-treatment serum potassium and blood glucose levels, dose of insulin, associated medications to treat hyperkalemia such as albuterol, sodium bicarbonate and sodium polystyrene sulfonate, as well as the use of calcium salts. Patients will be divided in to two groups based on whether they received 5 units (low dose group) or 10 units (high dose group) of insulin. The groups will then be compared to each other to assess differences in rates of hypoglycemia as well as differences in serum potassium levels from baseline.

**Poster Title:** Risk factors associated with QTc prolongation in a geriatric patient population presenting to the emergency department with community acquired pneumonia

**Primary Author:** Nicholas Yarbrough, Memorial Hermann Memorial City Medical Center, TX; 
**Email:** Nicholas.Yarbrough@memorialhermann.org

**Additional Author (s):**
Mohamed Hersi 
Terence Chau

**Purpose:** It is well known that patients with prolonged QTc are at an increased risk for life-threatening ventricular arrhythmias such as Torsade de pointes. Elderly patients presenting to the emergency department with pneumonia are a potentially high risk population for acquired QTc prolongation due to advanced age, comorbidities, chronic medications, and the standard therapy commonly utilized to treat community acquired pneumonia. The objective of this study is to assess which factors (if any) are most associated with moderate to high risk QTc prolongation in elderly patients started on empiric antimicrobial regimens for community acquired pneumonia in the emergency department.

**Methods:** This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients 65 years and older who were given at least 1 dose of levofloxacin or azithromycin in the emergency department before being admitted to the hospital. Radiology and provider documentation will be used to assess intended empiric coverage for suspected pneumonia. The following data will be collected: patient age, gender, past medical history, home medications, and medications administered during hospital stay, electrocardiogram readings, radiology and laboratory data. All data will be recorded without identifiers and maintained confidentially. Baseline and longest subsequent QTc reading will be recorded and evaluated for moderate prolongation defined as a QTc of 470ms (480ms in women) to 499ms or an increase of 30 to 59ms from baseline; or severe prolongation defined as any reading greater than 499ms or increase greater than 59ms from baseline. Factors known to prolong the QTc will then be analyzed amongst patients with prolonged QTc and those without to determine which factors are independently associated with a prolonged QTc.

Poster Title: Evaluating the impact of chronic obstructive pulmonary disease (COPD) exacerbation management recommendations on antibiotic utilization

Primary Author: Casey Dempsey, Memorial Hermann Southwest Hospital, TX; Email: casey.dempsey@memorialhermann.org

Additional Author (s):
Shivani Patel
Ngan Vo
Chase Waxler

Purpose: Antibiotic prescription rates for treating acute exacerbations of chronic obstructive pulmonary disease (COPD) have been reported as high as 85% in the United States. Research has shown that over 50% of COPD exacerbations are due to viral etiologies. Elevations in procalcitonin levels can be seen in bacterial infections and can help guide the need for antimicrobial therapy in this patient population. The goal of this study is to evaluate the impact of management recommendations on antibiotic utilization in patients with COPD exacerbations.

Methods: This is a retrospective cohort study comparing antibiotic utilization in COPD exacerbation patients before and after the implementation of COPD management recommendations. Patients with a primary diagnosis of COPD exacerbation, at least 18 years of age, who had a procalcitonin level drawn within 24 hours of admission, and with an expected admission of at least 24 hours will be included. Exclusion criteria include patients presenting with severe trauma, sepsis, bacterial pneumonia, patients who require mechanical ventilation, and patients with an initial admission to the ICU. Data collection variables include baseline characteristics, laboratory values, vital signs, microbiology cultures and sensitivities, antibiotic use data, and the final diagnosis. Using the implemented management recommendations, antimicrobial therapy recommendations are made based on initial and subsequent procalcitonin levels. The primary outcome of this study is antimicrobial duration of therapy. Secondary outcomes include hospital length of stay, 30-day readmission rates, and treatment failure defined as ICU admission, requirement of mechanical ventilation, or death.

Poster Title: Comparison of patient risk factors for methicillin-resistant staphylococcus aureus (MRSA) vs. MRSA PCR screening in cardiac and orthopedic surgery patients

Primary Author: Andrew Mulder, Memorial Hermann Southwest Hospital, TX; Email: amulder16@gmail.com

Additional Author (s):
Shivani Patel
Samuel Akinyele
Edward Septimus
Johanna Higgins Clowney

Purpose: Methicillin-resistant staphylococcus aureus (MRSA) is a significant cause of health care-associated infections in cardiac and orthopedic surgery patients. Current guidelines recommend assessing multiple MRSA risk factors in addition to the MRSA colonization status, via MRSA polymerase chain reaction (PCR), to determine the need for the addition of vancomycin to standard surgical prophylaxis. Studies have yet to determine how MRSA PCR results correlate to established risk factors for MRSA surgical site infections. The purpose of this study is to determine the degree of correlation between risk factor-based screening and MRSA PCR based screening in cardiac and orthopedic surgery patients.

Methods: This will be a retrospective case-control study conducted at a 568 bed community teaching hospital. The study will compare the MRSA risk factors found in patients who had a positive MRSA PCR result versus patients that had a negative MRSA PCR result. Eligible patients were 18 years or older who underwent cardiac or orthopedic surgery and were screened for MRSA colonization via MRSA PCR testing. All included patient charts will be reviewed for baseline characteristics and the MRSA risk factors of diabetes mellitus, hemodialysis (ESRD), hospitalization within the previous 90 days, prolonged hospitalization greater than seven days, history of MRSA infection, antimicrobial use within the previous 90 days, and MRSA colonization status defined as a positive MRSA PCR test. The primary endpoint of this study is the correlation between MRSA risk factors and the MRSA PCR result.

Poster Title: Impact of a sedation pathway on mechanically ventilated adults in the intensive care unit

Primary Author: Kathaleya Yindeemark, Memorial Hermann Southwest Hospital, TX; Email: kathaleya.yindeemark@memorialhermann.org

Additional Author(s):
Malarvizhi Narayanan
Samuel Akinyele
Todd Kelly
Jennifer Steenburg

Purpose: Critically ill, mechanically ventilated patients require adequate sedation to optimize patient comfort and minimize unintended consequences of improper sedation. Over-sedation may lead to prolonged time on mechanical ventilation, while inadequate sedation may lead to pain, anxiety, and unplanned extubation. Current guidelines recommend targeting light sedation utilizing a sedation pathway that incorporates frequent assessment of pain, agitation, and delirium. The purpose of this study is to evaluate the potential clinical benefits associated with the implementation of a sedation pathway in an adult medical and surgical intensive care unit.

Methods: This is a retrospective, observational study conducted at a 629 bed community hospital. Data will be collected from a three-month time frame before and a three-month time frame after the implementation of a sedation pathway for mechanically ventilated patients in the intensive care unit (ICU). The comprehensive pathway was designed to target light sedation with frequent assessment of patients’ pain, depth of sedation, and presence of delirium. Patients who were 18 years or older, admitted to the medical/surgical ICU, and mechanically ventilated for at least 24 hours will be included in the study. Patient charts will be reviewed for baseline characteristics, clinical outcomes, assessment results and frequency, and doses of sedatives, analgesics, and antipsychotic medications used during mechanical ventilation. The primary endpoint of this study is the duration of mechanical ventilation. The secondary endpoints include hospital and ICU lengths of stay, hospital mortality, percent of time target
sedation was achieved, percent of time delirium was present, incidence of tracheostomy, unplanned extubation, and ventilator associated pneumonia.

Poster Title: Multimodal analgesia versus routine care pain management for pancreatitis: A medication use evaluation

Primary Author: Felicia Kasra, Methodist Dallas Medical Center, TX; Email: feliciakasra@mhd.com

Additional Author (s):
Betina Daniel
Ilka Ratsaphangthong

Purpose: Pain management is a critical factor that affects quality of life in patients with pancreatitis. Multimodal analgesia strategies, supported by current practice guidelines, can offer pain relief while minimizing opioid use and associated risks. Methodist Dallas Medical Center, a tertiary care teaching hospital, recently implemented a standardized multimodal analgesia management protocol to guide pain management in hospitalized patients with pancreatitis. The purpose of this study is to evaluate the use of multimodal analgesia in managing pancreatitis pain. Results will be assessed for implementation of pain management to improve both safety and efficacy.

Methods: A retrospective chart review of patients hospitalized with pancreatitis before and after introduction of the protocol will be performed. Data collected via electronic medical record review will include pain medication prescribing patterns (scheduled, as needed, and one-time medication orders). Doses of analgesic medications during the course of hospitalization for each subject will be recorded. The impact of protocol implementation on parenteral narcotic use, the transition to oral pain medications, and utilization of non-narcotic analgesics will be assessed. Usage of reversal agents will be analyzed for safety outcomes and patient reported pain scores will be assessed for managing pain control. All data will be recorded without patient identifiers to maintain confidentiality.

**Primary Author:** Paul Nguyen, Methodist Dallas Medical Center, TX; **Email:** paulnguyen@mhd.com

**Additional Author(s):**
Matthew Crotty
Ilka Ratsaphangthong

**Purpose:** To determine prescribing patterns of micafungin in hospitalized adult patients, and evaluate clinical response and at Methodist Dallas Medical Center. The goal is to use this information to determine potential improvements that can be made in the utilization and management of micafungin.

**Methods:** A retrospective chart review of patients at Methodist Dallas Medical Center hospitalized from July 31, 2015 to July 31, 2016 will be performed to gather appropriate information. An electronic medical record query will be used to identify patients who were administered micafungin. Appropriate uses of micafungin at Methodist Dallas Medical Center are considered to be: candidiasis prophylaxis in post-liver transplant (up to 30 days post-transplant), treatment of invasive candidiasis, and empiric treatment for septic shock. Manual chart review will be performed to collect: diagnosis, blood culture results, micafungin dose, treatment duration, the presence of a beta-D-glucan assay, rate of discontinuation with negative blood cultures, subsequent Candida infection, subsequent Clostridium difficile infection, and risk factors for usage in septic patients as well as other data that is not obtained via the medical record query. Clinical outcomes analyzed will include disposition, length-of-stay, as well as mortality. All data will be recorded without patient identifiers and confidentiality will be maintained.

**Poster Title:** Evaluating the use of aprepitant for postoperative nausea and vomiting (PONV) at an acute care academic institution

**Primary Author:** Jeremy Chen, Methodist Dallas Medical Center, TX; **Email:** jeremychen2@mhd.com

**Additional Author (s):**
Ilka Ratsaphangthong

**Purpose:** PONV is a complication seen during the postoperative period. Aprepitant is an NK-1 receptor antagonist that works in the central nervous system to prevent acute and delayed vomiting. The FDA approved dose for PONV is 40 mg orally 3 hours prior to anesthesia induction. At Methodist Dallas Medical Center (MDMC) aprepitant is available to anesthesiology providers for use in high-risk patients with documented PONV risk factors. The purpose of this study is to evaluate safety and efficacy of aprepitant in the MDMC postoperative setting. Data obtained will be used to evaluate prescribing patterns and identify areas to improve cost-effectiveness.

**Methods:** A retrospective chart review of MDMC patients who were administered aprepitant 40 mg for prevention of PONV between January 1, 2015 and June 1, 2015 will be performed. To evaluate aprepitant efficacy, the incidence of nausea and vomiting 24 and 48 hours after surgery, patient specific risk for PONV as determined by Apfel score (predictors include female gender, prior history of PONV, nonsmoking status, and concurrent opioid use), and use of antiemetic rescue therapy and/or concomitant prophylactic agents will be assessed. Review of documented adverse effects from aprepitant use will identify patient safety risks.

**Poster Title:** Evaluation of the safety and appropriate implementation of the diabetic ketoacidosis and hyperosmolar hyperglycemia protocol at a teaching hospital

**Primary Author:** Jeena Jacob, Methodist Dallas Medical Center, TX; Email: jeena.jacob108@gmail.com

**Additional Author(s):**
Kristen Hillebrand
Tamara Reiter
Ilka Ratsaphangthong

**Purpose:** Diabetic ketoacidosis (DKA) and hyperosmolar hyperglycemic syndrome (HHS) are severe metabolic complications occurring in patients with decompensated diabetes and can result in significant morbidity and mortality. Patients presenting with either of these hyperglycemic crises require timely diagnosis and appropriate medical management consisting of fluid resuscitation, insulin therapy, and electrolyte replacement. Methodist Dallas Medical Center (MDMC) has a computerized physician order entry for the initial management of DKA and HHS. The purpose of this medication use evaluation is to review the protocol’s safety and appropriateness of implementation. Results will be analyzed for consideration of changes to the institution’s protocol.

**Methods:** A retrospective chart review of all MDMC patients who were hospitalized between January 1, 2016 and May 31, 2016 and initiated on the DKA/HHS protocol will be performed. Data to be collected and analyzed include: admitting blood glucose, admitting anion gap, time for blood glucose to normalize, time to gap closure, time to initiation of titratable insulin drip or subcutaneous insulin regimen after gap closure, incidence of hypoglycemia, and adherence, both nursing and provider, to electrolyte replacement and fluid management. Continuous data will be assessed for normality of distribution and the appropriate parametric (Student’s t-test) or non-parametric analog (Wilcoxon Rank Sum) will be utilized to determine statistical significance. Categorical data will be analyzed using the Fisher’s exact test. Descriptive analysis will also be performed as indicated.

Poster Title: Evaluation of readmission rates among patients discharged on P2Y12 receptor inhibitors for the management of acute coronary syndrome

Primary Author: Kathleen Ubina, Methodist Dallas Medical Center, TX; Email: kathleenubina@mhd.com

Additional Author(s):
Ilka Ratsaphangthong
Betina Daniel

Purpose: The use of P2Y12 inhibitors is a key management strategy following a cardiovascular event and can reduce the risk of a subsequent thrombotic event. These agents, however, are also associated with an increased bleeding risk. The purpose of the study is to evaluate the appropriate use, dosing, and monitoring of P2Y12 inhibitors for ACS compared to national guidelines recommendations and FDA approved indications. The primary objective is to evaluate readmission rates within 1 year of discharge related to a bleeding or thrombotic event. The secondary objective is to assess the impact of medication access on readmission.

Methods: The study follows a retrospective chart review study design and will include medical records of patients initiated on P2Y12 inhibitor maintenance therapy for acute myocardial infarction. The P2Y12 inhibitor agent prescribed during hospital stay and at discharge, along with dosing and indication, as well as cardiovascular procedures performed during hospitalization, and concomitant antiplatelet therapies during intervention or discharge, will be collected for review. Impact on hospital readmissions within 1 year of initiation of P2Y12 inhibitor maintenance therapy related to a thrombotic or bleeding event will be evaluated. The utilization of patient assistance programs will also be assessed. All data will be recorded without patient identifiers and maintained confidentially.

**Poster Title:** Evaluation of the impact of beta-lactam allergy on the management of gram-negative fluoroquinolone-resistant bacteremia in the community hospital setting

**Primary Author:** Sarah McDaniel, Methodist Hospital San Antonio, TX; **Email:** snmcdaniel@utexas.edu

**Additional Author(s):**
Gerard Gawrys

**Purpose:** Fluoroquinolone resistance has significantly impacted the management of gram-negative infections for decades. In certain parts of the United States, resistance rates approach 40 percent. It is imperative that clinicians appreciate this epidemiologic reality when selecting empiric therapy. However, in the setting of beta-lactam allergy many physicians are compelled to use non-beta-lactam alternatives, particularly fluoroquinolones. Beta-lactam allergy and subsequent use of a fluoroquinolone may lead to inappropriate empiric coverage. The purpose of this study is to evaluate the impact of beta-lactam allergy on the management of gram-negative bacteremia caused by resistant gram-negative pathogens.

**Methods:** The protocol for this study will be submitted to the Institutional Review Board (IRB) for approval and will consist of a multicenter, retrospective chart review completed at several community hospitals in the Methodist Healthcare System. A review of patients admitted over a 33-month period will be conducted to evaluate the management of fluoroquinolone-resistant gram-negative bacteremia in two patient populations: those with a documented beta-lactam allergy and those without. Inclusion criteria will be patients admitted for at least 24 hours who produced a gram-negative isolate from blood that was resistant to levofloxacin. Patients meeting the inclusion criteria will be divided into two groups: those with and without a documented beta-lactam allergy. Each group will be further divided into those that received a beta-lactam antibiotic and those that did not. The following parameters will be collected for all patients: bacteremia source, patient age, unit, presence of infectious disease consultation, type and severity of beta-lactam allergy, previous safe administration of a beta-lactam, antibiotic utilized for treatment, adequacy of empiric coverage and resolution of clinical symptoms.
Results: Results will be presented at TSHP/Alcalde regional residency conference in the Spring of 2017.

Conclusion: Conclusions will be presented at TSHP/Alcalde regional residency conference in the Spring of 2017.

Poster Title: Evaluating the impact of rapid microbiological diagnostics on the management of bacteremia due to extended-spectrum beta-lactamase (ESBL) producing Enterobacteriaceae

Primary Author: Michelle Kennedy, Methodist Hospital San Antonio, TX; Email: mkennedy4@angelo.edu

Additional Author (s):
Gerard Gawrys

Purpose: Resistant gram negative pathogens are a continuous threat in the health care setting. Recent advances in rapid diagnostic technology have allowed for timely detection of such organisms. However, optimal utilization of such technologies remains challenging at many facilities. The objective of this study is to evaluate the impact of rapid diagnostic testing on early treatment of bacteremia due to ESBL-producing Enterobacteriaceae.

Methods: The protocol for this study will be submitted to the Institutional Review Board for approval and will consist of a multicenter, retrospective chart review conducted at three community hospitals. An evaluation of patients admitted over a 33-month period will be completed to evaluate the antimicrobial management of ESBL-producing Enterobacteriaceae. Inclusion criteria for review will be as follows: patients admitted for at least 24 hours who produced an Enterobacteriaceae isolate from blood that was resistant to a third-generation cephalosporin. Additionally, the following parameters will be collected: resistance patterns of isolates, presence of an infectious diseases consultation, empiric versus targeted therapy, time to optimal therapy, timing of PCR result publication, provider specialty, microbiological clearance, and time to resolution of infection symptoms.

Results: Results will be presented at TSHP/Alcalde regional residency conference in the Spring of 2017.

Conclusion: Conclusions will be presented at TSHP/Alcalde regional residency conference in the Spring of 2017.

**Poster Title:** Antibiotic prescribing patterns in adults diagnosed with nosocomial pneumonia: Retrospective chart review

**Primary Author:** Sana Qureshi, Scott & White Memorial Hospital, TX; **Email:** sana.quireshi.1@gmail.com

**Additional Author(s):**
Charlotte Farris
Tiffany LaDow

**Purpose:** Unnecessary broad-spectrum antibiotics and increased duration of therapy can lead to numerous negative patient outcomes. The most recent Infectious Disease Society of America guidelines for hospital-acquired (HAP) and ventilator-associated (VAP) pneumonia provide limited guidance on de-escalation of antibiotics, but have recommended a shorter duration of therapy for all patients of approximately 7 days. Anecdotal observation of the duration of therapy and oral antibiotics chosen for patients with nosocomial pneumonia at Scott & White Memorial Hospital indicates inconsistencies in prescribing patterns. Our study aims to review the current trends in prescribing patterns, focusing on duration and intravenous to oral therapy transitions.

**Methods:** A retrospective chart review will be conducted on nosocomial pneumonia patients admitted between August 25th 2015 to August 25th 2016. Inclusion criteria will be as follows: patients age 18 years or older with documented diagnosis of HCAP, HAP or VAP. Data will be collected with a focus on microbiological cultures, days of antibiotic administration prior to de-escalation to oral therapy, final oral antibiotic and total duration of therapy. Primary endpoints are to categorize the types of oral antibiotics these patients are transitioned to when completing therapy and the total duration of antibiotic therapy prescribed. Secondary endpoints will include time to de-escalations, length of stay, and 30-day readmission rate. All data will be maintained confidentially according to Scott & White Memorial Hospital protocol for private health information.

**Poster Title:** Evaluation of inpatient management of supratherapeutic INR in warfarin patients

**Primary Author:** Alejandra Ibarra, Scott & White Memorial Hospital, TX; **Email:** alejandra.ibarra@bswhealth.org

**Additional Author (s):**
Sebastian Perez
Delaney Ivy
Charlotte Farris

**Purpose:** In 2012, the American College of Chest Physicians (ACCP) updated their guidelines to facilitate warfarin reversal in the setting of supratherapeutic INR. However, a recent study has demonstrated that only about 25 percent of vitamin K utilization is in concordance with ACCP guideline recommendations and has led to variability in the management of patients with supratherapeutic INR. The aim of this study is to evaluate Scott & White Memorial Hospital physician’s prescribing patterns of vitamin K in patients with a supratherapeutic INR in comparison to 2012 ACCP Evidence-Based Management of Anticoagulant Therapy guidelines.

**Methods:** This study will be submitted to the Institutional Review Board for approval. A retrospective review will be conducted from March 1, 2014 through August 31, 2016 to include adult patients on warfarin who received vitamin K in response to a supratherapeutic INR with or without bleeding complications. Patients diagnosed with cirrhosis or acute hepatitis will be excluded. The following data will be collected: patient age, gender, height, weight, race/ethnicity, indication for anticoagulation, INR goal, OBRI score, INR values, dose and route of vitamin K, number of doses of administered, time to target INR, incidence of minor or major bleed, location of minor or major bleed, hemoglobin, delay in procedure due to supratherapeutic INR, and diagnosis of stroke/VTE within 30 days of warfarin reversal. All data will be collected without patient identifiers and kept confidential. Reviewers will subsequently determine if vitamin K dose and route was concordant with the 2012 ACCP guideline recommendations.

Poster Title: Antibiotic prescribing patterns in pyelonephritis
Primary Author: Justin Shanks, Scott & White Memorial Hospital, TX; Email: justin.shanks@bswhealth.org

Additional Author(s):
Sebastian Perez
Megan Roberts
Jerry Smith
Hannah Ehrenfeld

Purpose: The Infectious Diseases Society of America (IDSA) recommends fluoroquinolones for the treatment of pyelonephritis. In facilities where resistance exceeds 10% alternative regimens augmented with ceftriaxone or aminoglycosides have been recommended. Nevertheless, practitioners routinely prescribe fluoroquinolones as monotherapy. Additionally, the IDSA recommends cautionary use of oral beta-lactams for the treatment of pyelonephritis due to high rates of resistance, inferior efficacy, and higher rates of relapse. Consequently, the use of oral beta-lactams for pyelonephritis remains unclear. This study is designed to retrospectively categorize antibiotic regimens prescribed for pyelonephritis and to collect data about the local antibiotic susceptibilities of urinary pathogens.

Methods: Once approved by our Institutional Review Board, this retrospective review will be conducted on patients with pyelonephritis admitted to a 636-bed teaching level I trauma regional health science center. Inclusion criteria will be as follows: patients at least 18 years of age, ICD-9 or ICD-10 code for pyelonephritis, and symptoms of pyelonephritis upon admission. Data collected will include: antibiotic choice, dose, route, frequency, duration, and the time from empiric therapy to targeted oral therapy. The primary endpoint is the incidence of prescribed empiric and targeted antibiotic regimens for pyelonephritis. The secondary endpoint is the antibiotic susceptibility rate of urinary pathogens.

**Poster Title:** Evaluation of periprocedural bleeding rates in patients receiving rivaroxaban based on preprocedural hold times  

**Primary Author:** Hannah Eberle, Seton Healthcare Family, TX; Email: heberle@seton.org  

**Additional Author (s):**  
Tamara Knight  
Evan Peterson  
Paige Parsons  

**Purpose:** Periprocedural management of direct oral anticoagulants is not well defined; hold times are taken from package insert and pharmacokinetic data because this subject has not been evaluated prospectively. Our main objective is to identify periprocedural major bleeding rates in patients receiving rivaroxaban and to determine what effect preprocedural hold times have on these rates. Secondary objectives include identifying the rate of clinically relevant non-major bleeding events and the rate of thrombosis.  

**Methods:** This study will be approved by the Institutional Review Board. It will be a retrospective, multicenter, cohort study comparing bleeding rates in patients receiving periprocedural rivaroxaban based on hold time and renal function. Rates of bleeding will be compared between patients who had rivaroxaban held for the recommended time of three to five half-lives - at least 48 hours for CrCl greater than 30 mL/min or at least 72 hours for CrCl less than 30 mL/min - to those who had rivaroxaban held for less than the recommended time. Patients will be identified using ICD-9 codes for surgical procedures and a home medication database identifying patients receiving rivaroxaban 15 mg or 20 mg. Orthopedic, kidney, bladder, prostate, intra-abdominal, cardiac, and CNS procedures will be included; low risk bleeding procedures will be excluded. Exclusion criteria include thrombocytopenia, low hemoglobin, preprocedural bleeding, or unknown timing of last rivaroxaban dose. The following data will be collected: age, sex, height, weight, ethnicity, comorbidities, hemogram, serum creatinine, liver function tests, doses of rivaroxaban, concomitant medications that increase bleeding risk, type and timing of surgery, occurrence of bleeding, and receipt of blood transfusions. Given an estimated baseline event rate of 12 percent in the arm with shorter than
recommended hold times, we will need 358 patients to provide 80 percent power to detect a 67 percent reduction in event rate.

Poster Title: Clinical outcomes of hospital-acquired and healthcare-associated pneumonia with and without empiric vancomycin in a non-critically ill population

Primary Author: Wenxi Liu, Seton Healthcare Family, TX; Email: wenxiliu1@gmail.com

Additional Author(s):
Dusten Rose
Brady Helmink
Theresa Jaso
Kristin Mondy

Purpose: Hospital-acquired pneumonia (HAP) and healthcare-associated pneumonia (HCAP) are leading causes of hospital-acquired infections. Infectious Disease Society of America (IDSA) guidelines recommend empiric anti- methicillin-resistant Staphylococcus aureus (MRSA) therapy for this patient population. However, recent evidence suggests that many HAP/HCAP patients are not at risk for MRSA, and initial therapy should be tailored to patient-specific factors. Currently, there are no studies comparing outcomes of empiric vancomycin use in this setting. Thus, the objective of this study is to evaluate clinical outcomes of non-critically ill HAP/HCAP patients who receive empiric vancomycin compared to those who do not.

Methods: This study is a multi-center, retrospective cohort of non-critically ill adult patients diagnosed with HAP/HCAP. Retrospective chart review will be used to identify patients who presented with new-onset pneumonia with one or more risk factors for HAP/HCAP and received intravenous antibiotics for greater than 72 hours. Treatment groups will be defined as patients who received empiric anti-MRSA therapy with vancomycin versus those who did not. The primary endpoint is clinical success at the time of antibiotic completion or discharge on antibiotics. Clinical success is defined as patients who did not experience death, did not require admission to the intensive care unit, and did not switch or require additional intravenous antibiotic(s) due to treatment failure. Secondary endpoints include hospital length of stay, time to clinical stability, in-hospital all-cause mortality, time to therapy de-escalation, and 30-day readmission rate for pneumonia. Safety will be examined through incidence of nephrotoxicity. Categorical variables will be analyzed using Chi-square or Fisher’s Exact test, while continuous
variables will be analyzed using Two-Sample t-test or Wilcoxon Rank-Sum based on variable distribution. Logistic regression will be used to determine predictors of clinical success.

**Poster Title:** Does the Sepsis Core Measure impact discordance with local guidelines for first dose antibiotic prescribing in patients with sepsis from cellulitis?

**Primary Author:** Elizabeth Lass, Seton Healthcare Family, TX; **Email:** elass@seton.org

**Additional Author(s):**
Manasa Murthy
Mitchell Daley
Emily Hodge
Dusten Rose

**Purpose:** In 2015, the Centers for Medicare and Medicaid Services (CMS) implemented the SEP-1 core measure, focused on sepsis treatment and outcomes. This measure provides accountability for very specific antibiotic selections which may not be consistent with clinical practice. Specifically, based on patient risk and local susceptibilities, cefazolin or vancomycin is recommended as first line therapy for cellulitis in local guidelines, yet both would be non-compliant as monotherapy for SEP-1. The purpose of this study is to determine if SEP-1 increases discordance with local guidelines for first-dose antibiotic prescribing in patients with sepsis from cellulitis.

**Methods:** The present study is a multi-center, retrospective chart review of patients aged 18-89 years old, admitted to the hospital with sepsis and severe sepsis, secondary to cellulitis. Patients will be identified with corresponding ICD-9 and ICD-10 codes between September 1, 2014 and September 1, 2016. SEP-1 was implemented in October 1, 2015, which will be used to categorize patients as either pre-SEP or post-SEP. Patients will be excluded if requiring vasopressor therapy, presence of multiple sources of infection, transfer from an outside hospital, history or risk of multi-drug-resistant organisms on admission, immunocompromised status, documented beta-lactam allergy, and/or confirmed pregnancy. The primary outcome is to determine if SEP-1 increases discordance with local guidelines for first-dose prescribing in patients with sepsis from cellulitis. Secondary outcomes will include empiric coverage for methicillin-resistant Staphylococcus aureus or Pseudomonas aeruginosa, switch from initial antibiotic(s) selected to maintenance antibiotic therapy, efficacy of antibiotic selection based on culture results and the incidence of Clostridium difficile infections.
To achieve 80% power, an estimated 152 patients in each group are needed to detect a 15% difference in rate of guideline discordance based on an estimated 40% rate of discordance in the control group. Nominal data will be evaluated via a Chi-square analysis or Fisher’s Exact test. A forward, stepwise logistic regression will be done to identify variables associated with guideline discordance.

Poster Title: Cefepime with or without metronidazole versus piperacillin/tazobactam for the treatment of intra-abdominal infections caused by potential AmpC beta-lactamase producing organisms

Primary Author: Stephanie Chang, Seton Healthcare Family, TX; Email: schang2@seton.org

Additional Author(s):
Mitchell Daley
Dusten Rose
Manasa Murthy
Emily Hodge

Purpose: A wide range of Enterobacteriaceae produce AmpC beta-lactamases, which confer resistance to penicillins and most cephalosporins. Recent studies have established cefepime as an effective treatment option for AmpC beta-lactamase producing organisms; however, the efficacy of beta-lactam/beta-lactamase inhibitors (BLBLI) is unclear. A BLBLI is potentially appealing for intra-abdominal infections as a single drug regimen with coverage of Enterococcus spp. and anaerobic organisms. The objective of this study is to determine if there is a difference in outcomes for patients with intra-abdominal infections caused by AmpC beta-lactamase producing organisms treated with cefepime with or without metronidazole versus piperacillin/tazobactam.

Methods: This multicenter, retrospective cohort study will include adults greater than 17 years of age with at least one intra-abdominal culture positive for an AmpC beta-lactamase producing organism (Enterobacter spp, Citrobacter spp, Morganella spp, and Serratia marcescens) that received intravenous cefepime with or without metronidazole or piperacillin/tazobactam as definitive therapy. Patients must have undergone at least one source control procedure during the hospital admission. The primary outcome is the composite of surgical-site infections, recurrent intra-abdominal infections, or death. Secondary outcomes include differences in the individual components of the composite outcome, length of stay from index source control procedure, microbiologic failure, length of antibiotic treatment, time to clinical resolution, and incidence of Clostridium difficile infection. Based on a 20% rate of composite complications, a sample size of 276 patients will be needed to achieve 80% power and to detect a 15%
difference in complication rate between groups. Pearson’s Chi-square test will be used to analyze the primary composite outcome. For secondary outcomes for dichotomous variables, Pearson’s Chi-square test or a Fisher’s exact test will be used. For continuous variables, a Shapiro-Wilk test will determine if the data is parametric. The Student’s t-test will be used for parametric data and the Mann-Whitney U-test will be used for non-parametric data. A Kaplan-Meier estimation and Cox regression will be conducted to describe time to clinical resolution.

**Poster Title:** Comparison of dexamethasone versus prednisolone, prednisone, or methylprednisolone for the use of acute asthma exacerbations in hospitalized pediatric patients

**Primary Author:** Kristin Bohannon, Seton Healthcare Family, TX; **Email:** kbohannon@seton.org

**Additional Author(s):**
Ronda Machen
Carolyn Ragsdale
Eimeira Padillo-Tolentino
Patty Cervenka

**Purpose:** Systemic corticosteroids play an important role in acute asthma exacerbations. The use of dexamethasone has been well studied in the emergency department setting, but there is limited research on its use for hospitalized pediatric patients. The purpose of this study is to determine if two days of dexamethasone decreases the length of hospital stay for pediatric patients hospitalized with an acute asthma exacerbation compared to a five day course of prednisolone, prednisone, and/or methylprednisolone.

**Methods:** This study is a single-center, retrospective, chart review of pediatric patients hospitalized for an acute asthma exacerbation. In October of 2013, Dell Children’s Medical Center of Central Texas implemented a new pediatric asthma pathway which primarily utilizes a two day course of dexamethasone for a mild-moderate asthma exacerbation as compared to a previously used five day course of prednisolone, prednisone, and/or methylprednisolone. Pediatric patients who received dexamethasone or prednisolone, prednisone, and/or methylprednisolone for an acute asthma exacerbation between June 1, 2011 and January 31, 2016 will be identified. Patients 2-18 years old who are hospitalized for more than 24 hours with a principle discharge diagnosis of asthma and received a course of a corticosteroid will be included. The primary endpoint will be length of hospital stay between the two corticosteroid groups. Secondary endpoints include asthma symptom scores, milligrams of albuterol used in the first 24 hours, milligrams of ipratropium, time until albuterol at a frequency of every four hours, time until oxygen supplementation is no longer needed, days of systemic steroid use, readmission at 7 days, and cost of hospital stay. Using an assumed 10% decrease in length of
stay and a standard deviation of 0.7 days, 200 patients in each arm are required to achieve 80% power. Data collection will begin after Institutional Review Board approval.

Poster Title: Effect of adjunctive clindamycin duration on time to resolution of complicated skin and soft tissue infections.

Primary Author: Tanner Moser, Seton Healthcare Family - Austin, Texas, TX; Email: t.moser91@gmail.com

Additional Author(s):
Kathryn Merkel
Theresa Jaso
Neil Pan

Purpose: It is not unusual to see clindamycin therapy utilized in combination with other antibiotics in complicated skin and soft tissue infections (cSSTI) due to its potential to reduce bacterial toxin production. cSSTI are frequently caused by bacteria that are capable of producing toxins that cause severe local and systemic effects. While clindamycin is recommended in several infection types, the optimal duration has not been defined. The purpose of this study is to discover if short-term or long-term adjunctive clindamycin affects time to resolution in cSSTI.

Methods: This is a multi-center, retrospective, cohort study assessing the effect of clindamycin duration on time to objective resolution. The inclusion criteria are as follows: age ≥ 18 years, diagnosis of cSSTI, ≥ 2 systemic inflammatory response syndrome (SIRS) criteria, and combination beta-lactam, vancomycin, or daptomycin therapy. Exclusion criteria include: pregnancy, immunosuppressed state, protein-synthesis inhibiting antibiotics besides clindamycin used during hospitalization, receipt of clindamycin for < 24 hours, concomitant infection, and diagnosis of diabetic foot infection, osteomyelitis, septic arthritis, endocarditis, meningitis, epidural abscess, or device-related infections. The definition of cSSTI for this study includes cellulitis, erysipelas, abscess, necrotizing fasciitis, and gas gangrene. The direct comparison will be between patients who receive ≤ 2 days of clindamycin and ≥ 3 days. Patient data collected will include the following: demographics, vitals and laboratory values, severity of illness, comorbidities, infectious etiology, surgical intervention, and antibiotics utilized. The primary endpoint will be time to objective resolution, consisting of the complete normalization of SIRS criteria. Secondary endpoints will include length of stay, readmission within 30 days,
and Clostridium difficile infection (CDI) rates within 30 days. The primary endpoint will be analyzed using a Cox's proportional hazards model. The secondary endpoints will be evaluated using Student’s t-test or Mann-Whitney U test as appropriate for continuous data, and χ² test for nominal data.

Poster Title: Historical standard of care versus liposomal bupivacaine in video-assisted thoracoscopic surgery (VATS): a retrospective single-centered cohort study

Primary Author: Jennifer Shin, St. David’s South Austin Medical Center, TX; Email: jenshin06@gmail.com

Additional Author(s):
Eardie Curry
Eric Hoenicke
Kyle Maskell
Nicolas Forcade

Purpose: Pain management is an essential component of postoperative care. Suboptimal analgesia contributes to poor coughing effort, resulting in retention of upper airway secretions. Additionally, inadequate pain control interferes with early ambulation, thus, predisposing patients to venous thromboembolic events. Liposomal bupivacaine is a locally-acting anesthetic, labelled for post-operative analgesia. Currently available data is sparse for post-operative analgesia in patients undergoing video-assisted thoracoscopic surgery (VATS). Prior to the approval of liposomal bupivacaine, our cardiothoracic surgeons utilized other locally-acting anesthetics. The overall purpose of this study is to determine whether liposomal bupivacaine contributes to better outcomes compared to historical standard of care.

Methods: This retrospective single-centered cohort study has been submitted to the Institutional Review Board for approval. The electronic medical record system will be utilized to identify patients who have undergone lobectomy by video-assisted thoracoscopic surgery (VATS). The following data will be collected: patient age, gender, weight, height, and visit number. Data collected will be divided into two groups based upon liposomal bupivacaine use or historical standard of care. The primary outcome will compare opioid consumption measured in morphine equivalence through post-operative day seven in patients that were administered liposomal bupivacaine vs historical standard of care. The secondary outcomes will compare length of hospital stay, intensive care unit duration, readmission within 30 days of discharge, overall non-opioid consumption measured in cumulative dose for each class of analgesic, naloxone utilization, pain scores through post-operative day seven, anti-emetic
medication use, and post-operative days until ambulation. Descriptive statistics will be used to summarize the data and nonparametric comparative tests will be used to assess differences between outcomes in the liposomal bupivacaine group and historical standard of care group.

**Results:** Data are being collected and analyzed and results will be described once complete.

**Conclusion:** Conclusions will be drawn from analyzed data and presented once complete.

Poster Title: Rates of drug therapy problems in an inpatient heart failure population readmitted within 30 days of previous hospitalization

Primary Author: Brette McDonald, SW Memorial Hospital, TX; Email: brette.mcdonald@hbswhealth.org

Additional Author(s):
Charlotte Farris

Purpose: Medication regimen problems have been identified as contributory factors in heart failure exacerbations. The objective of this study is to characterize drug therapy issues occurring in heart failure patients readmitted within 30 days of an acute exacerbation. The information uncovered by this study will add to the body of knowledge on heart failure and identify a potential target area for drug therapy optimization and decreasing 30-day readmissions in this population.

Methods: After approval from the Institutional Review Board, this retrospective chart review will be conducted in chronic heart failure patients admitted to the hospital for an acute heart failure exacerbation then readmitted within 30 days after discharge. The inclusion criteria for this study will be: patients 18 years of age or older, a documented primary diagnosis of heart failure, readmission within 30 days of the previous discharge date. The following information will be recorded: patient demographics, primary diagnosis, medication allergies or intolerances, pertinent laboratory data, chronic comorbidities, and discharge medication list. The primary endpoint of the study will be identification and characterization of drug therapy errors in patient discharge medications including omission of therapy, failure to achieve target medication doses, and drug-drug or drug-disease interactions. Secondary endpoints include patient adherence rates to the prescribed regimen and analysis of the principal admission diagnosis upon readmission.

Poster Title: Implementation of a pharmacy student-led medication history program in a large, tertiary pediatric emergency center

Primary Author: Claire McClain, Texas Children's Hospital, TX; Email: camcclai@texaschildrens.org

Additional Author(s):
M. Brooke Bernhardt
Julianna Fernandez

Purpose: The Joint Commission defines the medication reconciliation process as “obtaining and maintaining an accurate, detailed list of all medicines taken by a patient and using this list to provide correct medicines anywhere within the health care system.” This process at a large pediatric institution is complex and inconsistently performed across transitions of care. Unfortunately, this has led to various medication-related errors which have impacted patient care. Errors are classified according to The National Coordinating Council for Medication Error Reporting and Prevention. This project aims to implement pharmacy student-initiated medication histories in the Emergency Center to identify and prevent medication-related errors.

Methods: This is a twelve-week pilot study evaluating the implementation of a medication history program within a large, tertiary pediatric Emergency Center. Pharmacy students were trained and validated by a pharmacist to complete medication histories for patients with admission status in the Emergency Center. Nurses within the Emergency Center were educated on the purpose and methods of this pilot study. When the patient transitions to admission status, the student completes the medication history with an established documentation form. The student compares the current medication list in the electronic medical record to the medication list obtained through the patient interview. The following discrepancies are documented on the data collection form: incorrect/missing dose, incorrect/missing route, incorrect/missing frequency, incorrect/missing medication, incorrect/missing allergy, incorrect/missing formulation, and discontinued/not taking medication. Additional information collected includes: time to complete medication histories, number of outside pharmacies used, total number of home medications in the record, and total number of medications reported.
during the interview. Demographic information includes: sex, age, weight/height, race/ethnicity, preferred language, admission diagnosis, and primary diagnosis. The collected data will be consolidated and analyzed using descriptive statistics. The results will be used to justify additional resources to expand pharmacy-led medication histories within the institution. This study has been approved by the Institutional Review Board.

Poster Title: Analysis of voriconazole dosing and serum concentrations in pediatric oncology patients

Primary Author: Amy Kiskaddon, Texas Children's Hospital, TX; Email: amykiskaddon@gmail.com

Additional Author(s):
Kate Reichert
Brady Moffett
Maria Gramatges
Debra Palazzi

Purpose: Voriconazole is commonly utilized for antifungal prophylaxis in immunocompromised patients and treatment for invasive fungal infections. Several pharmacokinetic studies conducted in immunocompromised pediatric patients indicate higher doses are needed compared to adults. Given the pharmacokinetic variability in pediatric patients, therapeutic drug monitoring (TDM) and the use of judicious and appropriately-timed serum measurements are required to ensure optimal therapy. This study will evaluate the dose (mg/kg) required to achieve a therapeutic voriconazole trough of 1 to 5.5 mg/L in pediatric oncology patients with possible, probable, or proven fungal infection.

Methods: This is a single center, retrospective study evaluating targeted dosing of voriconazole in patients less than 18 years of age with a diagnosis of acute lymphocytic leukemia (ALL) or acute myeloid leukemia (AML) and a concomitant possible, probable, or proven fungal infection. All patients were treated at a large pediatric academic medical center between October 1, 2010 and September 30, 2016. All serum voriconazole levels will be included. Pharmacokinetic analysis using Non Linear Mixed Effects Modeling (NONMEM®) will be conducted for comparison of our findings to current recommended dosing regimens. The primary outcome of this study is to identify the dose (mg/kg) required to achieve a therapeutic voriconazole trough of 1 to 5.5 mg/L in specific age groups. Secondary outcomes will include: confirmation of current proposed dosing strategies, validation of published pharmacokinetic models, and reporting of treatment related adverse outcomes. Where available, pharmacogenomics data will be collected and incorporated into our findings. All research has
been approved by the institutional review board and performed in accordance with the Declaration of Helsinki.

Poster Title: Medication adherence in adolescents with systemic lupus erythematosus (SLE)

Primary Author: Andrea White, Texas Children's Hospital, TX; Email: aawhite1@texaschildrens.org

Additional Author (s):
M. Brooke Bernhardt
Anna Carmela Sagcal Gironella
Eyal Muscal
Marietta DeGuzman

Purpose: Hydroxychloroquine (HCQ) is a critical agent in the treatment of adolescents with systemic lupus erythematosus (SLE). HCQ has been shown to help prevent flares, protect against diabetes mellitus, thrombotic events, dyslipidemia, and overall damage accrual in these patients. Nevertheless, studies suggest nonadherence to be a pervasive problem, with only 30 to 60 percent of SLE patients taking medications as prescribed. Ultimately, lack of adherence is associated with poor disease control. Understanding the barriers to medication adherence is vital. The purpose of this study is to assess potential barriers to medication adherence, and to improve HCQ adherence in adolescents with SLE.

Methods: This is a single-center study. Face-to-face interviews between the pharmacist and the patient/caregiver will occur during regularly-scheduled clinic visits to assess specific barriers to medication adherence. The patient specific interventions will be derived from information gathered. The primary aim is to address the barriers to HCQ adherence. Secondary aims include the following: to describe the effectiveness of various tools in improving medication adherence and to obtain HCQ levels and correlate them with reported adherence. Concurrently, a new practice standard of monitoring HCQ levels will be implemented. HCQ levels should be collected at baseline, 3 months, and 6 months. Levels will be interpreted as follows: complete non-adherence: less than 200 ng/mL; partial adherence 200 to 1000 ng/mL; therapeutic/adherent: greater than 1000 ng/mL. A future, retrospective study will be planned to analyze the correlations of interventions to improved compliance/HCQ levels. Patients will be included if treated at the institution or clinic by the Pediatric Rheumatology Service during a 6 month study timeframe. They must have a diagnosis of SLE and have received HCQ for at least 3 months.
These patients will be excluded: newly diagnosed, receiving HCQ for the duration of the study period, have known HCQ-induced retinopathy, patients with a history of HCQ intolerance, and pregnant.

**Poster Title:** Effect of Inhaled Nitric Oxide on Respiratory Status in Patients with Congenital Diaphragmatic Hernia

**Primary Author:** Cynthia Toy, Texas Children's Hospital, TX; Email: chtoy@texaschildrens.org

**Additional Author(s):**
Kimberly Dinh
Karen Johnson
Frank Placencia
Caraciolo Fernandes

**Purpose:** Congenital diaphragmatic hernia (CDH) is a congenital malformation of the diaphragm resulting in lung hypoplasia and persistent pulmonary hypertension (PPHN) which often results in a need for extracorporeal membrane oxygenation (ECMO) and carries a high mortality rate early in life. General treatment of PPHN with inhaled nitric oxide (iNO) has been established, though the effects and recommendation to utilize iNO therapy in CDH patients is not well established due to minimal data in this population. Conducting this research will provide the pediatric community additional evidence regarding the efficacy of iNO and a better understanding of treatment options in this population.

**Methods:** An IRB-approved, retrospective chart review in a large quaternary care free-standing children’s hospital will be performed on all patients with a diagnosis of congenital diaphragmatic hernia from October 1, 2010 to August 31, 2016. Baseline demographics will be collected: gender, gestational age, postmenstrual age, postnatal age, birth weight, diagnosis at birth or prenatally, syndromic versus non-syndromic CDH, additional comorbidities, position of the liver on echocardiogram, time to surgical repair, fetal tracheal occlusion, and lung-to-head ratio. The blood gas that triggered initiation of iNO treatment will be collected and 2 blood gases 30 minutes and 1 hour after treatment initiation will be recorded. The number of days of ventilation after the start of iNO and type of ventilation will be collected. The inhaled nitric oxide parameters will be collected and will include: dose, duration of therapy, methemoglobin levels, and days of iNO prior to ECMO cannulation. Concurrent medications will be recorded. Two oxygenation index readings will be recorded at baseline, specifically the OI that triggered the initiation of iNO, as well as two readings after iNO therapy. ECMO parameters such as
duration of ECMO, venoarterial or veno-venous ECMO, age at time of ECMO cannulation, and duration of ECMO therapy. Lastly, cost parameters in regards to ventilator time, iNO therapy, and ECMO therapy will be collected and time to discharge will be recorded.

Poster Title: Tocilizumab use in children and adolescents with systemic juvenile idiopathic arthritis

Primary Author: Swati Jain, Texas Children's Hospital, TX; Email: swati.jain.email@gmail.com

Additional Author(s):
Melanie Bernhardt
Andrea Ramirez
Anna Carmela Sagcal Gironella
Marietta De Guzman

Purpose: Monoclonal antibodies (mAbs) have the ability to target cell specific factors and mimic endogenous immune factors. Tocilizumab is a humanized mAb that is active against interleukin-6 receptors. Interleukin-6 plays a key role in modulating T-cell activation and initiating the immune cascade. Tocilizumab is indicated for the treatment of systemic juvenile idiopathic arthritis (sJIA) in patients 2 years old or older. There are limited data on the use of tocilizumab outside the setting of a controlled clinical trial. The purpose of this project is to examine the clinical use of tocilizumab in a single-center population of patients with sJIA.

Methods: This is a single-center, retrospective analysis of use of tocilizumab in children and adolescents treated at our institution over a course of 6 years (October 1, 2010 – September 30, 2016). The primary objective is to describe usage patterns of tocilizumab in a cohort of children and adolescents treated at a large, academic free-standing children's hospital. Secondary aims include safety profile (including but not limited to rates of infection) and reasons for medication discontinuation. Patient inclusion criteria are: receipt of treatment from the Texas Children's Hospital Pediatric Rheumatology Clinic, 18 years of age or younger, and receipt of at least 1 dose of tocilizumab during the course of their treatment regimen for sJIA. General demographic and anthropometric data will be collected for all patients. The following dosing information will be documented: age at sJIA diagnosis, age at initiation of tocilizumab, dates of initiation, “place” in line of therapy (i.e., first, second), prior therapy received, dose of tocilizumab used, use of premedications to prevent infusion related reactions, use of concurrent immunosuppressive therapy, reason for discontinuation, date of discontinuation, and first agent used following discontinuation. Any infections and infection-related information
will be collected (including treatment). All research methods were approved by the institutional review board of Baylor College of Medicine.

Poster Title: Evaluation of Aprepitant for Chemotherapy-Induced Nausea and Vomiting in Children and Adolescents with Acute Lymphoblastic Leukemia Receiving Methotrexate

Primary Author: Femi Felix-Ukwu, Texas Children's Hospital, TX; Email: fefelixu@texaschildrens.org

Additional Author (s):
Eric Schafer
Amanda Berger
Kate Reichert

Purpose: The purpose of this study is to describe emetic control in patients with ALL who received aprepitant as part of an enhanced antiemesis regimen with methotrexate compared to those who received only a standard antiemesis regimen (i.e. no aprepitant) and to explore the potential drug-drug interactions between aprepitant and methotrexate by analyzing inpatient methotrexate pharmacokinetics both with and without concomitant aprepitant.

Methods: A retrospective cohort analysis will be conducted on patients with ALL who received methotrexate (≥1 g to ≤ 5 g/m2/dose) with and without concomitant aprepitant at Texas Children's Hospital between October 1, 2010 and January 31, 2016.

Primary Objective: Evaluate emetic control when patients with ALL receive methotrexate concomitantly with aprepitant compared to not receiving concomitant aprepitant
• Each patient will serve as their own control to evaluate the impact aprepitant on the number of emetic episodes and PRN antiemetic rescue medication use
  – Compare the number emetic episodes during 72 hours following methotrexate initiation or until methotrexate level < 0.1 micromoles/L (whichever occurs later), with and without aprepitant
  – Compare number PRN rescue medications doses during 72 hours following methotrexate initiation or until methotrexate level < 0.1 micromoles/L (whichever occurs later), with and without aprepitant

Secondary Objective: Evaluate the pharmacokinetics of methotrexate for patients with ALL receiving methotrexate concomitantly with aprepitant compared to not receiving concomitant
aprepatant Perform and compare intra-patient pharmacokinetic analysis of methotrexate exposure with and without aprepatant co-administration
    -AUC will be calculated using available data from methotrexate levels at times 0, 24, 36, 42 and 48 hours STATA 10.1 software (STATA Corp, College Station, TX, USA)
    • Incidence of delayed methotrexate clearance
    • Match patients by age, sex, methotrexate dose, phase and day of therapy

**Poster Title:** Effect of exogenous antithrombin administration on anti-Xa levels in infants treated with enoxaparin

**Primary Author:** Brittany Logston, Texas Children's Hospital, TX; **Email:** bblogsto@texaschildrens.org

**Additional Author (s):**
Emily Rodman
Danielle Rios
Kimberly Dinh
Brady Moffett

**Purpose:** Infants are born with low physiologic levels of antithrombin, which could make adequate anticoagulation with enoxaparin more difficult to achieve. As a result, exogenous supplementation of antithrombin III has been utilized in order to achieve therapeutic anti-Xa levels more effectively. It is unknown whether exogenous antithrombin III has any effect on improving time to goal anti-Xa levels in infants being treated with enoxaparin. The purpose of this study is to determine the effect of exogenous antithrombin III administration on low molecular weight heparin anti-Xa levels in the context of enoxaparin dosing in infants.

**Methods:** This is an IRB-approved, retrospective chart review of infants at a large, free-standing, quaternary care children’s hospital who received enoxaparin supplemented with antithrombin III from October 1, 2010 to August 31, 2016. The primary objective is to determine the median change in anti-Xa level within 12 hours of antithrombin III supplementation. The review will also analyze the median change in antithrombin III levels within 12 hours of supplementation, the correlation between median antithrombin III levels and anti-Xa levels at baseline, the median antithrombin III levels up to 3 days after supplementation, and include a subgroup analysis on premature infants. All patients less than one year of age admitted to Texas Children’s Hospital, who received enoxaparin treatment supplemented with antithrombin III will be included. Patients will be excluded if they received additional anticoagulation within 3 days, had a predisposition to bleeding or thrombus formation, experienced renal dysfunction, if anti-Xa levels were drawn inappropriately, or if dosing was inappropriately managed. The data points to be collected include the patient’s
chronological age, postmenstrual age, indication for enoxaparin, initial enoxaparin dose, final enoxaparin dose, number of dose changes, anti-Xa levels, antithrombin III levels, number of antithrombin III doses, antithrombin III dose administered, duration of antithrombin therapy, complete blood count, serum creatinine, urine output, and any noted bleeding.

Poster Title: Addition of a pharmacist in the management of septic patients in the emergency department

Primary Author: Sameer Afghani, Texas Health Harris Methodist Hospital Fort Worth, TX; Email: sameerafghani@texashealth.org

Additional Author(s):
Michael Olmos
Patricia Newcomb
Dave Spear

Purpose: The Surviving Sepsis guidelines demonstrate that patients who do not meet the three-hour treatment bundles have increased morbidity and mortality. A major component of this is appropriate antibiotic administration within three hours. Many of these patients present to the emergency department and often they are not treated within the appropriate time window and thus are at risk for deleterious outcomes. Our objective is to see if pharmacist involvement at the bedside in patients presenting with sepsis in the emergency department can reduce antibiotic administration times and a consequent reduction in mortality.

Methods: This study is being submitted to the Institutional Review Board for approval. The electronic medical record (EMR) system will be used to identify patients who present to the emergency department with septic parameters. Criteria for inclusion will be all patients greater than 18 and presumed septic. The following parameters are of interest and will be identified: age, gender, temperature, blood pressure, heart rate, respiratory rate, white blood cell count, lactate levels, source-of-infection, Glasgow Coma Scale and diagnostic imaging. Using a pharmacist developed protocol, potentially septic patients will be identified upon presentation to the emergency department. If a patient presents with SIRS criteria >2 and/or a qSOFA score >2 and a presumed infection, pharmacy will notify physicians of the patient if an antibiotic has not been ordered. Pharmacists will evaluate appropriateness of antibiotic based on patient allergies, site/source of infection, previous cultures and susceptibilities. Pharmacy will have access to the PYXIS medication storage unit and will remove the antibiotic and provide it to the nursing staff at the bedside for administration. Pharmacists will follow up every 20 minutes to
ensure antibiotic is administered as quickly and safely as possible. Patient will be followed throughout the course of emergency department stay and antibiotic appropriateness will be reviewed based on any new information. Data will be compared against patients who receive the standard of care.

Poster Title: Retrospective evaluation for culture correlation using a microarray-based, multiplexed rapid diagnostic instrument (Verigene system) for bloodstream infections

Primary Author: Van Ngo, Texas Health Harris Methodist Hospital Fort Worth, TX; Email: vanthengo@yahoo.com

Additional Author(s):
Troy Stillings
Patricia Newcomb
Jooyeon Chae

Purpose: Early de-escalation of antimicrobial therapy with the use of rapid diagnostic testing has shown to improve patient outcomes, decrease length-of-stay, decrease costs, and ultimately lead to the decreased development of resistant pathogens. Despite this knowledge, it is still not used as the absolute identifier for de-escalation of therapy at this point because of the uncertainty of its ability to catch poly-microbial infections or other infectious sources. The purpose of this retrospective study is to assess the accuracy of the Verigene system to routine microbiology methods in identifying the true offending pathogen in patients with bacteremia at multiple community based hospitals.

Methods: This study was submitted to the Institutional Review Board for approval. This is an ongoing retrospective observational study via electronic chart review on patients who have been identified with positive blood cultures via traditional culture methods and underwent rapid pathogen identification with the Verigene system from January 1, 2015 to December 31, 2015. Information was collected from 4 different community hospitals within the same healthcare system. Patients were included if they were >18 years of age and had a positive blood culture. Data collection includes pathogen identity, resistance markers, microbiology data from other sources, and central venous access points.

Adlia Ebeid
Nora Osemene

Purpose: The aim of this study is to utilize The Eighth Joint National Committee (JNC 8) treatment algorithm to evaluate the effectiveness and proper recommendation utilization of anti-hypertensive treatment among patients of African descent. Study results will inform medication adherence and medication therapy management.

Methods: Submission of this study will be sent to the Institutional Review Board for approval. A chart review will be conducted to evaluate active patients 18 years or older of African decent with a diagnosis of hypertension. Patients included in the study will be those who are prescribed a minimum of two anti-hypertensive medications and have two or more blood pressure readings dated between January 1-August 31, 2016. Data collected will include: demographics (age, gender, ethnicity), recorded clinical assessments (SBP, DBP, heart rate), comorbidities, current medications, and medication refill history. Medication adherence will be assessed per patient’s refill history. All patient identifiers will be removed and maintained confidential. Primary endpoints will be the attainment of their respective goal per JNC 8 guidelines for hypertension dependent upon the patient’s current health status and medication adherence while receiving treatment at San Jose Clinic. Comparative assessments will be along the dimensions of utilization of JNC 8 guidelines, blood pressure goals, and medication adherence. Appropriate sample size and comparison groups will be analyzed to report statistically significant results.

**Poster Title:** Prescribing patterns of HMG-CoA reductase inhibitors

**Primary Author:** Jacy Malone, Texas Tech University Health Sciences Center - School of Pharmacy - Amarillo, TX; Email: jacyth@gmail.com

**Additional Author(s):**
Rachel Basinger
Melissa Hunter
Marie Rapier

**Purpose:** The 2013 American College of Cardiology and American Heart Association guideline on the treatment of blood cholesterol to reduce atherosclerotic cardiovascular risk in adults has identified patients most at risk for experiencing an atherosclerotic cardiovascular disease event. These at-risk patients have been divided into the four Statin Benefit Groups. The primary objective of this study is to assess the adherence to the current guidelines of prescribers in the local internal medicine and family medicine clinics.

**Methods:** This project has been approved by the Quality Improvement Review Board. The study is designed as a retrospective chart review of patients who have been prescribed a HMG-CoA reductase inhibitor (statin) by one of the clinics’ attending physicians. All patient data will be de-identified and kept confidential. Data collection will include patient characteristics such as age, gender, race, blood pressure, and tobacco smoking status along with pertinent lab values (lipid panel, liver function tests), medical history (history of diabetes, history of heart disease), and current medications. Any history of adverse drug events with HMG-CoA reductase inhibitors or hospital admissions with an atherosclerotic cardiovascular disease diagnosis will also be recorded. The patients’ charts will be reviewed for any notations from the prescriber giving reasons for noncompliance with the guidelines. Researchers will assess if the prescribed HMG-CoA reductase inhibitor is of appropriate intensity based on the Statin Benefit Group the patients qualify under per the current guidelines.

Poster Title: Impact of propofol on hemodynamic control in mechanically ventilated septic shock patients

Primary Author: Vi Bui, Texas Tech University Health Sciences Center - School of Pharmacy/Hendrick Medical Center, TX; Email: vi.bui@ttuhsc.edu

Additional Author (s):
Young Lee

Purpose: Propofol is one of the sedatives of choice in the ICU settings due to its rapid onset and offset, allowing quick titration, daily sedation interruption, and less delirium effect. However, in septic shock patients, propofol-induced hypotension may complicate hemodynamic instability, necessitating dose increase or prolonged use of vasopressors. This study investigates the impact of propofol infusion on time to achievement of target blood pressure in mechanically ventilated patients with septic shock in comparison to other sedation agents.

Methods: This study will be submitted to the Institutional Review Board for approval. It is a retrospective, single-center, propensity-matched, cohort study conducting in septic shock patients on mechanical ventilation. Patients with septic shock will be identified by International Classification of Diseases diagnosis codes recorded in their electronic medical record. Prisoners, pregnant females, age less than 18 years, and those not on concurrent sedation and pressor, or not on mechanical ventilation will be excluded. Patients will be assigned to either the study group (propofol) or control group (other sedatives) based on their ICU sedation agent. The primary outcome is time to achieve target blood pressure, defined as mean arterial pressure of at least 65 mmHg or systolic blood pressure of at least 90 mmHg. Secondary outcomes include time to off pressor, duration of mechanical ventilation, length of stay, incidence of ICU delirium, and mortality. Data collection includes demographic information, baseline characteristics, and treatment progression such as age, weight, gender, comorbidities, primary sepsis sources, vitals, laboratory values, APACHE II and SOFA scores, Richmond agitation-sedation scale, medications, duration of treatment, as well as delirium and mortality incidence. The Mann-Whitney U or Student t-test will be used for continuous data while nominal data will be analyzed by chi-square or Fisher’s exact test.

Poster Title: Uninvestigated influences on acute kidney injury with concomitant piperacillin-tazobactam and vancomycin

Primary Author: Cody Faubion, Texas Tech University Health Sciences Center - School of Pharmacy/Hendrick Medical Center - Abilene, TX; Email: cody.faubion@ttuhsc.edu

Additional Author(s):
Pamella Ochoa
Kolton Bevel

Purpose: Recent literature describes the risk of nephrotoxicity with concomitant use of piperacillin-tazobactam and vancomycin. While risk factors that influence the risk of developing nephrotoxicity have been studied, additional influences on risk for nephrotoxicity in this patient population remains uninvestigated. The objective of this study is to evaluate factors associated with development of nephrotoxicity in patients receiving concomitant vancomycin and piperacillin-tazobactam.

Methods: This study has been submitted to the Institutional Review Board for approval. A retrospective chart review will be performed to identify patients receiving vancomycin, piperacillin-tazobactam, or concomitant vancomycin and piperacillin-tazobactam. Instances of nephrotoxicity will be identified based on increase in serum creatinine from baseline. Risk factors for development of nephrotoxicity will be identified and evaluated including use of intravenous contrast agents, time from administration of intravenous contrast agents to development of nephrotoxicity, and use of proton-pump inhibitors. Use of statin medications and ascorbic acid will be evaluated for effect on development of nephrotoxicity. Evaluation will include the following groups: vancomycin monotherapy, piperacillin-tazobactam monotherapy, and vancomycin with piperacillin-tazobactam.

Poster Title: Retrospective analysis of empiric antibiotic trends in emergency department patients

Primary Author: Devlin Smith, The University of Texas - MD Anderson Cancer Center, TX; Email: smith.devlin@gmail.com

Additional Author(s):
David Ursic
Joyce Broyles

Purpose: In the setting of possible or confirmed sepsis, the specific time frame for antibiotic administration has not been determined and no randomized controlled trials exist due to the ethical ramifications of such research. This pilot investigation was conducted to determine the need for further refinement of our institution’s emergency department antibiotic protocols and identify administration time goals for patients with possible sepsis presenting to our emergency department.

Methods: This retrospective analysis utilized data from the emergency department of a 617-bed academic medical center in Memphis, TN. The investigators excluded patients with < 1 antibiotic order, those that did not receive any of the ordered antibiotics, and those with a length of stay < 1 day. Antibiotics were divided by coverage type (e.g. gram positive, gram negative, anaerobic, atypical) to more easily assess the type of therapy patients received first. The patient population was identified from an antibiotic use report that is reviewed each month by pharmacy services for the emergency department. Retrospective chart review and data collection was performed for patients included in the January 2016 antibiotic use report that met the inclusion criteria. The data were analyzed using SPSS software.

Results: Final results are pending.

Conclusion: Final results are pending.

**Poster Title:** Measuring changes in adherence associated with incorporating tailored messaging in antibiotic counseling by community pharmacists

**Primary Author:** Mikaela DeBarba, The University of Texas at Austin College of Pharmacy/H-E-B Pharmacy, TX; **Email:** mikaelafarrell@utexas.edu

**Additional Author(s):**
Nathan Pope
Austin Green
Ken Lawson
Jennifer Wilbanks

**Purpose:** The CDC launched a program called “Get Smart About Antibiotics.” The initiative states that community pharmacists play an integral role in promoting safe antibiotic use partly by educating the patient about properly taking antibiotics and the potential harms of antibiotic use, including antibiotic resistance and adverse drug events. According to a review of counseling practices, antibiotics are a therapeutic class that pharmacists were more likely to counsel on; however, discussing antibiotic resistance was not mentioned. The purpose of this study is to determine if pharmacists providing tailored messaging about antibiotic resistance during patient counseling improves adherence, thereby preventing antibiotic resistance.

**Methods:** Prescriptions for antibiotics at selected grocery-store based community pharmacies will be selected for special counseling. Informed consent will be requested of participants. This study will consist of three phases. Each phase will last six weeks and will include a follow-up phone call to measure adherence based on proportion of doses taken. Phase one will consist of usual care. Phase two will consist of usual care and a handout explaining antibiotic resistance, how it occurs, and how completing full courses of antibiotics helps prevent resistance. Phase three will consist of tailored messaging within the pharmacists’ counseling to the patient. The tailored messages will teach the patient how antibiotic resistance occurs and how finishing the complete course of antibiotics can help prevent resistance. A handout about antibiotic resistance will also be distributed during the tailored message counseling session. Descriptive statistics will be reported for counseling group adherence and covariates (age, sex, type of infection, dosing frequency, level of education). Chi-squared analysis will be performed to
evaluate the relationship between counseling group and adherence status. ANOVA will be used for adherence measured as a continuous variable. Logistic regression will be used to assess the relationship between counseling group and adherence status while controlling for covariates. This proposed study will be submitted for review by the Institutional Review Board of The University of Texas at Austin.

Poster Title: Optimization of automated dispensing cabinets to improve utilization and efficiency of dispensing workflow at an academic medical center

Primary Author: Tony Rudisill, The University of Texas Medical Branch at Galveston, TX; Email: torudisi@utmb.edu

Additional Author (s):
Nelvin Daniel
Regina Ramirez

Purpose: The purpose of this pre-post intervention study is to evaluate automated dispensing cabinet (ADC) utilization rates and the impact of ADC optimization achieved through a series of medication stock modifications. Pre- and post-optimization analysis will be conducted to evaluate the impact of changes made to the ADC. In addition, secondary endpoints for the study will evaluate the trends of Patient Safety Net (PSN) reports, cabinet stockout rates, in-basket messages, as well as medication redispenses.

Methods: Data reported from electronic health records (EHR) and ADC systems will be utilized to improve ADC inventory levels and stock. Approximately ten ADCs will be selected for optimization based on a combination of current utilization rates, number of stockouts, and number of PSN reports. Aggregated data will be analyzed for each cabinet for a period of two months prior to the optimization. The process of optimization will include medication addition and removals, par level adjustments, and pocket relocations. The primary endpoint of ADC utilization rate will be calculated by the total number of medication doses dispensed from an ADC divided by the total number of medication doses dispensed to that unit. Rates for secondary endpoints will utilize daily and monthly trends for comparison. Stockouts will be defined as the number of instances a medication is unable to be obtained from an ADC and a stockout bulletin is generated due to zero inventory. Patient Safety Net rates will be defined as the number of nursing reported occurrences in which a patient was delayed receiving his/her medication due to unavailability. In-basket messages will be defined as the number of new messages sent to the distribution pharmacists’ requesting missing medication dosages. Redispensed medications will be defined as the total number of medications dispensed following the first preparation at the request of the unit nursing staff.

Poster Title: Morphine versus methadone: differences in duration of therapy in the management of neonatal abstinence syndrome

Primary Author: Samantha Vogel, University Medical Center Brackenridge, TX; Email: svogel@seton.org

Additional Author (s):
Lyndrick Hamilton
Carolyn Ragsdale
Eimeira Padilla-Tolentino

Purpose: Neonatal abstinence syndrome (NAS) is a constellation of symptoms as a result of sudden opioid withdrawal following birth from in-utero exposure to opioids. Treatment of NAS is important to prevent sequelae such as poor weight gain and seizures. Currently there is no guideline consensus for the ideal treatment of NAS. The goal of this research is to establish the mean duration of therapy (DOT) for neonates treated for NAS with morphine or methadone. Our hypothesis predicts that neonates who are treated with morphine require shorter DOT compared to neonates treated with methadone.

Methods: In August 2014, The Seton Healthcare Family Pediatric and Network Pharmacy and Therapeutics committees implemented a new NAS management protocol. The new protocol shifted the focus of NAS treatment strategies to a morphine-driven protocol compared to a methadone-driven protocol. Neonates diagnosed with NAS at Seton Healthcare Family will be identified through a national neonatal database. Neonates who received NAS treatment with methadone between January 2011 and August 2014 and morphine between August 2014 and October 2016 will be included in this study. The primary objective is DOT of each opioid. DOT of morphine-treated neonates will be compared the DOT of methadone-treated neonates. Hospital length of stay, need for adjunctive treatment (i.e., clonidine or phenobarbital), need for escalation in therapy (e.g., requiring a dose increase in opioid used), time to NAS capture (time which NAS symptoms were controlled and allowed for subsequent weaning of morphine), cumulative opioid dose received, number of neonates who experienced wean failure (e.g., requiring a dose increase in opioid used after weaning was initiated), and hospital readmissions within 30 days will be included as secondary outcomes. Assuming a 25% reduction in DOT, 28
neonates will be required in each arm to achieve 80% power. Data collection will begin after Institutional Review Board approval.

Poster Title: Assessing treatment outcomes when switching HIV-1 infected patients from various antiretroviral therapy (ART) regimens to darunavir/cobicistat monotherapy

Primary Author: Alexa Vyain, University of Houston College of Pharmacy, TX; Email: alexavyain@gmail.com

Additional Author(s):
Rustin Crutchley
Anne Le
Joseph Gathe
Carl Mayberry

Purpose: Protease inhibitor (PI) monotherapy for treatment of HIV-1 infection has been shown as an effective alternative to traditional combination ART in already virologically suppressed individuals. The newly introduced one tablet, once-daily formulation of the PI darunavir paired with the pharmacokinetic enhancer cobicistat (DRV/c) recently gained FDA approval based on previous studies showing bioequivalence to once daily ritonavir-boosted darunavir. No clinical studies have evaluated treatment simplification to DRV/c monotherapy. The primary objective of this study is to assess the proportion of patients who achieve or maintain virologic suppression after 12 weeks when switching from a previous ART regimen to DRV/c monotherapy.

Methods: This study will be submitted to the University of Houston Institutional Review Board for approval. Adult HIV-infected patients at Therapeutic Concepts (HIV outpatient clinic) and switched to DRV/c monotherapy from a previous ART regimen containing either combination ART or PI monotherapy with a different PI/pharmacokinetic enhancer combination (i.e. lopinavir/ritonavir) will be identified using electronic medical records. Eligible patients will include those with both detectable and undetectable HIV viral loads prior to switching. Patients with any prior major PI mutations to darunavir will be excluded from analysis in this retrospective study. All data will be recorded without patient identifiers and maintained confidentially. Demographics (age, sex, ethnicity, baseline ART regimen, and other concomitant medications) will be collected as well as self-reported adherence information to ART before and after switch. Baseline laboratory parameter data at the time/prior to switch including HIV...
treatment surrogate markers (CD4, CD4% and HIV viral load), lipid parameters (triglycerides, high-density lipoprotein (HDL), low-density lipoprotein (LDL) and total cholesterol) and renal parameters (serum creatinine (SCr) and eGFR (estimated glomerular filtration rate)) will all be collected as well as at 12, 24 and 48 weeks after switch to DRV/c monotherapy. Any resistance testing including genotype results completed during study period after the switch will also be collected. Statistical tests including Pearson Chi-square and Student’s t-test will be used for categorical variables and continuous variables, respectively.

Poster Title: Correlation between antidepressant dose optimization and achievement of glycemic or blood pressure control

Primary Author: Catlin Grisham-Takac, University of Texas at Austin, TX; Email: catlin.grisham-takac@communitycaretx.org

Additional Author (s):
Phillip Lai
Lindsay Vasquez
Maaya Srinivasa
Karen Rascati

Purpose: Depression is becoming a recognized cause of disability globally, and if left untreated has proven to become a chronic and recurrent issue. Furthermore, patients with depression and other comorbidities, such as coronary artery disease and diabetes, have been found to have worse health-related outcomes. While a number of studies have investigated the correlation between improvement in depression and chronic disease, none have reported on achievement of target doses of antidepressant therapies. The objective of this study is to determine the influence of antidepressant dosing optimization on reducing hemoglobin A1c and blood pressure.

Methods: This study is in the process of being granted approval from the University of Texas at Austin’s and CommUnityCare Health Center’s institutional review boards. It will be a retrospective, cohort study design and will include patients newly initiated on an antidepressant from January 2015 to September 2015. Patients must also have uncontrolled diabetes (hemoglobin A1c greater than 7 percent), hypertension (blood pressure greater than 140/90 mmHg) or both. Patients will be followed from initiation of antidepressant and for 12 months afterwards. Data collected will include demographic information, past medical history, encounter type and frequency, hemoglobin A1c, visit blood pressure, body mass index, patient health questionnaire scores, anti-hypertensive medications, antidiabetic medications, class of antidepressant, antidepressant dose and any dose changes. Primary outcome will be change in hemoglobin A1c and/or blood pressure at the end of study period in relation to achievement of antidepressant target dose, while controlling for baseline characteristics. Select secondary
outcomes include percent of patients to reach target doses and correlation between goal achievement and improvement in depression, while controlling for baseline characteristics. Primary outcome will be assessed through the use of a linear regression and secondary outcomes by using logistic regression. Significance level will be assigned as p value less than 0.05. Patient information will be released only to reviewers and will be de-identified at the earliest opportunity.

Mark Comfort  

**Purpose:** Studies recognize the positive impact medication therapy management (MTM) has on patient outcomes and healthcare costs, but there are barriers to efficiently and effectively implementing it into the community pharmacy workflow. Such barriers include inadequate documentation systems, lack of time and staffing, and varied processes among sites. The purposes of this study are 1) to determine whether implementing a systematic approach to MTM has an impact on a) MTM completion rates and b) perceived MTM barriers; and 2) to assess pharmacists’ and technicians’ satisfaction and perceptions regarding feasibility of the process.  

**Methods:** This pre-post study will include 4 central Texas grocery store-based community pharmacies. Pharmacists and technicians at each site will be trained on a systematic process to integrate MTM opportunities into pharmacy workflow. MTM opportunities will include both Comprehensive Medication Reviews (CMRs) and Targeted Intervention Program (TIP) opportunities. The primary outcome will be change in MTM completion rates (CMR or TIP completed/CMR or TIP available) pre- and post- process implementation. MTM completion rates will be extracted from each pharmacy’s commercial MTM documentation system. An online survey instrument will be created to assess perceived MTM barriers (documentation software, patient engagement and follow-up) and perceptions regarding feasibility of the process (pre-work time, CMR/TIP counseling time, workflow efficiency) and satisfaction. MTM data collection will occur for 2 months post-process implementation will be compared to 2 months pre-process implementation with each site serving as its own control. The online survey will be administered at baseline and at 2 months post process implementation. Descriptive
statistics will be used and 0.05 will serve as the a-priori significance level. McNemar’s test will be employed to compare paired MTM completion rates (pre-to-post) and paired t-tests will be used to assess changes (pre-to-post) in perceived MTM barriers. No patient-level data will be used. This study will be submitted to The University of Texas Institutional Review Board for approval.

Paige Parsons

**Purpose:** The objective of this study is to examine the impact of utilizing community pharmacists to follow patients through a continuum of care from discharge to follow-up on hospital readmission rates, medication-related problems, and patient satisfaction.

**Methods:** This is a prospective cohort study in which hospitalized patients will receive face-to-face discharge counseling and follow-up phone calls 7 days, 30 days, and 60 days post-discharge by a community pharmacist. Pharmacists involved in the study are employed by a common community chain pharmacy. Partnership between the hospital and community pharmacy will allow pharmacists to use patient’s electronic health records from both entities. Pharmacists will provide medication reconciliation, assess and resolve medication-related problems, and ensure optimal drug therapy. Discharged patients will only be included in this study if they pick up a majority of their prescriptions from the partnered community chain pharmacy. Patients will be enrolled and followed from January to June 2017.  
The study will compare readmission rates at baseline and at conclusion of this pilot. Descriptive and multivariate statistics will be used for data analysis. The primary endpoint for this study is the change in readmission rate and the secondary endpoints include the type and number of medication-related problems addressed and patient satisfaction with the transitions of care process. Medication-related problems documented include but are not limited to: drug-drug interactions, duplicate therapy, adverse drug events, omission of therapy, suboptimal or supraoptimal therapy, and adherence barriers. Patient satisfaction will be measured by a survey
post-intervention. This study will be submitted for review by the Institutional Review Board of The University of Texas at Austin.

Poster Title: Impact of a pharmacist-led educational session in prescribers’ knowledge about pharmacogenetics testing and their interest in its availability in community pharmacy settings

Primary Author: Ashley Floyd, University of Texas at Austin College of Pharmacy/H-E-B Pharmacy PGY1 Community Pharmacy Residency, TX; Email: afloyd525@utexas.edu

Additional Author(s):
Nathan Pope
Carolyn Brown
Mitchell Shelton

Purpose: To assess the effect of a pharmacist-led education session on physician knowledge about pharmacogenetics’ role in patient therapy and interest in using a pharmacist for pharmacogenetic testing. Pharmacogenomics is the future of pharmacy and medical practice, as treatments become individualized per patient to provide specific care. The particular genotypes of enzymes can greatly affect how efficacious and safe certain medications are per individual. Currently, physicians and other healthcare providers do not have readily available access to pharmacogenetic testing through their local pharmacies and lack the ability or comfort in utilizing the new technology to provide personalized care for their patients.

Methods: This pre-/post-test study will be employed to determine changes in outcomes (knowledge and interest) of physician participants. The educational session will take place in a large room with appropriate technology for establishing an educational presentation. Inclusion criteria include any physician or physician representative whose patients fill prescriptions at HEB pharmacies with special emphasis on pain management and cardiology specialists. Exclusion criteria include the presence of any condition that would hinder the completion of a survey, such as cognitive impairment. Participants will be recruited over a 2 month period with the educational session to soon follow. Participants will be asked to complete a survey measuring their interest and knowledge regarding pharmacogenetics prior to the educational session and immediately following the presentation. The presentation is expected to last for 30-45 minutes. Differences in pre- and post-test scores will be determined using t-tests. This
Proposed study will be submitted for review by the Institutional Review Board of The University of Texas at Austin.

April Hinds  
Lucas Hill  

**Purpose:** The patient-centered medical home (PCMH) is a new model of primary care delivery that has been implemented in many outpatient settings. One type of PCMH is the physician-pharmacist collaborative management (PPCM) model. Studies have shown that PPCM models have made a positive impact on patient care and safe medication use, especially among patients with uncontrolled diabetes. To improve efficiency of healthcare delivery within CommUnityCare (CUC), the PPCM model was implemented in 2013 through coordinated pharmacist-physician co-visits. The purpose of this study is to evaluate the impact of pharmacist-physician co-visits on clinical outcomes among patients with uncontrolled diabetes.  

**Methods:** This will be a retrospective multi-center cohort study and will include adults (18 years or older) with uncontrolled (hemoglobin A1c (HbA1c) of 8 percent or greater) Type 1 or Type 2 diabetes who were seen at CUC between 10/1/14 and 10/1/16. Cohorts include an intervention (at least 2 co-visits) or usual care (no co-visits, but at least 1 physician visit). The primary clinical outcome is mean change in HbA1c from baseline (within 1 year prior to the initial co-visit/physician visit) to follow-up (3 to 6 months post co-visit/physician visit). Secondary outcomes include mean change in fasting blood glucose, lipids and blood pressure levels, body mass index (BMI) and medication adherence; as well as adherence to ADA standards of care (documented immunizations, foot exams, eye exams, microalbumin/serum creatinine ratio, appropriate preventative medications). To assess changes from baseline to follow-up between the intervention and usual care groups, inferential statistics will be used. Chi-square or Fisher’s exact tests will be used for categorical variables and student’s t-tests and Mann Whitney-U
tests will be used for continuous/ordinal variables. Significance level will be p-value less than 0.05.

Swee-Ling Levea

**Purpose:** The objective of this quality-improvement study is to assess the impact of a pharmacist-driven renal dose protocol on medication safety, cost, and efficiency in pharmacy order verification.

**Methods:** In September 2016, a renal dose-adjustment protocol by which pharmacists can automatically renally dose-adjust pre-specified medications was approved through the institution’s Pharmacy and Therapeutics Committee. The protocol allows a pharmacist to automatically renally dose-adjust medications for patients > 18 years of age with exclusion criteria for transplant patients, cystic fibrosis patients, and patients with conditions resulting in reduced muscle mass. Thirty-one medications were included in the protocol including 28 antimicrobials and a minority of other commonly renally dose-adjusted medications. The protocol requires a pharmacist to document the intervention in the patient’s electronic medical record via a pharmacy consult note. Accompanying the protocol implementation will be a tool to help pharmacists identify patients that may require renally-adjusted medications. To standardize pharmacy practice and utilization of the protocol, a supplemental renal dosing chart will be made available to all pharmacists. The two-phase (pre-implementation and post-implementation) quality-improvement study will compare rate of adverse drug events secondary to inappropriately dosed medications, cost-savings, and time to pharmacist order verification. The study is currently under review for exemption by the Institutional Review Board.

Poster Title: Analysis of the impact of missing doses and wastage of IV medications at an academic medical center

Primary Author: Rachel Yue, UT Southwestern Medical Center, TX; Email: rachel.yue@utsouthwestern.edu

Additional Author (s):
Jacque Borel
Brian Cohen
Latresa Billings

Purpose: Missing medication messages are sent when a nurse cannot find a medication that should be administered. Missing doses have implications related to efficiency, efficacy, and cost. In April 2015, a medication tracker system, Pharmtrac, was implemented with one of its goals to help decrease the number of missing doses that have to be redispensed by tracking exactly where the drug is in the delivery process. The main objective of this project is to determine elements of the process which are affecting efficiency, workflow, and cost, and to model an improved methodology for data collection to help with ongoing waste tracking.

Methods: A list of some of the most frequently missing and most expensive IV medications will be identified based on both the number of missing doses and cost. Six months of missing dose data before Pharmtrac implementation will be compared and analyzed to six months of data after Pharmtrac implementation. The missing doses that had to be redispensed will be further looked at. The financial impact of both labor and product costs associated with the missing medications will be determined before and after implementation. The current medication distribution, delivery, and documentation process will be observed and evaluated. This will be done by performing a prospective two week observational study to more closely identify the point of distribution breakdown that create an opportunity for the missing doses and observe the details of the missing medication messages and tracking in Pharmtrac. Opportunities to help further decrease the number of missing doses and eliminate unnecessary costs will be identified through the observations and results of this project. Expected results include identifying the top causes of missing doses, areas in improvement in process, and cost from doses that are wasted in the hospital setting.

**Poster Title:** Need for a standardized transitions of care program in an interdisciplinary academic family medicine clinic located in a border community

**Primary Author:** Rachel Kennedy, UTEP/UT Austin Cooperative Pharmacy Program (Candidate), TX; **Email:** morgans.rachel91@gmail.com

**Additional Author(s):**
Margie Padilla
Emily Christenberry
Stella Winters
Amanda Loya

**Purpose:** The Department of Family and Community Medicine at the Texas Tech University of Health Sciences Center-El Paso serves a diverse population along the US-Mexico border. Currently, there is a transitional care process to follow patients post-discharge from the inpatient family medicine service. However, the process does not meet CMS requirements for Transitional Care Management (TCM) billing codes. The aim of this project is to determine the need for a standardized transitions of care (TOC) program, identify the current TOC workflow, define improvements needed to utilize TCM billing codes, and estimate the potential reimbursement if a standardized TOC program was developed.

**Methods:** A retrospective chart review will be performed via electronic medical record (EMR) review on patients 65 year and older with traditional Medicare fee-for-service insurance who were admitted to the inpatient family medicine service from October 1, 2015 to May 30, 2016. The primary objectives are to: 1) determine the percentage of patients being followed-up post-discharge in alignment with TCM follow-up requirements (i.e. specified time frame for telephone contact, clinic visits); 2) determine the amount of funding that could have been accrued for patients who were discharged and met TCM requirements (i.e. follow-up, 30 readmission free days); and 3) determine the number of missed opportunities in funding for patients with 30 readmission free days who did not meet the TCM follow-up requirements. Secondary objectives will identify the current standard of care for follow-up appointments and the scheduling of post-discharge patients transitioning from the inpatient service to outpatient care. For analyses of data, descriptive statistics will be utilized for the purposes of this quality
improvement project. The outcome of this project will help administrators better understand the impact of a standardized TOC program on patient readmission rates in a low-income, ethnically diverse, family medicine population. This project will be submitted for review through the University of Texas at El Paso and Texas Tech University of Health Sciences International Review Board (IRB).

Poster Title: Impact of Verigene assay and antimicrobial stewardship intervention on time to targeted antibiotic therapy for Staphylococcus aureus bacteremia at an academic medical center

Primary Author: Joylaina Speaks, UTMB Health, TX; Email: jospeaks@utmb.edu

Additional Author(s):
Natalie Williams-Bouyer
Wai-Ying Lam
Regina Ramirez
Scott Ferren

Purpose: Over recent years, significant developments in rapid diagnostic testing have decreased the time to microbial identification. Traditional microbiology culture and susceptibility testing takes days to provide results. The Verigene Blood Culture-Gram Positive (BC-GP) assay is an FDA-approved test that provides the genus, species, and resistance of bacteria detected from blood cultures in 2.5 hours. The purpose of the study is to investigate the impact of the Verigene BC-GP assay in conjunction with an antimicrobial stewardship intervention (ASI) on the time to targeted antibiotic therapy for the treatment of methicillin-sensitive Staphylococcus aureus (MSSA) and methicillin-resistant Staphylococcus aureus (MRSA) bacteremia.

Methods: A retrospective chart review will include all adult patients 18 years or older with a positive blood culture for MSSA or MRSA at UTMB Health. Patients will be included in one of three study groups: the pre-Verigene group (March 2013 to January 2014), the Verigene only group (March 2014 to January 2015), and the Verigene with ASI group (March 2016 to January 2017). The following patient characteristics and indicators of clinical status will be collected: demographic and co-morbidity data, TPN status, presence of Infectious Diseases consult, date of hospital and Intensive Care Unit (ICU) admission and discharge, maximum temperature, peripheral white blood cell count, and ICU status at time of the blood culture draw. Microbiology data will include date and time of culture collection, positive culture per gram stain and culture results. Antibiotic data collected will include: all antibiotics received by the patient and date and time antibiotics were initiated and discontinued. Additional data to be
Resident Poster Abstracts

collected include suspected source of infection and date of death, if available. The primary outcome is to determine the impact of the Verigene BC-GP assay with ASI on time to targeted antibiotic therapy. Secondary outcomes include hospital length of stay (LOS), ICU LOS, 30-day mortality, antibiotic costs, and 30-day readmission rate. The study will be submitted for Institutional Review Board approval.

**Poster Title:** An analysis of the efficacy of continuous bupivacaine infusion pump (On-Q® pump) in bariatric surgery patients

**Primary Author:** Nathalie Quach, Valley Baptist Medical Center - Brownsville, TX; **Email:** nathalie.quach@valleymbt.net

**Additional Author (s):**
Shyi Geng
Y-nha Nguyen

**Purpose:** With an increasing obese population nationwide, there has been an increase in the number of laparoscopic surgeries performed. However, there have been few studies evaluating different methods to reduce pain in bariatric patients after laparoscopic surgery. Bupivacaine infusion pumps (On-Q® pumps) have been shown effective in reducing post-operative pain in other surgical population, such as orthopedic patients. Therefore, the purpose of this project is to investigate whether the use of On-Q® pumps improves postoperative pain control and decrease length of hospital stay in bariatric patients.

**Methods:** This is a retrospective study where the electronic health records of adult patients who underwent bariatric surgery during the period of January 2015 until August 2016 will be reviewed. Patients who received a prescription for an opioid within 30 days before bariatric surgery will be excluded from the study. The following data will be collected: age (years), gender, BMI (kg/m²), presence of diabetes, hypertension, obstructive sleep apnea, hyperlipidemia, asthma, osteoarthritis, or depression, and operative time (minutes). The primary endpoints are length of stay (hours from surgery end-time to time of discharge) and postoperative narcotic use (measured in terms of oral morphine equivalent from surgery end-time to time of discharge). Secondary endpoints include post-operative pain scores (scale of 1 – 10, with 0 being no pain and 10 being maximal pain), inpatient daily use of non-narcotics, complications due to opioids (i.e., respiratory depression requiring naloxone), and complications due to bupivacaine (i.e., bradycardia, cardiac arrest, heart block, ventricular arrhythmia). These secondary endpoints will be collected for the first 24 hours and the first 48 hours after surgery.

**Poster Title:** Evaluation the Use of adjusted body weight (dosing weight) for vancomycin dosing in overweight patients

**Primary Author:** Khiet Nguyen, Valley Baptist Medical Center-Brownsville, TX; **Email:** khiet.nguyen@valleybaptist.net

**Additional Author (s):**
Y-Nha Nguyen
Mario Varela

**Purpose:** The 2009 IDSA/ASHP guidelines for vancomycin recommended to use actual body weight (ABW) for initial dosing in all patients, which may expose overweight patients to a large daily dose of vancomycin. At our institution, for non-dialysis patients, those with ABW above ideal body weight (IBW) by at least 30% will receive vancomycin 10-15 mg/kg/dose based on adjusted body weight (AdjBW). For other non-dialysis patients, they will receive vancomycin dose calculated using ABW. The objective of this retrospective study is to assess the appropriateness of using AdjBW for vancomycin dosing in overweight patients compared to using ABW in normal weight patients.

**Methods:** All adult patients with pharmacy consult for intravenous vancomycin from August 2015 to August 2016 will be retrospectively identified using a searchable patient database. Patients will be included if they had baseline creatinine clearance of at least 60 ml/min, received at least three identical maintenance vancomycin doses, and had at least one trough level drawn at stead state. Patients will be excluded if they have acute kidney injury (AKI) on admission or prior to first trough level. The following data will be collected: age, gender, weight, height, serum creatinine (Scr), vancomycin indications, loading and maintenance dosing regimen, and concurrent nephrotoxic medications. Creatinine clearance, IBW, body mass index, and AdjBW will be calculated. The primary outcome is the proportion of patients achieving therapeutic vancomycin level (10-20 mg/L) at first trough. Secondary outcomes include the proportion of patients with subtherapeutic (< 10 mg/L) or supratherapeutic (> 20 mg/L) level at first trough and proportion of patient with AKI (SCr increase by 0.5 or 50% from baseline) after first level until discharge.

Poster Title: Assessing federally qualified health center providers need for clinical services provided by community pharmacists

Primary Author: Haroon Waseem, Walgreens/University of Houston College of Pharmacy, TX; Email: hanowaseem1990@gmail.com

Additional Author (s):
Angela Tompkins
Lynn Simpson

Purpose: Community pharmacists can play a key role in managing patients’ health by providing medications, counseling, point of care testing, addressing adherence issues, and more. What is unknown are the clinical activities and services other health care providers would like to see community pharmacists provide.

The purpose of this study is to identify the clinical activities Federally Qualified Health Center (FQHC) based health care providers would like to see community pharmacists provide in the care of patients.

Methods: A survey is emailed to the Federally Qualified Health Centers (FQHCs) in Texas to be completed by all healthcare providers. A Community Pharmacist who has a relationship with that FQHC emphasizes the importance of taking the survey either through email, phone call, or walk in.

The health care providers will provide demographic information such as their health care discipline, years of practice, and their specialty. The providers will be asked to identify the clinical services they believe a community pharmacist can provide, which clinical services will benefit their practice and record any additional services they would like to see provided by a community pharmacist.

The results will be collected and descriptive analysis will be conducted to assess trends of popular and unpopular services among the providers. The trends differences between disciplines will also be assessed. IRB approval has been submitted and is pending.

Poster Title: Evaluating the effectiveness and feasibility of a pharmacist driven penicillin allergy testing program provided through an antimicrobial stewardship program

Primary Author: William Lukkes, Cheyenne Regional Medical Center, WY; Email: william.lukkes@crmcyw.org

Additional Author(s):
Nathon Parker
Hoo Feng Choo

Purpose: Allergies to penicillin and related antibiotics are reported in approximately 10% of the United States population. However, only about 1% have a true penicillin allergy. Penicillin allergic patients are more likely to receive broad spectrum antimicrobials, combination therapy and alternative agents. Overuse of broad spectrum antimicrobial agents promotes the emergence of multi-drug resistant organisms and Clostridium difficile infections. Many of these patients are classified unnecessarily, as over 85% of these patients are found not be allergic, and can safely tolerate penicillins. Penicillin skin testing can help antibiotic stewardship efforts, leading to improved efficacy, reduced antimicrobial resistance, and decreased costs.

Methods: The primary outcome measures is the percentage of patients that are not truly allergic to penicillin and cost saving when switching to alternative antibiotic’s due to this negative allergy confirmation. These two primary measures will be analyzed using the chi-square and student-t test methods. The pharmacist will contact the patient’s physician to receive authorization to complete the penicillin allergy skin test. The target population will be patients 18-65 years old in the inpatient setting with a penicillin or similar derivative allergy. Patients will be included in the study if they successfully meet the inclusion/exclusion criteria checklist sheet that the pharmacist will complete. Once they meet the criteria the antimicrobial stewardship team will confirm allergy with questionnaire and the patient must consent to skin testing. The skin testing will be performed in a two-step process according to the package insert instructions for benzylpenicilloyl polylysine (Pre-Pen). Appropriate safety measures have been included in the protocol for each test to minimize patient risks. The number needed to treat is between 30 and 100 and successful completion of the study on March 31st 2017. If successful
in meeting the primary outcome measures the penicillin skin testing study will become part of the antimicrobial stewardship program.

Poster Title: Transitions of care: Randomized trial of pharmacist-led interventions to decrease hospital readmissions for patients with chronic obstructive pulmonary disease and heart failure after hospitalization

Primary Author: Angela Crotsenberg, Cheyenne Regional Medical Center, WY; Email: angela.crotsenberg@crmcwyo.org

Additional Author(s):

Purpose: Inadequate patient education and care coordination at transitions of care such as hospital discharge may result in increased hospital readmission. Patients with chronic disease may be at a higher risk for hospital readmission due to complex disease states and large numbers of medications. Current studies show that pharmacy-led interventions at hospital discharge may positively impact patient outcomes and decrease hospital readmission. The purpose of this study is to determine if pharmacy-led interventions during hospitalization and following hospital discharge among patients with chronic obstructive pulmonary disease and heart failure result in a lower 30-day hospital readmission rate.

Methods: In this randomized, controlled trial, patients 18 years of age and older with a primary diagnosis of chronic obstructive pulmonary disease or heart failure or a related diagnosis will be randomized to an intervention or control group. Patients in the control group will receive standard care including nursing and physician-provided education on all medications at hospital discharge and a follow-up phone call. Patients in the intervention group will receive standard care plus a pharmacist-led comprehensive medication review, a medication action plan and medication education prior to discharge. Barriers to medication adherence will be addressed during hospitalization. The pharmacist will call patients twice after discharge to discuss the patient’s diagnosis and health status, treatment goals, medications, and what to do if a problem arises using a modified version of the post discharge follow-up phone call guide from Boston University’s Project Red (Re-Engineered Discharge). Study participants receiving the pharmacist-led intervention are expected to have a lower 30-day hospital readmission rate compared to control subjects.

Poster Title: Liposomal bupivacaine utilization for gynecologic procedures at a community hospital

Primary Author: Erica Hoversland, University of Wyoming Family Medicine Residency and School of Pharmacy - Healthcare for the Homeless, WY; Email: ehoversl@uwyo.edu

Additional Author(s):
Lanae Fox
Christie Nelson
Jaime Hornecker

Purpose: Exparel, liposomal bupivacaine, is a nonopioid analgesic that is approved as a single-dose injection for postsurgical analgesia. Exparel utilizes the drug delivery system DepoFoam that is designed to slowly deliver bupivacaine over an extended period of time, elongating its pharmacologic effect. As a result of this prolonged analgesic effect, Exparel is considered a useful agent in various surgical procedures because it is thought to decrease opioid use post-surgery and decrease risks that come with using catheters or pumps. The purpose of the study is to evaluate the use of Exparel in gynecological procedures and the resulting patient outcomes.

Methods: This study will be submitted to the Institutional Review Board for approval. A retrospective chart review will be conducted on patients who received Exparel for gynecological procedures in the last year at Wyoming Medical Center. These patients will be matched with patients who received the same procedures but did not receive Exparel. Data collection will include: type of procedure, dose of Exparel used, length of hospital stay, use of patient-controlled analgesia (PCA) post-surgery, total opioid dose 24 hours after surgery, total opioid dose over entire hospital stay, and average pain scores during the first 24 hours after surgery. Results will be presented.

Poster Title: Statin optimization in patients with diabetes at a family medicine residency program

Primary Author: Karsten Josie, University of Wyoming Family Medicine Residency Program, WY;
Email: karsten.josie@gmail.com

Additional Author(s):
Jaime Hornecker

Purpose: In 2013, the American College of Cardiology/American Heart Association (ACC/AHA) Task Force published practice guidelines aimed at reducing atherosclerotic cardiovascular disease (ASCVD) in four high-risk patient groups. Patients with diabetes mellitus (DM) represent one of the groups that should be treated with statins for LDL cholesterol reduction. Even though these patients exhibit increased ASCVD risk, studies show that only about half of patients over 40 years old with DM are taking a statin. The purpose of this study is to evaluate statin utilization and optimization in patients with DM at a family medicine residency program patient-centered medical home (PCMH).

Methods: This study will be submitted to the Institutional Review Board for approval. A retrospective review of de-identified data of patients with Type 1 and Type 2 DM between the ages of 40 to 75 years old will be obtained from the clinic electronic health record (EHR). Patients will be assessed as to whether they are on any statin therapy, which will then be further evaluated for statin intensity optimization based on the intensity of statin that the ACC/AHA guidelines recommend. The ACC/AHA guidelines recommend at least a moderate intensity statin in patients with DM between the ages of 40 to 75 years. Additionally, patients in this group with an estimated ASCVD risk greater than or equal to 7.5 percent would be considered optimized on high-intensity statin therapy. Patients not taking a statin or the recommended intensity of statin will be evaluated for precluding factors. Results of this study will be presented to providers of the family medicine residency program by the primary researcher. The 2013 ACC/AHA guideline recommendations will also be presented with the study results to encourage providers to increase optimal statin use in patients with
high risk of ASCVD. Ongoing analysis will determine if this intervention improves statin utilization.

**Poster Title:** Retrospective review of intravenous unfractionated heparin monitoring at Alaska Native Medical Center: Assessment of monitoring using antifactor-Xa versus activated partial thromboplastin time

**Primary Author:** Julie Anne Loughlin, Alaska Native Medical Center, AK; **Email:** jaloughlin@anthc.org

**Additional Author(s):**
Adam Harris  
John Carothers  
Ashley Scaber  
Deidra Newbrough

**Purpose:** The purpose of this review is to evaluate data surrounding the use of the antifactor-Xa (anti-Xa) based protocol for continuous infusion heparin monitoring at our facility. Prior to the implementation of this protocol in 2011, heparin dosing was titrated using activated partial thromboplastin time (aPTT). The most effective protocol to use remains questionable due to a known discordance of Anti Xa and aPTT levels present in the literature. This review will look at efficiency, cost, and safety of both strategies. After completion, this information will be shared with our facility to optimize patient care.

**Methods:** This study was deemed non-research and approved by the Alaska Area IRB. The review will evaluate data surrounding the use of the antifactor-Xa (anti-Xa) based protocol versus the activated partial thromboplastin time (aPTT) based protocol for continuous infusion heparin monitoring. All aPTT and anti-Xa lab values will be collected from two separate date ranges. One data set will be pulled from a year where an aPTT based protocol for heparin monitoring and one data set will be pulled from a year when the anti-Xa based protocol. The date ranges include January 2013-January 2014 and January 2009- January 2010. All data will be collected utilizing available reporting systems to depersonalize patient information whenever possible. To mitigate risk, any patient specific information that is accessed will be stored within password protected Microsoft Excel spreadsheets and Microsoft Word documents. Each data set will be evaluated by reviewing the number of lab draws per patient, time to therapeutic values, number of times patients were supratherapeutic or subtherapeutic, and how many
patients had both anti-Xa and aPTT drawn. Conclusions about the cost, how well the hospital follows protocols, and benefits of each test will be drawn from this study.

**Poster Title:** Safety of patient-controlled analgesia in obstructive sleep apnea: a retrospective analysis  

**Primary Author:** Amanda Tobias, Providence Alaska Medical Center, AK; **Email:** tobiasa@onid.orst.edu  

**Additional Author(s):**  
Karen Thompson  
Elaine Reale  

**Purpose:** Patient-controlled analgesia (PCA) provides a method for quick pain relief, but carries significant risks that include respiratory depression and opioid overdose. Patients with obstructive sleep apnea (OSA) are among those at highest risk. The purpose of this analysis is to evaluate whether providers are addressing OSA risk prior to ordering PCAs. This includes utilizing the preoperative STOP-BANG risk scoring tool and appropriately ordering PCAs from the hospital’s low dose order set. Analysis will include evaluating adherence to safety monitoring protocols and whether noncompliance with any of the hospital’s PCA policies led to adverse events necessitating opioid reversal.  

**Methods:** This study has been approved for exemption by the Western Institutional Review Board (WIRB). A report will be generated of all patients who received a PCA after any surgery, between the month prior to WIRB approval and the preceding 12 months. An estimated 1,800 patient charts will be generated in this report and will be reviewed for documentation of a completed STOP-BANG score and presence of OSA. Further data collection for patients with a STOP-BANG score greater than or equal to 5 and/or a history of OSA diagnosis will include: age, sex, surgical procedure, STOP-BANG score, history of OSA diagnosis, PCA order set used, medication start date, ordering provider and credentials, hospital unit, overlap of intravenous and oral opioids greater than 2 hours, evidence of continuous pulse oximetry and capnography monitoring, respiratory depression (less than 8 breaths per minute), and naloxone administration, including dose and time of administration from the PCA start time.

Poster Title: Dexmedetomidine for the treatment of alcohol withdrawal in non-intubated patients in the intermediate medical care unit (IMCU)

Primary Author: Ian Ingram, Providence Alaska Medical Center, AK; Email: ian.ingram@providence.org

Additional Author(s):
   Dominique Lauten
   Roberto Iaderosa
   Elaine Reale

Purpose: Dexmedetomidine is used off-label for the treatment of alcohol withdrawal, but little data exists outside of intubated patients in an intensive care unit. At this tertiary care facility, dexmedetomidine is used for alcohol withdrawal in non-intubated patients in the IMCU, but no specific protocol exists to guide appropriate prescribing. The purpose of this project is to create a guideline for appropriate dexmedetomidine use in this patient population. A medication use evaluation will be performed to determine whether dexmedetomidine is being used in accordance with the new guideline. Information from this evaluation may identify areas for quality improvement and patient safety.

Methods: A retrospective report using the electronic health record system will be generated for patients who received dexmedetomidine in the IMCU and had a confirmed diagnosis of alcohol withdrawal using ICD10 codes F10.230- F10.239 between January 2016 and August 2016. Patients will be excluded if they were under 18 years old, pregnant or incarcerated, received dexmedetomidine for an indication other than alcohol withdrawal, or if they were intubated before their first dose of dexmedetomidine. The following data will be collected: dose and duration of dexmedetomidine; concurrent use of benzodiazepines; frequency and total daily dose of benzodiazepines; CIWA scores prior to the first dose of dexmedetomidine and 24 hours after starting dexmedetomidine; whether or not the CIWA protocol was followed; intubation after initiation of dexmedetomidine; potential contraindications to dexmedetomidine (bradycardia, left ventricular dysfunction, atrial ventricular block, concurrent use of vasodilators or negative chronotropic agents); and adverse effects (bradycardia, hypotension, and seizures).
Data will be analyzed to determine whether patients treated during the assessment period met eligibility requirements for dexmedetomidine, whether dosing guidelines were followed for dexmedetomidine and benzodiazepines, whether goals of therapy were achieved, and whether there were any adverse effects attributable to the dexmedetomidine. If patient numbers permit, patients managed in compliance with the guideline will be compared to those who weren’t to evaluate any differences in goal achievement or adverse effects.

Poster Title: Intraperitoneal chemotherapy outcomes in gynecological malignancies: A single-center, retrospective study.

Primary Author: Alyssa De Castro, Providence Alaska Medical Center, AK; Email: alyssamae.decastro@providence.org

Additional Author (s):
Teresa Slagle
Melissa Hardesty

Purpose: Ovarian cancer remains the most common cause of gynecological cancer-associated death in the United States. The NCCN guidelines endorse the use of intraperitoneal (IP) chemotherapy for optimally debulked stage II through IV disease, which accounts for 79% of newly diagnosed patients. Profound abdominal pain is one of the most common reasons for inability to complete all planned IP cycles. Our institution has been using IP bupivacaine to minimize IP chemotherapy associated pain. This study will evaluate the outcomes of patients that received IP bupivacaine before and after administration of IP chemotherapy.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will be used to identify patients receiving IP chemotherapy and to collect data for the study. The following data will be collected: patient age, ethnicity, ECOG scores, type and stage of gynecological malignancy, type and dose of IP chemotherapy received, CA-125 levels, number of months before disease progression, and overall survival. If available, provider/nurse documentation will be reviewed to determine the side effects related to IP bupivacaine administration and the severity of abdominal pain associated with IP chemotherapy in the presence of IP bupivacaine use. Inclusion criteria are patients diagnosed with gynecological cancer who received at least one cycle of IP chemotherapy and received IP bupivacaine before and after administration of IP chemotherapy. Patients younger than 18 years old, with known drug allergy to bupivacaine, pregnant/breast feeding, and prisoners will be excluded. The primary outcomes are the progression free survival and overall survival of patients receiving IP bupivacaine before and after IP chemotherapy. All data with patient information will be stored securely in password protected electronic files to protect
confidentiality. Patient information will not be shared with any person or party not directly involved in the data collection or analysis.

Poster Title: Clinical impact of pharmacist-led, hospital-based discharge medication reconciliation service

Primary Author: Lisa Ohnstad, Providence Alaska Medical Center, AK; Email: joyohnstad@hotmail.com

Additional Author(s):
Elaine Reale
Coleman Cutchins

Purpose: Medication reconciliation at transitions of care has been a Joint Commission National Patient Safety Goal since 2005. The objective of this study is to assess the impact of pharmacist-led discharge medication reconciliation in patients at high risk for readmission, and to improve quality of care. The Pharmacy Transitions of Care Service (TOC) was implemented in two phases. During phase one, a dedicated pharmacist, and pharmacy technicians provided the service. During phase two, the service team consisted of all clinical pharmacist staff, and dedicated pharmacy technicians. Patients were enrolled in the service if they met criteria for high risk of readmission.

Methods: This study was approved for exemption by the Western Institutional Review Board. This is a retrospective review of approximately 650 patients eligible for medication reconciliation via the Pharmacy TOC Service at this tertiary care community hospital between November 2015 and April 2016. Patients were enrolled in the service if they were identified as high risk for readmission, had a diagnosis of Chronic Obstructive Pulmonary Disease (COPD), or were receiving anticoagulation medications on admission. The following data will be gathered from the electronic medical record: Phase one, and phase two: initial enrollment and all reencounters during the 90 days post discharge which include: 30 day emergency department visits, 90 day emergency department visits, 30 day readmissions, 90 day readmissions, adverse drug events occurring within 30 days of discharge, adverse drug events occurring within 90 days of discharge, medications involved in adverse drug events, number of chronic (required for at least 30 days) medications on admit, number of chronic (required for at least 30 days) medications on discharge, length of stay in days for COPD exacerbation, length of stay in days for any return COPD exacerbation, number of times the patient was enrolled in TOC during
each of the two phases of TOC services. The TOC program will be assessed for clinical effectiveness during each phase, as well as during the overall program.

Poster Title: Clinical impact of an antimicrobial stewardship program targeting Staphylococcus aureus bacteremia at a 401-bed, tertiary-care community hospital

Primary Author: William Barany, Providence Alaska Medical Center, AK; Email: william.barany@providence.org

Additional Author(s):
Ryan Stevens
Elaine Reale

Purpose: Staphylococcus aureus bacteremia (SAB) is a serious medical condition with a mortality rate approaching 20%. Complications from SAB, including infective endocarditis and implanted hardware infection, further contribute to disease severity. Because of this, SAB is best managed through the consultation of infectious diseases specialty physicians. The purpose of this project is to evaluate whether an antimicrobial stewardship program (ASP) targeting SAB was associated with an increased rate of infectious diseases physician consultations, and whether these consultations improved clinical outcomes.

Methods: This project is a retrospective chart review of all patients admitted with SAB since implementation of an electronic medical record on March 1, 2011. Patients included in this study will be identified through utilization of a microbiology laboratory report of all S. aureus blood cultures. For inclusion, patients must be at ≥ eighteen years old and have had S. aureus blood cultures obtained on inpatient units or within the Emergency Department. Patients will be excluded if they meet any of the following criteria: pregnant, incarcerated, under 18 years old, expired within 48 hours of admission, or if their inpatient hospitalization duration was ≤ 24 hours.
Records that meet the above criteria will be evaluated for the presence of a formal infectious disease consultation for management of SAB to determine whether ID consultation rates have changed since implementation of the ASP in August 2013. Consultation rates between a baseline period and the three years following ASP implementation will be compared.
To determine if infectious diseases consultation improved clinical outcomes, the following parameters will be evaluated through a chart review: duration of bacteremia, verification of bloodstream clearance, echocardiogram evaluation (TEE or TTE), time to optimal and effective
antimicrobial therapy (including drug and dosing selection), 30 and 90 day mortality, 30 and 90 day readmission, length of stay, inpatient duration of therapy, and total planned duration of therapy.

**Poster Title:** Medication use evaluation of gentamicin for empiric treatment in neonates at a level III neonatal intensive care unit

**Primary Author:** Lauren Dartois, 82004, CO; **Email:** lauren.dartois@uchealth.org

**Additional Author(s):**
Gina Harper
Jeff Homann

**Purpose:** Gentamicin is commonly used in the neonatal intensive care unit (NICU) as empiric treatment for early-onset sepsis. A wide variety of dosing strategies have been studied. At Poudre Valley Hospital (PVH), neonatal providers order gentamicin via an order set with postnatal age and weight guiding the gentamicin dose. Often, antibiotics are discontinued at 48 hours when sepsis is ruled-out, but serum gentamicin concentrations are obtained if therapy continues. The purpose of this medication use evaluation is to determine the frequency and appropriateness of gentamicin levels, assess current prescribing practices, and evaluate the strategy used for dose adjustment.

**Methods:** A retrospective chart review was performed in neonates who received at least one dose of gentamicin in the NICU at PVH from June 1, 2015 to August 10, 2016. Patients were evaluated for gestational age at birth, post-natal age, initial dose, indication, and duration of treatment. If peak and trough levels were drawn, they were evaluated as subtherapeutic, therapeutic, or supratherapeutic. Clinical parameters such as axillary temperature, white blood cell count, serum creatinine, and microbiological cultures were also collected.

**Results:** A total of 211 initial orders for gentamicin were evaluated in 200 neonates. The average gestational age was 36.23 completed weeks of gestation (range: 25-42). Early-onset sepsis was the indication for 188 (89.1%) of the orders and the average gentamicin course was 3.7 days. An initial dose of 4 mg/kg every 24 hours (for patients less than or equal to 7 days old and greater than or equal to 1200 grams) was ordered 88.6% (187/211) of the time. Overall, 118 levels (56 peak and 62 troughs) from 200 neonates were evaluated. Of the 56 peaks, 41 were considered therapeutic (73.2%) and 32 of 62 troughs (51.6%) were within goal. For those levels that were not considered therapeutic, the initial dose was changed by the provider 31
times based on recommendations by the pharmacist. The two most common adjustments were to extend the dosing interval from 24 to 36 hours (22/31), or reduce the dose (4/31). However, these accepted adjustments were sometimes delayed or inconsistently implemented based on order entry processes.

**Conclusion:** Results indicate that early onset-sepsis was the most common reason for gentamicin use in the NICU. Although 62% (132/211) of gentamicin orders were discontinued after 48 hours or less, 118 drug levels were performed. Half of patients with levels performed required a dose adjustment that was universally accepted by providers. As a result, it is recommended to develop and implement a pharmacist-driven dosing protocol. This would help standardize the dosing references used and allow for a more consistent and effective process. Additional evaluation is recommended to assess the impact on the frequency of therapeutic gentamicin levels attained.

Poster Title: Effect of pharmacist driven procalcitonin ordering on antibiotic duration in patients with hospital-acquired and ventilator-associated pneumonia

Primary Author: Nicholas Tinker, Centura Health Saint Anthony Hospital, CO; Email: ntinker86@gmail.com

Additional Author(s):
Alyssa Walker

Purpose: Recent Infectious Disease Society of America guidelines for the treatment of hospital-acquired pneumonia (HAP) and ventilator-associated pneumonia (VAP) provide a recommendation to use procalcitonin (PCT) along with clinical criteria to guide discontinuation of antibiotics. Despite these recommendations, the practice of ordering PCT and the interpretation of its value is often inconsistent, depriving providers of a valuable tool for determining optimal antibiotic therapy. The purpose of this study is to determine the potential impact of a pharmacist driven protocol for ordering PCT on antibiotic duration in patients with HAP or VAP.

Methods: This study will be submitted to the Institutional Review Board for approval. Education will be provided for pharmacists and providers about the implementation of a new protocol allowing pharmacists to order PCT in certain patients. The electronic medical record (EMR) will be used to identify eligible patients who meet one of the following criteria: an order for antibiotics with an indication for pneumonia entered greater than 48 hours after admission, a physician diagnosis of HAP, or a physician diagnosis of VAP. Eligible patients will be divided into two groups based on if their treatment began before or after the protocol was implemented. The following data will be collected for eligible patients: age, gender, indication, PCT, microorganism culture results, temperatures, white blood cell counts, and diagnoses in any admission during the study period. If available, duration and settings of mechanical ventilation will be collected. If not already ordered, pharmacists will order PCT for eligible patients based on the process outlined in the approved protocol. Provider documentation will be reviewed to evaluate clinical criteria and determine potential for antibiotic discontinuation. All data recorded will be maintained confidentially, and analyzed without patient identifiers. The
primary outcome of average duration of antibiotic exposure will be measured in days and compared for each group to identify the presence of a difference.

**Conclusion:** N/A
**Submission Category:** Ambulatory Care  
**Submission Type:** Research-in-Progress  
**Session-Board Number:** 9-009  

**Poster Title:** Virtual pharmacist consultation services in an ambulatory care setting: a single site pilot  

**Primary Author:** Chelsey Hess, Centura Health St. Anthony Hospital, CO; **Email:** chelseyhess@centura.org

**Additional Author(s):**  
Claire Swartwood  
Clint Hinman  
Karlyn Jenkins

**Purpose:** It is well documented that pharmacist intervention for complex medication management improves patient outcomes, however these services are not typically offered in primary care settings although the need has been studied. Virtual pharmacy is an evidence-based approach that allows pharmacists to extend their expertise to multiple locations without the burden of physical presence. Implementation could increase patient engagement and appropriate use of medications, leading to better health outcomes and system management. The purpose of this study is to implement virtual pharmacy services at a single ambulatory care clinic, and evaluate patient outcomes, as well as provider and patient satisfaction.

**Methods:** This is a prospective, observational, cohort study and will be submitted to the Institutional Review Board for approval. Patients to be seen by a pharmacist will be identified by running a report that will identify patients falling into at least one of three categories: polypharmacy (defined as patients taking 10 or more medications), geriatric risk (defined as patients 65 years and older taking at least five medications), and transitional care risk (defined as patients hospitalized within the previous 14-30 days unable to obtain an appointment with their primary care physician). Other patients that might be seen will be identified by their provider as needing pharmacy services. Patients meeting criteria will be scheduled for a 30 minute video conference call with a resident pharmacist, prior to their primary care appointment. The resident pharmacist will perform in-depth medication reviews with patients, then report findings and recommendations to providers via progress notes in the electronic medical record. Providers see the patients next, and may either accept or reject pharmacy’s recommendations with opportunity for the patient to follow-up with the pharmacist for any
further questions/clarifications. The primary outcome is 30 day readmissions or emergency room visits for patients seen by a pharmacist. Secondary outcomes are number of pharmacy recommendations and provider acceptance rate, pharmacist driven avoidance of adverse drug reactions (ADRs), and patient and provider satisfaction with the service.

**Poster Title:** Evaluation overload: implementation of concentrated learning experiences to reduce unnecessary evaluations in an ASHP-accredited residency program

**Primary Author:** Ann Heble, Children's Hospital Colorado, CO; **Email:** aheble91@gmail.com

**Additional Author (s):** Jennifer Hamner

**Purpose:** Within the competency areas for ASHP-accredited pharmacy residency programs, there are goals and objectives for which a resident must be evaluated throughout the residency year. While many goals may be taught and evaluated multiple times throughout the year, certain goals are achieved quickly and only need to be taught and evaluated once. Historically at Children’s Hospital Colorado, residents have completed quarterly evaluations for multiple activities, which generated evaluation fatigue and decreased the quality of evaluations. Therefore, concentrated learning experiences were created to decrease unnecessary evaluations, improve evaluation quality and provide adequate feedback while completing the necessary goals and objectives.

**Methods:** Children’s Hospital Colorado pharmacy residency program is an ASHP-accredited program consisting of four PGY-1 pharmacy residents and two PGY-2 pediatric pharmacy residents. We examined the ASHP goals and objectives in conjunction with each program’s activities to identify goals and objectives fitting into a concentrated learning experience, or an experience with goals and objectives only needing to be taught and evaluated once throughout the residency year. After identification, a learning experience description was developed for each concentrated learning experience describing activities, associated goals and objectives, and methods for which they would be achieved. An evaluation was developed for each concentrated learning experience and is assigned to each resident and preceptor within Pharmacademic upon assignment of the activity. The resident and preceptor must complete the evaluation prior to the project due date. The program director will follow up with residents quarterly to assess their progress in completing the concentrated learning experiences. In order to evaluate the effectiveness and attitudes towards this process, outcomes will be compared between the 2015-2016 and the 2016-2017 residency classes and preceptors. A survey will be conducted between both groups and address opinions on number of evaluations, quality of
feedback, and completion of goals and objectives. The 2015-2016 residency class and preceptors will be surveyed in October 2016. The 2016-2017 residency class and preceptors will be surveyed upon completion of the residency program.

Poster Title: Evaluation of use and cost effectiveness of fosphenytoin in a pediatric academic medical center

Primary Author: Meghan Kolf, Children’s Hospital Colorado, CO; Email: meghan.kolf@childrenscolorado.org

Additional Author (s):

Purpose: The aims of this project are to evaluate the use of fosphenytoin with respect to appropriate use and prescribing patterns as well as waste and fiscal responsibility at a pediatric academic medical center. Current practice commonly involves fosphenytoin being ordered as a rescue medication to be kept at the patient’s bedside upon admission to the neurological unit. This evaluation will examine medication use to determine if the existing prescribing patterns and use of fosphenytoin is in accordance with hospital and national clinical care guidelines and if preventable waste is occurring.

Methods: This study will be submitted to Organizational Research Risk and Quality Improvement Review Panel for approval at this institution. A retrospective review will be performed to evaluate the appropriate use of fosphenytoin ordered from January 1st 2015-January 1st 2016. Analysis will be done on all ordered doses during this time to evaluate usage by unit. All ordered doses will be randomized and 10% will be selected for further review. Orders selected will be reviewed and the following data points will be collected: number of doses dispensed, administered, and wasted, concurrent lab collection orders placed for fosphenytoin levels, if doses were administered after at least one dose of a benzodiazepine was administered, time between the last administration of a benzodiazepine and administration of fosphenytoin, and number of orders placed as part of an order set. To evaluate the fiscal aspect of medication use, estimated cost will be determined for doses ordered but not administered and added to the estimated cost of doses wasted for other reasons (i.e. expiration of medication prior to administration).

Poster Title: Implementation of a pharmacist-driven education program for at home administration of pegfilgrastim in pediatric oncology patients

Primary Author: Amanda Rounds, Children’s Hospital Colorado, CO; Email: amanda.rounds@childrenscolorado.org

Additional Author(s):
Abby Kim

Purpose: Pegylated granulocyte colony-stimulating factor, pegfilgrastim, is increasingly prescribed for outpatient use in pediatric oncology patients. This medication serves to stimulate the production of white blood cells and reduce risk of infection in patients receiving certain myelosuppressive chemotherapy regimens. Pegfilgrastim is available as a pre-filled syringe suitable for adult dosing. Outpatient administration is complicated for pediatric patients who require smaller doses. Education was historically completed by nursing staff prior to hospital discharge. Pharmacist-driven discharge medication consultation is essential to improve accuracy and reduce medication errors in pediatric patients who receive pegfilgrastim at home.

Methods: A comprehensive educational handout for pegfilgrastim was developed by a pediatric oncology-focused pharmacy resident and mentor. This educational handout contained proper storage, preparation, administration and disposal of pegfilgrastim for patient-specific pediatric doses using pre-filled syringes. Information was focused on accurate preparation of patient-specific pediatric dosing using images to display dose measurements. Education materials were reviewed by a multidisciplinary oncology team including pharmacy, physicians, nursing and nursing educators. A hospital policy on pegfilgrastim use and administration was updated to require use of educational handout during discharge consultation and the responsibility for discharge consultation was shifted from nursing to pharmacy personnel.

Results: Development and implementation of pharmacist-driven pegfilgrastim discharge medication consultation for pediatric oncology patients was successfully established. Multidisciplinary review of educational materials resulted in comprehensive completion of educational handouts for patients. Support for transition of discharge education was expressed by nursing and physician groups alike. Oncology pharmacy staff were well equipped to
complete thorough discharge medication consultation. Images displayed on educational handouts were useful in demonstrating appropriate dose measurements despite having pre-filled adult dose syringes to prepare medication from. Pharmacists involved felt more confident in teaching proper administration of patient-specific doses as well as ensuring patients and families could accurately prepare and measure doses at home.

Conclusion: Pharmacy expertise was instrumental in developing educational handouts for patients and families. Given the complication of properly preparing and administering pediatric doses from an adult dose pre-filled syringe, comprehensive education is necessary prior to outpatient use of pegfilgrastim. Pediatric patients face unique challenges with dosing and avoiding medication errors with manufactured products that are geared towards adults. Pharmacist-driven medication consultation may be utilized to ensure understanding of accurate dose preparation and administration for at home use of pegfilgrastim in pediatric patients. Future studies are needed to compare medication errors pre- and post-implementation of pharmacist-led education.

Poster Title: Evaluation of the appropriate use of intravenous and oral sildenafil for pulmonary hypertension at a pediatric academic medical center

Primary Author: Esther Bae, Children’s Hospital Colorado, CO; Email: esther.bae@childrenscolorado.org

Additional Author(s):

Purpose: Sildenafil, a phosphodiesterase type 5 inhibitor, is used off-label in pediatrics for pulmonary hypertension. Sildenafil has shown to improve exercise capacity and hemodynamics in the pediatric population. Sildenafil is currently available as an intravenous solution, oral solution, and oral tablet on the hospital formulary. The purpose of this evaluation is to identify patterns in prescribing and dispensing of the different formulations of sildenafil and to optimize the use and expenditure of sildenafil in pediatric patients based on literature.

Methods: The study will be submitted to the institution’s Organizational Research Risk and Quality Improvement Review Panel (ORQRIP) for approval. A retrospective chart review will be performed to analyze the appropriate utilization of sildenafil from September 1, 2015 to August 31, 2016. A list of sildenafil order numbers will be collected from EPIC, the electronic medical record, and then randomized in Microsoft Excel to generate a 5 percent sampling of the total orders. The following variables will be collected for data analysis: patient name, patient medical record number, medication order name, age at time of order, gender, weight, specific diagnosis, indication for use, dose, frequency of administration, dosage formulation, and duration of treatment. In addition, information on the drug acquisition cost, adjunctive usage of inhaled nitric oxide, and preparation of both intravenous and oral formulations will be collected. With the data obtained, a comparative assessment of the two different formulations will be completed. All recorded data will maintain confidentiality by omitting patient specific information.

**Poster Title:** Continuous aztreonam infusion in the treatment of multidrug resistant pseudomonas in a pediatric patient

**Primary Author:** Kailynn DeRonde, Children's Hospital Colorado, CO; **Email:** kailynn.deronde@childrenscolorado.org

**Additional Author(s):**

**Purpose:** Infections caused by multidrug resistant (MDR) gram-negative bacteria are becoming an increasing concern in the immunocompromised pediatric population. Current therapeutic options for MDR gram-negative infections are limited, and the development of new antimicrobials has been slow to catch up to the rise in resistance. Here we describe a three-year-old male, weighing 14.6 kilograms, who developed a MDR pseudomonas ventilator-associated pneumonia treated with continuous infusion aztreonam. The patient had a past medical history significant for DiGeorge Syndrome and impaired T cell function, Tetralogy of Fallot, tracheostomy dependence, reactive airway disease, and multiple admissions for respiratory infections, leading to multiple antibiotic exposures. He presented with ten days of fever, otorrhea, and increased respiratory distress, and was admitted for observation. He had a history of growing pseudomonas, and was started on vancomycin, levofloxacin, and metronidazole. The Infectious Disease Team was consulted and recommended to continue vancomycin, start meropenem 40 milligrams per kilogram per dose (mg/kg/dose) every eight hours infused over three hours, and to discontinue levofloxacin and metronidazole. Extended infusion meropenem was chosen as the patient had grown levofloxacin-resistant pseudomonas in the past, and there was concern for a resistant organism.

A bronchoalveolar lavage culture revealed 10,000 colony forming units (CFU) of pseudomonas aeruginosa and 200 CFU of methicillin-resistant staphylococcus aureus. Microscan identified a MDR pseudomonas, and Kirby-Bauer testing provided the following minimum inhibitory concentrations (MICs): Aztreonam 48 (resistant or R), Ceftazidime 256 (R), Ciprofloxacin 1 (susceptible or S), Meropenem 32 (R), Piperacillin/Tazobactam 256 (R), and Tobramycin 1,024 (R). As a result of the Kirby-Bauer testing, meropenem was discontinued and continuous infusion aztreonam was initiated. With his regimen of meropenem infused over three hours, the antibiotic serum concentration was calculated to be above the MIC for only 25% of the dosing interval. For gram-negative infections, the goal for serum concentrations is to be greater
than the MIC for 40% of the dosing interval, or even higher in the most acutely ill. Continuous aztreonam allowed for optimal time (ideally 100%) over MIC, and had the lowest induction potential for inducible beta-lactamase production. His aztreonam dose was calculated using equations published in a case series by Moriyama et al and are as follows: Loading dose = Cpeak (mcg/mL) x Vd (L/kg) x weight (kg) = 100 mcg/mL x 0.2 L/kg x 14.6kg = 292mg = 20mg/kg/dose; Maintenance infusion rate (mg/h) = Csteadystate (mcg/mL) x Clearance (L/h) = 100 mcg/mL x 1.1 L/h = 110 mg/hour = ease of dosing = 121.6 mg/hour (2,920 mg/day). We targeted a serum concentration of 100mcg/mL to aim for two times greater than the MIC while still using safe dosing for the patient. After a continuous serum level resulted as 51mcg/mL, an increased rate of 178.87mg/hr (294mg/kg/day) was initiated. This increased rate was chosen after calculating patient specific clearance and aiming for a serum concentration of 75mcg/mL for both efficacy and safety as adverse effects are associated with high doses. Overall, the patient received 17 days of continuous aztreonam with concomitant ciprofloxacin for seven days. Ciprofloxacin was added due to a fever spike after becoming afebrile, and we were unable to get an aztreonam level after the dose increase. He also received two doses of cidofovir for adenovirus viremia detected on peripheral blood polymerase chain reaction testing. The patient improved clinically over this course, despite multiple tracheostomy cultures that continued to grow MDR pseudomonas. While it was challenging to determine the overall cause of symptoms and factors leading to resolution, upon discharge, he had clinically improved. We feel continuous infusion of aztreonam was an effective treatment for the patient, and a viable therapeutic option for him in the future.

**Session-Board Number:** 9-015  

**Poster Title:** Albumin: Evaluation of the utilization, administration, and cost-effectiveness in a pediatric academic medical center  

**Primary Author:** Stephanie Pennington, Children's Hospital of Colorado, CO; **Email:** stephanie.pennington@childrenscolorado.org

**Additional Author(s):**

**Purpose:** Albumin is a blood product derivative used for large volume paracentesis, plasma volume expansion, and nephrotic syndrome, along with many other conditions. It is available in two different concentrations - 5% and 25% - each with their own indications, which is a common source of error. While albumin is a commonly used and essential medication, it may not the most cost-effective. This retrospective chart review will evaluate if albumin is being used appropriately, if the correct product is being prescribed based on indication, the cost associated with waste of doses, and the proper administration technique of the product.

**Methods:** This study will be submitted to Organizational Research Risk and Quality Improvement Review Panel for approval at this institution. A retrospective chart review will be performed on patients who received albumin, 5% or 25%, from September 1st, 2015 – September 1st, 2016. The patients who have received albumin during that time will be randomized and 10% of the patients will be evaluated. The following data will be collected: age, weight, hospital unit, serum albumin, indication, appropriateness of indication, albumin product used, appropriateness of product chosen based on indication, dose, number of doses received, if the dose was given, continuous or bolus administration, appropriate administration, length of infusion, and where the medication was dispensed from. The indications will be recorded and broken down into three categories: appropriate, conditionally appropriate, and inappropriate. To assess cost effectiveness of medication, the manufacturer of albumin stocked will be recorded and the cost will be compared to the cost of albumin products produced by other manufacturers. Also, the cost of the doses wasted as well as given inappropriately will be added together to determine the amount the hospital could have saved. Lastly, to ensure patient safety, the administration will be classified as appropriate or inappropriate based on the length of infusion and if a filter was used. There are no exclusion criteria for this study.

Poster Title: Prophylactic Ertapenem Use in Elective Colorectal Procedures: A Pre and Post Intervention Analysis

Primary Author: Amelia Nelson, Denver Health Medical Center, CO; Email: amelia.nelson@dhha.org

Additional Author(s):
Bryan Knepper
Kathrine Shihadeh

Purpose: Ertapenem is a broad spectrum antibiotic. Guidelines recommend ertapenem for perioperative prophylaxis for elective colorectal procedures. Ertapenem is superior to cefotetan in preventing surgical site infections for these procedures. Ertapenem has not been shown to be more effective as prophylaxis for other procedures. At Denver Health, a review of ertapenem use for perioperative prophylaxis was performed in 2015 and showed opportunities to improve appropriate use. Two interventions were performed, surgeon education and removal of ertapenem from operating room Pyxis machines. The objective of this study is to evaluate ertapenem use as prophylaxis for elective colorectal procedures after intervention implementation.

Methods: This is a retrospective quality analysis study of patients who received at least one dose of ertapenem for perioperative prophylaxis. Patients will be identified through the electronic medical record system. The following data will be collected: ertapenem use, date of administration, type of procedure, date of procedure, and urgency of colorectal surgery. All data will be reviewed by a team of pharmacists and infection prevention specialists. Ertapenem use will be evaluated for appropriateness and categorized as appropriate or not appropriate based on type of surgery performed and urgency of colorectal procedure. This data will be compared to the pre-intervention data to determine if the intervention was effective or if further interventions are needed to optimize ertapenem use for perioperative prophylaxis.

**Poster Title:** Dexmedetomidine use in a safety-net teaching hospital

**Primary Author:** Lana Al-Omar, Denver Health Medical Center, CO; **Email:** lana.al-omar@dhha.org

**Additional Author(s):**
Candice Preslaski
James VandenBerg

**Purpose:** Dexmedetomidine is an alpha-2 adrenergic agonist used for sedation of intubated, mechanically ventilated patients in an intensive care unit setting. It is also used for procedural sedation in non-intubated patients. In September 2012, dexmedetomidine was added to our institution’s formulary. Given the high drug cost, prescribing restrictions were also implemented at that time. The objective of this study is to determine the extent to which our institution complies with its current restriction criteria for dexmedetomidine, identify any safety concerns, and further assess other potential indications for use.

**Methods:** Adult patients 18 years or older who have received dexmedetomidine from January 1, 2016 to June 30, 2016 will be identified based on dexmedetomidine charges using the electronic health record system. This quality assurance study will determine if our institution is complying with our restriction criteria, which includes use in awake fiberoptic intubation, management of shivering during hypothermic therapy after cardiac arrest, and use in adult intensive care units in patients who are ventilated with delirium or to assist with their transition from mechanical ventilation to noninvasive ventilation or extubation. Data to be collected includes: patient age, gender, weight, length of hospital stay, dexmedetomidine infusion rates, duration of dexmedetomidine use, reasons for initiating and discontinuing dexmedetomidine, ventilator status and number of days intubated (if applicable), number of days with delirium, mortality, cost, and specific exclusion criteria for our institution including concomitant neuromuscular blockade other than for intubation, and hemodynamic instability defined as a heart rate less than 60 beats per minute, systolic blood pressure less than 90 mmHg, heart failure, heart block, or myocardial infarction.

Poster Title: An Evaluation of Clindamycin Use for Necrotizing Soft Tissue Infections (NSTI)

Primary Author: Ashley Schuler, Denver Health Medical Center, CO; Email: ashley.schuler@dhha.org

Additional Author(s):
Candice Preslaski
Katherine Shihadeh

Purpose: Necrotizing fasciitis, or necrotizing soft tissue infections (NSTIs), occurs in approximately 1500 patients annually. Although rare, mortality rates can range from 20% to 50%. The mainstay of therapy remains to be frequent surgical debridement, supportive therapy, and broad spectrum antibiotics. Clindamycin may decrease the toxin production of bacteria and is recommended for use in empiric antibiotic regimens. While useful for NSTI treatment, clindamycin is associated with severe gastrointestinal side effects, increased incidence of clostridium difficile infections, and increased resistance rates. The objective of this study is to evaluate the use of clindamycin in suspected and confirmed cases of NSTI.

Methods: This is a quality assurance project. The electronic medical record system will identify patients who have received one of three identified antibiotic combinations, vancomycin and clindamycin combined with either piperacillin/tazobactam, cefepime, or aztreonam, started empirically for the treatment of presumed NSTI between the dates of January 1st, 2015 and December 31st, 2015. Patients are categorized as diagnosis of NSTI or rule out of NSTI based on emergency room documentation of suspicion, operation notes, and discharge summaries. Patients who received one of the antibiotic combinations for non-skin and soft tissue infections will not be included in the study. The following data will be collected: patient age, gender, race, height, weight, body mass index, allergies, past medical history, antibiotics given, dates of initiation of antibiotics, dates of discontinuation of antibiotics, operation room trips, use of vasopressors, wound culture results, length of stay, clostridium difficile incidence, and initial labs of: c-reactive protein, white blood cell count, hemoglobin, serum sodium, serum creatinine, and blood glucose. All data recorded will be maintained confidentially. Laboratory risk indicator for necrotizing fasciitis (LRINEC) will be calculated. Data will be reviewed by clinicians to determine patient characteristics with confirmed NSTI diagnosis, average LRINEC
score for NSTI diagnosis, appropriate initiation of clindamycin based on LRINEC score, duration of clindamycin treatment, time to clindamycin discontinuation after NSTI was ruled out or last debridement, and side effects.

**Results:** To be determined

**Poster Title:** Medication Therapy Management (MTM) pharmacist services in a homeless population

**Primary Author:** Kristin Lutek, Kaiser Permanente Colorado, CO; **Email:** kelutek@gmail.com

**Additional Author(s):**
Kristin Alvarez
Anita Hedge

**Purpose:** Homelessness is a serious public health problem. Previous studies have investigated the benefit of interventions by pharmacists in a homeless population; however, evidence continues to be somewhat limited and variable. In an effort to expand clinical pharmacy and medication therapy management (MTM) services to the homeless population, pharmacist-led MTM services were established at a homeless shelter clinic in November 2014. The purpose of this study is to determine the impact of a pharmacist-led MTM visit within a homeless population on clinical outcomes, specifically blood pressure lowering. Additionally, to quantify the number and types of interventions made in this population.

**Methods:** A retrospective study was conducted from January 2015 to December 2015. All patients with a completed appointment with the clinical pharmacist at the Bridge homeless shelter during this time period were included in the study. The primary outcome was to determine the systolic and diastolic blood pressure lowering for hypertensive patients in the study.

**Results:** A total of 144 patients were seen in the homeless clinic, with 86 of these diagnosed with hypertension. Of these 86 patients, 48 patients had at least 2 blood pressure readings recorded during the study period. Both systolic and diastolic readings decreased over the study period, by 4.2 mmHg and 1.8 mmHg, respectively. The average number of pharmacist interventions in this population was 1.3 ± 1. The most common intervention was education on medication adherence.

**Conclusion:** A pharmacist-managed clinic in a homeless population demonstrated potential for improvement in clinical indicators, including improvement in blood pressure readings. Drug
related interventions performed during clinic visits by a pharmacist were primarily education on medication adherence.

Poster Title: Evaluation of non-activated 4-factor prothrombin complex concentrate use in adult patients at a community hospital

Primary Author: Anton Nguyen, Memorial Hospital - University of Colorado Health, CO; Email: anton.nguyen@uchealth.org

Additional Author(s):
Alyssa Douville
Michael Holowatyj
Lauren Loeper

Purpose: Kcentra, a non-activated 4-factor prothrombin complex concentrate (4F-PCC), is FDA-approved for vitamin K antagonist reversal in patients with acute major bleeding or need for urgent surgery or an invasive procedure. The purpose of this evaluation is to evaluate off-label use of 4F-PCC in adult patients at a community hospital.

Methods: All adult patients who received 4F-PCC from October 1st, 2014 to September 1st, 2016 at a community hospital will be included. All data will be collected and recorded without patient identifiers and maintained confidentially. The following data will be collected: age, gender, sequential organ failure assessment score, anticoagulation therapy (if applicable), indication for anticoagulation (if applicable), actual body weight, service and authorizing provider of 4F-PCC, administration location, off-label indication, dose, pre-international normalized ratio (INR) value (if available), re-doses given within 24 hours, coagulation lab parameters (prothrombin time, INR, activated partial thromboplastin time, platelet count, anti-Xa level, and thromboelastography parameters if available), hemoglobin, thromboembolic adverse drug events (defined as stroke, acute myocardial infarction, pulmonary embolism, or venous thrombosis following 4F-PCC administration), in-hospital mortality, and concomitant use of blood and factor products. Provider documentation will be reviewed to identify off-label use. Off-label indications considered appropriate based on supporting literature are direct oral anticoagulant reversal, reversal of coagulopathy of hepatic disease, and reversal of coagulopathy in trauma patients. The primary endpoint is appropriate use of 4F-PCC for off-label indications. Secondary endpoints include rate of achieving INR less than 1.5, normalization
of coagulation parameters, mortality, thromboembolic events, cost, and concomitant use of blood and factor products.

Poster Title: Evaluation of heparin-induced thrombocytopenia (HIT) rates at a community hospital

Primary Author: Chelsea Goldsmith, Memorial Hospital – University of Colorado Health, CO; Email: chelsea.goldsmith@uchealth.org

Additional Author(s):
Kate Jeffers
Lauren Loeper

Purpose: HIT is associated with significant disease burden and substantial use of hospital resources. Recent data suggests low molecular weight heparin (LMWH) lowers the risk of HIT compared to unfractionated heparin (UFH). This two part, retrospective chart review, seeks to evaluate incidence of suspected cases of HIT versus confirmed cases of HIT at a community hospital over one year. Primary outcome is to evaluate incidence of suspected and confirmed cases of HIT. Secondary outcomes include the comparison between the use of UFH and LMWH, and evaluation of 4 T scores for each platelet factor 4 (PF4) test ordered during hospital admission.

Methods: The electronic medical record system will identify patients who have had a PF4 test ordered during hospital admission over one year (January 1, 2015-December 31, 2015). The following data will be collected: patient age, sex, height, body weight, length of hospital stay, if patient had cardiac surgery or continuous veno-venous hemofiltration (CVVH) during stay, mortality rate, calculated 4 T score, the use of UFH, LMWH, and drugs used for treatment of HIT. If available, PF4 test and confirmatory test results, heparin allergy noted and HIT documented on patient hospital problem list. Inclusion criteria for this study will be patients ≥18 years old who had a PF4 test ordered during hospital admission over 1 year and exclusion from the study will be patient’s with >1 PF4 ordered during same hospital admission and patient’s who were in a clinical trial. Descriptive statistics will be used to analyze the data.

Poster Title: Retrospective analysis to compare the safety and efficacy of a standardized versus weight-based PCA dosing protocol in a community hospital

Primary Author: Krista Sanchez, Parkview Medical Center, CO; Email: krista_sanchez@parkviewmc.com

Additional Author (s):
Melissa Balian

Purpose: With sufficient guidance, patient-controlled analgesia (PCA) is an effective method for managing severe acute pain. However, imprecise dosing and monitoring parameters can increase the risk of over-sedation and respiratory depression, particularly in patients that are opioid-naïve, elderly, obese, or have certain chronic comorbidities such as chronic lung disease, and renal or hepatic impairment. To combat the risks of PCA, Parkview Medical Center switched from a weight-based dosing regimen to a standardized dosing protocol. The objective of this evaluation is to determine if standardizing the PCA dosing has reduced adverse events and demonstrates similar or improved pain scores.

Methods: A single-center retrospective chart review will be conducted as a quality assurance project in a community hospital. The study will evaluate patients that have been prescribed a fentanyl, morphine, or hydromorphone PCA. Patients who received the weight-based PCA dosing regimen from October 1, 2014- November 29, 2015 and those receiving the standardized dosing protocol from time of implementation, November 30, 2015, to October 1, 2016, were identified using the electronic medication dispensing reports. Data will be collected through electronic medical record review. The primary endpoints will assess safety of the new dosing regimen by comparing overall use of naloxone, and evaluate efficacy by contrasting average pain scores. Secondary endpoints to further assess safety include: sedation scores, occurrence of a respiratory rate of < 10 breaths/min, SPO2< 80% and hypotension defined as SBP< 90 mmHg. This study will be submitted to the Institutional Review Board for exemption, as no active patients will be included and all protected health information will be de-identified and destroyed upon completion. Ultimately, this project will serve to assess the appropriateness of the standardization of the PCA dosing protocol, and to determine if further steps are warranted to provide the safest and optimal pain relief to the patients of Parkview Medical Center.

**Poster Title:** Impact of pharmacist led discharge counseling and bedside medication delivery on hospital readmission rates within 30 days of discharge

**Primary Author:** Leticia Ritz, Parkview Medical Center, CO; **Email:** lritz123@gmail.com

**Additional Author(s):**
Melissa Balizan

**Purpose:** With readmission rates increasing, hospitals have increased efforts to reduce complications at discharge. Hospital discharge is a critical time where patients are likely to have questions regarding medications, regimens and adverse effects. Many patients are unwilling or unable to pick up medications at discharge. This lag in therapy can cause serious adverse effects. With increased efforts to minimize complications, hospitals are now increasing the utilization of clinical pharmacists at discharge. The objective of this study is to determine the impact pharmacist led discharge counseling and medication delivery at the bedside is having on readmission rates within 30 days of discharge.

**Methods:** This study will be submitted to the Institutional Review Board for approval. Retrospective data collection will be conducted and reviewed to identify patients who have been readmitted within 30 days of hospital discharge. Among those patients who are readmitted, analysis of patients who received pharmacist led discharge counseling and medication delivery at the bedside will be conducted. The following data will be collected: reason for readmission, current disease states, medications at discharge, pharmacists who counseled patient, and the date of discharge and readmission. All data involving patient information will be recorded without identifiers and maintained confidentially and onsite at this institution. Data from patients who are readmitted within 30 days of discharge will be reviewed to determine: the impact of pharmacist led discharge counseling, which disease states are the most common for readmission, whether or not certain medications are a cause, or if medication delivery at the bedside is having an effect on readmission rates.

Poster Title: Assessing community pharmacists’ knowledge and comfort with natural products commonly used in cardiovascular disease

Primary Author: Veronia Guirguis, Safeway Pharmacy, CO; Email: veronia.guirguis@safeway.com

Additional Author (s):
Robert Willis
Tonna Farinha
Jeff Hamper

Purpose: The popular use of natural products can be due to a patient’s perception of their presumed efficacy, safety and the misconception of fewer side effects. The ease of availability and low cost have also increased the use of natural products. The objective of this study is to assess the knowledge and comfort level of community pharmacists in recommending coenzyme Q-10, fish oil and garlic; natural products commonly used for cardiovascular disease, in accordance with their safety and efficacy. The outcome of this study was observing increase in knowledge and comfort of these particular natural products following educational materials provided.

Methods: The study design of this project will be a pre- and post- quiz. The study population will include all approximately 300 Albertsons and Safeway community pharmacists within the Denver Division. A $10 Starbucks gift card offered as incentive if a pharmacist completed the pre- and post- quiz. The primary investigator drafted two educational materials addressing coenzyme Q-10, fish oil and garlic, commonly used in cardiovascular disease in accordance to their efficacy and safety. Education materials included a narrated power point presentation in conjunction with a comprehensive handout discussing background, studies and recommendations of these products to targeted patient populations. These short educational materials, expected to be completed in less than 10 minutes. An identical pre- and post-educational quiz conducted via email to these pharmacists to gauge their knowledge and comfort level in recommending these specific natural products. The multiple-choice quiz measured common knowledge of these particular products including their efficacy and safety. Comfort level measured in a combination of Likert scale and open-ended questions. The
education materials used to gauge if they increased the pharmacists’ knowledge and comfort level when recommending these natural products for cardiovascular disease.

Poster Title: Evaluating patient satisfaction with pharmacist-administered specialty long-acting injectable antipsychotics in the community pharmacy practice setting

Primary Author: Emanuela Mooney, Safeway Pharmacy/Regis University, CO; Email: emanuela.mooney@safeway.com

Additional Author (s):
Jeffrey Hamper
Robert Willis
Charlotte Ricchetti
Tonna Farinha

Purpose: Patient satisfaction plays an essential role in adherence to long-acting injectable antipsychotics (LAIAs). This ultimately can impact treatment outcomes and healthcare costs. There is a lack of published studies evaluating the impact of specialty injectable antipsychotics administered in community pharmacy practice settings, including patient satisfaction. This project was designed to evaluate patient satisfaction with an existing pharmacist-administered specialty long-acting injectable antipsychotic service in the community pharmacy practice setting.

Methods: This study will be submitted to the Institutional Review Board for approval. A patient questionnaire assessing patient satisfaction will be provided to patients receiving specialty long-acting injectable antipsychotics administered by a pharmacist in a community pharmacy setting. Satisfaction will be assessed using a Likert scale in the following areas: level of privacy, convenience of scheduling appointments, convenience of location, comfort with service provided by pharmacy, confidence in pharmacist’s ability to administer the injectable medication, trust in pharmacist, pharmacist communication, pharmacist knowledge about service, duration of appointment, and likelihood of recommending service to others. Patients who have had LAIAs administered at an alternative setting (e.g. mental health clinic) will be asked to compare the service at these different locations. The questionnaire also includes a section on patient demographic characteristics, including: age, gender, highest education level, annual income, state of residence, number of years with current condition, and number of
months enrolled in this service. Patient questionnaires will be anonymous and will be provided and collected by administering pharmacists.

**Poster Title:** Implementation of an opioid reduction protocol utilizing alternatives for the treatment of pain in the emergency department of a level 1 trauma center

**Primary Author:** Michelle Maguire, Swedish Medical Center, CO; **Email:** michelle.maguire@healthonecares.com

**Additional Author(s):**
Rachael Duncan

**Purpose:** Pain is the number one reason for emergency room visits in the United States. Many emergency room physicians find it quick and effective to prescribe opioids for patients that present complaining of pain. However, not all pain is effectively treated with opioid medications. In some cases, opioids may be ineffective and do greater harm by contributing to abuse. By using an opioid-free, multimodal treatment approach to pain management, we hope to better control pain in patients entering the emergency department, as well as decrease the use of opioids in a population at high risk for abuse and misuse.

**Methods:** This is a retrospective pre- and post-implementation analysis of an opioid reduction protocol in the emergency department at Swedish Medical Center in Englewood, Colorado. A 2-month education program was provided by pharmacy to both nursing and physician staff regarding effective alternative non-opioid options for the treatment of pain. Staff huddles, weekly newsletters, lectures, and competencies were used to provide appropriate education. For patients arriving in the emergency department with a chief complaint of pain, physicians were also provided with a protocol containing a variety of non-opioid medication options per pain indication.

Chart review to identify numerical pain scores will be collected at baseline, 30 minutes, and 60 minutes. Data regarding use of naloxone therapy, amount of opioids used, and patient satisfaction scores will also be collected and compared to data prior to the implementation of the opioid reduction protocol. Secondary outcomes include analysis of effectiveness and adverse effects in patients treated with intravenous ketamine and lidocaine for pain. Pain reduction per indication including headache, musculoskeletal pain, renal colic, abdominal pain, and joint dislocation/fracture will also be analyzed. Primary and secondary outcomes will be analyzed using the chi square and student t test.

Poster Title: Evaluation of daptomycin utilization at a large community hospital

Primary Author: Catherine McCall, University of Colorado Health - Memorial Hospital, CO; Email: catherine.mccall@uchealth.org

Additional Author(s):
Alexander Novin
Leslie Devlin
Lauren Loeper

Purpose: Daptomycin is a cyclic lipopeptide antibiotic that exhibits rapid concentration-dependent bactericidal activity against a variety of Gram-positive organisms, including those resistant to vancomycin. Approved indications include the treatment of complicated skin and skin structure infection caused by susceptible strains of Gram-positive organisms as well as Staphylococcus bloodstream infections, including those with right-sided infective endocarditis. The primary objective of this medication utilization evaluation is to describe the indications, dosing, and duration of daptomycin therapy at our hospital and identify potential areas for quality improvement.

Methods: A retrospective chart review will be performed to include all patients greater than 18 years of age who received daptomycin at University of Colorado Health - Memorial Hospital, from January 1, 2016 to June 30, 2016. Patients will be identified through electronic medical records. Data to be collected will include patient demographics, indication for antibiotic use, daptomycin dose in mg and mg/kg, dosing weight, infectious disease physician prescribed or not, baseline creatinine clearance, creatinine phosphokinase monitoring, organism cultured with minimum inhibitory concentrations if available, other antibiotics given in the course of treatment, concomitant statin therapy, readmission or emergency department visits within 30 days, and mortality. Compliance to outpatient therapy will be assessed if daptomycin therapy was continued through the hospital outpatient infusion clinic. All data will be collected without patient identifiers and maintained confidentially. Descriptive statistics will be utilized to characterize daptomycin use and potential areas for quality improvement will be identified.

Poster Title: Assessment of stress ulcer prophylaxis practice and rates of Clostridium difficile-associated diarrhea at a community hospital

Primary Author: Heather Johnson, University of Colorado Health Memorial Hospital, CO; Email: heather.johnson2@uchealth.org

Additional Author(s):
Alyssa Douville
Lauren Loeper

Purpose: Proton pump inhibitors and histamine-2 receptor antagonists are often over-prescribed for the purpose of preventing stress ulcers during hospitalization. The association between gastric acid suppression therapy and Clostridium difficile-associated diarrhea (CDAD) has been well documented throughout the literature for hospitalized patients, with a risk ranging from 1.4 to 2.75 times higher among patients with proton pump inhibitor exposure compared to those with no exposure. The objective of this study is to determine whether or not there is a correlation between inappropriate prescribing of acid suppression therapy and increased rates of CDAD at the University of Colorado Health Memorial Hospital.

Methods: A retrospective chart review will be performed utilizing an electronic medical record to identify patients who had a positive Clostridium difficile toxin assay from January 1, 2015 to August 30, 2016. The following data will be collected: hospital service, comorbid disease states (gastroesophageal reflux disease (GERD), peptic ulcer disease, Helicobacter pylori-associated disease, cirrhosis, gastrointestinal bleed or variceal bleed), mechanical ventilation status, age, sex, body mass index, medication for acid suppression therapy and number of doses, antibiotics prescribed within ten days of positive CDAD diagnosis, hospital length of stay, appropriateness of acid suppression therapy, diet ordered and steroids prescribed within seven days of CDAD diagnosis. A predetermined set of appropriate indications for stress ulcer prophylaxis (SUP) and acid suppression will be used including: continuation of home regimen, patient-reported symptoms of heartburn/dyspepsia/epigastric pain/regurgitation/gastritis, erosive esophagitis, GERD, peptic ulcer disease, proven or suspected gastrointestinal bleed, Barrett’s esophagus, admission to an intensive care unit plus coagulopathy or mechanical intubation greater than forty eight hours. All data will be recorded without patient identifiers and will be maintained.
confidentially. A review of the incidence of CDAD in all patients prescribed SUP will also be undertaken. The primary endpoint of this review will be the incidence of CDAD associated with gastric acid suppressing agents prescribed for SUP and the percentage of inappropriate SUP prescribed to patients with an eventual diagnosis of CDAD.

Poster Title: Evaluation of tacrolimus trough levels and impact on early acute rejection in heart transplant recipients

Primary Author: Samantha Steiger, Hartford Hospital, CT; Email: samantha.steiger@hhchealth.org

Additional Author(s):
Spencer Martin
Jason Funaro

Purpose: Calcineurin inhibitors, specifically tacrolimus, are considered the cornerstone of anti-rejection therapy post heart transplant. However, to ensure safe and effective use, extensive therapeutic drug monitoring is required. Our objective is to assess if the time it takes to achieve therapeutic tacrolimus levels has any impact on the incidence of early acute rejection in heart transplant recipients. Additionally, we aim to assess whether the duration for which a patient remains within their goal therapeutic range in the first 30-days of transplant impacts the risk for early acute cellular rejection.

Methods: This study has been approved by the Institutional Review Board. A retrospective chart review of heart transplant patients at our institution from January 1, 2010 to December 31, 2015 will be performed. Patients will be excluded if they were under the age of 18 at the time of transplant, received a heart transplant outside of the date range specified above, died within 7 days post-transplant, or if they received a prior solid organ transplant. Heart transplant early acute rejection, defined as an acute cellular rejection episode within the first 6 months post-transplant, will be confirmed by two methods: [A] via biopsy proven acute rejection (BPAR), or [B] an episode of heart transplant dysfunction that demonstrates improvement after treatment with high-dose methylprednisolone. The 1990 and 2004 International Society for Heart and Lung Transplantation (ISHLT) criteria will be used to determine the severity of BPAR. Patient demographics, transplant characteristics, tacrolimus doses, tacrolimus trough levels, laboratory values, and histology outcomes will be collected retrospectively from both inpatient and outpatient electronic records to assess the primary and secondary endpoints. The investigators estimate that a finite sample size of approximately 80 patients will be evaluated. For descriptive analyses, continuous variables will be represented as a mean standard deviation.
or a median with interquartile range, depending on distribution of the data, and categorical data will be represented as a percentage.

**Poster Title:** Impact of delayed introduction of tacrolimus post-liver transplantation  

**Primary Author:** Heather Kutzler, Hartford Hospital, CT; **Email:** heather.kutzler@hhchealth.org  

**Additional Author (s):**  
Spencer Martin  

**Purpose:** Calcineurin inhibitors (CNI), such as tacrolimus, are considered the cornerstones of immunosuppression after solid organ transplantation. However, calcineurin inhibitor-induced acute kidney injury (AKI) presents a challenge for safe use in the post-transplant setting. Delaying the start of tacrolimus to preserve renal function is a strategy commonly used immediately after liver transplantation to avoid AKI. The purpose of this study is primarily to identify the differences in allograft function by rate of biopsy proven acute rejection in patients who have a delayed CNI introduction versus those who do not. Secondary outcomes include renal function, allograft loss, patient survival, and infection.  

**Methods:** The Institutional Review Board has approved this study. Adults 18 years of age or older who underwent liver transplantation at our institution from January 1, 2016 to July 28th 2016 were included in the study population. Patients were excluded if they are less than 18 years old, received dual organ transplantation at the time of liver transplant, or did not receive tacrolimus as an immunosuppressant during the first month after transplantation. Demographics, transplant characteristics, baseline co-morbidities, medication regimens, laboratory outcomes, biopsy proven acute rejection episodes, infection history, and laboratory parameters will be collected retrospectively from both inpatient and outpatient electronic records. Tacrolimus medication management will be assessed by time to initiation of therapy, starting dose, time until the goal trough level is achieved, and time within goal trough level during the first 30-days of transplant. Study data will be transcribed into an electronic format and will require a password for access.

**Poster Title:** Utility of gabapentin in the management of inpatient acute alcohol withdrawal  

**Primary Author:** Matthew Morrison, Hartford Hospital, CT; **Email:** matthew.morrison@hhchealth.org  

**Additional Author(s):**  
Elizabeth Udeh  
Michelle Krawczynski  

**Purpose:** Benzodiazepines have been the mainstay therapy for managing the symptoms of alcohol withdrawal. However, this class of medications carries many undesirable side effects such as delirium and impairment in psychomotor function which can be detrimental to patient care. The goal of this proposed study is to evaluate whether the use of a high dose gabapentin taper as an adjunctive therapy for alcohol withdrawal will decrease benzodiazepine usage compared to patients who didn't receive gabapentin.  

**Methods:** This study has been submitted to the Institutional Review Board for approval. A retrospective chart review will be performed to identify patients for inclusion into the study. Patients meeting inclusion criteria will be separated into two groups, a pre-gabapentin based alcohol withdrawal protocol group, and a post-gabapentin based alcohol withdrawal protocol group. The following data will be collected and utilized to evaluate endpoints: patient demographics, length of stay, baseline co-morbidities, total daily dose of lorazepam, days of gabapentin taper received, use of adjunctive medications, initial and highest recorded Clinical Institute Withdrawal Assessment of Alcohol Scale, Revised (CIWA-Ar) scores, daily Confusion Assessment Method for the intensive care unit (CAM-ICU) scores, recorded transitions to higher level of care, and number of rapid responses. The primary endpoint will be difference in average daily lorazepam usage in each cohort. Secondary outcomes will include length of stay, number of intensive care unit days, total rapid responses called, number of delirium free days, and rates of transferring to higher level of care.  

We anticipate enrolling 50 patients in each group. Sample sizes were selected in order to afford 80 percent power to detect a relative difference of 33 percent between the null and alternative hypothesis using an alpha of 0.05 with a two-sided-t-test. Endpoints will be examined using appropriate statistical tests.

**Poster Title:** Assessing venous thromboembolism in liver failure patients

**Primary Author:** Alyssa Boutin, Hartford Hospital, CT; **Email:** alyssa.boutin@hhchealth.org

**Additional Author(s):**

Spencer Martin

**Purpose:** The purpose of this study is to evaluate whether hospitalized patients with liver failure receive appropriate venous thromboembolism (VTE) prophylaxis when admitted to a medicine service. The specific aims are to determine the rate of VTE prophylaxis in hospitalized liver failure patients, determine the rate of VTE and bleeding events in hospitalized liver failure patients and retrospectively assess whether the International Medical Prevention Registry on Venous Thromboembolism (IMPROVE) Score is an appropriate tool for determining VTE risk in this patient population.

**Methods:** This retrospective cohort study is approved by the Institutional Review Board. Patients will be included if they are admitted to our institution between January 1, 2014 and July 31, 2016 with a primary or secondary diagnosis of liver failure based on International Classification of Diseases (ICD) 9 and 10 codes. Additional inclusion criteria include being at least 18 years of age and admitted to the medicine service during hospitalization. Patients were excluded if they were no longer followed by the medical service at any time during their admission, had an observational or outpatient admission, were pregnant, or were admitted for a pre-existing VTE. Demographic data, inpatient laboratory data, and length of stay will be collected through the electronic medical record system. Contraindications to prophylaxis, type of prophylaxis received, and other medical conditions that increase the risk of experiencing a thromboembolic event will be analyzed. Bleeding and clotting events will be assessed using discharge ICD 9 and 10 codes. Based on the information collected, the researcher will determine each patient’s IMPROVE score and assess whether appropriate prophylaxis was given. The prevalence of appropriate VTE prophylaxis will be calculated as a percentage of those who get appropriate therapy divided by the total sample size. A 95 percent confidence interval (CI) will be generated.

**Poster Title:** Prospective identification and follow-up of the low-risk pulmonary embolism population at a tertiary teaching hospital

**Primary Author:** Candice Sherwood, Hartford Hospital, CT; **Email:** candice.sherwood@hhchealth.org

**Additional Author (s):**
Michelle Krawczynski

**Purpose:** Traditionally, initial management of pulmonary embolism (PE) has occurred in the inpatient setting, regardless of the patient’s presentation and/or risk for adverse clinical outcomes. However, recent guidelines suggest that PE patients identified as low-risk for adverse clinical outcomes may be candidates for management in an outpatient setting. The purpose of this study is to identify and quantify patients with acute PE admitted to Hartford Hospital through the emergency department that would be low-risk for adverse clinical outcomes based on a proposed venous thromboembolism treatment guideline, and to assess whether these patients experience any harms within 30 days of initial presentation.

**Methods:** This prospective study will be submitted to the Institutional Review Board for approval. A pre-built report that contains patients who underwent computed tomography angiography for suspected PE in the emergency department will be run daily to identify the patients that will be included in this study. Electronic charts will then be reviewed to collect patient demographics, simplified Pulmonary Embolism Severity Index (sPESI) score, Hestia score, and length of stay. If the chart review is insufficient to categorize the patient as high-risk for adverse clinical outcomes, the principal investigator will contact the admitting physician to gather additional information from the time of admission. Informed consent will be obtained from all patients identified as low-risk according to the guideline so that data can be collected to assess the composite endpoint (recurrent venous thromboembolism, rehospitalization, or death within 30 days of initial presentation) via telephone follow-up on day 30 plus or minus 3 days after admission to the hospital.

Poster Title: Barriers and adherence to implementing extended three-hour infusion rates of intravenous beta-lactam antibiotics with activity against Pseudomonas aeruginosa

Primary Author: Rachel Comito, Hartford Hospital, CT; Email: rachel.comito@hhchealth.org

Additional Author (s):
Michael Nailor

Purpose: The Infectious Diseases Society of America has published guidelines promoting antimicrobial stewardship programs and methods to optimize the use of antibiotics. Hartford Healthcare is a five hospital healthcare system introducing three-hour infusions of beta-lactam antibiotics with activity against Pseudomonas aeruginosa. Previous clinical trials have revealed greater cure rates, mortality benefits, and shorter length of stay by optimizing the pharmacodynamics of beta-lactam antibiotics. This study will determine adherence rates as well as barriers to implementing the three-hour protocol at a large hospital compared to a smaller community hospital.

Methods: This study has been approved by Hartford Healthcare’s Institutional Review Board. A retrospective chart review will be conducted utilizing the EPIC computer systems at Hartford Hospital (HH) and MidState Medical Center (MMC) from October 1, 2016, until data on 250 patients has been collected. Adult patients admitted to all medical units at MMC and three similar medical floors at HH will be included if they received a beta-lactam antibiotic with activity against Pseudomonas aeruginosa. Data to be collected includes patient demographics, administration information, and the antibiotic infusion rate. Variables potentially affecting the chosen infusion time such as peripherally inserted central catheter lines, intensive care unit stay, and the availability of other hospital resources will also be studied. The sample size will consist of records taken as a retrospective convenience sample of 250 patients in a 1:1 ratio between institutions. A comparison among two samples of 125 patients would afford 90 percent power to determine if the rate of implementing the three-hour infusion is similar (within 5 percent) to the conventional infusion time. Baseline demographics and nursing data will be reported using descriptive statistics. Inferential statistics will be used to make between-group comparisons.

Poster Title: Assessing Immediate and Long-term Safety of Recombinant Tissue Type Plasminogen Activator for Use in Ischemic Stroke in Patients 80 Years and Older: A Retrospective Review

Primary Author: Andrew Gentry, John Dempsey Hospital at University of Connecticut Health Center, CT; Email: agentry@uchc.edu

Additional Author (s):
Kevin Chamberlin
Sanjay Mittal
Allison Dias
Jennifer Sposito

Purpose: Since its inception in 2013 and certification in 2014, the UConn Stroke Program has had many patients that fall into the demographic of 80 years and older. The purpose of this retrospective study is to analyze rTPA use in this patient population and assess immediate, short-term and long-term outcomes in patients that received this medication. The data obtained from this study will serve to clarify the safety of rTPA use in the elderly at various follow-ups not commonly addressed in the literature and guide the therapeutic use of rTPA at UConn John Dempsey Hospital as part of the stroke program.

Methods: This study is a retrospective cohort analysis. It will analyze patients that were admitted to John Dempsey Hospital for acute ischemic stroke. Patients that are 80 years or older will be stratified into two cohorts based upon whether or not they received recombinant tissue type plasminogen activator. Their medical information, including diagnosis, comorbidities and functionality score, will then be reviewed and extracted as needed to obtain the data necessary for our study. Data collection will be undertaken in a confidential manner. The data collected will not permanently contain any identifiable protected health information (PHI) and no new data will be generated from our study. A preliminary power analysis determined that an alpha of 0.05 and a beta of 0.8 can be achieved with a sample size of approximately 80 patients per cohort. This project has been submitted for IRB approval.

Poster Title: Evaluation of pharmacy involvement in outpatient based transitions of care: assess uptake quality and outcomes

Primary Author: Adam Whalley, John Dempsey Hospital at UConn Health, CT; Email: awhalley@uchc.edu

Additional Author (s):
Marissa Salvo
Kevin Chamberlin
Susan Levine
Danielle Beaudoin

Purpose: Transitions of care is currently a point of emphasis in the inpatient setting, but pharmacy is not currently involved in the outpatient setting at this institution. This project will evaluate the uptake, quality, and outcomes associated with pharmacy involvement in the transitions of care for patients of an academic medical center’s primary care practice (General Medicine Associates at UConn Health) with a recent discharge from UConn John Dempsey Hospital. The findings will determine if a pharmacy driven medication review will decrease the number of medication errors experienced by patients following hospital discharge.

Methods: This project received approval from the Investigational Review Board as a Quality Assurance/Quality Improvement project. Patients who have are discharged from UConn John Dempsey Hospital will be contacted by a medical assistant to schedule a transitions of care management (TCM) appointment and the medical assistant will obtain and record an accurate medication list for the patient. A pharmacist will review each patient’s discharge instructions, medication list, and current outpatient medication profile to identify medication discrepancies and opportunities for pharmacy intervention. Areas of focus will be errors of omission, discontinued medications, dosing changes, therapeutic duplications, drug interactions, and appropriate dosing based on patient specific factors. Following the review, a summary of pharmacist’s recommendations will be created and provided to the appropriate provider for the patient prior to the TCM appointment. Following each patient’s TCM visit, the acceptance rate of pharmacist’s recommendations will be assessed through review of physician
documentation. The findings of this project will be utilized to determine the overall benefit of pharmacy involvement in an outpatient setting following a patient’s recent hospital discharge.

Poster Title: Outcomes of front-loaded diazepam in patients experiencing severe alcohol withdrawal syndrome

Primary Author: Jane Mueller, Saint Francis Hospital and Medical Center, CT; Email: jane.mueller@stfranciscare.org

Additional Author(s):
Emma Gimose
Scott May
Tera Stock

Purpose: Severe alcohol withdrawal syndrome (AWS) is a life-threatening condition possibly leading to withdrawal seizures, delirium tremens, and increased mortality. Benzodiazepines remain the mainstay of treatment but these agents are not without complications including over-sedation, respiratory depression, and incidence of delirium. At our institution, inpatients at high risk of severe AWS are initiated on a fixed schedule of lorazepam with or without front-loaded diazepam. The decision to front-load is widely variable. The goal of this study is to explore the impact of front-loaded diazepam on overall benzodiazepine use and incidence of adverse effects.

Methods: The study will be submitted to the Institutional Review Board for approval. This retrospective matched cohort study will include patients that met criteria for severe AWS and were admitted between April 2014 and August 2016. Patients will be identified by an admitting diagnosis of alcohol withdrawal, a maximum Clinical Institute Withdrawal Assessment for Alcohol (CIWA) score of 20 or greater, and a history of delirium tremens or alcohol withdrawal seizures. Patients will be matched according to baseline characteristics and AWS risk factors. The primary outcome is total benzodiazepine use among patients with severe AWS who received front-loaded diazepam versus those who did not. Secondary outcomes include change in daily CIWA scores, incidence of over-sedation, reloading of diazepam, duration on benzodiazepines, incidence of antipsychotic administration, incidence of delirium tremens, incidence of withdrawal seizure, incidence of intubation, mean length of hospital stay, and transfer to a higher level of care among patients with severe AWS who received front-loaded diazepam versus those who did not.

Poster Title: Barriers to effective medication reconciliation: Identifying discrepancies in medication documentation at discharge

Primary Author: Christine Kubus, Saint Francis Hospital and Medical Center, CT; Email: christine.kubus@stfranciscare.org

Additional Author(s):
Amanda Williams
Tera Stock

Purpose: Medication reconciliation has proven to be a challenge in a variety of care settings, including hospital discharge. Two types of mismanagement are thought to contribute to discrepancies in patients’ discharge medications: provider discrepancies and patient discrepancies. One reason provider discrepancies may occur is because of the multiple places for medication documentation at discharge. Studies have shown upwards of 50%-70% of discharged patients have at least one discrepancy in their medication documentation. The objective of this study is to determine where the provider discrepancies lie within discharge documentation at a 600-bed teaching hospital in an urban setting.

Methods: The first phase of this study is to identify provider discrepancies in the documentation of patients’ discharge medications. This will be conducted using a retrospective chart review. For inclusion, patients must have a post discharge follow-up visit in the outpatient clinic between December 15th 2015 and January 15th 2016. Patients’ charts will be reviewed for discrepancies in the following four documents: discharge plan, discharge summary medication list, after visit summary and profile medication list. Discrepancy will be defined as variations in patients’ medication list (either additions or omissions of medications), prescribed dose, direction, duration or route. The primary outcome is the number of patients with one or more discrepancy in any of the four documents. Secondary outcomes will include a subgroup analysis identifying which documents were most likely to have a discrepancy from the others.

Poster Title: Evaluation of antibiotic utilization in patients with urinary tract infection
Primary Author: Gabrielle Ruggiero, Saint Francis Hospital and Medical Center, CT; Email: gabrielle.ruggiero@stfranciscare.org
Additional Author(s):
Tera Stock
Ulysses Wu
Dora

Purpose: Antibiotic optimization is essential to effectively treating patients, avoiding harmful side effects, and limiting the development of drug resistant pathogens. Yet around 50% of all antibiotic prescriptions are inappropriate, as noted in a 2013 report on antibiotic resistance published by the Centers of Disease Control and Prevention. The purpose of this study is to evaluate antibiotic prescribing practices in patients with urinary tract infection (UTI) for appropriateness and to identify opportunities for improvement.

Methods: This project will be submitted to the Institutional Review Board for approval. UTI antibiotic prescribing patterns will be assessed by performing a retrospective review of the electronic medical record. Admitted patients diagnosed with UTI will be identified using International Classification of Diseases, 10th Revision (ICD-10) codes. The following data will be collected for each patient: age, gender, allergies, concurrent infections, relevant comorbidities, pregnancy status, history of urinary tract infections, presence of urinary catheter, organisms isolated, susceptibilities obtained, antibiotics prescribed for current UTI (drugs, doses, routes, length of therapies), recent prior antibiotics used, hospital length of stay, and readmission data. UTIs will be classified as uncomplicated, complicated, or catheter associated, and antibiotic therapies will be assessed for appropriateness according to these classifications and current clinical practice guidelines. Baseline characteristics and antibiotic utilization will be summarized using descriptive statistics.

**Poster Title:** Implementation of a COPD transition of care pharmacist  

**Primary Author:** Andrea Bastiaanse, Saint Francis Hospital and Medical Center, CT; Email: andrea.bastiaanse@gmail.com  

**Additional Author(s):**  
Amanda Williams  

**Purpose:** In hospitalized patients, transitions of care (TOC) pose a safety risk associated with adverse events, higher readmission rates and cost. The Affordable Care Act established the Hospital Readmissions Reduction Program which requires Centers for Medicare and Medicaid Services to reduce payments to hospitals with excess readmissions for certain diseases, including chronic obstructive pulmonary disease (COPD). Previous studies found pharmacist-care in COPD was associated with improvements in health-related quality of life, medication compliance, and patient satisfaction. Furthermore, pharmacist-care was associated with reduced hospital admissions and overall costs. The purpose of this project is to implement a COPD transition of care pharmacist.

**Methods:** The COPD transition of care pharmacist is being implemented in a 617-bed teaching hospital. The service is part of a larger, hospital-wide initiative to improve the care of COPD patients. The pharmacist meets with patients before discharge to review their medication list, provide inhaler education and review an action plan. Education is provided with the use of printed inhaler and action plan education sheets, inhaler technique demonstration, and teach-back reinforcement. Following hospital discharge, the pharmacist provides post-discharge phone follow-up. The follow-up phone call includes an evaluation of medication understanding, reinforcing appropriate inhaler use, review of action plan, and a reminder of any upcoming appointments. Finally, patients scheduled with an appointment in the “Comprehensive COPD Center” receive face-to-face follow-up with the pharmacist as part of their pulmonary appointment. At this visit, the pharmacist ensures appropriate inhaler technique, evaluates and reinforces medication understanding, and discusses the action plan. The service will be evaluated in the future to determine if there is an impact on healthcare utilization.

**Results:** N/A
Conclusion: N/A
Purpose: One objective of this study is to examine the indications for which cefepime is utilized at Saint Vincent’s Medical Center. For the most common indication(s), further investigation will be conducted to determine the appropriateness of cefepime. This information will be utilized to make decisions about where to target limited resources to make interventions that may optimize the use of this broad-spectrum anti-infective at SVMC.

Methods: This study was granted exemption by the Institutional Review Board. The first 60 patients who received treatment with Cefepime over a three month period between January and March 2016 will be reviewed and the following information will be compiled and analyzed: prescribed indication, microbiological cultures and results, microbiological screening, risk factors for resistant pathogens requiring treatment with 4th generation cephalosporins, and number of days on treatment. Descriptive statistics will be used to determine frequencies of indications for cefepime use, patient risk factors for Pseudomonas aeruginosa, potential to de-escalate treatment, whether or not de-escalation was done, and overall appropriateness of antibiotic selection. Recommendations on opportunities for improvements in prescribing practices will be made to direct future antibiotic stewardship efforts.

Poster Title: Implementation of GeneXpert MRSA/SA blood culture assay and its effect on vancomycin therapy in a community teaching hospital

Primary Author: Robert Ambrose, St. Vincent's Medical Center, CT; Email: robert.ambrose@stvincents.org

Additional Author(s):
Amanda Volpe

Purpose: Studies have shown that de-escalation from vancomycin to beta-lactam therapy in methicillin-susceptible Staphylococcal aureus (MSSA) bacteremia, results in improved clinical outcomes. Longer duration of vancomycin therapy is also associated with nephrotoxicity and increased prevalence of vancomycin resistant enterococci. Our hospital recently implemented a new polymerase chain reaction (PCR) assay that detects methicillin-resistant Staphylococcal aureus (MRSA) or MSSA bacteremia quicker than traditional testing. The objective of this study is to determine if the PCR assay is leading to quicker de-escalation of vancomycin in patients with MSSA bacteremia.

Methods: The study was approved by the Institutional Review Board. This retrospective study will compare the duration and de-escalation of vancomycin therapy in patients with MSSA bacteremia before and after the implementation of the new PCR assay. Days of vancomycin therapy, time to de-escalation, length of stay, and mortality will be collected from the medical record. The study will have two groups. The control group will be the first 51 patients going backward from the date of implementation of the PCR assay. Group two will be the first 51 patients going forward after implementation of the assay. Patients will be included if they have at least one positive blood culture for Staphylococcal aureus and received at least one dose of vancomycin. Patients will be excluded if they have a mixed culture or if culture is coagulase-negative staphylococcus.

**Poster Title:** Impact of pharmacist interventions at discharge on hospital readmission rates

**Primary Author:** Yeo Jung Lee, St. Vincent's Medical Center, CT; **Email:** yjsally.lee@gmail.com

**Additional Author (s):**
Cindi Souphonevat
Gina Mozzicato
Amy Kurzatkowski

**Purpose:** With the Affordable Care Act, hospitals have had an increased financial burden when patients are readmitted. Due to some of the consequences of readmissions and decreased reimbursement rates, our institution implemented a pharmacy service called “Meds to Bed” to improve transitions of care during the discharge process. This service allows medications and counseling to be delivered to the patient’s bedside by a pharmacist prior to the patient’s discharge. This retrospective pilot study will compare the 30-day readmission rates of patients who received Meds to Bed services with pharmacist involvement versus those who did not receive the services.

**Methods:** The Institutional Review Board approved this pilot study. The pharmacy resident will conduct a retrospective chart review for patients who were discharged from the inpatient unit during March 1, 2016 to September 1, 2016. Using a medium effect size, it was determined that 51 participants per group would yield 80 percent power to detect a difference of 0.5 percent between groups for statistical significance. We will evaluate at least 51 participants from a random sampling of discharged patients who did not receive Meds to Bed services and at least 51 participants who received Meds to Bed services with pharmacist involvement. The primary outcome measures to be studied are unplanned readmissions within a 30-day time frame post-discharge. Secondary outcome measures to be studied include emergency department (ED) visits following patient discharge. A student t-test will be used to determine statistical difference between the two groups. All data with patient-sensitive information will be de-identified using study numbers and will not appear during presentation and publication of this study. All information will be stored in a password-protected computer and locked in a passcode-protected safe.

**Email:** rlikar@uchc.edu  
**Additional Author(s):**  
Kevin Chamberlin  
Robyn Wahl  
Joseph Palomba  

**Purpose:** About 1.4 million people in the United States identify as transgender. While the topic of transgender issues has garnered much attention from the media, transgender and gender non-conforming people continue to face discrimination when accessing health care. The purpose of this study is to see if a pharmacist-directed transgender medicine and cultural competency training program can help increase pharmacists’ knowledge, confidence, and comfort in treating transgender patients.  

**Methods:** This study will be submitted to the Institutional Review Board for approval. The study population will be pharmacists and pharmacy residents practicing at an ASHP-accredited residency practice site. Points of contact at each practice site will be identified using the ASHP Online Residency Directory. Participants will be sent two surveys and an educational handout, which serves as the transgender medicine and cultural competency training program. One survey will be completed before reading the educational handout and one survey will be completed after reading the educational handout. The surveys will be used to assess pharmacists’ comfort, confidence, and knowledge level when caring for transgender patients; surveys will also assess whether subjects found value in this training and any feedback they may have for improvement. All survey data will be submitted anonymously. Survey responses will be reviewed by investigators to compare pre-training and post-training responses to questions.

**Poster Title:** Correctional prescribers opinions towards use of sliding scale insulin versus basal bolus therapy

**Primary Author:** Lauren Mullings, UCONN Health Center - Correctional Managed Health Care, CT; **Email:** mullings@uchc.edu

**Additional Author (s):**
Kevin Chamberlin
Robert Guynn
Adam Jankowski

**Purpose:** The use of sliding scale insulin is discouraged in current practice. The use of sliding scale insulin is not effective at producing consistent glycemic control. However, adequate glycemic control can be obtained through the use of basal bolus therapy. The objective of this study is to evaluate the opinions of physicians on sliding scale insulin to determine a possible transition to basal bolus therapy practice.

**Methods:** This study will be submitted to the Institutional Review Board for approval. The study population will include all Correctional Managed Health Care prescribers in the Connecticut correctional setting will be recruited via email to participate in an online survey. The online survey will take approximately 30 minutes to complete. The survey will consist of multiple choice and open ended questions to assess prescriber’s opinions on the use of sliding scale insulin in the correctional setting. All data submitted will be anonymous. The responses will be reviewed by the investigators to assess the overall opinion of prescribers on the use of sliding scale insulin.

Poster Title: Admission errors with medications that have multiple dosage forms

Primary Author: Francis Lerz, Waterbury Hospital, CT; Email: flerz@wtbyhosp.org

Additional Author(s):
Sehjan Bhura
Aaron Burton
Eileen Deptula

Purpose: Medication histories obtained upon hospital admission are major sources of medication errors in hospitals. Many times these errors lead to adverse drug reactions, side effects, and interruptions of therapy. In addition, the unique delivery system of medications provides potential for error. Many health care providers are unaware of the differences in the release patterns of different dosage forms and the effects on therapeutic outcomes and side effects. The objective of this study is to retrospectively determine the rate of medication reconciliation errors requiring pharmacist interventions, specifically involving quetiapine, bupropion, metoprolol, diltiazem, and oxycodone.

Methods: This is a retrospective Institutional Review Board exempt analysis of patients that were admitted to Waterbury Hospital from 2014 to 2016. Patients included in this study had medical reconciliation done upon admission and have been on quetiapine, bupropion, metoprolol, diltiazem, or oxycodone in various dosage forms. Data will be compiled using the hospital medical record system to identify errors in medical reconciliation and risk factors for medication errors. Demographic data such as age, gender, comorbid conditions, and patient residence will be collected. Each group must have at least 60 patients, which provides 80% power to detect a two-fold difference in possible risk factor incidence. Data analysis and statistical testing will be performed using Microsoft Excel® software. P-values less than .05 will be considered statistically significant.

Results: The results are pending data collection.
Conclusion: The conclusion is pending results.

Poster Title: Evaluating the use of double gram negative coverage in septic patients in the emergency department

Primary Author: Kwame Darko, Waterbury Hospital, CT; Email: kdarko@wtbyhosp.org

Additional Author(s):
Scott Hogrefe

Purpose: The optimal approach for empirical antibiotic therapy in patients with severe sepsis and septic shock remain controversial. The objectives of this study are to determine the appropriate administration of dual gram-negative coverage in severe sepsis/septic shock patients after quality improvement measures were implemented in the emergency department.

Methods: This study is an Institutional Review Board exempt observational electronic medical chart review because there will be no active subjects involved and protected health information will be de-identified. Data will be collected retrospectively on patients that visited the emergency department between October 2016 and December 2016 who satisfy the inclusion criteria. Data collected for each study participant will include demographics, date and time of diagnosis in the ED, empiric antibiotic regimen, time to administration of antibiotics, time to de-escalation of empiric antimicrobial therapy, narrowed antibiotic regimen, length of stay and discharge outcome.

Results: Pending data collection.

Conclusion: Pending results.

**Session-Board Number:** 9-048  

**Poster Title:** Medication use evaluation of methylnaltrexone versus alvimopan in the treatment of postoperative constipation  

**Primary Author:** Nibal Fadhil, Waterbury Hospital, CT; **Email:** nfadhil@wtbyhosp.org  

**Additional Author(s):**  
Sehjan Bhura  

**Purpose:** Postoperative constipation can lead to significant complications in the healing process of a patient after surgery. About 15-50 pct of patients suffer from constipation problems early after undergoing a surgical procedure. Methylnaltrexone and alvimopan, peripherally acting opioid antagonists, are used in the treatment of this constipation. Over the years, there’s been little to no evidence of the superiority of one of these agents over the other in the treatment of postoperative constipation. We will compare the efficacy and safety of the use of methylnaltrexone or alvimopan in patients suffering from postoperative constipation to determine superiority, if any, for either agent.

**Methods:** This study will be a retrospective chart review of the post-use outcomes for methylnaltrexone and alvimopan in the treatment of postoperative constipation. We will identify patients who underwent surgery at the hospital between July 2015 and June 2016, and who received either methylnaltrexone or alvimopan for postoperative constipation treatment. Patients’ age, sex, race, body mass index, diagnosis, type of procedure, history of opioid use (during and postoperative analgesia), time to return of bowel movement, length of hospital stay and 30-day readmission will be collected. Length of stay will be calculated from day of procedure to discharge. Inclusion criteria will include patients aged greater than or equal to 18 years old, underwent surgical procedure at the hospital, received opioid analgesia and received either methylnaltrexone or alvimopan for the treatment of postoperative constipation. Exclusion criteria will include any patient that does not qualify for any of the inclusion criteria listed above and use of either drug was contraindicated. The primary efficacy end point will be time to constipation resolution after receiving the treatment. Secondary outcomes will include length of hospital stay, length of treatment, constipation recurrence while inpatient and safety outcomes.

**Poster Title:** Improving determination of accessibility and affordability of discharge medications through electronic health record enhancements  

**Primary Author:** Ruhaniyah Alam, Yale New Haven Health, CT; **Email:** alamruh.alam@ynhh.org  

**Additional Author(s):**  
Julie D’Ambrosi  
Kimberly Boothe  
Amy D'Silva  
Tiffany Gray  

**Purpose:** The lack of an electronic, systematic process to identify high-cost medications limits the number of patients evaluated for assistance and ultimately results in barriers to affordable medication access, significant work for the healthcare team post-discharge, and medication non-adherence. Determining discharge medication affordability and accessibility is challenging because insurance coverage varies greatly. For select medications initiated during admission at Yale New Haven Hospital (YNHH), a pharmacy technician identifies the copay, need for prior authorization (PA), and eligibility for medication assistance. This project’s purpose is to implement an electronic PA identification process prior to discharge and a toolkit to assist with affordability.  

**Methods:** This project will validate the consistency between prior authorization identified for the sample of select discharge medications initiated during admission by the pharmacy technician and an electronic prescribing-based option. In addition to soliciting input on discharge medications that frequently requiring PA, prescribers and their support staff will be surveyed to determine the current PA process for various medical group practices at YNHH. A process map will be developed to capture best practices that will support consideration of alternative medications or initiation, and ideally completion, of PA to improve medication accessibility at discharge. A medication access and affordability toolkit will be developed to readily identify MAP options that the healthcare team can employ to increase affordability of discharge medications. Primary outcomes include number of PAs identified prior to discharge as well as number of patients offered MAP options for discharge medications. The number of
PAs completed prior to discharge or alternate medications initiated will be included in secondary endpoint analyses.

Poster Title: Implementing a 72-hour stop for empiric piperacillin/tazobactam orders to decrease broad spectrum antibiotic use.

Primary Author: Nadya Jammal, Yale New Haven Hospital, CT; Email: nadya.jammal@ynhh.org

Additional Author(s):
Dayna McManus
Jeffrey Topal

Purpose: With the rise of antimicrobial resistance the CDC and Joint Commission have recently created a national initiative to promote antimicrobial stewardship programs (ASP). Historically, ASPs have utilized a multimodal approach to optimize antibiotic therapy through methods that include; dose optimization, intravenous to oral conversions, and antibiotic time outs. This institution has incorporated these concepts into their ASP including an automatic 72-hour stop in the electronic medical system on empiric piperacillin/tazobactam dosing. We retrospectively evaluated the outcomes of the 72-hour stop for empiric piperacillin/tazobactam orders including duration of empiric therapy, percent de-escalated, appropriateness of dosing and cost saving outcomes.

Methods: This was a retrospective cohort study involving electronic medical chart review with no planned intervention. Cases were defined as adult inpatients with empiric orders placed for piperacillin/tazobactam and no documented cultures at the time of ordering from September 2014 to October 2014, prior to the 72-hour stop time initiative, and September 2016 to October 2016, after the electronic medical record order set was implemented. The gap between 2014 and 2016 was done in order to avoid skewing data due to the national shortage of piperacillin/tazobactam in 2015. Patients with documented susceptible infections, current or prior transplants, febrile neutropenia or piperacillin/tazobactam for surgical prophylaxis were excluded. Additionally, patients were only analyzed once, repeat admissions and treatment courses were not included for analysis. Data collection forms were used to abstract baseline demographics, admission date, renal function, piperacillin/tazobactam dosage and frequency, appropriateness of dosing, indication and ultimate antibiotic selection (post 72 hour stop). Demographic and clinical data are to be analyzed using descriptive statistical methods and quantifying duration of therapy and cost saving outcomes.
Results: Not available at this time.

Conclusion: Not available at this time.

Purpose: Medication safety events affect over 5% of hospitalized patients, making them one of the most prevalent types of inpatient errors. Hospital reporting of medication errors helps optimize medication event analysis, which may drive process improvement and reduce incidence of errors. Event tracking aids in creating sustainable quality improvement plans to create better data integrity and prevent medication events from recurring. The purpose of this project is to identify opportunities to streamline and standardize the medication event reviewing process across a three hospital healthcare system, as a means to better understanding where in the medication use process errors take place.

Methods: Pharmacists will evaluate and assess our current process for reviewing medication event reports and create quality improvement plans to address opportunities identified through the reviewing process. The quality improvement plans will be focused primarily on standardizing the evaluator form within the online event reporting system with the goal of creating better data integrity to identify opportunities for process improvement. The analysis will be performed on the medication event reports regarding precursor events from all three hospitals within the healthcare system; precursor events are those deviations from generally accepted performance standards (GAPS) that reach the patient but result in minimal or no detectable harm. The evaluator forms used to review medication event reports will be analyzed, with the goal of creating the most optimal documentation of event follow-up. Various fields analyzed may include error category, which identifies the source of the error in the medication use process, and levels of harm, including precursor event or near-miss event. Error categories may involve prescribing, dispensing, transcribing, monitoring and storage. Upon
analysis of the current process, quality improvement plans will be created to address any concerns regarding the evaluation form used by medication error reviewers. Finally, pharmacists will document the selected method for event follow-up and ensure compliance by measuring the success rate of implementing the modifications in the evaluator form.

**Poster Title:** Intravenous (IV) drug waste minimization as a cost management initiative

**Primary Author:** Chelsea Welsh, Yale New Haven Hospital, CT; **Email:** chelseakwelsh@gmail.com

**Additional Author (s):** Viktoriya Svirskiy
Florence Egri
Melanie Liptrot

**Purpose:** Medication waste is costly to health organizations, with compounded sterile products (CSPs) making up a large portion of that cost. With recent changes in regulations regarding the preparation and storage of intravenous (IV) medications, many hospitals have shifted to preparing these medications in their IV compounding rooms. Current practice at our institution involves compounding many of these medications as patient specific doses or storing them in automated dispensing cabinets (ADC) at room temperature. The aim of this study was to evaluate the extent to which IV CSPs were wasted and find a cost effective alternative for their preparation and storage.

**Methods:** We used data collection tools from our IV room workflow management system to monitor the amount of waste between the months of June 2016 to August 2016. The study institution is a 1, 541 bed academic medical center with a 24-7 IV admixture services. We collected data regarding high-cost CSPs including the following: bumetanide, daptomycin, desmopressin, insulin regular drips (both stock doses and patient-specific doses), levetiracetam, norepinephrine, sodium bicarbonate, thiamine, vancomycin, and vasopressin. Wasted medications, for the purposes of this study, included CSPs that were compounded, sent as patient specific doses or stocked in the ADC, and returned and scanned back into our IV room workflow management system as doses to be discarded. Average wholesale prices (AWPs) were used to determine a dollar amount for waste over a three-month period, which was further extrapolated to 12-month time frame to estimate annual potential for savings.
**Results:** Between the months of June 2016 to August 2016 1,947 CSPs from the above list were wasted. The dollar amount in waste totaled $85,441, resulting in an estimated $316,408 potential annual savings. The breakdown of waste by medication and cost was as follows: bumetanide 2.60%, daptomycin 2.50%, desmopressin 0.31%, insulin 8.4% (including patient-specific and stock doses), levetiracetam 8.6%, norepinephrine 10.3%, sodium bicarbonate 14.9%, thiamine 4.4%, vancomycin 0.34%, and vasopressin 47.5%. The breakdown of waste by medication and quantity wasted was as follows: bumetanide 7.60%, daptomycin 0.2%, desmopressin 0.30%, insulin 21.3% (including patient-specific and stock doses), levetiracetam 17.3%, norepinephrine 9.7%, sodium bicarbonate 28.2%, thiamine 7.7%, vancomycin 1.8%, and vasopressin 6.1%.

**Conclusion:** The application of a drug waste minimization model for high-cost IV CSPs may be an effective drug cost containment strategy, which may produce durable benefits. Vasopressin was the top contributor with regards to cost and therefore, should be considered a priority target for cost minimization efforts. Possible solutions to reducing IV CSP waste include compounding doses in real time, utilizing our IV room workflow management system to re-use unused doses, and adjusting current par levels for standard stock doses. Further investigation is required to determine the durability of these methods with regards to reducing IV CSP waste.

Poster Title: Multi-center evaluation of parenteral desmopressin for severe, non-hemophiliac uremic bleeding

Primary Author: Lydia Tran, Yale New Haven Hospital, CT; Email: lydia.tran@ynhh.org

Additional Author(s):
Michael Guerra
Michael Liu
Nilesh Amin

Purpose: Desmopressin is used to rapidly reduce bleeding time and blood loss in critically-ill and perioperative patients at risk for severe, non-hemophiliac, uremic bleeding. The recent shortage and resulting increased cost of parenteral desmopressin has prompted utilization reassessment and inventory optimization. The primary objective is to evaluate appropriate parenteral desmopressin use in non-hemophiliac severe bleeding in the presence of acute or chronic renal failure, or use of antiplatelet agents within 5 days of therapy in hospitalized patients at a multi-center health system. Secondary outcome is to evaluate the appropriate dosing regimen for other indications such as central diabetes insipidus or nocturia.

Methods: The study comprises of a retrospective electronic medical record review of 100 patients in a multi-center health system that has received parenteral desmopressin throughout the year 2015. Appropriate usage is defined as, non-hemophiliac patients with documented acute or chronic renal failure who present with severe bleeding (documented systolic blood pressure less than 90 mmHg, on a parenteral vasopressor, or necessitate infusion of packed red blood cells or other blood products) at the time of administration. Other data points to be evaluated include indication for use, patient weight, dosing regimen, relevant complete blood count values (platelet count, hemoglobin, and hematocrit), total quantity of blood products utilized, and time variance between order entry to medication administration. The evaluation and cost analysis of current data is underway, and if the results show inappropriate use by up to 50 percent, we will optimize our current medication use process of parenteral desmopressin health-system wide.

**Poster Title:** Optimization of inpatient glycemic control in patients managed on concentrated insulin products

**Primary Author:** Kathleen Adams, Yale New Haven Hospital, CT; **Email:** kathleen.k.adams@gmail.com

**Additional Author(s):**
Kristina Shvets
Rachel Eyler
Julie D’Ambrosi

**Purpose:** In 2015, the FDA approved two new concentrated insulin products (NCIP): insulin degludec and insulin glargine recombinant. Data is lacking regarding the comparative safety and efficacy of NCIPs as well as guidance on transitioning patients to common formulary basal insulins such as detemir or glargine. Patients are potentially at risk of medication errors when converted from their home NCIP regimen. The purpose of this project is to evaluate the incidence of glycemic events and medication errors in patients admitted to our institution on an outpatient NCIP vs. insulin glargine.

**Methods:** A retrospective chart review was performed of all adult patients within the health-system since 2012 with a NCIP (Afrezza, Tresiba, Toujeo, and Humulin R U-500) on their home medication list. This study included patients 18 years of age and older, diagnosed with type 1 or type 2 diabetes, that were admitted to a hospital. Patients were excluded if the NCIP was started after their most recent admission, if the NCIP was stopped prior to admission, or if the patient was admitted with an insulin pump. Efficacy endpoints included proportion of blood glucose levels within goal range of 70 – 179mg/dL, glucose range during admission, and appropriate insulin regimen at 24 hours after admission. Safety endpoints were defined as any blood glucose less than 70mg/dL, greater than 180mg/dL, diabetes-related 30-day readmission rates, and accurate admission and discharge medication reconciliation. Patients were also evaluated for concomitant use of glucose-altering medications that may influence the clinician’s ability to manage insulin therapy. Descriptive statistics will be used to describe patient demographics and medication conversion errors. Patients receiving an NCIP will be matched to patients receiving insulin glargine based on total daily basal dose within the same admission
year. Logistic regression will be used to compare the odds of having a safety endpoint between patients receiving NCIPs and the control group, controlling for age, gender, and Charlson comorbidity score.

Poster Title: Decentralizing non-formulary management at a large academic medical center: a pre and post analysis

Primary Author: Kaitlyn Loi, Yale New Haven Hospital, CT; Email: kaitlyn.loi@ynhh.org

Additional Author(s):
Robyn Pisacane
Catherine McGeary
Phu Huynh
Molly Leber

Purpose: In 2001, a non-formulary process was developed at a large academic medical center where non-formulary and restricted drug requests are evaluated by drug information pharmacists at the point of order entry. An increasing number of non-formulary requests over the years has led to inefficiencies in evaluation of non-formulary requests. As a result, in Fall 2015, the traditional non-formulary process was decentralized to include evaluation by either unit-based pharmacists or drug information pharmacists. The objective of this analysis is to compare financial expenditures, compliance with drug use guidelines, and documentation rates between the traditional non-formulary pager process and the decentralized process.

Methods: Annualized financial expenditure for top 10 non-antibiotic non-formulary and restricted drugs and annualized financial expenditure for top 10 antibiotic non-formulary and restricted drugs will be calculated and compared between the pre-decentralization model time period, Fall 2014 through Fall 2015, and the post-decentralization model time period, Fall 2015 through Fall 2016. Approval and denial rates of top 10 non-antibiotic non-formulary and restricted drugs and approval and denial rates of top 10 antibiotic non-formulary and restricted drugs will be calculated and compared between the two time periods for compliance with the hospital's pharmacy department drug use guidelines. The number of requests documented by pharmacy staff will be compared between the two time periods.

Poster Title: Inventory management: the impact of National Drug Code (NDC) standardization across a health-system

Primary Author: Scott Bourret, Yale New Haven Hospital, CT; Email: scott.bourret@ynhh.org

Additional Author(s):
Robyn Pisacane
Marjorie Lazarre

Purpose: Health-system formulary standardization is a long-standing corporate objective driven by the positive clinical impact and economic value of formulary management. While the health-system formulary is standardized, formulary procurement decisions require standardization to the granular level of the NDC. Health-system NDC standardization efforts were undertaken to optimize contractual compliance, increase wholesaler service levels, and reduce information technology systems (ITS) maintenance. The secondary objective was to improve inventory cost management through the expansion of the health-system shared inventory model.

Methods: The NDC standardization initiative began with the appointment of a project team consisting of pharmacy leadership, ITS specialists, and pharmaceutical wholesale distributor representatives.
The two overlapping review phases included an eight-week assessment of oral solid medications and a six-week evaluation of non-oral solids. Interviews with pharmacy stakeholders at each institution were conducted to understand workflow processes and proactively identify barriers to NDC standardization. A one-year pharmaceutical purchase history, bulk medication repackaging history, and a list of exclusion items were collected from each delivery network.
Selection of the preferred NDC was based on best contracted sales price per unit, package size, and the associated costs to repackage bulk pharmaceuticals. Furthermore, a review of slow moving inventory, defined as procurement of less than three packages annually, was completed to detect additional medications for inclusion in the existing shared inventory model. The storage site for each shared inventory addition was determined based on the patient population served. Recommendations for standardization and shared inventory were presented
to leadership at each facility for approval. All implementations were completed within one fiscal quarter to maximize contract price-dependent selections. Post-implementation monitoring was conducted using the following metrics: pharmaceutical expenditures, purchase volume, contract compliance percentage, wholesaler service level, and ITS workload impact. A sustainable process for continued NDC standardization was established to manage formulary additions, pharmaceutical supply shortages, product discontinuations and contractual changes.

Poster Title: Optimizing inventory management through interventions focused on low use medications in automated dispensing machines (ADMs)

Primary Author: Jonathan St. Onge, Yale New Haven Hospital, CT; Email: jonathan.stonge@ynhh.org

Additional Author(s):
Nilesh Amin
Daniel Kilcoyne
Kathleen Ferencz
Paul Rochefort

Purpose: An opportunity exists to optimize medication inventory in ADMs. At our large academic medical center we maintain an average daily inventory of approximately 3.5 million dollars in medication. Twenty-five percent of this is stored in ADMs with one quarter of that not being utilized over a 90-day time period. The purpose of this project is to develop a standardized procedure to identify any medication not used in greater than 90 days and return it to our central pharmacy supply. By relocating inventory, we will decrease our purchasing needs and maximize utilization.

Methods: We will target specific medications by analyzing which are stored in ADM and identifying those not vended over a 90-day time period. Medications required for emergent or urgent situations will be excluded. At this time the unit-dose cost of each medication will be factored in and ultimately determine if the medication is suitable for unloading. The qualifying medications will be compiled into a daily automatically generated report and incorporated into current operational workflow to facilitate their return to the central supply. The goal being to reduce medication purchase orders overtime reflecting an increased utilization of medication on hand.

Poster Title: Hyaluronate derivatives drug class review across a health system

Primary Author: Rahul Samudralwar, Yale New Haven Hospital, CT; Email: rahuls1392@gmail.com

Additional Author(s):
Michael Liu
Charles Jones
Nilesh Amin

Purpose: Hyaluronate derivatives are medications that are used for multiple indications including as surgical aids in ophthalmic procedures, for osteoarthritis of the knee, and extravasation. Currently, there are multiple formulations of hyaluronate derivatives used within the health system. The purpose of this drug use optimization is to minimize formulary duplications while also reducing costs for the health system.

Methods: Patients admitted to any hospital or visiting any outpatient clinic within the health system from January 1, 2015 to January 1, 2016 who received a hyaluronate derivative will be retrospectively evaluated. Patients will be identified from an electronic health record and assessed based on the indication for use, the formulation used, the dose, and the route of administration. The target sample size for this drug use optimization is 100 patients within the health system including both inpatients and outpatients. A cost analysis will be performed comparing all hyaluronate derivatives while also assessing the frequency of utilization of each formulation and ultimately, its role on the health system formulary. Competitors will also be analyzed in terms of use and cost in order to further narrow the formulary of all members of the health system.

Poster Title: Meds to beds program development to increase medication adherence at a large academic medical center

Primary Author: Brianne Giordano, Yale New Haven Hospital, CT; Email: brianne_giordano@yahoo.com

Additional Author (s):
Terri Sue Bukowski
Tiffany Colandrea
Renee Havriliak
Julie D’Ambrosi

Purpose: According to WHO, only about 50% of patients take their medications correctly. This is partly due to the low percentage of patients that pick up their prescriptions immediately following discharge, estimated at 40%. Surgery patients are an important population that require adherence to post-surgical medications. These patients will be discharged on pain medications and antibiotics which are important for the safest recovery possible. This project is designed to determine the impact of expanding the medical center’s Meds to Beds program to the surgical patient population to improve patient adherence, and provide data to support a business plan for further expansion.

Methods: The multidisciplinary approach to the Meds to Beds program is currently initiated by the concierge pharmacist who visits surgical patients in the recovery area to discuss the availability of the service. The pharmacy resident, supported by the concierge pharmacist, students, and pharmacy technicians, will work with the medical team to facilitate medication prescribing and discussion regarding patients who would benefit from the program. A retrospective review of hospital data and pharmacy records will be utilized to measure both the profitability and safety outcomes of this outlined program. The primary endpoint measuring the program’s success will be the percent of patient’s obtaining their medications within 24 hours of discharge compared to patients not using the program. Secondary endpoints will include increase in pharmacy revenue, number of prescriptions captured through the program, and percent capture rate on the surgical floor. The number of prior authorizations resolved by the pharmacy by discharge will also be captured.

**Poster Title:** Alteplase for pulmonary embolism: Evaluation of drug usage patterns and budget impact within a health system

**Primary Author:** Danielle McKimmy, Yale New Haven Hospital, CT; **Email:** danielle.mckimmy@ynhh.org

**Additional Author (s):**
Agnes Zajac
Ginger Rouse

**Purpose:** Pulmonary embolism (PE) is a serious medical event responsible for greater than 500,000 deaths per year. Intravenous alteplase is a treatment option for PE that accounts for significant budget impact within this health system. The primary objective of this study is to evaluate the usage patterns of alteplase for PE and to identify opportunities to decrease drug cost throughout the health system.

**Methods:** This study is a multi-center, retrospective chart review conducted across all sites within the 2,130 bed health system. Electronic medical records will be queried for all adult inpatient alteplase orders with an indication of PE from 6/2015 to 6/2016. The following data will be collected: patient demographics (age, gender), indication for drug use (lysis of PE associated with unstable hemodynamics in imminent or actual cardiac arrest, lysis of PE in non-cardiac arrest), dose of alteplase ordered, and documented drug administration. Electronic health record documentation will be reviewed to determine reason for drug not administered, if applicable. Total alteplase use and waste will be calculated based on drug ordered and admixed, but not administered. Cost analysis will be performed based on calculated waste of alteplase.

Poster Title: Rituximab for non-oncology indications in the inpatient setting

Primary Author: Kimvi Diep, Yale New Haven Hospital, CT; Email: mzkdiep@gmail.com

Additional Author(s):
Mabel Wai
Michael Liu
Nilesh Amin

Purpose: In addition to the treatment of certain hematologic cancers, rituximab is also used in the treatment of rheumatoid arthritis, immune thrombocytopenia, graft versus host disease, and antibody mediated rejection in solid organ transplantation. Though inpatient administration may be clinically indicated for some patients, often it may be deferred to outpatient administration to improve workflow and cost-effectiveness. The purpose of this retrospective review is to assess the medical necessity of inpatient rituximab administration for non-oncology indications.

Methods: The electronic medical records of 100 patients that received rituximab from 2014–2016 will be evaluated. Patients >18 years of age that received rituximab inpatient for non-oncology indications will be included in this study. Patients receiving rituximab as part of a clinical trial will be excluded from the study. The following data will be collected for this study: patient’s demographic information, indication for rituximab, date of rituximab administration and discharge, insurance information, adverse events, and initiation or continuation of therapy. The primary endpoint will be to evaluate the percentage of inappropriate inpatient administrations of rituximab based on pre-specified criteria. Criteria considered appropriate for inpatient administration includes: patients that are medically unstable, located in an intensive care unit, documented prior life-threatening anaphylactic reaction to rituximab who requires inpatient monitoring, patients with life-threatening autoimmune disorders, factor VIII deficiency requiring transfusions to prevent bleeding, antibody-mediated rejection in solid organ transplant recipient deemed unstable for discharge, and chronic graft versus host disease. Indications deemed inappropriate for inpatient administration will include non-approved indications or no literature that supports rituximab as appropriate therapy, or admission to hospital for irrelevant reasons. Secondary outcomes will include the incidence of
documented adverse events, number of days between rituximab administration and hospital discharge, and a cost analysis comparing inpatient and outpatient administration.

Poster Title: Evaluating the usage of intravenous magnesium at a large academic medical center

Primary Author: Muhammad Effendi, Yale New Haven Hospital, CT; Email: muhammad.effendi@ynhh.org

Additional Author(s):
Lauren Wagner
Lauren Bendel
James Nunez
Nilesh Amin

Purpose: A recent medication use evaluation of intravenous (IV) magnesium showed high rates of inappropriate usage for magnesium repletion. It was found over a six-month period that 51 percent of IV magnesium usage had no proper indication. Some of the appropriate criteria for the usage of IV magnesium includes new onset arrhythmias, seizure disorders, chronic alcoholism, and others. A new laboratory order set was implemented where magnesium was no longer coupled with calcium and phosphate; instead, providers would have to individually order magnesium levels. We seek to determine the impact this change will have in the prescribing patterns of IV magnesium.

Methods: We will collect data on the ordering of IV magnesium sixty days after the implementation of the new laboratory ordering system. The data that will be collected are the following: total serum magnesium levels ordered, total number of orders for IV magnesium, total oral magnesium supplementations ordered, and total dollars saved from implementation of the new lab ordering service. A cost analysis will be made based on a comparison of before and after implementation of the new lab ordering system. In addition, a sub group analysis will be performed looking at specific units in the hospital to assess the usage of IV magnesium on specific floors.

Poster Title: Expanding the pharmacy practice advancement initiative (PAI) through student engagement in direct patient care activities

Primary Author: Serena Chew, Yale New Haven Hospital, CT; Email: serena.chew@ynhh.org

Additional Author(s):
Chelsea Bast
Elizabeth Cohen
Amber Castle
Kimberly Boothe

Purpose: The Practice Advancement Initiative is a national program led by the American Society of Health-System Pharmacists whose goal is to positively impact the health and well being of patients by supporting innovative practice that supports the effective use of pharmacists as direct patient care providers. Engaging student pharmacists in direct patient care activities such as medication reconciliation and therapeutic drug monitoring may prevent or mitigate medication errors, and optimize pharmacists’ time expenditure. The purpose of this study is to assess and quantify the impact of student pharmacists by the amount of clinical interventions made and pharmacist time saved.

Methods: This is a multi-center observational study. All student pharmacists completing an advanced pharmacy practice experience rotation at our health system will document their interventions, projects, patient interactions, and the student time spent per activity. The pharmacist time saved per intervention type will also be documented. Student’s rotation syllabi will be standardized in which students will be responsible for a specific number of clinical interventions per week. Some of these clinical interventions include medication reconciliation, intravenous to oral conversion, patient interaction, renal dose adjustment, addition of a new drug, and therapeutic drug monitoring. Each student will have a weekly goal based on rotation structure. Both preceptors and students will be educated on the new standardized syllabus. In addition, students will be trained on proper intervention documentation and will receive weekly feedback regarding the quantity and quality of their interventions. Data including the total number of interventions made, student time spent per intervention, and pharmacist time saved will be collected from August 2015 to October 2016. The primary endpoint is the average
pharmacist time saved by students completing direct patient care activities. The secondary endpoint is the number of clinical interventions completed per student week and the amount of pharmacist time saved compared to the amount of student time spent per intervention. Descriptive statistics will be used to compare the pre and post syllabus standardization.

**Poster Title:** Leveraging medication history technicians in the pre-operative setting  

**Primary Author:** Lionel Picot-Vierra, Yale New Haven Hospital, CT; **Email:** Lionel.Picot-Vierra@YNHH.org  

**Additional Author (s):**  
Sara Cohn  
Casey Marchetti  
Kimberly Boothe  

**Purpose:** Approval of a medication reconciliation business plan at a large academic medical center has expanded pharmacy resources to include an additional ten full-time equivalent (FTE) medication history technician (MHT) positions. The aim of this project is to develop, implement and evaluate a medication reconciliation process in which MHTs obtain pre-admission medication histories for 100 percent of pre-operative surgery admission patients. The primary endpoint is the number of unintentional history and reconciliation errors identified in admission orders with potential for patient harm.  

**Methods:** From October 2016 to June 2017, MHTs will gradually be assigned the responsibility of performing all medication histories for pre-operative surgery admission patients. Pre-operative surgery admission patients will be included regardless of age, gender, race or ethnicity. Medication histories will be taken by trained MHTs via telephone, immediately following an initial pre-operative nursing phone call. MHTs will use a standardized interview technique adopted from the Multi-Center Medication Reconciliation Quality Improvement Study (MARQUIS) to obtain the best possible medication history, ensuring that all home medications are verified with two independent, agreeable sources. Discrepancies will be documented in the patient’s electronic health record (EHR) in a standardized format. A pharmacist will then review and make pertinent updates to the home medication list based on the MHTs notations. The updated list will be accessible to all members of the healthcare team throughout the patient’s admission. As part of MARQUIS and in order to assess quality of medication histories, a study pharmacist will audit medication histories obtained by nurses and MHTs and collect data in a de-identified online database. Representatives from the preadmission testing area and pharmacy services will collaborate during monthly meetings to
streamline implementation, monitor progress, and evaluate feedback from nurses, providers, and MHTs. The information and data gathered will serve to identify best practices, barriers, and lessons learned from the implementation of this medication reconciliation process.
