**Methods:** This is a retrospective cohort study that will first be reviewed by the Institutional Review Board. The study population will consist of individuals who underwent a total hip replacement or a total or partial knee replacement, who are at least 18 years old, and who have the ability to use the pain scales to measure pain. Subjects in the intervention group will have had their surgery between March 1, 2016 and September 1, 2016. The control subjects will have had their surgery between April 9, 2012 and October 9, 2012, which is before IV acetaminophen was put on the formulary. The time to first narcotic and total opioid use within 24 hours as documented in the medication administration record will be collected. The secondary objective will be achieved by looking at patient-reported pain scores documented in the electronic medical records. An Excel spreadsheet will be created with the subjects’ demographic information as well as the data for the endpoints. Both the primary and the secondary endpoints will be compared for both groups using a Student’s t-test. To measure the total opioid consumption, the mean morphine equivalent (ME) dose will be calculated for each
subject. Descriptive characteristics will be used for baseline demographic information in the form of means.

**Poster Title:** Impact of protocol for the management of acute alcohol withdrawal syndrome (AAWS) in the intensive care units of a community based health care system

**Primary Author:** Roaa Khinkar, Hallmark Health System, Inc., MA; **Email:** rmkhinkar@gmail.com

**Additional Author(s):**
Christina Kazazian
Nicole Clark

**Purpose:** Many cases of severe alcohol withdrawal syndrome are refractory to benzodiazepines. Thus, the demand for an appropriate protocol to manage such cases is on the rise. This study will evaluate a new alcohol detoxification protocol using phenobarbital as a synergistic or additive therapy to the intravenous push of benzodiazepines for patients not responding to benzodiazepine monotherapy. The objectives of this study is to increase ventilator free days, and decrease ICU length of stay, use of benzodiazepines, and mortality rate related to AAWS

**Methods:** This study is awaiting approval through the institutional review board. Physicians will utilize the new alcohol detoxification protocol when managing severe cases of alcohol detoxification resistant to benzodiazepines. Physicians will evaluate if a patient is an appropriate candidate for the new alcohol detoxification protocol using protocol parameters and available patient data. This protocol will start the patients on IV bolus lorazepam and assess their response using RASS scale. If they are still not responding, patients will then be started on IV bolus phenobarbital. Dexmedetomidine, clonidine, or propofol can be used as supportive therapy due to their anxiolytic properties, and may promote weaning patients from mechanical ventilation. The primary outcome of this study will compare the number of ventilator free days for 90 days in 2017 to pre protocol implementation of 90 days in 2016. Moreover, the secondary outcomes including ICU length of stay, use of benzodiazepine, and mortality rate will be compared in the similar manner; for 90 days in 2017 to pre protocol implementation of 90 days in 2016. This study will utilize a prospective chart review to assess the number of ventilator free days. For continuous variables, a two-sample t-test will be used. Likewise, for categorical variables, a chi-squared test will be used

Poster Title: Impact of pharmacist medication assessment and intervention on reducing falls in a community hospital health system

Primary Author: Alaa Alhubaishi, Hallmark Health System, Inc. Melrose, Massachusetts, MA; Email: ALAA.ALHUBAISHI@MCPHS.EDU

Additional Author(s):
Rose Wanjiru
Nicole Clark

Purpose: Falls in hospitalized patients has received a lot of attention in recent years. Each year between 700,000 and 1,000,000 people in the United States fall in the hospital. A fall may result in an injury that can add to overall healthcare costs. Several medications are associated with an increased fall risk. Fall prevention through medication management via pharmacists’ interventions has consistently been shown to reduce risk of falls. This project is aiming to implement an assessment tool and an intervention guide to be used by a pharmacist to manage patient medications that can contribute to falls on the medical floors.

Methods: Prospective review chart study for the period of 3 months pre and post implementation of the pharmacist assessment tool and intervention guide. The primary endpoint is reducing the number of patients that are on multiple medications that are linked to falls. The secondary endpoint is to reduce the number of falls on medical floors. For the primary end point, the data will be collected based on the number of patients on multiple medications that are potential of falls and had a fall event at the hospital. This continuous variable endpoint will be evaluated using student t-test while the categorical data for the secondary endpoint will be using chi square with level of significant of alpha = 0.05. The study will include patients who had a fall event on the medical floors during the study period. Patients in emergency department or labor & delivery unit will be excluded.

Poster Title: Development and validation of an asthma action plan assessment tool (AAPAT) for use in pediatric asthma

Primary Author: Alfred Yeung, Harbor Health Services, Inc. - Community Health Centers/Northeastern University, MA; Email: a.yeung@northeastern.edu

Additional Author(s):
Thomas Matta
Fay Goldenshteyn
Sara Zekery-Saad

Purpose: The purpose of this project is to develop a validated Asthma Action Plan Assessment Tool that evaluates the caregivers’ perception of their child’s health in relation to his or her asthma treatment and control. Asthma is one of the most common chronic conditions seen in children today, affecting about 6.3 million lives. Despite advances in care and the use of asthma action plans, asthma-related emergency room visits and hospitalizations have not decreased. One possible component contributing to the uncontrolled status of pediatric asthma is the perceived understanding of the patient and caregiver about the control and management of asthma symptoms.

Methods: The Asthma Action Plan Assessment Tool (AAPAT) was designed to target specific aspects of the Asthma Action Plan where caregivers may find difficulty in understanding the information. The AAPAT consists of questions that assess the understanding about asthma and management of symptoms, and were developed to recognize what areas require emphasis and counseling. Resources used in the development of the questions included Guidelines for Diagnosis and Management of Asthma as well as literature researching poor asthma control. The assessment tool will be distributed to recognized asthma specialists for feedback by September 1, 2016. Feedback from the identified asthma specialists will be requested by November 2016. From the feedback of these healthcare providers, we hope to obtain validation for the assessment tool and its viability for use in patient clinical care.

Poster Title: Improving access to care: Evaluation of clinical pharmacist-led comprehensive medication reconciliations in patients with mental health illnesses in a primary care setting

Primary Author: Alana Regan, Massachusetts College of Pharmacy and Health Sciences/Greater Lawrence Family Health Center, MA; Email: alanasregan@gmail.com

Additional Author(s):
Alicia Mam daCunha
Alexia Sroka

Purpose: At Greater Lawrence Family Health Center (GLFHC), a federally-qualified, primary care clinic in Massachusetts, patient access to outside psychiatrics and mental health specialists is limited. GLFHC’s Behavioral Health Initiative is currently working to improve and integrate access to mental healthcare across the organization. One aspect of this initiative is clinical pharmacist-led medication reconciliation as a mainstay of the clinic’s mental healthcare model. This purpose of this study is to (1) assess and evaluate the skills and contributions of the clinical pharmacists in the management of patients with mental illnesses and (2) to identify potential areas requiring additional training or support.

Methods: This study will be submitted to the Institutional Review Board for approval. Currently, GLFHC clinical pharmacists (CPs) work side-by-side with clinicians to provide comprehensive medication management for patients with a variety of chronic conditions, including psychiatric disorders. Patients with a mental illness receiving medication therapy who have been referred to a CP for comprehensive medication reconciliation will be included. Following the current CP referral process, patients can be referred to a CP for comprehensive medication reconciliation by any GLFHC clinician. Patients will be scheduled with a CP for an initial 60-minute visit. The CP will review patient demographics, history of present illness, psychiatric/medical history, past and current medications, allergies, and family/social history. CPs will also compile a prescription refill history to assess adherence. Patients’ drug therapy problems and any interventions performed by the CP will be noted. CPs will document summaries of their visits in the patients’ charts, which will be reviewed. All data will be recorded without patient identifiers and maintained confidentially. All CPs involved will receive additional CE/webinar training. Clinic staff and clinicians will receive refresher-education on the clinical pharmacy services offered at
the clinic and the benefits for patients, especially those with psychiatric and comorbid conditions.

**Poster Title:** Opioid prescribing: Can we write for less? A retrospective analysis of opioid prescription requests for acute pain in a multisite, ambulatory care organization.

**Primary Author:** Semie Durrani, MCPHS University/Atrius Health, MA; **Email:** semie.durrani@mcphs.edu

**Additional Author(s):**
Kathy Zaiken

**Purpose:** On March 14, 2016, the Commonwealth of Massachusetts passed a law to amend MGL 94C Section 18 which states that initial prescriptions for opioids may not exceed more than a seven day supply. Studies have shown approximately seventy percent of patients prescribed an opioid had pills left over. Furthermore, on average, the days’ supply remaining on opioids that were returned to a ‘take-back’ program was 3.3 days. The objective of this study is to determine the request rate for additional opioid prescriptions compared to the original prescribed days’ supply. This is an outcome that has not been studied.

**Methods:** The Institutional Review Board at MCPHS University has approved this study. Atrius Health patients who received an initial prescription for a short-acting oral opioid indicated for acute pain management that was a fourteen-day supply or less between May 1, 2016 and October 1, 2016 will be included in this study. A retrospective chart review will be completed by the primary investigator. Patients will be excluded if they are receiving palliative care, have a diagnosis of cancer, chronic prescription for opioids, a second separate pain episode within 30 days, if we cannot determine if the prescription is the first or second prescription, or if the prescription was prescribed for a condition other than acute pain. The primary outcome will be to determine the percentage of additional patient short-acting opioid prescription requests after an initial prescription for acute pain management was prescribed. We will also aim to determine if certain patient characteristics such as; substance/alcohol abuse, documented history of smoking and age have an effect on the request for additional opioid prescriptions.

**Poster Title:** Impact of a pharmacist-driven education and physicians’ reassessment of antibiotic usage after 48 hours at a community teaching hospital

**Primary Author:** Jeffrey Pearson, Mount Auburn Hospital, MA; **Email:** jcpearso@mah.harvard.edu

**Additional Author (s):**
Vito Iacoviello
Patricia Masters
Oussayma Moukhachen

**Purpose:** The Joint Commission recently approved standards for antimicrobial stewardship consisting of seven core elements, effective January 1, 2017. New data published in August 2016 showed that only 39.2 percent of hospitals currently implement all seven core elements. One of these elements is “action,” described as an evaluation of ongoing treatment need after a set period of time. The purpose of this study is to assess if pharmacist-led education and providing a self-assessment tool for the physician after 48 hours will have an impact on antibiotic duration and improve antibiotic usage, thereby helping optimize efforts to meet Joint Commission requirements.

**Methods:** Using a pre-post design, patients’ charts will be reviewed retrospectively and antibiotic usage will be compared before and after the implementation of a pharmacist-driven program. This program will consist of an initial education phase for prescribers, pharmacists and nurses on the practice of routinely reassessing antibiotic therapy. Then, each time a targeted broad spectrum antibiotic order has been active for over 48 hours, a standard pre-approved note will be placed in a patient’s chart and the assigned provider will be paged. Targeted antibiotics include cefepime, ertapenem, meropenem, piperacillin/tazobactam, and tigecycline. The chart note will contain a self-assessment questionnaire prompting the prescriber to re-assess the patient’s antibiotic therapy. Data collected will include baseline patient characteristics, antimicrobial regimen prescribed, indication for therapy, duration of therapy, and culture and sensitivity results. The primary outcome is the difference in the median duration of therapy for the targeted antibiotics. Secondary outcomes include differences in median length of stay, median durations of intravenous versus oral therapy, and
percentage of antibiotics de-escalated within 48 hours after intervention. At least 50 patients will be analyzed in each group. This study proposal will be submitted to the Institutional Review Board for approval and all findings will be presented to the Antimicrobial Stewardship Committee and the Pharmacy and Therapeutics Committee.

**Conclusion:** N/A
Poster Title: Effects of pharmacist-driven interventions on dosing selected anticoagulants

Primary Author: Peter Nguyen, Mount Auburn Hospital, MA; Email: phnguyen@mah.harvard.edu

Additional Author(s): Susan Krikorian

Purpose: Several anticoagulants have manufacturer guidelines for dose recommendations based on renal function, weight, indication, and age. The potential for confusion while dosing is a major concern with these drugs. Because appropriate dosing is critical in anticoagulants, and numerous cases of bleeding with incorrect dosing have been reported at our institution, a study will be performed to evaluate appropriateness of dosing for patients receiving the anticoagulants. The aim of this study is to evaluate the effects of pharmacist-driven dosing interventions for selected anticoagulants that require dosing adjustments.

Methods: This study is a prospective cohort design, with an analysis comparing the data to a retrospective review. Medications included in the study are the direct oral anticoagulants (DOACs) on formulary and enoxaparin. Evaluation of appropriate dosing will be based on drug manufacturers’ dosing guidelines. Initially, a pharmacist will conduct a two-month retrospective drug utilization review using hospitalized patients who have received at least one dose of the anticoagulants. Next, during a two-month period, the pharmacist will conduct the prospective interventional phase by evaluating all active orders for the included medications daily and consider them for dosing appropriateness. If dosing adjustments are recommended, the pharmacist will contact the prescriber to suggest a drug or dose change. Data will be collected from the electronic medical record, including hemoglobin, serum creatinine, age, gender, height, weight, length of stay, physicians’ notes regarding indication, dose, frequency, use of interacting drugs, and transfusions received. The analysis will compare the interventional phase to the historical data to evaluate the study outcomes. The primary outcome will tabulate the difference in the number of patient-days with inappropriately dosed medication therapy. The secondary outcomes will tabulate the number of prescriber-accepted interventions, the rates of major bleeding, and median length of stay. This study will be submitted to the hospital’s
institutional review board for approval, and will be presented to the hospital’s pharmacy and therapeutics committee.

Poster Title: Utilization of Concomitant Adjunctive Therapies to Opioid Regimens for the Management of Chronic Pain in an Ambulatory Care Setting

Primary Author: Themio Papadopoulos, Northeastern University/Harbor Health Services, Inc: PACE, MA; Email: th.papadopoulos@northeastern.edu

Additional Author (s):
Alfred Yeung
Jacqueline Dunning

Purpose: The 2016 Centers for Disease Control and Prevention Guidelines for Prescribing Opioids for Chronic Pain recommends that nonpharmacologic and nonopioid pain medications should be used concurrently when opioid therapy is necessary for chronic pain management. Currently, there is limited data reflecting the prevalence of adjunctive therapies used in conjunction with opioid therapies in patients with chronic pain in an ambulatory care setting. The objective of this study is to report the prevalence and patterns of nonopioid and nonpharmacologic pain management therapies used concurrently with opioids for chronic pain in an ambulatory care setting.

Methods: This observational study will be conducted at five federally qualified community health centers and one Program of All-Inclusive Care for the Elderly program. Eligible patients will be identified through electronic medical record (EMR) queries with the following criteria: eighteen years of age or older, currently on chronic opioid therapy (defined as continuous opioid therapy for at least three months), active patient status at a health center (defined as seeing a provider at least twice between May 1, 2016 to October 1, 2016), and receive their opioid prescriptions only from providers employed at one of the study sites. Once eligible patients are identified, the EMR will be reviewed for active prescriptions of nonopioid medications used for pain management. Data on nonpharmacologic treatments, as well as over-the-counter nonopioid medications that may not be documented in the EMR, will be collected via standardized surveys, phone calls and patient interviews. Finally, each patient’s total daily morphine milligram equivalents will be calculated and analyzed to identify any trends in total daily morphine milligram equivalents, based on concurrent use of nonpharmacologic and nonopioid therapies. Institutional Review Board approval will be obtained at all sites.

Poster Title: Impact of pharmacist-enhanced antimicrobial stewardship on the utilization of two unrestricted antimicrobials and the incidence of clostridium difficile infection in a community teaching hospital

Primary Author: Ahmad Mahrous, Steward St. Elizabeth's Medical Center of Boston, MA; Email: ahmad.mahrous@mcphs.edu

Additional Author(s):
Salwa Elarabi
Jorge Fleisher

Purpose: Antibiotic stewardship program (ASP) is a multidisciplinary collaboration that requires coordinated interventions to improve patient outcomes and reduce adverse events including clostridium difficile infection (CDI), our institution currently incorporates all the elements of antimicrobial stewardship, primarily restriction and preauthorization. However, recent studies have linked CDI with the utilization of certain cephalosporines and fluoroquinolones antibiotic, ceftriaxone and levofloxacin are not infectious disease restricted antimicrobials in our institution. The objective of this study is to evaluate interventions by the pharmacists on the reduction of the utilization of two unrestricted antimicrobials (levofloxacin, ceftriaxone) and the effect on the incidence of CDIs.

Methods: The study will be submitted to Institutional Review Board for approval. Data will be collected retrospectively from electronic medical records on all patients who received either levofloxacin or ceftriaxone for a period of three months. Data will include patient demographics, indications, number of doses, and duration of therapy. The study will also include a three months prospective period. A pharmacy resident will evaluate antimicrobial therapy and intervene when therapy is not aligned with treatment guidelines. Intervention will include calling physician to de-escalate (discontinue antimicrobial, streamline therapy), renal dosing, IV to PO conversion and adherence to duration of therapy. During the prospective period, data collected will be microbiology lab results, percentage of antibiotic prescriptions not complaint with guidelines, and pharmacist interventions. Outcome measures will be lengths of hospital stay, 30-day readmission rate, and the incidence of hospital acquired CDI. Results will be compared and presented to the Pharmacy and Therapeutics Committee.

Poster Title: Evaluation of the use of unfractionated heparin versus bivalirudin for adjunctive antithrombotic therapy in patients undergoing percutaneous coronary intervention

Primary Author: Diala Nicolas, Steward St. Elizabeth’s Medical Center of Boston, MA; Email: diala.nicolas@steward.org

Additional Author (s):
Mirembe Reed

Purpose: Patients undergoing percutaneous coronary intervention (PCI) require adjunctive anticoagulant therapy during the procedure. The anticoagulants recommended for use during PCI in the 2011 ACCF/AHA/SCAI guideline include unfractionated heparin (UFH), bivalirudin, enoxaparin or fondaparinux. Of these drugs, UFH and bivalirudin are the two most commonly used at our institution. The objective of this study is to examine the prescribing patterns and use of anticoagulants in patients undergoing PCI and to identify criteria that would help guide anticoagulant use in order to optimize efficacy, safety and resource utilization.

Methods: This study will be submitted to the Institutional Review Board for approval. The hospital’s electronic medical record will be used to identify patients who underwent PCI over a three-month period. The use of UFH and bivalirudin will be retrospectively evaluated and prescribing patterns will be analyzed. Data collected will include demographics, anticoagulant used, drug dosing, laboratory parameters and length of hospital stay. The clinical outcomes that will be evaluated will include the incidence of ischemic events, revascularization, mortality and bleeding. Data will be analyzed to compare clinical outcomes associated with each drug, with the intention to distinguish patients that may benefit from using one drug over the other. The results of this study will be presented to the Pharmacy and Therapeutics committee.

**Poster Title:** Acid suppression for stress ulcer prophylaxis: impact of a pharmacy monitor  

**Primary Author:** Awatif Hafiz, Steward St. Elizabeth's Medical Center of Boston, Inc., MA; **Email:** awatifhafiz@yahoo.com  

**Additional Author (s):**  
Claire McManus  

**Purpose:** Risk factors such as mechanical ventilation and coagulopathy have been associated with stress ulceration. Current stress ulcer prophylaxis (SUP) guidelines are outdated and are due to be updated imminently. Acid-suppression for SUP is recommended and proton pump inhibitors (PPI) are widely prescribed. Meanwhile, there are controversies such as incidence of stress ulcers, choice of agent and PPI-related adverse events. Thus, the objective of this project is to evaluate prescribing patterns of SUP agents at our institution and to identify the impact of a pharmacy monitor on their use.  

**Methods:** The study will be submitted to Institutional Review Board for approval. There will be a retrospective phase followed by a prospective phase, each with a duration of 8 weeks. During the retrospective phase, from the 1st August to 30th September, the following data shall be collected using electronic medical records for inpatients treated for SUP: patient demographics, indication, medication, route, class, dose and duration. Pharmacological agents to be targeted will include proton pump inhibitors and histamine receptor blockers. Next, in the prospective phase the pharmacy resident will print a daily report of SUP agents hospital-wide. This phase will be conducted from 1st November to 31st December. Recommendations will be made if needed based on indication, duration etc. according to available literature guidelines. The same data will be collected in the prospective phase and compared to that of the retrospective phase. Primary outcomes will be based on the net effect of the pharmacist’s interventions: 1) appropriate indication for SUP; and 2) timely discontinuation of prophylactic agent. Secondary outcomes will include conversion from intravenous to oral route and accurate dosing regimen. The results will be presented to the Pharmacy and Therapeutics Committee.

**Poster Title:** Assessment of the impact of quality improvement interventions on the prescribing patterns of venous thromboembolism prophylaxis at one large, tertiary care, academic medical center

**Primary Author:** Brian Carlone, UMass Memorial Medical Center, MA; **Email:** brian.carlone@umassmemorial.org

**Additional Author (s):**
Patrick O’Day
Katelyn Springer
Kathleen Sargent
Diana Houng

**Purpose:** Venous thromboembolism (VTE) affects over 350,000 patients annually, contributing to increased morbidity, mortality, and hospital days. National accreditation organizations are incentivizing institutions to develop best practices to ensure patients are receiving appropriate VTE prophylaxis while hospitalized. Prior literature conveys that active interventions (e.g. direct education, development of standardized order sets) may improve rates of appropriate VTE prophylaxis. The objective of this study is to assess the current prescribing patterns for VTE prophylaxis at our institution and evaluate the impact of active quality improvement interventions on prescribing practices.

**Methods:** This is a retrospective chart review of adult patients admitted to medical and surgical services at our institution from November 2016 to January 2017. Patients with a primary diagnosis of VTE will be excluded. Initial evaluation of prescribing patterns will be utilized to identify challenges with prescribing VTE prophylaxis. Active monitoring and education will be provided by pharmacy staff to overcome these challenges for a predetermined period of time. Following the intervention period, VTE prescribing will be further evaluated. The primary endpoint is the change in rate of appropriate VTE prophylaxis prescribed for at-risk patients (as defined by the American College of Chest Physicians guidelines) after implementation of active intervention(s). Secondary endpoints include the assessment of appropriate dosing of VTE prophylaxis and barriers to best practices in an academic medical center without computerized order entry capabilities.
**Results:** Research in progress.

Poster Title: Assessment of patient engagement and satisfaction in community pharmacy to increase pneumococcal vaccination rates in high risk patients

Primary Author: Malerie Dooling, Walgreens and MCPHS University- Boston, MA; Email: mrdooling@gmail.com

Additional Author (s):
Matthew Machado
Amee Mistry
Enrique Seoane-Vazquez

Purpose: Studies have evaluated efficacy of pharmacist-driven education on pneumococcal vaccination rates in the hospital. However, in the community, studies have only looked at increasing pneumococcal vaccination rates in those ≥ 65 years. This research project will provide pharmacist intervention to high risk patients and those ≥ 65 years. We will incorporate the use of the Massachusetts Immunization Information System (MIIS) in workflow. MIIS is an important tool as it provides complete, accurate, real-time immunization history for residents of Massachusetts. This research project will increase utilization of MIIS to improve pharmacists’ understanding of patients’ vaccination history and prevent unnecessary vaccinations.

Methods: Patient Recruitment: During data review and at the time of flu shot administration, pharmacists will review patient profiles to assess if the patient is a candidate for pneumococcal vaccination. If deemed eligible for pneumococcal vaccination, the pharmacist will place a consultation on the prescription to educate patients on pneumococcal vaccination requirements upon pick-up.
Pharmacist Intervention: First inform the patient and obtain patient consent. Then provide patient questionnaire and education on current ACIP recommendations. Immunization history will be obtained via immunization registry to confirm patients’ pneumococcal vaccination history. If patient is not an accurate historian at time of intervention and records are not available on the immunization registry, vaccination record will be obtained from PCP. The questionnaire and educational documents will be reviewed with the patient to provide further education. Patients will then be offered the opportunity to receive the vaccination in the community pharmacy. For patients who agree to vaccination during pharmacist intervention,
provide same day pneumococcal vaccination if possible. If patients decline the vaccination at time of intervention, the pharmacist will assess barriers to receiving vaccine and obtain consent to provide follow-up call to patient.

Technician Engagement: Technicians will be required to complete an ACPE accredited immunization CE. Learning objectives and exam questions will be reviewed with a pharmacist. Technicians will take a pre/post-survey to assess effectiveness of technician teaching/engagement.

Poster Title: Implementing a collaborative partnership model to assist in the transitions of care for patients receiving oral chemotherapy

Primary Author: Patryk Kornecki, Walgreens and Northeastern University School of Pharmacy PGY-1 Community Residency, MA; Email: patkornecki@gmail.com

Additional Author (s):
Andrew Skirvin
Roy Youn
Karen Poliskey

Purpose: Oral chemotherapy patients often take medications with increased toxicities and complex dosing, requiring significant education and patient support. These complicated medications are often specialty pharmacy restricted and require comprehensive education. An innovative outpatient oral oncology program will provide specialized pharmacy services utilizing multiple platforms and tools to assist the oral oncology patient in their transitions of care through a collaborative partnership between a local health system in Boston and a local specialty pharmacy of a large chain pharmacy.

Methods: Patients receiving select oral chemotherapy will be referred by their health-system oncology team to participate in program services provided by the local community pharmacy. Upon establishing a patient relationship and obtaining patient consent, pharmacy financial experts will conduct a benefits review to proactively identify required pre-authorizations and financial assistance needs. Pharmacist prospective drug utilization reviews will compare the chemotherapy order to the patient’s medication profile within and outside of the local specialty pharmacy network. An appointment will be made with the patient and their caregiver to provide for: Comprehensive medication teaching, adherence counseling, and tools to assist with medication and disease management. Follow-up appointments will be created during the patient’s cycle at 5 to 7 days post oral chemotherapy initiation, and monthly thereafter for monitoring of adherence and adverse related events. Documentation of communications will be made and sent to the provider for input in the patient’s Online Medical Record. Patients will be evaluated through adherence with indirect measures and standardized toxicity assessment tools. Patient satisfaction will be measured through the administration of surveys for
continuous quality improvement measures. Outcomes will be assessed through descriptive methods and correlative statistics will be used to evaluate patient satisfaction and assessments. The research question will be submitted to the Institutional Review Board for approval.

Susan Szpunar

Purpose: To evaluate the utilization of daptomycin in MRSA bacteremic patients who have failed vancomycin treatments at a community teaching institution.

Methods: This single center, retrospective observational study of adult patients receiving daptomycin secondary to persistent MRSA bacteremia was approved by the Institutional Review Board. Failure of vancomycin treatment will be defined as persistently positive blood culture(s) despite receiving more than 72 hours of vancomycin or vancomycin MIC of 2 mcg/ml or greater. A list of patients who received daptomycin from January 2009 to September 2016 will be reviewed. Patients with bacteremia from presumed pneumonia or MRSA bacteremia within 30 days of admission will be excluded. Daptomycin dose will be evaluated for appropriateness based upon patient weight and renal function. Duration of bacteremia will be evaluated, including whether source control was achieved. Creatinine phosphokinase (CPK) levels drawn during daptomycin therapy will be assessed to evaluate safety. Hospital length of stay and patient disposition will be collected for each patient. Data will be presented with descriptive statistics.

Poster Title: Evaluation of the dosing appropriateness of erythropoietin stimulating agents (ESAs)

Primary Author: Chantale Daifi, Beaumont Health System - Troy, MI; Email: chantale.daifi@beaumont.org

Additional Author(s):

Purpose: Erythropoietin stimulating agents stimulate the bone marrow to produce red blood cells. Inappropriate dosing of ESAs can lead to adverse events such as myocardial infarction, stroke, thromboembolism, and death. One of the FDA approved indications of ESAs is anemia of chronic kidney disease (CKD). The formulary ESA at Beaumont Health System is darbepoetin. The purpose of this study is to evaluate the appropriateness of darbepoetin dosing in CKD patients within the health system.

Methods: An institutional review board (IRB) approved retrospective chart review was conducted of patients prescribed darbepoetin for the indication of anemia in CKD. Patients were included if they were 18 years or older and admitted to Beaumont Health between July 1st, 2014 and June 30th, 2016. Patients with active chemotherapy orders, pregnant patients, and patients taking zidovudine for human immunodeficiency virus (HIV) were excluded. The primary endpoint is to evaluate the appropriateness of initial weight-based ESA dosing in CKD patients with anemia. Data collected included patient characteristics, darbepoetin dosing, date and time of administration and discontinuation, number of doses administered and corresponding lab values including hemoglobin, ferritin, transferrin saturation, and blood pressure values. Data was collected at baseline and up to 24 hours after each administration of darbepoetin. Appropriate statistical methods were used for data analysis.

**Purpose:** Increasing concern surrounding the opioid abuse epidemic has led the Centers for Disease Control and Prevention (CDC) to release recommendations for safe opioid prescribing. These guidelines recommend that clinicians utilize urine drug tests (UDTs) before starting opioid therapy and at least annually thereafter to assess for prescribed medications or illicit substances. However, UDT’s can be difficult to interpret and subject to misinterpretation as other medications taken by patients may cause false positive results. The purpose of this study is to assess the impact of a pharmacist educational intervention on medical resident’s knowledge and comfort in UDT interpretation in clinical practice.

**Methods:** This prospective educational intervention study will utilize survey responses to assess the impact of an educational intervention on medical resident knowledge and comfort level with UDTs. All internal medicine (IM) and internal medicine/pediatric residents currently training at our facility will be eligible for inclusion. Residents will be offered a survey consisting of 15 multiple choice questions assessing their knowledge and comfort with interpreting UDTs before, immediately following, and two months after attending an educational lecture given by a pharmacist. The 20 minute lecture will be given monthly for four consecutive months to allow all medical residents to be included. Topics covered will include: types of UDTs, initial and confirmatory testing, sample adulteration, dilution and substitution, and potential causes of false positives in UDTs screening for controlled substances. The primary outcome will assess the impact of pharmacist UDT education on the medical resident’s correct interpretation of UDTs and comfort in UDT interpretation. Secondary outcomes include: composite impact of pharmacist education on medical resident knowledge and comfort in UDT interpretation, level
of knowledge retention post pharmacist education, and differences in comfort and knowledge of UDTs by residency year. Descriptive statistics will be utilized to analyze data. Exploratory analysis will be conducted to determine any associations within collected data.

Poster Title: Evaluation of the use of four-factor human prothrombin complex concentrate in the reversal of acute major bleeding

Primary Author: Stephanie Everard, Beaumont Hospital – Dearborn, MI; Email: stephanie.everard@beaumont.org

Additional Author(s):
Jessica Jones
Neha Desai

Purpose: Acute major bleeding is a life threatening event. Safe and effective treatment is crucial to survival and quality of life post bleed. Four-factor human prothrombin complex concentrate (PCC) or Kcentra is the only available four-factor PCC and is approved for urgent reversal of warfarin. Our institution currently uses four-factor PCC for the reversal of warfarin and all direct oral acting anticoagulants (DOAC) except for dabigatran, which now has its own specific reversal agent. The goal of this study is to evaluate the safety and efficacy of four-factor PCC in both warfarin and DOAC reversal.

Methods: This medication use evaluation is in the process of being submitted to the Institutional Review Board for approval. This study will be conducted as a retrospective chart review. Patients will be included if they had been administered four-factor PCC since January 1st, 2015 for the reversal of either warfarin or a DOAC and were 18 to 89 years of age at the time of administration. Chart review will be conducted using the electronic medical record and patients will be identified using medical record number. Data collection variables will be stored in a de-identified excel spreadsheet. Indication for use, location of administration within the hospital, and four-factor PCC dose given will be recorded and evaluated. Kcentra does contain heparin; therefore proper patient selection is crucial. Inappropriate patient selection can lead to adverse drug effects, so existence of contraindications and precautions will be evaluated. Monitoring of four-factor PCC will be assessed by incidence of adverse effects, which will include presence of any thrombotic events and hypersensitivity reactions. Monitoring will also include time to first international normalized ratio (INR) post-treatment with four-factor PCC. Safety and efficacy will be evaluated by achievement of hemostasis (measured by vital signs
and hemoglobin), time to an INR less than or equal to 1.3, and survival at discharge. Potential benefits include improving the current policy in place for internal improvement.

Poster Title: Characterization of Major and Clinically Relevant Bleeds Following Alteplase Administration for Pulmonary Embolism (PE)

Primary Author: Nouran Salem, Beaumont Hospital - Royal Oak, MI; Email: nouran.salem@beaumont.org

Additional Author(s):
Mona Ali
Jenna Holzhausen

Purpose: Systemic and catheter-directed thrombolytic therapy with alteplase facilitates resolution of acute pulmonary embolism (PE) and associated complications. Alteplase use has increased at our health system for treatment of submassive PE due to evolving data to support its use. Limited data exists regarding specific patient characteristics associated with increased bleed risk following alteplase administration. The objective of this study is to evaluate patients who bled after receipt of alteplase for acute PE in order to characterize the types of bleeding events and management strategies, identify patient characteristics that increase bleed risks, and report patient outcomes.

Methods: This is a retrospective chart review of patients who bled after receiving alteplase for acute PE treatment. Patients treated with alteplase between November 1, 2012 and July 31, 2016 at three institutions within one Health System will be considered for inclusion. Patients will be identified using electronic prescription (ERx) codes for alteplase. A retrospective chart review will be performed to confirm patients received alteplase for PE and experienced major or clinically relevant bleeding. The International Society on Thrombosis and Haemostasis (ISTH) major bleed criteria will be used (i.e. clinically overt bleeding plus >2 g/dL hemoglobin drop, clinically overt bleeding requiring > 2 units of packed red blood cells, critical site involvement, or fatal bleed). Patients will be excluded if oral anticoagulation administration preceded the bleed event. Those who meet criteria will undergo a retrospective chart review by utilizing a systematic data collection tool. Data collection will include patient demographics, co-morbidities, baseline laboratory parameters, vital signs, PE severity, alteplase regimen, concurrent and subsequent anticoagulant administration, diagnostic tests for bleed diagnosis, bleed severity, time to bleed from alteplase administration, and bleed management strategies.
Outcomes will include bleed location/type, hospital and ICU lengths of stay, recurrent thromboembolic events, re-admissions within 30 days (stratified for thromboembolic events and bleeds), in-hospital and 30-day mortality, and patient disposition upon discharge. Descriptive statistics will be used to analyze and report the data.

**Results:** Results will be presented at the conference.

**Conclusion:** Conclusion will be presented at the conference.

Poster Title: Utilization of data analytics for investigating controlled substance diversion to support a Code N team at a large academic medical center

Primary Author: Hoan Hoang, Beaumont Hospital - Royal Oak, MI; Email: hikaru.hoang@gmail.com

Additional Author (s):
Stephanie Rybak
Kathy Pawlicki

Purpose: The opioid epidemic continues to significantly burden the public health landscape. Controlled substance diversion by healthcare workers contributes to this epidemic as a source for personal use and illegal sales to the public. Patient safety may also be compromised under an addicted worker’s care. Health-system pharmacies should develop standardized practices for reviewing controlled substance documentation. A proactive approach utilizing data analytics to detect potential diversion ensures compliance with regulatory requirements and minimizes impact to patients and caregivers. The goal of this project is to standardize the pharmacy-driven investigation and reporting of diversion as part of the multidisciplinary Code N team.

Methods: The project will be submitted to the Institutional Review Board for approval. Current process of pharmacy-driven investigation of controlled substance diversion will be evaluated by direct observation. Data such as average number of in-depth investigations per month and the time required to carry out the investigation will be collected using surveillance software integrated with the automatic dispensing cabinets. Standardization of the current process will occur after the initial evaluation. Finally, a method for utilizing pharmacy-driven reporting will be developed to support a multidisciplinary Code N team.

Poster Title: Effect of induction immunosuppression selection on three year opportunistic infections and safety outcomes in adult renal transplant recipients

Primary Author: Kirsten Wallskog, Beaumont Hospital - Royal Oak, MI; Email: kirsten.wallskog@beaumont.org

Additional Author(s):
Maxine Ng
Megan Cadiz
Ekamol Tantisattamo

Purpose: The fundamental purpose of this study is to assess the effect of induction immunosuppression selection on the risk of opportunistic infections and safety outcomes in renal transplant recipients within three years of transplant. Studies completed at other transplant centers have limited applicability to our institution due to institution-specific protocols. An investigation to examine the differences in outcomes between these induction agents has not been completed at our institution.

Methods: This study will be submitted to the Institutional Review Board for approval. A list of all patients who received a renal transplant at our institution between January 2011 and December 2013 will be obtained from the transplant clinic. Patients who received induction immunosuppression with basiliximab, alemtuzumab, or rabbit anti-thymocyte globulin will be included. Patients who were younger than 18 years of age at the time of transplant, received simultaneous liver-kidney transplant, or required pre-transplant desensitization will be excluded. Electronic medical records will be reviewed to assess eligibility criteria and to collect data. A systematic data collection form will be used to collect recipient demographics, available donor demographics, immunologic risk factors, induction immunosuppressant received, opportunistic infection prophylaxis and treatment, renal function, biopsy results, and treatment of rejection. The primary endpoint is the incidence of opportunistic infection(s) during the identified study period. Secondary endpoints include incidence of graft survival, patient survival, and re-hospitalization due to all causes and due to stratified causes (acute kidney injury, chronic kidney disease, infectious disease, gastrointestinal complications, and surgical-related complications). Continuous data will be analyzed using a Student’s t-test. Regression
analyses will be performed to assess the impact of treatments on outcomes, controlling for patient characteristics.

Poster Title: Vancomycin for the treatment of coagulase-negative staphylococcus bacteremia: Does MIC matter?

Primary Author: Shaina Kalasho, Beaumont Hospital - Royal Oak, MI; Email: shaina.kalasho@beaumont.org

Additional Author(s):
Christine Yost
Prakash Shah

Purpose: Staphylococcus aureus and coagulase-negative staphylococcus (CoNS) have different vancomycin MIC susceptibility breakpoints of 2mcg/mL and 4mcg/mL, respectively, as defined by the Clinical and Laboratory Standards Institute (CLSI). An increased risk of treatment failure with vancomycin has been reported in S. aureus infections with higher MICs. This research is mostly limited to Staphylococcus aureus infections, but some physicians will extrapolate this data to CoNS infections. It is unknown, however, if CoNS species with higher vancomycin MICs impact treatment success. The objective of this study is to determine if the vancomycin MIC affects outcomes in patients with CoNS bacteremia.

Methods: This study will be submitted to the Institutional Review Board for approval. This is a multi-center retrospective chart review of patients with coagulase-negative staphylococcus (CoNS) bacteremia admitted between January 2013 and September 2016. Patients will be identified by using vancomycin administration data and microbiology reports for positive cultures with CoNS. Eligible patients must be at least 18 years of age with a clinical diagnosis of CoNS bacteremia and have received at least five days of inpatient treatment with IV vancomycin. Patients will be excluded if their absolute neutrophil count is less than 500 cells/µL and there is no documented trough within 5 days of vancomycin initiation. The following information will be collected: patient baseline characteristics, microbiology results, and details of vancomycin therapy. The primary clinical endpoint is to compare treatment failure rates in patients with CoNS bacteremia treated with vancomycin with an MIC less than 2mcg/mL versus greater than or equal to 2mcg/mL. The secondary outcome will be to determine the incidence of nephrotoxicity in patients treated with vancomycin with an initial trough less than 15mcg/mL compared to patients with a trough greater than or equal to 15mcg/mL. Various statistical
methods will be used, including descriptive statistics for continuous variables, Students t-test for comparative statistics, and Chi-squared or Fishers exact tests for nominal data. A p-value less than 0.05 will be considered statistically significant.

Poster Title: Major bleeding with apixaban in atrial fibrillation: patient characteristics, bleed management, and outcomes

Primary Author: Sarah Eisho, Beaumont Hospital - Royal Oak, MI; Email: sarah.eisho2@beaumont.org

Additional Author (s):
Nouran Salem
Janet Hoffman
John Koerber
Maureen Smythe

Purpose: Apixaban is one of the most recently approved oral anticoagulants for prevention of stroke and systemic embolism in patients with non-valvular atrial fibrillation. Clinical data shows that apixaban has similar efficacy and lower risk of overall major bleeding when compared to the more traditional oral anticoagulant, warfarin. The objective of this study is to assess patient characteristics, bleed management, and outcomes in patients with non-valvular atrial fibrillation who develop a major bleed while taking apixaban. The study will also identify opportunities to improve the safe use of apixaban.

Methods: The institutional review board approved this study. This is a retrospective cohort analysis of patients taking apixaban for stroke prevention in non-valvular atrial fibrillation who develop a major bleed within the timeframe of January 1, 2013 to May 31, 2016. An electronic medical record search is performed to identify patients with an apixaban prescription. From this list, patients are identified as having a hemorrhage, atrial fibrillation, and transfusion through International Classification of Diseases (ICD) codes. Patients with an ICD code for intracranial hemorrhage do not require an ICD code for transfusion. An internal adverse event reporting system is also used for patient identification. The identified patients are further evaluated for determination of major bleed (based on International Society on Thrombosis and Haemostasis criteria) and a temporal relationship to apixaban use. Patients that meet all of the above criteria will undergo a comprehensive chart review, consisting of the following data collection: patient baseline characteristics, pertinent laboratory values, apixaban and additional medication use, bleeding and stroke risk assessments, bleed management, and bleed outcomes. Bleed
outcomes include post-bleed intensive care unit and hospital length of stay, transition to hospice/comfort care/palliative care, in-hospital mortality, 30-day mortality, occurrence of thrombotic event, hospital readmission within 30 days, transition to new anticoagulation agent, and anticoagulation status at discharge and at 30 days post-discharge. Descriptive statistics will be used to present findings.

**Poster Title:** Evaluation of the safety of patients receiving triple therapy with dual antiplatelet therapy and oral anticoagulation

**Primary Author:** Elizabeth Crish, Beaumont Hospital - Royal Oak, MI; **Email:** elizabeth.crish@beaumont.org

**Additional Author (s):**
Jenna Holzhausen
Mona Ali

**Purpose:** Triple antithrombotic therapy consisting of dual antiplatelet therapy and anticoagulation is commonly prescribed in clinical practice. However, it has been shown to increase the rate of bleeding events compared to one or two antithrombotic agents alone. There is a lack of data comparing the bleeding rate of triple antithrombotic therapy with warfarin versus triple therapy with a direct oral anticoagulant (DOAC). The primary objective of this study is to evaluate the risk of major bleeding events in patients receiving triple therapy with warfarin compared to triple therapy with a DOAC.

**Methods:** This is a multicenter, retrospective study. Following Institutional Review Board approval, electronic medical records will be used to identify patients who received triple therapy while in the hospital and who were discharged on triple therapy from January 1, 2013 to December 31, 2015. Patients aged 18 to 89 years old will be included. Patients will be excluded from the trial if they were on triple therapy prior to admission, had an indication for short-term anticoagulation (less than or equal to 45 days), or were pregnant on admission. The data collected will include: demographic information, indication for anticoagulation, indication for dual antiplatelet therapy, bleeding events, thrombotic events, recurrent hospitalizations, past medical history and comorbidities, anticoagulation and antiplatelet medication regimens, concomitant medications, lab values, bleeding and thrombosis risk scores, and mortality rates. The data will be analyzed using descriptive statistics and additional statistical tests, including, but not limited to, the Wilcoxon rank-sum test and t-test. The primary outcome will be the rate of major bleeding events in patients receiving triple therapy with warfarin compared to triple therapy with a direct oral anticoagulant. The secondary outcomes will include the time to bleed and the risk factors of bleeding events.

**Poster Title:** Compliance to United States Pharmacopeia (USP) 800: A gap-analysis  
**Primary Author:** Jaimini Patel, Beaumont Hospital - Royal Oak, MI; **Email:** jaimini.patel@beaumont.org  
**Additional Author(s):**  
Davinderpreet Dulai  
Priti Patel  

**Purpose:** The United States Pharmacopeia (USP) recently published new standards for compounding hazardous drugs, which go into effect July 2018. Compliance to USP standards for compounding hazardous drugs is imperative for patient safety, employee health safety, and environmental protection. Michigan law (Public Act 280 of 2014) requires hospitals that compound sterile pharmaceuticals to be accredited by a national accrediting organization, approved by the Michigan Board of Pharmacy, prior to June 2017. The objective of this study is to evaluate current compliance to USP 800 at a large academic hospital, and to develop and implement an action plan for areas of non-compliance.

**Methods:** This study will be submitted to the Institutional Review Board for approval. In order to identify compliance to the current USP 800 standards, a gap analysis will be performed. A gap analysis tool will be used to cross examine the current status at our hospital as it pertains to each standard. Compliance will be measured by evaluating policies, assessing equipment, and observing staff as it applies to the standard. Each standard consists of varying number of requirements to meet compliance. To measure compliance for the following areas: environmental quality and control, personal protective equipment, receiving hazardous drugs, and compounding standards; 200 unannounced direct staff observations will be performed over a 2 month period. A competency checklist with the requirements to meet each standard will be utilized to assess staff. Pharmacy staff scheduled to work within the cleanroom who are performing the activity scheduled for assessment will be included. Percent compliance will be calculated using the number of noncompliant observations over the number of total observations for each requirement. Noncompliance is defined as less than 100% compliance on any requirement. A plan will be developed to remediate all areas of noncompliance. Example
interventions may include writing required policies and procedures, educating and training pharmacy staff, performing staff competencies, and obtaining equipment.

**Poster Title:** Evaluation of a pharmacist-led Patient Controlled Analgesia (PCA) dosing service

**Primary Author:** Katie Stollar, Beaumont Hospital - Royal Oak, MI; Email: katie.stollar@beaumont.org

**Additional Author(s):**
Levi Hall
Allycia Natavio
Alen Dezia

**Purpose:** A pharmacist-led Patient Controlled Analgesia (PCA) dosing service was developed and implemented in January 2015 at a 1,070-bed, private, non-profit, tertiary academic hospital. Evaluation of the service is to be conducted to determine efficacy of the program, to identify areas for service improvement, and to explore the opportunity to expand the service to a larger number of physician groups. The objective of this study is to compare physician versus pharmacist-led PCA dosing in an effort to assess clinical efficacy and safety of PCA use.

**Methods:** All pharmacist-dosed PCA consults to date will be retrospectively reviewed. Each pharmacist consult will be examined and patients will be classified as a surgical or medical case. These cases will then be matched to patients receiving physician-dosed PCAs based on medical or surgical classification. A chart review will be conducted to review clinical efficacy and safety endpoints. The following information will be collected from the electronic medical record: baseline demographics, indication for PCA, opioid chosen for PCA, risk factors for respiratory depression, pain scores, Richmond Agitation-Sedation Scale (RASS), length of stay, length of PCA therapy, utilization of medications to prevent and treat opioid-induced adverse effects, and adjustments made to PCA regimen. The primary endpoint will be time until sustained pain control defined as pain score less than 5 for two consecutive assessments. Secondary endpoints include time to first pain score less than 5 without a pain score greater than or equal to 7 in the following 24 hours, time to pain score less than 5, number of PCA adjustments, time to oral conversion, and assessment of adjunct medications ordered. Safety endpoints include naloxone administration, cardiopulmonary resuscitation/rapid response team calls, RASS scores less than negative 2, and death. Data collected from this study will be further evaluated to determine
effectiveness of the current service and the feasibility to extend the service to additional physician groups.

Poster Title: Dose appropriateness of renally cleared medications in patients with impaired renal function

Primary Author: Craig Sauer, Beaumont Hospital, Dearborn, MI; Email: crsauer@gmail.com

Additional Author(s):
David Wilpula

Purpose: Prescribing errors have been shown to affect 7 percent of medication orders and 50 percent of hospital admissions with incorrect dose being the most common error. Medications that are renally eliminated often require dose adjustments to maintain efficacy and avoid toxicity. Patients with chronically impaired and/or acutely changing renal function are at a higher risk for dosing errors. We aim to identify the most commonly prescribed renally eliminated medications and to quantify the extent of over and under dosage in this vulnerable population.

Methods: This quality improvement project has been submitted to the Institutional Review Board for approval. The electronic medical record system will be used to identify patients admitted to the hospital between January and December 2015 with chronic kidney disease stages 3, 4, or 5, end stage renal disease, or acute kidney injury using ICD-10 codes. Data on patient demographics (i.e., age, height, weight), comorbidities, renal function, medications and respective doses administered, and hospital location will be collected. The dosing of medications with significant renal elimination will be assessed for appropriateness based on a patient’s estimated creatinine clearance and the regimen recommended by either: hospital protocol, drug manufacturer, or literature recommendations. Creatinine clearance will be estimated using the Cockcroft-Gault equation, consistent with hospital policy. The primary outcome of this study is to determine the appropriateness of medication doses. The information obtained from this medication use evaluation will be used to assess the need for analysis of related adverse events and the implementation of protocol changes and technology enhancements.

Poster Title: Demographic and socioeconomic factors associated with nonadherence to chronic medications in a Marketplace population

Primary Author: Jacob Chaffee, Blue Cross Blue Shield of Michigan, MI; Email: jchaffee@bcbsm.com

Additional Author(s):
Laurie Weselowicz
Ed Rothman
Alexandra Tungol Lin

Purpose: The Pharmacy Quality Alliance (PQA) developed a measure specific to medication adherence that is included in the Quality Rating System (QRS) for Marketplace plans. As an insurer offering Qualified Health Plans (QHPs) on the Marketplace, Blue Cross Blue Shield of Michigan (BCBSM) is dedicated to developing targeted clinical programs and interventions aimed at improving adherence and health outcomes. The primary objective of our research is to identify demographic and socioeconomic factors associated with nonadherence, measured by Proportion of Days Covered (PDC), to chronic medications in the Marketplace population.

Methods: This study is a retrospective cohort of BCBSM patients enrolled in a Marketplace QHP during 2015. Endorsed by the PQA as a measure of medication adherence, PDC will be used to quantify medication adherence rates of eligible patients. Patients are eligible for the PDC measure if they had an index prescription start date (IPSD) of an eligible therapeutic category between January 1, 2015 and September 30, 2015. As specified by PQA’s measures specifications, eligible therapeutic categories include: renin-angiotensin system antagonists (RASAs), statins or non-insulin diabetes. Medication adherence rates are calculated using BCBSM pharmacy claims. Data for explanatory variables including zip code, age, sex, index claim, cost share, and plan type will be extracted from BCBSM pharmacy claims data. Income and ethnicity data are provided by Acxiom, a proprietary marketing tool containing census data not available in claims data. Individuals with PDC less than 80 percent are classified as nonadherent to the therapeutic category. Differences in demographic and socioeconomic factors between adherent and nonadherent groups are assessed using a chi-square test for
categorical variables and t-tests for continuous variables. Associations between demographic and socioeconomic factors with nonadherence are evaluated using a linear model-based regression analysis.

Poster Title: Adjunctive naloxegol for the treatment of post-operative induced constipation in spinal surgery patients: A pilot study

Primary Author: Taylor Highland, Bronson Battle Creek Hospital, MI; Email: highlant@bronsonhg.org

Additional Author (s):
James Curtis
Amanda Ackerman
Shaun Phillips

Purpose: Constipation is common after spinal fusion surgery and can be exacerbated by duration of surgery, amount of narcotics administered postoperatively, and intraoperative blood loss. Average length-of-stay for a lumbar laminectomy involving on average 3 levels is 3.5 days and average hospital billing for the related hospital stay is $14,766. The objective of this study is to evaluate the effectiveness of adding naloxegol, a peripherally-acting mu-opioid receptor antagonist, to a standard post-operative protocol that included a stool softener, osmotic agent, and a stimulant agent for patients receiving spinal surgery at a medium-sized, community teaching hospital in northwest Michigan.

Methods: This study is a retrospective chart review of patients who received spinal surgery from January 2014 through December 2016. Patients were included if they were between the ages of 18-84 years old, had a laminectomy, discectomy, and/or fusions, and received an opioid morphine equivalent daily dose of between 30 mg and 1000 mg per day prior to surgery. Patients were not included if they had pain associated with cancer, documented to be end-of-life, had pre-existing diarrhea or constipation, had evidence of gastrointestinal obstruction or increased risk of bowel perforation, or if they were already taking a peripherally-acting mu-opioid receptor antagonist prior to admission. The primary efficacy outcome is mean time to first bowel movement after spinal surgery. Secondary efficacy outcomes include incidence of postoperative constipation, mean hospital length-of-stay, and total hospital cost. Safety outcomes include prevalence of post-operative adverse effects including abdominal pain, diarrhea, nausea/vomiting, incidence of ileus, and premature discontinuation of naloxegol or other peripherally-acting mu-opioid receptor antagonist.
**Results:** Data from 59 patients was collected with 26 in the study group and 33 in the control group. Amount of daily opioid use (converted to oral morphine equivalence) was 66.7 mg (mean +/- S.D. 16.7) in the study group and 74.4 mg (mean +/- S.D. 27.1) in the control group (p = 0.2093). Days until the first post-operative bowel movement significantly decreased in the study group with 2.83 days (mean +/- S.D. 1.3) compared to 4.36 days (mean +/- S.D. 2.3) in the control group. Hospital length-of-stay significantly improved in the study group with 4.6 days (mean +/- S.D. 1.7) compared to 10.3 days in the control group (p < 0.001). Adding naloxegol to our standard post-operative bowel regimen protocol saved the hospital $19,731 when comparing average variable cost ($14,944 in the study group, $34,675 in the control group).

**Conclusion:** Adding naloxegol to a standard post-operative bowel regimen protocol for spinal surgery patients appears to decrease time to first post-operative bowel movement, decrease length of stay, decrease hospital costs, whilst not significantly causing harm to patients.

Poster Title: Incidence and risk factors for cefepime-induced neurotoxicity in end stage renal disease patients

Primary Author: Jennifer Chou, Detroit Medical Center, MI; Email: jchou@dmc.org

Additional Author(s):
Elizabeth Wilpula
Krista Wahby

Purpose: This retrospective cohort study aims to determine the incidence of cefepime-induced neurotoxicity in end stage renal disease patients on hemodialysis, to identify potential risk factors, and to quantify the number of patients requiring transfer to the intensive care unit due to severe encephalopathy.

Methods: Through retrospective chart review, patients 18 years or older on hemodialysis who have received at least two doses of cefepime during their inpatient stay will be identified. The following data will be collected: age, gender, height, weight, prior history of central nervous system disease or epilepsy; hemodialysis information such as date and time received, total run time, and filter type; cefepime administration information such as date and time of each dose, dose given, and frequency; laboratory data such as blood urea nitrogen, serum creatinine, albumin, white blood count, ammonia level, and microbiology results; and diagnostic testing results such as electroencephalogram reports, magnetic resonance imaging and computed tomography of the head, and Glasgow coma scores. Any new transfers to the intensive care unit or consultations to neurology for altered mental status or lethargy will be collected. Specific criteria and the Naranjo Adverse Drug Reaction Probability Scale will be used to determine probable cases of cefepime-induced neurotoxicity. Patient-specific factors, such as number of missed dialysis days and total daily cefepime dose, will be compared between those experiencing neurotoxicity and those who did not experience neurotoxicity. This analysis will determine whether there is an association between these factors and the likelihood of developing cefepime-induced neurotoxicity and can identify any potential areas for improvement in this institution’s cefepime dosing and monitoring protocol in hemodialysis patients.

**Poster Title:** Evaluation of the efficacy of combination dual antiplatelet therapy with oral anticoagulant therapy.

**Primary Author:** Whitney Gibson, Detroit Medical Center, MI; Email: wgibson@dmc.org

**Additional Author(s):**
Denise Sutter-Long
Raymond Yost
Elizabeth Petrovitch
Elizabeth Wilpula

**Purpose:** The combination of dual antiplatelet therapy (DAPT) with an oral anticoagulant used for various indications to prevent future thrombotic events is referred to as “triple therapy.” Current data has focused on warfarin-containing combinations, which have showed no significant difference regarding risk of thrombosis with use of triple therapy compared to dual therapy or antiplatelet therapy alone, while only sparse data exists regarding efficacy when the direct oral anticoagulants (DOACs) are prescribed. The purpose of this study is to evaluate the risk of thrombosis in patients treated with DOAC-containing triple therapy compared to warfarin-containing triple therapy.

**Methods:** This is a multicenter, retrospective, chart review which will include the six institutions within the metro Detroit area institutions. Each site will query their medical record database to identify both patients who were initiated on triple therapy during their hospitalization as well as patients admitted to the hospital for a thrombosis event. After the data is collected at each individual site, patient records will be assigned a unique code prior to de-identification to allow for identification of cross site readmission. Accuracy of extracted data will be verified through chart review of a sample of patients. Tests used for statistical analysis will be utilized as follows: descriptive data will be used to analyze prescribing patterns, chi-squared tests will be used to evaluate all nominal data, the Student’s t test will be used to analyze continuous data, hazard ratios will be used to analyze events over time, log-rank tests will analyze time to events, survival will be analyzed using Kaplan-Meier, and sensitivity analyses will be performed using logistic regression.

- Keith Kaye

**Purpose:** Sulfamethoxazole/trimethoprim (SMX/TMP) is a first-line option for urinary tract infections, skin and soft tissue infections, and pulmonary infections due to Pneumocystis jirovecii and Stenotrophomonas maltophilia. SMX/TMP use is sometimes limited because of nephrotoxicity concerns. Evidence supporting these concerns is largely limited to small, noncomparative case reports/series and historical concerns with less soluble sulfonamides. These concerns are further complicated by small rises in serum creatinine caused by trimethoprim due to inhibition of tubular secretion of creatinine. The primary objective of this analysis is to determine if there is a true association between SMX/TMP use and AKI.

**Methods:** A retrospective matched cohort study of 600 patients within a multicenter hospital system who received treatment with SMX/TMP or a non-nephrotoxic comparator agent (300 patients in each group) will be performed. Patients will be eligible for inclusion if they received a target antimicrobial for at least 48 hours from January 1, 2014 to September 30, 2016. Patients will be excluded if creatinine clearance at onset of therapy was less than 30 mL/min, or they had a pre-existing need for renal replacement therapy. Eligible patients will be identified through a review of the pharmacy database. Each SMX/TMP patient will be matched 1:1 to a patient receiving an alternative, non-nephrotoxic, antimicrobial therapy for the same indication. Matching parameters will consist of severity of illness, number of concomitant nephrotoxic agents, duration of therapy with targeted antibiotic, and intensive care unit (ICU) status at the commencement of therapy. Data collection will include demographics, co-morbid conditions, severity of illness, dose and duration of all antimicrobial exposures, ICU admission, relevant laboratory parameters, microbiology data, and receipt of concomitant nephrotoxic agents. The primary outcome will be defined as meeting the "Injury" classification of the Risk,
Injury, Failure, Loss, and End-stage kidney disease criteria (a 2-fold increase in the serum creatinine or decrease in GFR by 50 percent) to avoid misclassification of AKI due to insignificant rises in creatinine caused by trimethoprim.

Poster Title: Analysis of inpatient medication requests to improve medication distribution processes

Primary Author: Paulina Reizian, Detroit Medical Center - Children's Hospital of Michigan, MI; Email: preizian@dmc.org

Additional Author(s):
Rana Fayad
Holly Masteller
May Saba
Dennis Gates

Purpose: Children’s Hospital of Michigan utilizes a medication request service as part of the electronic clinical information system. Nurses will file medication requests for various reasons including, inability to locate a medication, medication replacement, and medications requiring rescheduling. A surplus of medication requests to the pharmacy staff can significantly disrupt the efficiency and productivity for both pharmacy and nursing workflow, which ultimately leads to delayed medication delivery and administration. The purpose of this study is to examine the medication requests qualitatively, identify root causes, and develop recommendations that will improve medication distribution process.

Methods: This retrospective quality improvement project was conducted at Children’s Hospital of Michigan of the Detroit Medical Center. Medication request data were pulled from the hospital’s clinical information system from July 1, 2016 to July 14, 2016 and September 1, 2016, to September 14, 2016. Data included inpatient unit, medication name, route of administration, strength and schedule, nursing comments, status of request (i.e. completed, rejected, label printed), time of request input and time of response or action by pharmacy. Medication requests were categorized as either value-added or non-value-added. Value-added was defined as unavoidable medication requests (e.g. rescheduling, emergency and observation unit requests, bulk medication replacement). Non-value-added was defined as avoidable medication requests that hindered workflow (e.g. missing medications, floor stock shortages). The primary outcome of this study was to determine the percentage of medication requests that were defined as value-added versus non-value-added. The secondary outcomes of this study were to
determine the most frequently requested medications and the main reasons for non-value-added medication requests. Microsoft Excel software was used to classify and analyze the data. In November 2016, pharmacy will conduct a nursing survey regarding the medication distribution processes. This information will be used to develop protocol changes that are aimed at improving the efficiency of the medication distribution system. Medication requests will be evaluated in March 2017 to determine whether protocol changes were successful.

**Poster Title:** Effect of cefepime versus piperacillin/tazobactam on hospital-acquired Clostridium difficile infections  

**Primary Author:** Danny Salem, DETROIT MEDICAL CENTER - DETROIT RECEIVING HOSPITAL, MI;  
**Email:** dsalem2@dmc.org  

**Additional Author (s):**  
Linda Park  
Ryan Mynatt  

**Purpose:** Clostridium difficile is a major cause of healthcare-associated infections. Studies demonstrate increased hospital length of stay and expenditures with an average increase length of stay of 2.8-5.5 days and a mean of $3,000-$15,000 per episode. Identifying antibiotics associated with a higher incidence of Clostridium difficile infection (CDI) can be valuable in terms of reducing hospital-acquired CDI and establishing hospital standards. This study will evaluate the incidence of hospital-acquired CDI in patients who received cefepime versus piperacillin/tazobactam. Secondary objectives will include incidence of antibiotic-associated diarrhea and incidence of obtainment of Clostridium difficile polymerase chain reaction (PCR) amplification test.

**Methods:** This study is a retrospective investigation into the incidence of CDI at the Detroit Medical Center (DMC). Patients 18 years of age who received either cefepime or piperacillin/tazobactam for greater than 48 hours between January 1, 2012 and June 30, 2016 will be included. Data collected will include patient age, gender, race, past medical history, past medication history, admitting diagnosis and service, antimicrobial information, CDI severity, and hospital length of stay. CDI will be defined as 3 or more unformed stools within 24 hours plus a positive PCR amplification test. Antibiotic-associated diarrhea will be defined as 3 or more loose stools per day for at least 2 days with no positive stool PCR. CDI severity will be defined as mild to moderate for patients with a white blood cell count (WBC) less than or equal to 15,000 cells per microliter or a serum creatinine (Scr) less than 1.5 times baseline, severe for patients with a WBC greater than 15,000 cells per microliter or Scr greater than 1.5 times baseline, or severe complicated for patients with hypotension or shock, ileus, or megacolon.
Categorical variables will be analyzed using a Chi-Squared test or Fisher exact test, continuous variables will be analyzed with the Student’s t-test, a linear regression model will be utilized for the primary endpoint and a P-value less than 0.05 will be considered statistically significant.

Poster Title: Management of alcohol withdrawal in medical intensive care unit patients

Primary Author: Rachel Wein, Detroit Medical Center - Detroit Receiving Hospital, MI; Email: rwein@dmc.org

Additional Author(s):
Joshua Raub
Suprat Wilson
Linda Park

Purpose: Both scheduled and symptom-triggered dosing with benzodiazepines have been studied for the treatment of Alcohol Withdrawal Syndrome (AWS). Previous studies have concluded that symptom-triggered dosing is advantageous, leading to reduced doses of benzodiazepines and shorter treatment duration. The two dosing regimens have not been extensively compared in critically-ill patients. Order sets which utilize symptom-triggered dosing may help standardize patient care and minimize incomplete prescribing. The aim of this study is to evaluate the management of AWS in medical intensive care unit (MICU) patients before and after the implementation of an AWS order-set with symptom-triggered dosing of benzodiazepines.

Methods: This is a retrospective review of patients admitted to the MICU at the Detroit Medical Center from January 1, 2013 to July 30, 2016 with an ICD-9/10 admitting diagnosis of AWS. All patients must have received at least one dose of a benzodiazepine. Exclusion criteria include: allergy to benzodiazepines, active withdrawal from toxins other than ethanol, delirium unrelated to AWS, concurrent psychiatric disorders necessitating the use of benzodiazepines, and patients who are pregnant. Baseline characteristics to be collected include demographics, past medical history, laboratory tests (blood ethanol level, urine toxicology screen, liver tests, and electrolytes), SOFA score, CIWA-Ad score for the post order-set group, and baseline RASS score for those intubated. For all patients, the benzodiazepine dose (route, cumulative dose in lorazepam equivalents, and duration), use of adjunctive agents, and incidence of adverse outcomes will also be documented. The primary outcome of this study is to compare MICU length of stay between the scheduled and symptom-triggered dosing groups. Secondary outcomes include total dose of benzodiazepine, evaluation of adjunctive agents, serious
adverse effects, overall hospital length of stay, and mortality. A Chi-Square test or Fisher’s Exact test will be used to assess nominal data and a student t-test or Mann-Whitney U test will be used to assess continuous data that are parametric and non-parametric, respectively. A p-value less than 0.05 will be considered statistically significant.

Poster Title: Validation of a checklist to evaluate student performance in a problem based learning group

Primary Author: Alison Lobkovich, Detroit Medical Center - Harper University Hospital, MI; Email: alobkovi@dmc.org

Additional Author(s):
Sheila Wilhelm
Francine Salinitri

Purpose: Problem-Based Learning (PBL) is a student-centered pedagogy that uses authentic, ill-structured cases as the stimulus for learning pharmacotherapy. At Wayne State University-Eugene Applebaum College of Pharmacy and Health Sciences (WSU-EACPHS), PBL is integrated as a course series in the curriculum. Evaluation of student performance in a group is one component of the PBL process. Standardization of the evaluation process using valid tools optimizes assessment of student learning. The objective of this study is to validate the checklist used in the PBL course series.

Methods: In 2015, pharmacy educators, committee members, and community volunteers helped create a standardized facilitator evaluation checklist for the assessment of student performance in a small group. The checklist was created based on course and program objectives as well as the goals associated with PBL. The Angoff Method for Standard Setting was used to determine the weighting of the score of each item on the checklist. The checklist is used to evaluate individual student performance in the small-group PBL setting. To evaluate the validity and reliability of the checklist, evaluation scores from 2015-2016 will be evaluated along with overall program GPA, and knowledge and problem solving exam scores. We hypothesize that facilitator evaluation scores will have moderate correlation with overall GPA and knowledge exam scores and strong correlation with problem solving exam scores. Descriptive statistics will be used to characterize the student population. Correlation will be assessed using the IBM Statistical Package for the Social Science (SPSS) predictive analytics software.

Results: N/A
Conclusion: N/A
Purpose: Treatment recommendations for submassive/massive pulmonary embolism (PE) and a concurrent deep vein thrombosis (DVT) are lacking in current guidelines. Available treatment options include: anticoagulants alone; endovascular catheter-directed thrombolysis with low-dose alteplase plus anticoagulation; or systemic thrombolytics plus anticoagulation. To date there are no studies comparing all treatment options for DVT/PE; our study will evaluate the safety/efficacy of the various anticoagulation treatment options in patients with concurrent PE/DVT. The primary objective of the study is to assess the recurrence of PE or other thrombotic events within 90 days; as well as in-hospital mortality, 30 day mortality and major/minor bleeding.

Methods: The study has been approved by the Institutional Review Board. This is a retrospective chart review that will include all patients presenting with a massive or submassive PE and a concurrent DVT from July 2010 to August 2016. Data collected will include: Patient demographics (weight, age, height), length of stay (hospital stay, intensive care unit length of stay), prior history for venous thromboembolism, co-morbidities, vital signs (blood pressure, heart rate), right ventricle diameter/left ventricle diameter ratio, complete blood count, BUN/SCr, liver function tests, fibrinogen, D-dimer, concomitant antiplatelet agents, concomitant systemic anticoagulation, total tPA dose infused, as well as start date/time, anticoagulant agent used, dose and start date/time, inferior vena cava filter placement, vasopressor requirement, diagnostic tests (echocardiogram, duplex ultrasound, CT, VQ scan), BNP, N-terminal pro-BNP, troponin I, troponin T, minor bleeding, major bleeding, in hospital mortality, 30-day mortality, 30 day readmission, recurrent PE or any other thromboembolic event within 90 days. Data will be grouped based on the treatment option used: Anticoagulants
alone (parenteral and/or oral); endowave catheter-directed thrombolysis with low-dose alteplase plus anticoagulation; or thrombolytics plus anticoagulation. Data will be analyzed using the Chi-Squared test for nominal data and Student’s T-test for continuous data.

**Poster Title:** Bleeding risk with apixaban versus warfarin in patients with kidney dysfunction

**Primary Author:** Claudia Hanni, Detroit Medical Center- Harper University Hospital, MI; **Email:** channi@dmc.org

**Additional Author(s):**
Elizabeth Petrovitch
Elizabeth Wilpula
Denise Sutter
Raymond Yost

**Purpose:** The use of apixaban in patients with impaired kidney function has not been extensively studied. Large clinical trials evaluating apixaban in patients with atrial fibrillation and/or acute venous thromboembolism excluded patients with creatinine clearance less than 25 mL/min. Small pharmacokinetic/pharmacodynamic studies have reported limited data, but did not include efficacy and safety outcomes. Furthermore, patients with impaired kidney function are at increased risk of bleeding without the presence of anticoagulation. This study will evaluate the risk of bleeding and the time to first bleeding event in patients on apixaban versus warfarin with creatinine clearance less than 25 mL/min.

**Methods:** This is an Institutional Review Board approved retrospective study. It will be conducted at three tertiary academic medical centers. Chart review will be performed on all adult patients 18 to 89 years old who were admitted from January 1, 2014 through December 31, 2015. Patients will be included who were initiated on apixaban or warfarin for at least 45 days of treatment with a creatinine clearance less than 25 mL/min. The target sample size is 1,000 patients. Data will be collected to include comorbidities, past medical history, social history, indication for anticoagulation, concomitant medication, stroke and bleeding risk scores, renal function, bleeding events, thrombosis events, complete blood count, and coagulation blood testing. This data will be used to determine rate of bleeding and time to first bleeding event of apixaban versus warfarin. Patients will be identified through each site’s electronic medical record database, then de-identified data will be combined to create one database for analysis. The Chi-squared test will be used to evaluate all nominal data, student’s t test will be used to analyze continuous data, and log-rank test to analyze time-to-event.

**Poster Title:** Outcomes of chronic care management (CCM) in primary care practice  

**Primary Author:** Insaf Mohammad, Detroit Medical Center/Harper University Hospital, MI;  
**Email:** imohamma@dmc.org  

**Additional Author(s):**  
Candice Garwood  

**Purpose:** Chronic disease states are a leading cause of morbidity and mortality. Management of conditions such as diabetes, hypertension, and heart failure requires ongoing care delivered beyond a primary care visit. As of January 1, 2015, Medicare began reimbursing non-face-to-face Chronic Care Management (CCM) services provided to patients with multiple chronic conditions. CCM focuses on care coordination, management at care transitions, and medication management. In August 2015, the pharmacy team in a patient-centered medical home serving geriatric patients implemented a CCM program. The purpose of this project is to evaluate the impact of this service on health outcomes and cost utility.  

**Methods:** This is a quasi-experimental study evaluating the impact of a pharmacist-led CCM service. The electronic medical record will be utilized to collect glycated hemoglobin, blood pressure, LDL cholesterol, vaccinations, preventative health service provision, and acute care service utilization for each patient who received the CCM service. These variables will be collected from one year prior to and one year after the implementation of the CCM service. A validated survey will be used to assess patient satisfaction with pharmacist-led CCM services. An interrupted time series analysis will be used to evaluate the impact of CCM on the health-related variables collected. Standard parametric statistics will be used to analyze the results from the patient satisfaction surveys. A cost utility analysis will be conducted to determine if the CCM service is economically favorable.

Poster Title: Evaluation of risk factors and treatment strategies for major bleeds in patients on warfarin therapy

Primary Author: Sean McConachie, Detroit Medical Center/Harper University Hospital, MI; Email: smcconac@dmc.org

Additional Author(s):
Johseph Johnson
Elizabeth Petrovitch
Krista Wahby

Purpose: Warfarin is a commonly prescribed anticoagulant and is used in a variety of disease states including atrial fibrillation and venous thromboembolisms. Warfarin has a narrow therapeutic index and is associated with high rates of bleeding at international normalized ratio (INR) values above the target range. Despite many years of clinical experience, patient-specific risk factors that are associated with major bleeding are largely unknown. This study sought to determine which clinical factors predispose patients to major or fatal bleeding on warfarin therapy, and which reversal strategies or products are associated with positive clinical outcomes.

Methods: A retrospective observational study was performed using electronic medical record (EMR) review to identify adult inpatients with major or fatal bleeding on active warfarin therapy from July 1, 2014 to July 31, 2016. Major bleed was defined as hemoglobin drop greater than or equal to 2mg/dL, need for anticoagulant reversal products or blood transfusion, or ICD-9 or ICD-10 codes associated with major or fatal bleeding. Data was collected on pertinent laboratory information, concomitant medications, and specific patient diagnoses. Statistical analysis was performed to determine which patient-specific risk factors were associated with major or fatal bleeding on warfarin therapy and which reversal strategies and medications were most effective in patients who presented with major bleeding on warfarin therapy. Adherence to health system warfarin reversal guidelines was also assessed.

Results: Results are currently in progress.
Conclusion: Results are currently in progress.

**Poster Title:** Effectiveness of a written continuing education module for specialty pharmacists: a prospective patient benefit analysis

**Primary Author:** Michael Phalen, Diplomat, MI; Email: mphalen@diplomat.is

**Additional Author (s):**
Stephen Lott
Stephanie LaPointe
Bradley Behrend
Michael Crowe

**Purpose:** Continuing education is an important facet of pharmacy practice that has demonstrated improvement in knowledge of pharmacy professionals. However, few studies demonstrate how an increase in pharmacist knowledge translates into enhanced patient knowledge and improved outcomes. The objective of this study is to determine the effectiveness of the continuing education activity created by Pharmacy Times Continuing Education titled “Pharmacists Reaching Out: The Pharmacist Role in Management of Psoriasis and Psoriatic Arthritis” in improving patient knowledge of their disease state and therapy through increased pharmacist competence.

**Methods:** This study will be submitted to an external institutional review board for approval. This investigation will consist of two patient cohorts and one pharmacist cohort from a single specialty pharmacy. The first patient cohort will consist of patients with either psoriasis or psoriatic arthritis who have received counseling from a specialty pharmacist during a three month period prior to the study’s start date. This cohort will be offered a survey that aims to assess the patient’s knowledge of their therapy and disease state. Next, the pharmacy’s patient-facing pharmacists will be educated using an Accreditation Council for Pharmacy Education (ACPE) certified continuing education module for psoriasis and psoriatic arthritis during the month of October 2016. The second patient cohort will consist of patients similar to the first patient cohort, except that they will have received counseling from a specialty pharmacist who completed the continuing education module. This cohort will receive the same survey as the first patient cohort. The primary efficacy outcome of this study will be the comparison of correct patient answers from both patient cohorts. Secondary outcomes of this
study will include: analysis of pharmacist short-term and long-term information retention following the education intervention, examination of the impact of patient information source on knowledge of key counseling points, and comparison of patient attitudes towards adherence before and after counseling.

Poster Title: Development, implementation, and assessment of a site-of-care program for specialty infusion products

Primary Author: Jonathan Clark, Diplomat, MI; Email: jclark@diplomat.is

Additional Author(s):
Stephen Lott
Elizabeth Duruz
Amy Clarke
Michael Chester

Purpose: Specialty infusion drugs used in the treatment of chronic, rare conditions are usually administered to patients in a physician office, hospital outpatient, or home setting. Variations in cost of therapies and services across such settings have led to challenges for health plans in managing health care costs while maintaining adherence. Redirection of patients to lower-cost sites-of-care has been shown to effectively reduce copay and health plan expenditures. The objectives of this study are to assess the outcomes of a novel site-of-care program in the success of site-of-care redirection, cost avoidance, and patient satisfaction.

Methods: This prospective implementation, cost evaluation, and patient satisfaction study will collect claims data in order to identify patients receiving specialty infusion drugs that can be given safely and effectively at home. Patients will be identified between October 10, 2016 and June 1, 2017. The following data will be collected: patient age, gender, ethnicity, diagnosis codes, infused drug details, number of patients redirected to home infusion, costs for medical and pharmacy expenses, and patient satisfaction surveys. All data will be recorded without patient identifiers and maintained confidentially. Eligible therapies for redirection will include select alpha-1 proteinase inhibitors, enzyme replacement therapies, hemophilia factors, hereditary angioedema treatments, immune globulin products, and intravenous auto-immune therapies. Successful site-of-care redirection will be defined as the percentage of patients that achieve infusion site-of-care redirection from the physician office or hospital outpatient setting to home infusion upon their initial or second infusion dose. Evaluation of successful site-of-care redirection will be further analyzed based on drug category. Total health care costs and infusion
day costs will be measured using average monthly cost and per patient per month (PPPM) cost. Patient satisfaction will be assessed using a call-based survey.

**Poster Title:** Evaluation of the appropriate empiric use of vancomycin and its implications

**Primary Author:** Hannah Beard, Henry Ford Allegiance Health, MI; **Email:** hannah.beard@allegiancehealth.org

**Additional Author(s):** Gay Alcenus

**Purpose:** The Centers for Disease Control and Prevention (CDC) published a guideline for implementing hospital antimicrobial stewardship programs with a checklist of core elements. One of those elements is ensuring optimal antibiotic use for the treatment of common infections, such as skin and soft tissue infections and the empiric coverage of methicillin-resistant Staphylococcus aureus (MRSA). The objectives of this study are to see how vancomycin is currently used at this institution to stem further research into specific infections and de-escalation, and to examine its use in a specific infection, cellulitis, to determine if appropriate utilization of empiric MRSA coverage is occurring.

**Methods:** This medication utilization evaluation will be a retrospective chart review of a random sample of patients admitted to this institution who were prescribed vancomycin starting between May 1, 2016 and July 31, 2016, and received three or more doses. Children, prisoners, pregnant women, patients who received a dose in the operating room or had vancomycin prescribed by a surgeon, and patients who were on vancomycin prior to admission will not be included. The data collected will include patient demographics (age and sex), indication for use, the doses of vancomycin and number of days given, length of stay, whether or not de-escalation to narrow spectrum antibiotics occurred, discharge antibiotic orders, and specific indicators for MRSA coverage (presence of systemic inflammatory response syndrome, history of MRSA or injection drug use, immunocompromised state, failure of outpatient antibiotics, penetrating trauma, and documentation of severity of infection). The data will be analyzed using descriptive statistics. Institutional Review Board approval will be obtained.

**Poster Title:** Update on the comparison of pharmacist managed warfarin therapy versus physician managed warfarin therapy

**Primary Author:** Richard Bramer, Henry Ford Allegiance Health, MI; **Email:** richard.bramer@allegiancehealth.org

**Additional Author(s):** Gay Alcenius

**Purpose:** Warfarin is a narrow therapeutic index medication requiring frequent international normalized ratio (INR) lab monitoring to assess efficacy and safety. Appropriate dose adjustments and follow up are vital in the safe and effective management of warfarin patients. A study four years ago at this institution showed that pharmacist managed outpatient anticoagulation care led to a higher percentage of therapeutic INRs and fewer hospital admissions for bleeding or clots compared to management by physicians. This study will provide updated data to assess whether pharmacist managed warfarin care is still superior to physician managed care.

**Methods:** This study will be a medication use evaluation to assess the appropriateness of warfarin dosing in the outpatient setting. This study will involve patients who were admitted to a Medication Therapy Management (MTM) clinic for outpatient warfarin management and were subsequently discharged from the clinic between May of 2012 and August of 2016. Patients will be excluded if they have less than two months of INR values available in their medical record at either the clinic or their physician’s office after they are stabilized on warfarin. Stabilized patients will be defined as those who are started on warfarin and have at least two consecutive INRs in range, patients who completed bridging with another anticoagulant, such as enoxaparin, and those who were admitted or discharged from the MTM clinic to or from their primary care physician. Data will be collected on these patients using their medical records. Data that will be collected includes demographic information, enrollment and discharge dates from the MTM clinic, INR values during warfarin therapy, number of hospital admissions for bleeding or clots, indication for anticoagulation, and the patient’s physician. This study was approved by the Institutional Review Board.

Poster Title: Evaluation of the use of oral anticoagulation in the intensive care unit

Primary Author: Julie Thomson, Henry Ford Hospital, MI; Email: jthomso2@hfhs.org

Additional Author(s):
Krishna Rangarajan
Mathew Jones
Long To
Laura Hencken

Purpose: Limited published literature exists regarding the use of oral anticoagulation (OAC) in patients in the intensive care unit (ICU). Anticoagulation in critically ill patients often involves the use of agents that can be administered parenterally, closely monitored, and easily reversed. Earlier initiation of OAC in stabilized ICU patients has the potential to reduce hospital length of stay (LOS). However, such benefits should be balanced against any potential adverse events in this patient population. The purpose of this study will be to characterize the prescribing patterns and outcomes of OAC in patients admitted to the ICU at Henry Ford Hospital.

Methods: This will be a retrospective, observational cohort study conducted via electronic and manual chart review at Henry Ford Hospital. Non-pregnant adults over the age of 18 who received an OAC agent – including warfarin or a direct oral anticoagulant (DOAC; dabigatran, apixaban, edoxaban, or rivaroxaban) – while admitted to an ICU at the study institution from January 2015 to October 2016 will be included. One hundred and twenty subjects will be randomized for the data collection and evenly divided based on whether they received warfarin or one of the DOAC agents. Major outcomes of concern include adverse bleeding, thromboembolic events, and ICU and hospital LOS. The following data will be collected: patient demographics, OAC dosing regimen, sequential organ failure assessment (SOFA) score, indication for OAC, adverse events, use of reversal agents, and LOS. Descriptive results will be reported as number (percentage, %), mean (standard deviation), or median (interquartile range), as appropriate.

Poster Title: Evaluation of appropriateness and safety of oral clonidine in Josephine Ford Cancer Institute (JFCI) infusion centers

Primary Author: Matthew Lei, Henry Ford Hospital, MI; Email: leimingzhe@gmail.com

Additional Author(s):
Katelyn Patterson
Beejal Ganti

Purpose: In the United States, an estimated 32% of adults have hypertension, of whom 32% are considered to be controlled. Clonidine, a centrally acting alpha-2 adrenergic agonist, is the agent of choice in Josephine Ford Cancer Institute (JFCI) JFCI infusion centers for the treatment of hypertensive urgency and emergency. If the patient’s blood pressure decreases, the scheduled infusion is given without further intervention. The purpose of this study is to assess the appropriateness of clonidine use in the JFCI infusion centers to develop a protocol for the management of hypertensive urgency and emergency.

Methods: This is a single-center, retrospective, cross-sectional study to assess the use of oral clonidine at four locations of the JFCI locations through in the Henry Ford Health System between November 2013 and June 2016. All adult patients who received oral clonidine for the treatment of hypertensive urgency or emergency on presentation to the infusion centers will be included. Pertinent exclusion criteria include patients under 18 years of age, pregnant or breastfeeding women, and prisoners. A retrospective chart review will be conducted to collect patient demographics, current antihypertensive regimen, the medication for infusion or purpose for the scheduled appointment, dose and frequency of oral clonidine administered, timing of clonidine administration, and administration of other anti-hypertensive medications during the scheduled appointment time. Descriptive statistics will be used for analysis. Measures of proportion, central tendency and variation will be described.

Results: To be presented.

Conclusion: To be presented.

Amber Lanae Smith  

**Purpose:** Pharmacists in hospital-based ambulatory clinics provide extensive patient care services including: improving patient access, providing medication education, and assessing medication related problems that ultimately improve patient outcomes. However, pharmacists are limited in their ability to generate revenue and justify their services if unable to bill third party insurances. In order to successfully be reimbursed, pharmacists must adequately document their services per Centers for Medicare and Medicaid Services (CMS) standards. The purpose of this study is to describe current ambulatory pharmacy services and identify opportunities to improve documentation in order to maximize potential return on investment at Henry Ford Hospital (HFH).  

**Methods:** This retrospective, descriptive study was approved by the HFH Institutional Review Board. Over 900 pharmacy encounters will be analyzed for potential CMS billing opportunities from January 1, 2015 to December 31, 2015. The analysis will focus on patient-pharmacist encounters in the oral chemotherapy and pulmonary clinics at HFH in Detroit, Michigan. Each encounter will be quantified and classified based on CMS definitions and standards, specifically chronic care management, transitions of care management, or incident-to-physician billing opportunities. All pertinent descriptors included in CMS requirements will be collected and analyzed. The primary endpoint is percentage of encounters that meet CMS documentation standards. Secondary endpoints include: the average complexity of pharmacist encounters; estimated return on investment using reported reimbursement rates from the CMS physician fee schedule; and identifying areas in the current documentation that can be improved to maximize reimbursement. Data analysis will consist of descriptive statistics.

Purpose: A number of different risk factors can increase the likelihood of developing venous thromboembolism (VTE) during a hospital admission. Selection of an antithrombotic prophylaxis agent and its congruence to evidence-based medicine can play a role in preventing clot formation. At our institution, the perioperative VTE rate is higher than the national benchmark. However, recent data regarding VTE rates at our institution for medical patients is lacking. As such, this study will characterize antithrombotic prescribing patterns for the prophylaxis of acute VTE at an urban acute care hospital in order to identify potential risk factors for VTE development.

Methods: This IRB approved descriptive study will evaluate adult patients admitted to general practice units during a six-month period diagnosed with a VTE. Patients with a history of chronic or recurrent VTE or receiving therapeutic anticoagulation prior to admission will be excluded. Baseline demographics, antithrombotic medications, and sequential compression device (SCD) orders will be collected. Descriptive statistics will be used to analyze the data. This study will determine if the antithrombotic therapy prescribed followed established guidelines and/or institutional protocols for VTE prophylaxis in antithrombotic selection, dosage, and duration of therapy based on indication. The selected guidelines include American Academy of Orthopedic Surgeons (AAOS), American College of Chest Physicians (ACCP), American College of Physicians (ACP), and National Comprehensive Cancer Network (NCCN). The results from this study will be used to initiate targeted education for health care providers and standardize the prophylaxis prescribing habits with the goal of improving patient outcomes.

Poster Title: Evaluation of Outcomes in Patients Discharged with Warfarin without Notification of Pharmacy Department

Primary Author: Stephen Kaurala, Henry Ford Hospital, MI; Email: skaural1@hfhs.org

Additional Author(s):
Eric Magnan
Jona Lekura
Octavia Jordan

Purpose: Warfarin is used to treat a variety of thromboembolic conditions. Careful management of warfarin therapy is required to reduce the risk of adverse events including, thromboembolism or bleeding. Inpatient pharmacists within the hospital in which the study is being conducted are involved in the transition of care of warfarin patients and provide warfarin recommendations at discharge. These recommendations include discharge regimen and time to next INR draw. However, some patients are discharged without obtaining these pharmacy recommendations. The goal of this study is to evaluate outcomes in patients discharged with warfarin without notification of the pharmacy department.

Methods: This retrospective chart review has been approved by the Institutional Review Board. The electronic medical records of 100 patients from January 1, 2015 to August 1, 2016 will be reviewed to identify patients for inclusion based on greater than or equal to eighteen years of age and who were discharged on warfarin without pharmacist discharge recommendations. The following data will be collected upon the initial discharge: patient demographics, warfarin indication, outpatient warfarin provider, INR goal, discharge time and floor. These data points will be assessed through descriptive statistics. Data to assess the appropriateness of the warfarin regimen at discharge will be home warfarin regimen, last inpatient warfarin regimen, INR upon discharge, recommendation for first outpatient INR check, discharge warfarin regimen, and new or discontinued medications which interact with warfarin. Data points that will be collected and assessed after discharge include time to initial follow up and readmission status at thirty, sixty and ninety days. If readmission data is available, additional data points that will be collected and assessed include INR upon readmission and whether or not patient
experienced a new thrombotic or bleeding event. These data points will be assessed through the use of descriptive statistics.

**Poster Title:** Vancomycin use for pneumonia in the medical intensive care unit: Is this necessary?

**Primary Author:** J. Spencer Dingman, Henry Ford Hospital, MI; **Email:** jdingma1@hfhs.org

**Additional Author(s):**
- Salin Nhean
- Klarita Seïtliari
- Michael Peters
- Rachel Kenney

**Purpose:** Improper use of antimicrobials limits their future effectiveness by promoting the development of multidrug-resistant pathogens. Infections caused by these organisms are associated with morbidity and mortality, particularly in critically ill populations. Approximately 27% of intravenous (IV) vancomycin use in United States hospitals may be unnecessary, and 36% of patients who receive IV vancomycin have potential for improvement in prescribing. One potential target for improved antimicrobial use is the proper utilization of vancomycin for serious Gram-positive infections. The objective of this study is to evaluate the inappropriate use of vancomycin therapy for patients with pneumonia in medical intensive care units (MICU).

**Methods:** This is a retrospective cross-sectional study of adult patients receiving IV vancomycin for pneumonia in the MICU between June 1st and July 31st, 2016. Patients are excluded if they are pregnant, are transferred from an outside hospital, or have a concurrent infection other than pneumonia. Each day of vancomycin therapy is characterized as appropriate or inappropriate based on pre-specified criteria. Empiric and definitive therapies are denoted by days of therapy (DOT) prior to and after culture results, respectively. Empiric therapy is assessed daily and may be considered appropriate for up to 72 hours in patients with hospital-acquired pneumonia or ventilator-associated pneumonia, pending the results of the Gram stain or culture. Definitive therapy is considered appropriate from the time the Gram stain or cultures show Gram-positive infection with: methicillin-resistant Staphylococcus aureus; Streptococcus pneumoniae with penicillin minimum inhibitory concentration >2 mcg/mL; or methicillin-sensitive Staphylococcus aureus, Streptococcus pneumoniae, Group A, B, C, or G Streptococcus, or viridans streptococci in patients with severe beta-lactam allergy. Any DOT not
meeting criteria for appropriate therapy will be considered inappropriate. Acute kidney injury is assessed by Acute Kidney Injury Network and American Society of Health-System Pharmacists position statement definitions. Baseline characteristics include demographics, antibiotic allergies, pneumonia classification, and imaging reports. Endpoints include total DOT, proportion of inappropriate DOT, and prevalence of acute kidney injury. Statistical analysis is descriptive in nature.

Results: Results will be presented at the 2016 Midyear Clinical Meeting.

Conclusion: Conclusions will be presented at the 2016 Midyear Clinical Meeting.
**Submission Category:** Drug-Use Evaluation/ Drug Information  

**Submission Type:** Research-in-Progress  

**Session-Board Number:** 11-154  

**Poster Title:** No home antipsychotic medication in the intensive care unit? I’m shocked.  

**Primary Author:** Mary Musgrove, Henry Ford Hospital, MI; Email: maryamusgrove@gmail.com  

**Additional Author(s):**  
Vince Procopio  
Kate Starosta  
Mike Peters  
Opal Bacon  

**Purpose:** While discontinuation of antipsychotic medications initiated in the hospital for temporary indications has been a popular topic in current literature, few studies have been conducted to investigate home psychotropic continuation on admission to an intensive care unit. The purpose of this study is to evaluate the continuation of home antipsychotics and/or mood stabilizers upon admission to an intensive care unit (ICU), assess patient safety outcomes while admitted, and to evaluate what antipsychotic or mood stabilizer the patient is prescribed upon transfer out of the ICU and upon discharge.  

**Methods:** This study was accepted by the Institutional Review Board of Henry Ford Health System. A retrospective chart review of 100 ICU patients admitted to Henry Ford Hospital between January 1, 2015 and June 30, 2016 will be completed. The electronic medical record will identify patients who had a home medication list with an antipsychotic or mood stabilizer present within 3 months of admission. The primary outcome is the frequency of continuation of home antipsychotic or mood stabilizer medications upon admission to an ICU. Secondary outcomes to be evaluated are antipsychotics or mood stabilizers that the patient was transferred out of the ICU and/or discharged home with, incidences of delirium and agitation, and over/under sedation. Furthermore, if a home antipsychotic or mood stabilizer was discontinued on admission, documentation of the reason for discontinuation or an appropriate, undocumented indication for discontinuation will be investigated. Appropriate discontinuation will be defined as a patient presenting with a medical condition that could be attributed to the psychotropic medication or supratherapeutic psychotrophic medication levels. Finally, we will collect data evaluating safety events, all antipsychotic or mood stabilizer medications that the
patient had initiated or discontinued throughout the hospital admission, mental health disorder diagnosed, length of stay in both the ICU and hospital, and intubation days. Descriptive statistics will used to interpret the findings.

**Poster Title:** Evaluating clozapine missed doses after the implementation of the new clozapine risk evaluation and mitigation strategies (REMS) program

**Primary Author:** Sarah Yousif, Henry Ford Macomb Hospital, MI; Email: syousif2@hfhs.org

**Additional Author(s):** Pamela Muaj
Idan Hannawa
Norm Buss
Eric Craig

**Purpose:** The recent update to the clozapine REMS program requires prescribers to be certified prior to prescribing the medication. In accordance with the updated program, Henry Ford Health System incorporated the required changes and implemented a new clozapine protocol in March, 2016. Shortly after implementation, several inpatient pharmacists identified missed clozapine doses in comparison to the previous program. The purpose of this study is to look into the possible increase in missed clozapine doses and investigate the potential impact the new program may have had on these incidental findings.

**Methods:** This study will be submitted to the Institutional Review Board for approval. We conducted a retrospective chart review to compare the number of missed doses before implementing the updated REMS requirements to the number of missed doses after the program and protocol implementation. Using the electronic health record system, we generated a list of all patients who missed a dose of clozapine from January 2015 through September 2016. We identified the missed orders due to REMS registration issues compared to the number of missed doses due to other reasons. The data collection includes demographic information of patient age and gender. In regard to the order information, we included the following: the date of the order, date of administration, duration of the delay, the reason for the delay, patient registration with REMS, provider registration with REMS, psychiatric provider involvement and documentations provided in the patient chart regarding the cause of the missed dose. Data were recorded without patients’ identification and maintained confidentiality.
Resident Poster Abstracts

Results: To be presented at the 2016 ASHP Midyear Clinical Meeting in Las Vegas, NV.

Conclusion: To be presented at the 2016 ASHP Midyear Clinical Meeting in Las Vegas, NV.
Purpose: Acute lymphoblastic leukemia (ALL) is a malignant disease of the bone marrow in which early lymphoid precursors proliferate and replace the normal hematopoietic cells. Asparaginase is one of the primary chemotherapy drugs used to treat ALL. The asparaginase product has three formulations; the natural product derived from Escherichia coli (E. coli), a pegylated formulation of E. coli form, and another isolated from erwinia chrysanthemi. Asparaginase's side effect profile includes: hepatic transaminitis, hyperbilirubinemia, hypersensitivity, pancreatitis, thrombosis, and coagulopathies. The primary objective is to analyze the safety profile related to the route of administration with different asparaginase agents.

Methods: This is a retrospective study in patients receiving E. coli asparaginase or pegasparaginase at an adult cancer center from January 2011 through June 2016. A list of patients on asparaginase agents will be generated from the pharmacy dispensing record for screening study patients’ eligibility. All patient identifiers will be removed and each patient will be assigned a unique ID number. Patient inclusion criteria includes: age between 18 and 90, diagnosis of ALL, and treatment with a chemotherapy regimen including E. coli asparaginase or pegasparaginase. Exclusion criteria include pregnancy. The following basic demographic information will be collected: patient specific identifiers, age, gender, race, allergies, height, weight, body surface area, regimen of chemotherapy containing E. coli asparaginase or pegasparaginase, dosage, number of doses, and route of administration. Clinical notes will be reviewed and collected for adverse drug reactions associated with asparaginase agents. Descriptive statistics will be applied. This study is currently under review for approval by the Institutional Review Board.

Poster Title: Evaluating the time to de-escalation of antibiotics following positive blood culture results in a community hospital

Primary Author: Chaundra Cox, Mercy Health Muskegon, MI; Email: chaundra.cox@mercyhealth.com

Additional Author (s):
Lindy Farwig
Todd Capron
James Avila

Purpose: In addition to the patient’s clinical response, blood culture results are utilized to direct appropriate therapy including de-escalation of antibiotics. De-escalation of empiric antibiotic therapy such as using fewer agents and/or using reduced spectrum agents has advantages including reducing antibiotic toxicity and decreasing the development of resistance. In addition, de-escalation can decrease the emergence of antibiotic exposure-related infections such as Clostridium difficile. The purpose of this study was to determine the length of time from positive blood culture results to antibiotic de-escalation.

Methods: Data was collected for 30 days via a report generated from an electronic surveillance system. Inclusion criteria consisted of adult inpatients admitted to the hospital with positive blood culture results and antibiotic administration during hospitalization. Patients were excluded if their blood cultures did not direct the course of antibiotic treatment or if their antibiotic regimen was not de-escalated after finalization of blood culture results. Primary outcome was time to antibiotic de-escalation after organism identification and time to antibiotic de-escalation after sensitivity results. Secondary outcomes included number of infectious disease consults and type of bacteria identified on blood culture.

Results: Research in progress to be presented on poster at midyear meeting.

Conclusion: Research in progress.

**Poster Title:** Evaluation of current practices for transitioning patients from direct oral anticoagulants to warfarin at Mercy Health Muskegon

**Primary Author:** Brandon Cushman, Mercy Health Muskegon, MI; **Email:** brandon.cushman@mercyhealth.com

**Additional Author(s):**

**Purpose:** Since 2010, direct oral anticoagulants (DOACs) have been available as an option for patients requiring anticoagulation for deep venous thrombosis, pulmonary embolism, or atrial fibrillation. Unlike warfarin, DOACs do not require coagulation lab monitoring or dietary restrictions. Sometimes patients need to transition from a DOAC to warfarin which can be challenging due to lack of evidence-based recommendations and limited published research. The purpose of this study is to evaluate the current management of patients transitioning from DOACs to warfarin at Mercy Health Muskegon.

**Methods:** This study was submitted to the Institutional Review Board for approval. A report from the primary care electronic health record identified patients who were transitioned from dabigatran, rivaroxaban, or apixaban to warfarin at Mercy Health Muskegon. Inclusion criteria consisted of patients transitioning from a DOAC to warfarin from January 2016 to September 2016. Exclusion criteria included patients less than 18 years of age. The primary outcome was the method of transition used for each patient. Methods of transition included overlapping warfarin with a DOAC, overlapping warfarin with a parenteral agent, and no overlap at all. Secondary outcomes evaluated include adverse events, indication for anticoagulation, and reason for transition to warfarin.

**Results:** Research In Progress

Session-Board Number: 11-159

Poster Title: Patient adherence to hepatitis c medications at an outpatient specialty pharmacy

Primary Author: Matthew Ferro, Mercy Health Muskegon, MI; Email: matt.ferro@mercyhealth.com

Additional Author(s):

Purpose: Historically, treatment for hepatitis C has been relatively poor, with cure rates below 60%. Patient compliance has been an issue with previous treatments due to a myriad of negative side effects. The emergence of new treatment options has helped raise cure rates above 90% with minimal side effects. Clinical trials have demonstrated that patient compliance is a key factor in achieving cure rates and preventing spread of disease. The purpose of this medication review was to assess patient adherence to current hepatitis C medications at an outpatient specialty pharmacy.

Methods: This evaluation will be submitted to the Institutional Review Board for approval. Retrospective data was collected over a 5 month time period in 2016. Reports were generated from the pharmacy management software and included prescribed medication, initial pick-up date, refill pick-up dates, number of refills authorized, and quantity of medication filled. Inclusion criteria consisted of hepatitis C treatment with ledipasvir-sofosbuvir, and elbasvir-grazoprevir for a full 12 week prescribed course. Patients were excluded if they did not begin and finish treatment within the 5 month study period. The primary endpoint was percent adherence to therapy based on prescription pick-up date. Secondary endpoints included the number of pharmacy phone calls made to the patient and potential cost of non-compliance to the health system.

Results: Research in progress.

Conclusion: Research in progress.

**Poster Title:** Analysis of patient and provider interactions with ambulatory pharmacists in the primary care setting

**Primary Author:** Kendyll Erickson, Mercy Health Muskegon, MI; **Email:** kendyll.erickson@mercyhealth.com

**Additional Author(s):**

**Purpose:** Mercy Health Muskegon ambulatory pharmacists have been embedded in primary care physician office practices since 2005. Ambulatory care pharmacists have many roles including co-managing chronic conditions, educating patients on medications and disease states, and serving as a resource to the healthcare team. Currently, patient visits to the pharmacist are by provider referral. Patient interaction with the pharmacist includes scheduled face-to-face appointments and/or phone consultations. Medications are managed through collaborative practice agreements and discussions with the healthcare team. This study was conducted to analyze the number of patient and provider interactions and time spent devoted to patient care.

**Methods:** This study will be submitted to the Institutional Review Board for approval. Ambulatory pharmacists collected data over a period of four weeks using an internal protected online spreadsheet. Twelve internal medicine or family practice physician offices with ambulatory pharmacists were included for review. Data collection by the ambulatory pharmacists was dependent on their scheduled clinic days ranging from once monthly to three times weekly. Primary objectives included number of patient and provider interactions. Secondary objectives included time spent interacting with patients and staff, number of missed initial and follow-up appointments, and provider referral frequency.

**Results:** Research in progress.

**Conclusion:** Research in progress.
Submission Category: Drug-Use Evaluation/ Drug Information

Session-Board Number: 11-161

Poster Title: Gastric Acid Suppression in Stress Ulcer Prophylaxis at a Western Michigan Teaching Hospital

Primary Author: Thomas Beuschel, Mercy Health Saint Mary's, MI; Email: thomas.beuschel@mercyhealth.com

Additional Author(s):
Julie Belfer

Purpose: Utilization of gastric acid suppression such as proton pump inhibitors (PPIs) and histamine-2 receptor antagonists (H2RAs) to prevent stress ulcer development is a common concern amongst the critically ill. Across healthcare systems, there has been reports of stress ulcer prophylaxis (SUP) being continued longer than indicated as patients are transferred out of the critical care unit or discharged home. The primary objective of this study is to assess use and selection of gastric acid suppression for SUP. Secondary objectives include evaluation of dosing regimens utilized, route of administration, potential cost savings of early pharmacist intervention, and discontinuation of therapy.

Methods: This International Review Board approved retrospective chart review will be conducted at Mercy Health Saint Mary's, a community teaching hospital. An electronic medical record will be used to generate a list of patients that meet the following inclusion criteria: age greater than 18 years, admitted to critical care or have a critical care consult, and received at least one dose of a gastric acid suppressing agent (defined as pantoprazole, lansoprazole, or famotidine). Total sample size was calculated to be 150 patients total (75 in the famotidine group and 75 in the PPI group). Data points to be collected include agent, dose, route, criteria to meet appropriate therapy, days of unnecessary intravenous (IV) therapy and days SUP not indicated. Appropriate interchange from IV formulations to enteral administration will also be assessed to determine if IV to enteral switches are being made and to quantify unnecessary IV therapy use. A calculation will be completed using unnecessary days of therapy to determine how potential pharmacist-led discontinuation of inappropriate therapy may impact healthcare costs. Potential costs saved will also include missed IV to oral conversion opportunities. All variables will be evaluated using descriptive statistics. Descriptive statistics will mostly employ
means to describe total days of therapy, days of inappropriate therapy, and days of inappropriate IV therapy.

Poster Title: Evaluation of an intravenous to oral policy for antiepileptic medications and vitamins

Primary Author: Benjamin Kulwicki, Mercy Health Saint Mary’s, MI; Email: benjamin.kulwicki@mercyhealth.com

Additional Author(s):
Katie Axford
Abby Sturm

Purpose: While there are circumstances that dictate the need for medications to be given intravenously (IV), the oral (PO) route is preferred when available. Mercy Health Saint Mary’s (MHSM) has a policy that allows pharmacists to convert medications from IV to PO when criteria are met. Along with antimicrobials, the policy includes antiepileptics, vitamins and levothyroxine. The objective of this study is to evaluate the proportion of appropriate conversions from IV to PO when policy criteria are met. Additionally, this study will quantify the cost associated with failing to convert eligible patients and identify opportunities for process improvement.

Methods: The Institutional Review Board approved this retrospective cohort study. This study will review 120 randomly selected adult patients who received more than one dose of IV lacosamide, levetiracetam, valproic acid, thiamine, folic acid, or levothyroxine at MHSM between January 1 and June 30, 2016. Patients will be excluded if they were discharged home from the emergency department, have short gut syndrome, unable to take oral medications at baseline, or if their IV medication was converted to PO by providers other than pharmacists. Data will be collected from the MSHM's electronic medical record database and include patient characteristics, medication characteristics, and IV to PO eligibility criteria. Using the policy's criteria, a determination will be made if patients were eligible for conversion from IV to PO. Any additional IV doses given past the eligible conversion time will be considered inappropriate and associated with a cost. Analyses will be performed using descriptive statistics.

**Poster Title:** Impact of Rapid Identification and Antimicrobial Stewardship Intervention on Bacteremia in a Community Teaching Hospital

**Primary Author:** Derek VanderHorst, Munson Medical Center, MI; **Email:** dvanderhorst@mhc.net

**Additional Author (s):**
Nicholas Torney
Anne Gore

**Purpose:** Bacteremia has been associated with poor patient outcomes including a high mortality and extended hospital length of stay. Several studies have shown that the use of rapid diagnostic tests when coupled with real-time intervention from a pharmacist has shown improvements in patient outcomes and decreased health-system costs. The majority of this data stems from large academic institutions with a large amount of resources. The purpose of this study is to determine the impact of rapid identification and antimicrobial stewardship intervention on patients with bacteremia on improving patient outcomes and decreasing health-system costs within a community teaching hospital.

**Methods:** This study will be submitted to the Munson Medical Center Institutional Review Board for approval. To be included in the study patients must be at least eighteen years of age and have at least one positive blood culture. Patients with the following characteristics will be excluded from this study: less than eighteen years of age, pregnancy, polymicrobial blood cultures, active hospice/palliative care, known culture results at the time of admission, or history of solid organ/hematopoietic stem cell transplant. The primary endpoint of the study will be in-hospital mortality. Secondary endpoints include hospital length of stay, intensive care length of stay, cost of hospital stay, time to effective antimicrobial therapy, time to optimal antimicrobial therapy, and thirty day readmission rate. A protocol was created for the notification of positive blood cultures to the infectious diseases pharmacist and rapid pathogen identification via the BioFire FilmArray® system. Patients with at least one positive blood culture prior to the implementation of the rapid identification protocol will be retrospectively selected as the control arm. Patients with at least one positive blood culture after the implementation of the rapid identification protocol will be retrospectively selected as the
intervention arm. This study will select seventy-five of the most recent patients to meet inclusion criteria for both arms. Information will be collected via a manual chart review with the Cerner system.

**Results:** N/A

**Conclusion:** N/A
**Submission Category:** Ambulatory Care  

**Submission Type:** Research-in-Progress  

**Session-Board Number:** 11-164  

**Poster Title:** Role of ambulatory care pharmacist in outpatient cardiology clinic: Focus on atrial fibrillation  

**Primary Author:** Allie Wasik, Munson Medical Center, MI; **Email:** awasik@mhc.net  

**Additional Author(s):**  
Heather Tolfree  

**Purpose:** Atrial fibrillation (AF) is the most common cardiac arrhythmia in the United States and is associated with increased mortality. Emergency department visits and hospital admissions related with uncontrolled atrial fibrillation are on the rise while the treatment of AF alone accounts for 26 billion dollars annually. Patients with atrial fibrillation are at increased risk for significant adverse drug events and medication errors due to polypharmacy and high-risk medications. The objective of this study is to justify cost of clinical pharmacist to be involved in medication therapy management, drug monitoring and integration into the ambulatory cardiology decision-making process.

**Methods:** This study will take place at Traverse Heart and Vascular, a service partner of Munson Medical Center. This clinic serves 37,000 residents in northern Michigan across 11 practice locations. This study is meant to evaluate pharmacy services at the Traverse City location only. This study is pending approval of the institution’s Internal Review Board and is meant to identify the most high risk population for readmission of poorly controlled atrial fibrillation. The electronic medical record will identify patients for inclusion based on: diagnosis of atrial fibrillation, 2 or more hospital admissions in the last year related to AF, those on an oral anticoagulant (OAC) and patients on either rate or rhythm control. Patients will be excluded if they are less than 18 years of age or pregnant. Data points to be collected include: classification of AF, type of OAC, which antiarrhythmic or rate control therapy, optimization status of doses, proper monitoring of OAC and antiarrhythmic and adherence. All data will be deidentified and recorded on the secure Munson Information Systems network. A clinical pharmacist will work with primary electrophysiologist to optimize medication management through patient education, close monitoring of high risk medications such as amiodarone and novel anticoagulants, and coordinate transitions of care from the inpatient to outpatient setting.

Poster Title: Implementation and evaluation of a pharmacy led rounding team for patients enrolled in the alcohol withdrawal protocol

Primary Author: Bradley Haan, Munson Medical Center, MI; Email: bhaan2@mhc.net

Additional Author(s):
Molly Scott

Purpose: Patients with alcohol use disorders who are admitted to the hospital must be managed for the possibility of alcohol withdrawal syndrome. The high mortality rate associated with alcohol withdrawal syndrome makes it of high importance if caring for one of these patients. Currently, there is no standardized practice for managing these patients leading to inconsistent care and mismanagement during hospitalization. The purpose of this study is to implement a devoted pharmacist role to care for these patients and retrospectively assess its effectiveness.

Methods: This study will be a retrospective, chart review evaluating patients who have been enrolled in the alcohol withdrawal protocol before and after the implementation of a pharmacist led rounding team. The pharmacist led rounding team will include a standard work-up for the pharmacist in order to assess symptoms, medication use and potential interventions. Outcomes of this study will include hospital length of stay, duration of alcohol withdrawal, adherence to the protocol, cumulative amounts of benzodiazepine doses, incidence of adjunct therapy use, and rates of intubation. The patients must be enrolled in to the alcohol withdrawal protocol and over the age of eighteen to be enrolled in the study. Descriptive statistics will be used to assess outcomes.

Results: To be determined.

Conclusion: To be determined.

Poster Title: Optimization of Clostridium difficile treatment utilizing patient risk factor assessment and an antimicrobial stewardship bundle

Primary Author: John Robinson, Munson Medical Center, MI; Email: jrobinson7@mhc.net

Additional Author(s):
Nicholas Torney
Derek Vander Horst

Purpose: Clostridium difficile infections (CDIs) have been identified as an urgent threat by the Centers for Disease Control (CDC) and is a major focus of antimicrobial stewardship programs across the United States. This study will analyze the impact that an antimicrobial stewardship team has on compliance of an evidence-based C. diff bundle for patients with active CDI in a community hospital.

Methods: This study will be submitted to the Institutional Review Board for approval. The study will be quasi-experimental in nature. Patients will be identified by positive C. diff toxin PCR and/or active orders for oral vancomycin. Data that will be collected include patient age, gender, serum creatinine, white blood cell count, number of bowel movements, blood pressure, systemic antibiotic use, acid suppressant use, probiotic use, anti-peristaltic use, and appropriate CDI treatment (antibiotic selection and duration of therapy). All data will be recorded without patient identifiers and stored securely. The primary outcome is incidence of compliance with bundle elements. Bundle elements will be weighted based on their association with disease recurrence, complications, and impact on outcomes. Secondary outcomes include compliance with each individual bundle element, in-hospital mortality, length of stay, and recurrence rates up to 60 days. Appropriate statistical analysis will be applied to parametric and non-parametric data.

Poster Title: Identification of modifiable risk factors for delirium in mechanically ventilated patients in a community-based medical center

Primary Author: Joseph Zerka, Munson Medical Center, MI; Email: jzerka@mhc.net

Additional Author(s):
Trevor Warner

Purpose: Delirium affects 30-80% of ICU patients and is associated with increased time on the ventilator, longer ICU length of stay, and increased mortality. At Munson Medical Center, the incidence of delirium within the intensive care unit is unknown. The primary objective of this analysis is to identify the incidence of delirium within the ICU, defined by a single positive CAM-ICU exam. The secondary objective is to identify modifiable risk factors that will contribute to positive CAM-ICU scores. This will be accomplished by a retrospective chart review of mechanically ventilated patients at a 400-bed community based medical center.

Methods: Prior to initiation, this project will be submitted for review to the Institutional Review Board. The electronic medical record will be used to identify patients who are CAM-ICU negative at admission and become CAM-ICU positive during their time in the intensive care unit. Inclusion criteria include patients admitted to the intensive care unit with mechanical ventilation. Exclusion criteria include patients with active alcohol withdrawal and patients ≤18 years. The following baseline data will be collected: sex, age, admission diagnosis, and patient type (i.e. medical, trauma). The incidence of delirium will be defined as a positive CAM-ICU exam having followed a negative CAM-ICU exam whilst in the ICU. Patients who are CAM-ICU positive will then be matched with CAM-ICU negative patients based on age and admission diagnosis. Modifiable risk factors, including cumulative benzodiazepine and steroid administration and nighttime medication administration 24 hours preceding delirium incidence, will be examined between groups.

**Poster Title:** Impact of pharmacist intervention on duration of antibiotic therapy in patients with non-intensive care unit community acquired pneumonia: a quasi-experimental study

**Primary Author:** Katelin Anderson, Munson Medical Center, MI; **Email:** kanderson22@mhc.net

**Additional Author(s):**
Nicholas Torney
Derek Vander Horst

**Purpose:** Current literature suggests that antimicrobial stewardship programs can have a significant impact on optimizing therapy and improving outcomes for common disease states, such as community-acquired pneumonia (CAP). The primary objective of this study is to determine if pharmacist intervention decreases length of antibiotic therapy in patients with non-intensive care unit (ICU) community acquired pneumonia (CAP) at Munson Medical Center. The antimicrobial stewardship team currently performs prospective audit and feedback on patients receiving broad-spectrum antibiotics, but does not target pneumonia patients specifically.

**Methods:** This study is awaiting investigational review board approval. This study is a quasi-experimental chart review of patients with a diagnosis of pneumonia who presented to Munson Medical Center. Retrospective data were collected as a part of the Michigan Hospital Medicine Safety Consortium by a nurse data specialist. Patients with an admitting diagnosis of pneumonia will be included. Patients will be excluded: if they are admitted to an intensive care unit, less than eighteen years of age, have a CD4 count less than 200, have neutropenia, are status post-transplant. For the prospective arm of the study, the infectious diseases (ID) pharmacist and physician will review patients with pneumonia and make recommendations to the primary provider in regards to the antimicrobial agent and duration of therapy. Outcomes will be compared to historical data that were collected without targeted ID pharmacist intervention. The primary outcome of this study is to determine if patients who receive pharmacist intervention have a decreased duration of therapy. Secondary outcomes include concordance with Infectious Diseases Society of America guidelines, Clostridium difficile infection rates, thirty day readmission rate, bacterial pathogen, length of hospital stay, and
mortality. Appropriate statistical analysis will be applied to parametric and non-parametric data.

Poster Title: Evaluation of alcohol withdrawal management at a large community teaching hospital

Primary Author: Daraoun Mashrah, not applicable, MI; Email: daraoun.mashrah@beaumont.org

Additional Author(s):
Tania Paydawy
Jennifer Pilotto
Rebecca Goldsmith
Patricia Pentiak

Purpose: Prevalence of alcohol abuse in the United States is approximately 18%. Alcohol withdrawal syndrome (AWS) occurs when there is a cessation or reduction of alcohol use leading to severe withdrawal symptoms affecting patients overall quality of health. These patients are at higher risk for longer intensive care unit and hospital length of stays, as well as mortality. Benzodiazepines are traditionally the treatment of choice for AWS; however, there are alternative methods of treatment. The purpose of this study is to evaluate compliance of a protocol for AWS treatment in a large community teaching hospital.

Methods: This is a single-center retrospective study of adult patients being treated for AWS from July 1, 2015 through June 30, 2016. The electronic medical record will be used to identify patients treated for AWS. Pregnant patients will be excluded from this study. Compliance to our institutional protocol for AWS, which uses the Clinical Institute Withdrawal Assessment for Alcohol tool and standardized lorazepam doses, will be evaluated, as well as pertinent data in order to identify appropriate management and treatment strategy. The patient demographics and past medical history will also be collected. Descriptive statistics will be used to compare patient baseline demographics and characteristics. Results from this data may help improve AWS treatment practice in our institution as well as provide better quality of care for our patients.

Poster Title: Impact of warfarin dosing on short-term bleeding events in left-ventricular assist device patients

Primary Author: Audrey Rosene, Spectrum Health, MI; Email: audrey.rosene@spectrumhealth.org

Additional Author(s):
CJ Michaud

Purpose: While the outpatient anticoagulation management in left-ventricular assist device (LVAD) patients is somewhat well-described, there is a paucity of data related to peri-operative warfarin use and its associated outcomes. Evidence exists to guide heparin and aspirin use, but the lack of data regarding warfarin causes high variability in dosing strategies to mitigate the risks of thrombotic and bleeding events. The objective of this study is to compare the incidence of peri-operative bleeding events between LVAD patients who achieved a therapeutic INR in less than or equal to 7 days versus greater than 7 days.

Methods: This study is a retrospective review of adult patients admitted to Spectrum Health Butterworth Hospital for an LVAD implantation from January 1st, 2011 to July 30th, 2016. A minimum of 51 patients will be included in each arm to meet 80% power and to detect a 33% difference in bleeding events between the two comparator groups. Data that will be collected includes: baseline demographics, LVAD-related data, history of bleeding or thrombotic event, anticoagulation therapy prior to LVAD implantation, and relevant pre-and post-operative laboratory values. Intraoperative data to be collected includes surgical technique, need for cardiopulmonary bypass, and administration of fresh frozen plasma, cryoprecipitate, packed red blood cells, platelets, Factor IX complex (Profilnine®), Prothrombin complex concentrate (Kcentra®), and Antihemophilic Factor/von Willebrand Factor Complex (Humate-P®). Post-operative coagulation data, including heparin and aspirin use, will be collected as well as timing of warfarin initiation and time to therapeutic INR (days). The primary outcome comparing the incidence of major or minor bleeding events between the two aforementioned groups will be defined using INTERMACS definitions. Other outcomes include incidence of pump thrombosis, ICU length of stay, hospital length of stay, and mortality.

**Poster Title:** Implications of high-dose intrapartum maternal gentamicin on neonates

**Primary Author:** Andrea McCarty, Spectrum Health, MI; **Email:** andrea.mccarty@spectrumhealth.org

**Additional Author(s):**
Sara Ogrin
Beata Rivard
Lindsay Schray

**Purpose:** The use of intrapartum high-dose extended interval gentamicin is becoming standard practice for various obstetric conditions; however, literature is lacking on the ideal dosing of gentamicin in neonates born to mothers who received high-dose extended interval gentamicin during the intrapartum period. The purpose of this study is to evaluate the safety and efficacy of one institution’s gestational age-based gentamicin protocol in neonates whose mothers received intrapartum high-dose extended interval gentamicin.

**Methods:** This retrospective chart review will be conducted at a single institution in Grand Rapids, Michigan. Neonates will be included in the study if they were born to mothers who received high-dose extended interval gentamicin at least once during the intrapartum period and if they received at least one dose of gentamicin within 24 hours post-delivery. Maternal data to be collected includes age, delivery method, baseline serum creatinine, and number of gentamicin doses prior to delivery. Neonatal data to be collected includes gestational age, birth weight, gentamicin dose, initial gentamicin trough, urine output or diaper count, and length of hospitalization. The primary objective is to compare the proportion of neonates with a gentamicin trough level greater than 1 mcg per mL from a historical control group within the literature to the proportion of neonates with a gentamicin trough level greater than 1 mcg per mL from the present study where the mother received intrapartum high-dose extended interval gentamicin. Secondary objectives include the incidence of neonatal dose adjustment, calculated sepsis risk score, mean change in urine output and diaper count, length of hospitalization, and in-hospital mortality. Statistical analysis will include independent samples t-test for quantitative variables and chi-squared test for qualitative variables. A one-tailed two-proportion z-test will
be used to evaluate the primary endpoint. This study will be submitted to the Institutional Review Board for approval.

Poster Title: Effect of desmopressin on hematoma expansion in patients with spontaneous intracranial hemorrhage on antiplatelet agents

Primary Author: Brooke Crandall, Spectrum Health, MI; Email: brooke.crandall@spectrumhealth.org

Additional Author (s):
Kyle Schmidt

Purpose: Spontaneous intracranial hemorrhage (sICH) is a devastating condition with a high incidence of early deterioration. Antiplatelet therapy at the time of sICH diagnosis may be associated with worse outcomes. Desmopressin has been shown to increase von Willebrand factor in patients with platelet dysfunction and help restore coagulation. Current guidelines for the reversal of antithrombotic agents in ICH recommend consideration of a single dose of desmopressin in sICH associated with antiplatelet agents, although data supporting its use is minimal. This study aims to evaluate the efficacy of desmopressin in patients with sICH on an antiplatelet at the time of diagnosis.

Methods: This study will be submitted to the Institutional Review Board for approval. This is a retrospective chart review of adult patients admitted to Spectrum Health Butterworth Hospital with spontaneous intracranial hemorrhage. ICH and APACHE-II scores will be utilized to match patients on an antiplatelet agent at diagnosis of sICH who received desmopressin similar to patients who did not receive desmopressin for comparison. Patients will be excluded if they presented with traumatic brain injury, have an active coagulopathy (including anticoagulation) and/or have thrombocytopenia. Data will be collected to characterize patient demographics, length of stay, discharge disposition, hemodynamic data, functional neurological outcomes, concomitant medications and blood product utilization. The primary outcome will be incidence of hematoma expansion on follow-up head computed tomography scanning performed after the initial scan. Secondary outcomes will include in-hospital mortality and change in Modified Rankin Scale from baseline.

Poster Title: Impact on renal function and tolerability of everolimus based immunosuppression in adult thoracic transplant patients

Primary Author: Shelby Kelsh, Spectrum Health, MI; Email: shelby.kelsh@spectrumhealth.org

Additional Author(s):
Jennifer McDermott

Purpose: Everolimus based immunosuppression has been increasingly utilized off-label in heart and lung transplant patients due to a different adverse effect profile than standard first-line immunosuppressive therapy of tacrolimus, mycophenolate mofetil, and prednisone. Everolimus may offer potential benefits in select patients including those that develop renal dysfunction, malignancy, cytomegalovirus infection, cardiac allograft vasculopathy, and bronchiolitis obliterans syndrome post-transplant. The purpose of this study is to assess the efficacy and safety of everolimus based immunosuppressive therapy in heart and lung transplant patients.

Methods: This retrospective chart review has been submitted to the Institutional Review Board for approval. Patients that underwent a heart or lung transplant and received everolimus between November 2010 and September 2016 with at least 90 days follow-up will be included. Baseline demographics and characteristics will be collected and include age, sex, race, transplant type, transplant indication, concomitant immunosuppression, cytomegalovirus donor and recipient serostatus, and everolimus indication and start date. The following endpoints will be collected and compared prior to and after everolimus initiation: estimated glomerular filtration rate utilizing the modification of diet in renal disease equation, need for renal replacement therapy, incidence of rejection and grade if applicable, presence of donor specific anti-HLA antibodies, incidence of infection and type if applicable, incidence of malignancy, incidence of cardiac allograft vasculopathy in heart transplant, and incidence of bronchiolitis obliterans syndrome in lung transplant. In addition, total cholesterol, triglycerides, LDL cholesterol, presence of leukopenia defined as white blood cell < 3,000 cells/mm3, presence of neutropenia defined as absolute neutrophil count < 1,000 cells/mm3, presence of proteinuria, documented edema, and documented delayed wound healing will be collected at baseline and after everolimus initiation to assess tolerability. The primary endpoint is the
change in estimated glomerular filtration rate utilizing the modification of diet in renal disease equation, from baseline to 3 months post-everolimus initiation.

Poster Title: Duration of steroid taper after vasopressor cessation in septic shock

Primary Author: Ahlam AlMansoub, Spectrum Health, MI; Email: ahlam.almansoub@spectrumhealth.org

Additional Author(s):
Matthew Gurka

Purpose: The Surviving Sepsis Campaign guidelines recommend hydrocortisone in an effort to restore hemodynamic stability in patients with septic shock refractory to fluid resuscitation and vasopressor therapy. Hydrocortisone is recommended to be tapered off when vasopressor therapy is no longer required; however, current guidelines make no recommendation regarding the optimal duration of hydrocortisone taper. The purpose of this study is to investigate the effects of the duration of hydrocortisone taper on 28-day incidence of return to vasopressor support.

Methods: This retrospective cohort study will evaluate patients admitted to the intensive care units (ICUs) at Spectrum Health Butterworth and Blodgett campuses in Grand Rapids, MI for septic shock between December 15, 2015 and November 30, 2016. Patients included in the study must be 18 years of age or older, initiated on the institutional severe sepsis order set, required treatment with at least two vasopressors or a dose of a single vasopressor of norepinephrine or epinephrine greater than or equal to 0.2 mcg/kg/min, dopamine greater than or equal to 10 mcg/kg/min, or phenylephrine greater than or equal to 100 mcg/min, treated with vasopressors for at least one hour, and treated with at least 200 mg total daily doses of hydrocortisone for at least 24 hours before taper. Data will be collected for two intervention arms: patients exposed to an initial total daily dose of 200 mg or greater of hydrocortisone until vasopressor cessation and then (1) tapered over 3 or fewer days or (2) tapered over greater than 3 days. The primary outcome will be incidence of vasopressor resumption, defined as restarting vasopressor support during or after hydrocortisone taper within 28 days of initial withdrawal. Secondary endpoints will include ICU length of stay, hospital length of stay, ICU mortality, hospital mortality, total duration of hydrocortisone exposure, total hydrocortisone dose exposure, and duration of vasopressor use.

Conclusion: N/A
**Poster Title:** Antithrombin III dose response in children on extracorporeal membrane oxygenation

**Primary Author:** Courtney Carroll, Spectrum Health (Helen DeVos Children's Hospital), MI; Email: ccarroll141@gmail.com

**Additional Author(s):**
Emily D'Anna

**Purpose:** Systemic anticoagulation is imperative during extracorporeal membrane oxygenation (ECMO) to prevent thrombus formation on non-biological surfaces of the ECMO circuit. Unfractionated heparin, the anticoagulant agent of choice, functions by potentiating antithrombin III (ATIII), an endogenous anticoagulant. Inadequate ATIII levels are often supplemented with ATIII concentrate when increased rates of heparin are required to maintain therapeutic anticoagulation. However, there is little published evidence on best practices for ATIII dosing in pediatric patients on ECMO. The purpose of this study is to evaluate the dose response to ATIII concentrate in pediatric patients by assessing the change in ATIII plasma levels post-supplementation.

**Methods:** An antithrombin III dosing guide for neonatal and pediatric patients was implemented at Helen DeVos Children’s Hospital (HDVCH) in November 2013, which utilizes a patient-specific dosing weight to account for the ECMO circuit volume. This single-center, retrospective study aims to analyze pediatric patients who received at least one dose of ATIII concentrate while on ECMO in the pediatric intensive care unit at HDVCH between November 1, 2013 and August 31, 2016. The primary objective of this study is to determine the change in ATIII plasma levels after administration of ATIII concentrate. Secondary objectives include evaluating the effects of ATIII concentrate on unfractionated heparin requirements, correlated changes in coagulation lab values, and transfusion requirements at time of ATIII dose and up to 72 hours post-ATIII supplementation. Safety endpoints include number of bleeding and thrombosis events. Descriptive statistics will include patient demographics, indication, type, and duration of ECMO, ICU and hospital length of stay, and in-hospital mortality. Quantitative data will be expressed as mean ± standard deviation, while qualitative data will be expressed as a percentage. Linear regression analysis will be performed to determine the change in ATIII
plasma levels after the first administration of ATIII concentrate, and subsequent ATIII doses will be analyzed via linear multiple regression. The effects of ATIII supplementation on heparin requirements will be evaluated via repeated measures ANOVA.

Poster Title: Evaluations of medications upon discharge utilizing automatic therapeutic interchanges

Primary Author: Raymond Phung, St. John Hospital and Medical Center, MI; Email: raymond.phung@ascension.org

Additional Author(s):
Christopher Giuliano
Michelle Dehoorne-Smith
Roseanne Paglia
Melissa Lipari

Purpose: Automatic therapeutic interchanges (ATIs) have been employed by many institutions to optimize medication utilization while reducing cost. Automatic therapeutic interchanges are described as the exchange of a therapeutically equivalent drug from a patient's home regimen to a medication on a hospital's formulary. There are concerns that if automatic therapeutic interchanges are not executed properly, patients may be discharged with potential detrimental medication errors. The purpose of this study is to evaluate the frequency a patient is returned to original home therapy upon discharge following automatic therapeutic interchange of a medication to the hospital's formulary.

Methods: This single-center, retrospective chart review will evaluate adult patients who were admitted to St. John Hospital and Medical Center with at least one home medication documented as an angiotensin-converting enzyme (ACE) inhibitor, angiotensin receptor blocker (ARB), antidepressant, insulin, inhalers, or metformin, and switched to a hospital formulary medication via automatic therapeutic interchange (ATI). Patients will be identified by an order from the Cerner system for a therapeutic interchange from January 1, 2016 to June 30, 2016. Patients will be excluded if they expired prior to discharge. Data collected will include patient's baseline demographics, including patient's age, gender, and race; admission drug name, strength, and dose; ATI drug name, strength, and dose; discharge drug name, strength, and dose; length of stay, hospital service responsible for patient care, and patient disposition.

**Poster Title:** Loose use of continuous infusion midazolam  

**Primary Author:** Nathan French, St. John Hospital and Medical Center, MI; **Email:** nathan.french@ascension.org  

**Additional Author(s):**  
Stephanie Edwin  
Carrie Hartner  
Renee Paxton  

**Purpose:** Benzodiazepines are discouraged for routine sedation in critically ill patients due to deleterious side effects; however, use may be appropriate in select situations. The goal of this study is to evaluate the appropriateness of benzodiazepine infusions in critically ill patients requiring mechanical ventilation.  

**Methods:** This study has been approved by the Institutional Review Board. This retrospective, observational study will evaluate adult patients (n=150) with an order for midazolam infusion from January – August 2016. Criteria for appropriate use will be defined as history of alcohol abuse/withdrawal, status epilepticus, refractory agitation or ventilator dyssynchrony with hypotension maximized on alternative agents, therapeutic paralysis, or chronic benzodiazepine use. Patients will be evaluated to determine if appropriate analgesia and “as needed” benzodiazepine were trialed prior to initiation of midazolam infusion. Adverse effects while receiving midazolam infusion will be collected, including delirium, over sedation, and need for a head CT prior to extubation. Renal function, hepatic function, and CYP3A4 drug interactions will be assessed to determine the risk of midazolam accumulation.  

**Results:** N/A  

**Conclusion:** N/A

Poster Title: Tissue plasminogen activator (tPA) administration accuracy and timing in the emergency department (ED) with a pharmacist versus no pharmacist present

Primary Author: Samantha Scalia, St. John Hospital and Medical Center, MI; Email: samantha.scalia@ascension.org

Additional Author (s):
George Delgado

Purpose: An observational retrospective review assessing tPA administration time and accuracy has the potential to decrease medical errors in the emergency department. This study will investigate the effectiveness of having pharmacist coverage in the emergency department to assist with tPA administration.

Methods: This single-center, retrospective, chart review study will evaluate all patients 18 years and older who received tPA in the ED at St. John Hospital and Medical Center. A list of all patients receiving tPA from January 2013 to July 2016 will be generated from the St. John Pharmacy Information System. Patients will be further categorized to include only the patients who received tPA in the ED. No patient will be excluded if they fit these criteria. Data collection will include age, gender, race, time patient arrived to the hospital, symptom onset, NIH stroke scale classification (initial, 24 hours after, 48 hours after, discharge), tPA administration information (order time and needle time), whether a pharmacist was present, and reason for delay in tPA administration (if applicable). Door to Needle times will be assessed, with the goal door to needle time of 60 minutes or less.

Poster Title: Safety and efficacy of high-dose intravenous labetalol

Primary Author: Syeda Mahmood, St. Joseph Mercy Hospital, MI; Email: maahin@umich.edu

Additional Author(s):
Jason Hecht

Purpose: The intravenous (IV) labetalol package insert suggests a maximum daily dose of 300 milligrams despite the widespread use of much higher daily doses in hypertensive emergencies. Multiple studies have looked at patients that received more than 300 milligrams per day but none specifically looked at safety outcomes. The only literature available on the safety of this practice are case reports. This will be the first study of its kind to assess the safety and efficacy of this practice.

Methods: This is a retrospective, multi-center study, whose patients will be identified using the electronic medical medical record. Patients are eligible for the study if they have received at least 300 milligrams of IV labetalol within a 24 hour period. Patients will then be followed from that point for 24 more hours to ascertain the occurrence of study outcomes. The primary outcome will examine the incidence of hypotension (systolic blood pressure less than 90 mmHg) or bradycardia (heart rate less than 60 beats per minute). Secondary outcomes will evaluate the incidence of hypotension alone, the incidence of bradycardia alone, the time to reach blood pressure goal, presence of symptomatic bradycardia or use of rescue agents, and the effects on length of stay or mortality. The following data will be collected: patient demographics, comorbidities, and past medical history as well as primary diagnoses, blood pressure and heart rate information during the admission, IV labetalol rate, cumulative dose, number of drug titrations, hospital length of stay, intensive care unit length of stay, and mortality information. Multivariate Cox proportional hazards model will be used to model the association between additional doses of IV labetalol beyond 300 milligrams and the time to events. This study will be submitted to the Institutional Review Board for approval, and all data will be recorded without patient identifiers and maintained confidentially.

Poster Title: Clinical and economic outcomes from a community hospital's ASP: Part II

Primary Author: Scott Kollmeyer, St. Joseph Mercy Hospital - Ann Arbor, MI; Email: kollmey2@gmail.com

Additional Author(s):
Curtis Collins

Purpose: Antimicrobial resistance, Clostridium difficile infection (CDI), and cost of infection are a serious public health issue and a continuing concern for hospitals across the country. Many studies have been published reporting the beneficial effects of antimicrobial stewardship programs (ASP), some of which include reduced rates of resistance and CDI as well as reduced cost. A previous study at our institution reported decreases in CDI and antimicrobial cost during the first year of the ASP. Since then, our ASP has continued to evolve. The objective of this study is to evaluate the sustained success of our ASP following our initial report.

Methods: This study has been submitted and approved by our organization's Institutional Review Board. All adult patients with an antimicrobial order admitted to our facility between January 2011 and December 2015 will be included. Study outcomes will include: the incidence of multi-drug resistant infections, hospital length of stay, intensive care unit days, readmission within 30 days, mortality within 30 days, total antimicrobial costs, antimicrobial costs per patient-day, criteria restricted antimicrobial cost per patient day, and antimicrobial days of therapy per 1,000 patient days. Outcomes will be stratified by calendar year and trended. A cost-analysis will be performed analyzing indirect cost-avoidance due to reductions in CDI and MDR infection rates.

Poster Title: Evaluation of a protocol implemented for the inpatient management of acute agitation

Primary Author: Sarah Kean, St. Joseph Mercy Hospital, Ann Arbor, MI; Email: sarah.kean@stjoeshealth.org

Additional Author (s):
Nina West

Purpose: Outside of the intensive care setting and for patients in alcohol withdrawal, there is little data and no standardized way to manage acutely agitated patients. The objective of this study is to determine if the use of a nursing-driven treatment protocol, which includes a standardized assessment scale, for the management of acute agitation will reduce adverse events, improve appropriate dosing of antipsychotic/anxiolytic medications, and reduce the need for restraints.

Methods: A treatment protocol for the management of acute agitation, which includes a standardized scale for assessing level of agitation, will be designed by a multidisciplinary team and approved by the medical staff. The use of this protocol will be piloted on two medical nursing units. The efficacy of this protocol will be studied via a retrospective chart review pre- and post- implementation, after receiving approval from the Institutional Review Board. All adult patients who received medical management for agitation will be included. Patients being treated for alcohol withdrawal will be excluded. The following patient data will be collected: medical unit, date of admission and discharge, age, gender, weight, creatinine clearance, ethnicity, marital status, medication allergies, home medications, primary reason for agitation, fall (yes/no), anxiolytics/antipsychotics prescribed and number of doses given, concurrent medications, restraints (yes/no), total time in restraints, and nursing assessment documentation. The following outcomes will be evaluated: percentage of patients requiring restraints, mean number of hours in restraints, percentage of falls, risk of QTc prolongation based on categories defined by hospital guidelines, and the use of “as needed” doses of anxiolytics/antipsychotics. Additionally, nursing perception and comfort level in managing acutely agitated patients will be evaluated through two anonymous surveys, given pre- and post- protocol implementation.

Poster Title: Determining an optimal blood glucose management strategy for acute coronary syndrome patients at a community teaching hospital

Primary Author: Jennifer Gregory, St. Joseph Mercy Hospital-Ann Arbor, MI; Email: jennifer.gregory001@stjoeshealth.org

Additional Author(s):
Beena Cherian
Kay Lyn Stalker

Purpose: There has been considerable controversy regarding the appropriate therapeutic strategy for managing blood glucose levels in acute coronary syndrome (ACS) patients. Controversy regarding blood glucose management in this patient population stems from several studies providing conflicting mortality results with aggressive glycemic control. The goal of this study is to evaluate the aggressiveness of blood glucose management in ACS patients at our institution, by comparing insulin drips to conventional therapy (i.e. insulin sliding scale/basal-bolus), specifically evaluating the safety and efficacy of each.

Methods: This study will be submitted to the Institutional Review Board for approval. Patients who are admitted between the dates of October 2014 and October 2016 with a diagnosis of ACS will be eligible for review. To be included in this study, patients must present with an admission blood glucose value greater than or equal to 180 mg/dL, be managed via insulin therapy, and have a hospital length of stay of at least 48 hours. Patients will be excluded from review if they have any type of hypersensitivity reaction to insulin, are pregnant, are less than 18 years of age, are undergoing therapeutic hypothermia, or are transferred to a non-cardiac unit during their hospital admission. Patient data will be gathered retrospectively from electronic medical records. The efficacy of blood glucose management will be determined from the patient’s average blood glucose value during hospital admission, considering all blood glucose recordings from the entire hospital length of stay. The safety of each blood glucose management strategy will be determined via the incidence of hypoglycemic events. Patient outcomes in accordance to blood glucose management strategy, such as 30-day hospital mortality and 30-day hospital readmission rate, will also be evaluated.

Poster Title: Appropriateness of pharmacy renal dosing service interventions

Primary Author: Krystyna Mott, St. Joseph Mercy Oakland, MI; Email: krystynamott@gmail.com

Additional Author(s):
Tana Hannawa
Dustin Gladden

Purpose: Renal drug dosing services provided by a pharmacist have been shown to increase appropriate dose recommendations, decrease adverse drug events, and decrease drug costs. The purpose of this study is to assess the current appropriateness and clinical outcomes associated with the pharmacy adjusted renal dosing service approved at St. Joseph Mercy Oakland. This study will also serve to assess the appropriateness of documentation being done on these patients through the medication surveillance advisor.

Methods: The medication surveillance advisor will be used to identify patients to include in a retrospective chart review. Within a six-month time period, all patients on antimicrobial, anticoagulant, or famotidine therapy within the renal dosing protocol, with alerts for renal function dose adjustment will be included. Patients that are pregnant or less than eighteen years of age will be excluded. Baseline demographic information collected will include: age, sex, and ethnicity. Appropriateness of pharmacy adjusted dosing based on renal function will include patient clinical outcomes. These outcomes will include: effectiveness, such as clinical resolution of infection, and adverse drug events, such as bleeding. Kidney function will be assessed at baseline, and over the length of stay of the patient. Assessment of whether medication doses have been increased or decreased appropriately according to the pharmacy renal dosing protocol will be documented. The number of alerts fired by the medication surveillance advisor will be compared to the number of alerts documented by pharmacy to assess the appropriateness of documentation being done.

Poster Title: Assessment of appropriate use of stress ulcer prophylaxis in hospitalized patients

Primary Author: Megan Cruz, St. Joseph Mercy Oakland, MI; Email: meondusky@yahoo.com

Additional Author (s):
Eric Lambart
Sawsan Shayota
Dustin Gladden

Purpose: The incidence of stress related mucosal damage has decreased over time. In patients with risk factors, proton pump inhibitors (PPI) and histamine-2 receptor antagonists (H2RA) are the recommended drugs of choice for stress ulcer prophylaxis (SUP). There are currently guidelines for SUP prescribing at Saint Joseph Mercy Oakland (SJMO), but adherence has not recently been assessed. The purpose of this study is to assess the current management of SUP in hospitalized patients, including the appropriateness of use and discontinuation.

Methods: This retrospective chart review, submitted to the Institutional Review Board for approval, will be conducted by identifying patients admitted to the hospital in August 2016 that received more than one dose of a PPI or H2RA. Data will be collected from electronic medical records. Patients will be excluded from the study if they have a history of gastroesophageal reflux disease, if they are on a home regimen of a PPI or H2RA, if they are pregnant or breast feeding, if they are less than eighteen years of age, and if they have an indication for PPI or H2RA use other than SUP. Clinical outcomes and parameters assessed will include indications for SUP, patient history, inpatient medications, discharge medications, renal function, hepatic function, length of stay, acquired infections such as pneumonia and clostridium difficile, total drug costs, appropriateness of dose, and conversion from intravenous to oral dosage form. All data will be recorded without patient identifiers and maintained confidentially. Primary outcomes include the appropriate utilization and discontinuation of SUP as defined by SJMO SUP guidelines. Secondary outcomes consist of adverse events associated with the SUP treatment and total drug costs.

Results: To be presented at the 2016 ASHP Midyear Clinical Meeting in Las Vegas, NV.

Poster Title: State of outpatient opioid analgesia prescribing in a community teaching hospital: A surveillance study assessing acute pain patients presenting to the emergency department

Primary Author: Michelle Stewart, St. Joseph Mercy Oakland, MI; Email: michelle.stewart@stjoeshealth.org

Additional Author(s):
Andrew Arter
Tana Hannawa

Purpose: When it comes to prescribing opioid pain medications, Emergency Room practitioners are at the front lines of the ongoing opioid epidemic. With nearly two-thirds of all emergency room visits accounting for a pain related illness, the task of providing compassionate and responsible patient care is becoming increasingly more difficult. The purpose of this study is to assess the current state of ambulatory analgesia prescribing for adults by Emergency Department providers at St. Joseph Mercy Oakland (SJMO) to determine key impact areas for a pharmacist-delivered provider education series.

Methods: This is a retrospective chart review study of patients presenting the SJMO Emergency Department (ED) during a six-month time period. The study will use de-identified patient information to analyze the rates and respective trends of opioid and nonopioid prescribing at discharge. The specific opioid analgesics that will be included in the analysis are hydromorphone, morphine, oxycodone, hydrocodone, codeine, and tramadol. The specific nonopioid analgesics that will be included are acetaminophen, ibuprofen, and naproxen. Data to be collected from the electronic medical record (EMR) will include, but not limited to: patient demographics, primary care provider designation, relevant inpatient and outpatient prescribing information, admitting diagnosis, pain scores, and source of primary payment. Patients will be included in the study if they presented to the ED with a chief complain of abdominal pain, back pain, chest pain, headache, musculoskeletal pain, tooth/mouth pain, or ear pain. This study will exclude any patients who are less than eighteen years of age, pregnant or breastfeeding, have a history of cancer or sickle cell disease, or were subsequently admitted to the hospital from the ED for further medical attention.
Results: To be presented at the 2016 ASHP Midyear Clinical Meeting in Las Vegas, NV.

Conclusion: To be presented at the 2016 ASHP Midyear Clinical Meeting in Las Vegas, NV.

Poster Title: Appropriateness of clostridium difficile management at a community teaching hospital

Primary Author: Drita Nicaj, St. Joseph Mercy Oakland, MI; Email: drita.nicaj@stjoeshealth.org

Additional Author(s):
Dustin GLadden
Richard Valone

Purpose: Clostridium difficile (C. diff) is an anaerobic bacteria causing colitis symptoms in patients. Literature indicates that this infection is responsible for the majority of nosocomial infectious diarrhea. But the burden of this infection extends beyond the patient and is staggering for the healthcare system. The Infectious Diseases Society of America (IDSA) has identified therapy guidelines for the treatment and prevention of C. diff infection. St. Joseph Mercy Oakland (SJMO) has tailored their C. diff guideline to reflect the IDSA recommendations. The objective of this medication usage evaluation (MUE) is to determine the compliance rate with the C. diff treatment guideline.

Methods: This study has been submitted to the Institutional Review Board for approval. Retrospective data will be collected via the electronic medical record. The inclusion criteria of this MUE is 18 years of age or older, having a diagnoses of C. diff through a positive stool culture test/enzyme immunoassay for C. diff toxins, and receiving treatment for C. diff with oral vancomycin or oral metronidazole. Data collection will include: patient demographics (age, gender), antimicrobial lab culture results, medications prescribed, white blood cell count, serum creatinine level, number of prior episodes of C. diff, consultation orders for an infectious disease specialist, physician notes, length of stay at the hospital, presence of vasopressors, toxic megacolon or ileus, probiotic therapy, and documented pharmacy interventions. The primary outcome of this MUE is to assess the appropriate choice of antimicrobial therapy based upon the currently approved SJMO C. diff guidelines. Secondary outcomes will include the percent completion of the entire C. Diff bundle. Complete compliance with the C. Diff bundle will include the discontinuation of unnecessary acid-suppressing medications and unnecessary antibiotics.

Poster Title: Impact of in-utero exposure to selective serotonin reuptake inhibitors (SSRIs) and opioids on neonatal abstinence syndrome (NAS)

Primary Author: Jessika Richards, University of Michigan Health System, MI; Email: richarjr@med.umich.edu

Additional Author (s):
Varsha Bhatt-Mehta
Robert Schumacher

Purpose: The use of opioids and antidepressants during pregnancy is widespread and the incidence of infants born with neonatal abstinence syndrome (NAS) has steadily increased over the past decade. Prenatal exposure to both of these drug classes can have significant impact on the neurobehavior of infants often leading to long, complex, and costly hospitalizations. The objective of this study is to compare short term outcomes of neonatal abstinence syndrome treatment in infants exposed in-utero to opioids alone or opioids plus selective serotonin reuptake inhibitors (SSRIs).

Methods: This single-center retrospective cohort study has been submitted to the Institutional Review board for approval. All infants admitted to the Brandon Newborn Intensive Care Unit (NICU) at C.S. Mott Children’s Hospital between January 2009-July 2016 meeting criteria will be identified through electronic health records and the Vermont Oxford Network (VON) database. Infants will be grouped into two cohorts based on in-utero exposure to an opioid alone or an opioid plus an SSRI. Infants whose mother received an opioid or an opioid plus an SSRI and was greater or equal to eighteen years of age with a gestation greater or equal to thirty-four weeks and who required treatment of NAS with methadone at a postnatal age of less than or equal to seven days of life based on NICU treatment guidelines will be included in the study. Infants will be excluded if they received methadone for treatment of iatrogenic withdrawal or were prenatally exposed to psychotropic medications other than SSRIs. Neonatal and maternal demographic data will be collected. Additionally, the following data points will be collected: max Finnegan score, time to symptom control, length of methadone treatment, length of hospitalization, cumulative methadone dose, second medication use, and discharge therapy.
The primary endpoint of this study will be the total length of treatment with methadone for resolution of NAS symptoms.

**Poster Title:** Outcomes in the Treatment of Previously Untreated Elderly Acute Myeloid Leukemia: A Comparison of Clofarabine versus Fludarabine (FLAG)

**Primary Author:** Gianni Scappaticci, University of Michigan Health System, MI; **Email:** gbscapp@med.umich.edu

**Additional Author(s):**
Anthony Perissinotti
Dale Bixby
Vera Vulaj
Bernard Marini

**Purpose:** Optimal therapy for Acute Myeloid Leukemia (AML) in elderly patients remains controversial and the presence of comorbid conditions, decreased drug clearance, and an increased proportion of unfavorable cytogenetics all contribute to poor response rates and overall survival (OS). Data regarding the optimal induction strategy in these patients are limited. Our institution utilizes a Clofarabine based or FLAG induction regimen upfront for fit elderly AML patients, whereas unfit elderly patients receive Decitabine. This study will compare complete response rates, long-term efficacy outcomes, along with treatment related morbidity and mortality between Clofarabine based and FLAG induction regimens.

**Methods:** This study will be a retrospective case-control study of previously untreated elderly (>60 years old) patients with AML who were treated at the University of Michigan Hospital between January 1st, 2003 and December 31st, 2013 with Clofarabine or FLAG induction regimen. The primary outcome of the study is the complete response rate after induction therapy. Data collection points will include patient demographics, performance status, disease-related information (WBC, Blast %, Cytogenetics, Molecular markers, etc.), clinical outcomes (Induction response, time to achieve response, duration of response, etc.), and toxicities. Overall response rate (ORR) includes complete remission (CR = ANC ≥ 109/L, PLT ≥ 100 x 109/L, and Blasts ≤ 5%), CR with incomplete platelet recovery at 28 days (CRI), and partial response (PR = 50% decrease in marrow blasts with ≤ 25% remaining). Propensity score analysis will be performed on baseline demographics and disease characteristics to minimize bias between both cohorts. Dichotomous variables such as response rates and incidence of toxicities will be
analyzed using Fisher’s exact test. Continuous outcomes will be measured from the date induction therapy started and will be compared using Student’s t-test and Mann-Whitney U tests. Kaplan-Meier estimated of overall survival will be performed using the log-rank test and a cox proportional-hazards model.

**Results:** N/A

**Conclusion:** N/A
**Purpose:** Tobramycin is an aminoglycoside antibiotic utilized in critically ill, septic patients as empiric coverage for gram negative pathogens. Bactericidal activity of tobramycin is optimized when peak concentrations of 8-10 times the minimum inhibitory concentration (MIC) are attained. However, critically ill patients demonstrate elevated volumes of distribution and common dosing strategies of tobramycin dosing have been shown to be ineffectual in consistently attaining peak values above 15 mcg/mL in this patient population. As a result, some clinicians at a large, academic institution utilize a tobramycin dose of 3 mg/kg using actual body weight to target tobramycin peak concentrations of 8-10 mcg/mL.

**Methods:** This is a retrospective, single center review of critically ill medical and surgical patients receiving empiric tobramycin therapy. After administration of an initial dose, two tobramycin levels were assessed to calculate an elimination rate constant. Using the elimination rate constant, the peak tobramycin level and volume of distribution will be determined. Patients will be included if they receive an initial dose of tobramycin at 3 ± 0.3 mg/kg using actual body weight. Exclusion criteria include cystic fibrosis, greater than 20% body surface area burns, previous tobramycin administration during admission, use of intermittent hemodialysis, initiation of continuous renal replacement therapy between procurement of tobramycin levels, failure to achieve an initial tobramycin level within four hours following dose administration, and failure to obtain two tobramycin levels. The primary outcome is percentage of patients achieving a goal tobramycin peak level of 8-12 mcg/mL. Secondary outcomes include identification of risk factors associated with tobramycin volumes of distribution ≥ 0.4 L/kg. Goal study enrollment is 250 patients. Statistical analysis will be conducted using...
descriptive statistics and Chi-Square test. Patient demographics including age, weight, sex, height, and ideal body weight will be collected. Factors affecting volume of distribution that will be assessed also include sepsis, heart failure, hepatic failure, renal failure, use of continuous renal replacement therapy, use of extracorporeal membrane oxygenation, vasopressor requirement, and inotrope requirement.

Poster Title: Risk factors for clofarabine hepatotoxicity in patients with acute leukemia

Primary Author: Allie Snoke, University of Michigan Health System, MI; Email: asnake@med.umich.edu

Additional Author(s):
Anthony Perissinotti
Bernard Marini
Dale Bixby

Purpose: Currently there is limited data examining risk factors for clofarabine hepatotoxicity. The objective of this study is to identify risk factors for clofarabine hepatotoxicity in order to optimize therapy in acute leukemia patients. This will result in avoidance of severe treatment-related morbidity and mortality and ultimately improve clinical outcomes in this high-risk patient population.

Methods: Patients with AML or ALL who are at least 18 years of age and received clofarabine chemotherapy at UMHS for remission induction between January 2010 and September 2016 will be included in this study. Patient's with incomplete medical records will be excluded. The primary outcome will be the proportion of patients that developed hepatotoxicity. Secondary outcomes will include complete remission rate, event free survival, overall survival, and proportion of patients able to receive subsequent consolidative chemotherapy or allogeneic stem cell transplant. The following data will be collected: demographic (age, gender, weight, BSA, type of leukemia), laboratory (Scr, LDH, AST/ALT, bilirubin, alkaline phosphatase, albumin, INR, aPTT, CBC), other (dose of clofarabine, current chemotherapy regimen, stem cell transplant history, concomitant hepatotoxic drugs). Patients will then be divided into two groups: those with clofarabine hepatotoxicity and those without. Hepatotoxicity grading will be defined by the common terminology criteria for adverse events (CTCAE) developed by the National Cancer Institute. Multivariate analysis will then be conducted to determine if specific risk factors significantly affect the risk of developing hepatotoxicity with clofarabine therapy.

**Poster Title:** Use of LACE score as a predictor of unplanned hospital readmission or death in palliative care patients

**Primary Author:** David Dadiomov, University of Michigan Health System, MI; **Email:** ddadiomo@umich.edu

**Additional Author(s):**
Michael Smith

**Purpose:** The LACE score is a tool used to predict unplanned hospital readmission or death within 30 days of hospital discharge. The tool has been validated in medical and surgical patients; however, palliative care patients likely have a higher baseline LACE scores due to comorbid conditions, which may limit the predictive value of the score. The objective of this study is to evaluate the utility of the LACE score in the palliative care population to drive resource utilization to highest risk patients.

**Methods:** The study will be a single-center retrospective cohort design. Palliative care patients will be identified by their consultation to the inpatient palliative care team and assessed to determine their LACE score. Data collected will include, but is not limited to: Length of stay, acuity of admission, Charlson comorbidity index, emergency department use, medications at discharge, insurance coverage/utilization. The primary outcome assessed is unplanned hospital readmission or death within 30 days of discharge. The outcome will be evaluated against the predictive value of the LACE score using logistic regression analysis. Other criteria will be assessed alongside the LACE score to determine whether other clinical characteristics correlate more closely with outcomes.

Poster Title: Establishing a drug intensity index (DI2) to track and project future drug expenses

Primary Author: Casey Spitzer, University of Michigan Health System, MI; Email: cspitzer@med.umich.edu

Additional Author(s):
Bruce Chaffee

Purpose: Inpatient medication expenses continually rise and it’s challenging for pharmacy management to proactively predict medication expenses. Different models have been generated to predict medication expenses. However, actual costs can vary from 25 to 374% from the predicted costs demonstrating a need to develop a more accurate model. The purpose of this project is to develop and validate an innovative DI2 model that more accurately forecasts pharmacy drug expenses and variations by using predictive analytics. A new pharmacy-specific drug expense prediction model will help UMHS understand drug expenses and predicts the implications of changing population demographics when budgeting and explaining variances.

Methods: This study has been submitted for approval to the University of Michigan institutional review board. The training sample population includes patients discharged over a two-year time period from July 2014 through June 2016. Inpatient medication cost data will be extracted from the patients’ electronic medical record along with the assigned diagnosis related group (DRG), total number of doses administered, age, and other patient specific demographic data. A predictive model will be assessed using multivariable linear regression in an effort to correlate total medication costs with the aforementioned independent variables to predict total medication cost for a six-month test sample population. To account for drug cost variation and inflation over the two-year period, we adjust costs utilizing the percentage change of prescription drug expenditures from the AJHP National trends in prescription drug expenditures and projections for 2016. Utilizing the regression model, we will use the independent variables from the training sample with adjustments representative of health system and demographic forecasts to predict the total medication expenses for a six-month period. An evaluation assessing our prediction of medication expenses and actual medication expenses data will be compared to validate our model.
Results: N/A

Conclusion: N/A
Purpose: Treatment outcomes in secondary acute myeloid leukemia (sAML) are poor, as patients respond poorly to conventional chemotherapy and frequently experience treatment-related morbidity and mortality. Despite the dismal prognosis, progress has been stagnant. The standard of care for sAML remains the same as de novo AML, which consists of an anthracycline plus cytarabine (3 + 7). There is currently no literature comparing various induction regimens and no evidence to suggest that outcomes can be improved beyond 3+7. The purpose of this study is to compare the complete remission rates of high-dose cytarabine-based regimens to other regimens in the induction of sAML.

Methods: A retrospective study will be conducted in adult patients with sAML who were treated with various induction chemotherapy regimens at the University of Michigan Health System from January 2009 to September 2016. Data to be collected include baseline demographic and clinical characteristics, induction chemotherapy regimen received, response rate (complete remission + incomplete remission), treatment-related toxicities, incidence of infection, hospital length of stay, intensive care unit (ICU) admission, ICU length of stay, disease progression, and mortality. Propensity score matching will be utilized to estimate the effect of treatment on obtaining a complete remission. Chi-square and Fisher exact tests will assess differences in baseline patient characteristics. Furthermore, time-to-event analyses for the secondary endpoints, including event-free survival, progression-free survival, and overall survival, will be performed using the Kaplan Meier method. This study has been submitted to the University of Michigan Institutional Review Board for approval.

**Poster Title:** Evaluation of a multidisciplinary transitions of care service on readmission rates in a geriatric patient-centered medical home

**Primary Author:** Nada Farhat, University of Michigan Health System, MI; **Email:** nmhammou@med.umich.edu

**Additional Author (s):**
Sarah Kelling
Vince Marshall
Tami Remington

**Purpose:** The Turner Geriatric Clinic is a patient-centered medical home (PCMH) at the University of Michigan Health System. A transitions of care (TOC) service, staffed by a multidisciplinary team composed of nurse navigators, clinical pharmacists, and board certified geriatric medicine physicians and nurse practitioners aims to improve patient outcomes for older adults recently discharged from the hospital setting. A previous study documented reduced readmission rates among patients who received the service. Since then, several processes have changed; this study aims to evaluate the effect of the current TOC service on readmission rates in the geriatric population.

**Methods:** This is a single-center retrospective cohort study of adults age 60 years or older discharged from an inpatient stay at University of Michigan Hospital (UH). Patients discharged from UH, including inpatient, emergency department, observation, and short-stay units, between 7/1/2013–2/21/2016, will be included in our study. Patients who received the TOC service at the Turner Geriatric Clinic will be compared to patients who received standard care at other PCMH sites. Patients must have an established primary care provider (PCP), defined as a completed PCP visit within 2 years prior to the index hospitalization date, which will be the first hospitalization meeting inclusion criteria during the study period. Patients will be excluded if they are discharged to sub-acute rehabilitation or nursing home facilities, as data from these institutions will not be reliably available to collect. Additionally, patients will be excluded if they are admitted for a planned procedure. Based on the results of a previous iteration of this clinic model, we will need a population of 1120 patients for 90% power. All-cause 14, 30, and 90-day readmission rates between propensity score matched study groups will be evaluated by
intention-to-treat, per protocol, and as-treated methods. Data will be analyzed using descriptive statistics, univariate, and multivariate analyses. The multivariate analyses will be performed by logistic regression and will include a Cox proportional hazards survival regression on time to readmission.

**Poster Title:** Assessment of documented interventions in a required inpatient generalist advanced pharmacy practice experience (APPE) program at an academic medical center.

**Primary Author:** Cory Smith, University of Michigan Health System, MI; **Email:** coryas@med.umich.edu

**Additional Author(s):**
Michael Kraft
Paul Walker

**Purpose:** Training student pharmacists requires significant time investment by preceptors. However, student pharmacists may contribute to productivity and patient care by incorporating them into pharmacy practice models under pharmacist supervision. A required inpatient generalist APPE rotation was developed to provide educational experience while incorporating student pharmacists into the practice model to support pharmacists’ services. Limited data exist quantifying the benefit student pharmacists have on the overall provision and documentation of pharmacists’ services. The objective of this study is to assess the impact on the documentation of interventions and patient care when incorporating student pharmacists into a generalist pharmacist APPE rotation.

**Methods:** This is a retrospective, observational study conducted at the University of Michigan Hospitals and Health Centers. Generalist Pharmacists who served as preceptors for a 5-week APPE rotation were identified. The total number of documented patient care notes and interventions for each pharmacist will be evaluated during two randomly-selected 5-week time periods: when the pharmacist served as a preceptor for a 4th-year pharmacy student and when they were not serving as a preceptor. The primary outcome will be the average number of documented notes and interventions made per pharmacist while serving as a preceptor for a 5-week time period compared to the average number documented notes and interventions for a 5-week time period when pharmacists were not serving as preceptors. Secondary outcomes will include the number and type of patient care interventions documented by clinical pharmacist generalists while serving as a preceptor (pharmacist + APPE student) compared to a similar time frame when not serving as a preceptor (pharmacist alone). Continuous variables will be compared using a paired Students t-test (normally-distributed data) or Mann-Whitney U (non-
parametric data). Ordinal variables will be compared using Chi-square or Fisher’s Exact test. Statistical significance will be considered at a p-value of < 0.05.

**Session-Board Number:** 11-196

**Poster Title:** Effectiveness of a pharmacist population health intervention for newer medications in cardiology

**Primary Author:** Moniuqe Conway, University of Michigan Health System, MI; **Email:** mrconway@med.umich.edu

**Additional Author(s):**
Kristen Pogue  
Sarah Hanigan  
Josephine Tan  
Mike Dorsch

**Purpose:** Health systems struggle to integrate new medications into clinical practice despite updated guideline recommendations. Amongst providers at the University of Michigan Health System, there is a discrepancy between new drug approval and uptake resulting in a reduced number of patients receiving life-saving medications. Notably, previous literature demonstrates higher prescribing rates by providers after contact with a pharmaceutical representative or after obtaining drug information from an external source. This study aims to evaluate the effectiveness of an Electronic Medical Record, pharmacist-based, population health intervention on physician prescribing patterns for newer cardiology medications in patients at the Internal and Family Medicine clinics.

**Methods:** This is a prospective, cluster-randomized controlled study. Patients seen by providers at the Internal and Family Medicine clinics at UMHS between 11/1/2016 and 10/31/2017 will be included. There will be an intervention and a control group, with five clinics included in each group. Within the intervention group, study personnel will screen patients that meet criteria for the study medications by implementing filters within the EMR and ensuring patients meet practice-based guideline criteria for new drug treatments. Intervention notifications will be sent by a pharmacist to providers of eligible patients two-weeks prior to a clinic visit. Intervention notifications will include pertinent patient-specific medication and insurance coverage information. The primary endpoint for this study is the proportion of patients prescribed one of the four study drugs, ivabradine, sacubitril/valsartan, evolocumab, or alirocumab, within three months of the intervention. A logistic regression will be performed to determine whether there
is an association between the intervention and new drug uptake. A p-value ≤ 0.05 will be considered statistically significant. Descriptive statistics will be performed and presented as mean +/- standard deviation for continuous and frequency data, with percent representing categorical data. A chi-square test will be used for evaluation of categorical data and a 2-sided student’s t-test will be used to analyze outcomes between groups with and without the use the intervention.

Poster Title: Predictors for requiring re-induction chemotherapy in acute myeloid leukemia patients with residual disease on day 14 bone marrow assessment

Primary Author: Victoria Nachar, University of Michigan Hospitals and Health Centers, MI; Email: vnachar@med.umich.edu

Additional Author (s):
Anthony Perissinotti
Bernard Marini
Dale Bixby

Purpose: Following 3+7 induction chemotherapy in AML, the National Comprehensive Cancer Network and European LeukemiaNet recommend performing a bone marrow biopsy around day 14 to assess treatment response. For patients with inadequate blast reduction (blasts >5-10%), a second course of chemotherapy is immediately recommended. Given the poor predictive value of day 14 bone marrow assessment, many patients are not immediately re-induced and still achieve complete remission without further therapy. The objective of this study is to optimize the predictability of a day 14 bone marrow assessment by identifying risk factors for failure to achieve CR in patients receiving 3+7 induction chemotherapy.

Methods: This study will be submitted to the Institutional Review Board for approval. Patients with AML who have undergone 3+7 induction chemotherapy at the University of Michigan Health System from January 2011 until September 2016 will be screened for inclusion in this study using the electronic medical record and leukemia database. Patients with positive bone marrow biopsies on day 14 (defined as >5% blasts) who do not undergo re-induction chemotherapy based on this day 14 bone marrow biopsy result will be identified. These patients will then be divided into two cohorts based on whether or not complete remission was achieved upon count recovery (CR and No-CR cohorts). The following data will be collected: patient age, gender, type of AML (de novo, treatment related, secondary to an antecedent hematologic disorder), WBC count at presentation, anthracycline dose, cytogenetics and microarray results, molecular mutations, bone marrow blast percentage at diagnosis and on day 14, peripheral blood blast percentage at diagnosis, bone marrow cellularity at diagnosis and
on day 14, and LDH at diagnosis and on day 14. Rate of peripheral blast clearance will be calculated. All data will be recorded without patient identifiers and maintained confidentially.

**Poster Title:** Evaluation of clinical pharmacist services in a transitions of care program provided to high-risk patients

**Primary Author:** Jessica Fennelly, University of Michigan Hospitals and Health Centers, MI; Email: jegilson@med.umich.edu

**Additional Author(s):**
Kellie Kippes
Tami Remington
Hae Mi Choe

**Purpose:** Hospital readmissions are costly and can lead to detrimental effects for both patients and their families. To prevent hospital readmissions, eligible highest-risk patients were scheduled for a post-discharge transition of care (TOC) comprehensive medication review (CMR) by ambulatory care pharmacists via telephone. The objectives of this study are: 1) to examine 30-day hospital readmission rates, 2) to describe the ambulatory care pharmacist-recommended interventions, and 3) to quantify the acceptance rate of these interventions by primary care providers in patients who participated in a CMR with an ambulatory care pharmacist.

**Methods:** The TOC program at our institution was implemented in February 2016 with multiple interventions to improve transitions of care following hospitalization. In the ambulatory care setting, these include a nurse navigator phone call, pharmacist CMR via telephone, and post-discharge primary care follow-up visit. Eligible patients were identified using the validated LACE risk stratification tool, which is utilized to prospectively identify patients that are at risk for readmission or death within 30 days of discharge. The ambulatory care pharmacist service was available to University of Michigan Health System highest-risk (LACE score ≥ 13) patients discharged from inpatient general or family medicine services. Of the eligible patients, approximately half were scheduled for the CMR service. During their phone call, pharmacists reviewed medications, reconciled current medications against those prescribed prior to admission and at hospital discharge, identified actual and potential drug therapy problems, and documented recommendations in the electronic medical record for the provider’s review at the follow-up visit. Readmission rates between the group that received the pharmacist CMR service...
and the group that was not scheduled to receive the service will be compared. This study will be submitted to the Institutional Review Board for approval. All data, including demographics, readmissions information, recommended interventions and provider acceptance rates will be collected via retrospective chart review and readmissions claims data. Descriptive statistics and multivariable analyses will be utilized.

Poster Title: Evaluation of the frequency of dispensing electronically discontinued medications and associated outcomes

Primary Author: Erin Copi, University of Michigan Hospitals and Health Centers, MI; Email: ecopi@med.umich.edu

Additional Author(s):
Kaleigh Fisher
Lindsey Kelley

Purpose: With the implementation of electronic prescribing systems, prescription orders can be discontinued electronically and might not be appropriately relayed to the pharmacy. One study showed a 1.5% frequency of dispensing of electronically discontinued medications. This same study also identified the ten most frequently discontinued medications. Our study seeks to evaluate the frequency of dispensing of these ten medications within our outpatient pharmacies after the prescription has been electronically discontinued. This data will then be used to determine if there is a correlation with readmission rates.

Methods: Prescription data from three outpatient pharmacies will be analyzed to identify all new electronic prescriptions for lisinopril, hydrochlorothiazide, amlodipine, metoprolol, irbesartan, metformin, simvastatin, atenolol, enalapril, and warfarin that were filled for patients age 18 and older. Prescription data evaluated will include medication, dose, directions, date written, date dispensed, and date and time picked up. This data will then be compared to the electronic medical record to determine if the prescription was electronically discontinued before it was dispensed to the patient. Medical record data will include date and time of discontinuation, and reason for discontinuation, if documented. For all the prescriptions where the prescription was dispensed after being discontinued, a chart review will be performed to determine if there is a correlation between the cancelled dispensed medication and 30-day all cause readmission. All data will be documented without patient identifiers and stored securely.

Poster Title: Epidemiology and outcomes of mild-to-moderately immunosuppressed patients with community-acquired pneumonia (CAP)

Primary Author: Deeter Neumann, University of Michigan Hospitals and Health Centers, MI; Email: drneuman@med.umich.edu

Additional Author(s):
Scott Flanders
Tejal Gandhi
Valerie Vaughn
Jerod Nagel

Purpose: Numerous studies have identified immunosuppression as a risk factor for infections caused by multi-drug resistant organisms. However, this body of literature does not possess consistent criteria for defining immunosuppressed individuals and often focuses on high-levels of immunosuppressive conditions and therapies. Furthermore, the current guidelines for the treatment of CAP do not address the inpatient management of immunosuppressed patients. The objective of this study is to determine whether a difference exists between the epidemiology of CAP in mild-to-moderately immunosuppressed patients as compared to immunocompetent patients with CAP, and determine if they take longer to reach clinical stability.

Methods: This multi-center, retrospective, cohort study will include patients admitted to a medical service with pneumonia between December 1, 2015 and November 30, 2016. Patients admitted to one of 10-pilot hospitals participating in the Michigan Hospital Medicine Safety (HMS) Consortium were included if they had an International Statistical Classification of Diseases and Related Health Problems (ICD) revision 10 discharge diagnosis for pneumonia. Subjects will be grouped into cohorts of either mild-to-moderately immunosuppressed or immunocompetent on the basis of our definition of mild-to-moderately immunosuppressed. Mild-to-moderately immunosuppressed will be defined by one or more of the following: greater than or equal to prednisone 15 milligrams, or the equivalent, for greater than 30-days; weekly methotrexate dose less than or equal to 30 milligrams; taking azathioprine; infected with Human Immunodeficiency Virus and CD4 count greater than or equal to 200; greater than...
one-year post-kidney transplant without rejection; receiving a tumor necrosis factor inhibitor, including adalimumab, certolizumab, etanercept, golimumab, or infliximab; asplenia; active solid malignancy; or active leukemia with chemotherapy administered in the past 30-days. Infectious epidemiology will be evaluated through a comparison of CAP and non-CAP pathogens between immunocompetent and mild-to-moderately immunosuppressed patients, respectively. Time to clinical stability will be assessed as the primary clinical outcome between the two cohorts.

Poster Title: Effect of a transitions of care medication coverage service on patient outcomes

Primary Author: Sarah Aldrich, University of Michigan Hospitals and Health Centers, MI; Email: smaldric@med.umich.edu

Additional Author(s):
Michael Dorsch
Kristen Pogue
Sarah Hanigan

Purpose: Transitions of care is an increasingly important area of pharmacy practice. One example of transitions of care is a medication coverage service. These services work to decrease the significant medication barriers of cost and access. Our institutions’ medication coverage assistance service started as a pilot project in 2011 and works to verify medication coverage before patient discharge. Since that time, the service has grown to include three technicians who complete copay checks, prior authorizations and provide access to copay assistance programs. Providers of patients prescribed medications with high copays or those commonly requiring prior authorizations initiate the service.

Methods: This is a single-center retrospective cohort study to determine the impact of a transitions of care medication coverage service. Our primary hypothesis is that patients have increased adherence and thus improved outcomes as a result of the transitions of care medication coverage service. We also hypothesize that patients receiving the program will have less 30-day and 60-day hospital readmissions, less provider follow-up time and smaller copay amounts. The rationale is to quantify the benefits of this program on patient care and allow better service expansion. Patients included will be those receiving dabigatran (Pradaxa), rivaroxaban (Xarelto), apixaban (Eliquis), edoxaban (Savaysa), enoxaparin (Lovenox), prasugrel (Effient), ticagrelor (Brilinta), sacubitril/valsartan (Entresto), ivabradine (Corlanor), or rosuvastatin (Crestor) for the first time during hospital admission and subsequently discharged on the medication between June 2014 and December 2016. The study will compare patients who received the transitions of care medication coverage service and those who did not for each of the study medications. Baseline characteristics, treatment intervention and outcomes data will be collected for each patient and analyzed. The objective of this study is to determine
the impact of a transitions of care medication coverage service on medication adherence, provider follow-up time, copay costs and hospital readmissions. The study will be approved by the Institutional Review Board.

Poster Title: Implementing interventions to reduce the number of pharmacist order clarifications within the electronic health record (EHR)

Primary Author: Lukasz Przychodzien, University of Michigan Hospitals and Health Centers, MI; Email: lpprzychodzien@gmail.com

Additional Author(s):
Christopher Zimmerman
Mohammad Ateya

Purpose: Order clarifications are a typical and time consuming part of pharmacist workflow, despite implementation of computerized physician order entry, and continue to drain time from pharmacist clinical activities. At our health system, the number of monthly order clarifications logged by pharmacists within the electronic health record (EHR) (Epic Systems Inc., Verona, WI) are in the thousands. With such a significant number, this quality improvement effort aims to provide a more detailed analysis on what is contributing to order clarifications with the intention of implementing interventions targeting the source of these clarifications.

Methods: Phase 1: A three-month historical extract of pharmacist order clarification interventions will be obtained from the EHR. Number of order clarifications per medication will be plotted over time on a controlled pareto chart; which will allow us to identify the 20 percent of medications that make up 80 percent of order clarifications. Furthermore, number of order clarifications per medication will also be standardized against their relative number of medication orders. Thus producing a set of medications that cause the majority of order clarifications and a large portion of their respected orders.

Phase 2: A detailed subgroup analysis of order clarifications based on associated medication orders, associated patient characteristics, associated ordering user characteristics, and order clarification creator (pharmacist) characteristics will be performed to detect sources of variability and identify any common causes or special causes leading to increase in number of order clarifications. Based upon patterns identified through the subgroup analysis, it will be determined if interventions can be aimed at these scenarios within the EHR to have the greatest impact on reducing the requirements for order clarification.
Phase 3: These interventions will then be implemented sequentially in the EHR through a series of plan-do-study-act (PDSA) cycles. Statistical Process Control (SPC) methods will be used to determine the overall effect of each intervention in relationship to each intervention and on the total number of clarifications.

Poster Title: Evaluating whole genome sequencing for diagnosis of meningitis and encephalitis, and implications for antibiotic management

Primary Author: Maressa Santarossa, University of Michigan Hospitals and Health Centers, MI; Email: msantaro@med.umich.edu

Additional Author (s):
Evan Snitkin
Duane Newton
Michael Bachman
Jerod Nagel

Purpose: Multiple studies have demonstrated the low culture positivity rate of cerebrospinal fluid (CSF) samples and the need for improved diagnostic techniques for central nervous system (CNS) infections. Recent literature has confirmed that whole genome sequencing (WGS) is a novel diagnostic tool for patients with suspected CNS infections, yet utilized invasive methods of brain or spinal cord biopsies. In our proposed research, we aim to further investigate the utility of WGS by utilizing non-invasive CSF samples, and to determine the sensitivity and specificity of WGS.

Methods: This study will be submitted to the Institutional Review Board for approval. This is a single center observational comparative study that has been designed to evaluate the utility of WGS in the diagnosis of CNS infections. CSF samples will be collected from the microbiology lab from patients with suspected CNS infections who underwent a lumbar puncture (LP). Sample collection will occur from December 2016 to February 2017 and analysis will occur in March 2017. We will perform WGS on these CSF samples in order to evaluate the sensitivity and specificity of WGS compared to traditional diagnostic methods. Confirmatory testing through real-time PCR will be performed for patients with negative results by traditional methods and positive results by WGS. In addition, we will determine whether the results of WGS could have altered antimicrobial therapy and influenced clinical outcomes if it was performed in real time. Secondary outcomes to be evaluated will include time to optimal therapy, antibiotic utilization past 48 hours, as well as microbiologic resource utilization and cost.

**Poster Title:** Implementation of a step-wise, multi-layered education and intervention approach to reduce the use of restricted antimicrobials and improve patient outcomes

**Primary Author:** Anthony Boyd, University of Michigan Hospitals and Health Centers, MI; **Email:** anthony.boyd8@gmail.com

**Additional Author(s):**
Jerod Nagel
Greg Eschanauer
Tejal Gandhi
Twisha Patel

**Purpose:** Clostridium difficile infection (CDI) is a hospital-acquired infection that increases morbidity and healthcare-related costs. Antimicrobial use, especially third-generation cephalosporins, clindamycin, and fluoroquinolones, is a major risk factor for CDI. Previous literature has demonstrated the ability of pharmacists to increase adherence to antimicrobial treatment bundles with antimicrobial stewardship oversight. However, limited data exists evaluating the impact of a multi-tiered stewardship initiative involving an entire pharmacy department. The objective of this study is to evaluate the effect of a step-wise, multi-layered education and intervention model that will provide initial coaching and consistent feedback on use of restricted antimicrobials and patient outcomes.

**Methods:** This is a pre-post, quasi-experimental, single-center study comparing a 6-month historical control period and 20-month intervention period comprised of three distinct phases. Phase 1 consists of passive intervention with treatment guideline updates made by the antimicrobial stewardship team (AST). Phase 2 consists of pharmacist intervention with prospective AST oversight and feedback in addition to monthly automated reports with clinical outcomes and antimicrobial utilization data. Phase 3 consists of pharmacist interventions with only automated monthly reports and no direct AST oversight. During, the historical control period, clinical pharmacists ensured appropriate use of select antimicrobials with limited AST oversight. Adult (>18 years) patients who were admitted from January 2015 through May 2017 to an inpatient service were included if receipt of one of the following restricted antimicrobial agents occurred during hospitalization: fluoroquinolones, ceftriaxone, or clindamycin. The
primary outcome will be days of therapy on the restricted antimicrobial agent(s) per 1000 patient-days. Secondary outcomes include appropriate use of restricted antimicrobial agent(s), rate of hospital-acquired CDI, and incidence of antibiotic-associated CDI. Data to be collected includes antibiotic indication, culture(s) (including organism and source), current restricted antimicrobial agent(s) (start date, discontinuation date, appropriateness), and allergies. Appropriate descriptive statistics will be utilized to analyze these data.

**Poster Title:** Evaluation of the impact of duration of antibiotics for the treatment of symptomatic lower urinary tract infections in kidney transplant recipients

**Primary Author:** Suhail Shaikh, University of Michigan Hospitals and Health System, MI; Email: suhail@med.umich.edu

**Additional Author(s):**
Twisha Patel
Sarah Tischer
Abhijit Naik
Daniel Kaul

**Purpose:** The American Society of Transplantation (AST) published guidance on diagnosis and treatment of UTIs; however the optimal duration remains unclear. The current recommendation ranges from 5 to 14 days for cystitis, which is longer than the recommendation set by the Infectious Diseases Society of America. Additionally, it has been recommended by some to treat mild cases of cystitis for 7-10 days within the first 6 months of transplant. Therefore, the primary objective of this study is to evaluate the impact of antibiotic duration on recurrence of symptomatic lower urinary tract infections and incidence of pyelonephritis.

**Methods:** Single-center retrospective chart review of adult renal transplant recipients from the University of Michigan Health System who received antibiotic treatment for symptomatic lower urinary tract infections. Patients transplanted between January 2009 and December 2015 will be included for analysis. Patients with symptomatic lower urinary tract infections from time to ureteral stent removal to three months after renal transplant will be included for analysis. Symptomatic lower urinary tract infection will be defined as a positive urine culture in addition to the presence of at least one urinary symptom (dysuria, urinary urgency/frequency, or suprapubic pain). Patients will be grouped into cohorts on the basis of duration of antibiotic treatment (≤7 days or >7 days), and groups will be matched 1:1 based on antibiotic agent/class used.

Poster Title: Measuring hepatitis C virus (HCV) drug treatment adherence in patients that use intravenous drugs

Primary Author: Connor Luczak, University of Michigan Prescription Drug Plan, Mi; Email: csluczak@med.umich.edu

Additional Author(s):
Cheryl Kaltz
Rima Mohammad

Purpose: Newer therapies for HCV are more effective and better tolerated compared to peginterferon and ribavirin. Current HCV guidelines recommend treating all patients with a history of intravenous drug abuse (IVDA). However, many payers are reluctant to pay for HCV therapy in such patients. In studies of HCV treatments containing peginterferon and ribavirin, adherence and efficacy rates did not differ significantly between patients who used injection drugs and patients who didn’t. The purpose of this study is to determine whether adherence to current HCV treatment differs between patients with a history of IVDA compared to patients without a history of IVDA.

Methods: This study will be submitted to our institutional review board for approval. This study will be a retrospective cohort study comparing patients with a history of IVDA to patients without this history. Patients who completed HCV treatment with a direct acting agent regimen at the University of Michigan Health System between September 1, 2015 to September 30, 2016 will be included. Patients with HIV co-infection or liver transplantation will be excluded. The following data will be collected: patient age, gender, ethnicity, HCV medication used, treatment duration, medication refill dates, and sustained virological response (SVR) rate. Among patients with a history of IVDA, IVDA treatment used will be collected. The primary endpoint will be HCV treatment adherence defined as proportion of days covered (PDC). The secondary endpoint will be treatment effectiveness defined as SVR. Among patients with a history of IVDA, the comparator groups of patients who did or did not receive addiction treatment will be examined as a subgroup analysis.

Poster Title: Compliance with the ACC/AHA 2013 guideline on the treatment of blood cholesterol to reduce atherosclerotic cardiovascular risk in adults

Primary Author: Stephanie Seibel, CHI St. Alexius Health, ND; Email: smseibel@primecare.org

Additional Author(s):
Dan McPherson
Deb McPherson
Jen Paluh

Purpose: The objective of this study is to determine whether patients admitted to CHI St. Alexius Health with acute coronary syndrome were on the proper dose of a statin medication, according to the 2013 American College of Cardiology/American Heart Association (ACC/AHA) guideline on the treatment of blood cholesterol to reduce atherosclerotic cardiovascular risk in adults, prior to admission and on discharge from the hospital.

Methods: This study will be submitted to the Institutional Review Board for approval. Patients who were admitted to the hospital with a diagnosis of acute coronary syndrome will be identified using the electronic medical record system. The following data will be collected: patient age, gender, ethnicity, lipid panel results, current cholesterol medications, allergies, vital signs on admission, past medical history, and tobacco use history. Provider documentation will be reviewed to determine potential reasons for noncompliance to the ACC/AHA guideline. All data will be recorded without patient identifiers and be maintained confidentially. Based on patient data, statin dosing prior to admission and upon discharge will be compared to the ACC/AHA guideline to determine compliance.

Results: N/A

Conclusion: N/A
**Purpose:** Due to the severity of complications associated with sepsis, early optimization of antimicrobial therapy is imperative. Literature regarding alternative dosing strategies for vancomycin in patients with sepsis has recently been published. The objective of this study is to evaluate the efficacy of CHI St. Alexius Health’s current vancomycin dosing guidelines to achieve therapeutic trough concentrations in this patient population.

**Methods:** This study will be submitted to the Institutional Review Board for approval. It will consist of a single-center, retrospective chart review including patients 18 years of age or older admitted October 1, 2015 through October 1, 2016, being treated for sepsis, with a consult to pharmacy to manage vancomycin and one trough concentration at steady state. Exclusion criteria consist of pediatric patients, end-stage renal disease patients receiving hemodialysis or peritoneal dialysis, patients with unstable renal function, and perioperative vancomycin doses. The following data will be collected: patient age, gender, height, weight, body mass index, ethnicity, serum creatinine, blood urea nitrogen, creatinine clearance, blood culture results, vancomycin loading dose, lab draw time, doses in mg per/kg, concurrent antibiotics, white blood cell count, platelet count, and neutrophil percentage. Patients will be evaluated to determine if vancomycin trough levels were subtherapeutic, therapeutic, or supratherapeutic.

**Poster Title:** Pharmacy neonatal intensive care unit (NICU) discharge education program  
**Primary Author:** Sydney Johnk, Sanford Medical Center Fargo, ND; **Email:** sydney.johnk@sanfordhealth.org  
**Additional Author(s):**  
Julia Muzzy Williamson  
Carlina Grindeland

**Purpose:** Caregivers of Neonatal Intensive Care Unit (NICU) patients have a multitude of responsibilities upon discharge. In order to comprehend medical information at discharge, health literacy must be addressed. A study on baseline health literacy showed that one in three parents of NICU infants had suspected limited health literacy. Administration technique can be difficult, as improper use of standardized dosing tools can lead to incorrect dosing. Individualized patient counseling, utilizing hand-outs and teaching tools, can improve child outcomes. The objective of this study is to assess caregiver health literacy and medication understanding with a pharmacy discharge education program.

**Methods:** This study will be submitted to the Institutional Review Board for approval. The study will be divided into a pre- and post-implementation phase of 10-12 weeks each. Caregivers of patients who are discharging from the Neonatal Intensive Care Unit (NICU) will be identified for participation during discharge rounds for both phases. Demographic information collected from participants will include sex, age, race, total household income, employment status, and education level. The medication list of the NICU patient will be accessed. To assess medication education knowledge, medication education satisfaction, and overall health literacy; a questionnaire will be utilized. This will consist of the validated Parental Health Literacy Assessment Tool (PHLAT) and a question regarding caregiver medication education satisfaction. The first phase will consist of assessment based on current discharge education processes that involve nursing alone. Pharmacy discharge counseling will begin in the second phase of the study, and will include medication use while breastfeeding, correct usage of a medication syringe, patient specific medication counseling, and a dosing schedule for the caregiver. Counseling will consist of visual, oral, and written education materials. Questionnaire results
from both phases will be compared to assess changes in health literacy, medication understanding, and satisfaction.

**Poster Title:** Effect of an ambulatory electronic health record (EHR) alert on inappropriate antibiotic prescribing for sinusitis and otitis media

**Primary Author:** Megan Hansen, Sanford Medical Center Fargo, ND; **Email:** megan.hansen@sanfordhealth.org

**Additional Author (s):**
Heidi Twedt
Nathan Leedahl

**Purpose:** Recent studies have shown that sinusitis and otitis media are diagnoses that generate the most antibiotic prescriptions among ambulatory care visits in the United States. An EHR alert was created based on the American Academy of Family Physicians Choosing Wisely initiative to alert physicians regarding potentially inappropriate antibiotic use for sinusitis and otitis media. This initiative recommends a period of watchful waiting in otitis media and discourages routine prescribing of antibiotics in non-severe sinusitis. The objective of this study is to assess the effects of an EHR alert on antibiotic prescribing during ambulatory care visits for sinusitis and otitis media.

**Methods:** This study is pending Institutional Review Board approval. Data will be collected retrospectively for clinic visits that result in a diagnosis of sinusitis or otitis media. Patients meeting the following criteria will be included: patients with a clinic visit diagnosis of otitis media and between the ages of 2 to 12 years or a diagnosis of sinusitis. This data will be collected on patients seen within any clinic under Sanford Health during 10/25/15-3/25/16 as the control group and 10/25/16-3/25/17 as the intervention group. The primary outcome is to measure the impact of the EHR alert on antibiotic prescribing for sinusitis and otitis media based on the change in the pre-intervention to post-intervention periods. The primary safety outcome will be to assess return visits within 30 days due to complications. This outcome will look at complications due to prescribing antibiotics, such as Clostridium difficile diarrhea, and complications due to withholding antibiotics, such as mastoiditis or pneumonia. Patients will be excluded if they have a concurrent diagnosis warranting antibiotic therapy. Additionally they will be excluded if they are immunocompromised, or have conditions such as chronic lung...
disease. If a patient was diagnosed with a bacterial or respiratory tract infection within the past 30 days they will also be excluded from the study.

**Poster Title:** Effectiveness of umclidinium-vilanterol for protocolized management of chronic obstructive pulmonary disease (COPD) exacerbation in hospitalized patients: A sequential period analysis

**Primary Author:** Todd Chapin, Sanford Medical Center Fargo, ND; **Email:** todd.chapin@sanfordhealth.org

**Additional Author (s):**
David Leedahl
Gary Brown

**Purpose:** COPD affects 5% of the population and is characterized by persistent airflow limitations and progressive inflammatory airway response. Inhaled medications can prevent and treat COPD exacerbations and are a cornerstone of therapy, although they are often associated with multiple doses per day and significant expense. Burdens of optimized management are counterbalanced by the benefits of improved lung function, reduced exacerbation frequency, and prolonged survival. This study will evaluate whether a once-daily anticholinergic and long acting beta agonist combination is effective within a COPD exacerbation management protocol for hospitalized patients compared to historical controls managed with twice daily formoterol plus tiotropium.

**Methods:** We will conduct a retrospective sequential period analysis comparing 30-day readmission rates in hospitalized patients with COPD exacerbations before and after protocolized use of once-daily umclidinium-vilanterol. All index admissions for patients admitted to our hospital with COPD exacerbations during the pre-intervention period (September 2015 through February 2016) and post-intervention period (April 2016 through September 2016) will be eligible for inclusion. Patients who are deemed unable to use oral inhalers according to inspiratory flow measurement will be excluded. COPD treatment at our hospital utilizes a respiratory therapist managed, algorithm-based protocol, in which twice-daily formoterol plus daily tiotropium was replaced with once-daily umclidinium/vilanterol in March 2016. The primary outcome will be 30-day readmission rate, and secondary outcomes will include hospital length of stay and mortality. We will collect the following additional information for each patient: age, sex, body weight, body mass index, smoking status within the
last 12 months, outpatient medications used for COPD treatment, Global Initiative for Chronic Obstructive Lung Disease classification, pulmonary function test results, and concurrent treatment of exacerbation with antibiotics or glucocorticoids. Chi squared tests and t-tests will be used for statistical analysis of categorical variables and continuous variables, respectively. This study will be submitted to and approved by our institutional review board prior to commencing chart review.

Poster Title: Ticagrelor versus clopidogrel for neurointerventional procedures: a case control study

Primary Author: Elizabeth Olafson, Sanford Medical Center Fargo, ND; Email: elizabeth.olafson@sanfordhealth.org

Additional Author(s):
Jodi DeGrote
Nathan Leedahl
David Leedahl

Purpose: In neurointerventional procedures, dual antiplatelet therapy with aspirin and a P2Y12 receptor antagonist is often used to prevent thrombotic complications when vascular stents are placed. However, differences in clinical outcome between P2Y12 agents selected in this setting remain unknown. Although most of the published experience is with clopidogrel, ticagrelor may be a reasonable alternative, most notably in patients who may be considered non-responders to clopidogrel. The objective of this study is to retrospectively compare the efficacy and safety of ticagrelor versus clopidogrel in the setting of isolated neurointerventional procedure.

Methods: Patients who were prescribed a P2Y12 medication and underwent a neurointerventional procedure will be considered for inclusion in our study. Patients who received ticagrelor will be matched to a patient who received clopidogrel by age, gender, and type of procedure according to the IRB approved protocol. The following data will be collected: sex, age, race, weight, body mass index, aneurysm location, aneurysm size, national institute of health stroke score, endovascular technique (extracranial or intracranial), vascular access (femoral or radial), hemorrhagic complications, thrombotic complications, death and time to hemorrhagic, thrombotic complication or death and baseline co-morbidities. If available, results of platelet reactivity units, whether patient is a non-responder to clopidogrel, Hunt-Hess scores, and Modified Rankin scores will be collected. The primary endpoint will be any hemorrhagic complication. Secondary endpoints will include thrombotic events and a 30-day composite endpoint of hemorrhagic complications, thrombotic events and mortality. The definition of hemorrhagic complications used in this study will be intracranial hemorrhage, computerized technology of abdomen and pelvis and femoral access site bleeding documented in the

Poster Title: Evaluating the characteristics and outcomes of infants before and after implementation of a standardized treatment protocol for neonatal abstinence syndrome: A quality improvement project

Primary Author: Siera Zimmerman, Trinity Hospitals, ND; Email: siera.k.zimmerman@gmail.com

Additional Author(s):

Purpose: The objective is to compare primary and secondary outcomes of babies treated with a standardized treatment protocol for neonatal abstinence syndrome (NAS) versus babies treated prior to the protocol. NAS occurs in neonates exposed to addictive substances while in-utero. The substances are immediately discontinued at birth, leading to withdrawal. Symptoms include irritability, seizures, neurodevelopmental abnormalities, and can be life-threatening. Nationally, NAS has been on the rise; incidence averages from 0.339% of all births to 2.7% of NICU admissions. Current statistics suggest Trinity Hospital’s incidence could be up to 6.4%, though this has not been formally evaluated.

Methods: The study will be approved by the IRB prior to data collection. The Vermont-Oxford Database, Burlington, VT will be used to identify patients who meet inclusion criteria. Inclusion criteria include workup or diagnosis for NAS. The exclusion criteria are babies with no diagnosis or workup for NAS. Patient charts will be reviewed retrospectively with data collection from January 2012 to September 2016 (prior to protocol- arm one) and October 2016 to May 2017 (post protocol implementation- arm two). Primary outcomes include length of stay, infant discharge disposition, and symptom control recorded as Finnegan score. Secondary objectives include patient demographics: birth weight, APGAR score, gestational age, sex, delivery type, age at treatment, age at discharge; parent demographics: age, gravidity, parity, prenatal care history, drugs (opioids, antidepressants, psychotropics, anti-seizure, or other medications) or substances (illicit drugs, alcohol, nicotine, or others) used during or prior to pregnancy, ethnicity, highest education achieved; breastfeeding status; symptoms experienced; non-pharmacological treatments; medications administered and side effects; length of treatment; and hospital cost. Provider and nurse documentation will be used when gathering data. All of
the data collected will be de-identified and kept confidential. The data for each arm will be averaged and compared.

Submission Category: Cardiology/ Anticoagulation

Submission Type: Research-in-Progress

Session-Board Number: 11-214

Poster Title: Anticoagulation use in patients with atrial fibrillation and end stage renal disease receiving hemodialysis

Primary Author: Dallin Darais, CHI Health – Bergan Mercy Medical Center, NE; Email: dallindarais@creighton.edu

Additional Author (s): Estella Davis

Purpose: Warfarin has been the drug of choice to prevent stroke or systemic embolism for patients with nonvalvular atrial fibrillation (AF) in end-stage renal disease (ESRD) on hemodialysis. Anticoagulant therapy has evolved due to the development of direct thrombin and factor Xa inhibitors, leading to additional therapeutic options for use in these patients. As these patterns are not well-described, the objective of this study is to identify prescribing patterns of anticoagulation agents in AF patients with ESRD on hemodialysis. Secondary outcomes include the incidence of stroke or thromboembolic events, and the incidence of major or minor bleeding events.

Methods: This will be a multicenter, retrospective, chart review, cohort study evaluating patients with ESRD on hemodialysis diagnosed with nonvalvular AF who are receiving anticoagulation (warfarin, dabigatran, rivaroxaban, apixaban, and edoxaban). This population will be identified by International Classification of Disease (ICD)-9 and ICD-10 codes between April 30, 2010 and April 30, 2016. Inclusion criteria are: patients 19 years of age and older, with concurrent diagnoses of AF and ESRD, and are on chronic and stable hemodialysis. The following patient data will be collected: age, gender, race/ethnicity, weight, body mass index, serum creatinine, creatinine clearance based off Cockcroft-Gault equation, hemodialysis schedule, hemodialysis location, and CHA2DS2-VASc score. The following data will be collected about each patients’ anticoagulation therapy: initial anticoagulant, dose, subsequent changes to anticoagulation or other dose adjustments, and international normalized ratio if on warfarin. Adverse event data will be collected for hemorrhagic or ischemic stroke, and both major and minor bleeding events. Prevalence plots will be used to describe point prevalence (monthly) of anticoagulant agent use and standardizing it with the study population. Comparisons of patient outcomes based off anticoagulation use will be assessed using chi square test or Fisher’s exact
test. Continuous variables will be analyzed by Student’s t test or analysis of variance (ANOVA). A p-value of less than or equal to 0.05 will be considered significant.

**Poster Title:** Retrospective analysis of pirfenidone in pulmonary fibrosis patients

**Primary Author:** Lauren Bricker, CHI Health Creighton University Medical Center, NE; **Email:** lauren.bricker@alegent.org

**Additional Author(s):**
Stanley Thomas
Mary Pote
Lee Morrow
Mark Malesker

**Purpose:** Idiopathic pulmonary fibrosis is a chronic fibrosing interstitial pneumonia with no known cause. The median survival after being diagnosed is just two to three years. Until recently, there have been no FDA-approved treatments available for pulmonary fibrosis. The 2015 ATS/ERS/JRS/ALAT updated guidelines only recommend the use of two new antifibrotic drugs approved in 2014, pirfenidone and nintedanib. There is limited long-term published data available for the use of pirfenidone in pulmonary fibrosis treatment. The goal of this study is to use nearly five years of data at one university to evaluate long-term efficacy and safety of pirfenidone.

**Methods:** This study was approved by the university’s Institutional Review Board. This retrospective analysis will identify patients who received pirfenidone therapy for pulmonary fibrosis treatment from 2011 to 2016 using consecutive patient records. The following data will be collected: patient demographics, comorbidities, creatinine clearance, length of pulmonary fibrosis diagnosis, smoking status, and environmental exposure risks. Additional information will be gathered regarding lung function at baseline and following pirfenidone treatment: forced vital capacity, forced expiratory volume in one second, diffusing capacity of the lungs for carbon monoxide, oxygen requirements, six-minute walk test, dyspnea score, frequency of exacerbations, time to exacerbation, time to death, and high-resolution computed tomography. Finally, variables relating to treatment with pirfenidone will be collected: day of treatment initiation, duration of treatment, daily dose, concurrent medications, adverse events reported, and therapeutic switch to nintedanib. All data will be recorded without patient identifiers and maintained confidentially. The primary endpoint for efficacy will be forced vital capacity and...
death. Secondary endpoints will include six-minute walk distance, progression-free survival, dyspnea, and death from any cause or from pulmonary fibrosis. A secondary endpoint related to safety is the tolerability of pirfenidone therapy. The investigators will use descriptive statistics to summarize the efficacy and safety of pirfenidone therapy in pulmonary fibrosis patients.

**Poster Title:** Evaluation of the management of extended spectrum beta-lactamase (ESBL) producing Enterobacteriaceae infections  

**Primary Author:** Scott Shipley, CHI Health Creighton University Medical Center - Bergan Mercy, NE; Email: scott.shipley@alegent.org  

**Additional Author (s):**  
Chris Destache  

**Purpose:** ESBL-producing Enterobacteriaceae capable of hydrolyzing broad spectrum cephalosporins have become a dominant concern for anti-infective treatment worldwide. In 2013 the CDC categorized ESBL Enterobacteriaceae threat level as “serious”, estimating upwards of 40,000 dollars per patient in excess hospital costs for ESBL bloodstream infection. Carbapenem antimicrobials are the gold standard for treating ESBL-producing pathogens. The CDC recommends laboratory reporting all penicillins, cephalosporins, and monobactams as resistant to ESBL pathogens regardless of minimum inhibitory concentration. The purpose of this study is to assess definitive treatment regimens used within CHI Health Omaha and the appropriateness of the treatment based on patient outcomes.

**Methods:** This retrospective electronic medical record review will focus on patient outcomes of treating ESBL-producing bacteria throughout five Omaha metro hospitals. Patients enrolled will be greater than 19 years of age and have a positive inpatient culture at a CHI hospital between January 1, 2014 and December 21, 2015. These patients will be identified from the Microbiology Department of CHI health system. Patients will be excluded if there was inadequate follow-up within seven days of admission (death, hospice care, refusal of treatment, or transfer to an outside hospital). Outcomes will include appropriate empiric and definitive therapy (carbapenems will be recognized as appropriate), length of hospitalization, infectious disease consult, number of antimicrobial changes, and treatment failure. Treatment failure, defined as patients who do not respond to therapy (recurrent fever, abnormal white blood cell counts, positive blood cultures greater than 10 days after initial blood culture, but prior to completion of antimicrobial therapy, or death). Comparisons of patient outcomes between the different hospitals will be assessed using Chi-squared test or Fisher’s exact test for discrete variables and Student’s t test or analysis of variance for continuous variables. A P value of less
than 0.05 will be considered significant. This study is approved by Creighton University Institutional Review Board for Human Studies.

Poster Title: Clinical significance of discordant empiric antimicrobial selection for inpatient treatment of pyelonephritis at two CHI Health Omaha metro area hospitals

Primary Author: Carmen Frerichs, CHI Health Creighton University Medical Center - Bergan Mercy, NE; Email: carmen.frerichs@alegent.org

Additional Author(s):
Renuga Vivekanandan
Christopher Destache
Jennifer Anthone

Purpose: The Infectious Diseases Society of America (IDSA) and European Association of Urology (EAU) guidelines suggest that appropriate empiric therapy for complicated urinary tract infections (UTI) include either fluoroquinolones or extended-spectrum cephalosporins, among others. These two evidence-based guidelines also suggest that if local resistance rates to fluoroquinolones exceed 10-20 percent, empiric therapy with an alternative agent should be considered. This study aims to determine local antimicrobial resistance rates and how empiric selection of discordant antimicrobial therapy affect outcomes in hospitalized patients with pyelonephritis.

Methods: This study is a retrospective electronic health record review (EHR) and will be approved by the Institutional Review Board. Non-pregnant patients 19 years and older with a diagnosis of pyelonephritis as determined by International Classification of Diseases (ICD)-10 codes and confirmed via review of the EHR from October 1, 2015 through September 30, 2016 will be included. Diagnosis of pyelonephritis will be confirmed with a urine culture containing at least 100,000 colony forming units per milliliter of a single Gram-negative pathogen and a temperature greater than or equal to 38.0 degrees Celsius in the presence of symptomatology describing “flank pain” or “costovertebral tenderness” as recorded in the EHR. Data collection will include patient demographics, comorbidities, urine cultures and sensitivities, and empiric antimicrobial selection. Discordant antimicrobial selection will be defined as empiric therapy to which the identified organism is resistant. The study will compare outcomes in patients receiving discordant empiric therapy to those receiving concordant empiric therapy at two hospitals. The primary objective of this study will be to determine if discordant empiric
antimicrobial selection had a detrimental impact on patient outcomes including length of hospitalization, time to clinical resolution of infection, and mortality. Descriptive statistics will be used on all discrete variables, student t-test will be used for continuous variables, and logistic regression will be used to identify risk factors associated with antimicrobial resistance.

Poster Title: Analysis of midodrine to decrease the norepinephrine dosing requirements in intensive care unit patients

Primary Author: Patrick Chadd Enriquez, CHI Health Creighton University Medical Center - Bergan Mercy, NE; Email: patrick.enriquez@alegent.org

Additional Author(s):
Dwight Shafer
Ryan Walters
Lee Morrow
Mark Malesker

Purpose: Intravenous (IV) norepinephrine (NE) is used to maintain tissue perfusion in hemodynamically unstable patients. IV NE administration requires invasive hemodynamic monitoring in the intensive care unit (ICU). The dose of IV NE is reduced as hemodynamic stability improves. Persistent hypotension requiring low rates of IV NE increase the ICU length of stay (LOS). Midodrine, an oral alpha agonist, is used adjunctively to facilitate IV NE discontinuation. There is limited evidence to support the use of midodrine for this indication. This study aims to evaluate the effect of midodrine on ICU LOS and duration of IV NE administration.

Methods: This retrospective study will be submitted to the Institutional Review Board for approval. This study will include patients 19 years or older who received IV NE while admitted to our ICU between September 2012 to September 2016. Patients will be divided into two groups for comparison: those who received midodrine and those who did not. Primary endpoints include ICU LOS and duration of IV NE administration. Patients will be excluded if they expire while receiving IV NE or if midodrine is used for an indication other than IV NE weaning. Baseline demographic variables to be collected include age, sex, comorbidities, ordering service, Acute Physiology and Chronic Health Evaluation (APACHE) II score, mechanical ventilation, ICU diagnosis, concomitant use of steroids, vasopressin and other vasopressors. Additional data to be collected include initial and maximum doses of midodrine, duration of IV NE prior to and after midodrine initiation, mean arterial pressure at time of midodrine initiation and IV NE discontinuation, IV NE rate at time of and 24 hours after midodrine initiation, time to
IV NE discontinuation and ICU discharge after midodrine initiation, time to ICU discharge after IV NE discontinuation and midodrine side effects. Descriptive statistics will be used to describe the study population. Chi-square and Mann-Whitney tests will be used to compare baseline characteristics. Negative binomial regression will be used to compare the endpoints between groups.

**Poster Title:** Launching a pharmacy technician-led medication history service

**Primary Author:** Sasha Haarberg, CHI Health- St. Elizabeth, NE; **Email:** sashahaarberg@stez.org

**Additional Author(s):**
Emily Mannscheek
Michael McQuade

**Purpose:** Medication reconciliation is widely recognized as an essential tool used to decrease medication discrepancies with potential for patient harm and increased health care spending. An accurate, prior to admission medication list is critical in order to aid healthcare providers with the information needed to provide quality patient care. The primary focus of this study is to assess the effect the introduction of a pharmacy technician-led medication history program has on the accuracy of medication lists upon admission to a community hospital.

**Methods:** This is a prospective, process improvement study at a 260-bed community hospital. This medication history program specifically involves medication history technicians under the supervision of a pharmacist. These medication history technicians, after three months of training, will complete the medication history process using patient interviews, Nebraska Health Information Initiative (NEHII) database, outside facility records, patient pharmacy records, and provider office records. The medication history technicians will focus on three main paths of admission; emergency department, direct admissions, and scheduled orthopedic joint replacement surgeries. After compiling an accurate medication list, technicians will then present it to a pharmacist for review and then to the admitting physician. Measured outcomes will include accuracy of previous medication history, productivity (defined as number of medication histories per 100 inpatient admissions and number of medication histories per medication history technician hours staffed), and employee satisfaction with medication history process measured by survey. All metrics will be measured over a 6-month period from October 2016 to March 2017.

**Results:** Research still in progress.

**Conclusion:** Research still in progress.

Poster Title: Clostridium difficile rates and antibiotic exposure among patients in a community teaching hospital

Primary Author: Morgan Pusek, CHI Health-Bergan Mercy Medical Center, NE; Email: morgan.pusek@alegent.org

Additional Author(s):
Kelly Nystrom

Purpose: Clostridium difficile infection (CDI) has multiple etiologies, with prolonged antimicrobial exposure being one of the most common. The Infectious Disease Society of America recommends minimizing the frequency, duration, and number of antimicrobial agents to reduce CDI risk. The primary objectives of this study are to evaluate antibiotic exposure among hospitalized patients with CDI and appropriateness of therapy.

Methods: This quality review will be submitted to our Institutional Review Board for approval. The health system’s electronic medical record system was used to identify patients diagnosed with CDI between March, 1, 2016 and August 31, 2016. The following data will be collected: demographics, antibiotic exposure, proton pump inhibitor (PPI) exposure, time to positive culture from admit, CDI treatment, and time to therapy from positive culture. The primary endpoint will be total antimicrobial exposure among CDI patients, defined as the number of antimicrobials per day divided by the number of days of antimicrobial therapy prior to CDI. Secondary endpoints will be PPI exposure, appropriateness of CDI therapy, and rate of CDI among medical teams. After identifying the antimicrobial exposure rates among CDI patients, the results of the study will help us identify areas where antimicrobial stewardship can be improved. We plan to re-evaluate prescribing habits, antimicrobial exposure, and CDI rates in the future.

Results: In progress

Conclusion: In progress
Purpose: The purpose of this study is to evaluate the impact of a pharmacist’s involvement in the discharge medication reconciliation process. The primary outcome of this study is patient readmission within 30-days after discharge. The secondary outcomes include the number and type of pharmacist interventions made, patient compliance, and patient presentation to an Emergence Department within 30-days after discharge.

Methods: This study is comparing 30-day hospital readmission rates for patients who had a pharmacist review their medications prior to discharge verses those who did not. Pharmacist interventions will be based on patient-specific factors and clinical judgment. Once a discharge order is entered, a pharmacist will receive an alert via the electronic medical record (EPIC). A pharmacist will then review the discharge medications, make interventions if necessary, counsel on any new medications, and notify nursing that pharmacy discharge counseling is complete. The floor pharmacist will complete an intervention note in EPIC to allow the primary investigator to track outcomes. The primary investigator will collect data on all patients discharged from an inpatient unit, other than psychiatry or labor and delivery, at Immanuel Medical Center between October 1, 2016 and March 31, 2016. Utilizing EPIC the following data will be collected: 30-day readmissions, pharmacist interventions made, patient compliance, and patient presentation to an Emergence Department within 30-days after discharge. It is expected that the majority of pharmacist interventions will focus on medications for high-risk conditions such as cardiovascular, pulmonary, endocrine, and infectious disease. Quantity and type of pharmacist interventions made will be recorded. Patient compliance will be defined if a patient picked up their discharge prescriptions within 48 hours of discharge. The primary investigator will verify this by calling the patient’s pharmacy.

Poster Title: Comparison of GLP-1 Agonists and SGLT-2 Inhibitors on Patient Outcomes: A Retrospective Study

Primary Author: Haley Kessinger, Creighton University School of Pharmacy, NE; Email: hmk56080@creighton.edu

Additional Author(s):
Emily Knezevich

Purpose: Current diabetes guidelines do not show preference between SGLT-2 inhibitors and GLP-1 receptor antagonists. Both drug classes have been shown to be very efficacious at hemoglobin A1c (HbA1c) reduction in patients with type 2 diabetes mellitus (T2DM). Drug selection must take into account patient-specific factors, such as cost, route of administration, and adverse events. Little research has directly compared patient outcomes in those taking GLP-1 agonists to patients taking SGLT-2 inhibitors in a real world setting. The purpose of this study is to examine and compare outcomes, specifically HbA1c, in patients taking GLP-1 agonists versus patients taking SGLT-2 inhibitors.

Methods: This research study will be a retrospective cohort that uses data from EPIC, the electronic health record for patients in a single outpatient clinic located in the Dundee Neighborhood of Omaha, Nebraska. This endocrinology and internal medicine clinic serves an adult patient population where T2DM is common.

Inclusion criteria will include patients who are 18 years and older, have T2DM, and were prescribed a GLP-1 agonist or SGLT-2 inhibitor by a CHI Health Dundee provider. Patients must have been started on a GLP-1 agonist or SGLT-2 inhibitor at a CHI Dundee clinic appointment (their “initial visit”) and return for a follow-up visit (3 to 6 months after their initial visit), and an additional follow-up visit (at least 12 months after their initial visit).

Exclusion criteria will include patients who have any other type of DM other than T2DM, were prescribed the GLP-1 agonist or SGLT-2 inhibitor outside of CHI, do not return for any follow-up visit, and discontinue the medication before both of their follow-up visits. At their follow-up visits, patients may receive dosage changes, but should they discontinue the medication for any reason, they will be excluded. If the patient does stop a medication before returning for both follow-up visits, the reason why will be documented.
Secondary outcomes that we will evaluate include changes in body mass index, weight, and blood pressure.

**Poster Title:** Confidence is Key: an Educational Intervention Following Family Medicine Resident's Confidence in Writing for Opioids Prescriptions

**Primary Author:** Elizabeth Scheffel, Creighton University School of Pharmacy and Health Professions, NE; **Email:** ecs51711@creighton.edu

**Additional Author (s):**
Laura Klug
Michael Greene

**Purpose:** Studies have shown that prescribers who are not specialized in pain management rate confidence levels in writing opioids for chronic pain at a much lower rate than pain management specialists. The objective of this study is to assess the impact of a lecture series designed around the Center for Disease Controls’ (CDC) newest guideline update on managing chronic pain and the primary care resident prescriber’s assurance levels in confidently managing opioid regimens.

**Methods:** This study will be submitted to the Institutional Review Board for approval. First, second, and third year residents in Creighton University’s Family Medicine Residency Program in Omaha, Nebraska will be assessed on their confidence levels regarding opioid pain management prior to and after a two-part lecture series incorporated in their didactic lecture course. Faculty in the Department of Family Medicine who attend the lecture series will also have the opportunity to participate. Participants will be assessed using the KnowPain-12 questionnaire, a tool used to measure provider pain management knowledge. The questionnaires will be deposited in each of the participant’s mailboxes in a sealed envelope 30 days prior, directly after second lecture, and 3 months following the lecture series. The two-part lecture series will cover the 12-point CDC guideline update from March 16th, 2016 on the management of chronic pain. Each lecture will be approximately 1 hour in length and will contain at least 2 case presentations for the purpose of practicing learned material. Data will be collected to determine trends in prescriber confidence levels and determine weak areas in learning.

Poster Title: Appropriate use of fibrate therapy within Veteran's Affairs Nebraska-Western Iowa Health Care System

Primary Author: Maggie Hein, VA Nebraska-Western Iowa Health Care System - Lincoln Division, NE; Email: maggie.e.hein@gmail.com

Additional Author(s):
Rebecca White
Alexis Thomas

Purpose: The objective of this retrospective medication use evaluation is to evaluate the appropriateness of fibrate therapy within an ambulatory care setting based on the Veteran’s Affairs/Department of Defense Clinical Practice Guideline for the management of dyslipidemia for cardiovascular risk reduction. We predict that many patients on fenofibrate or gemfibrozil can discontinue fibrate therapy or be appropriately switched to monotherapy with a statin.

Methods: This medication use evaluation will review all patients receiving care from the ambulatory care clinic with an active prescription for gemfibrozil or fenofibrate within the past twelve months. The national Veteran’s Affairs/Department of Defense lipid guidelines will be utilized to assess if these prescriptions are appropriate based on literature recommendations. Each veteran’s active prescription will be reviewed within the electronic medical record and appropriateness will be assessed based on the aforementioned guidelines. The following data will be collected: active prescriptions for lipid statins, niacin, fish oil, bile acid sequestrants and pancreatic enzymes, baseline total cholesterol, baseline low-density lipoprotein, baseline high-density lipoprotein, baseline triglycerides, history of triglycerides greater than 2,000 mg/dL, highest recorded triglyceride level, nutrition appointment within the last three years, alcohol use, history of elevated thyroid stimulating hormone greater than 4.68 mIU/L, history of elevated creatinine kinase greater than 170 IU/L, history of elevated aspartate transaminase greater than 138 IU/L and alanine transaminase greater than 198 IU/L, history of elevated hemoglobin A1c greater than 9 percent, non-pharmacological recommendations, history of pancreatitis, history of adverse reaction to fibrate therapy, history of rhabdomyolysis, and history of statin intolerance. After reviewing the data, if a change in therapy is indicated the reviewers will make appropriate recommendations to the prescribing providers.

Poster Title: Initiation of a clinical pharmacist run discharge medication reconciliation program.

Primary Author: Stefanie Gann, Renown Regional Medical Center, NV; Email: sgann@renown.org

Additional Author(s):
Kate Ward
Michelle Barcelon

Purpose: Heart failure is one of the leading causes of hospital admissions and readmissions. Readmissions result in billions of dollars in healthcare costs, complex drug regimens and lower quality of life. Complex drug regimens can result in non-compliance, drug-drug interactions and adverse drug events all of which can lead to readmissions. Effective transition from hospital to home setting is a critical step in patient care. Studies have shown the impact on clinical outcomes of a clinical pharmacist’s involvement in discharge counseling.1,2 Currently at Renown Regional Medical Center (RRMC), the clinical pharmacist has limited involvement in discharge prescription review or patient counseling.

Methods: This study is a retrospective analysis of medication error rates for discharge prescriptions for the heart failure patient population before and after a pharmacist discharge counseling program (PDCP) implementation. The primary outcome will be the number of total medication errors. The secondary outcome will be rate of 30 day all-cause readmission to RRMC. The pre-PDCP evaluation period will be May – June 2016 and will include all patients discharged from RRMC with a heart failure diagnosis. The post-PDCP evaluation period will be January-February 2017 and will include all patients that received PDCP services. Patients who are pregnant, < 18 years of age, incarcerated or mentally ill will be excluded. Data collected will include patient demographics, laboratory values, and medication histories. Medication errors will be assessed based on the rate of duplications, omissions, interactions, indication, inappropriate dosing or drug for patient specific factors and access to medication. Primary outcome data will be analyzed using the descriptive statistics and Chi-squared test or Fisher’s exact test. This study is in process of being approved by the institutional review board.

**Poster Title:** Impact of a pharmacist consult on the medication management of psychiatric boarding patients in the emergency department  

**Primary Author:** Hannah Thomas, Renown Regional Medical Center, NV; **Email:** hthomas@renown.org  

**Additional Author (s):**  
Heather Townsend  

**Purpose:** Limited access to psychiatric care and resources has increased the number of patients seeking psychiatric evaluation in emergency departments across the country. The American College of Emergency Physicians created a guide to care for the psychiatric boarding patient. It does not include medication management for these patients who may be hospitalized for several days. It is hypothesized that with pharmacist involvement in medication reconciliation and chronic disease state management there will be a decrease in rescue medications for agitation and psychosis. This study will evaluate the impact of pharmacist directed medication management for psychiatric boarding patients in the emergency department.

**Methods:** Prior to commencement, this study will be evaluated by the Institutional Review Board for approval. The electronic medical record will be analyzed retrospectively to evaluate patients boarded in the emergency department while awaiting transfer to a psychiatric facility between September 1, 2014 to September 30, 2014 for the pre-implementation group, and September 1, 2015 to September 30, 2015 for the post-implementation group. The primary outcome for the study is the reduction in rescue medication doses required during the patient’s emergency department visit. The secondary outcomes of the study include medication reconciliation completed and home medications restarted during the patient stay. The following data will be collected from the patient’s medication administration record: doses of antipsychotics, benzodiazepines and antihistamines administered. The following data will be collected from the patient’s electronic medical record: admitting psychiatric complaint, length of stay, medical diagnoses, completion of a medication reconciliation, the number and class of home medications ordered, number of home medications not continued, and medication changes made by the pharmacist. If available, the number of interventions discussed with the physician by the pharmacist recorded in the pharmacy progress note will also be collected.
Statistical analysis will be performed using paired t-tests for the primary outcome and chi-squared tests for secondary outcomes.

**Poster Title:** Evaluation of Tigecycline for use in Clostridium difficile infection

**Primary Author:** Paige Rice, Renown Regional Medical Center, NV; Email: price@renown.org

**Additional Author (s):**
Jessica Thompson

**Purpose:** Clostridium difficile is one of the most common nosocomial infections. Despite utilization of IDSA guideline-concordant therapy with metronidazole and/or oral vancomycin, C. difficile infection is often associated with high rates of treatment failure and mortality. Limited case reports have shown clinical cure in severe and recurrent C. difficile infections after tigecycline administration. Currently there are no recommendations for tigecycline in patients with C. difficile. The objective of this study is to determine if tigecycline is associated with improved clinical outcomes in patients with C. difficile infection.

**Methods:** This will be a single-center, retrospective case control study of inpatients at Renown Regional Medical Center with C. difficile infection from June 1, 2011 to May 31, 2016. Prior to initiation, the study will be reviewed by the Institutional Review Board. Cases will be patients 18 years or older that received tigecycline for C. difficile infection. Each case will be matched to two controls by age, sex, disease recurrence, presence of the 027-NAP1-BI strain, and baseline white blood cell count and serum creatinine. Patients with C. difficile infection will be defined as those having diarrhea and C. difficile in stool confirmed by PCR. The primary outcome will be clinical cure defined as resolution of diarrhea, fever, leukocytosis, and abdominal pain. Secondary outcomes will include time to clinical cure, length of stay, mortality, and sustained response. Additional data collection will include acid-suppressive therapy, antimotility agents, laxatives, stool softeners, lactate, albumin, concurrent antibiotics, complications of infection, surgical interventions, fecal microbiota transplant, and adverse drug reactions. Chi-squared test will be used to analyze the primary outcome, and secondary outcomes will be analyzed by student t’s test for continuous data and Chi-squared test for categorical data.

**Poster Title:** Efficacy and safety of switching sodium-glucose cotransporter-2 (SGLT-2) inhibitor therapy in type-2 diabetes mellitus (T2DM)  

**Primary Author:** Joseph Bizier, Albany College of Pharmacy and Health Sciences, NY; **Email:** joseph.bizier@acphs.edu  

**Additional Author(s):**  
Michael Kane Kane  
Gary Bakst  
Robert Busch  
Robert Hamilton  

**Purpose:** Use of SGLT-2 inhibitors results in decreased blood glucose, caloric loss, and mild diuresis thereby promoting A1C lowering, weight loss, and blood pressure lowering. There are currently three SGLT-2 inhibitors on the market and the choice of one over the others is often dictated by insurance coverage, as well as the publication of a cardiovascular outcomes trial for empagliflozin (Empa-Reg). Changing insurance coverage often leads to switching between canagliflozin, dapagliflozin, and empagliflozin. There are no published studies comparing the efficacy of SGLT-2 inhibitors. This study will assess the safety and efficacy of switching from canagliflozin to dapagliflozin or empagliflozin.  

**Methods:** This study was approved by the Albany College of Pharmacy and Health Sciences Institutional Review Board. This pre-post observational study utilized patient medical records from an office-based endocrinology practice. The study population will consist of T2DM patients who received canagliflozin for a minimum of six months and were then switched to dapagliflozin or empagliflozin for a minimum of six months. Subjects will be identified via a computerized text search of the medication and problem lists of patient electronic medical records using the search terms canagliflozin, Invokana, dapagliflozin, Farxiga, empagliflozin, Jardiance, SGLT-2 inhibitor, and T2DM. Inclusion criteria include age 18–85 years of age, T2DM, received canagliflozin for a minimum of six months, use of dapagliflozin or empagliflozin for a minimum of six months, and baseline A1C of 6-10%. Exclusion criteria include T1DM, patients with renal impairment (CrCl < 45 ml/min), and initiation of additional diabetes, hypertension or cholesterol drugs during the follow-up period.
The primary study outcome is change in A1C. Secondary outcomes include: change in weight, percent of patients achieving A1C < 7%, changes in systolic and diastolic BP, changes in lipid parameters. Paired t-tests and the Wilcoxon rank-sum test will be utilized for statistical analysis. A sample size of 200 patients is required for a Beta error of 0.8 and an alpha error of 0.05, to detect an A1C change of 0.3%.

**Poster Title:** Intervention to decrease proton pump inhibitor usage and associated Clostridium difficile infection rates

**Primary Author:** Adrienne Rouiller, Albany Medical Center, NY; **Email:** rouilla@mail.amc.edu

**Additional Author (s):**
Ben Lomaestro
Sarah Elmendorf
Eileen Graffunder

**Purpose:** Clostridium difficile infection (CDI) is associated with annual national costs over $3 billion dollars, morbidity, and mortality, with severity ranging from mild diarrhea to fulminant colitis, and even death. Studies have suggested an increased risk of CDI when proton pump inhibitors (PPIs) are prescribed, and this risk appears to be less with histamine-2 receptor antagonists (H2RAs). The objective of this study is to determine if there is a practical way to have an impact on PPI prescribing patterns utilizing active interventions, order set changes, and education, to ultimately result in a decrease in CDI.

**Methods:** New PPI orders were reviewed between the dates of August 28, 2016 and September 9, 2016. These orders were evaluated for necessity and a decision was made to intervene recommending either discontinuation or a change to a H2RA when appropriate. This study was submitted to the Institutional Review Board for approval. Data collected included patients’ age, PPI duration, concomitant antibiotic use, the intervention made (if any), intervention acceptance rate, and whether or not CDI occurred during admission. Data collection was stopped after two weeks due to high patient volume and poor acceptance rates: 277 orders were reviewed, 3 of 20 interventions to discontinue were accepted, and 1 of 39 interventions to change therapy to a H2RA were accepted. There was also a review of 16 computerized physician order entry (CPOE) order sets which contain options for either PPI or H2RA use with no preferred guidance. We worked with information technology (IT) to develop a banner which could be added to these orders to caution against PPI use due to CDI risk and indicate H2RAs as the preferred agent. An education campaign is also being developed to inform providers about the association between CDI and PPI use and indications where H2RAs are suitable alternatives.
Ongoing data collection hopes to see a decrease in prescribing of PPIs along with a decrease in CDI with these efforts.

**Poster Title:** Comparison of an antifactor Xa (anti-Xa) protocol versus an activated partial thromboplastin (aPTT) protocol for heparin monitoring at a tertiary medical center: a pilot study

**Primary Author:** Apryl Jacobs, Albany Medical Center, NY; **Email:** jacobsa5@mail.amc.edu

**Additional Author(s):**
Martha Naber
Erica Maceira

**Purpose:** The two most common unfractionated heparin (UFH) monitoring methods are activated partial thromboplastin time (aPTT) and antifactor Xa assay (anti-Xa). Drawbacks to aPTT include poor correlation with heparin concentration, variable response to reagents, and sensitivity to acute phase reactants. Anti-Xa is the standard for determining in vivo UFH activity and is less susceptible to interference. The purpose of this study is to compare the performance of an anti-Xa protocol vs. an aPTT protocol using time to reach therapeutic range and percentage of values that were therapeutic. In addition, discordance between paired anti-Xa and aPTT values was analyzed.

**Methods:** A pilot anti-Xa protocol was implemented in the medical intensive care unit at a tertiary medical center. The standard dose protocol included an optional bolus of 60 units/kg, initial infusion of 18 units/kg/hr, and optional bolus. The goal anti-Xa range was 0.3 to 0.7 units/ml. The low dose protocol included an optional bolus of 40 units/kg, initial infusion of 12 units/kg/hr, and optional bolus. The goal anti-Xa range was 0.3 to 0.5 units/ml. Doses were not capped based on patient body weight. Anti-Xa and aPTT pairs were obtained at designated monitoring intervals.

The standard dose aPTT protocol included an optional bolus of 80 units/kg (maximum 10,000 units), initial infusion of 18 units/kg/hr (maximum 2000 units/hr), and optional bolus. The goal aPTT range was 40 to 70 seconds. The low dose aPTT protocol included an optional bolus of 60 units/kg (maximum 4,000 units), initial infusion of 12 units/kg/hr (maximum 900 units/hr), and optional bolus. The goal aPTT range was 35 to 39 seconds.

A retrospective chart review of all patients on the anti-Xa protocol and a random sample of patients on the aPTT protocol from May 2016 through August 2016 was conducted. Variables
assessed included demographics, indication and dosing, anti-Xa levels, and aPTT values. Descriptive and quantitative analyses were performed.

Poster Title: Implementation of asthma educational services provided by certified asthma educator pharmacists in an inner-city hospital.

Primary Author: Kristina Luo, Bronx Lebanon Hospital Center, NY; Email: knluo7@gmail.com

Additional Author(s):
Kyoung-Sil Kang
Lawrence Schiller

Purpose: In July 2014, clinical pharmacists in our institution who are certified asthma educators began providing asthma education services in the outpatient pulmonary clinic. During clinic visits, the pharmacists educate patients on asthma pathophysiology, trigger avoidance, medication instructions, and peak flow monitoring. An Asthma Action Plan is also provided to patients. The objective of this study is to determine if there is a difference between Asthma Control Test (ACT) scores before and after education by certified asthma educator pharmacists.

Methods: This study is under review by the Institutional Review Board. This study will be a retrospective, single center chart review conducted at our institution. Patients at least 18 years old who were provided asthma education by the certified asthma educator pharmacists between July 2014 to September 2016 will be included in the study. Data will be collected through the hospital's electronic medical record (EMR) system and patients information will be de-identified. Patients’ ACT scores will be collected during initial and follow up clinic visits. Other parameters such as patients’ baseline characteristics, medications, consult orders, and disease severity will be documented.

Poster Title: Impact of pharmacist discharge counseling on direct oral anticoagulants (DOAC)

Primary Author: Paula Baichoo, Bronx Lebanon Hospital Center, NY; Email: paula.baichoo@gmail.com

Additional Author(s):
Charncia Huggins
Kyoung-Sil Kang
Peter Lao
Lawrence Schiller

Purpose: Pharmacist counseling during transitions of care has resulted in improved patient outcomes. One area for potential impact is with direct oral anticoagulants (DOACS). These medications require dose transitions at specified time intervals for certain indications. However, limited data is available on whether these transitions are being done as recommended by manufacturers. Lack of follow-up could lead to medication errors and possible readmission as patients continue on inappropriate doses. The objective of this study is to evaluate the impact of discharge counseling and post-discharge follow-up conducted by pharmacists on the number of patients who receive appropriate DOAC dose transitions.

Methods: This study is pending approval by our Institutional Review Board. This retrospective chart review will include patients who were discharged from an inpatient hospitalization on apixaban or rivaroxaban. Patients will be included in the study if they have a primary care provider (PCP) at our institution and were previously on a DOAC or were newly initiated on a DOAC during their inpatient stay. Data collected will include: whether patient received pharmacist discharge counseling, name of medication, strength, quantity, and directions for use, and indication. We will also determine whether patients were given and attended a follow-up PCP/cardiology/pharmacist appointment post inpatient discharge to receive appropriate dose transitions. We will compare the number of patients who received appropriate DOAC dose transitions before and after implementation of care transitions counseling and post-discharge follow-up. We will also compare the patient follow-up rates and 30-day readmission post pharmacist counseling.

**Poster Title:** Impact of CPOE-assisted 'time-out' reassessment of intravenous vancomycin therapy 72 hours after initiation  

**Primary Author:** Randy Lao, Bronx-Lebanon Medical Center, NY; **Email:** randylao@outlook.com  

**Additional Author(s):**  
Frank Palmieri  
Cosmina Zeana  
Kyoung-sil Kang  
Lawrence Schiller  

**Purpose:** Antibiotic “time-outs” encourage prescribers to perform routine reassessments of antibiotic regimens. The use of a checklist during a “time-out” that promotes appropriateness of antibiotic therapies has been shown to decrease the duration of therapy and increase the correct targeting of pathogens. “Time-outs” have been proposed for antibiotic stewardship programs by the CDC and IDSA, but the literature on the implementation and effectiveness of such strategies is limited. Computerized physician order entry (CPOE) will be used to facilitate hospital-wide antibiotic “time-outs”. The objective of this study is to quantify the impact of a CPOE-assisted “time-out” of vancomycin.  

**Methods:** This study is under review by the institutional review board. This will be a retrospective, single center chart review study conducted at our institution. A third-party database will be utilized to generate a report of all adult patients that have received vancomycin therapy at our institution three months prior to and three months after implementation of the CPOE-assisted antibiotic “time-out.” The hospital's electronic medical record system will be used to access pertinent patient information including: antibiotic "time-out" document compliance information, vancomycin dose, frequency, length of therapy, culture results and antibiotic therapies thereafter. Primary outcome is defined as compliance with completion of antibiotic reassessment form. Secondary outcomes are average length of therapy for vancomycin and the rate of correct targeting of pathogens after 72 hours from the initial order placement.

Poster Title: Evaluation of hepatitis C pharmacy services in an ambulatory care urban setting: the impact of a collaborative drug therapy management agreement

Primary Author: Cathleen Mathew, Brookdale University Hospital and Medical Center, NY;
Email: cmathew@bhmcny.org

Additional Author(s):
Maria Sorbera
Shannon Ramdeen
Elizabeth Agard-Watson

Purpose: Hepatitis C virus (HCV) is one of the greatest public health threats within the United States. Establishment of a hepatitis C collaborative drug therapy management (CDTM) service in an ambulatory care clinic will allow for pharmacists to play a crucial role in providing improved quality of care to an underserved HIV-positive patient population. The concerted efforts of an interdisciplinary team treating those indicated for HCV therapy will lead to improved sustained virologic response rates (SVR) within the clinic. This study will evaluate the impact of pharmacy services within this interdisciplinary team.

Methods: After implementation of hepatitis C CDTM pharmacy services, data will be collected for HIV-positive patients who receive HCV services from August 1st, 2016 through July 30th, 2017. Data will be compared to HIV-positive patients who have previously received non-pharmacy HCV services at BHMC during the year of 2015. The primary endpoint is the percentage of patients achieving HCV cure, defined as SVR 12 weeks post treatment (SVR12). Secondary outcomes include HCV RNA levels at treatment weeks 4 and 12, patient adherence, and a composite of pharmacist interventions including medication acquisition as well as identification and resolution of drug therapy problems.

**Poster Title:** Pharmacy concierge financial outcomes for atypical long-acting injectable antipsychotics in the adult outpatient psychiatric department

**Primary Author:** Gerard Quinn, Brookdale University Hospital and Medical Center, NY; **Email:** gquinn@bhmcny.org

**Additional Author(s):**
Aliaksandr Budovich
Maria Claudio
Johnny Ha

**Purpose:** Many psychiatric patients are receiving long term maintenance therapy in the form of long-acting injectable (LAI) medications. This is an appealing choice for many patients as the medication adherence rates in this patient population are some of the lowest in any disease state. The American Psychiatric Association recommends atypical anti-psychotics as first-line treatment for initial episodes and LAI's for repeatedly non-adherent patients. The purpose of this project is to facilitate LAI acquisition for patients in the adult outpatient psychiatric department (AOPD) in conjunction with the BHMC outpatient pharmacy.

**Methods:** The study was approved by the Institutional Review Board and the results of the project will be presented to the Pharmacy and Therapeutics Committee. The inpatient and outpatient pharmacy electronic medical systems will be used to identify patients who are currently taking an atypical LAI. Medical notes may also be accessed in order to determine any changes made to patient therapy. The following data will be collected: medication patient is taking, type of insurance patient has, wholesaler acquisition cost, amount reimbursed by insurance company and reasons for insurance rejection to pay. All data will be recorded without patient identifiers and patient confidentiality will be maintained. The total financial outcomes for the LAI's will be calculated over a one month time period after implementation of the pharmacy concierge and compared to the financial outcomes over a similar period of time before the concierge was initiated in the AOPD to assess improvement.

**Results:** N/A
Conclusion: N/A
**Poster Title:** Impact of pharmacist intervention on the prescribing practices in the elderly population

**Primary Author:** Maureen Muthoni, Brookdale University Hospital and Medical Center, NY;  
**Email:** maureen366@gmail.com

**Additional Author(s):**  
Shannon Christy  
Shalonda Williams

**Purpose:** Certain medications are considered inappropriate in the elderly population due to increased risk of adverse events and potential harm. Different lists are available to aid clinicians identify these medications. The primary objective of this study is to assess potentially inappropriate medications (PIMs) prescribed in the elderly population using the STOPP (Screening Tool of Older Persons’ Prescriptions) and START (Screening Tool to Alert doctors to Right Treatment) Criteria and the Beers Criteria to make clinical recommendations to prescribers. Secondary objectives will be analyzing interventions made by the pharmacists, interventions accepted by prescribers and identifying which screening tool detects more PIMs.

**Methods:** This study has been submitted to the Institutional Review Board and is pending approval. This will be a retrospective study taking place in anticoagulation and medication management clinics. Pharmacists will review the medications of all patients age 65 and older seen in the clinics between September 2015 through September 2016. The pharmacists will identify any PIMs based on the STOPP/START and Beers Criteria. Pharmacists will complete a full chart review to check if there is a specific reason the patient has to be on a PIM. This should be completed before the pharmacist contacts the physician to make any recommendations on stopping medications. Pharmacists will then contact prescribers to make any medication recommendations based on the screening tools. Pharmacists will document all overall recommendations as well as specific recommendations accepted by the prescribers. The primary endpoint will be PIMs identified based on STOPP/START and Beers Criteria. The secondary endpoints will be number of medication recommendations made by the pharmacists and number of medication recommendations accepted by the prescribers. Descriptive statistics will be utilized.

Poster Title: Identification of patients at risk for opioid overdose and the implementation of a naloxone dispensing program at an urban medical center

Primary Author: Robert O’Connell, Brookdale University Hospital Medical Center, NY; Email: roboconnell514@yahoo.com

Additional Author(s):
Maria Sorbera
Maria Claudio-Saez
Johnny Ha

Purpose: In 2015, there were 937 unintentional drug overdose deaths in New York City which equated to a 66% increase in the overdose rate since 2010. To address this growing public health issue, New York State Department of Health has created an initiative to expand the availability of naloxone throughout communities. The objective of this study is to identify admitted patients who are at risk of a future opioid overdose and provide them with a naloxone overdose kit at the bedside prior to discharge.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will be used to identify patients who are determined to be at risk of future opioid overdose and should therefore receive a naloxone overdose kit upon discharge. Patients will be included if they were admitted to the medical center due to an opioid overdose, have a positive urine toxicology screening on admission, are taking high-dose opioids (>100mg/day morphine equivalent), or take methadone or buprenorphine/naloxone for opioid dependence. The following data will be collected: patient age, gender, ethnicity, current opioid medications, history of drug use, past medical history related to drug/opioid use, and urine toxicology. To maintain confidentiality, data will be recorded without patient identifiers. Patients will be counseled regarding their risks for future overdose and informed of the benefits of naloxone in the setting of overdose reversal. When necessary, referrals to an addiction treatment center will be made. With the patient’s consent, a standing order for naloxone will be used to dispense a naloxone overdose kit from an outpatient pharmacy. The kit will be brought to the patient’s bedside in which a pharmacist will counsel on the proper use of the
device with the aid of additional instructional materials. The investigators will also track opioid related readmissions during the study period.

**Poster Title:** Evaluation of alteplase utilization for ultrasound-assisted catheter-directed thrombolysis for pulmonary embolism in hospitalized patients

**Primary Author:** Sarah Buranich, Buffalo General Medical Center, NY; **Email:** sburanich11@jcu.edu

**Additional Author(s):**
Kimberly Zammit
Brian Kersten
Crystal Diep

**Purpose:** Thrombolysis is recommended for patients with pulmonary embolism (PE) associated with hypotension and a low risk for bleeding. Catheter-directed thrombolysis can achieve lysis of a thrombus more rapidly and with lower doses of thrombolytic therapy than intravenous administration since it is administered at the site of the clot. The addition of an ultrasound component is theorized to separate and disaggregate fibrin fibers, allowing the fibrinolytic agent to achieve greater penetration. The aim of this study is to evaluate the use of alteplase in ultrasound-assisted, catheter-directed thrombolysis for PE in hospitalized patients.

**Methods:** This retrospective review evaluated the use of alteplase in ultrasound-assisted catheter-directed thrombolysis of PE in hospitalized patients. All patients diagnosed with a PE who received this therapy between December 2015 and August 2016 were included in the study. Those patients who were ordered alteplase as part of the ultrasound-assisted catheter-directed thrombolysis protocol, but were never administered alteplase were excluded from the study. Data analysis was performed to determine the average total dose and duration of alteplase administered to patients and the appropriateness of alteplase products sent from the pharmacy in regards to waste and cost. Several secondary endpoints included major bleeding within 72 hours of alteplase initiation, recurrent venous thromboembolism during hospital stay, re-hospitalization within 30 days, and the need for additional alteplase infusion beyond initial administration. In addition, concurrent heparin/anticoagulant use, adverse events, outcome of therapy, length of hospitalization/ICU stay, and oral anticoagulant prescribed for long-term anticoagulation were collected for quality measures.
Results: The analysis of this review is pending.

**Poster Title:** Evaluation of antibiotic use in patients with asymptomatic bacteriuria identified in the Emergency Department

**Primary Author:** Magdalena Wrzesinski, Buffalo General Medical Center, NY; **Email:** mwrzesinski@kaleidahealth.org

**Additional Author (s):**
Melissa Danek  
Megan Nadler  
Morgan Lebrecht

**Purpose:** The purpose of this medication use evaluation is to identify the inappropriate administration of antibiotics to patients with asymptomatic bacteriuria. The primary objective is to identify the number of patients with asymptomatic bacteriuria who are inappropriately treated with antibiotics in the Emergency Department. The secondary objective is to identify the number of patients inappropriately continued on antibiotics after admission.

**Methods:** Cerner (electronic medical record) queries will be used to generate a list of patients with urinalyses ordered in the Buffalo General Medical Center Emergency Department during two consecutive weeks in March of 2016. The electronic medical records of these patients will then be reviewed to identify the evaluable population. Patients included in the study will be assessed for meeting UTI criteria. Meeting UTI criteria is defined as a positive urinalysis with fever of >38°C or urinary symptoms. Patients with a positive urinalysis who do not have a fever of >38°C or urinary symptoms will be categorized as having asymptomatic bacteriuria. In this study, a positive urinalysis is defined as meeting one of the following criteria: > 6-25 WBC/hpf, positive leukocyte esterase, or positive nitrites. Urinary symptoms are defined as urgency, frequency, dysuria, suprapubic tenderness, and costovertebral angle pain or tenderness. Inappropriate antibiotic initiation is defined as patients who received antibiotics despite not meeting UTI criteria. Inappropriate antibiotic continuation will be assessed in patients who are admitted as inpatients and will be defined as patients who are continued on antibiotics despite not meeting UTI criteria.

**Poster Title:** Impact of a pharmacist intervention on congestive heart failure patients identified as high risk for preventable disease-related hospital admissions.  

**Primary Author:** Jordan Rohder, Capital District Physicians' Health Plan, NY; **Email:** jordan.rohder@gmail.com  

**Additional Author (s):**  
Diana Nadler  
Tara Thomas  
Daniel Reynolds  
Stephanie Ross  

**Purpose:** Congestive heart failure (CHF) is a progressive, chronic disease for which low-quality care can lead to high costs from avoidable hospital admissions. CHF can generally be managed in the outpatient care setting to prevent exacerbations and the need for hospitalizations. Medication adherence and disease state education can help the patient self-manage their disease, thus reducing preventable hospitalizations, improving quality of care, and decreasing cost of care. The objective of this research is to understand the impact of a pharmacist-led intervention on reducing avoidable admissions when patients identified as high risk receive targeted medication therapy management (MTM) services.  

**Methods:** A predictive model that includes covariates such as comorbidities, adherence, demographics, and total cost of care will be used to identify members with CHF who are at high risk for a preventable disease-related admission. These members will be stratified based on the probability of a preventable hospital admission within six months. Those at highest risk will be identified for intervention with a pharmacist who will provide MTM services. During the intervention, the pharmacist will collect patient information, assess medication therapy using evidence-based guidelines, evaluate drug interactions, educate the patient, and address any identified problems. Criteria for this study includes members with a CHF diagnosis who are 18 and older and have continuous coverage during the study period. Those members with an intervention will be matched to a member with similar characteristics without an intervention to form a control cohort. Preventable hospitalization rates at six months post-intervention will be compared between the two groups to measure the effectiveness of the intervention.

**Poster Title:** Understanding the variation of prescribing patterns with disease-modifying antirheumatic drugs (DMARDs) for members newly diagnosed with rheumatoid arthritis (RA)

**Primary Author:** Ashir Shumunov, Capital District Physicians’ Health Plan (CDPHP), NY; **Email:** ashir.shumunov@cdphp.com

**Additional Author(s):** Diana Nadler, Tara Thomas, Theresa Nobles, Laurie Lincoln

**Purpose:** Rheumatoid arthritis (RA) is a chronic, debilitating condition that affects 0.4 to 0.47 percent of Americans. There is no cure for RA; however, disease-modifying anti-rheumatic drugs (DMARDs) are highly effective for protecting joints and minimizing inflammation in other organs. According to American College of Rheumatology guidelines, early intervention with DMARD therapy helps preserve function and prevent further complications. In 2014, DMARDs for all indications accounted for approximately 10 percent of the $310 billion U.S. prescription drug market, with costs steadily increasing. This project aims to evaluate the variations in prescribing patterns among area providers with respect to current clinical literature.

**Methods:** The study population includes members with a new diagnosis of RA. Inclusion criteria for the analysis are as follows: members must be at least 18 years old, have at least two RA-related diagnoses on a medical claim, and be continuously enrolled two years before and after the first RA diagnosis. Both clinical and economic metrics will be evaluated in this analysis. Clinical parameters include time to first pharmacologic therapy, subsequent medication(s) used, discontinuation rate, medication adherence, and dose changes. Additionally, the effect of a patient’s comorbidities on the treatment pathway chosen will be evaluated. The total cost of care associated with prescription drugs, labs, office, ambulatory, hospital, and emergency room visits will be assessed in the economic analysis. Trends will be evaluated with current clinical literature to identify variations. Data will be gathered from administrative medical and pharmacy claims databases.

Poster Title: Evaluation of the Appropriateness of Pegfilgrastim Use in Patients at a Small Community Oncology Clinic at Erie County Medical Center in Buffalo, NY

Primary Author: Stephanie Brennan, Erie County Medical Center/University at Buffalo, NY;
Email: slbrennan333@gmail.com

Additional Author(s):
Eugene Przespolowski
Michael Ott

Purpose: Pegfilgrastim (Neulasta) is indicated for reducing the incidence of febrile neutropenia in receiving myelosuppressive chemotherapy associated with a clinically significant incidence of febrile neutropenia. The primary objective of this study is to evaluate the appropriateness of use of pegfilgrastim based on both NCCN and ASCO guidelines and the stratification of associated risk factors for febrile neutropenia.

Methods: Potential subjects will be identified via an inquiry in the electronic health records for all patients at ECMC who were dispensed at least one dose of pegfilgrastim from December 2012-June 2016. Disease-state data collection includes type, site, and stage of malignancy, previous chemotherapy or radiation therapy, previous neutropenia, recent surgical procedures (3 months), performance and nutritional status, and other co-morbid conditions. Pharmacologic treatment data collection will include chemotherapy regimen and pegfilgrastim use. Patients will be stratified based on risk factors listed in both NCCN and ASCO guidelines, and use will be classified as either appropriate or inappropriate for each set of recommendations. The information elucidated from this study will be used to examine the current utilization of pegfilgrastim at this institution.

Poster Title: Use of cascading order questions to guide antibiotic selection for patients with a history of beta-lactam reactions: a focus on aztreonam

Primary Author: Melanie Johnson, Highland Hospital, NY; Email: melanie_johnson@urmc.rochester.edu

Additional Author(s):
Ann Montaperto
Jeff Huntress
Tina Khadem
Justin Foster

Purpose: Penicillin reactions are commonly reported by patients. Despite low cross-reactivity rates with cephalosporin antibiotics, clinicians may avoid all β-lactam antibiotics when selecting agents in patients with reported penicillin reactions. Aztreonam is an alternative agent that is often chosen but is more costly and, at our institutions, has a lower susceptibility rate to Pseudomonas aeruginosa than other broad spectrum gram-negative agents. The purpose of this study is to characterize aztreonam use and to evaluate the impact of the use of order questions on adherence to established institutional clinical practice guidelines for antibiotic selection in patients with a reported beta-lactam reaction.

Methods: This retrospective study will be submitted to the Institutional Review Board for expedited approval. The electronic health record (EHR) will be used to identify all subjects who received orders for aztreonam at our 2 institutions during a 6 month study period. We anticipate reviewing a minimum of 250-300 aztreonam orders from approximately 150 patients. All identified aztreonam orders will be included in this review. There are no gender, racial/ethnic, or age range restrictions. Data to be collected include the presence of any reported medication allergy information (allergy reaction and severity, date of allergy report), history of any prior beta-lactam or cephalosporin antimicrobial use, and provider responses to aztreonam cascading order questions. Provider responses to the order questions will be evaluated and compared to the specific patient chart information. Adherence to the institutional guideline will be characterized by the number of order questions considered to
have been documented appropriately in the EHR. Data will be summarized and analyzed using
descriptive statistics.

Poster Title: Evaluating a pharmacist’s impact on the treatment of urinary tract infections in a community hospital
Primary Author: Lewey Chan, Huntington Hospital Association, NY; Email: leweyc@hotmail.com
Additional Author (s):
Eric La
Agnieszka Pasternak
Robert Berger

Purpose: In Huntington Hospital, the majority of patients are overseen by individual hospitalists. As a result, there can be an array of differences in habitual prescribing patterns and the treatment of various diseases including urinary tract infections (UTIs). To compound on these differences, the presence of a unit-based pharmacist is not established on all floors. The purpose of this study is to determine the impact a pharmacist has in the course of hospitalization of patients due to UTIs.

Methods: This study has been submitted to the Institutional Review Board for approval. The patient list will be generated by the electronic medical record to include adult subjects (age ≥ 18 years) that have been classified by ICD-9 and ICD-10 codes for asymptomatic bacteriuria, acute cystitis, pyelonephritis and prostatitis. Only patients who were admitted to Huntington Hospital’s medical-surgical floors and maternity floors will be included. The following data will be collected: patient's age, sex, admitting diagnosis, presence of an infectious disease consult, type of UTI, urine culture and sensitivity, choice of empiric antibiotic, choice of targeted antibiotic, total days of antibiotic therapy, length of stay, time to defervescence, prevalence of hospital-acquired C. difficile infection, and readmission within 30 days for UTI-related symptoms and/or complications. Multiple logistic regression will be used to determine if there in an association between being treated on a medical-surgical floor that has a unit-based pharmacist and improved outcomes.

Poster Title: Intravenous immune globulin (IVIG) dosing based on ideal body weight: Evaluation of a new dosing protocol

Primary Author: Liz Wojakowski, Kaleida Health Buffalo General Medical Center, NY; Email: lwojakowski@kaleidahealth.org

Additional Author (s):
Brian Kersten
Shirley Chen

Purpose: IVIG is typically dosed based on a patient’s actual body weight. However, it might be better to base doses on ideal body weight, since immune globulin has a small volume of distribution and distributes minimally in lipophilic tissue. There are also a few small, pharmacokinetic studies to support this dosing strategy. In July 2015, Kaleida Health initiated a dose adjustment policy that allows pharmacists to automatically adjust doses based on ideal body weight. The objective of this study is to evaluate compliance to the dosing protocols before and after implementation and elucidate any further cost savings mechanisms.

Methods: A retrospective cohort will look at adult patients who received IVIG as an inpatient. A computer generated report identified patients who received IVIG from July 2014 through June 2015 who were dosed by actual body weight and from September 2015 through August 2016 who were dosed by ideal body weight based on the new protocol. Demographic data, condition treated, dose ordered, and dose dispensed, will be collected. The primary endpoint is the percentage of patients who were dosed appropriately based on the applicable protocol. The secondary objective is to compare the number of vials dispensed per dose before and after the dosing protocol. Opportunities for further cost savings initiatives will also be identified. This study was approved by the hospital’s Pharmacy and Therapeutics Committee.

**Poster Title:** Evaluation of sugammadex utilization for reversal of neuromuscular blocking agents in surgical patients

**Primary Author:** Joseph Palumo, Kaleida Health/Buffalo General Medical Center, NY; **Email:** jgpalumb@buffalo.edu

**Additional Author(s):**
Brian Kersten
Lisa Voigt
Rebecca Lucarelli

**Purpose:** Sugammadex is a novel drug that has been approved for the reversal of steroidal neuromuscular blocking agents (NMBA) rocuronium and vecuronium. Studies have shown that sugammadex rapidly reverses the effects of NMBA and has improved effectiveness compared to neostigmine. These studies have used sugammadex doses ranging from 0.5 to 16 mg/kg, with current recommended dosing of 2 to 4 mg/kg. This aim of this study was to evaluate the most commonly used dose of sugammadex and to ensure it aligned with recommended dosing.

**Methods:** This retrospective chart review evaluated the use of sugammadex in elective and non-elective surgical patients. Patients who received sugammadex for the reversal of rocuronium or vecuronium were included in this study. Any patient who was to remain intubated post-operatively or was under the age of 18 were excluded from the study. Data analysis was performed to determine the most commonly used dose of sugammadex in these patients. Several secondary endpoints included what neuromuscular blocking agent (NMBA) was given to the patient, time between the last NMBA dose and the dose of sugammadex, total dose of NMBA used, need for repeat dosing of sugammadex, the use of sugammadex after failed response to neostigmine, and cost of sugammadex dose. This study was approved by the institutions P&T committee.

**Primary Author:** Emma Gorman, Kaleida Health/Buffalo General Medical Center, NY; **Email:** egorman@kaleidahealth.org

**Additional Author(s):**
Stephanie Seyse  
Joshua Caraccio  
Ashley Lemmon

**Purpose:** Price hyperinflation of low use, high cost agents has become an increasingly common and problematic scenario in the hospital setting. Due to the huge cost potential associated with a usual course of therapy as well as the availability of appropriate alternatives, many pharmacy and therapeutics committees have proactively designed guidelines for use to combat this. The purpose of this study will be to describe the development of and to evaluate the implementation of a prospective medication use process for evaluating the effectiveness of these guidelines for use.

**Methods:** This is a prospective, multicenter evaluation of the guidelines for use of restricted agents at three adult facilities within our health system. Guidelines for the appropriate use of these restricted agents are created for individual agents at Pharmacy and Therapeutics committee. Adherence to these guidelines and potential cost avoidance will be evaluated. The development of and implementation of these criteria, including staff education, will be described. Restricted agents to be incorporated in this review include: parenteral calcitonin, ethacrynic acid, methylaltrexone, intravenous acetaminophen, and eptifibatide. Restricted antimicrobial agents will be excluded from this analysis as their use is monitored regularly. Results will be reported quarterly to the Pharmacy and Therapeutics committee.

**Poster Title:** Evaluation of appropriate concomitant use of dual antiplatelet therapy with an oral anticoagulant among patients at a tertiary care institution

**Primary Author:** Sarah Issa, Kaleida Health/Buffalo General Medical Center, NY; **Email:** sissa@kaleidahealth.org

**Additional Author(s):**
Stephanie Seyse
Anna Morien
Carolyn Hempel

**Purpose:** Several consensus documents have been published attempting to provide recommendations for optimal management of triple therapy with dual antiplatelet therapy plus an oral anticoagulant. The introduction of the novel P2Y12 inhibitors as well as the direct oral anticoagulants has further complicated this clinical scenario. The applicability of these agents in triple therapy management remains unclear, yet are still being utilized in practice. The objective of this study is to evaluate triple therapy utilization and determine the prevalence of appropriate prescribing in compliance with hospital policy as well as the proportion of patients utilizing a specific agent within each medication class.

**Methods:** This study has been approved by the institution’s Pharmacy and Therapeutics committee. Because this is a quality improvement initiative, institutional review board approval is not required. Patient charts will be identified through a pharmacy charge data query for aspirin plus P2Y12 inhibitor plus direct oral anticoagulant or warfarin use starting from policy implementation date in November 2012 to present. Patients on triple therapy with aspirin plus P2Y12 inhibitor plus direct oral anticoagulant or warfarin prior to admission will be excluded. Manual chart review will be conducted for data collection of demographics and clinical characteristics associated with calculating a CHA2DS2-VASc score. Indications for triple therapy will be evaluated for appropriateness in compliance with current hospital policy. Descriptive statistics will be used to summarize demographic and clinical characteristics of the included patients. The resultant data will be utilized to update current hospital policy and be evaluated for staff education opportunities and further research development.

**Poster Title:** Identifying a correlation between health literacy scores and frequency of preventative health screening in adults over fifty

**Primary Author:** Jillian Christy, Kings Pharmacy, NY; **Email:** jillian.c@kingsrx.com

**Additional Author (s):**
Brooke Fldler

**Purpose:** A patient’s ability to understand health information also determines their ability to make health related decisions. Although not routinely performed, health literacy assessment tools can be used to assess this ability and may allow healthcare providers to tailor information for patients. The primary endpoint of this study will be to determine if there is a correlation between health literacy scores and frequency of preventative health screening. The secondary and tertiary endpoint will be to determine whether the number of disease states a patient has or recent hospitalizations, respectively, correlates to level of health literacy and frequency of preventative health screening.

**Methods:** As part of the pharmacy's Medication Therapy Management (MTM) service, patient's will be contacted via phone to participate in the study. After consent, a modified Short Assessment of Health Literacy in English (SAHL-E) health literacy assessment tool will be used to determine their health literacy score. Patients will also be asked a series of questions regarding preventative health screening, as well as the number of treated medical conditions and number of hospitalizations in the past twelve months. This information will be used to determine if there is a correlation between health literacy scores and patient's overall health management. At the completion of both questionnaires, patients will be counseled on the importance of preventative health screening (mammograms, vaccinations, prostate exams, etc). Adult patients fifty years and older will be identified using the Kings Pharmacy management system OPUS-ISM® in addition to Mirixa® and Outcomes® which are subscription based programs that help facilitate and deliver MTM services.

**Results:** Pending.

**Conclusion:** Pending.

**Poster Title:** Improving transitions of care from the hospital to community setting: The role of the community pharmacist.

**Primary Author:** Porfibert Crisantos, Kings Pharmacy, NY; Email: porfibert.c@kingsrx.com

**Additional Author(s):**
Brooke Fidler

**Purpose:** Hospital readmission rates within thirty days continues to be a concern in the health care system. This evaluation will assess readmission rates of patients enrolled in the transitional care service with Kings Pharmacy within three weeks post discharge from New York Methodist Hospital. The secondary endpoint will identify which medication counseling information was retained by the patient three weeks post discharge as a result of receiving bedside counseling at discharge by a pharmacist. The tertiary endpoint will assess whether the patient has already seen their doctor for discharge follow up and if they already have a scheduled appointment.

**Methods:** Patients who are part of the Meds to Bed Transitional Care Service at NY Methodist Hospital have their discharge medications filled and delivered to their bedside by Kings Pharmacy and also receive discharge counseling by a pharmacist on all of their discharge medications. This select group of patients will be followed up by a Kings Pharmacy resident at their three week post discharge date. The three week follow up phone call is based on a standard list of counseling points highlighted during discharge counseling. The counseling points retained by the patient, whether they have already seen their primary care provider or have a scheduled appointment and readmission status at three weeks will be recorded. Patients will be educated and counseled on the importance of follow up with their primary care provider and to refill all prescription medications. All data will be recorded without patient identifiers and maintained confidential. The Kings Pharmacy OPUS-ISM pharmacy software system will be used to obtain their medication profile. The New York Methodist Hospital health information technology Cerner system will be accessed periodically to view discharge information such as specific discharge dates and medications prescribed.

Poster Title: Impact of electronic bracelet medication reminder technology on medication adherence in heart failure patients

Primary Author: Jessica Snead, Kingsbrook Jewish Medical Center, NY; Email: jsnead@kingsbrook.org

Additional Author(s):
Darko Todorov
April Von Allmen

Purpose: Poor medication adherence in heart failure has been linked to worse cardiovascular outcomes and is a critical aspect of heart failure exacerbation and hospital readmission. Evaluation of medication adherence with electronic medication reminder technology such as telephone calls, alarm devices, and text messaging has been studied with positive results on adherence and health outcomes. However, there is no literature investigating electronic bracelet (EB) medication reminder technology. The primary objective of this study is to evaluate the impact of EB medication reminder technology on medication adherence and the secondary objective is the impact on 30-day readmission rates in heart failure patients.

Methods: Patients are eligible to be enrolled in the study if they have heart failure admission diagnosis documented in the chart; be 18 years of age; have a Bluetooth enabled smart phone; demonstrate ability to utilize the reminder technology; sign informed consent; be discharged to home. The electronic bracelet will be synchronized to the patient’s smart phone via Bluetooth and programmed to send notifications based off their individual medication regimen. Each medication will be color-coded and the patient will get a notification both on their phone and on their bracelet with a corresponding medication name and color at the appropriate time for administration. The following data will be collected as part of the study: age, gender, ethnicity, insurance status, contact information (phone number and email), number of prescribed medications, name, dosage, route, frequency, and directions of each medication, medication fill history, medical history, and historical hospital admission data over the last year. This data will be compiled and medication adherence will be recorded as a percentage. The electronic medical record system will be monitored to determine if the patient has been readmitted within the next 30 days. All readmission data collected will be compared to the historic heart
failure 30-day readmission rates at Kingsbrook Jewish Medical Center provided by the Centers for Medicare and Medicaid.

Poster Title: The effect of parenteral ibuprofen (Caldolor) on opioid use in surgery patients

Primary Author: Etty Vider, Kingsbrook Jewish Medical Center, NY; Email: evider@kingsbrook.org

Additional Author(s):
Rachel Sarekhhatoun
Michael Biglow
Henry Cohen
William Lois

Purpose: Caldolor was approved by the FDA in June 2009. Caldolor is indicated in adults and pediatric patients 6 months and older for the management of mild to moderate pain and the management of moderate to severe pain as an adjunct to opioid analgesics. The analgesic and peripheral anti-inflammatory effects of Caldolor in conjunction with opioids attenuate post-operative pain more than each class alone. The purpose of this study is to determine if the use of Caldolor has increased and if this has improved pain management and decreased opioid use in the surgery unit in a community hospital setting.

Methods: A retrospective review of the institutional utilization of Caldolor and several opioids will be conducted on data from January 1, 2012 to December 31, 2015. This will examine the various trends of Caldolor usage by years, doses used, adverse effects and subsequent opioid use. A report of narcotic use from January 1, 2012 to December 31, 2015 will be generated for commonly utilized opioids in oral, IV/SQ and PCA formulation. A prospective review of current analgesic prescribing habits will also be conducted for 5 days per week for 6 weeks and will examine opioid use, as well as adverse effects. A record will be created with the patient’s name, medical record number, pain medications ordered and used, with corresponding pain scores. Pain scores will be trended alongside Caldolor and opioid use to discern any correlation between pain scores and opioid use. Data will be sorted into tables using a Microsoft excel spreadsheet. Descriptive statistics will be used to characterize data and observe trends.

Poster Title: Optimizing medication administration through proactive pharmacy led interventions in a community hospital setting

Primary Author: Mayer Goldberg, Kingsbrook Jewish Medical Center, NY; Email: mgoldberg@kingsbrook.org

Additional Author (s):
Rachel Sarekhhatoun
Henry Cohen

Purpose: Medication errors can precipitate serious, devastating consequences and its prevention is one of the National Patient Safety Goals. The use of barcoding has grown exponentially over the last few years and is designed to enhance patient safety. Barcoding ensures that nurses always comply with the 5 R’s: right patient, right drug, right dose, right route, and right time before administering the medication. The purpose of this study is to assess a pharmacy led intervention to reduce barcoding overrides and streamline the medication administration process.

Methods: Medication Administration check, also known as MAK, provides hospitals with the newest innovative technology used to combat medication error. In this study, we implemented proactive procedures such as assigning a technician to cross reference the daily inventory to ensure that updated national drug codes (NDCs) are assigned in the electronic medical administration record. Concurrently, we assessed the pharmacy inventory and the medications available as unit dose packaging. Based on our assessment, of the latter, we revised the process of our unit dose packaging using a cost-benefit analysis to reduce the number of non-barcoded dispensation. In addition, we generated reports from six months prior to the intervention looking at barcode overrides and compared them to reports generated in real-time two weeks after the implementation of the interventions. Using the barcoding override reports, we identified the top 10 medications that nurses have to override. These medications were correlated to our institution’s top 10 medication errors and adverse drug events.

Results: The results is pending.
Conclusion: The conclusion is pending.

Poster Title: Utilization review of an innovative pain management order set to improve pain management in a community hospital

Primary Author: Chava Davidovits, Kingsbrook Jewish Medical Center, NY; Email: c davidovits@kingsbrook.org

Additional Author (s):
Darko Todorov
Michael Biglow
Henry Cohen

Purpose: The Institute of Safe Medication Practices noted that well-designed order sets ensure evidence-based care with reduced risk of medication errors. When trying to manage patients’ pain, pain management order sets ensure the appropriate use of opioids and non-opioid therapies. Our institution developed an innovative pain management order set to guide clinicians in providing optimal evidence-based pain treatment. The objective of this drug utilization review was to evaluate patient use of medications ordered via the order set and assess hospital-wide physician utilization of the pain management order set after instruction on the order set was provided.

Methods: This drug utilization review was a concurrent observational project. In October 2016, educational sessions on the pain management order set were provided to internal medicine medical residents. A daily IT report was generated detailing pain medications ordered in the hospital. The report review examined the number of times the order set was utilized and which medications were frequently selected via the order set. Additional aspects examined were the number of times patients utilized the pain medications ordered via the order set, the frequency of additional pain medications ordered when the order set was utilized and the utilization of agents used to treat pain medication adverse events. In order to determine if the educational session increased the utilization of the pain order set, IT pain reports generated prior to October 2016 were also reviewed. Here too the aspects reviewed were the number of times the order set was utilized, which medications were frequently selected via the order set, patients’ utilization of the pain medications ordered, and the utilization of agents used to treat pain medication adverse events. A Microsoft excel spreadsheet was created to document the
above findings. Descriptive statistics was then applied to observe trends and to identify if further instruction on pain order sets was warranted.

Poster Title: Intramuscular haloperidol for the treatment of cannabinoid hyperemesis syndrome: a case report

Primary Author: Sora Vysotski, Kingsbrook Jewish Medical Center, NY; Email: sora.vysotski@gmail.com

Additional Author (s):
Kristin Bohnenberger

Purpose: Cannabinoid hyperemesis syndrome (CHS) is a medical condition triggered by chronic cannabis overuse and characterized by compulsive bathing behaviors and recurrent episodes of vomiting unresponsive to conventional antiemetics. This case describes the use of haloperidol for cannabinoid hyperemesis syndrome. A 36-year-old female presented to emergency department (ED) and complained of recurrent vomiting and abdominal pain. The pain began 4 days prior to presentation to the ED and was reported as severe, sharp and radiated to the epigastric region. She denied fevers, chills, diarrhea, constipation, or melena. She was seen at an outside facility for the same complaint 3 days prior to her presentation at this ED and was given ondansetron. Although the patient denied relief with ondansetron, she did report temporary relief with hot showers. Her past medical history was significant for hypertension, gastritis, and asthma. She had no history of a similar problem. The patient admitted to smoking marijuana with unknown frequency, daily cigarette use, and occasional alcohol use. Her home medications included: pantoprazole, budesonide/formoterol and albuterol. Laboratory work-up was unremarkable and pregnancy test was negative. In the ED the patient was initially treated with intravenous (IV) fluids, metoclopramide IV, diphenhydramine IV, and famotidine IV. Four hours later the patient still complained of nausea and abdominal pain, so the decision was made to administer intramuscular (IM) haloperidol. Approximately one hour later the patient reported significant relief of her symptoms. She was discharged from ED 2 hours later, symptom free, with instructions to discontinue cannabis use. Although the pathophysiology of cannabinoid hyperemesis syndrome (CHS) remains unclear at this time, this case illustrates the successful use of IM haloperidol for relief of CHS refractory to conventional pharmacologic agents.

**Poster Title:** Probable valproic acid induced Stevens-Johnson Syndrome without concomitant lamotrigine

**Primary Author:** Justine Choe, Kingsbrook Jewish Medical Center, NY; **Email:** jchoe@kingsbrook.org

**Additional Author (s):**
- Chanie Wassner
- Samuel Uter
- Henry Cohen

**Purpose:** Stevens-Johnson Syndrome (SJS) is a severe mucocutaneous reaction where epidermis detachment occurs in less than 10% of the body surface area. SJS may also manifest with mucous membrane involvement, most commonly ocular, oral or genital mucosal tissues. SJS is usually caused by drugs, the most common offenders including carbamazepine, allopurinol, lamotrigine, nonsteroidal anti-inflammatory drugs and sulfa antibiotics. This case report describes a patient who developed SJS likely secondary to valproic acid. The patient was a 49-year-old female who presented to the emergency room (ER) with a generalized rash that began about five days prior. She was seen by a dermatologist, who obtained a skin biopsy and then referred her to the ER. On presentation, she had a generalized skin rash on the upper mid chest that covered greater than 80% of the body surface area but had less than 10% skin detachment. The patient’s past medical history included diabetes, asthma, human immunodeficiency virus and bipolar disorder. She reported a penicillin allergy secondary to rash. The patient’s home medications prior to admission included quetiapine 100mg by mouth once daily, metformin 1000mg by mouth twice daily, insulin detemir 20 units subcutaneously at bedtime fluticasone/salmeterol diskus 100/50mcg twice daily, albuterol sulfate inhaler as needed, zolpidem 10mg by mouth at bedtime and valproic acid immediate release 250mg by mouth twice a day. Recent medication changes included an increase of her valproic acid dose to 250mg twice a day (unknown initial dose) and a recent start of zolpidem. All home medications were discontinued upon admission and patient was admitted to the critical care unit. Ophthalmology and gynecology were consulted for the mucosal tissue involvement. The patient was started on diphenhydramine 50mg intravenously every eight hours, methylprednisolone 40mg intravenously every eight hours, and famotidine 40mg intravenously every morning.
Supportive care included petroleum jelly and gauzes for her skin rashes and a suspension of diphenhydramine 12.5mg/5mL, nystatin, viscous lidocaine 2% and aluminum hydroxide/magnesium hydroxide for the oral lesions. After dermatology consult, methylprednisolone was discontinued and cyclosporine 4mg/kg PO twice daily was started. After skin biopsy returned positive for SJS, patient was accepted for transfer to a burn center for further management. After applying the Naranjo algorithm for causality, a score of probable was obtained for valproic acid causing SJS. Patients with infections such as HIV or with HLA B*1502 phenotype may be at a higher risk for the development of SJS. Valproic acid has a less than 1% risk of SJS according to the manufacturer. Upon review of the literature, this adverse event was only seen in two prior case reports when given without concomitant lamotrigine. This case highlights the importance of obtaining a thorough medication history, acquiring a timeline of new medications and dose adjustments to help determine the probable cause of SJS, and the possibility of valproic acid monotherapy causing SJS.

Poster Title: Achromobacter xylosoxidans bacteremia in a long term care facility: a case report

Primary Author: Ovadyah Avraham, Kingsbrook Jewish Medical Center, NY; Email: oavraham@kingsbrook.org

Additional Author(s):
Chanie Wassner
Marian James

Purpose: Achromobacter xylosoxidans is a rare nosocomial pathogen that has a high mortality rate. Documentation exists that this pathogen causes bacteremia, pneumonia, ventriculitis, endocarditis, meningitis and osteomyelitis. Although not inherently virulent, the pathogen can complicate outcomes due to host factors such as comorbidities, immunosenesence, and other pathogen factors. Pathogen factors can include multidrug resistance and biofilm formation. Appropriate treatment strategies may be delayed due to misidentification. Achromobacter xylosoxidans, Pseudomonas aeruginosa, Burkholderia cepacia and Stenotrophomonas maltophilia have all been mistakenly identified as one another due to similar growth requirements, standard media appearance and antibiotic sensitivity patterns. This case investigates Achromobacter xylosoxidans bacteremia in a geriatric patient secondary to an unknown etiology in a long term care facility. The patient developed fever and tachycardia, and was transferred to an acute care facility to be evaluated for sepsis. Over the course of several days, the patient deteriorated and developed tachypnea, leukocytosis, hypokalemia, hypotension, coagulopathy, hyperlactatemia, hypomagnesemia, acute renal and hepatic failures. The patient’s past medical history was significant for anemia, seizures, paralysis, hypertension, diabetes mellitus, respiratory failure, cognitive impairment, multiple decubital ulcers, multiple cerebral infarcts and systemic lupus erythematosus. Past surgical history included tracheostomy and percutaneous endoscopic gastrostomy. Medication history prior to admission included docusate, pantoprazole, multivitamins, levetiracetam, chlorhexidine, acetaminophen, ipratropium-albuterol and ferrous sulfate, aspirin, ascorbate, metoprolol, atorvastatin, zinc sulfate, bacitracin, collagenase and nystatin-triamcinolone. Imaging displayed right basilar pleural effusion and/or parenchymal disease indicative of pneumonia. Empiric treatment with cefepime and vancomycin was initiated to cover decubiti, bacteremia, and pneumonia. Blood, stool and sputum cultures revealed Achromobacter xylosoxidans,
Clostridium difficile and Pseudomonas aeruginosa respectively. Urine and wound cultures were negative. Achromobacter xylosoxidans bacteremia was initially treated with intravenous cefepime which was then switched to meropenem. The other bacterial infections were managed appropriately. The patient recovered, infections resolved, and the patient was subsequently discharged to a long-term care facility. The final microbiology report revealed bacterial sensitivity to cefazolin, ertapenem, ampicillin-sulbactam, ceftazidime-avibactam, ceftazidime, imipenem, meropenem, piperacillin-tazobactam, sulfamethoxazole-trimethoprim, and amoxicillin-clavulanate. These findings are remarkable given the extensive resistance profile typical of Achromobacter species. To our knowledge this is the only reported isolate with susceptibility to cefazolin.

**Poster Title:** Transdermal scopolamine for treatment of paliperidone-induced sialorrhea

**Primary Author:** Kendra Nielsen, Kingsbrook Jewish Medical Center, NY; **Email:** knielsen@kingsbrook.org

**Additional Author(s):**
Megan Flinchum
Michael Biglow
Henry Cohen

**Purpose:** Antipsychotic agents are difficult to differentiate on efficacy alone, placing the decision of drug therapy primarily on adverse effect profiles given individual patient characteristics. These adverse effects commonly include sedation, extrapyramidal symptoms, orthostasis, hyperprolactinemia, and weight gain. Many antipsychotics have potent anticholinergic properties and tend to cause dry mouth, constipation, and blurred vision. One paradoxical adverse effect of some antipsychotics is sialorrhea; this is most often seen and reported with clozapine specifically. The theory behind clozapine-induced sialorrhea involves muscarinic M4 receptor agonism and adrenergic alpha-2 receptor antagonism by clozapine, both leading to an increase in salivary flow. The reported incidence of hypersalivation in patients taking clozapine is up to 48 percent. However, a recent study found hypersalivation to occur in 92 percent of clozapine users. Excess drool can soak clothes and furniture, cause nighttime awakenings, and hinder speaking, having an overall negative impact on patients’ quality of life. Hypersalivation can also lead to more life-threatening complications, such as choking and aspiration. Unfortunately, there is currently insufficient data to confidently determine appropriate and effective pharmacological interventions for clozapine-induced hypersalivation. More so, clozapine is often a last line agent, and there is minimal data that reports on other antipsychotics’ ability to induce hypersalivation, despite the similar properties among these agents. A PubMed search of clozapine and sialorrhea produces 135 results, while paliperidone and sialorrhea produces none. The following case report examines an incidence of paliperidone-induced sialorrhea and subsequent treatment with scopolamine. A 62-year-old white male with schizoaffective disorder was admitted to an inpatient geriatric psychiatry unit. His past medical history included hypertension, diabetes mellitus, hyperlipidemia, anemia, gastro-esophageal reflux disease, vitamin D deficiency, and movement disorder (likely
antipsychotic-induced). The patient’s previous antipsychotic drug therapy regimen included chlorpromazine, haloperidol, olanzapine, and risperidone, of which he was occasionally compliant. Relevant labs were within normal limits (other than the documented anemia), including his creatinine clearance, which was approximately 85 mL/minute. After oral tolerability of risperidone was confirmed, the patient was started on the long-acting injectable paliperidone palmitate (Invega Sustenna). A few days prior to his next scheduled dose the following month, nursing progress reports began noting excessive drooling by the patient, objectively recorded as drool stains on his shirt and a towel wrapped around him to catch drool. A week after his second paliperidone injection, the patient reported the drool being bothersome. Ten days after that first complaint, in an attempt to block the cholinergic stimulation of the salivary glands, he was given the anticholinergic scopolamine hydrobromide (Transderm-scop) 1.5 milligram transdermal patch. After just a couple of days, progress notes noted a reduction in drooling. Patient continued to receive monthly paliperidone injections for three doses (until discharge) and scopolamine patch every three days for four doses (until patient refused). Patient tolerated the scopolamine patch well and appeared to experience minimal anticholinergic effects; no dizziness, falls, or urinary retention were reported. The successful reduction in paliperidone-induced sialorrhea by scopolamine introduces its use for treatment of paliperidone-induced hypersalivation.

Poster Title: Performance on a composite quality measure for optimal diabetes care in a patient centered medical home.

Primary Author: Anthony Chiappelli, Lifetime Health Medical Group, NY; Email: chiappelli@gmail.com

Additional Author(s):
Erin Slazak
Klara Manning
Stephen Urbanski

Purpose: Quality measure outcomes incentivize higher caliber patient care by scaling reimbursement based on achievement of clinical outcomes. Lifetime Health Medical Group (LHMG) is a primary care physician group and National Committee for Quality Assurance (NCQA) level 3 patient-centered medical home (PCMH). In 2018, the reimbursement structure will transition from a set of individual quality measures for patients with type 1 or type 2 diabetes mellitus to a composite quality measure. A composite measure may be more difficult to attain and reimbursement negatively impacted. The objective of this study is to assess current performance on this new composite quality measure.

Methods: This retrospective record review will be submitted to the Institutional Review Board for approval prior to commencement. The electronic health record (EHR) will identify LHMG patients that are 18 to 75 years of age with type 1 or type 2 diabetes mellitus. The following data will be collected: patient age, most recent HbA1c, most recent blood pressure, presence of nephropathy or nephropathy screen and dilated retinal exam, and medication adherence as measured by proportion of days covered (PDC) within the calendar year. The goal HbA1c and blood pressure defined as “at goal” result is a measurement less than 8% and less than 140/90 mmHg, respectively. This retrospective record review will be used to assess performance on the new composite measure for LHMG as a whole and individually across its 3 Western New York (WNY) locations. The individual components of the composite measure will also be assessed to determine which parameters are most likely to reduce performance on the overall composite measure. Following comprehensive evaluation of our current performance, a plan for improved performance will be developed.

Poster Title: Assessing the effect of the International Medical Prevention Registry on Venous Thromboembolism (IMPROVE) risk assessment model on the use of venous thromboembolism prophylaxis

Primary Author: Sweta Patel, Long Island Jewish Medical Center, NY; Email: spatel56@northwell.edu

Additional Author(s):
Gurpreet Kaur
Christopher Ho

Purpose: The International Medical Prevention Registry on Venous Thromboembolism risk assessment model (IMPROVE RAM) is an evidence-based model used to determine the risk of venous thromboembolism (VTE) and the need for VTE prophylaxis in hospitalized medical patients. Education on use of IMPROVE RAM was performed at the hospital in July 2016. Since then, increased use of the score to determine the need for VTE prophylaxis has been encouraged. The objective of this study is to assess the effect of the implementation of IMPROVE RAM within a tertiary care, teaching hospital on the use of VTE prophylaxis in hospitalized medical patients.

Methods: This study will be a chart review submitted to the Institutional Review Board for approval. The electronic medical record (EMR) system will be used to identify patients that were admitted to the hospital and followed by the medicine team prior to and after IMPROVE RAM education. Patients will be divided into those prior to education who were not exposed to the IMPROVE RAM (non-RAM) and those after education who had utilized the IMPROVE RAM (RAM) to determine the need for VTE prophylaxis. The primary outcome will be the proportion of patients receiving VTE prophylaxis in the RAM arm versus the non-RAM arm. Secondary endpoints will include proportion of patients that had an IMPROVE score documented after education, proportion of patients that had mechanical prophylaxis, prevalence of additional VTE risk factors not included in the IMPROVE score, proportion of patients on antiplatelet agents, and incidence of new VTE or bleeding events during admission. Only patients 18 years of age or older followed by the medicine team during the hospital stay will be eligible. IMPROVE
score must also be documented in the EMR for the RAM arm. Patients requiring full anticoagulation or diagnosed with suspected or confirmed VTE on admission will be excluded.

Poster Title: Effect of dispensing inhalers with or without pharmacist counseling to patients admitted with chronic obstructive pulmonary disease (COPD) exacerbations on thirty-day COPD readmission rates

Primary Author: Caitlyn Cummings, Long Island Jewish Medical Center, NY; Email: caitlyn.cummings@yahoo.com

Additional Author(s):
Jaheera Rehmat
Mayto Nam
Shamsul Islam
Vincent Carnovale

Purpose: Our hospital will be creating a new standard of care whereby all patients will be discharged home with their inpatient inhalers properly labeled for outpatient use. This study will first assess the impact of dispensing inhalers at discharge to patients admitted with COPD exacerbations by comparing post-implementation endpoints to those in a pre-implementation (retrospective) cohort. Additionally, within the prospective post-implementation cohort, patients will be randomized to receive pharmacist counseling or receive standard of care. The impact on 30-day COPD readmission rates will be compared among the three groups.

Methods: This study has been submitted to the Institutional Review Board for approval. Patients admitted to the hospital with a COPD exacerbation will be identified retrospectively and prospectively using the hospital’s COPD Analytics Dashboard. Patients will be excluded if they are hospice care, discharged against medical advice, unable to give informed consent, cognitively impaired, or expected to reside in a long-term care facility. The post-implementation group will receive properly labeled inhalers to take home at discharge. Enrollment will take place for four months based on practicability, not on formal power calculations. The pre-implementation group will be oversampled for the past year. Data collection will include: gender, race, sex, age, LACE score, home oxygen, length of stay, past medical history, smoking history, inhalers on admission, inhalers on discharge, mortality, 30-day COPD and 30-day all-cause readmission status, and HCAHPS scores related to medication metrics. All data will be de-identified and confidentiality will be maintained. The two post-
implementation groups include: inhalers labeled at discharge or inhalers labeled at discharge plus pre-discharge pharmacist counseling. Following initial consent, randomization will take place using the Biostatistics Randomization Management System (BRMS) and a second consent form will be collected for those patients randomized to receive pre-discharge pharmacist counseling. Thirty days post-discharge, internal data will be reviewed to assess readmission status or patients will receive a follow-up phone call to assess outside hospital readmissions.

**Poster Title:** Assessing the risk of nephrotoxicity associated with non-renally adjusted intravenous polymyxin B compared to traditional dosing  

**Primary Author:** Bejoy Maniara, Long Island Jewish Medical Center, NY; **Email:** bejoymaniara@gmail.com  

**Additional Author (s):**  
Thien-Ly Doan  
Lauren Healy  

**Purpose:** Antibiotics are paramount in reducing morbidity and mortality secondary to bacterial infections, but they are associated with the development and propagation of multidrug-resistance. To combat this, broad-spectrum antibiotics with significant toxicities, such as polymyxin B, are forcibly utilized. Due to nephrotoxicity, polymyxin B was inadequately studied and seldom utilized. Prior data states polymyxin B is renally cleared; newer data suggests polymyxin B is predominantly non-renally cleared. This project aims to determine whether non-renally adjusted doses of intravenous polymyxin B produce a similar incidence of nephrotoxicity as renally adjusted doses of intravenous polymyxin B in patients with multidrug-resistant Gram-negative infections.

**Methods:** This study has been submitted to the Institutional Review Board for approval. This will be a retrospective observational chart review of the electronic medical record, evaluating patients who received intravenous polymyxin B at any dose. The aim is to enroll approximately 50 subjects in each arm. Exposed subjects received non-renally adjusted doses of polymyxin B, while unexposed subjects received renally adjusted doses of polymyxin B. Information to be collected may include (not limited to): demographics, height, weight, care setting, serum creatinine, comorbidities, concomitant nephrotoxic agents, site of infection, indication for polymyxin B, dose of polymyxin B, concomitant antibiotics, duration of therapy, length of stay, outcome of infection (resolution or failure), adverse effects, need for renal replacement therapy, all-cause mortality, 7- and 30-day readmission with acute kidney injury, time to nephrotoxicity, albumin level, bilirubin level, and concomitant ascorbic acid. Data will be confidentially recorded without patient identifiers. Survival analyses will compare time until acute kidney injury. Subjects discharged without having developed acute kidney injury will be
Censored at the day of discharge. Cox proportional hazards multivariable regression will determine whether an association exists between polymyxin B dosing method and acute kidney injury incidence. Relative risk, odds ratios, and 95% confidence interval will be computed.

**Poster Title:** Cefoxitin vs piperacillin/tazobactam for acute appendicitis in pediatric patients  

**Primary Author:** Hana Paek, Maimonides Medical Center, NY; Email: hanapaek@gmail.com  

**Additional Author (s):**  
Heiu Pham  
Christina Gagliardo  
Patricia Caruso-Prendergast  
Fred Cassera  

**Purpose:** Appendicitis is a medical emergency that usually necessitates surgery and antimicrobial therapy in pediatric patients. There is a lack of consensus regarding the optimal choice of antimicrobial therapy for pediatric appendicitis, with varying recommendations in the IDSA guidelines and PPAG Red Book. Recent studies have shown that narrow-spectrum and broad-spectrum antibiotics produce similar outcomes in the treatment of pediatric appendicitis. At our institution, cefoxitin has supplanted piperacillin/tazobactam for the management of pediatric appendicitis. The purpose of this study is to compare readmission rates, length of stay, and fever duration among patients treated with either cefoxitin or piperacillin/tazobactam for pediatric appendicitis.  

**Methods:** This study will be submitted to the Institutional Review Board for approval. This is a single-center, retrospective study comparing cefoxitin to piperacillin/tazobactam for prophylaxis and treatment of acute appendicitis in pediatric patients. We will review charts of surgically managed pediatric patients between the ages of 3 to 18 years with a confirmed diagnosis of appendicitis. Two groups of patients will be compared: those who received piperacillin/tazobactam from 8/1/14-8/1/15 to those who received cefoxitin from 9/1/15-9/1/16. Patients will be excluded if they received antimicrobial therapy for other indication or if they received antimicrobial therapy at another facility prior to transfer. Data collection will include age, gender, race, insurance status, duration of antimicrobial therapy, length of stay, duration of fever and readmission within 30 days of discharge. The primary outcome will be treatment failure defined as inpatient readmission necessitating abdominal surgical procedure, percutaneous drainage, wound infection, or other complication within 30 days. Secondary outcomes will include hospital length of stay and duration of fever. Sub-group analyses will be
performed in patients with appendiceal perforations and patients without appendiceal perforations.

**Poster Title:** Enoxaparin versus rivaroxaban for post-orthopedic surgical patients with a body mass index greater than or equal to 35 (RENOX35).

**Primary Author:** Nicole Banks, Maimonides Medical Center, NY; Email: nbanks@maimonidesmed.org

**Additional Author(s):**
Alexandra Spivak
Patricia Caruso-Prendergast
Frederick Cassera

**Purpose:** The occurrence of venous thromboembolism (VTE) is estimated to be 50-60 percent in orthopedic surgical patients if optimal pharmacologic prophylaxis is not used. Studies have shown that there is a positive correlation between the risk of VTE and Body Mass Index (BMI) and a negative correlation between BMI and anti-Xa levels. The objective of this study is to assess whether a non-weight- based anticoagulant, rivaroxaban, is superior to a weight- based anticoagulant, enoxaparin, in obese patients for post-operative deep-venous thromboembolism (DVT) prevention in total knee and hip arthroplasty procedures.

**Methods:** This study will be submitted to the Investigational Review Board for approval. This will be a single site, retrospective study comparing post-operative VTE rates between prophylactic therapy with either oral rivaroxaban or subcutaneous enoxaparin for patients with a BMI greater than 35. A computer generated report containing diagnosis codes for hip or knee orthopedic surgery, in patients with a BMI ≥ 35 will be used to identify patients. The de-identified data that will be collected includes patient BMI, age, VTE prophylaxis received, type of surgery, hospital occurrence of VTE, and readmission in 90 days. Readmission rates or hospital occurrence of related VTE will be analyzed.

**Poster Title:** Aripiprazole vs. quetiapine for hyperactive delirium in a medical intensive care unit: a retrospective analysis

**Primary Author:** Peymon Tavangar, Maimonides Medical Center, NY; **Email:** ptavangar@maimonidesmed.org

**Additional Author (s):**
Daniel Lindsay
Patricia Caruso
Frederick Cassera

**Purpose:** Delirium remains a frequent challenge for the practicing intensivist. The mainstays of treatment include utilizing a number of non-pharmacologic therapies but antipsychotics are frequently employed when these strategies fail. Both quetiapine and aripiprazole, atypical antipsychotics, are utilized at our institution for delirium. Aripiprazole is reserved for patients with pre-treatment QT-prolongation owing to its lessened effect on the QT-interval. We will gather data from patients in the medical intensive care unit (MICU) who were treated with these medications for delirium. We predict that aripiprazole will be as effective as quetiapine and serve as a safer alternative for patients with baseline QT-prolongation.

**Methods:** This retrospective single-center equivalency study has been submitted to the institutional review board. We will review all patients admitted to the MICU on aripiprazole or quetiapine from September 2014 to September 2016. We will collect baseline characteristics for comparison as well as any identified risk factors for delirium discussed in the 2013 Pain, Agitation, and Delirium (PAD) guidelines. We will include any patient age 18 years or greater who were on either aripiprazole or quetiapine. Patients will be excluded if they are older than 85 years, on an antipsychotic prior to admission, pregnant or breastfeeding, or are thought to be experiencing delirium attributed to a drug withdrawal syndrome (e.g., alcohol). Our primary outcome will be ICU length of stay (LOS) and secondary outcomes will include hospital LOS, number of ventilator-dependent days, and any significant change in the pre-treatment QTc as defined by an increase of more than 60 milliseconds.

**Results:** N/A
Conclusion: N/A

**Poster Title:** Clinical outcomes of an inpatient pharmacist-directed anticoagulation service in a community hospital

**Primary Author:** Shaili Patel, Mercy Hospital of Buffalo, NY; **Email:** shaills1210@gmail.com

**Additional Author(s):**
Melissa Zalenski
Timothy Vink
Richard Geisler

**Purpose:** In 2008, the Joint Commission released a National Patient Safety Goals document that requires institutions to implement practices that reduce the likelihood of patient harm associated with use of anti-coagulation therapy. Common causes of errors with anticoagulants are knowledge deficits, failure to follow policy/procedure/protocol, and communication issues. In order to improve anti-coagulation management and safety, our institution implemented an inpatient pharmacist-directed anti-coagulation service. The primary objective will be to analyze time in therapeutic range (TTR) for the patients on warfarin and appropriate renal dose adjustment for other anticoagulants, including rivaroxaban, apixaban, edoxaban, and dabigatran.

**Methods:** This study is pending Institutional Review Board approval. This is a prospective/retrospective cluster randomized study which will include all adult patients who are part of the internal medicine teaching service either being initiated on an oral anticoagulant or continued on home anti-coagulation therapy during hospitalization. Dialysis patients, pregnant females, and patients managed by the hematology team will be excluded. The primary study outcome will be to compare the percentage of time warfarin patients were within the therapeutic range, and appropriateness of renal dose adjustment for apixaban, edoxaban, rivaroxaban, and dabigatran between the prospective and retrospective groups. The retrospective data will be extracted from an existing hospital software program, and will include goal INR (International Normalized Ratio), patient demographics, diagnosis, medication dosage, and appropriateness of renal dose adjustment. This study will involve collaboration with the internal medicine teaching team in order to gather prospective data on patients whose anticoagulant dose required pharmacist intervention. After a patient is initiated on an
anticoagulant by the medical team, warfarin doses will be adjusted using protocol implemented by the hospital, whereas other applicable anticoagulants will be adjusted based on renal function by the centralized or clinical pharmacists. Documentation of recommendations will be made directly into the patient’s chart, and available to the physicians.

**Poster Title:** Effect of code cart rearrangement on compliance with advanced cardiac life support (ACLS) guidelines

**Primary Author:** Danielle Davide, Mercy Hospital of Buffalo, NY; **Email:** ddamide@chsbuffalo.org

**Additional Author(s):**
Melissa Guarino
Richard Geisler

**Purpose:** Given the high mortality rate associated with cardiac arrest, the proper medical management of cardiac arrest patients is critical, and adherence to current guidelines is essential to maximize chances for survival. The purpose of this study is to evaluate the effect of rearranging code carts, based on the recommendations of the 2015 American Heart Association (AHA) Cardiopulmonary Resuscitation and Emergency Cardiac Care (CPR & ECC) Guidelines, on guideline compliance. The results of this study will help guide future code cart adjustments, as well as identify areas where further education is needed.

**Methods:** This study has been approved by the Institutional Review Board. Code records from January 2016 through July 2016 have been obtained (prior to code cart rearrangement). Patients will be included if they were treated for cardiac arrest (asystole, pulseless electrical activity, ventricular fibrillation, or pulseless ventricular tachycardia), were ≥18 years of age, had at least one drug from the code cart administered, and for whom the code record sheet was completely and properly filled out. Data to be collected includes: age; cardiac rhythm(s); name of physician leading the code; name, dose, route, and time of drugs administered; code outcome; and location of patient at time of arrest. Code records will then be obtained post-code cart rearrangement (August 2016 through December 2016). The same information described above will again be collected. The data will then be analyzed to determine the percentage of drugs administered correctly according to ACLS guidelines, time to administration of first drug, and location of drugs administered (code cart, automated dispensing cabinet, or pharmacy). The results will then be compared for pre- and post-code cart rearrangement, and for in-hospital versus out-of-hospital arrests.

Poster Title: Awareness of medication costs and impact of pricing transparency on prescribing practices in Type 2 Diabetes Mellitus: Preparing for payment model reform

Primary Author: Andrew Putzak, Mercy Hospital of Buffalo, NY; Email: andrew.putzak@gmail.com

Additional Author(s):
Gregory Blette
Richard Kraft

Purpose: According to the National Diabetes Statistics Report 2014, an estimated 29.1 million Americans (9.3%) have diabetes. The burden on the health care system includes $176 billion in direct medical cost per year. The objective of this study is to evaluate primary care prescribers’ awareness of medication costs and the impact of cost transparency on their prescribing practices for Type 2 Diabetes Mellitus patients. Additionally, set the stage for further considerations on care delivery as we shift payment models and strive to design optimal metrics of quality as well as total cost of care.

Methods: This study will be submitted to the Institutional Review Board for expedited approval. Prescribers will be surveyed about their prescribing practices using a hypothetical case involving a patient with Type 2 Diabetes Mellitus. This disease state offers well-established practice guidelines and a variety of medication combinations with significant variance in cost and tolerability with smaller differences in terms of biomarker-measured efficacy. This online survey was developed to collect and evaluate the prescribing choices of primary care providers as it pertains to add-on therapy to metformin in Type 2 Diabetes Mellitus patients. The survey will be distributed through various residency programs throughout the country and is designed to provide information in a segmented basis, revealing one additional piece of information at a time. Information will include A1C lowering percentages of various drug classes, guideline recommended therapy, typical adverse reactions, and the average wholesale price of one month and one year’s supply of the various classes of medications. The survey will also include general questions pertaining to the prescriber's current awareness of the total cost of medications that they routinely prescribe to patients. Lastly, it will investigate how cost transparency, at the time of prescribing, impacts the selection of these medications.

Poster Title: Medication use evaluation of ceftolozane/tazobactam and ceftazidime/avibactam for multidrug-resistant (MDR) Gram-negative infections in an urban academic medical center

Primary Author: Kevin Vu, Montefiore Medical Center, NY; Email: kvu@montefiore.org

Additional Author(s):
Phillip Chung
Yi Guo

Purpose: The rise in resistant Gram-negative bacteria is a major concern and has led to difficulty in treating MDR infections. Ceftolozane/tazobactam and ceftazidime/avibactam are two novel beta-lactam/beta-lactamase inhibitor combination agents with activity against selected resistant Gram-negative pathogens, including Enterobacteriaceae, Pseudomonas aeruginosa and/or carbapenemase-producing Klebsiella pneumoniae. Both antibiotics are usually reserved as last-line treatment, restricted to patients who have limited or no alternative therapies. At our institution, a formal infectious diseases evaluation is required for use. The purpose of this study is to evaluate the usage of ceftolozane/tazobactam and ceftazidime/avibactam for the treatment of MDR Gram-negative infections.

Methods: In this retrospective chart review, patients who received ceftolozane/tazobactam or ceftazidime/avibactam between January 2016-November 2016 will be identified using Sentri 7. Information collected will include patient demographics, type of infection, microbiology data, clinical outcome, medication dose/frequency/duration of therapy, hospital length of stay, and adverse events, etc. The data will be analyzed using descriptive statistics. To maintain patient confidentiality, all data will be de-identified with each patient receiving a unique numerical code.

Poster Title: Ceftaroline utilization review for methicillin-resistant staphylococcus aureus (MRSA) infections

Primary Author: Adeola Okoduwa, Montefiore Medical Center, NY; Email: aokoduwa@montefiore.org

Additional Author(s):
Yi Guo
Phillip Chung

Purpose: MRSA-associated infections, such as bacteremia and infective endocarditis, have been related to increased morbidity and mortality. Challenges to treatment have increased alongside the growing resistance to antibacterial agents. Ceftaroline is a fifth-generation cephalosporin that was approved by the FDA in 2010 for the treatment of complicated skin and skin structure infections and community-acquired bacterial pneumonia. Furthermore, it exhibits anti-MRSA activity and has demonstrated efficacy in MRSA bacteremia, endocarditis, and osteomyelitis. The use of ceftaroline requires a formal infectious diseases consultation at our institution. The objective of this study is to review the usage of ceftaroline in MRSA infections.

Methods: All adult patients who received ceftaroline for greater than or equal to 48 hours will be included in this retrospective review. All patient data will be obtained from the electronic medical record systems CareCast and Epic. The following data will be collected: patient demographics, creatinine clearance, history of MRSA, source and type of infection, organism, minimum inhibitory concentrations, antibiotics prior to ceftaroline therapy, reason for switching to ceftaroline, dose, frequency, duration, time to first negative blood culture, microbiological data, clinical outcome, etc. Consults provided by the infectious disease specialists will be reviewed and documented as well. Any patient information collected will be de-identified and maintained confidentially. Additionally, descriptive statistics will be used to analyze the data obtained.

**Poster Title:** Evaluation of treatment, duration, and outcomes of urinary tract infections in kidney transplant recipients

**Primary Author:** Todd Larson, Montefiore Medical Center, NY; **Email:** tlarson@montefiore.org

**Additional Author(s):**
Alesa Courson

**Purpose:** Urinary tract infection (UTI) is the most common bacterial infection following kidney transplantation. It is not uncommon for renal transplant recipients to receive UTI treatment, regardless of colony forming unit (CFU) count or presence of symptoms. This practice can lead to unnecessary exposure to antibiotics as well as increase the risk for antibiotic resistance. The purpose of this study is to evaluate the appropriateness of UTI treatment, with regard to antibiotic choice, dose and duration, within the first year post-renal transplantation, and compare the incidence of antimicrobial resistance in those who receive appropriate vs. inappropriate or unnecessary treatment.

**Methods:** Patients who received a kidney transplant from January 2012 to June 2015 will be retrospectively reviewed using the electronic medical record system. Adults (greater than 21 years old) with documented positive urine culture within the first year post-transplantation will be included. Patients with urinary fungal infections, incomplete culture and susceptibility data, follow up of less than 1 year post-transplant, and recipients of combined organ transplants will be excluded. Patient data collection will include demographics (age, gender, indication for transplant, duration of dialysis pre-transplant, type of transplant, induction therapy and dosing, and number of transplants); date of UTI diagnosis; causative organism and antimicrobial susceptibility, antibiotic agent prescribed, dose, and treatment duration; incidence of UTI recurrence; development of antibiotic resistance; immunosuppressive therapy and dosing at the time of UTI; incidence of biopsy proven acute rejection; serum creatinine (SCr) and estimated glomerular filtration rate (eGFR) 1 month after each UTI and at 12 months post-transplant; concomitant administration of prostatitis prophylaxis; and incidence of cytomegalovirus, BK virus, and C. difficile infections within the first post-transplant year. Patient information will be stored confidentially and all collected data will have patient identifiers removed.

Submission Type: Research-in-Progress

Session-Board Number: 11-272

Poster Title: Evaluation of the screening and treatment practices for bone health in prostate cancer patients receiving adjuvant androgen deprivation therapy

Primary Author: Sherin Jacob, Montefiore Medical Center, NY; Email: sjacob1228@gmail.com

Additional Author(s):
Royston Browne

Purpose: The NCCN Clinical Practice guidelines and ESMO Clinical Practice guidelines for prostate cancer recommend that patients initiated on androgen deprivation therapy (ADT) be evaluated for bone health at baseline regardless of age or sex with periodic follow-up. Guidelines encourage pharmacological therapy if definitive diagnosis of osteoporosis or risk for bone loss or fracture exists. Prostate cancer growth is driven by androgen hormones. Suppression of such hormones benefits cancer therapy but negatively affects bone metabolism. The objective of this study is to determine if screening and treatment of prostate cancer patients on ADT complies with NCCN or ESMO guidelines.

Methods: This retrospective chart review study using an electronic medical record system will identify prostate cancer patients started on androgen deprivation therapy in 2014 at Montefiore Medical Center. Current clinical practice of bone mineral density (BMD) screening, fracture risk analysis, and treatment with Denosumab, Pamidronate, or Zoledronic acid in patients started on androgen deprivation therapy will be evaluated. ADT therapy to be included in this analysis includes Degarelix acetate, Goserelin acetate, and Leuprolide acetate. Data to be collected includes but is not limited to patient age, diagnosis, anti-androgen therapy, FRAX analysis, DEXA imaging, serum 25 (OH) levels, T score, pharmacological therapy chosen, and documented reason for noncompliance. Patient information will be de-identified and maintained confidentially. Initiation of pharmacological therapy is strongly recommended in patients whose T score is less than or equal to -2.0 at certain sites, if the FRAX 10-year absolute risk of fracture is greater than 20% for any major fracture or greater than 3% for hip fracture, or if T score is less than -1.5 in individuals who have lost significant bone mineral density. Therefore, data will be analyzed to confirm bone health care as compliant, noncompliant, and noncompliant but clinically appropriate with NCCN or ESMO guidelines. Data yield may
establish requirement of a new protocol implementation within the institution or confirm current bone health care is appropriate.

**Poster Title:** Evaluation of the utilization of vasopressin in shock

**Primary Author:** Teresa Poon, Mount Sinai Beth Israel, NY; Email: tspoon@chpnet.org

**Additional Author (s):**
Jerry Altshuler
Daryl Paris

**Purpose:** Vasopressin, also known as antidiuretic hormone, is an endogenous hormone that regulates both volume status by altering water reabsorption, and blood pressure through vasoconstriction. In the setting of septic shock, vasopressin levels are acutely elevated and then subsequently decrease as the state of shock is prolonged. Studies have shown benefits with low-dose vasopressin as an adjunctive agent to norepinephrine when introduced in early and less severe septic shock, leading to decreased mortality when compared with norepinephrine alone. The objective of this study is to evaluate how vasopressin is being utilized at Mount Sinai Beth Israel in the management of shock.

**Methods:** A retrospective chart review will be performed in which adult patients are selected based on a medication utilization report of vasopressin at our center prior to September 1, 2016. The objective of this chart review is to analyze the appropriate use of vasopressin based on the indication and place in therapy amongst other vasopressors. Data regarding the order of initiation and discontinuation of vasopressin, as well as the doses of other vasopressors upon vasopressin initiation will be evaluated. Pertinent information such as the median dose of vasopressin used, volume of fluids administered, and mean arterial pressure at time of initiation will be reviewed. In addition, baseline demographic data, lengths of hospital and intensive care unit stay, and adverse events will be collected.

Poster Title: Fixed versus weight-based dosing of rasburicase for prophylaxis and treatment of malignancy-associated hyperuricemia

Primary Author: Victoria Huang, Mount Sinai Beth Israel, NY; Email: vhuang@chpnet.org

Additional Author(s):
Jerry Althshuler
Daryl Paris

Purpose: Tumor lysis syndrome (TLS) is a complication of chemotherapy caused by release of tumor cell contents such as uric acid into the circulation. As a recombinant form of urate oxidase, rasburicase degrades uric acid and can be used for prevention and treatment of TLS-induced hyperuricemia. Although the package insert recommends weight-based dosing for up to 5 to 7 days, there is evidence to support that a single, fixed, low-dose is equally effective. The purpose of this study is to assess the use of fixed versus weight-based dosing of rasburicase in malignancy-associated hyperuricemia pre and post implementation of a hospital protocol.

Methods: Adult cancer patients at Mount Sinai Beth Israel that received rasburicase for the prevention or treatment of TLS-induced hyperuricemia between February 1, 2015 and August 19, 2016 will be included in the analysis. Patient charts will be evaluated for demographics, hospital course, cancer type, chemotherapy regimen, TLS risk, rasburicase regimen, renal function, pertinent laboratory values, and adverse effects. The primary endpoint for this study will be the total cost of rasburicase therapy. Secondary endpoints will include the normalization of uric acid levels at 24, 48 and 72 hours, incidence of acute kidney injury, and rate of adverse effects including methemoglobinemia and hemolysis. Descriptive and inferential statistics will be used to analyze the results as appropriate.

Poster Title: Evaluation of calcitonin use in the management of hypercalcemia of malignancy at an academic teaching hospital

Primary Author: Seah Kim, Mount Sinai Beth Israel, NY; Email: skim3@chpnet.org

Additional Author (s):
Jerry Althuler
Daryl Paris

Purpose: Hypercalcemia is a complication of malignancy that is associated with increased morbidity and mortality. Synthetic calcitonin, which functionally antagonizes the effects of parathyroid hormone, lowers calcium levels by inhibiting osteoclast bone resorption and increasing urinary calcium excretion. In patients with severe, symptomatic hypercalcemia, calcitonin is used in addition to hydration and bisphosphonates when rapid reduction of calcium levels is desired. However, administration beyond 72 hours is not recommended due to development of tachyphylaxis. The objective of this study is to evaluate calcitonin use in the management of malignancy-associated hypercalcemia at Mount Sinai Beth Israel.

Methods: A single-center, retrospective chart review will be performed in adult patients that received calcitonin between January 1, 2014 and October 31, 2016. Patients that received either intramuscular or subcutaneous calcitonin for malignancy-associated hypercalcemia will be identified from a medication utilization report. The primary endpoint is the proportion of patients with appropriate use of calcitonin for the management of malignancy-associated hypercalcemia. Secondary endpoints include the dose of calcitonin, total doses received per patient, and reductions in serum calcium levels. Data regarding patient demographics, hypercalcemia symptoms, hydration status, bisphosphonate therapy, dosage and duration of calcitonin therapy, and pertinent laboratory values (eg. albumin, calcium, parathyroid hormone, parathyroid hormone-related protein, and 1,25-dihydroxyvitamin D) will be collected. Descriptive statistics will be used to analyze the results.

**Poster Title:** Evaluation of daptomycin use at Mount Sinai Beth Israel

**Primary Author:** Oludamilola Olugbile, Mount Sinai Beth Israel, NY; **Email:** oolugbile@chpnet.org

**Additional Author(s):**
Marianna Fedorenko
Polina Lerner

**Purpose:** Daptomycin is a cyclic lipopeptide with activity against a broad spectrum of gram-positive bacteria, including methicillin-resistant Staphylococcus aureus (MRSA), and vancomycin-resistant Enterococcus (VRE). Daptomycin depolarizes the bacterial cell membrane causing cell destruction. Dosing regimens of 4-12 mg/kg/day are utilized for various indications. Weekly creatinine phosphokinase (CPK) monitoring is recommended as it causes myopathy, muscle weakness, and rhabdomyolysis. At Mount Sinai Beth Israel, daptomycin is fully-restricted to protect its activity and limit cost. The goal of this study is to evaluate appropriate use of daptomycin at Mount Sinai Beth Israel in order to identify areas for improvement.

**Methods:** This will be a retrospective evaluation of adult patients, aged 18 years and older, that received at least one dose of daptomycin at Mount Sinai Beth Israel between January 1st and March 31st, 2016. The primary endpoint is the percentage of patients deemed to be appropriately treated with daptomycin therapy based on set criteria. Secondary endpoints include the indications for daptomycin use, the proportion of patients with appropriate daptomycin dosing, the number of approvals per provider, the appropriateness of provider approvals, and a description of CPK monitoring. Appropriate rationale for daptomycin use will be defined as MRSA infections unresponsive to vancomycin, VRE infections, vancomycin-related adverse reactions and/or allergy, and daptomycin use as first dose for outpatient parenteral antimicrobial therapy. Data will be collected through electronic chart review and will include the dosing regimen, rationale for daptomycin use, infectious indication, microbiological information, patient demographics, renal function, and CPK levels. Data will be analyzed using descriptive statistics.

Poster Title: Pharmacy directed strategy implementation to improve Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) scores in pain management and communication about medications domain

Primary Author: Samia Ahsan, Mount Sinai Beth Israel Brooklyn, NY; Email: samiahsan11@gmail.com

Additional Author(s):

Purpose: The Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) score in communication about medicines domains has shown to influence readmission rates in pneumonia and heart failure patients in the past. Communication regarding pain management also has a significant impact on patients’ perception of care during hospital stay regardless of their pain level. This project was designed to implement strategies to improve frequency and quality of communications between nurses and patients regarding pain management and medication therapy. The objective of this project is to improve patient satisfaction with communication about medications and pain management by enhancing nursing communication to patients.

Methods: One general medicine unit will be chosen with non-critically ill patients to maximize nurse and patient communication. At the initiation of the project, a nursing education on teaching techniques and pain management will be developed and completed by a pharmacist. A database with simplified patient education material based on drug classes will be made available at the nursing station to assist during communication about medications. Nurses will be asked to inform each patient about new medications prior to administration. In order to improve pain management, at each shift change, nurses will be asked to record patient’s current pain level, goal pain level and last dose received. Nurses will also follow up on the pain level hourly. A work group will be formed including health care professionals and leaders from both nursing and pharmacy to implement these strategies and assess nursing compliance. Results will be assessed by the HCAHPS score result from following quarter as compared to the baseline score for both of these domains.

Poster Title: Pharmacist-led identifications of factors related to 30-day readmissions at a community hospital

Primary Author: Ida Yenoukian, Mount Sinai Brooklyn, NY; Email: ida.yenoukian@mountsinai.org

Additional Author (s):
Yuliya Baratt
Heather Brener
Dora Li

Purpose: The Center for Medicaid and Medicare reports that one in five patients discharged from the hospital will be readmitted within 30 days. Although, readmission rates have been slowly decreasing, the national average for 30-day all-cause readmission is 17.5%. Reducing readmission rates is an important part of improving patient outcomes. The objective of this study is to identify factors that influence 30-day all-cause readmission.

Methods: This study will be submitted to the Institutional Review Board for approval. A system-generated report will identify hospital-wide all-cause-readmissions within 30-days past discharge. Data will be collected by interviewing patients utilizing a standardized survey to establish potential causative factors that lead to readmission. All data will be recorded with patient identifiers and maintained confidential. The primary endpoint is all causative factors related to readmission with emphasis on medication-related readmissions. Secondary endpoints that will be evaluated are condition specific core measures related to pneumonia, chronic obstructive pulmonary disease (COPD), and heart failure. This study will identify potential factors related to all-cause readmission and assist in improving the transitions of care discharge process.

Poster Title: Implementation and evaluation of a vancomycin dosing per pharmacy protocol in large academic medical center

Primary Author: Shaydul Hassan, Mount Sinai Hospital, NY; Email: shaydul.hassan@mountsinai.org

Additional Author(s):
Paticia Saunders-Hao
Garci Patel
Joanne Meyer
Gina Caliendo

Purpose: Monitoring and dosing vancomycin appropriately is pivotal in securing positive patient outcomes. Drawing levels at optimal times and dosing accordingly leads to decreased adverse events and prevention of bacterial resistance. A previous medication use evaluation (MUE) was conducted in an inpatient oncology unit to assess vancomycin dosing and monitoring per pharmacy. The primary objective of this study is to gain an understanding of the efficacy of vancomycin dosing per pharmacy based on outcomes in the pilot units. The goal is to expand the service to other inpatient units and ultimately implement a hospital-wide vancomycin dosing per pharmacy protocol.

Methods: A medication use evaluation was conducted to assess physician based vancomycin dosing and revealed improper dosing and monitoring. This led to the conception of the vancomycin per pharmacy protocol. The vancomycin per pharmacy program was initiated in two inpatient oncology units in 2013 and is now being expanded to additional units. Education will be provided to physicians, nurse practitioners, and pharmacists through the use of previously developed in-service materials. Modifications will be made to the current in-service materials including the addition of area under the curve (AUC) vancomycin education for pharmacists. Pharmacists conducting the service will keep track of data through computerized chart logging and monitoring sheets developed specifically for the routine follow-ups. All patients receiving at least one dose of vancomycin will be included in the data. The data collection parameters are patient age, weight, gender, serum creatinine and calculated creatinine clearance, treatment dose and time, vancomycin levels and time the level was
drawn. The two treatment groups are allocated as dosing per pharmacy and traditional dosing. Traditional dosing is based on a physician-managed treatment approach as opposed to the pharmacist-managed per pharmacy protocol. The outcomes are the percentage of patients receiving correct initial doses, frequency, timing of levels, the percentage of patients with levels obtained who were on therapy for five days or more, and the percentage of patients achieving therapeutic range.

Poster Title: Outcomes associated with the use of revised risk assessment strategies to predict resistance in community onset pneumonia: A stewardship perspective

Primary Author: Ron Stern, Mount Sinai St. Luke's and Mount Sinai West, NY; Email: rostern@chpnet.org

Additional Author(s): Andras Farkas

Purpose: Recent literature suggests the risk of multidrug-resistant organism (MDRO) infections in community onset pneumonia is largely overestimated leading to unnecessary use of extended-spectrum antibiotics associated with negative collateral effects including increased length of stay, drug toxicity, and resistance. This information has contributed to the removal of healthcare-associated pneumonia (HAP) from the most recent Infectious Diseases Society of America guidelines; however, outdated literature is still influencing current practices. The aim of this study is to evaluate select outcomes associated with the implementation of revised risk stratification strategies to predict MDROs in patients with community onset pneumonia at an academic medical center.

Methods: Restricted antibiotics are requested for approval and reviewed by the infectious diseases clinical pharmacist and pharmacy resident under supervision. Subsequently, requests are accepted or denied utilizing current literature outlining the risk of resistance in community onset pneumonia. Data will be comprised of antibiotic requests for gram negative MDRO coverage in admitted cases of pneumonia. These requests will make up one arm of the study and will be compared to an equal number of randomly selected patients that were treated for suspicion of MDRO community onset pneumonia from January 2016 to June 2016, prior to the implementation of the aforementioned processes. Patients will be eligible for inclusion if they are aged 18 years and older and were admitted for a primary diagnosis of pneumonia. Patients will be excluded if they have an active thoracic malignancy or cystic fibrosis. The primary outcome will evaluate the difference in anti-pseudomonal days of therapy between the two groups. Secondary outcomes will include length of stay indices and costs of drug therapy. Descriptive statistics and regression analysis, as appropriate, will be applied to interpret results and the study will be submitted to the Institutional Review Board for approval.

Poster Title: Evaluation of apixaban dose reductions deviating from standard criteria

Primary Author: Funnce Liu, Mount Sinai St. Luke’s and Mount Sinai West, NY; Email: fliu@chpnet.org

Additional Author(s):
Amy Wang

Purpose: Apixaban is a commonly used direct oral anticoagulant for nonvalvular atrial fibrillation (NVAF) to prevent thromboembolic events. In a recent study re-evaluating the data from the ARISTOTLE trial, patients who received apixaban 5mg twice daily, and met only one criterion for dose reduction were at increased risks for bleeding and thromboembolic events. Prescribers may reduce the dose deviating from label’s recommendations to decrease risks of bleeding. We will investigate whether this method of dose adjustment may lead to increased risks of bleeding or thromboembolic events, and identify patient factors associated with these dose reductions.

Methods: We will perform a retrospective study of adult patients at least 18 years of age or older using either apixaban 2.5 mg or 5 mg twice daily for stroke and systemic embolism prevention in NVAF using the Prism electronic medical record system. We will review the appropriateness of the doses based on the label’s recommended criteria for dose reduction (two or more of the following: serum creatinine ≥1.5 mg/dL, ≥80 years old, or ≤60 kg), and compare endpoints such as bleeding and thromboembolic risk between the improperly dosed and properly dosed groups. Additionally, we will evaluate any factors that prescribers are using when choosing the reduced dose deviating from the label’s criteria. Such factors for dose adjustment may include elderly age, low weight, low hemoglobin, low platelets, altered mental status, very high serum creatinine, concomitant antiplatelet therapy, comorbidities, or compliance. Prior to the start of the study, an application will be submitted to the Institutional Review Board for approval. After the data collection, descriptive statistics will be used to assess the data. Upon review of the results, we will work to educate our medical teams and assess the impact of deviation from standard recommendations.

Results: Still pending.
Conclusion: Still pending.

Poster Title: Analysis of opportunistic infection (OI) medication management of HIV/AIDS-infected patients at an academic teaching hospital

Primary Author: Daniella Badal, Mount Sinai St. Luke's and Mount Sinai West, NY; Email: dbadal@chpnet.org

Additional Author(s): Kimberly Sarosky

Purpose: Although the use of highly effective antiretroviral medications has increased within the HIV/AIDS infected population, the proportion of patients with a risk factor for, history of, or active opportunistic infection remains a concern. Opportunistic infections pose a direct impact upon hospital costs, mortality, as well as the overall treatment success of the HIV/AIDS patient. The aim of this analysis is to evaluate whether medications used for OI prophylaxis or treatment are appropriately initiated and dosed correctly throughout inpatient management for patients diagnosed with HIV/AIDS.

Methods: This is a retrospective analysis where the electronic medical record will be used to identify patients with a diagnosis of either HIV or AIDS from January 1, 2015 to July 31, 2016. Patients will be included in the analysis if they have a reported CD4 count of less than or equal to 250 cells per milliliter. Patients will be excluded if they are less than 18 years of age, pregnant or receiving immunosuppressive therapy. The primary outcome will assess appropriateness for OI medication order entry, based on patient weight, CD4 count, organ impairment and allergies. The secondary outcomes include compliance with the AIDSinfo Guidelines for OI prophylaxis and treatment initiation, length of stay and incidence of medication errors or adverse events related to OI medications. Patient demographics, laboratory values and genotypic results will be collected. Descriptive statistical methods will be used to calculate results. The study will be submitted to the Institutional Review Board for approval.

Poster Title: Intravenous bolus versus continuous infusion of loop diuretics in patients with acute decompensated heart failure (ADHF): A retrospective analysis

Primary Author: Yeon Hee Yu, New York Methodist Hospital, NY; Email: yey9004@nyp.org

Additional Author(s):
Meggie Chan
Erin Oh
Teena Abraham
Kumudha Ramasubbu

Purpose: Acute decompensated heart failure has a high risk for recurrent hospitalization, as well as a high 1-year mortality rate of approximately 30%. Patients commonly present with signs and symptoms of fluid overload including dyspnea, fatigue and/or peripheral edema. According to the current American Heart Association (AHA) heart failure guidelines, intravenous loop diuretics are recommended for symptomatic relief. There is limited literature comparing different diuretic strategies for the management of patients with ADHF. The objective of this study is to compare intravenous bolus and continuous infusion of loop diuretics in ADHF patients.

Methods: This retrospective study will be submitted to the Institutional Review Board for approval. Inpatient data will be collected for a prespecified time period and divided into two groups: patients who received intravenous bolus loop diuretics and patients who received continuous infusion of loop diuretics. Adult patients diagnosed with ADHF with a left ventricular ejection fraction of 40% or less who were admitted to a unit with hourly urine output monitoring will be evaluated for inclusion to the study. Primary efficacy endpoints include duration of intravenous diuretic use, urinary output change, and average weight loss. Secondary endpoints include length of hospitalization, re-hospitalization within 30 days for heart failure, and heart failure symptoms resolution. Safety endpoints include decline in renal function, electrolyte imbalance, hyperuricemia, hypotensive episodes, and ototoxicity.

**Poster Title:** Computerized Dose Range Checking Initiative: Preventing prescribing errors

**Primary Author:** Brian Park, New York Methodist Hospital, NY; **Email:** brp9056@nyp.org

**Additional Author (s):**
May Jabra
Righard van Niekerk
Eileen Chung
Teena Abraham

**Purpose:** Prescribing errors are the most frequently occurring subtype of medication errors. According to the PROTECT study, 7.5 percent of prescribed orders were associated with errors, and the errors affected more than one third of the patients. Studies have shown that the implementation of a computerized provider order entry (CPOE) system significantly reduces medication errors. Dose Range Checking (DRC) is a clinical support system that alerts the ordering prescriber of medication dosages that are outside of the recommended ranges. We hypothesize that the utilization of CPOE with DRC will reduce inpatient prescribing errors in an acute care teaching hospital.

**Methods:** This study will be submitted to the Institutional Review Board for approval. The DRC system was designed based on dose ranges from published drug references, and was customized based on the standard of practice at New York Methodist Hospital. Data used to design the dose range system includes single and daily dose ranges based on age, weight, and route of administration. The DRC system was implemented on a drug by drug basis. Initial prescribing orders with dosages outside of the set range generated silent alerts. Silent alerts were not shown to the prescriber but were documented to be reviewed by the pharmacy staff on a daily basis. After the completion of DRC design and testing, the providers will be prompted with a popup alert at the point of entry and will be required to cancel the order, ignore the alert with explanation or modify the order to continue. The pharmacists will be notified with the same alert upon order verification. Pre-implementation data was collected from past occurrence reports. The primary endpoint of this study is the number of alerts generated from prescribing errors post-implementation of DRC. The secondary endpoints are the types, severity and frequency of the prescribing errors.

Poster Title: Development and implementation of titrate orders at an acute-care hospital

Primary Author: David Li, New York Methodist Hospital, NY; Email: dhl9005@nyp.org

Additional Author (s):
May Jabra
Righard van Niekerk
Joseph Samid
Teena Abraham

Purpose: Up to 25% of audited hospitals in 2014 were cited under Joint Commission Medication Management Standard 04.01.01. This standard mandates that medication orders be documented clearly, accurately, completely, and that they comply with established hospital policies. Titratable orders are one area that many institutions struggle with as these orders must have specific parameters defined. These include: initial and maximum rates, frequency of rate changes, indication, and goal. The purpose of this study is to evaluate the implementation of a process change in a critical care teaching hospital and describe lessons learned as well as ease of adoption by hospital staff.

Methods: This is a post-implementation study that will be conducted at New York Methodist Hospital and will be submitted to the institutional review board for approval. Prior to implementation free-text fields were utilized to document titration parameters, which had the potential to be incomplete. A new workflow was adopted which included the addition of mandatory parameters to all medications intended to be titrated. Updated order sentences were created that included separate fields for all the parameters. These order sentences were then grouped and placed in order sets for ease of ordering. The final design included automatic rate calculations based off of the initial dose, simplified ordering, and standardized concentrations. Data collection will consist of real time order review, the correction of incomplete orders, and adjustments to the CPOE system to prevent future deviations. The endpoints being evaluated include adherence to ordering policy and capture of ordering methods that fall outside of established workflow. Data will be analyzed to derive best-practices for future implementations of similar workflow optimizations.

**Poster Title:** Evaluation of continuous infusion midazolam, propofol, and ketamine in refractory status epilepticus in the intensive care unit

**Primary Author:** Waqas Arif, NEW YORK METHODIST HOSPITAL, NY; **Email:** waqas0120@gmail.com

**Additional Author (s):**
Spencer Lee
Teena Abraham
Joseph Samide

**Purpose:** Current American Epilepsy Society guidelines recommend adding a second antiepileptic drug (AED) or initiating a continuous infusion AED (cIV-AED) such as midazolam, propofol or pentobarbital for refractory status epilepticus (RSE). There is, however, insufficient evidence to preferentially support the use of one continuous agent over another. Additionally, there is emerging case report and small series data that suggest ketamine may be an effective agent for RSE. The objective of this study is to retrospectively evaluate the comparative efficacy, safety, and tolerability outcomes of continuous infusion midazolam, propofol, and ketamine in RSE.

**Methods:** A retrospective study utilizing the electronic medical record will be conducted on adult patients admitted to the intensive care unit (ICU) for status epilepticus (SE). Patients of at least 18 years of age who were treated with continuous infusion midazolam, propofol, or ketamine for RSE as determined by electroencephalogram (EEG) will be included. Patients who were deemed not to be in SE will be excluded. Primary endpoints will include time to termination of SE, permanent seizure control, and incidence of cIV-AED-related adverse drug reactions. Secondary endpoints will include recurrence of SE, evaluation of dosage regimens utilized, incidence of serious adverse drug reactions requiring discontinuation of therapy, mortality, and ICU length of stay. Institutional Review Board approval will be obtained.

Poster Title: Evaluation of neuromuscular blockade in the Intensive Care Unit (ICU) setting with a focus on adjunct therapies and monitoring

Primary Author: Shabia Rehmat, New York Methodist Hospital, NY; Email: sjr9010@nyp.org

Additional Author(s):
Joseph Samide
Spencer Lee
Teena Abraham

Purpose: Neuromuscular blocking agents (NMBAs) are frequently used in the ICU setting for indications that include facilitation of mechanical ventilation, reduction of elevated intracranial pressure, and the attenuation of oxygen consumption. These agents are, however, associated with significant complications that impact the overall patient recovery process, including risk of generalized deconditioning and residual weakness after discontinuation of blockade. NMBAs may also result in subpar evaluation of sedative needs. The objective of this study is to determine if patients are adequately sedated prior to initiation of paralysis and if optimal monitoring with targeted train of four (TOF) is routinely performed.

Methods: This is a single-center, retrospective study that will include adult patients who have received NMBAs as a continuous infusion. Patients who received NMBAs for rapid sequence intubation in procedural areas will be excluded. Patients who attained a Richmond Agitation-Sedation Scale (RASS) score of -4 preceding paralysis will be compared to those who did not. Similarly, patients will be assessed to determine if TOF monitoring with a goal of adjusting the degree of neuromuscular blockade to achieve one or two twitches was utilized. Primary endpoints will include duration of mechanical ventilation and time to discharge from the ICU and from the hospital. Secondary endpoints will include analysis of the recovery index defined as the time required for TOF to increase to baseline, evaluation of dosing regimens of analgesic, sedative, and paralytic agents, timing of sedative administration with respect to paralysis, inappropriate use of sedative agents, and administration of neuromuscular blocking reversal. Institutional Review Board approval will be obtained.

Poster Title: Evaluation of the appropriate use of coagulation factors and reversal agents for the management of oral anticoagulant reversal

Primary Author: Eunah Cheon, New York Methodist Hospital, NY; Email: cheonea@gmail.com

Additional Author(s):
Joseph Samide
Teena Abraham

Purpose: Patients experiencing a major bleed or those requiring an urgent invasive procedure while taking oral anticoagulants require immediate and appropriate reversal. Current management strategies consist of a host of options including vitamin K, prothrombin complex concentrates (PCC), fresh frozen plasma (FFP), and idarucizumab. In an effort to ensure consistent evidence-based anticoagulation reversal, our institution created comprehensive reversal protocols and consolidated the dispensing of coagulation factors to a single location. This study is intended to evaluate the appropriate use after protocol implementation and the centralized dispensing of coagulation factors from pharmacy.

Methods: This retrospective, observational study will include all patients receiving coagulation factors or reversal agents at our institution from June 2016 through June 2017. The reversal protocols were implemented through the creation of comprehensive order sets which included step-by-step clinical pathways for the reversal of warfarin, dabigatran, and factor Xa inhibitors. Physicians, medical residents, pharmacists, and nurses were trained to properly order, dose, verify, dispense, and administer coagulation factors and reversal agents. The primary endpoint will be compliance with our internal reversal protocols. Electronic medical records and each step of the ordering and verification process will be reviewed. Secondary endpoints will include the timeliness of dispensing and administration, international normalized ratio (INR) correction, hemostatic efficacy, time to INR correction and number of packed red blood cell transfusions received. Variables such as clinical response, prothrombin time (PT), INR, activated partial thromboplastin time (aPTT), hemoglobin, hematocrit, and other coagulation assays, if available, will be collected for evaluation. Safety endpoints will include adverse events such as thromboembolic events. Institutional Review Board approval will be obtained.

Poster Title: Assessing the impact of clinical pharmacy monitoring services at a small urban teaching hospital

Primary Author: Bryan Fitzgerald, Niagara Falls Memorial Medical Center, NY; Email: bryan.fitzgerald@nfmmc.org

Additional Author (s):
Amy Wojciechowski

Purpose: Due to their role in medication management, pharmacists are in a unique position to improve patient outcomes and reduce medication costs through focused medication monitoring. Pharmacists practicing in the setting of small teaching hospitals may have a more measurable impact on patient outcomes by performing closer clinical monitoring, an increased number of interventions, and working more closely with other healthcare professionals. The purpose of this study is to determine the effects of increased pharmacy-led clinical monitoring programs on patient outcomes at a small urban teaching hospital.

Methods: A retrospective chart review will be performed of patients at a small urban teaching hospital before and after implementation of increased pharmacy clinical monitoring services. The intervention group will consist of patients who received levofoxacin or ciprofloxacin between March and August 2016 (after implementation) and the control group will consist of an equal number of patients who received two or more doses of levofoxacin or ciprofloxacin between March and August 2015 (before implementation). Clinical information gathered will include whether a pharmacist makes a clinical intervention for renal dose adjustment, hospital length of stay, ICU length of stay, death, hospital readmissions, emergency room visits, duration of antibiotic therapy, and adverse reactions. Patients will be included in the study if they are aged 18 years and older and received two or more doses of levofoxacin or ciprofloxacin as an inpatient during the study time periods. Exclusion criteria are pregnancy, mental disability, or treatment on a mental health unit, emergency department, or labor/delivery unit. The primary outcome will be a comparison of the number of clinical interventions made in the intervention group with enhanced pharmacist monitoring compared to the control group. Secondary measures include clinical outcomes such as length of stay and readmissions, as well as the economic impact of increased pharmacist medication monitoring.

**Poster Title:** Assessing the clinical and economic impact of resident-run pharmacy services in a primary care clinic

**Primary Author:** Joel Costanzo, Niagara Falls Memorial Medical Center, NY; **Email:** joel.costanzo@nfmmc.org

**Additional Author (s):**
Amy Wojciechowski
Michelle Lewis

**Purpose:** The role of a pharmacist is expanding into different areas of patient care, beyond the traditional role of dispensing medications. One of these evolving roles is as a collaborative member of a health care team in a primary care clinic. A model of health care called the Patient Centered Medical Home (PCMH), is one where care for a patient is team-based. The objective of this study is to evaluate the clinical and economic impact that the resident-run services of a clinical pharmacist have in a primary care clinic that utilizes the PCMH model of care.

**Methods:** This study has been approved by the Institutional Review Board. This study was designed to evaluate the recommendations made by the pharmacist to physicians at our primary care clinic between October 1, 2016 and March 31, 2017. Patients with 8 medications or more, or at the request of the physician are included. The workup includes an evaluation of current medications, assessment of available laboratory information, and conduction of patient interviews. Based on the information collected, the pharmacist makes clinical interventions with the physician. These recommendations will be categorized and correlated to an economic impact. Categories and values are extrapolated from a study conducted by the VA that placed dollar amounts on pharmacist interventions. The pharmacist will also be collecting data on the type of counseling provided to patients and questions they have been asked by providers that are not a direct recommendation from the pharmacist. The counseling data will be categorized by disease state to assess the most common counseling points and the questions will be categorized in a similar manner as the recommendations. The primary outcome of this study will be the percentage of pharmacist-initiated recommendations that were accepted by physicians in the primary care clinic. Secondary outcomes will include the number and types of
counseling performed with patients, number and type of physician-initiated questions answered, and an economic analysis of pharmacist-initiated recommendations.

**Poster Title:** Effects of gender and age on adverse drug reactions with ticagrelor and aspirin dual antiplatelet therapy  

**Primary Author:** Julia Galea, North Shore University Hospital, NY; **Email:** jgalea1@northwell.edu  

**Additional Author(s):**  
Samantha Ling  

**Purpose:** Ticagrelor is an antiplatelet medication that is used in combination with aspirin for the treatment of acute coronary syndromes (ACS). Studies have shown that systemic exposure to ticagrelor was higher in both women and elderly patients compared to men and younger patients. No dose adjustments for ticagrelor are currently recommended based on gender or age. The purpose of this study is to determine if the incidence of adverse effects consisting of bleeding and dyspnea with ticagrelor and aspirin dual antiplatelet therapy (DAPT) is higher in women and elderly patients greater than 65 years of age.  

**Methods:** This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients who are receiving ticagrelor and aspirin dual antiplatelet therapy. The following data will then be collected: patient age, gender, admission diagnosis, reason for dual antiplatelet therapy, ticagrelor and aspirin dose plus start date of therapy, blood pressure, heart rate, platelets, hemoglobin, serum creatinine, documented adverse drug reactions and 30 day readmission rates based on diagnosis terms for adverse drug events consisting of bleeding or dyspnea. If available, prior antiplatelet use, dose and reason for switch, as well as anticoagulation use, dose and any labs pertaining to anticoagulation use will also be collected. Consent to follow-up 30 days after treatment will be obtained from the patient or caregiver while the patient is still in the hospital. Follow-up with patients about the incidence of adverse drug effects not warranting readmission or resulting in readmission at a different health system will be obtained by calling the patient with a predetermined script to determine if any adverse drug events occurred. Patient medication adherence will also be assessed during follow-up.  

**Results:** N/A

Poster Title: Exploratory analysis of potential prognostic factors for achieving sustained virologic response versus virologic failure in chronic hepatitis C infected patients treated with direct-acting antivirals

Primary Author: Svetlana Akbasheva, North Shore University Hospital, NY; Email: sakbashev1@northwell.edu

Additional Author(s):
Susan Lee
David Bernstein

Purpose: The recent advent of direct-acting antiviral (DAA) medications for chronic hepatitis C infection has revolutionized the treatment of this disease. Regimens depend on viral genotype, liver fibrosis score, and treatment history. In clinical trials, 97 percent of all patients achieved sustained virologic response, but up to 12 percent still experienced treatment failure in individual trials. The purpose of this study is to analyze a real-world population of patients who completed treatment with a DAA regimen within a large health system to determine whether certain patient and viral characteristics may serve as potential prognostic factors for treatment success versus failure.

Methods: This chart review study will be submitted to the Institutional Review Board for approval. Electronic medical records will be used to identify and collect information about patients who completed chronic hepatitis C treatment with a direct-acting antiviral (DAA) regimen. In the first part of the study, we will assess the baseline characteristics of patients who experienced virologic failure. Information collected will include the treatment regimen; treatment length; patient age, race, ethnicity, and sex; viral genotype; baseline viral RNA, platelets, and alanine aminotransferase level; IL28B genotype; presence of resistance variants; liver fibrosis score; presence of extrahepatic manifestations; and concomitant proton pump inhibitor use. Next, we will perform a case control study, with the patients who failed a DAA regimen as the cases and a matched group of controls who achieved sustained virologic response (SVR). Cases and controls will be matched with regard to viral genotype, treatment regimen, history of treatment experience, and liver fibrosis score. Odds ratios will be calculated for each baseline characteristic compared. Finally, we will assess all of the patients who
achieved SVR on a DAA regimen to determine whether certain baseline characteristics are statistically more prominent in these patients and may serve as prognostic factors for treatment success.

**Poster Title:** Assessing the clinical impact of pharmacist intervention on glycemic control during inpatient hospital stay

**Primary Author:** Tasnima Nabi, North Shore University Hospital, NY; **Email:** tnabi@northwell.edu

**Additional Author (s):**
Amanda Lin
Evelyn Luo

**Purpose:** At our 825-bed hospital, approximately 300 patients have type I or type II diabetes and require inpatient glycemic control. The Joint Commission and Centers for Medicare and Medicaid Services (CMS) follow American Diabetes Association (ADA) guidelines for inpatient diabetes management. The ADA recommends a basal-bolus regimen for most patients with good nutritional intake, and discourages exclusive use of correctional insulin. The objective of this study is to evaluate whether pharmacist intervention can help improve glycemic control in patients with persistent hyperglycemia who are receiving correctional scale insulin only.

**Methods:** This study will be submitted to the Institutional Review Board for approval. The investigators will use the electronic medical record system to identify patients with point-of-care blood glucose levels greater than 200 mg/dL, who are managed on correctional scale insulin only. Taking into account patient-specific factors, such as age and weight, and various factors that can contribute to hyperglycemia, such as concurrent corticosteroid use and nutritional intake, the pharmacist will recommend a basal insulin regimen best suited for the patient. If the recommendation is accepted, the pharmacist will continue to monitor the patient’s point-of-care glucose levels and recommend adjustments as needed. If the recommendation is not accepted, or if the patient is deemed not appropriate for basal insulin at the time of evaluation, the pharmacist will continue to monitor and intervene as needed. The primary efficacy endpoint will be the number of days since pharmacist intervention to achieve a fasting point-of-care glucose of less than 200 mg/dL for two consecutive days. The secondary efficacy endpoint will be the percentage of patients initiated on basal insulin. The primary safety endpoint will be the number of hypoglycemic events, defined as point-of-care blood glucose levels less than 70 mg/dL.

Poster Title: Evaluation of warfarin nomogram provider adherence and subsequent achievement of target INR values following pharmacy intervention at a quaternary care teaching hospital

Primary Author: Erika Da Costa, North Shore University Hospital, NY; Email: erika.m.dacosta@gmail.com

Additional Author(s):
Michele Graci
Samrah Ahmad
Gregory Hughes
Jomi Oommen

Purpose: Previous studies have demonstrated that the initiation of warfarin therapy based on the use of a nomogram, compared to standard decision making and care, is superior in both patient outcomes, in terms of obtaining desired therapeutic INR levels, and patient safety. The purpose of this study is to assess how well providers adhere to the warfarin nomogram already in place at North Shore University Hospital, and if pharmacy intervention plays an impact on improving adherence to this nomogram in providers who are not utilizing the warfarin nomogram in an appropriate manner.

Methods: This prospective cohort study will be submitted for approval to the Institutional Review Board and will focus on patients who are initiated on warfarin therapy in the inpatient setting, as well as patients who were initiated on warfarin during a previous hospitalization during a pre-determined time frame (collected retrospectively). Patients will be selected from a chart review based on assignment to particular medical teams to be followed and/or evaluated and will be included if they were initiated on warfarin therapy during an inpatient hospitalization during a pre-determined time frame for specified indications, including Atrial Fibrillation, Atrial Flutter, Ischemic Stroke, Thromboembolism in the form of Deep Vein Thrombosis (DVT) or Pulmonary Embolism (PE), etc. Patients who were previously on warfarin therapy prior to admission to North Shore University Hospital and patients who are initiated on warfarin therapy for any indication other than those listed in the inclusion criteria will be excluded from the study. Following evaluation, pharmacy intervention will occur in cases where
the nomogram was not appropriately followed. The primary efficacy objective of this study is to assess the adherence patterns of providers to the warfarin nomogram for patients who are initiated on warfarin therapy in the inpatient setting. The secondary efficacy objective is to evaluate the frequency at which target INRs are achieved.

**Poster Title:** Retrospective evaluation of a medication regimen complexity index (MRCI) score to identify a correlation with adherence of antiretroviral therapy and virological success in HIV-infected patients

**Primary Author:** Megan Lam, Northwell Health Division of Infectious Diseases, NY; **Email:** mlam2@northwell.edu

**Additional Author(s):**
Loyce Mol
Joseph McGowan
Donna Sym

**Purpose:** The purpose of this study is to determine if a correlation exists between a patient’s medication regimen complexity index (MRCI) score and subsequent adherence to antiretroviral therapy (ART) and virological success at the Center for AIDS Research and Treatment (CART) at Northwell Health's Division of Infectious Diseases.

**Methods:** This research project is a retrospective chart review and is pending IRB approval. Inclusion criteria include patients who: are at least 18 years of age, were treated at CART between June 2014 and January 2016, have a confirmed diagnosis of HIV, and are currently on ART for the treatment of HIV plus or minus medications for the treatment of other co-morbid illnesses. Exclusion criteria include patients who: were not taking ART for at least one year at the start of the study period, and did not receive ART from Northwell Health’s affiliated outpatient pharmacy (VIVO Health). The following data will also be collected: patient demographics (age, gender, ethnicity), patient medical history (length of HIV diagnosis, co-morbid illnesses, medication history, history of substance use, history of mental illness, HIV resistance at start of/during study period, lost to follow-up), measures of adherence (timely refills documented by VIVO, pill trays, HIV-1 RNA, self-reported adherence via chart note), and other data points (change in ART or other medications during study period). All data will be recorded without patient identifiers and maintained confidentially. MRCI scores will be calculated and reviewed to determine correlation with medication adherence and virological success.

Poster Title: Local intra-articular anesthetic injection vs. Ropivacaine Nerve Block for total knee replacement at Northwell Health - Huntington Hospital

Primary Author: Gabrielle Plaia, Northwell Health Huntington Hospital, NY; Email: gplaia1@northwell.edu

Additional Author(s):
Agnieszka Pasternak
Robert Berger
Lisa Rodolico

Purpose: Total knee replacement (TKR) involves a prolonged length of stay (LOS), increased pain burden necessitating use of opioids, consequently predisposing patients to opioid-related side effects. Various local intra-articular anesthetic (LIA) compounds demonstrated a reduction in pain, less opioid use, improved ambulation and a reduction in LOS. The purpose of this study is to examine the effectiveness of LIA compared to ropivacaine nerve (RNB) block in TKR.

Methods: This IRB approved retrospective study analyzed patients who have received RNB (Control group) between February – May 2016 vs patients who had received LIA (Intervention group) between August – October 2016. A multidisciplinary team consisting of pharmacy, orthopedic surgeons, and physical therapy created an order set approved by the Pharmacy and Therapeutics committee in July 2016 for LIA in TKR to standardize the medication content. LIA consists of ropivacaine 246 mg, epinephrine 0.5 mg, ketorolac 30 mg and clonidine 0.08 mg. The primary outcome was percent of patients discharged home. Secondary outcomes included LOS, distance walked post-surgery, opioid use and side effects of opioids post-surgery. Logistic regression will be used to model discharged home (vs. rehab) as a function of pain management group (LIA vs. RNB), while adjusting for potential confounders, such as, surgeon, OR time, age and BMI. Cox proportional hazards regression will be used to model LOS as a function of pain management, while adjusting for potential confounders. The log of the time from post-surgery to discharge will be used as an offset to adjust for varying observation times.

Poster Title: Assessing effectiveness of intravenous and intramuscular hydromorphone at a community hospital

Primary Author: Emmanuel Knight, Nyack Hospital, NY; Email: knighte@nyackhospital.org

Additional Author(s):

Purpose: Acute care for patients admitted to community hospitals often requires pain management. Prescribers within our community hospital routinely order various opioids to be given intramuscularly. There is evidence showing intravenous administration has a more rapid and extensive initial effect compared with the intramuscular route. Our institution has recently implemented a pilot policy for pharmacists to automatically switch prescriber orders for select opioids (including hydromorphone) from intramuscular to intravenous push route. To evaluate if this policy has an effect on patient pain outcomes, we will perform a medication use evaluation on intravenous hydromorphone and compare it to intramuscular hydromorphone.

Methods: The automatic switch pilot policy for hydromorphone went into effect on August 8, 2016 on an inpatient floor at Nyack Hospital. This retrospective chart review of patients admitted from July 8, 2016 through September 30, 2016 will include patients that received at least one dose of intravenous push or intramuscular hydromorphone. Group one will include patients who received intramuscular hydromorphone before the policy went into effect. Group two will include patients who received intravenous hydromorphone after the policy change. Twenty patients will be randomly selected for each group. The following data will be collected: hydromorphone dose, time of administration, pain score prior to and after administration, time of pain assessment, and type of pain being treated (acute versus chronic). The primary measure to be evaluated is average pain score reduction after administration of hydromorphone.

Poster Title: Evaluation of the effectiveness and safety of the antibiotic desensitization protocols at a large academic medical center

Primary Author: Karen Fong, NYU Langone Medical Center, NY; Email: karen.fong@nyumc.org

Additional Author(s):
Xian Jie (Cindy) Chen
Diana Altshuler
Yanina Dubrovskaya
John Papadopoulos

Purpose: Drug hypersensitivity reactions are immunologic responses to medications. For patients with IgE-mediated hypersensitivity reactions, the process of desensitization may be applied to induce drug tolerance. The antimicrobial desensitization protocols at our institution are performed using the novel approach of administering doses as a continuous infusion. This evaluation aims to assess the effectiveness and safety of the Department of Pharmacy-developed antimicrobial desensitization protocols at our institution, present this data to our Pharmacy and Therapeutics Committee for institution-wide approval, to create electronic order sets for each medication, and to continue to collect data for future research.

Methods: A retrospective chart review will be conducted of patients 17 years of age or older admitted to our institution who attempted antimicrobial desensitization utilizing our protocols from March 2013 through July 2016. An approval from the Institutional Review Board is not required for this study due to its nature as a quality assurance and safety investigation. Patients will be identified from our electronic medical records and evaluated for inclusion. Our desensitization protocols include the following antimicrobials: amikacin, ampicillin, ampicillin/subactam, cefepime, ceftaroline, ceftazidime, ceftolozane/tazobactam, ceftriaxone, cefuroxime, ertapenem, levofloxacin, meropenem, nafcillin, oxacillin, pencillin, and piperclillin/tazobactam. Specific instructions regarding reconstitution, infusion, monitoring, reactions, target dosing, and storage are included within each protocol. If a reaction is identified, instructions to address the reaction and modify the protocol are available rather than immediately terminating desensitization. The following data will be collected: patient demographics, past medical history, allergies, infectious disease indication, identified pathogen,
desensitization protocol, target dosing, concomitant medications, premedication, any reactions, time to target dose initiation, and dates of admission and discharge from the hospital and intensive care unit. The primary outcome measure will be the effectiveness of our desensitization protocols, defined as successful completion with or without reactions. Secondary outcomes include safety represented by incidence of reactions, duration in the intensive care unit, and length of in-hospital stay.

**Poster Title:** Medication use evaluation of continuous ketamine infusions for non-anesthesia indications at a large academic medical center  

**Primary Author:** Serena Arnouk, NYU Langone Medical Center, NY; **Email:** serena.arnouk@gmail.com  

**Additional Author(s):**  
Caitlin Aberle  
Diana Althshuler  
John Papadopoulos

**Purpose:** Ketamine acts as a potent N-methyl-D-aspartate (NMDA) receptor antagonist, which has historical use in general anesthesia. More recently, the clinical applications of ketamine have expanded to include the treatment of nociceptive and neuropathic pain syndromes, refractory status epilepticus, status asthmaticus, and depression. Our institution implemented a protocol for the use of ketamine in pain management to ensure appropriate prescribing and close clinical monitoring. The objectives of this medication use evaluation are to describe the use of ketamine infusions at our institution, determine safety and tolerability, and explore effectiveness in reducing opioid requirements and pain scores when used for analgesia.

**Methods:** This is a retrospective review of all patients who received a continuous ketamine infusion for a non-anesthesia indication between June 1, 2014 and June 30, 2016. Patients were excluded if ketamine was administered only as a bolus or infused only during an intraoperative period. The following patient-specific data will be collected: age, gender, race, body mass index, past medical history, medications taken prior to admission, indication for ketamine, medications tried prior to ketamine, ordering service, infusion rates and titration strategies, duration of infusion, adverse medication events, reasons for therapy discontinuation, pharmacy interventions, and frequency of nurse monitoring. For patients receiving ketamine for analgesia, the following additional data will be collected: documented history of opioid tolerance or intolerance, protocol compliance, co-administered analgesics and muscle relaxants, and opioid requirements and pain scores before and during the ketamine infusion. The primary objective being evaluated is compliance with the institutional protocol. Deviations from the protocol will be identified and characterized. Secondary endpoints include
Effectiveness of ketamine for analgesia, defined by reduction in opioid requirements and pain scores, as well as overall safety and tolerability. Data will be analyzed using descriptive statistics.

Poster Title: Medication use evaluation of carfilzomib at doses greater than 27 mg per square meter at a large academic medical center

Primary Author: Gee Youn Kim, NYU Langone Medical Center, NY; Email: geenykim@gmail.com

Additional Author(s):
Frank Cirrone
Tania Ahuja
John Papadopoulos

Purpose: Carfilzomib is a second-generation proteasome inhibitor that irreversibly inhibits chymotrypsin-like activities of the proteasome, and is indicated for relapsed or refractory multiple myeloma. Currently, neither clinical studies nor manufacturer’s package insert provides guidance for the optimal infusion time for doses between 27 and 56 mg per square meter. Pre-clinical pharmacokinetic data in rats suggests potential damage to cardiac myocytes with rapid bolus administration compared to intravenous infusion. The objective of this study is to assess the safety and tolerability of carfilzomib at doses greater than 27 mg per square meter.

Methods: An Institutional Review Board approval was not required because this is a medication use evaluation investigating the safety and tolerability of all patients who have received carfilzomib administrations at doses greater than 27 mg per square meter at a large academic medical center between June 1, 2014 and June 30, 2016. The following data will be collected from the electronic medical record: patient demographics, previous chemotherapy exposure, intravenous and oral concurrent chemotherapy agents, number of carfilzomib doses over 27 mg per square meter, significant cardiac co-morbidities, and relevant home medications. For each carfilzomib infusion, the following will be recorded: dose, dosing height, weight, and body surface area, infusion time, hematologic adverse events, non-hematologic adverse events, concurrent steroid dose, and concurrent chemotherapy infusions. If available, results of echocardiogram and N-terminal b-type natriuretic peptide levels before and after carfilzomib infusions will be documented. Provider documentations will be reviewed to detect any major changes to the chemotherapy regimens, rationale for the changes made, significant events between infusion appointments such as subsequent hospitalizations due to cardiotoxicity, and
overall clinical status of the patients. Nursing documentations will be reviewed to note any infusion-related adverse events. All data collected will be maintained confidentially. Categorical variables will be presented using percentage and quantitative variables will be assessed using mean with standard deviations or median with ranges.

**Poster Title:** Evaluation of ethacrynic acid use at a large academic medical center

**Primary Author:** Elaine Xiang, NYU Langone Medical Center, NY; **Email:** elaine.xiang@nyumc.org

**Additional Author(s):**
Cristian Merchan
Diana Altshuler
John Papadopoulos

**Purpose:** Ethacrynic acid is the only intravenous diuretic that does not contain a sulfonamide moiety and is primarily prescribed for patients with a reported sulfa allergy. However, the evidence of cross reactivity between anti-bacterial sulfonamides to non-antibacterial sulfonamides, including diuretics, is not clinically justified. The cost of ethacrynic acid has increased substantially warranting a re-evaluation of all administrations and increased awareness of how to recognize patients with true sulfa allergies. The objective of this medication use evaluation is to assess the current prescribing pattern of ethacrynic acid at our institution and formulate a protocol to assist providers on its appropriate use.

**Methods:** A retrospective chart review of adult patients who received at least one dose of intravenous ethacrynic acid, between January 2013 to July 2016, will be conducted. An approval from the Institutional Review Board was not required for this retrospective medication use evaluation due to its nature as a quality assurance and safety investigation. Data to be collected from the medical records will include patient demographics, category/location, co-morbidities, allergy and medication history. The evaluation of intravenous ethacrynic acid includes indication, dose strength, frequency, number of doses, route, and duration of therapy. Assessment of response to therapy will include daily urine output, total intake and output over 24 hours after ethacrynic acid, and weight difference post ethacrynic acid administration. Tolerability assessment will include changes in serum creatinine, daily electrolyte imbalances, and documented ototoxicity; cost of therapy will also be evaluated. The reviewers will take these endpoints to create proposed criteria for intravenous ethacrynic acid.

Poster Title: Stewardship evaluation of aztreonam use in a large academic medical center

Primary Author: Nabeela Ahmed, NYU Langone Medical Center, NY; Email: nabeela.ahmed@nyumc.org

Additional Author(s):
Justin Siegfried
Yanina Dubrovskaya

Purpose: Aztreonam is a beta-lactam agent which lacks the bicyclic nucleus of penicillins and cephalosporins, making it a safe option in patients with IgE-mediated beta-lactam allergies. Per our hospital guidelines, aztreonam is reserved for treatment of infections caused by gram-negative pathogens and perioperative prophylaxis for patients with severe beta-lactam allergies. At our institution, aztreonam use increased from 0.2 days of therapy (DOT)/1000 patient-days in 2009 to 9.2 DOT/1000 patient-days in 2015. This may be associated with incomplete allergy interpretation and documentation in electronic medical records. To this effect, we thought to conduct a stewardship evaluation of aztreonam use.

Methods: We will conduct a retrospective study at a large academic medical center to evaluate aztreonam use. An approval from the Institutional Review Board was not required for this retrospective medication use evaluation due to its nature as a quality assurance and safety investigation. We identified 337 patients who received aztreonam between January 1, 2015 and December 31, 2015, from a pharmacy database of administered antibiotics. We randomly selected 100 unique patients (30%) for inclusion. Data collected will include patient demographics, medical service at time of order, allergy documentation, details of hospital stay, microbiological evaluation, and appropriateness of aztreonam orders. Severe beta-lactam allergies were defined by anaphylaxis, angioedema, respiratory distress and/or urticaria. Inappropriate aztreonam use will be defined by orders for patients without severe beta-lactam allergy, allergy of any severity but prior tolerance, and those without a documented beta-lactam allergy. The objective of this study is to provide baseline assessment of the appropriateness of aztreonam use at our institution and identify services where utilization requires improvement. The secondary objectives include length of stay, estimated cost saving,
and evaluation of aztreonam dosing. Based on our findings, we will develop a plan for an antimicrobial stewardship led intervention to improve aztreonam utilization.

**Poster Title:** Clinical impact of a pharmacy resident on optimizing therapy in congestive heart failure patients to prevent re-hospitalization

**Primary Author:** Maryam Ahmed, Plainview Hospital, NY; Email: mahmed21@northwell.edu

**Additional Author(s):**
Jonathan Falsetta
Jaclene Dabbour

**Purpose:** Heart disease is one of the leading causes of death in America. Congestive heart failure (CHF) specifically affects over 23 million patients worldwide, with rates of hospital readmission on the rise. The primary objective of this study is to determine if pharmacist intervention in patients admitted with a diagnosis of CHF, through optimization of medication regimens as well as counseling, will prevent re-hospitalization due to CHF exacerbations and impact mortality rates. Incorporating pharmacy interventions can provide a new model of patient-centered care that can support patients with this condition, and may lead to a decrease in hospitalizations.

**Methods:** This study will take place at a community hospital over a period of six months. Patients admitted to the hospital will be reviewed retrospectively between January – March 2016, and prospectively between January – March 2017. The hospital’s electronic health record system will be used to identify a random sample of 50 patients age 18 years and older with a documented diagnosis of congestive heart failure. Exclusion criteria include patients less than 18 years of age, pregnant patients, and patients not admitted as inpatients. Data collected will include baseline demographics (such as age, gender, weight, congestive heart failure staging per the American Heart Association, ejection fraction), the patient’s discharge medication regimen and any pharmacy resident interventions made related to the diagnosis of congestive heart failure (including patient education regarding medication adherence and self-monitoring). Data recorded over the three month period of pharmacy resident intervention will be compared to data recorded during the baseline period of no pharmacy resident involvement to determine statistical impact. The primary endpoint of this study will be re-hospitalization due to heart failure. Secondary endpoints will include length of stay and mortality rate.

**Poster Title:** Impact of a pharmacy resident on reducing the incidence of Clostridium difficile infections at a community teaching hospital  

**Primary Author:** Anthony Juliano, Plainview Hospital, NY; **Email:** ajuliano2@northwell.edu  

**Additional Author(s):**  
Jonathan Falsetta  
Jaclene Dabbour  

**Purpose:** Healthcare-associated infections (HAI) are a major ongoing concern for hospitals across the country. Infection with Clostridium difficile (C. difficile) is a type of HAI that affects almost 500,000 patients in the United States annually leading to increased mortality and financial burden. Risk factors for acquiring C. difficile infection include advanced age, duration of hospitalization, chemotherapy, gastrointestinal surgery, enteral feeding, acid suppressing agents and exposure to antimicrobial agents. Longer duration of antimicrobial therapy along with multiple antimicrobial agents increases this risk. The primary objective of this study is to help reduce incidence of C.difficile infections at a community hospital.  

**Methods:** This study will be conducted at a community hospital over a period of six months. Patients admitted to the hospital will be reviewed retrospectively between October – December 2016. A prospective review will be performed between January – March 2017. The hospital’s electronic health record system will be used to identify admitted patients 18 years of age or greater receiving doses of a pre-defined list of antibiotics known to contribute to C.difficile infections. Exclusion criteria for this study include patients with active cancer, immunosuppressed patients, or pregnancy. The pharmacy resident will evaluate selected medications associated with C.difficile incidence and identify opportunities for intervention, specifically de-escalation or discontinuation of therapy. The pharmacy resident will also help identify instances where diarrhea may be due to confounding circumstances (e.g. laxative use) and assist in questioning and discontinuing unnecessary C.difficile laboratory orders. Data collection will include patient demographics (eg. age, gender, weight, creatinine clearance), antimicrobial medication orders, presence of cultures and susceptibility results, total duration of antibiotic therapy, C. difficile laboratory testing, proton pump inhibitor usage, laxative usage, duration of hospital stay and cost of antibiotic therapy. Data collected during the baseline time
period without resident interventions will be compared to data collected during the three month period with resident interventions. The primary outcome is development of C. difficile infection. Secondary outcomes include length of stay, and cost.

**Poster Title:** Clinical impact of pharmacy resident intervention on antimicrobial stewardship at a community teaching hospital

**Primary Author:** Kimberly Pough, Plainview Hospital, NY; Email: kpough@northwell.edu

**Additional Author(s):**
Jonathan Falsetta
Jaclene Dabbour

**Purpose:** Antimicrobial resistance has increased significantly over the years because of inappropriate use of antimicrobial agents. Studies suggest that microorganisms have been developing new mechanisms of resistance over time, which impedes the ability to treat and control common infections. Antimicrobial stewardship programs are being established in clinical practice settings in order to minimize the consequences of inappropriate antimicrobial use, such as increased resistance, morbidity and mortality from toxicity and secondary infections, and increased healthcare costs. The primary objective of this study is to determine if antimicrobial stewardship interventions initiated by a pharmacy resident will lead to improvements in these areas.

**Methods:** This chart review will be conducted at a community hospital over a period of six months. Patients admitted to the hospital will be reviewed retrospectively from October – December 2016, and prospectively from January – March 2017. The hospital’s electronic health record system will be used to identify a random sample of admitted patients who are ≥18 years of age and have received antibiotics deemed inappropriate for at least three days. Exclusion criteria include patients < 18 years of age, patients not admitted as an inpatient, patients on antibiotics for less than three days, pregnancy, and presence of active cancer and/or immunosuppressive disorders. Data collection will include patient baseline demographics (e.g., age, gender, weight, serum creatinine), selected antimicrobial agent, route of administration, presence of cultures and susceptibility results for the infection, clinical markers of infection (e.g., fever, elevated lactate), total duration of antibiotic therapy, development of secondary infections, duration of hospital stay, and cost of antibiotic therapy. Data collected pre- and post- pharmacy resident intervention will be compared to assess appropriateness with the intent of improving patient outcomes. Appropriateness will be evaluated based on
recommended durations provided in treatment guidelines for infections and signs of clinical improvement in patients. The primary outcome measured will be the total duration of antibiotic therapy. Secondary outcomes will include the development of opportunistic infections, length of hospital stay, and cost.

**Poster Title:** Nitrofurantoin utilization review in the elderly at a community teaching hospital  

**Primary Author:** John Snyder, Rochester General Hospital, NY; **Email:** john.snyder@rochesterregional.org

**Additional Author(s):**  
Mary Staicu  
Mary Lourdes Brundige

**Purpose:** Nitrofurantoin is a widely used antibiotic for the treatment of urinary tract infections (UTI). The current package insert indicates that the use of nitrofurantoin is contraindicated in patients with an estimated creatinine clearance (eCrCL) of less than 60mL/min, however The Beers’ Criteria for Potentially Inappropriate Medication Use in Older Adults recommends that it may be used in patients ≥ 65 years of age with eCrCL ≥ 30mL/min. This medication utilization evaluation is a quality improvement project designed to assess and evaluate the current prescribing practices of nitrofurantoin in elderly patients.

**Methods:** A retrospective chart review was conducted in patients ≥ 65 years of age who received nitrofurantoin for the treatment or suppression of UTIs between June 2015 and June 2016. The following data was collected for each patient: gender, age, total body weight, eCrCl, serum creatinine (Scr), nitrofurantoin dose and frequency, indication, symptoms consistent with a UTI, drug allergies, presence of a urinary catheter, urinalysis and urine culture, treatment duration, and prescriber. The Cockcroft-Gault equation was used to calculate an eCrCL. A modified eCrCL was determined for patients with actual Scr < 0.8 mg/dL for comparison. The primary objective was to describe the prescribing patterns of nitrofurantoin in the elderly at our institution and compare them to the standards of care, as defined by the Infectious Disease Society of America’s uncomplicated UTI guidelines, the Beer’s Criteria, and the package insert for nitrofurantoin. Secondary objectives include adverse drug events, treatment rates of asymptomatic bacteriuria, and discrepancies between the utilization of nitrofurantoin between both methods of eCrCL.

 Poster Title: Management of QTc prolongation at a large community, teaching hospital

 Primary Author: Kelly Lam, Rochester General Hospital, NY; Email: kelly.lam@rochesterregional.org

 Additional Author(s):
 Melanie Symoniak

 Purpose: Prolongation of the QT interval has been linked with a high risk of adverse cardiovascular outcomes, including arrhythmias like Torsades de Pointes. A prolonged QTc has generally been defined as a value above 450 msec, but QTc intervals greater than 500 msec have the highest association with arrhythmias. Common risk factors for QTc prolongation in hospitalized patients included advanced age, structural heart disease, electrolyte disturbances, and certain medication. Since, there are no standardized guidelines for the management of QTc prolongation in hospitalized patients, the objective of this evaluation is to capture practice management of QTc prolongation at Rochester General Hospital.

 Methods: This retrospective study has been approved by Institutional Review Board at Rochester General Hospital. Randomly selected adult patients with a QTc greater than 480 msec admitted between August 2015 to August 2016 will be included. Patients with a pacemaker or automatic implantable cardioverter defibrillator, history of congenital QT prolongation, being started on dofetilide during the admission, and with an electrocardiogram showing an active arrhythmia will be excluded. Patients will be identified via a report generated from the electronic medical record system and then manually screened for inclusion. The following data will be collected: age; gender; weight; BMI; ethnicity; creatinine clearance; past medical history; primary reason for admission; length of stay; drug name; dose; and route for medications administered with 72 hours of the prolonged QTc; electrolyte concentration, vital signs, and electrocardiogram information; and management of QTc prolongation. All data will be recorded without patient identifiers and maintained confidentially. The primary outcome will be the strategy used to manage the QTc prolongation. Management strategies will include medication modification, correction of electrolyte disturbance, monitoring, other, or none. Secondary outcomes will be the percentage of patients deemed to have received clinically appropriate management of QTc prolongation and the percentage of patients who developed...
Torsades de Pointes. Clinically appropriate management will be determined on an individual case basis using evidence-based medicine by two licensed pharmacists working independently.

Poster Title: Effectiveness of a pharmacy driven vancomycin pharmacokinetic dose calculation model

Primary Author: Min Young Son, Southside Hospital, NY; Email: smy912001@hotmail.com

Additional Author(s):
Gregory Morgano

Purpose: The hospital implemented the health system approved vancomycin pharmacokinetic dose calculation model designed as an excel file, to calculate appropriate initial vancomycin dosing. The purpose of this study is to investigate the effectiveness of a pharmacy driven vancomycin dose review using the system approved vancomycin pharmacokinetic calculation model and to anticipate if the hospital can implement a complete pharmacy driven vancomycin dosing protocol in the near future.

Methods: This is a single-centered, randomized, retrospective study based on the electronic medical record of patients who received vancomycin. The control group will be randomly selected from patients who received vancomycin before the vancomycin pharmacokinetic calculator was implemented and intervention group will be randomly selected from patients who received vancomycin after the vancomycin pharmacokinetic calculator was implemented. Data collection will include: basic demographics, vancomycin dose, frequency, route, date(s) of administration, vancomycin trough level, time vancomycin trough level obtained, indication of vancomycin, serum creatinine level, and calculated creatinine clearance. Target trough level will be evaluated based on its indications. Data will be extracted and/or retrieved from the electronic medical record.

**Poster Title:** Implementation of a multi-disciplinary approach to improve hypoglycemia protocol adherence in the inpatient setting

**Primary Author:** Han Zhang, Southside Hospital, NY; **Email:** hzhang2@northwell.edu

**Additional Author(s):**

**Purpose:** Hypoglycemia is prevalent yet a critical barrier to optimal glycemic control for hospitalized patients. Institutional hypoglycemia protocol provides evidence based recommendations to care providers on the timely and accurate management of hypoglycemic episodes. The objective of this retrospective cohort study is to evaluate the benefits of a pharmacy driven educational intervention targeting nursing staff to improve hypoglycemia protocol adherence rate in the inpatient setting.

**Methods:** This study has already been submitted to the Health System Institutional Review Board for approval. Electronic medical record and a site specific electronic clinical management dashboard system will be utilized to identify patients with at least one hypoglycemic episode defined as a glucose reading of less than 70mg/dL. The following patient specific data will be collected: age, gender, admission diagnosis, diabetes diagnosis, insulin therapy, time of hypoglycemia episode, glucose reading, and medications administered to reverse hypoglycemia. Nursing documentation will also be reviewed to determine agents administered to reverse hypoglycemia. The rate of accurate hypoglycemia protocol activation and subsequent administration of protocol indicated medications will be calculated and compared between pre-educational intervention and post-intervention period. For each hypoglycemic episode, reviewer will rate hypoglycemia treatments as adherent with protocol and protocol therapy administered, non-adherent with protocol but protocol therapy administered, non-adherent with protocol and protocol therapy not administered. All data will be recorded without patient identifiers and maintained through a confidential database system. Deviations from protocol will be evaluated and incorporated into future process improvement. In addition, patient specific characteristics associated with hypoglycemic episodes will also be analyzed, to assist in monitoring and identification of high risk population for hypoglycemia prevention in the future.

Poster Title: Use of direct oral anticoagulants and bleeding incidence in HIV Patients

Primary Author: Grace Lee, St Lukes Hospital Center, NY; Email: grlee@chpnet.org

Additional Author(s):
Kimberly Sarosky
Jose Fefer
Maisoun Sioufi

Purpose: Few studies have been completed on assessing the risk of bleeding in HIV patients who have concomitant diagnoses that require anticoagulation therapy. Antiretroviral treatment regimens often have interactions with many medications of different classes. Because bleeding risk can be a major concern with the use of anticoagulation, concomitant use with antiretrovirals can exacerbate bleeding risk by inducing or inhibiting the metabolism of anticoagulants. The objective of this study is to determine whether HIV/AIDS patients on warfarin have greater bleeding risk than those on direct oral anticoagulants.

Methods: This study will be submitted to the Institutional Review Board for approval. Using International Classification of Diseases (ICD) diagnostic codes, the electronic medical record will identify HIV/AIDS patients who were admitted in the last 5 years with a major or minor bleed. This will include patients from Mount Sinai St. Luke’s and Mount Sinai West hospitals who were diagnosed with atrial fibrillation, deep vein thrombosis, venous thromboembolism, pulmonary embolism, gastrointestinal bleed, subarachnoid hemorrhage, or intracranial hemorrhage. Patients will be not included in the study if they have one or more of the following: greater than 80 years old, concomitant diagnosis of end stage liver disease, pregnancy, or severe renal insufficiency (SCr > 2.5 mg/dL). Chart reviews will be completed to identify any upward trends in INR, aPTT, or bleeding adverse events during the course of their hospitalization. Upon classification of anticoagulation therapy into warfarin or direct anticoagulant categories, statistical comparisons will done to determine if HIV/AIDS patients on a direct anticoagulant such as dabigatran, apixaban, edoxaban, or rivaroxaban have a greater risk of bleeding than HIV/AIDS patients on warfarin.

Poster Title: Assessing student knowledge of substance use identification, reduction and prevention before and after the completion of Screening, Brief Intervention, and Referral to Treatment training

Primary Author: Shannon Tellier, St. John's University, NY; Email: telliers@stjohns.edu

Additional Author(s):
Donna Sym
Wenchen Wu
Olga Hilas

Purpose: Screening, Brief Intervention, and Referral to Treatment (SBIRT) is a national initiative used to identify, reduce and prevent the problematic use, abuse and dependence of alcohol and drugs. A training project was designed for students of the pharmacy, physician assistant and public health programs at St. John’s University College of Pharmacy and Health Sciences to identify and correct gaps in the existing curricula on substance abuse and addiction training. The purpose of this study is to determine the difference in student’s knowledge before and after the implementation of SBIRT training.

Methods: SBIRT training was completed for the first cohort of students in the spring 2016 semester within required courses of Doctor of Pharmacy, Physician Assistant and Master of Public Health programs of the College. The training in the required courses included objectives focused on effective communication, counseling, interviewing skills, and health screenings. A pre-survey was completed online by the students before the training to assess baseline knowledge and a post-survey was completed after the training and completion of and online virtual assessment program. Data obtained from these surveys were converted into a spreadsheet to aid in the comparison of the student surveys. The results from the pre- and post-surveys will be compared to assess changes in baseline knowledge for all health professions students, and among the three disciplines. This study was reviewed and approved by the University Institutional Review Board.

**Poster Title:** Impact of a pharmacist-driven insulin glargine dosing protocol on fasting blood glucose at a 451 bed community teaching hospital: a retrospective observational study  

**Primary Author:** Daniel Parshall, St. Joseph's Hospital / St. John Fisher College Wegman's School of Pharmacy, NY; **Email:** danielimaparshall@gmail.com  

**Additional Author (s):**  
Alicia Heh  
Karen Whalen  

**Purpose:** Subcutaneous basal/bolus insulin (BBI) is utilized for inpatient management of diabetes mellitus. The most common adverse effect is hypoglycemia, which is associated with increased morbidity and mortality. In June 2015, the hospital BBI order set was amended to include an insulin glargine (IG) dosing protocol. This revision requires pharmacists to perform a 20 percent IG dose reduction for patients with a fasting blood glucose (FBG) at risk for hypoglycemia (FBG of 70 to 100mg/dL). This study will evaluate the effectiveness of this protocol at decreasing the number of patients at risk for fasting hypoglycemia.  

**Methods:** This retrospective chart review was approved by the Institutional Review Board. Insulin glargine patients with an active order for rapid-acting insulin between January 1st and March 31st of 2015 (pre-protocol) and 2016 (post-protocol) were identified using the electronic health record. Medical/surgical patients age greater than 17 were included if they had at least one occurrence of the inclusion event, defined as a fasting blood glucose of 70 to 100mg/dL between the hours of 0300 and 0900. Exclusion criteria consisted of patients admitted to intensive or progressive care units, receiving tube feeds or total parenteral nutrition 24 hours prior to, or 72 hours following the inclusion event, or an incident of hypoglycemia (blood glucose less than 70mg/dL) prior to the inclusion event. Patient demographics, doses of IG administered, FBG levels, and hypoglycemic events were collected. The primary outcome was success rate of the protocol, defined as a FBG greater than 100mg/dL for 3 consecutive days following the inclusion event. Secondary outcomes were rate of hypoglycemia and protocol compliance.

Purpose: Aminoglycosides (AMG) are used for multi-drug resistant gram negative infections, surgical prophylaxis and gram positive synergy. AMG are adjusted based upon weight to ensure therapeutic concentration and to limit toxicities. The hospital health center policy contains guidelines for use of total body weight (TBW), ideal body weight (IBW) or adjusted body weight (AdjBW) for AMG dosing. AMG doses per policy are pulse (5mg/kg), standard (2mg/kg), and surgical prophylaxis (1.5-5mg/kg). This study will assess compliance with policy weight based dosing of AMG and patient outcomes.

Methods: The Institutional Review Board granted exempt status to this retrospective medication use evaluation. The electronic health record (EHR) was used to identify patients (18 years or older) who received an AMG dose from January 1st through June 30th 2016. Patients were excluded if route of administration was not intravenous. The primary outcome is policy compliance with weight based dosing. Policy based dosing uses IBW unless 1.) TBW is less than IBW (TBW is used for dosing) or 2.) TBW is greater than 20% of IBW (AdjBW is used). Secondary outcomes include: time to therapeutic peak (time of first dose administered to time of therapeutic peak), hospital length of stay (LOS), rate of nephrotoxicity (50% increase in baseline creatinine) and ototoxicity (documentation in EHR). Data collection included: drug, dose, indication, type of surgical procedure, patient location, baseline renal function, and concomitant nephrotoxic medications (contrast dye, vancomycin, piperacillin-tazobactam, loop diuretics).

Poster Title: Evaluation of an adjusted body weight based vancomycin dosing guideline
Primary Author: Emily Falli, St. Peter's Hospital, NY; Email: emily.falli@sphp.com

Additional Author (s):
Amilee Poucher
Christina Lombardi
Daniella Ferri
Monique Bidell

Purpose: Vancomycin has been in use for decades; however, optimal dosing strategies remain undefined. In July 2015, a vancomycin dosing guideline using adjusted body weight (AdjBW) and renal function was developed and distributed within the pharmacy department at our institution to standardize vancomycin dosing. AdjBW was chosen over actual body weight to avoid over-dosing in obese patients; this was expected to have minimal impact on dosing for non-obese patients. The objective of this study is to validate the effectiveness of the pharmacy department vancomycin dosing guideline.

Methods: This study will be a retrospective medical chart review of inpatients at St. Peter’s Hospital from July 2015 through September 2016. This study is approved by our institution's investigational review board. Patients will be included if they are at least 18 years of age, received at least 2 doses of vancomycin dosed according to guideline recommendations, and had a documented trough concentration within 1 hour before the next vancomycin dose. Patients will be excluded if they were pregnant, required peritoneal dialysis, received vancomycin for perioperative prophylaxis, or had acute kidney injury or a Creatinine Clearance less than or equal to 15 ml/min. The primary outcome will be attainment of therapeutic trough concentrations of 15 to 20 mcg/ml for serious infections (e.g. bacteremia, pneumonia) as outlined in the guideline. Secondary outcomes include attainment of therapeutic trough levels of 10 to 15 mcg/ml for less serious infections (e.g. cellulitis) and patient variables associated with lack of goal trough attainment (e.g. age, weight, renal function, treatment in the intensive care unit). Primary outcome findings will be descriptive. Categorical and continuous variables associated with lack of target trough attainment will be determined using Fisher’s exact and Mann-Whitney U, respectively. Variables with a p value less than 0.2 on univariate analysis will
be entered into a multivariate regression model to determine patient factors independently associated with lack of target attainment.

**Poster Title:** Hazard vulnerability analysis of medications for inpatient medical emergencies

**Primary Author:** Francesca Sosnowski, St. Peter's Hospital, NY; **Email:** francesca.sosnowski@sphp.com

**Additional Author (s):**
Joseph Muench

**Purpose:** A multitude of medical emergencies occur in hospitals which require medication administration. These emergencies commonly include physiologic, medication, or toxin-induced events. In 2009, an interdisciplinary team at our hospital conducted an antidote hazard vulnerability analysis in response to the Expert Consensus Guidelines for Stocking of Antidotes in Hospitals that Provide Emergency Care. While there have not been guideline updates, the hospital's stock of antidotes has likely since changed. The primary objective is to perform a hazard vulnerability analysis to assess the availability of medications used for various inpatient medical emergencies and includes an update to the antidote hazard vulnerability analysis.

**Methods:** This emergency medication hazard vulnerability analysis will enlist an interdisciplinary team representing multiple specialties in order to compile a list of possible inpatient medical emergencies. A value will be assigned to the probability and risk of an event in our hospital based on this team’s consensus, ranging from not likely to very likely and minimal harm to permanent damage or death, respectively. Preparedness will then be determined based on adequate supply of timely, accessible medications indicated in these medical emergencies. A hazard vulnerability score will be calculated as a composite of these three variables to determine the hospital's medication preparedness for the most common and most severe events. To update the antidote hazard vulnerability analysis, preparedness will be assessed based on current stock and accessibility. The preparedness assessment will enlist pharmacy management, evaluate stock in the storeroom, and analyze current protocols to access understocked medications.

Poster Title: Assessment of institutional fluoroquinolone use for uncomplicated infections

Primary Author: Steven Brown, St. Peter’s Hospital, NY; Email: steven.j.brown@sphp.com

Additional Author (s):
Steven Lane
Monique Bidell

Purpose: In May and July of 2016 the Food and Drug Administration issued drug safety communications warning of risk-benefit concerns with fluoroquinolones for treatment of uncomplicated infections. Infections of interest are acute bacterial exacerbations of chronic bronchitis, acute bacterial sinusitis, and uncomplicated urinary tract infections in adults. Considering fluoroquinolone usage for these infections is now discouraged due to safety concerns, the purpose of this study is to characterize fluoroquinolone prescribing for the aforementioned uncomplicated infections at our community hospital. Findings will be used to identify interventions to improve institutional prescribing practices and promote patient safety.

Methods: Fluoroquinolone usage in both the emergency department and inpatient for treatment of uncomplicated infections will be retrospectively assessed between February 2016 and August 2016. This study has been approved by our institutional review board. Patients will be included if at least 18 years of age and prescribed a fluoroquinolone (levofloxacin, ciprofloxacin, moxifloxacin, gemifloxacin) for acute bacterial sinusitis, acute bacterial exacerbation of chronic bronchitis, or uncomplicated urinary tract infections. Data to be collected include age, gender, ethnicity, co-morbidities, antibiotic allergies, baseline renal function, evidence of sepsis, cultures, admission or discharge after prescription, prescriber type, presentation from a healthcare facility or home, documented antibiotic use within 3 months, and readmission within 30 days with evidence for toxicity potentially due to fluoroquinolone use. Adequate sample size permitting, univariate and multivariate regression analyses will be conducted to determine patient characteristics associated with fluoroquinolone prescription for the infection of interest.

Poster Title: Improving medication related omissions associated with medication holding

Primary Author: Kaitlin Farley, St. Peter's Hospital, Albany NY, NY; Email: kaitlin.farley@sphp.com

Additional Author(s):
Lynn Hamil
Nicholas Nobles
Allan Patnode
Lukas Waller

Purpose: Risk of venous thromboembolism (VTE) in hospitalized patients may be related to missed doses of prophylactic anticoagulants. The Institute of Safe Medication Practices (ISMP) states medication hold orders are not safe unless they include specific instructions indicating when to resume. In a 450-bed community hospital, a Failure Mode and Effect Analysis (FMEA) related to anticoagulation medication events revealed risks or errors can happen, including medications held prior to procedure. Identifying specific points involved with holding anticoagulants may lead to less medication omissions and risk of hospital-related VTE.

Methods: Initially, in this Institutional Review Board approved medication use evaluation, inpatients added to the endoscopy and interventional radiology procedure list for next day procedures will be evaluated for use of anticoagulation. The process for holding or stopping anticoagulation prior to procedure and how the medication is restarted post-procedure will also be reviewed. A large sample size of physicians or physician groups will reveal the current representation of anticoagulation hold processes prior to a procedure. Data collected will include: date and type of procedure, anticoagulant prescribed, how anticoagulant was held, how and when anticoagulation was resumed, if it was resumed and prescribing physician. All data will be recorded without patient identifiers and maintained confidentially. An evaluation to compare the data of the hospital’s current practices versus the existing procedure will allow for revision and implementation of best practice for medication holding pre-procedure and restarting post-procedure.

Poster Title: Potential tumor flare and risk factors in patients receiving anti-PD-1 antibodies.

Primary Author: Ankit Gohel, Stony Brook University Medical Center, NY; Email: ankitsgohel@gmail.com

Additional Author(s):
Jeannene Strianse
Edmund Hayes
Dayna McCauley
Roger Keresztes

Purpose: Nivolumab and pembrolizumab are both novel PD-1 antibodies used for a variety of cancers. Tumor flare is a false-positive increase in tumor mass on radiographic evidence due to inflammation secondary to the drug. This false positive mimics progression of cancer rather when in reality it could indicate a positive therapy response. The incidence of tumor flare was not defined by the manufactures of either medication. There is little evidence on whether some medications may reduce the risk of this false positive result which prompted further study to categorize and define the true incidence of tumor flare.

Methods: Inclusion Criteria:
• Receive study drug for at least 3 months
• Any patient who has received Nivolumab or Pembrolizumab for at least 3 months with no greater than 6 week interruption in therapy.

Exclusion Criteria:
• Patients receiving more than 1 oncologic immunotherapy
• Any treatment, radiologic evidence, laboratory parameter beyond September 14th, 2016.
• Patients with less than 3 months immunotherapy

Age Range:
• 18-99 years old

Procedures
• Retrospective Chart Review
• Stony Brook University Hospital (via Powerchart)
Resident Poster Abstracts

• Will request dispensing report for Nivolumab and Pembrolizumab to track all eligible patients at SBUMC
• Will check in patient dispensing records and physician progress notes at week 2, 4, 8, 12, and 24 weeks for use of any corticosteroid during time of radiologic scans.

**Poster Title:** Comparing outcomes of re-induction after standard 7+3 chemotherapy in acute myeloid leukemia

**Primary Author:** Olivia Zalewski, Stony Brook University Medical Center, NY; **Email:** olivia.zalewski@stonybrookmedicine.edu

**Additional Author(s):**
Edmund Hayes
Jeannene Strianse
Matthew Perciavalle

**Purpose:** Acute myeloid leukemia (AML) is the most common type of acute leukemia among the adult population. Many of these patients have refractory disease that doesn’t respond adequately to induction chemotherapy. There are various regimens that can be utilized for patients with primary refractory disease requiring re-induction, however there have been minimal clinical trials performed that compare these intensive regimens. The objective of this study is to compare the outcomes of re-induction regimens to determine which regimen provides the best complete remission rates and most optimal toxicity profile for refractory AML patients treated at Stony Brook University Hospital (SBUH).

**Methods:** This is a retrospective medical record review that includes all adult patients 18 years of age and older diagnosed with AML, who received 7+3 induction chemotherapy (7 days of cytarabine and 3 days of an anthracycline) and then re-induction for primary refractory disease at SBUH from January 2013 to January 2016. Primary refractory disease is defined by not achieving complete remission (CR) after up to two cycles of frontline induction chemotherapy, with a remaining blast count of 5% or more. Data collection will include patient demographics, cytogenetics, date and dose of 7+3 induction received, dates and doses of re-induction regimens received, length of remission following re-induction, total length of stay, length of stay following the start of re-induction, use of granulocyte-colony stimulating factor, progression to stem cell transplant; and white blood cell count, absolute neutrophil count, and blast percentages prior to and after induction treatment and re-induction treatment. Data regarding hematologic toxicities will be collected, including duration of neutropenia and thrombocytopenia; as well as incidence of febrile neutropenia and infections following re-
induction therapy. In addition, data will be gathered to determine if CR, complete remission with incomplete recovery (CRI), or no response was achieved after re-induction therapy. All data will be recorded without patient identifiers and will be maintained confidentially. Study protocol was submitted for approval by the Institutional Review Board.

Poster Title: Correlation between methicillin-resistant staphylococcus aureus infections and methicillin-resistant staphylococcus aureus nasal swab results for empiric antibiotic decisions in the medical intensive care unit

Primary Author: Alyssa Polotti, Stony Brook University Medical Center, NY; Email: alyssa.hellreich@stonybrookmedicine.edu

Additional Author(s):
Edmund Hayes
Jeannene Strianse
Caesar Alaienia

Purpose: Antimicrobial stewardship has been shown to reduce antibiotic resistance, improve patient outcomes and cut costs. One of the more common infectious organisms, Staphylococcus aureus, has developed resistance to not only penicillin (MRSA), but also vancomycin (VRSA). Yet not all patients are at risk of infection with these resistant strains. The MRSA nasal swab is a common test done at ICU admission with results of this test correlating with MRSA infections. This project was designed to determine if negative MRSA swabs can be used to eliminate the use of empirical anti-MRSA agents in medical ICU patients when it is not needed.

Methods: This study was designed as a retrospective study at Stony Brook University Medical Center. The desired patient population was identified using ICD-9 and ICD-10 codes indicating a diagnosis of community-acquired pneumonia, bacteremia or sepsis within the first 48 hours of ICU admission. Data was obtained for patients admitted to the medical intensive care unit between January 1, 2010 and December 31, 2015 who had a MRSA nasal swab PCR and either sputum or blood culture obtained within 48 hours of admission and subsequently diagnosed with pneumonia, bacteremia or sepsis. The results will be analyzed to determine the negative predictive value of MRSA nasal swab PCR in this patient population by comparing the rates of MRSA infections with the results of the nasal swab obtained at admission to assess its utility in empiric therapy decision making in the medical intensive care unit.

**Poster Title:** Drug use evaluation: the use of meropenem at a tertiary care institution

**Primary Author:** Amanda Conenna, Stony Brook University Medical Center, NY; **Email:** amanda.conenna@stonybrookmedicine.edu

**Additional Author(s):**
Edmund Hayes
Jeannene Strianse
Melinda Monteforte
Roderick Go

**Purpose:** The urgent threat of carbapenem-resistant Enterobacteriaceae (CRE) highlights the need for stewardship of carbapenem use. The development of antibiotic resistance is multifactorial. Nevertheless, evidence strongly supports the correlation between increased antibiotic use and resistance development. At our institution, the rate of carbapenem resistant Klebsiella pneumoniae has been approximately 10 to 15 percent; however, an increasing trend of carbapenem use over the past two years at our institution warranted an examination of carbapenem use. The purpose of this study is to evaluate the use of meropenem and identify strategies for stewardship interventions.

**Methods:** A retrospective chart review was performed using the electronic medical record at our institution. A data inquiry was requested to include all adult patients who received meropenem over three months. The data collection included but was not limited to: prescriber information, hospital units, empiric indications of meropenem, de-escalation based on culture results, duration of therapy, and appropriate dosing per renal function. Patient specific data collected included demographics as well as a history of multi-drug resistant gram negative organisms within six months of the index admission. Data will be evaluated to determine the appropriateness of meropenem, including dose, indication, and duration of therapy as per clinical guidelines. Opportunities for improvement in stewardship of carbapenems will be identified.

Poster Title: Clinical evaluation of treatment of asymptomatic bacteriuria at an academic medical center

Primary Author: Jane Ching, SUNY Downstate Medical Center, NY; Email: jane.ching@downstate.edu

Additional Author(s):
Stanley Moy

Purpose: Asymptomatic bacteriuria (ASB) is a common clinical finding defined as presence of bacteria in urine without signs and symptoms suggestive of a urinary tract infection (UTI). Inappropriate use of antibiotics to treat ASB contributes to antibiotic overuse and is associated with higher rates of resistance and adverse effects. Unfortunately, rates of antimicrobial prescribing for ASB are still high despite the availability of guidelines from Infectious Diseases Society of America (IDSA). The purpose of this study is to retrospectively assess compliance to IDSA guideline recommendations on management of ASB in an academic teaching hospital in order to implement an in-hospital guideline.

Methods: This was a single-center, retrospective, observational study. A retrospective chart review was performed on patients who had a positive urine culture between January 2013 and September 2016. Hospitalized patients were included in this study if they had a positive urine culture (defined as a single urine specimen that yielded an organism in quantitative counts equal to or greater than 100,000 colony forming units per mL). Patients were excluded if they were under the age of 18, exhibited signs and symptoms of UTI, diagnosed with nephrolithiasis on admission, neutropenic (absolute neutrophil count less than 1,500 mm3), had a renal transplant, or had an urologic abnormality or intervention (defined as having benign prostate hyperplasia, urinary incontinence, prostate or bladder cancer, prostatitis, or a transurethral resection of the prostate). Patients determined to have ASB were evaluated on whether treatment was initiated and if antibiotics prescribed were compliant to IDSA recommendations for treatment of UTI. The primary outcome was percentage of patients treated for ASB. Secondary outcomes were appropriateness of empiric antibiotic therapy in patients prescribed antibiotic treatment, total duration of antibiotic treatment, percentage of patients who had antibiotics de-escalated or
discontinued after susceptibility data became available, percentage of patients with removal of catheter, and whether Infectious Diseases consult was obtained.

Poster Title: Incidence and risk factors associated with leukopenia following renal transplantation at a single center.

Primary Author: Yanmen Yang, SUNY Downstate Medical Center, NY; Email: yanmen.yang@downstate.edu

Additional Author(s): Christina Guerra

Purpose: Leukopenia in the setting of renal transplantation (RT) increases the risk for infections in these recipients. Commonly used immunosuppressive medications, including rabbit antithymocyte globulin and mycophenolate mofetil, antimicrobial medications, race, and age may contribute to this development of leukopenia. A high percentage of patients at our institution are unable to tolerate their immunosuppression regimen due to leukopenia, which leads to dose adjustments or discontinuation of therapy, as well as additional hospitalizations. The objective of this study is to determine the incidence of leukopenia and identify risk factors associated with leukopenia in RT recipients at our transplantation center.

Methods: This study is a retrospective chart review of adult patients receiving a renal transplant at our center from January 2011 to March 2016. Data was collected on patient demographics, laboratory values such as white blood cell count (WBC) before and at various timepoints after transplantation, medications used for immunosuppression and treatment of leukopenia, and documented infections up to 2 years post transplantation. Percent change in WBC was calculated at different timepoints and time to each leukopenic episode and episode resolution recorded. The results of this study will be analyzed through regression analysis.

Poster Title: Ceftolozane/tazobactam for non-FDA approved indications caused by multi-drug resistant gram negative organisms

Primary Author: Subin Sunny, The Brooklyn Hospital Center, NY; Email: subin.sunny1@gmail.com

Additional Author(s): Thy Le

Purpose: Bacterial resistance is a growing problem that poses a significant threat to public health. Infections caused by gram-negative multi-drug resistant organisms (MDROs) are particularly problematic due to their adaptability and multiple mechanisms of resistance. Ceftolozane/tazobactam is a novel antibiotic that has activity against multiple gram-negative MDROs. Ceftolozane/tazobactam is approved for the treatment of complicated intra-abdominal infections in combination with metronidazole and for complicated urinary tract infections. Limited evidence exists that evaluates its use for other indications. The objective of this study is to describe the use of ceftolozane/tazobactam for the treatment of non-approved indications caused by gram-negative MDROs. Adult patients (age > 21 years) who were treated with ceftolozane/tazobactam during hospitalization at The Brooklyn Hospital Center for indications other than complicated urinary tract or complicated intra-abdominal infections will be included in this retrospective chart review. The following data will be collected: age, gender, race, comorbidities, renal function, MDRO risk factors, previous antibiotics, source of infection, causative organism, ceftolozane/tazobactam MIC (as available), duration of antibiotics, duration of hospital stay, clinical outcome and microbiologic outcome.

**Poster Title:** Comparing the hemodynamic adverse effects of dexmedetomidine and propofol in adult critically ill patients  

**Primary Author:** Yae-Ji Kim, The Brooklyn Hospital Center, NY; Email: yjkim@tbh.org  

**Additional Author(s):**  
Karina Muzykovsky  

**Purpose:** Non-benzodiazepine based sedation, such as propofol and dexmedetomidine, are preferred in mechanically ventilated adult ICU patients; however, both of these agents are linked to hemodynamic adverse effects. Propofol is a short acting, lipophilic IV sedative that is largely used for ICU sedation that is known to cause hypotension due to systemic vasodilation. Dexmedetomidine is a selective 2 receptor agonist that can be used as an alternative for ICU sedation which also commonly causes hypotension. The purpose of this study is to compare hemodynamic adverse effects of dexmedetomidine and propofol in adult intensive care unit.  

**Methods:** A retrospective chart review will be conducted on mechanically ventilated patients, age 21 years and older, in the ICU and SICU that have received dexmedetomidine and/or from January 2011 to June 2016. Patients will be included if they received the above mentioned sedatives for at least 24 hours. Patients who received dexmedetomidine and/or propofol for procedural sedation, hypothermia management, and cardiac patients will be excluded from the study. Heart rate, blood pressure, the amount of IV fluid boluses given, vasopressor and antihypertensive use will be compared. This is a quality improvement project and has been granted exemption from IRB review.  

**Results:** Currently in progress. Will present at midyear clinical meeting.  

**Conclusion:** Currently in progress. Will present at midyear clinical meeting.

Poster Title: Efficacy and safety of administering more than 80 units of insulin degludec in a single dose

Primary Author: Shujaat Bhatti, The Brooklyn Hospital Center, NY; Email: shujaat.b.bhatti@gmail.com

Additional Author(s):
Elise Kim

Purpose: There is a growing population of patients with uncontrolled diabetes, leading to more patients requiring larger amounts of insulin. As the maximum amount of injection per dose is 80 units on most insulin pens, patients are often needing to administer two separate injections of their daily basal insulin. Fortunately, the new ultra-long acting insulin, insulin degludec U-200 pen, is capable of administering up to 160 units in a single injection. However, it is unknown if there is a maximum amount of insulin degludec that can be administered in a single injection. In this case series, patients at the pharmacotherapy clinics of a hospital in Brooklyn, New York who receive more than 80 units of insulin degludec in a single injection per day will be discussed. Patient demographics, such as age, race, and BMI will be collected. To assess efficacy and safety, patient’s previous insulin regimen prior to insulin degludec, insulin degludec dose, A1c trend, self-monitoring blood glucose levels, and any self-reported symptoms of hypoglycemia will also be collected.

**Poster Title:** Assessing patient knowledge of hepatitis C virus (HCV), testing, and treatment among high-risk populations in the Emergency Department

**Primary Author:** Katlyn Grossman, The Brooklyn Hospital Center, NY; **Email:** kgrossman@tbh.org

**Additional Author (s):**
Agnes Cha

**Purpose:** New York State law requires patients born between 1945 and 1965 receiving hospital or primary care be offered a HCV screening test. At The Brooklyn Hospital Center, protocol requires all patients be offered HCV screening at triage in the Emergency Department. Previous literature has shown that public knowledge of HCV is low. There is concern that if high risk patients do not have appropriate knowledge of hepatitis C and its testing, they may deny hepatitis C screening. The objective of this study is to evaluate the knowledge of high risk patients on hepatitis C, testing, and treatment.

**Methods:** This study will be submitted to the institutional review board (IRB) for approval. Patients will be assessed after admission to the adult emergency department and considered high risk of being HCV positive per the Center for Disease Control (CDC) recommendations. Patients identified will include individuals born between 1945 and 1965, former or current intravenous drug users, patients on hemodialysis, individuals with HIV, and individuals with abnormal liver function tests. Patients who have previously been diagnosed with hepatitis C, those with altered mental status, inability to communicate, and those with life threatening emergencies will be excluded. Structured surveys will be used to assess patient knowledge of HCV and testing. Patients will be asked questions from an adapted version of the validated Canadian brief hepatitis C knowledge scale. Their knowledge of HCV testing will be determined by asking patients whether they were offered a HCV test by a medical provider and whether they are aware that they are indicated for routine HCV testing. Patient knowledge of HCV treatment will be assessed using questions regarding perceived indication, cure rate, side effects, and names of HCV medications.

**Poster Title:** Analysis of the implementation and optimization of automated dispensing cabinets in a mid-sized urban hospital

**Primary Author:** Keene Saavedra, The Brooklyn Hospital Center, NY; **Email:** keene.saavedra7590@gmail.com

**Additional Author (s):**
Gregory Stein

**Purpose:** Automated dispensing cabinets (ADCs) can improve pharmacy and nursing efficiency, decrease diversion, and reduce medication errors. However, there is a paucity of literature describing methods of confirming proper implementation and optimization of ADCs. At The Brooklyn Hospital Center, new ADCs were installed on the labor and delivery unit and the medical intensive care unit. The implementation of these ADCs presented unique challenges. The objective of this study is to describe and assess the effectiveness of the implementation and optimization interventions made after activation of the ADCs utilizing a variety of reportable measures.

**Methods:** This study will be submitted to the Institutional Review Board for approval. After activation of the ADCs, the interventions to improve performance were unique to each unit. Potential challenges of implementation will be illustrated by reportable measures, including manually admitted patients at the ADC, number of medications removed from the automated dispensing cabinet without an order (also known as overrides), number of medications removed on override without subsequent orders placed in the electronic medical records (EMR), also known as unreconciled orders, and overutilization or redundancies found in cart-fill medication delivery systems, including the robot cart-fill. After implementation challenges have been resolved, more routine optimization methodology will be performed utilizing a number of reports including: ordered med not stocked, stocked med without orders, expired medications, last pocket access, orders by unit, stock management by station, refill activities, and optimization by station. Appropriate measures and report data will be trended following the dates of implementation. Report data will then be analyzed before and after implementation and optimization interventions to assess effectiveness of the interventions made after activation of the ADCs.

Poster Title: Comparison of the efficacy and safety of filgrastim-sndz to filgrastim: a single center retrospective study

Primary Author: Julia Zecchini, The Mount Sinai Hospital, NY; Email: julia.zecchini@mountsinai.org

Additional Author(s):
Kendra Yum
Sara Kim

Purpose: Filgrastim-sndz (Zarxio®) was approved by the FDA in March 2015 as a biosimilar product of its reference product, filgrastim (Neupogen®) for all five indications. The NCCN Clinical Practice Guidelines has incorporated filgrastim-sndz into its recommendations as a category 1 recommendation for use in settings of febrile neutropenia, myelosuppressive chemotherapy administration, and post hematopoietic stem cell transplant. In March 2016, our institution switched from filgrastim to filgrastim-sndz for all indications as a cost saving initiative. The purpose of this study is to assess for any difference in clinical and safety outcomes between the biosimilar and reference product.

Methods: This study is pending approval by The Mount Sinai Hospital’s Institutional Review Board. A one year, single institution, retrospective chart review between September 2015 and August 2016 will be conducted of patients who received either filgrastim or filgrastim-sndz. Adults (age >18 years) who have received filgrastim or filgrastim-sndz for either prophylaxis of chemotherapy-induced myelosuppression or for neutrophil recovery after autologous stem cell transplant will be included. Patients will be excluded if they have a diagnosis of myeloid leukemia. The following patient data will be collected: age, weight, indication, dose, date of first dose, number of doses received, white blood cell count and absolute neutrophil count at initiation and discontinuation of therapy, number of previous chemotherapy regimens received, and reports of adverse events including bone pain, pulmonary toxicity, or splenic rupture. The objective of this study is to compare clinical efficacy and safety between filgrastim-sndz and filgrastim.

Poster Title: Impact of a 72 hour Best Practice Alert on Duration of Antibiotic Therapy

Primary Author: Kori Hamman, The Mount Sinai Hospital, NY; Email: kori.hamman@mountsinai.org

Additional Author(s):
Patricia Saunders-Hao
Gargi Patel
Gopi Patel
Meenakshi Rana

Purpose: Antimicrobial stewardship has reached a critical turning point in addressing antibiotic resistance. The CDC recommends hospitals adopt an “antibiotic time out” as a core element in antibiotic stewardship programs. At the Mount Sinai Hospital, a best practice alert (BPA) was implemented on all intravenous antibiotics in June 2015 notifying prescribers on days five, six and seven reminding them of an automatic antibiotic stop on day seven. An additional 72 hour notification will be implemented in November 2016. The purpose of this study is to evaluate the influence of the 72 hour BPA on overall length of antibiotic therapy.

Methods: A retrospective analysis will be performed assessing the effect of the 72 hour best practice alert on all intravenous antibiotics and their overall length of use. Data to be investigated includes adult patients on broad spectrum antimicrobials such as cefepime, ceftriaxone, ertapenem, imipenem/cilastatin and piperacillin/tazobactam. Patients to be excluded are those with less than one day of antibiotic therapy in the emergency department. The primary endpoint will be overall antibiotic usage expressed as days of therapy (DOT) per 1000 patient-days (PD). Secondary outcomes will include the number of orders discontinued on days three, four, five, six and seven; the number of orders ending on day seven; and the number of orders renewed after seven days. Appropriate statistical analysis will be performed to evaluate each outcome. This data will be analyzed three months prior and three months after implementation of the 72 hour best practice alert. All data will be analyzed discretely without personal identifiers and maintained confidentially.

Results: N/A
Conclusion: N/A
Purpose: Intestinal transplant is one of the least common forms of organ transplantation. Only 106 intestinal transplants were performed in the United States in 2012, representing a 46 percent decline from 2007. The contribution of HLA allosensitization to wait-list times and poor post-transplant outcomes can be dramatic. Classic desensitization strategies decrease preformed antibodies and facilitate immunologic compatibility, but do not target antibody secreting plasma cells responsible for alloantibody production. Bortezomib, a selective inhibitor of the 26S proteasome with anti-plasma cell activity, represents an additional therapeutic option for desensitization prior to small bowel transplant to decrease wait-times and increase transplantation rates.

Methods: This was a single center, retrospective cohort review of patients receiving an intestinal transplant at the Mount Sinai Hospital (institutional review board approval pending) to assess the safety and efficacy of bortezomib desensitization therapy relative to standard rituximab. Electronic medical records were reviewed to identify all patients that received an intestinal transplant between 2010-2016 with prior bortezomib or rituximab desensitization therapy. Any patients missing data were excluded from the chart review. Baseline demographic data was collected for all patients including: age, sex, weight, etiology of intestinal failure, body mass index, glomerular filtration rate, and total bilirubin. Appropriateness of desensitization therapy was determined by evaluating for the prescription of pre-medications, dose and date of first desensitization, route of administration, and cycles of desensitization administered. Efficacy was assessed by evaluating patient’s calculated panel reactive antibody pre-desensitization and post-desensitization, presence of donor specific antibodies, and rejection at one-year post-transplant. Additional safety data including: complete blood counts, infection rates within one-month post-transplant, and documented infusion reactions were also collected to account for drug related toxicities.

**Poster Title:** Delay in initiating prophylactic fluoroquinolones post autologous hematopoietic stem cell transplantation from Day 0 to neutropenia and the development of Clostridium difficile infection and bacteremia

**Primary Author:** Nicole Davis, The Mount Sinai Medical Center, NY; **Email:** nicole.davis@mountsinai.org

**Additional Author (s):**
Sara Kim
Kendra Yum

**Purpose:** Following hematopoietic stem cell transplant, patients are immunocompromised and are usually administered prophylactic antibiotics, commonly fluoroquinolones, in order to prevent bacterial infection. Determining the appropriate time to begin fluoroquinolone administration may minimize the risk of Clostridium difficile infection as studies have identified this infection as a common complication in this population. This study will evaluate the initiation of prophylactic fluoroquinolones at the time of neutropenia (ANC < 500) in comparison to Day 0 (day of stem cell infusion) and assess if this delayed initiation has a positive impact on the risk of Clostridium difficile infection without increasing the risk of bacteremia.

**Methods:** This study will be submitted to the Institutional Review Board for approval. In this 1-year, single-center retrospective cohort study, a bone marrow transplant database will be used to identify adult patients who received an autologous stem cell transplant at The Mount Sinai Hospital from April 2016 to September 2016. Patients who received levofloxacin as prophylaxis after their transplant will be included. In efforts to reduce the rate of Clostridium difficile, initiation of levofloxacin prophylaxis was initially delayed from Day 0 to Day +3 of transplant beginning April 30, 2015. This practice was subsequently revised to further delay the initiation once the ANC < 500 beginning April 2016. Objectives of this study are to assess the incidence of Clostridium difficile infection and incidence of bacteremia in patients who initiated levofloxacin once the patient’s ANC fell to at least 500 and compare to those who initiated on Day 0. The following data will be collected from the medical record: date of birth, gender, underlying malignancy, use of H2 receptor antagonist/proton pump inhibitors, conditioning regimen, ANC,
date of neutropenia, Clostridium difficile infection, and bacteremia within 30 days post-transplant. Appropriate statistical analysis will be performed to evaluate whether delaying the initiation of fluoroquinolone prophylaxis to ANC < 500 will lead to a decreased incidence of Clostridium difficile without having a negative effect on the rate of bacteremia in this population.

Poster Title: Evaluation of venous-thromboembolism risk assessment tools in medical and surgical patients in a 351-bed community teaching hospital

Primary Author: Robert Marquis, The Unity Hospital of Rochester, NY; Email: robert.marquis@rochesterregional.org

Additional Author(s):
Rebecca Wedow
Shashi Patel

Purpose: Venous-thromboembolism (VTE) can cause significant morbidity and mortality in medical and surgical patients. VTE prophylaxis assessments tools ensure patient risks are addressed in order to reduce the rates of VTE in the hospital setting. The Padua Prediction Score (PPS) and The Caprini Risk Assessment (CRA) are evidence-based scoring tools that reduce VTE incidence. This retrospective chart review will compare the results of the two risk assessment tools when applied to both medical and surgical patients.

Methods: Retrospective data will be obtained from a 351-bed community teaching hospital on medical and surgical patients. One hundred patients 18 years of age and older admitted from September 1, 2016 through September 30, 2016 will be randomly chosen for VTE risk assessment. Randomization will be performed using the patient census list for the month of September and a selection will be made at every third patient in the system until fifty surgical patients and fifty medical patients are chosen. Patients requiring full anticoagulation, patients continued on home anticoagulation, and patients under the age of 18 will be excluded during the randomization process. Data collected will include PPS score and CRA score as well as the corresponding risk level (low, medium, and high risk). The type of regimen initiated, number and type of pharmacological contraindications, number, type of mechanical contraindications, and appropriateness of initiated regimen will be collected. CRA and PPS scores will be compared using a descriptive statistical analysis.

Poster Title: Evaluation of a pharmacist-led discharge counseling program at a 351-bed community teaching hospital.

Primary Author: Matthew Rudy, The Unity Hospital of Rochester, NY; Email: matthew.r.rudy@gmail.com

Additional Author (s):
Christina Hanson
Shashi Patel

Purpose: Pharmacist-led discharge counseling has the capacity to elicit a positive influence on patient care. It is associated with a lower thirty day readmission rate, increase detection of preventable adverse drug events, and identification discrepancies in pharmacotherapy during transitions of care. This retrospective observational study aims to evaluate a pharmacist-led discharge counseling program and its effect on thirty day readmission rate.

Methods: This retrospective review will examine discharge data from medical units in a 351-bed community teaching hospital located in Rochester, NY. Data will be collected from patients with documented discharge counseling performed by a pharmacist during the time period of January through March 2016. Utilizing the hospital’s electronic medical record, the number of patients discharged with pharmacist counseling and thirty day readmission rate will be collected. Data will be compared to existing literature as well as hospital-wide thirty day readmission rate. Descriptive statistics will be conducted comparing the readmission rate of those patients with and without pharmacist-led discharged counseling. The primary outcome of this study will be the determination of the thirty day readmission rate for pharmacist-counseled patients. Discharge counseling involving alteration in medication regimens will be collected as a secondary outcome.

Results: An analysis of this review is pending.

Conclusion: To follow.

**Poster Title:** Clinical and economic utility of IV acetaminophen for analgesia in surgical patients

**Primary Author:** Brandon Bair, The University of Vermont Health-Network Champlain Valley Physicians Hospital, NY; Email: bbair@cvph.org

**Additional Author(s):**

**Purpose:** While, IV acetaminophen has a favorable pharmacokinetic profile over non-parenteral formulations, its therapeutic benefit remains controversial. A study by Kelly et al, concluded IV acetaminophen did not significantly decrease opioid use or length of stay (LOS) in knee arthroplasty compared to the control group. Whereas, a similarly designed study by Hansen et al, concluded a shorter LOS and decreased hospitalization costs in patients receiving IV acetaminophen in orthopedic surgeries. The effectiveness of adjunctive IV acetaminophen in various surgeries will be evaluated in this study.

**Methods:** In this retrospective study, the “treatment” group will include all patients who underwent surgery and received at least one dose of IV acetaminophen within corresponding time frames. Patients who underwent similar surgeries but received no doses of IV acetaminophen during the same time frame will serve as the “control” group. Retrospective reports will be obtained to determine the surgical procedure, average total charges, hospital length of stay and total patients for the primary objective. Each of the groups will be further classified as either outpatient or inpatient. Furthermore, the surgical procedures will be grouped into the following categories: abdominal (gall bladder/appendix), gynecological (uterus), obstetric, small intestine, large intestine, hip and knee. For the secondary objectives, pharmacy utilization reports will be utilized to determine the total opioid doses administered (daily and cumulative), total anti-emetics administered and total non-opioid analgesics administered. The total average charges between the two groups will be used to estimate the cost utility associated with IV acetaminophen. The total opioid doses administered between the two groups will be used to estimate any opioid sparing effect of IV acetaminophen. The total anti-emetics used will be used to estimate the difference in side effects between the two groups.

Poster Title: Evaluation of daptomycin use at a large teaching hospital

Primary Author: Arsheena Yassin, Touro College of Pharmacy/Mount Sinai Hospital, NY; Email: arsheenayassin@gmail.com

Additional Author(s):
Patricia Saunders-Hao
Gargi Patel
Meenakshi Rana
Gopi Patel

Purpose: Daptomycin is a lipopeptide antibiotic used in the treatment of systemic and life-threatening infections caused by gram-positive organisms. Evaluation of its use is essential for enhancing antimicrobial stewardship practices, especially at large hospitals. The objectives of this study will be to evaluate the current prescribing patterns of daptomycin at Mount Sinai Hospital, to determine the appropriateness of daptomycin use, and to aid the antimicrobial stewardship program in developing clinical decision pathways for the appropriate use of daptomycin.

Methods: This study will be a single center, retrospective evaluation of all adult patients admitted to Mount Sinai Hospital who received at least one dose of daptomycin. The electronic medical record system will be utilized for data collection. Information that will be collected for each patient will include patient demographics; renal function; allergies; co-morbidities; concomitant synergistic antibiotics or statin use; prior vancomycin use; dose, duration and indication for daptomycin; microbiology; prescribers; side effects; and monitoring parameters, such as weekly creatinine phosphokinase (CPK). For each patient, determination of whether the use of daptomycin was appropriate or not will be assessed. This will be done based on the indication and rationale for daptomycin use as determined by a clinical team of pharmacists and physicians. The primary outcome assessed will be the appropriate use of daptomycin. The secondary outcomes will include monitoring parameters done; occurrence of side effects, such as CPK elevation and Clostridium difficile infections; the cost of daptomycin from appropriate and inappropriate uses; and resistance patterns, including minimum inhibitory concentration (MIC) changes during daptomycin therapy. The results of this study will be used to guide
appropriate daptomycin prescribing practices and to implement clinical decision pathway to aid antimicrobial stewardship at Mount Sinai Hospital.

**Poster Title:** Determining the impact of a pharmacy-driven transition of care program on heart failure patient readmission rates at a community teaching hospital.

**Primary Author:** Neha Kumar, UHS Hospitals, NY; **Email:** nehakumar36@gmail.com

**Additional Author(s):**
Lyndsay Wormuth
Amber Jerauld

**Purpose:** Heart failure is one of the leading causes of hospital readmissions with adverse effects on the allocation of hospital resources and reimbursement. Therefore, compliance with the Joint Commission Heart Failure Core Measures and reduction in 30-day readmission rates following hospitalization for acute decompensated heart failure are established goals for health care systems nationwide. The objective of this study is to determine the impact of a pharmacy-driven transition of care program on unplanned healthcare utilization, specifically 30-day hospital readmission following discharge.

**Methods:** This is an observational study conducted at a community teaching hospital with a historical control utilizing a retrospective cohort study design. The control group included patients admitted with a diagnosis of heart failure or acute decompensated heart failure between September 2015 and February 2016. The intervention group included patients admitted with a diagnosis of heart failure or acute decompensated heart failure from September 2016 through February 2017. Interventions included pharmacist-led medication reconciliation at admission and discharge, inpatient medication/disease state counseling at admission with application of adherence tools (ie. patient education booklets, behavioral aids, and referral to relief services for those with financial concerns), inpatient medication/disease state counseling at discharge with application of adherence tools, and individualized telephone follow-up by a pharmacist within 72 hours of discharge. The primary outcome is time to first unplanned health care event, defined as hospital readmission within 30-days of discharge. The secondary outcome is impact on HCAHPS scores for the control group versus the intervention group.

Poster Title: Clinical impact of a pharmacist-managed renal dosing service

Primary Author: Taylor Kelsey, UHS Hospitals, NY; Email: taylorladdkelsey@gmail.com

Additional Author(s):
Caitlyn Burnett

Purpose: Appropriate drug dosing in patients with renal impairment is paramount to avoiding unwanted drug effects and promoting optimal patient outcomes. The purpose of this study is to assess the rate of inappropriate fluoroquinolone dosing and to evaluate the impact of a newly implemented, pharmacist-driven, renal dosing service on dose adjustment occurrences, adverse drug events, length of hospitalization, and duration of antibiotic use.

Methods: This is a retrospective, observational study comparing a pre-implementation and a post-implementation study groups from a 280-bed teaching hospital in upstate New York. The pre-implementation group, serving as a control, will include adult, non-pregnant, patients admitted to the hospital, receiving fluoroquinolone therapy with renal impairment, not requiring dialysis, between the months of January and March 2016. The post-implementation data will be collected one calendar year later and include patients with the same characteristics. The primary outcome of this study is incidence rate of inappropriate dosing of fluoroquinolone, defined as incorrect dose and/or frequency based on calculated creatinine clearance using the Cockcroft-Gault equation. Sub-group analyses of the primary outcome will include incidence of under-dose versus overdose and timing of inappropriate dose in relation to hospital stay. Secondary outcomes assessed will be length of hospital stay and number of adverse drug reactions.

Poster Title: Chronic Obstructive Pulmonary Disease (COPD): Pharmacist intervention on medication possession ratio (MPR) and inhaler technique

Primary Author: Tera McIlwain, Union Medical Pharmacy, NY; Email: tmcilwain@unionmedicalrx.com

Additional Author (s):
Gregory Notaro
James Notaro
Mary Lou Notaro
Victoria Belousova

Purpose: COPD is the third leading cause of death in the United States, responsible for over 134,000 deaths per year and $32.1 billion in medical costs in 2010. Non-adherence and improper use of inhalers can lead to treatment failure and increased risk of hospitalization. The primary objective of this study is to determine if pharmacist intervention can lead to improved medication adherence rates (measured by MPR) and inhaler technique. Secondary objectives include reduction in COPD symptoms and exacerbations, improvements in the Centers for Medicare & Medicaid Services (CMS) adherence Star Ratings, and improved health status through self-assessment.

Methods: This study has been submitted for approval to the Institutional Review Board at D'Youville College. The pharmacy’s refill reminder program, Health-Minder, will be utilized to identify patients prescribed inhalers who have a MPR < 80%. These patients will be screened for COPD or asthma, and those with COPD will be asked to participate in the study. If patient agrees, a pre- questionnaire will be administered over the phone, evaluating general information (e.g. smoking, occupational, and vaccination history; hospital admissions due to COPD exacerbation). In-person appointments will be scheduled with a dedicated pharmacist for medication reviews and assessments of health status and symptom and exacerbation occurrence. Patients will be evaluated on proper inhaler technique and be provided information on COPD and the importance of medication adherence. Post-interview, patients will receive handouts of all the information that was discussed and resources for self-management. Following the initial review, patients will be scheduled for three and six month...
follow-up appointments, for reassessment of medication adherence, inhaler technique, symptom/exacerbation occurrence, and health status. The study will track patient’s age, number and type of COPD medications, number and severity of exacerbations in the previous year, and adherence using a calculated MPR.

**Poster Title:** Influence of Pneumocystis jiroveci pneumonia prophylactic agents on the occurrence of bacteriuria after renal transplantation

**Primary Author:** Saloni Patel, University at Buffalo School of Pharmacy and Pharmaceutical Sciences / Erie County Medical Center, NY; Email: svpatel4@buffalo.edu

**Additional Author (s):** Michael Ott

**Purpose:** Urinary Tract Infections (UTIs) are a major cause of morbidity among renal transplant recipients. Trimethoprim-sulfamethoxazole (TMP-SMX) and other second line agents are often used for Pneumocystis jiroveci pneumonia (PJP) prophylaxis after renal transplantation. Some of the PJP prophylactic agents may have an added benefit of preventing UTIs. This study aims to determine the influence of TMP-SMX versus the composite of dapsone, atovaquone, and inhaled pentamidine intended as PJP prophylaxis on the occurrence of asymptomatic bacteriuria (ASB) and UTIs (cystitis or allograft pyelonephritis) during the post-renal transplant period.

**Methods:** This study has been submitted to the Institutional Review Board for approval. Recipients of renal transplants at Erie County Medical Center between January 1, 2013 and June 30, 2016 will be identified using the electronic medical record. Eligible patients will be divided into two groups based on the PJP prophylactic agent they received: TMP-SMX (group 1) or dapsone, atovaquone, or inhaled pentamidine (group 2), and followed for three months post-transplant. Data collection will involve recording the recipient’s demographics (age, gender, weight, race, allergies, transplant date, co-morbidities), type of primary renal disease (hypertension, cystic renal disease, immunoglobulin A nephropathy, unknown origin, others), donor factors (living vs. deceased donor), recipient factors (previous transplant, CMV disease, use of indwelling urinary catheter, rejection episodes), and outcomes data (time to first event, pathogen(s) in urine culture, reason for hospitalization, number of ASB/UTI episodes). All individually identifiable health information will be de-identified prior to entry of subject data into the study database. A Cox proportional hazard model will be used to determine the hazard of developing bacteriuria due to PJP prophylaxis. The group that developed ASB or UTI will be compared to the group that did not in order to determine the risk factors for bacteriuria. To
determine the risk of developing ASB or UTI according to TMP/SMX prophylaxis, variables for TMP/SMX use versus other PJP prophylactic agents will be compared.

**Poster Title:** Analysis of opioid treatment patterns for opioid naïve members at a regional health plan

**Primary Author:** Taylor Sanderson, University at Buffalo School of Pharmacy and Pharmaceutical Sciences/BlueCross BlueShield of Western New York, NY; **Email:** ts76@buffalo.edu

**Additional Author(s):**
Lisanne Holley
Gina DeRue
Mary Bellanti
Christopher Bole

**Purpose:** In response to increasing concerns about the opioid epidemic, we will analyze opioid utilization patterns using prescription claims data at a regional health plan.

**Methods:** This will be a retrospective analysis of prescription claims data at a regional health plan from July 1, 2013 to December 31, 2015. Opioid claims will be included for opioid naïve members 18 years and older, for all lines of business (Medicare, Medicaid, and Commercial). Members must have continuous enrollment for 1 year following the first fill of an opioid medication, which will be referred to as the incident fill. The incident fill must have occurred between January 1, 2014 and December 31, 2014. Members will be excluded if they have an opioid claim in the 6 months prior to the incident fill. The primary outcomes of the study will be total duration of opioid therapy and frequency of use. Infrequent use is defined as less than or equal to 90 days, moderate as 91-180 days and chronic as more than 180 days of therapy over the course of 1 year. Secondary outcome measures will include time to and rate of conversion from immediate-release (IR) to extended-release (ER) and factors associated with moderate and chronic use of IR opioids. Multivariate analysis will be used to assess factors associated with moderate and chronic use of IR opioids. This study will be submitted to the Institutional Review Board for approval.

Poster Title: Effects of statins and cholesterol on patient aggression: Is there a correlation?

Primary Author: Emily Leppien, University at Buffalo School of Pharmacy and Pharmaceutical Sciences/Buffalo Psychiatric Center, NY; Email: Emily.Leppien@omh.ny.gov

Additional Author(s):
Kimberly Mulcahy
Eileen Trigoboff
Tammie Lee Demler

Purpose: There is little data to support or refute the claim that statins or low serum cholesterol does in fact increase a patient’s risk of aggression. It is imperative we are aware of best practices to ensure that we are not unknowingly worsening a patient’s condition. This study will identify if there is a relationship between 1.) statin use and increased aggression and 2.) cholesterol levels and increased aggression in psychiatric inpatients.

Methods: This study evaluates a best practice medication use evaluation (MUE) conducted by our Pharmacy and Therapeutics (P&T) Committee and was then submitted to our Institutional Review Board of record (New York State Psychiatric Institute). A patient chart review will be conducted for all male and female patients greater than 18 years of age institutionalized at the Buffalo Psychiatric Center from January 1, 2011 to December 31, 2015. Statin therapy, measured lipid panel (including total cholesterol, low-density lipoprotein (LDL), high-density lipoprotein (HDL) and triglycerides) and requirement of a psychiatric emergency code (“Code Green”), as a result of agitation, will be noted. Inpatients who did not receive cholesterol-lowering therapy or require a “Code Green” will be used as controls. Individuals without a lipid panel obtained during hospitalization and those with a criminal procedural law (CPL) designation or unknown statin therapy status will be excluded. Appropriate statistical analyses will be conducted to determine if there is an increased risk of aggression with statin use and if aggression is a consequence of low serum cholesterol levels.

**Poster Title:** Effect of changing COPD triple therapy inhaler combinations on pulmonary function

**Primary Author:** Nicholas Ladziak, University at Buffalo/Buffalo Medical Group, NY; **Email:** naladzia@buffalo.edu

**Additional Author (s):**
Troy Hoelzl
Nicole Paolini-Albanese

**Purpose:** With recently approved inhaled agents, there are many therapeutic options for treatment of chronic obstructive pulmonary disease. Previous studies have shown superiority of long-acting beta agonist/long-acting muscarinic antagonist combination inhalers in reducing hospitalizations compared to inhaled corticosteroid/long-acting beta agonist combination inhalers. The objective of this study was to evaluate changes in lung function as measured by pulmonary function tests in patients receiving triple therapy when changed from an inhaled corticosteroid/long-acting beta agonist combination inhaler with separate long-acting muscarinic antagonist inhaler to a long-acting muscarinic antagonist/long-acting beta agonist combination inhaler with separate inhaled corticosteroid inhaler.

**Methods:** This retrospective, observational study will be submitted to the Internal Review Board for approval. As part of a cost savings program, patients with prescriptions for an inhaled corticosteroid/long acting beta agonist combination inhaler and a separate long-acting muscarinic antagonist inhaler were identified and changed to a long-acting beta agonist/long-acting muscarinic antagonist combination inhaler and a separate inhaled corticosteroid inhaler. Of the patients who were changed, those with pulmonary function tests available within the last 6 months prior to the change and repeat tests within the 6 months following the change will be included for evaluation. The following data will be collected: gender, age, pre-change chronic obstructive pulmonary disease regimen, post-change chronic obstructive pulmonary disease regimen, specific comorbidities (asthma, sleep apnea, obesity, heart failure), smoking status, influenza and pneumococcal vaccination status, pulmonary function tests (pre-, post-, and predicted forced expiratory volume in 1 second and pre-, post-, and predicted forced vital capacity), number of moderate exacerbations within the last 12 months prior to the change,
and number of severe exacerbations within the last 12 months prior to the change. All data will be de-identified prior to data analysis. For each patient, the PFTs before the change will be compared with PFTs after the change to evaluate the effects of the new regimen on pulmonary function.

Poster Title: Evaluation of a hepatitis C patient management program at a university specialty pharmacy.

Primary Author: Julie Wawrzyniak, University of Rochester Medical Center, NY; Email: julie_wawrzyniak@urmc.rochester.edu

Additional Author(s):
Nadia Jubran
Michelle Zaepfel
Tina Khadem
Lisa Cristofaro

Purpose: Specialty pharmacy is a unique and growing industry, where specialty medications are used in the treatment of complex, chronic or rare disease states, such as hepatitis C. University of Rochester Specialty Pharmacy hepatitis C patient management program comprises many unique qualities; one being integration with the Gastroenterology and Hepatology Division within the University of Rochester Medical Center (URMC), which offers the opportunity of increased involvement in patient care. The primary purpose of this study is to assess treatment success through the incidence of achieving a sustained virologic response (SVR) of patients served at UR Specialty Pharmacy versus other non-integrated pharmacies.

Methods: This is a single-center retrospective cohort study of adults belonging to the Gastroenterology and Hepatology Division within URMC prescribed hepatitis C therapy between January 1st, 2014 and July 31st, 2016. In addition to the primary objective of the incidence of achieving SVR, adherence to therapy will be assessed by the proportion-of-days-covered model (PDC). Also secondarily, delays in therapy initiation, early treatment discontinuation, and viral load obtainment 12 weeks or greater post-therapy completion will be measured. Lastly, a multiple logistic regression model will be used to identify pre-defined independent predictors of treatment failure.

Results: The total number of subjects prescribed hepatitis C virus therapy during the study duration will be presented. The number and percentage of subjects that achieved SVR will be
presented and compared between study arms. Pre-defined characteristics of treatment failure will be presented using odds ratios with associated 95% confidence intervals.

Conclusion: The evaluation of various aspects of hepatitis C therapy will be valuable in evaluating the success of the UR Specialty Pharmacy hepatitis C patient management program, which may be used as a framework for other institutions. Finally, identification of characteristics associated with hepatitis C treatment failure will have clinical implications for identifying areas of opportunity to optimize patient outcomes.

**Poster Title:** Evaluation of changes made by pharmacists during medication order verification process at an academic medical center  

**Primary Author:** Renad Abu-Sawwa, University of Rochester Medical Center, NY; **Email:** rabusawwa@gmail.com  

**Additional Author (s):**  
George Nimako  
Travis Dick  
Justin Foster  
Eric Kanouse  

**Purpose:** Pharmacists at Strong Memorial Hospital (SMH) and Golisano Children’s Hospital (GCH) of the University of Rochester Medical Center verify a large number of medication orders. Departmental data estimates that pharmacists spend a significant amount of time reviewing orders. In order to improve pharmacists’ workload efficiency, the verification process will be analyzed to assess the extent that pharmacists modify orders after providers’ entry. The primary objective is to quantify the number of medication orders changed during the verification process. The secondary objectives are to evaluate proportions of changed orders in each unit and aspects of order fields modified for process improvements.  

**Methods:** The study protocol was approved by the Institutional Review Board. All inpatient orders verified by pharmacists at SMH and GCH between April 1 and May 31, 2016 were extracted from the hospital electronic medical record. The orders are being retrospectively reviewed to classify the fields that pharmacists have the capability to modify during the verification process into clinical (medications, priority, administration dose, ordered dose, route, rate, duration, volume, frequency, first dose, number of doses, start time, end time, dispense code, note to pharmacy and administration instructions) and logistical (package) categories for further analysis. Preliminary analysis identified a total of 304,568 orders during the study time frame. Of this, 13,763 orders have been excluded because they were auto-verified by the system upon provider ordering due to being floor stock medications. A total of 290,805 orders have been identified as being verified solely by pharmacists and will be used for
further analyses. Data will be further investigated to determine the breakdown of order changes by the following patient care units: adult, pediatric, emergency department, surgical and cancer center as well as assess trends in modifications of order fields and medication orders in each patient care unit. Further analyses will target areas to improve workflow processes. Data will be analyzed using descriptive statistics.

Poster Title: Assessment of Extemporaneous Non-Sterile Compounding at a Large Academic Medical Center

Primary Author: Rachna Burman, University of Rochester Medical Center, NY; Email: rachna.burman09@gmail.com

Additional Author (s):
Zachary Hayes
Susan Hughes
Justin Foster
Travis Dick

Purpose: This study is to characterize the non-sterile extemporaneously compounded medication orders generated to accommodate the needs of patients seen at large academic medical centers. Some of the prescribed therapies could not be fulfilled using commercially manufactured products, instead requiring compounding in the institution’s pharmacy. Extemporaneously compounded products require specialized equipment and staff, as well as carry additional risks as compared to commercially manufactured products (such as potential contamination or human error), and also have mandated shorter expiration dates (potential waste). A better understanding of the non-sterile extemporaneously compounded orders could help the large medical center improve overall care and efficiency.

Methods: The study protocol was deemed exempt by the hospital’s Institutional Review Board. An electronic medical record system was used to generate a list of products compounded at Strong Memorial Hospital between January 1, 2016 and June 30, 2016. Only non-sterile extemporaneously compounded products for inpatients were included. Data were collected to assess practices of ordering of non-sterile extemporaneously compounded products, the time and assets allocated to complete these orders and the details of these orders. Assessment of these data points were compared to commercially available products. Appropriate descriptive statistics were calculated for all variables. Microsoft Excel was used to organize and quantify data.

Burke Cunha  

**Purpose:** Clostridium difficile (C.difficile), an anaerobic spore-forming organism, attacks the colonic epithelium and causes cell death, resulting in C.difficile-associated diarrhea, pseudomembranous colitis, toxic megacolon, and death. Metronidazole and oral vancomycin have been the gold standard for treatment. Relapse rates with conventional dosing are as high as thirty percent, prompting a search for the most superior dosing regimen. Successful treatment has been achieved utilizing doses of vancomycin ranging from 125 to 500 milligrams four times daily, with limited data comparing their efficacy. The study objective is to compare each dose of oral vancomycin in the treatment of C. difficile to optimize outcomes.  

**Methods:** MedMined®, an online data mining software that is integrated with the hospital’s electronic medical record system, will identify patients who have tested positive for C. difficile toxin via polymerase chain reaction Patients who received oral vancomycin will be eligible for study inclusion. The following data will be collected: age, gender, date of admission, date of positive C. difficile test, date of initiation of vancomycin therapy, the various doses and duration of treatment of each dose, as well the reasons for dose changes. For patients concurrently on metronidazole, information regarding the dose and duration will be recorded. In order to evaluate efficacy, the initial number of stools per day, number of stools seventy two hours after treatment initiation and each dose change, progression to colitis, and days to soft stool will be recorded. All data will be recorded without patient identifiers and maintained confidentially. Data will be reviewed to determine if there is an optimal dose of vancomycin for the treatment of C.difficile.

Poster Title: Zolpidem given for the arousal of comatose patients in the intensive care unit

Primary Author: Peter Wirkowski, Winthrop University Hospital, NY; Email: pewirkowski@gmail.com

Additional Author(s):
Shan Wang
Elizabeth Wirkowski

Purpose: Zolpidem has traditionally been used to initiate sleep and is FDA approved for the short-term treatment of insomnia. However, there have been a series of case-reports that demonstrate a paradoxical effect in comatose patients in the intensive care unit (ICU). In a subset of these patients, Zolpidem actually induces arousal and increases activity. The objective of this study is to determine if a subset of comatose patients treated with Zolpidem in the intensive care units of a community hospital exhibit paradoxical arousal and increased activity.

Methods: This retrospective chart-review study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients in all of the hospital’s ICU’s who were prescribed Zolpidem between the hours of six in the morning and six in the evening. Patient charts will be reviewed and the following data will be collected: patient age, gender, ethnicity, physical examination, current medications, sleep times, neurological examination and provider notes. All data will be recorded without patient identifiers and maintained confidentially. Provider documentation of increased activity, sleep times, time awake, and Zolpidem dosage will be used to determine the effect of Zolpidem on patient arousal. The total group of patients analyzed will be separated into two groups: responders and non-responders. Average baseline characteristics, dosages of Zolpidem, time of increased activity and provider noted response in treatment will be averaged for both treatment groups to determine significance. The data collected will help determine if there is a statistically significant increased rate of arousal in comatose patients who are treated with Zolpidem. If there is enough patient data, the effect of different dosages and a possible correlation to increased activity will also be analyzed.

Poster Title: Evaluate the success of achieving therapeutic vancomycin trough levels in pediatric inpatients with existing dosing guidelines

Primary Author: Kanika Dunn, Winthrop University Hospital, NY; Email: kdunn1@winthrop.org

Additional Author(s):
Gladys El-Chaar
Leonard Krilov

Purpose: Vancomycin is a glycopeptide antibiotic used for the treatment of methicillin-resistant Staphylococcus aureus in pediatric patients. The minimum inhibitory concentration (MIC) has been used to determine its clinical efficacy. Recently, this MIC increased from 1 to 2mg/dL, requiring higher therapeutic ranges in adult patients. Existing vancomycin dosing guidelines in children rely on older MICs. As such, many pediatric patients have sub-therapeutic trough levels. Our goal is to evaluate whether our vancomycin trough levels fall within the new therapeutic ranges. These levels will be correlated to efficacy, safety, and patient outcome. Ultimately, we aim to update our dosing guidelines accordingly.

Methods: This study will be submitted to the Institutional Review Board for approval. This is a retrospective chart review of pediatric patients admitted to our institution, between September 1, 2015 and September 1, 2016. The electronic medical record system will be used to identify patients who qualify for inclusion in the study. Inclusion criteria are children less than 18 years of age who received vancomycin and had at least 1 trough level reported. Excluded are non-detectable levels, missed doses, or excessively delayed drug administration. The following data will be collected: patient medical history, age, weight, allergies, concomitant medications, indication for vancomycin, site of infection, culture results, white blood cell count and differential, and MIC of identified microorganisms, number of doses prior to level(s), vancomycin dosage and trough level(s), timing of dose(s) and level(s), serum creatinine, blood urea nitrogen, and urine output. We will record data on patient outcome to assess the efficacy of vancomycin, including positive culture site results or a documentation of a clinical cure, and reported adverse effects and events. Goal trough levels will range from 10 to 20 mg/L, depending on the site of infection. Patients who received vancomycin but did not have levels
sampled, will also be evaluated for their outcome from the infection. Vancomycin trough levels will be assessed for falling within the therapeutic range.

Poster Title: Changes in John Cunningham virus IgG antibody index in fingolimod, rituximab and dimethyl fumarate-treated multiple sclerosis patients

Primary Author: Stephen Farley, Winthrop-University Hospital, NY; Email: sfarley@winthrop.org

Additional Author (s):
Malcolm Gottesman
Sharon Friedman-Urevich
Mark Shen
Janin Ye

Purpose: Progressive Multifocal Leukoencephalopathy (PML) is an opportunistic viral infection caused by the John Cunningham virus (JCV). PML occurs in immunocompromised patients and may lead to disability or death. Natalizumab is a therapy for relapsing-remitting forms of multiple sclerosis (MS) that is known to cause PML. Medication monitoring includes trending JCV antibody titers. PML has occurred in MS patients who received fingolimod and dimethyl fumarate in the post-marketing setting. Although rituximab is associated with PML, this relationship has not been reported in MS patients. Our goal is to determine if treatment with fingolimod, rituximab or dimethyl fumarate alters JCV antibody titers.

Methods: This study has been submitted to the Institutional Review Board for approval. This is a retrospective chart review of patients treated at a comprehensive MS care center from January 1, 2013 to September 1, 2016. The electronic medical record will be used to identify patients who qualify for inclusion in this study. Inclusion criteria include: MS patients treated with fingolimod, rituximab or dimethyl fumarate that have a positive JCV antibody titer(s). Exclusion criteria are patients with non-detectable JCV antibody titer(s). The following data will be collected: patient age, gender, race, absolute lymphocyte count(s), and JCV antibody titer(s). With respect to each medication, the drug name, dose, and frequency will be collected. These values will be recorded on a data collection sheet for analysis. JCV antibody titer(s) values will be trended and analyzed for a correlation between their value and treatment by these agents. Elevated JCV antibody titers are known to increase the risk of PML in natalizumab-treated MS
patients. The relationship between JCV titers and PML risk in MS patients treated with fingolimod, rituximab or dimethyl fumarate will be explored.

**Poster Title:** Drug utilization evaluation of phytonadione (vitamin K) at a teaching institution  

**Primary Author:** Nora Jaber, Winthrop-University Hospital, NY; **Email:** njaber1234@gmail.com  

**Additional Author (s):**  
Mark Shen  
Alexander Hindenburg  

**Purpose:** Venous thromboembolisms and atrial fibrillation are common indications for anticoagulation. Atrial fibrillation is a frequently diagnosed condition which predisposes patients to embolisms and stroke. A common anticoagulant used to treat and prevent embolisms is warfarin, a vitamin K antagonist. In the case of high INR or bleeding, phytonadione is indicated as an antidote for the reversal of warfarin. The objective is to determine if vitamin K prescribing habits for warfarin-treated patients at a teaching institution are adherent to CHEST guideline recommendations based on dose and route of administration. The efficacy of such dosages and routes will also be evaluated.  

**Methods:** This retrospective chart review will be conducted by a pharmacist after obtaining a census of patients who received at least one dose of vitamin K between January 1, 2016 and September 1, 2016. The electronic medical record system will be used to identify such patients. The following data will be obtained from the charts: gender, age, indication for warfarin, type of bleed (if applicable), dose and route of vitamin K given, Kcentra or Fresh Frozen Plasma dose given (if applicable), INR before and after vitamin K dose, INR trend post-vitamin K, length of time it takes to achieve a therapeutic INR, and if warfarin was held/restarted. Patients who received vitamin K to reverse the INR for the purposes of a procedure will be excluded. The data will be collected and analyzed for the assessment of the use of vitamin K in this institution. The dosage and route of vitamin K will be correlated with the corresponding INR trend to determine its efficacy. The prescribed dose and route will also be compared to CHEST guideline dosing recommendations to assess adherence. The results will be presented to the hospital’s Pharmacy and Therapeutics Committee for evaluation and optimization of vitamin K usage. These results will be combined with the results of other drug evaluations and will be submitted for IRB approval.

**Poster Title:** Role of the pediatric cardiologist in medically clearing children prior to initiation of stimulant and antipsychotic medications

**Primary Author:** Hanan Cherqaoui, Winthrop-University Hospital, NY; **Email:** hcherqaoui@winthrop.org

**Additional Author(s):**
Glady El-Chaar  
Rahul Ramesh  
Estela Noyola  
Donna Better

**Purpose:** Reports of cardiovascular events in children receiving stimulant or antipsychotic medications resulted in the development of guidelines to minimize this risk. When initiating these medications, the pediatrician evaluates the child through history, physical exam, and current medications to evaluate the patient’s risk. If there is concern, an electrocardiogram is typically performed, with a consideration for a cardiologist referral. A cardiologist may interpret the electrocardiogram readings differently according to risk factors and may recommend an intervention, subsequently allowing the patient to be medically cleared. Our study aims to determine the added value of the pediatric cardiologist in medically clearing these children.

**Methods:** This retrospective study will be submitted to the Institutional Review Board for approval. The study will include patients referred to the pediatric outpatient cardiology clinic. The list of children who had a cardiac evaluation prior to initiating stimulant medications for attention deficit and hyperactivity disorder (ADHD) or antipsychotic medications, will be obtained. Inclusion criteria are children less than 21 years who were referred to a pediatric cardiologist prior to placement on stimulant or antipsychotic medications. Neonates will be excluded from the study. The following data will be recorded: patient’s age, weight, medical and social history, family history, vital signs (heart rate and blood pressure), medications (over-the-counter, herbal, and prescription), laboratory values, electrocardiogram (ECG), and other diagnostic tests, such as an echocardiogram. The cohort will be divided into two groups of children, those who were medically cleared to start taking these medications and those who were not. For patients who were not medically cleared, we will record the contraindication(s),
the plan established for the management of the patient, and the outcome of those interventions. Specifically, for both groups, we will evaluate any subsequent visits for cardiac-related symptoms or complications, patient admissions to the emergency department and/or our hospital due to cardiac events, as well as overall patient outcomes. A chi square test will be used to detect significant differences in outcomes between groups.

Poster Title: Use of ramelteon for reduction of as needed antipsychotics in elderly patients with delirium

Primary Author: Sara James, Winthrop-University Hospital, NY; Email: athulyasara@gmail.com

Additional Author(s):
Sum Lam
Aaron Pinkhasov

Purpose: Delirium is an acute condition resulting in reduced attention and cognition, disorganized thinking, and altered level of consciousness with a fluctuating course. The first line therapy for delirium is behavioral modification. If that fails, antipsychotics have generally been used off-label for delirium although it has been linked with increased mortality in the elderly. Delirium has been associated with dysregulation of melatonin secretions and there is data suggesting the benefit of ramelteon, a melatonin agonist, in patients with delirium. The goal of this study is to evaluate the role of ramelteon in decreasing the need for as needed uses of antipsychotics.

Methods: This retrospective study will be submitted to the Institutional Review Board for approval. The study subjects were identified from May 2015 to October 2015. A standardized template is utilized for data collection of the control and intervention group. The study is limited to patients over 65 years of age, admitted to Winthrop University Hospital, and diagnosed with delirium. They have been referred to the Psychiatry Consultation and Liaison team to be placed on constant observation and received antipsychotics as needed for delirium. The control group consists of patients who have not received ramelteon and the intervention group will have patients who are given ramelteon. The total number of doses of antipsychotics given is recorded for each group and the number of doses of ramelteon is recorded in the intervention group. The name of the antipsychotic, the strength, and dose is also recorded.

Poster Title: Evaluation of opioid induced constipation prevention in acute care patients

Primary Author: Jenny Mathew, Hillcrest Medical Center, OK; Email: jenny.mathew@hillcrest.com

Additional Author(s):
Edward Hudson

Purpose: Opioid medications are widely utilized in the acute care hospital setting for moderate to severe pain management. Opioid induced constipation (OIC) is a problematic adverse effect seen in up to 15 percent of patients. Studies have indicated prevention is preferred over management of OIC. Prophylactic pharmacologic therapy may be beneficial for patients with predisposing factors such as advanced age, immobility, and coadministration of other constipation-inducing medications. The focus of this study is to assess if prophylactic laxative use prevented constipation.

Methods: The study is to be submitted to the Institutional Review Board for approval. This is a retrospective electronic chart review of patients receiving greater than 30 mg morphine daily or the equianalgesic equivalent for a minimum of five inpatient days. Exclusion criteria were patients younger than 18 years of age, diagnosis of cancer, gastroparesis, bowel obstruction, and irritable bowel syndrome. Primary outcome focused on the number of bowel movements seen in patients started on a prophylactic laxative at the initiation of pain management compared to those who did not receive a laxative for at least 3 days after initiating opioid pain management. Secondary outcome will evaluate patients requiring methylnaltrexone therapy. Additional data obtained from patient records include demographics, length of stay, pain rating, mobility status, and use of other constipating medication.

**Poster Title:** Evaluation of pharmacist intervention using a data mining program on appropriate antibiotic de-escalation of gram negative cultures

**Primary Author:** Marinell Schoening, Hillcrest Medical Center, OK; **Email:** mkschoening@gmail.com

**Additional Author (s):**
Edward Hudson

**Purpose:** Gram negative infections have been associated with multiple resistance mechanism which lead to poor patient outcomes and increased hospital cost. An important reason for decreased mortality includes inappropriate streamline to a more effective antibiotic choice towards the targeted organism than the initial antibiotic selected and delay in starting effective antimicrobial therapy. Overuse of broad-spectrum antibiotic therapy may also lead to increased antimicrobial resistance. The objective of this study is to determine whether pharmacist intervention using a data mining program “MedMined” could aid in improved monitoring and correction of inappropriate narrow-spectrum antibiotic selection.

**Methods:** This is a retrospective chart review and data analysis study of patients with cultures for gram negative bacteria. Adult patients will be identified through computer-generated, MedMined Surveillance Advisor alerts and reports of any positive blood cultures for gram negative bacteria. Pharmacists have the opportunity to review all cultures and perform chart reviews to determine whether appropriate antibiotic therapy is utilized and administered in a timely manner. The data gathered from electronic medical records system will be used to identify how often inappropriate treatment was recognized and intervened on by the hospital pharmacist. This study will be submitted to the Institutional Review Board for approval.

Poster Title: Four-Factor prothrombin complex concentrate outcome measures in patients receiving weight-based dosing versus fixed-dosing in a hospital setting with established guidelines for use

Primary Author: John Cannedy, Integris Baptist Medical Center, OK; Email: john.cannedy@integrisok.com

Additional Author(s):
Julia Chiappe

Purpose: Four-Factor prothrombin complex concentrate (4FPCC) is labeled for urgent reversal of acquired coagulation factor deficiency, induced by vitamin-K antagonists, and off-label for oral anti-10a inhibitors. The health-system’s formulary committee instituted a fixed-dose protocol for 4FPCC dosing adapted from recent literature. The purpose of this study is to evaluate the clinical effectiveness, safety, cost effectiveness, and degree of prescriber compliance, with the newly established 4FPCC fixed-dose protocol, within the affiliated health system, by comparing patients and outcomes before and after its implementation.

Methods: This retrospective study will be submitted to the Institutional Review Board for approval. All protected health information will be recorded without patient identifiers and maintained confidentially. This study will include adult patients within the affiliated health system who received only 4FPCC for urgent reversal of warfarin or an oral anti-10a inhibitor before and after implementation of the fixed dose protocol between June 1, 2013 to May 19, 2016 and May 20, 2016 to February 28, 2017 respectively. Data for population comparison will include: patient demographics, agents and indications for chronic oral anticoagulation, presence of other prescription or inpatient medications affecting hemostasis, laboratory values and blood component use before and after 4FPCC administration. Additional data will be collected to derive the measures for evaluation of fixed-dose protocol clinical effectiveness, safety, cost-effectiveness and compliance including: number of 4FPCC doses to reach international normalized ratio (INR) less than 2 for warfarin reversal, cumulative 4FPCC units administered, rates of thrombotic complications within seven days from 4FPCC administration, patient mortality, and patient discharge disposition.

Poster Title: Pediatric delirium education: Comparing staff knowledge before and after a comprehensive education module in a pediatric intensive care unit

Primary Author: Allyson Gabbard-Caldwell, Integris Baptist Medical Center, OK; Email: adgpharmd@gmail.com

Additional Author(s):
Leslie Patatanian

Purpose: Increased awareness regarding the impact of pediatric delirium on patient outcomes has resulted in development of several validated screening tools for identifying and monitoring delirium in infants and children. This study will evaluate the degree to which educating pediatric intensive care unit staff impacts their knowledge on pediatric delirium.

Methods: A competency examination on pediatric delirium will be administered to hospital staff involved in the care of pediatric patients. This assessment will occur both prior to and upon completion of a comprehensive education module on pediatric delirium. Findings will be analyzed to assess the module’s impact on competency scores, and results will be stratified by individual, profession, and overall group performance. Staff will also be asked to evaluate the efficacy of the education module and to offer suggestions for improvement.

Results: To follow.

Conclusion: To follow.

**Poster Title:** The standardization of admission and specialty order sets to minimize duplicate medication orders

**Primary Author:** Victoria Felder, Norman Regional Health System, OK; **Email:** victoria.n.felder@gmail.com

**Additional Author (s):**
Jerri Cody

**Purpose:** The implementation of computerized physician order entry has led to an increase in the number of duplicate orders. These duplicate orders can potentially lead to medication errors, specifically multiple administrations of the same medication. The purpose of this study is to find an effective way to minimize the number of duplicate medication orders, and thereby reduce the number of associated medication errors.

**Methods:** Commonly used medications, particularly as needed medications, will be identified and removed from standard admission and specialty order sets, then added to a specific as needed order set. Prior to changing the order sets, an analysis of the frequency of duplicate orders will be done, then after implementation of the new order sets, another analysis will be done to assess the change in frequency. Additional analysis will be done on the number and types of order sets impacted by the changes.

**Poster Title:** Evaluation of the conversion from medication charge on dispensing to charge on administration in a community hospital

**Primary Author:** Robert Holliday, Norman Regional Health System, OK; **Email:** rholliday@nrh-ok.com

**Additional Author (s):**
Jenny Stemm
Darin Smith

**Purpose:** The pharmacy department of Norman Regional Health System currently generates a patient medication charge on dispensing, either directly from the pharmacy or from an automated dispensing cabinet. This creates a potential concern if the medication is not documented as administered or if there is a failure to credit unused medication. Such billing discrepancies can result in loss of revenue. By converting to a charge on administration process for medications, the health system ensures greater accuracy in billing. The health system benefits from prevention of potential loss of reimbursements due to billing errors identified during insurance audits.

**Methods:** A complete list of all areas where medications are dispensed and charged will be assembled. This includes the automated dispensing cabinets, crash carts, totes, trays, outpatient infusion center, and the dialysis unit. Representative areas will be selected and an audit comparing charges versus administration will be performed to check for accuracy. A baseline will be established using the number of discrepancies. Based on the audit, a determination will be made as to the readiness of each unit and the organization as a whole for conversion to charge on administration. The assessment will include a financial analysis of revenue impact. Pharmacy will work with Health Information Technology to identify electronic medical record conversion steps for charge on administration. After completion of the assessment, a formal proposal will be made to the executive team.

**Poster Title:** Evaluation of urinary tract infection (UTI) management in a community hospital with subsequent pathway development and implementation

**Primary Author:** Lauren May, Norman Regional Health System, OK; Email: laurenamay23@gmail.com

**Additional Author(s):**
Fran Esfahani
Brian Hughes

**Purpose:** During a patient’s workup in the hospital setting, positive urine cultures may be incidental discoveries of asymptomatic bacteriuria and not always necessitate antibiotic treatment. In recent years, exposure to unnecessary antibiotics has increased the development of antibiotic resistance. In light of this growing resistance, utilizing antibiotics in a responsible manner is of the highest priority. This study aims to evaluate current UTI-related practices, focusing on appropriate ordering, assessment, and treatment of urine cultures, with subsequent development and implementation of a UTI diagnosis and treatment pathway to decrease inappropriate urine culture ordering and streamline appropriate antibiotic treatment of true infection.

**Methods:** This study will utilize an observational, randomized electronic medical record review to gather data. The initial retrospective phase will consist of two months of data collection from a urine culture surveillance report dating from January to June 2016 with a goal of 150 subjects for final data analysis to provide evidence of current UTI-related practices and identify areas for improvement. Data that will be collected include: age, gender, admission date, nursing unit, symptoms warranting urine evaluation, urine collection method, dates and results of urine analysis and urine culture, diagnosis of UTI or suspected asymptomatic bacteriuria, antimicrobial start/stop dates and prescriber, and factors influencing treatment decisions including, other relevant microbial results, presence of sepsis and/or shock, history of recurrent UTIs, antibiotic allergies, and urinary catheterization. Patients who are pregnant and patients less than 18 years old will be excluded. The second phase of this study will consist of development and implementation of a UTI diagnosis and treatment pathway that will be presented to the Pharmacy & Therapeutics and the Medical Executive Committees for approval.
The final phase will consist of data collection in the same manner as phase one to assess the impact of pathway implementation on UTI management during the Spring of 2017. All patient data will be de-identified and kept confidential. This study has been granted expedited approval by the Institutional Review Board.

Poster Title: Evaluation of empiric appropriateness of discharge antibiotic prescriptions from an academic medical center emergency department

Primary Author: Sara Kim, Oklahoma State University Medical Center, OK; Email: saraeunkim@gmail.com

Additional Author (s):
Kelly Murray
Aaron Lane
Shelton Knudsen

Purpose: Antimicrobial resistance is a growing problem that could be improved by implementing antibiotic stewardship activities into different practice settings. However, this has been a challenge for emergency departments due to the unclear diagnoses and the fast-paced environment. Pharmacists can have a significant impact with stewardship in emergency departments by aiding practitioners with empiric antibiotic selection and dosage. The objectives of this study are to evaluate the appropriateness of empiric antibiotic prescriptions written upon discharge for emergency department patients at an academic medical center and to describe medication errors found in the sample of antibiotic prescriptions.

Methods: This study has been approved by the OSU Center for Health Sciences Institutional Review Board. The study will use content analysis to evaluate a random sample of 500 empiric antibiotics that were submitted into the electronic medical record for discharged emergency department patients from July 1, 2015 to June 30, 2016. One clinical pharmacy resident and one emergency department medical resident will review the medication orders for errors following training in error identification, operational definitions, coding, and other information included in content analysis procedures. Open-ended data will be coded and viewed by an emergency department clinical pharmacist for agreement on coding categories. Coding for the final data set will be based on majority rule. The final data set will then be evaluated based on age of patient, provider type, antibiotic prescribed, antibiotic and dosage selected, indication for antibiotic, type or description of error, and appropriateness of antibiotic selected. Clinical practice guidelines and institutional antibiograms will be used to determine the
appropriateness of empiric antibiotic selection. Descriptive statistics will be used to address the study objectives.

Poster Title: Assessment of inpatient antiretroviral stewardship at an academic medical center

Primary Author: Cullen Adre, Oklahoma State University Medical Center, OK; Email: cadre@osumc.net

Additional Author(s):
Christina Connel
John Bury

Purpose: As the population of patients with HIV grows, there is an increased need for monitoring of significant drug interactions and ensuring appropriateness of antiretroviral therapy upon initiation and maintenance in the inpatient setting. Therefore, the purpose of this study is to evaluate the need for pharmacist led antiretroviral stewardship in an inpatient setting. Specific aims include: identifying patients with HIV, determining the percent and type of errors that occur in a sample of antiretroviral regimens, and describing drug interactions between antiretroviral and other inpatient prescriptions.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients who have been prescribed antiretrovirals in the inpatient setting. The following data will be collected: patient sex, age, weight, height, serum creatinine, antiretroviral allergies, antiretroviral(s) selected, opportunistic infection medications, time medication was administered, admitting team/hospitalist group, inpatient medication list and home medication list. This data will be verified records from the patient’s outpatient provider when available. The researchers will review each profile to assess appropriateness of antiretroviral regimens prescribed as well as any potential interactions with other inpatient prescriptions. All data will be recorded without patient identifiers and maintained confidentially.

Poster Title: Comparison of time to absolute neutrophil count recovery in patients who received filgrastim or tbo-filgrastim

Primary Author: Nan Patterson, Saint Francis Hospital, OK; Email: nkpatterson@saintfrancis.com

Additional Author(s):
Jacynthia Sterling
Teresa Cooper

Purpose: Febrile neutropenia is a serious side effect of myelosuppressive chemotherapy. Granulocyte colony stimulating factors are used to reduce the severity of neutropenia and incidence of neutropenic fever. Filgrastim has been frequently prescribed by physicians to decrease the incidence of infection, as manifested by febrile neutropenia, reduce the time to neutrophil recovery and the duration of fever, and reduce the duration of neutropenia and neutropenia-related clinical sequelae. Tbo-filgrastim is a competitor to filgrastim with a similar safety profile, but a reduced cost.

Methods: This study has been approved by the Institutional Review Board. A retrospective chart review will be performed on inpatient and outpatient adult subjects who have received at least one dose of filgrastim or tbo-filgrastim from January 1, 2015, to December 31, 2015. Subjects will be identified using charge data for filgrastim or tbo-filgrastim. Patients will be excluded from the study if they are stem cell donors, have unknown treatment history, or have non-oncology neutropenia. Qualifying patients will be divided in two groups: those who received filgrastim and those who received tbo-filgrastim. Data will be collected regarding inpatient or outpatient status, hematologic or solid organ cancer, disease status, chemotherapy regimen, number of chemotherapy days, number of granulocyte colony stimulating factor doses, highest granulocyte colony stimulating factor dose, absolute neutrophil count nadir, day of absolute neutrophil count nadir, and discharge status. Eligible patients will be randomized and placed into two arms of filgrastim or tbo-filgrastim with 100 patients in each arm. Each arm will have a distribution of 75% inpatients and 25% outpatients. Patients will be enrolled consecutively until accrual goals are achieved. Patients who meet the time period and granulocyte colony stimulating factor requirements will be reviewed further. Data will be
analyzed using descriptive statistics. Results will be used to quantify ANC recovery time and compare the efficacy of filgrastim and tbo-filgrastim.

Poster Title: Evaluation of a pharmacist-led vancomycin dosing service in the management of obese versus non-obese patients

Primary Author: Molly Grasberger, Saint Francis Hospital, OK; Email: mmgrasberger@saintfrancis.com

Additional Author(s):
Ann Lloyd
Vivian Carson
Jacyntha Sterling

Purpose: Vancomycin dosing in obese patients is an area which lacks clear guidance due to altered pharmacokinetics when compared with non-obese patients. Pharmacist-led protocols for vancomycin dosing have been associated with a higher percentage of patients being dosed optimally, as well as a lower incidence of nephrotoxicity. The primary objective of this study is to evaluate vancomycin trough levels obtained through a pharmacist-led dosing service, specifically the procurement of goal troughs in obese and non-obese patients.

Methods: This study has been approved by the Institutional Research Ethics Board. The electronic medical record will be used to identify 200 adult patients admitted to the hospital from January 1, 2015, through December 31, 2015, who received a minimum of 48 hours of intravenous vancomycin therapy dosed per the pharmacy dosing service, with at least 1 trough lab value obtained. The following data will be collected: vancomycin loading and maintenance doses, dosing frequency, adherence to the dosing protocol for initial dosing, number of changes made to the dosing regimen, time to first dose, trough level, appropriateness of trough-timing, patient age, weight, serum creatinine (SCr), blood urea nitrogen, concurrent nephrotoxic drug administration (aminoglycosides, amphotericin, piperacillin/tazobactam, carbapenems, cephalosporins, colistin, and NSAIDs), subsequent nephrotoxicity (SCr increase of 0.5 mg/dL or a 50% or greater increase from baseline), diagnoses of ascites or congestive heart failure, and intensive care unit admission during vancomycin therapy. Exclusion criteria will include patients receiving >1 dose of vancomycin outside of the pharmacy dosing service, patients receiving hemodialysis, pregnancy, patient weight < 45 kg, length of therapy < 48 hours, and patients with no vancomycin trough values. Data will be analyzed using descriptive statistics.

**Poster Title:** Utilization of lockboxes for controlled medications to reduce drug diversion and prevent accidental overdose

**Primary Author:** Giau Phan, St John Medical Center, OK; **Email:** giau.phan@sjmc.org

**Additional Author(s):**
Polly Robinson
Stephanie Tillman

**Purpose:** Prescription drug abuse is a serious public health issue that affects every community. The most commonly abused medications are opioids and benzodiazepines. In Oklahoma, between 2007 and 2011, there were 2,535 death related to prescription drugs. Tulsa is ranked 18th out of all counties in the US for painkiller deaths. More than 68 percent of people age 12 and older obtain drugs from friends or relatives. This project is designed to assess the benefit of lockboxes in reducing Tulsa’s prescription drug abuse problem. The goals are to reduce the potential for diversion and prevent accidental overdose by unauthorized users.

**Methods:** The study is pending approval by the Quality and Safety Executive Committee as a quality improvement project. Patients, who are 18 years or older and discharged with prescriptions for controlled medications, will be prospectively selected from September 2016 to February 2016. Patients selected for study inclusion will be surveyed and provided a lockbox for home use along with written and verbal counseling on proper storage and disposal of medications. Follow up via telephone will be scheduled at 3 months to determine the benefit of the lockboxes as well as any behavioral changes in disposal of medications. All data will be recorded without patient identifiers to maintain confidentiality.

Poster Title: Effects of meropenem restriction on antimicrobial resistance rates: A before and after study

Primary Author: Amanda Bozell, St. John Medical Center, OK; Email: amanda.bozell@sjmc.org

Additional Author(s):
Kari McCracken

Purpose: Broad-spectrum antibiotics are often misused due to their wide range of coverage. Consequently, antimicrobial resistance to these agents has become more prevalent. Meropenem is an agent that has become overprescribed and subsequently has shown increased resistance patterns. In an attempt to improve resistance rates at a 550 bed tertiary care center in Tulsa, Oklahoma, meropenem will be restricted starting in October 2016 to use in patients with a history of or proven infection with an extended-spectrum beta-lactamase producing organism. This study will compare pre- and post- restriction susceptibility to meropenem to determine if an improvement in resistance patterns is evident.

Methods: This quality improvement project is pending approval by the Quality and Safety Executive Committee. Medication use data will be collected to identify patients who received meropenem from February 2016 through May 2017. Laboratory data will be analyzed to evaluate the susceptibility profile changes of Pseudomonas aeruginosa, Klebsiella pneumoniae, Acinetobacter baumannii, and Escherichia coli during the same time period. Data that will be collected and assessed include: patient’s demographic information, length of hospital stay, laboratory values, meropenem and other antimicrobial use, organism(s) isolated, source of isolate, and susceptibility patterns. Data will be recorded without patient identifiers to maintain patient confidentiality.

**Poster Title:** Bridging the Vaccination Knowledge Gap with an Educational Game to Increase Administration Rates in Adults, 50 years and older

**Primary Author:** Kristi Rice, SWOSU/Walgreens PGY-1 Community Pharmacy, OK; **Email:** kristi.rice@swosu.edu

**Additional Author (s):**
- Nancy Williams
- Henry Kinnard

**Purpose:** In the last few years, the United States has faced outbreaks of whooping cough in our infant population, increased occurrences and hospitalizations from shingles, and rising numbers of deaths from Streptococcus pneumonia. Many people realize that vaccinations are important for children; however, barriers inhibit adults from receiving their vaccinations. The objectives of this study are: 1) identify baseline knowledge and willingness to be vaccinated with Tdap (Tetanus, Diphtheria, acellular Pertussis), Prevnar 13, Pneumovax 23, and Zostavax; 2) analyze feedback on an educational game as a teaching tool; and 3) compare vaccination rate data to prior year, in adults 50+ years.

**Methods:** Approximately 50-75 adults 50 years and older will be recruited upon visiting the community pharmacy, picking up their prescriptions, and through informational signs. If recruitment is low at the primary site, then a secondary community pharmacy site nearby will be selected. This study will follow the Centers for Disease Control and Prevention and Advisory Committee on Immunization Practices guidelines. Patients who meet the study age requirement, with no exclusion criteria, will be asked to sign an informed consent form and participate in a pre-educational session survey assessing demographics, baseline knowledge, and willingness to receive vaccines. The educational session, lasting 15-30 minutes, involves a laptop-based, Jeopardy-style learning game. The session will cover Tdap, Prevnar 13, Pneumovax 23, and Zostavax. During the educational session, patients will be taught about these vaccine-preventable disease states, importance of adult vaccines, and herd immunity. After the educational session, patients will be given a post-education survey and administered any vaccines if interested. Participants with unknown vaccine history will be asked for permission to contact their physician and thus, may need to return at a later date to receive
vaccines. The study will last for a four-month period, with loyalty rewards points offered. The data will be analyzed with descriptive and quantitative statistics. The study will be submitted to the Institutional Review Board for approval.

Poster Title: Implementation of strategies to reduce alert fatigue associated with electronic order entry in a children’s hospital

Primary Author: Christine Hughes, The Children’s Hospital at Saint Francis, OK; Email: cchughes@saintfrancis.com

Additional Author(s):
David Donald
Marlene Hall
Bob John

Purpose: Electronic Health Record (EHR) systems have become a ubiquitous part of virtually all hospital operations and processes. The primary goal of this study is to reduce the number of medication alerts that could lead to alert fatigue by improving alert quality without negatively impacting patient health and safety. Evaluation and analysis of alerts will drive system and/or education changes to ensure that the most frequent alerts are more meaningful to the end user. The secondary aims are to gauge perception of medication alert quality and quantity by ordering providers; and describe successful methods for implementation of changes to the alerts.

Methods: This study will be submitted to the Institutional Review Board for evaluation. The study will identify the most frequent medication alerts and associated overrides drawn from data extracted from medication alert system reports from the institution’s EHR. Alerts and associated override rates within the medication warning types of dose, duplication medication order, and duplicate therapy alerts will be evaluated. Alerts that exceed 5% of the total within each warning class will be targeted for intervention assessment. If no category within a type meets the 5% threshold, medications will be aggregated and analyzed; any aggregate that exceeds a count of 50 will be included in the assessment. The most frequent triggered alerts with high corresponding override rates will be reviewed in more detail to better understand the processes involved with the alert triggers. A small clinical group will discuss these identified alerts and make recommendations regarding which alerts can be safely modified or removed to decrease alert fatigue. Recommendations for changes to the EHR alert settings and overrides in a way that is impactful and clinically significant will be
implemented. Medication alert system data will be then be compared for the same month of two consecutive years before and after implementation. A provider survey will also be conducted before and after implementation to evaluate differences in perceptions of the quality and quantity of the alerts.

**Poster Title:** Daptomycin dosing in obese patients: Analysis of adjusted body weight versus actual body weight

**Primary Author:** Ashley Fox, The University of Oklahoma College of Pharmacy, OK; **Email:** ashley-fox@ouhsc.edu

**Additional Author (s):**
Winter Smith
Ryan Owens
Brian White
Stephen Neely

**Purpose:** FDA-approved daptomycin dosing is based on actual body weight (ABW) for all patients, despite limited information regarding appropriate dosing in the obese population. Pharmacokinetic studies suggest daptomycin area under the curve (AUC) is increased in obesity, while clearance and volume of distribution are reduced. Additionally, daptomycin use in obesity is associated with safety concerns, as elevations in creatinine phosphokinase (CPK) levels are associated with increasing doses which may lead to cessation of daptomycin therapy. The purpose of this study is to compare clinical and safety outcomes in obese patients receiving daptomycin dosed by adjusted body weight (AdjBW) and ABW.

**Methods:** This retrospective study will evaluate daptomycin use in obese patients dosed with AdjBW (January 2014 – December 2015) versus a historical control (January 2012- December 2013) dosed using ABW. Inclusion criteria are: adult patients with a body mass index (BMI) greater than or equal to 30 kg/m2 who received daptomycin for at least 72 hours. Exclusion criteria are: daptomycin started prior to admission, infections with retained hardware, renal dysfunction, isolates not susceptible to daptomycin, or patients presenting with rhabdomyolysis. Demographics, concurrent medications, culture data, daptomycin indication, and daptomycin dose in mg/kg will be collected using a standard form. Safety data including baseline and serial CPK, patient-reported myopathy, and discontinuation of daptomycin secondary to adverse events will be collected. The primary outcome is clinical failure defined as: development of resistance or recurrent signs and symptoms of infection necessitating antibiotic modification. Secondary outcomes include microbiologic success defined as at least
one documented result of microbiologic eradication and no evidence of subsequent clinical failure. A combined safety endpoint including elevation in CPK, patient-reported myalgia, and rhabdomyolysis requiring discontinuation of daptomycin will also be evaluated. Baseline characteristics will be evaluated using descriptive statistics. Multivariate logistic regression will be used to determine differences among case and historical controls after adjusting for covariates in outcomes. Survival curves will be used to determine time to clinical success or failure.

Poster Title: Determination of medication possession ratio for viral suppression in HIV-infected antiretroviral-naïve patients

Primary Author: Marcus Autry, The University of Oklahoma College of Pharmacy/OU Medical Center, OK; Email: marcus-autry@ouhsc.edu

Additional Author(s):
Chris Rathbun
Michelle Liedtke
Jamie Miller
Grant Skrepnek

Purpose: Medication possession ratio (MPR) is an objective method to monitor adherence to antiretroviral therapy in HIV-infected patients. MPR thresholds associated with viral suppression have been identified in a mixed population of treatment-naïve and treatment-experienced patients at our institution. The purpose of this study is to refine MPR threshold estimates in an antiretroviral-naïve population.

Methods: A retrospective observational cohort study will be conducted of HIV-infected patients greater than 18 years of age at a university affiliated outpatient infectious diseases clinic. Treatment-naïve individuals who have received antiretroviral therapy at the OU Health Sciences Center Infectious Diseases Institute for at least one year between January 2011 and December 2016 will be identified. Antiretroviral claims data for MPR determination will be obtained from the designated drug assistance program pharmacy. Real-time PCR HIV-1 RNA, CD4, and demographic data will be collected from electronic medical records. Composite MPR will be calculated for the full antiretroviral regimen. Viral load area-under-the curve (vAUC) will be quantified using WinNonLin pharmacokinetic software to assess continuous viral suppression over the study period. Linear regression will be used to examine existing relationships between refill adherence rates and different levels of HIV viremia and will be offset for the overall duration of patient follow-up and controlled for age, sex, race/ethnicity, antiretroviral regimen type, and MPR. A marginal effects analysis will be used to determine the predicted probability of viral suppression (defined as HIV-1 RNA < 50 copies/mL) and MPR. Analysis will be stratified
by antiretroviral regimen class to determine whether differences in specific thresholds exist. Institutional Review Board approval will be obtained prior to study initiation.

**Poster Title:** Cystic fibrosis patient education – Is the CF center meeting patient and family needs?  

**Primary Author:** Kevin Lonabaugh, University of Oklahoma College of Pharmacy, OK; **Email:** kevin-lonabaugh@ouhsc.edu  

**Additional Author(s):**  
Michelle Condren  
Katherine O'Neal  
Heather McIntosh  

**Purpose:** Cystic fibrosis (CF) is a complex disease state affecting many organ systems throughout the body. Treatment of the disease requires complex medication regimens. The purpose of this quality improvement project is to assess the current provision of patient education to patients and families in a CF clinic as well as to identify patient attitudes related to provision of that information and when it should occur. In establishing our baseline provision of education as well as identifying topics important to patients and their families, a more streamlined system for providing that education can be created.  

**Methods:** The current quality improvement project will incorporate a survey-based design. The questionnaire will include demographic items, knowledge-based questions, questions related to patient opinions regarding clinic provision of education and confidence regarding their knowledge, questions related to educational goals, and questions related to sources of information. The knowledge questions have been taken from a prior validated scale. After a short pilot period, self-administered questionnaires will be given to patients and parents/caregivers at a normal office visit. Patients above the age of 10 will be given the questionnaire in addition to their parents. For patients 10 years old or younger, only the parents will be given a questionnaire. The project will target patients at the Cystic Fibrosis Center in Tulsa, Oklahoma, where a team of multidisciplinary practitioners provide care for approximately 145 patients. It is anticipated that up to 120 patients and 140 parents may participate in the study. Patients will be excluded if their primary language is a language other than English, if they have a history of lung transplantation, or if they have a diagnosis of CF-
related metabolic syndrome (CFMS). Patients will also be excluded if they are acutely ill at the time of their clinic visit, such that they are not seeing all members of the clinic team and are likely to be admitted to the hospital.

Poster Title: Clinical implications and prescriber attitudes regarding new FDA recommendations with metformin prescribing

Primary Author: Elizabeth Cook, University of Oklahoma College of Pharmacy - Tulsa Campus, OK; Email: elizabeth-cook@ouhsc.edu

Additional Author(s):
Katherine O’Neal
Michael Miller
Laura Chalmers
Ann Lloyd

Purpose: Metformin is endorsed by the American Diabetes Association as first-line therapy for type 2 diabetes (T2DM) because of its preferred safety and effectiveness profile in patients with adequate renal function. The U.S. Food and Drug Administration (FDA) recently revised prescribing recommendations to reflect dosing according to estimated glomerular filtration rate (eGFR) rather than serum creatinine. This expanded first-line treatment eligibility to those with mild to moderate renal impairment. Therefore, this study proposes to: (1) identify patients eligible for metformin treatment who are not currently treated; and (2) assess provider knowledge, attitudes, and willingness to adopt the new guideline revision.

Methods: This is a historical chart review. An electronic medical record system will be used to identify diabetic patients, seen by providers at an academic outpatient clinic in Tulsa, Oklahoma, from January 1, 2014 to December 31, 2015. Patients eligible for review must have a diagnosis of T2DM and not currently taking metformin and have at least one measurement of serum creatinine during the observation period. The following additional measurements will be collected: date of birth, sex, ethnicity, serum creatinine, eGFR,and corresponding date that these laboratory values were measured. The dates of outpatient appointments, prior to and following receipt of laboratory results, as well as the total daily dose of metformin, prior to and following lab results, will also be collected. These measurements will be used to calculate the proportion of patients eligible for metformin treatment who are not currently treated within the provider network based on the new ADA guidelines concerning dose adjustment based on eGFR. To accomplish the second objective, a non-identifiable survey will be developed and
distributed to physicians and advanced practice providers within the provider network. Providers will be asked a series of questions regarding their knowledge of, attitudes toward, and willingness to adopt the new prescribing information for metformin issued by the FDA. This study is pending IRB approval.

**Results:** N/A

**Conclusion:** Results of this project will identify opportunities to optimize treatment for diabetes treatment by identifying care gaps and potential strategies for intervention that will be readily adopted by providers.

**Poster Title:** Dose optimization of amikacin in pre-term and term neonates through physiologically-based pharmacokinetic simulation

**Primary Author:** Sin Yin Lim, University of Oklahoma College of Pharmacy/OU Medical Center, OK; **Email:** sinyin-lim@ouhsc.edu

**Additional Author(s):**

Peter Johnson
Sukyung Woo
Grant Skrepnek
Jamie Miller

**Purpose:** Dosing of amikacin in neonates remains a challenge due to the wide inter-individual variability of pharmacokinetics. Historically, providers from our institution utilized amikacin dosing recommended in NeoFax®; however, due to concerns for supratherapeutic peak concentrations our institution implemented a modified dosing regimen in 2014. The purpose of this study is to evaluate the modified-protocol dosing of amikacin utilizing a physiologically-based pharmacokinetic (PBPK) simulation, and to propose a revised dosing regimen for amikacin, if needed.

**Methods:** This pharmacokinetic (PK) simulation study will utilize the simulation software, Simcyp Pediatrics, to simulate a pre-term and term neonatal population. We will simulate 50 male and 50 female subjects per one week of post-natal age (PNA) starting at the gestational age (GA) of 23 weeks. The GA will range from 23 to 42 weeks with PNA up to 17 weeks (N equals 15,400). Population simulation will cease when both post-menstrual age (PMA) and PNA are greater than or equal to 40 weeks and 4 weeks, respectively. Previously published amikacin PK model and molecular characteristics, such as molecular weight, lipophilicity, and plasma fraction unbound, will be incorporated to the software. Then, we will simulate the PK profiles based on NeoFax and modified-protocol regimens. All subjects will subsequently be categorized into six subgroups (PMA less than or equal to 29 weeks with either PNA 0-7 days, 8-28 days, or greater than or equal to 29 days, PMA 30-34 weeks with either PNA 0-7 days or greater than or equal to 8 days, and PMA greater than or equal to 35 with any PNA). The primary objective of this study is to compare the goal peak concentration attainment rates between the NeoFax
dosing and the modified-dosing protocol. The secondary objective is to propose an optimized dosing regimen of amikacin for our institution.

Poster Title: Use and level of satisfaction among Puerto Rican women with pharmacy compounded bioidentical hormone therapy: a cross-sectional study

Primary Author: Joanel Cruet Torres, Nova Southeastern University, PR; Email: jc2727@nova.edu

Additional Author(s):
Blanca Ortiz
Jorge Reyes

Purpose: Menopause symptoms have a negative impact in women’s health affecting significantly their quality of life. Hormone therapy (HT) has been traditionally used to treat hormonal deficit and alleviate menopause symptoms, however, concerns with their safety profile have limited its use. Bioidentical Hormone Replacement Therapy (BHRT) has emerged as an innovative approach to manage menopause related symptoms in lieu of HT. The purpose of this study is to assess the use, improvement of menopause related symptoms, and self-perceived level of satisfaction with pharmacist compounded BHRT among Puerto Rican women.

Methods: Study participants will be conveniently recruited at Santa Cruz Pharma Care, which is a community pharmacy in Puerto Rico that specializes in compounding services including BHRT. Inclusion criteria consist on menopausal women > 21 years old who are able to read, understand, and write Spanish. Men and menopausal women with cancer or immunosuppression will not be eligible to participate. Eligible patients will be oriented about the purpose of the study and the requisites for participating by the primary investigator while collecting their prescribed BHRT at the pharmacy. A 26-item questionnaire will serve as the data collection tool. Voluntary completion of the study questionnaire will account as the patient’s consent to participate in the study. Once the survey is completed, the participant will deposit it in a sealed box available for this purpose. The final response rate will be calculated based on the number of questionnaires returned to the sealed box. Data analysis will include descriptive statistics and frequency distributions and will be analyzed using SPSS V.24. The study protocol and data collection tool is currently under review by the Institutional Review Board of Nova Southeastern University.

Poster Title: Impact of pharmacist intervention on physician prescribing pattern of proton pump inhibitors in a community pharmacy in Puerto Rico

Primary Author: Jose Garcia-Toledo, University of Puerto Rico School of Pharmacy, PR; Email: jose.garcia9@upr.edu

Additional Author(s):
Amilcar Rodriguez
Jose Rodriguez
Zaritza Cajigas
Kyle Melin

Purpose: Proton pump inhibitors (PPIs) are one of the most prescribed medications in the US. Growing data suggest an inappropriate use of PPIs related to incorrect indication, frequency, drug interactions, and duration of treatment. Furthermore, long-term inappropriate use may lead to drug related problems such as osteoporosis and kidney disease. The purpose of this study is to describe PPI utilization at a community primary care clinic and the measure the impact of pharmacist intervention on physician PPIs prescribing patterns.

Methods: This is a prospective study designed to assess PPI utilization in two outpatient clinics, Policlínica Castañer in Adjuntas, P.R and Hospital General Castañer in Lares, Puerto Rico. The clinic pharmacy system will be used to retrospectively identify the number of patients using PPIs and the number of prescriptions for the past 6 months. Patients who received a prescription for a PPI between February 2016 and July 2016 will be included. A sample of 120 patients (20 from each month) will be randomly selected for review of the electronic health record to identify indication, drug interactions, and duration of therapy. Patients without a chart in the electronic health record will be excluded. After identifying PPI prescribing patterns in both clinics, a pharmacist intervention will be implemented to educate physicians of the clinics on current PPI utilization and opportunities for improvement. The intervention will consist of pharmacist presentations to physicians, as well as follow-up email communications. Six months after the interventions are completed, PPI prescribing patterns will be re-assessed. The primary outcome of this study will be the difference in frequency of PPI prescriptions. The secondary outcomes will be the differences of quantity of drug interactions,
indications, and duration of therapy. Differences between the data will be analyzed using descriptive statistics. This study will be submitted to Institutional Review Board for approval.

Francisco Jimenez Ramirez  
Kyle Melin  
Lourdes Ramirez Acevedo  
Rosa Ramirez Acevedo  

**Purpose:** Pharmacists in Puerto Rico (PR) were given the authority to administer vaccines in 2010 and since that time, some community pharmacies in PR have integrated immunizations as part of their services. Satisfaction with pharmacist-provided immunization services has yet to be researched in PR. The assessment of satisfaction with immunization services may provide useful data for those currently providing these services, interested in providing them, or undecided of implementing them. The purpose of this study is to assess patient, physician, and pharmacy personnel satisfaction with immunization services offered at independent community pharmacies in PR.  

**Methods:** A cross-sectional, questionnaire based study describing the satisfaction of patients, physicians, and pharmacy personnel with pharmacist-provided immunization services will be conducted in 5 community pharmacies. All participants must be at least 21 years of age to be considered for participation and will be enrolled based on convenience sampling. An information sheet will be provided to each participant prior to participation. For patients, a paper-based survey will be distributed following the administration of at least one immunization at an independent community pharmacy. Physicians, pharmacy technicians, pharmacists, pharmacy administrators and pharmacy clerks will be provided the questionnaire electronically or on paper. The survey will contain a four point Likert-type scale (strongly agree, agree, disagree and strongly disagree). Baseline characteristics of age, gender, city of residence, and type of health insurance (for patients only), will also be collected by the survey. All data will be collected without identifiers and maintained confidentially. Results will be analyzed through

Poster Title: Development and implementation of a comprehensive heparin-induced thrombocytopenia protocol based on an evaluation of current management practices

Primary Author: Kristen Butler, Kent County Memorial Hospital, RI; Email: kabutler@kentri.org

Additional Author(s):
Michelle Kelley
Melinda Martland

Purpose: The 2016 Joint Commission National Patient Safety Goals (NPSG) include reduction of the likelihood of patient harm associated with the use of anticoagulants. In accordance with this goal, the objective of this study is to evaluate the current management of heparin-induced thrombocytopenia (HIT) at a medium-sized community hospital and determine discrepancies between current and optimal management. Based on this analysis, areas for improvement in patient care and cost-savings will be identified, and a comprehensive HIT management protocol will be developed and implemented.

Methods: This study will be submitted to the Institutional Review Board (IRB) for approval. The electronic medical record (EMR) system will identify patients with a diagnosis code for HIT, a HIT screening test ordered, or a medication order for argatroban or fondaparinux. The following variables will be evaluated: calculation and documentation of 4Ts score, appropriate screening test(s) ordered with appropriate timing, discontinuation of heparin, discontinuation of oral anticoagulant (if applicable), initiation of appropriate alternative parenteral anticoagulant at appropriate dose, continuation or discontinuation of alternative parenteral anticoagulant based on screening test results, oral anticoagulant re-initiated appropriately (timing, duration, and overlap with parenteral anticoagulant), decision to re-challenge in patients with a history of HIT, incidence of thrombotic events, and incidence of major bleeding. Percentage of patients managed appropriately will be determined for measured variables, and potential cost-savings will be calculated based on discrepancies between current and appropriate management for relevant variables. Information will also be collected on the types of testing utilized hospital-wide for HIT screening, and feasibility and potential benefits of updates to testing methods will be assessed. HIT protocol development will be based on best practices identified in guidelines, previous studies, expert consensus documents, and input from a multidisciplinary committee at
the institution. The final protocol will undergo review by the pharmacy and therapeutics committee prior to implementation.

Submission Category: Emergency Medicine/ Emergency Department/ Emergency Preparedness

Submission Type: Research-in-Progress

Session-Board Number: 11-378

Poster Title: Emergency department urinalysis orders resulting in antibiotic therapy for long term care facility patients with asymptomatic bacteriuria

Primary Author: Sarah Hendrick, Kent County Memorial Hospital, RI; Email: shendrick@kentri.org

Additional Author (s):
Monica Dorobisz
Alicia ZuWallack

Purpose: Asymptomatic bacteriuria (ASB) is an immense source of unnecessary antibiotic prescribing. ASB accounts for approximately 70% of presumed urinary tract infections (UTIs) in long-term care facilities (LTCFs). The Rhode Island Department of Health and LTCF stewardship programs are prioritizing the reduction of urinalyses across continuaums of care to help decrease inappropriate treatment of ASB; however, many LTCF patients sent to emergency departments (EDs) are sent back with antibiotics for ASB. The purpose of this study is to identify the number of urinalyses ordered in the ED resulting in antibiotic prescriptions for LTCF patients, before and after an educational intervention.

Methods: This retrospective chart review will be submitted to the Institutional Review Board for approval at a 359 bed community teaching hospital serving a large LTCF population and averaging approximately 200 ED visits per day. All patients discharged directly from the ED to a LTCF will be included for a 60 day period prior to an educational intervention and a 60 day period after the intervention (pre- and post-education groups). The educational intervention will include a panelist lecture with providers from the ED, inpatient and pharmacy departments, posters, and smaller peer-to-peer prescriber discussions. Data collection will include pertinent baseline characteristics, labs, vital signs, chief complaint, presence of an indwelling urinary catheter, presence of symptoms related to a possible urinary tract infection (symptoms will be classified as definite, vague or none), and whether or not a urinalysis was performed. Results of urinalyses, urine cultures and susceptibilities, and antibiotic treatment during the ED visit and/or prescribed at discharge will be collected if applicable. Provider documentation will be further reviewed for patients who had a urinalysis performed to determine appropriateness of testing and/or subsequent antibiotics. The primary outcome of this study is the percent of LTCF...
patients with urinalyses performed in the ED in the pre- versus post-education groups. A secondary outcome will include the percent of LTCF patients receiving antibiotics for ASB in the pre- versus post-education groups.

Poster Title: Evaluating inappropriate prescribing of proton pump inhibitors in a community hospital

Primary Author: Michelle Fishburn, South County Health, RI; Email: mfishburn10@my.uri.edu

Additional Author(s):

Purpose: Proton-pump inhibitors (PPI) are commonly prescribed in hospitalized patients for gastrointestinal ulcer prophylaxis. An association between inpatients prescribed PPIs and increased rates of Clostridium difficile infections (CDI) and hospital-acquired pneumonia (HAP) has been established. Inpatient prescribing of PPIs often lacks an indication and puts patients at an unnecessary risk for hospital-acquired infections (HAI), which prolong hospital stay, increase cost, and increase morbidity and mortality. The purpose of this study is to evaluate the appropriateness of PPIs prescribed inpatient, based on established clinical criteria, in order to highlight and direct more appropriate prescribing practices in the future at South County Hospital.

Methods: A retrospective chart review of all inpatients prescribed a PPI was completed over a 20-day period. Patient location (intensive care unit or medical/surgical floors), admitting diagnosis, and concurrent antibiotic administration were recorded. Medication reconciliation was completed on all patients to determine if the patient was prescribed the PPI as an outpatient. If the PPI was initiated inpatient, an extensive chart review was completed for each patient to determine if there was an acceptable indication. Acceptable indications, based on clinical studies and guidelines, included the following: gastroesophageal reflux disease, gastric and duodenal ulcers, Helicobacter pylori infection, long-term use of non-steroidal anti-inflammatory drugs, and stress ulcer prophylaxis for intensive care patients with at least one of the following: platelet count < 50,000 mm3, INR > 1.5 (not on warfarin therapy), aPTT greater than 2 times the control, mechanical ventilation greater than 48 hours, history of gastrointestinal ulceration or bleeding within one year of admission, Glasgow Coma score less than or equal to 10, major burn to greater than 35% of body surface area, multiple traumas, transplantation, spinal cord failure, or two or more risk factors (sepsis, stay greater than one week, occult bleeding lasting at least six days, high-dose corticosteroids (250 mg/day of
hydrocortisone equivalents). Of those PPI prescriptions initiated inpatient, an evaluation of all discharge medications was completed to determine if the PPI was continued outpatient.

**Results:** A total of 155 patients admitted to the hospital within a 20-day period received a PPI during their admission. All units of the hospital were included. Of those 155 patients, 88 of them were taking a PPI at home prior to admission (56.77%). A total of 67 of 155 patients were initiated on a PPI while admitted (42.23%). Out of these 67 patients, 45 of them were also receiving antibiotics (67.16%). Out of the 67 patients that were started on a PPI while inpatient, only 9 of them (13.43%) had an appropriate indication for initiation, based on acceptable criteria determined prior to data collection. A total of 58 out of 67 patients did not have an appropriate indication for use (86.57%). Only 6 out of 67 patients continued the PPI after discharge.

**Conclusion:** For admitted patients, an overwhelming amount of PPI prescribing lacks an appropriate indication and puts the patient at unnecessary risk of hospital-acquired infections. Co-administration of PPIs with antibiotics is known to increase the risk of developing a hospital-acquired infection and poses a serious threat of complicating an admission. Proton-pump inhibitors must only be prescribed if the patient has a clinical presentation that meets an indication for acceptable use.

Poster Title: Implementation of a pharmacist managed vancomycin dosing and monitoring service in a small community hospital

Primary Author: Stephanie Tang, South County Health, RI; Email: stang@southcountyhealth.org

Additional Author(s):

Purpose: Current vancomycin dosing guidelines recommend dosing to trough serum concentrations to achieve therapeutic doses and monitor toxicity. In several recent studies, pharmacy-managed vancomycin dosing and monitoring services increased the percentage of patients who were dosed at a therapeutic range while decreasing nephrotoxic events and duration of therapy. A pharmacist managed vancomycin dosing and monitoring program was implemented to ensure appropriate antimicrobial use in a small community hospital. The purpose of this study is to compare appropriate dosing of vancomycin prior to and after initiation of a pharmacist managed vancomycin dosing and monitoring service.

Methods: This study will be submitted to the Institutional Review Board for approval. There will be two comparative groups, with a retrospective analysis performed by patient group prior to initiation of the pharmacist managed vancomycin service. This will consist of a random selection of patients between January 1, 2014 and March 31, 2014. A prospective analysis will be done on patients who have their vancomycin managed by pharmacy after implementation of the protocol that was initiated in September 2016. Data collected to assess appropriateness of prescriber and pharmacy dosing, will include age, BMI, weight, ideal body weight, serum creatinine, creatinine clearance, vancomycin indication, vancomycin dosing regimen, initial vancomycin trough concentrations, and time to achieve trough concentrations of 15-20 mcg/mL were collected. Orders sent with an additional “Pharmacy to manage vancomycin” order will be compared to those dosed by prescriber prior to implementation of the intervention for optimal dosing. Additionally, there will be continual analysis to assess prescriber usage of the service and the impact of a vancomycin dosing calculator that was embedded into the electronic medical record to assist in accurately calculating the loading dose if a pharmacist was not requested to provide management services.

Poster Title: Pharmacist Driven Medication Evaluation Pilot in Geriatric Patients on a General Medicine Unit

Primary Author: Sara Alosaimy, Brigham and Women’s Hospital, MA; Email: SALOSAIMY@PARTNERS.ORG

Additional Author(s):
Alka Vaidya
Gretchen Stern
Kevin Day
Stephanie Sibicky

Purpose: Geriatric patients have a seven times higher risk than younger adults to be hospitalized due to an adverse drug event. This is often due to a combination of more complex medication regimens, and age-related changes in pharmacokinetics and pharmacodynamics. Approximately 40-60% of our general medicine patient population is over the age of 65. The Screening Tool of Older Persons’ potentially inappropriate Prescriptions (STOPP) and Screening Tool to Alert doctors to Right Treatment (START) criteria categorizes medications by disease state, recommends medications that should be stopped/avoided, and suggests alternative safer medication options if available. By using these tools, pharmacists can identify potentially inappropriate medications (PIMs) and recommend alternative options to the primary provider. It is likely that 12.5% of medications on admission are PIMs. The primary objective is to assess whether pharmacist’s review of medications especially in geriatric patients influences appropriate use of medication upon discharge from general medicine unit.

Methods: This is a prospective, single-center, interventional, before and after study at a tertiary medical center. The study was exempt from the Brigham and Women’s Institutional Review Board. Our inclusion criteria are all patients who are 65 years and older admitted to our general medicine floor with at least five or more medications. We will exclude patients who underwent medication reconciliation by a pharmacist in the emergency department or patients whose medication history cannot be obtained. Pharmacists will perform medication reconciliation, evaluate the appropriateness of therapy and communicate their recommendations to the medical team. The major outcome is the number of PIMs on admission compared to discharge.
This will be assessed using a 2-sample t-test calculator (alpha = 0.05 and 80% power). In order to detect a 50% decrease in PIM after pharmacist's intervention, we estimate that 120 patients will be needed. Minor outcomes include the percentage of accepted pharmacy interventions, most common PIM class identified and the type of pharmacy intervention taken by medical team. We expect that the results of this study will validate the creation of a geriatric pharmacy consult group in our general medicine units.

**Poster Title:** Reduced dosing strategy of four-factor prothrombin complex concentrate for the reversal of warfarin: An evaluation of efficacy

**Primary Author:** Jennifer Allen, Eastern Maine Medical Center, ME; **Email:** jjallen@emhs.org

**Additional Author (s):**
Marybeth Boudreau
Kael Mikesell
Vikram Kumar
Renee Ford

**Purpose:** The package insert for four-factor prothrombin complex concentrate (4F-PCC) recommends a dosing algorithm based on International Normalized Ratio (INR) and weight for the reversal of warfarin. Previously published studies have demonstrated that a lower fixed dose of 4F-PCC is effective; however, the ideal dose of 4F-PCC has yet to be determined. Our institution implemented a lower dosing strategy, based upon a stratified pre-administration INR level and body weight. The purpose of this study is to evaluate the efficacy of our dosing strategy.

**Methods:** This retrospective chart review will include patients who were administered 4F-PCC between September 2014 and September 2016 for the reversal of warfarin anticoagulation. One hundred thirty seven patients have been identified from billing records. This study will have Institutional Review Board approval. Data collection will include: patient demographics, dose of 4F-PCC administered, indication for warfarin anticoagulation and reversal, administration of phytonadione with or without other blood products, as well as, baseline and resulting INR. The primary outcome is efficacy defined as a reduction in INR to a target of less than 1.5 for intracranial hemorrhage or neuraxial intervention, and less than 2 for all others. Subgroup analysis will be stratified by dose, INR and weight. Secondary outcomes include: death and adverse events (bleeding and thrombotic events) within thirty days of 4F-PCC administration.

**Poster Title:** Time to antibiotics for pediatric patients presenting with febrile neutropenia  

**Primary Author:** Erin Tibbetts, Eastern Maine Medical Center, ME; **Email:** etibbetts@emhs.org  

**Additional Author (s):**  
Lynn Thornton  
Emily Tilton  

**Purpose:** Research has demonstrated the importance of prompt antibiotic administration in adult patients with sepsis and febrile neutropenia (FN). Current recommendations advocate for initiation of broad spectrum antibiotics with a goal of administration in less than 60 minutes from time of presentation. Recent research studying time to antibiotics in the pediatric population with FN have reached similar conclusions but also identified several barriers to achieving this goal. The purpose of this study is to evaluate time to antibiotics and outcomes in pediatric patients presenting with FN while also identifying the barriers to prompt administration.  

**Methods:** This study will be submitted to the Institutional Review Board for approval and will be a retrospective chart review identifying patients admitted through the pediatric oncology clinic or direct from home with a diagnosis of febrile neutropenia. Fever will be defined as temperature greater than or equal to 38.3 degrees Celsius or greater than 38 degrees Celsius on two occasions at least 1 hour apart. Neutropenia will be defined as absolute neutrophil count (ANC) less than 500 cells/mm3 or expected to decrease to less than 500 cells/mm3 in the next 48 hours. The study will include patients less than or equal to 18 years of age presenting with fever and neutropenia. Patients will be excluded if the cause of FN was not related to an oncologic diagnosis. De-identified data will be collected including basic demographic data, ANC, qualifying temperature, diagnosis, time to bed assignment, level of care, selected antibiotics and source of infection. Potential barriers will be collected including day of week, time of day, time and priority of order, time to culture collection, time of antibiotic order placement, verification and administration, lidocaine/prilocaine cream (EMLA) use and availability of premade antibiotic. The primary outcome is time to antibiotic administration. Secondary outcomes are time to antibiotic discontinuation, time to discharge and percent of patients requiring intensive care.

Poster Title: Cost-Effectiveness of Early Palliative Care Referral in Stage IV Lung Cancer Patients

Primary Author: Benjamin Landry, Eastern Maine Medical Center, ME; Email: brlandry@emhs.org

Additional Author(s):
Matthew Marston
Alexandra Lavoie
Riley Lizotte

Purpose: Palliative care consultation has been shown to improve quality of life, distress from symptoms, and mood in patients with advanced cancers. Outpatient consultations initiated earlier in disease progression have been associated with decreased utilization of acute healthcare services and improved end of life outcomes including lower chance of hospital death. While earlier consults have been shown to decrease healthcare utilization, a significant decrease in cost has not been demonstrated consistently. The purpose of this retrospective study is to determine whether earlier palliative care consultations in stage IV lung cancer patients are associated with a reduction in healthcare associated costs.

Methods: This single center retrospective cohort analysis will be submitted to the institutional review board and will be conducted using data from the electronic health record. The study will include 200 adult, stage IV lung cancer patients who were deceased prior to 2016. Patients will be stratified by whether they received a palliative care consult greater than 6 months from death, between 6 months and 1 month from death, 30 days or less from the date of death, or never received a consult. Demographic data points to be collected include gender, age, palliative care referral date, location of palliative care referral, code status at time of death, and date of stage IV lung cancer diagnosis. Quality associated data points include location of death, code status at time of death, and date from last chemotherapy administration. Cost associated data points include the number of palliative care visits, emergency room visits, inpatient days, intensive care unit days, and chemotherapy doses received. Average patient cost per visit and chemotherapy costs were compiled from the hospital accounting system and applied as standardized values to all patients. The primary outcome is the healthcare associated costs accrued from the time of initial stage IV cancer diagnosis to death.

Poster Title: Gentamicin for neonatal sepsis: Is our empiric dosing protocol producing target gentamicin concentrations?

Primary Author: Monica Litsas, Maine Medical Center, ME; Email: mlitsas@mmc.org

Additional Author(s):
Jonathan Bourque
Jessica Miller

Purpose: Guidelines from the American Academy of Pediatrics recommend ampicillin and an aminoglycoside to cover the most commonly isolated pathogens seen in early-onset neonatal sepsis; however, there is currently no dosing protocol supported by the American Academy of Pediatrics. The Neonatal Intensive Care Unit at Maine Medical Center adopted a standardized dosing protocol based on post-menstrual age (PMA). The objective of this study is to assess the Maine Medical Center neonatal sepsis gentamicin dosing protocol with regards to achieving goal peak and trough concentrations, and safety.

Methods: This study will be submitted to the Institutional Review Board for approval. EPIC reports will be utilized to identify all neonates who received gentamicin and had at least one trough and one peak concentration drawn between June 2015 and June 2016. Patients will be stratified into three groups based on the defined age groups in the current dosing protocol. The following data will be collected: medical record number, height, dosing weight, date of birth, gestational age, post-menstrual age, reason for being started on gentamicin, blood cultures and results, dose of gentamicin received, trough levels and timing of level, peak levels and timing of level, random levels and timing of level, if patient was on the hypothermia protocol, and patient’s outcome. If available, measurements of renal function will be evaluated, as well as risk factors for the development of nephrotoxicity. Risk factors for all outcomes will be evaluated with chi square. We will be conducting two subgroup analyses; in one analysis we will assess the outcomes for the dosing regimen for neonates on the hypothermia protocol, while for the other analysis we will identify neonates who had a positive blood culture and describe their outcomes. Study data will be collected and de-identified using REDCap electronic data capture tools hosted at Tufts University School of Medicine.

Poster Title: Pharmacist-managed inpatient dofetilide program: description and adherence rate post-root cause analysis

Primary Author: You Jung (Elena) Ko, Maine Medical Center, ME; Email: yko@mmc.org

Additional Author (s):
Anne Andrle

Purpose: The purpose of this quality initiative is to describe the pharmacist-managed dofetilide protocol at Maine Medical Center and assess the institution’s adherence rate before and after a sentinel event. Team members (nurses, providers and pharmacists) will benefit from analysis of our institutional experience, in order to identify areas of improvement in our care of these patients.

Methods: This quality project will be a retrospective chart review of dofetilide patients at Maine Medical Center from November 1, 2013 to October 31, 2015 before the sentinel event (Group A), and from January 1, 2016 to present after the sentinel event (Group B). Power analysis suggests that a sample size of 50 patients in each group will be adequate to detect a statistical difference in pre- and post-protocol adherence. Fifty patients in Group A will be included consecutively in reverse chronological order, starting from October 31, 2015. Adherence rate will be assessed by reviewing the electronic medical record. This quality initiative will assess adherence in the following categories:
1. Pharmacist note prior to each dose
2. Dose and interval chosen correctly per renal function
3. Presence or absence of conduction abnormality assessed, with appropriate QTc value cut-off chosen
4. Dofetilide drug-drug interactions assessed by pharmacists
5. Potassium and magnesium level assessed and if necessary, corrected before and/or during initiation
6. QTc measurement obtained and reviewed 2 hours after each dose
7. Appropriate dose adjustment per the most recent QTc result and presence of conduction abnormality
8. Documentation of patient education
Gender, length of stay, documentation of intentional non-adherence and all recorded adverse events will also be collected.

**Poster Title:** Concordance of antibiotic prescribing with treatment guidelines for acute uncomplicated cystitis in southern Maine

**Primary Author:** LaTasha Riddick, Maine Medical Center, ME; **Email:** lriddick@mmc.org

**Additional Author (s):**
Minkey Wungwattana
Corinn Martineau

**Purpose:** The updated 2010 Infectious Diseases Society of America (IDSA) guidelines for acute uncomplicated cystitis recommend nitrofurantoin, sulfamethoxazole-trimethoprim, and fosfomycin as first-line agents, with fluoroquinolones as alternative options. However, inconsistencies in prescribing practices remain a challenge. The purpose of this project is to evaluate prescriber concordance with guideline-recommended antibiotics and duration of therapy. Additionally, this study will assess explanations for prescriber non-concordance, including consideration of allergy and medication intolerance history. Results from this study will help guide possible interventions to assist prescribers in selecting optimal antibiotic therapy and treatment duration for acute uncomplicated cystitis in the primary care setting.

**Methods:** This retrospective observational study defined prescriber concordance as selection of IDSA-recommended antibiotics and duration of therapy, including selection of alternative antibiotics due to contraindications (including allergies) to one or more first-line agents. Patients screened for eligibility include: female gender, age 18 years or older, and with history of office visits at four affiliated family medicine practices between July 1, 2015 and June 30, 2016. International Classification of Diseases, Tenth Revision (ICD-10) diagnosis codes of N30.0 (acute cystitis), N30.9 (unspecified cystitis), and N39.0 (urinary tract infection) were used to identify office visits of interest. The following data will be collected: age, race, comorbidities (e.g. diabetes), antibiotic prescribed, treatment duration, allergies, pertinent laboratory values at time of visit (e.g. serum creatinine, white blood cell count), insurance status, and presence of follow-up encounter. A survey will be distributed to primary care providers to evaluate the approach to treatment and prescribing tendencies. Descriptive statistics will be used to examine baseline characteristics, antibiotic selection, and treatment duration. Rate of concordance and prescribing trends will be analyzed with a chi-square test. The use of
multivariate logistic regression will evaluate effects of independent variables on prescribing practices. All study data will be analyzed with Microsoft Excel and SPSS. This study has been exempt by the Maine Medical Center Institutional Review Board.

Poster Title: Incidence of heparin resistance in patients diagnosed with heparin-induced thrombocytopenia

Primary Author: Stefanie DiLoreto, Maine Medical Center, ME; Email: sdiloreto@mmc.org

Additional Author(s):
Kathryn Smith
Wesley Zemrak
Timothy Hayes
Gilles Fraser

Purpose: Heparin-induced thrombocytopenia (HIT) is a rare, but serious adverse reaction of heparin therapy that may lead to additional thromboembolic complications. Previous case studies have identified a correlation between increased heparin requirements, or heparin resistance, and the occurrence of HIT. We hope to investigate a cohort of patients with confirmed HIT (cases) in comparison with a cohort of patients with suspected HIT and negative laboratory testing (controls) to determine if heparin resistance is associated with HIT using contemporary definitions and heparin dosing strategies.

Methods: The populations include those diagnosed with HIT at MMC between January 1, 2013 and June 30, 2016. Patients with intermediate or high clinical suspicion by 4 T’s score and positive anti-heparin/PF4 antibody with optical density 0.4 or greater or positive serotonin release assay with 20 percent or greater platelet reactivity will be included in the confirmed HIT cohort. These cases will be compared to a cohort of patients with suspected HIT per 4T’s score and negative laboratory testing. Patients will be excluded if they received heparin subcutaneously for venous thromboembolism (VTE) prophylaxis, low molecular weight heparin for VTE prophylaxis or treatment, or intraoperative heparin for procedures other than cardiac surgery. The primary outcome is the incidence of heparin resistance, defined as daily heparin requirements exceeding 35,000 units or an increase in daily heparin requirements of 25% or greater, in patients diagnosed with HIT compared to those without HIT. Secondary outcomes include the timing of increasing heparin requirements to presentation with thrombocytopenia, the timing of increasing heparin requirements in relation to presentation with thrombosis, intraoperative heparin requirements of HIT positive cardiac surgery patients, incidence of
heparin requirements greater than or equal to 25 units/kilogram/hour or increase in daily heparin requirements of 50 percent or greater, and the differences in the clinical presentation of HIT in patients who developed heparin resistance versus those who did not.

**Poster Title:** Medication use evaluation of 4-Factor Prothrombin Complex Concentrate in patients on vitamin K antagonists following protocol implementation

**Primary Author:** Ashley White, MaineGeneral Medical Center, ME; **Email:** ashley.white@mainegeneral.org

**Additional Author(s):**
Rachael Elias
Ellie Provisor
Christopher Gauthier

**Purpose:** Although reported bleeding rates are low, vitamin K antagonists are associated with hemorrhagic complications. Anticoagulation reversal is often necessary in patients requiring urgent surgical intervention or those presenting with a major life-threatening bleed. The use of 4-factor prothrombin complex concentrate (PCC4, Kcentra®) for anticoagulation reversal may be beneficial in providing quicker reversal and in reducing the need for transfusions. Its use may attenuate the potential for transfusion-associated circulatory overload, acute lung injury, and anaphylactic-type reactions. In order to ensure appropriate use of Kcentra® on an institutional level, it is necessary to evaluate the effectiveness of the currently established protocol.

**Methods:** This is a single-center retrospective cohort study evaluating the appropriate use of 4-factor prothrombin complex concentrate comparing 17 patients pre-protocol to 60 patients following protocol implementation in May 2015 (n=78). The primary outcome was to evaluate the effectiveness of the current Kcentra® protocol for warfarin reversal. Secondary outcomes include evaluating the potential financial implications associated with inappropriate Kcentra® utilization at MaineGeneral Medical Center.

Poster Title: Correlation between vancomycin dosing and therapeutic trough accuracy following implementation of institutional protocol

Primary Author: Danielle Dunn, MaineGeneral Medical Center, ME; Email: danielle.dunn@mainegeneral.org

Additional Author(s):
Rachael Elias
Ellie Provisor

Purpose: New vancomycin dosing algorithms for traditional (non-obese) and obese patients were implemented at the institution. The objective of this study was to evaluate if patients were able to achieve therapeutic trough goals sooner after treatment initiation.

Methods: In a single-centered, retrospective, cohort study, data was collected and evaluated from pharmacy-maintained vancomycin dosing/monitoring sheets including: patient age, gender, weight, creatinine clearance (CrCl), trough goal based on indication, loading dose, maintenance dose/interval, trough levels, and accuracy of protocol implementation. The traditional (non-obese) and obese dosing protocols were assessed separately. Patient data was excluded in the final analysis if the new protocol was not followed in its entirety. The primary endpoint assessed if the new protocol allowed patients to reach goal quicker based on loading and maintenance phase trough levels.

Poster Title: Implementation of a pediatric antimicrobial stewardship in a primary care setting

Primary Author: Meagan Rusby, Penobscot Community Health Care, ME; Email: mrusby@pchc.com

Additional Author(s):
Anthony Casapao

Purpose: Antibiotics are the most common class of drugs to cause adverse drug events (ADEs) in children, resulting in 7 out of the top 15 drugs that often lead to pediatric ADE-related emergency department visits. Currently, there is abundant data in the literature regarding the effectiveness and importance of inpatient antimicrobial stewardship programs, but there is limited data on outpatient antimicrobial stewardship programs. Performing this study in Penobscot Community Health Care (PCHC), a federally qualified health center, allows for the assessment of efficacy and feasibility of an outpatient antimicrobial stewardship program in the primary care setting.

Methods: This is a retrospective observational descriptive study design that consisted of 2 years of data, June 2014 to June 2016, and includes patients less than 18 years of age with a diagnosis of acute sinusitis, chronic sinusitis, otitis media (suppurative or non-suppurative), pharyngitis, acute bronchitis or bronchiolitis, pneumonia (viral or non-viral), acute nasopharyngitis, influenza, or urinary tract infection identified by diagnosis using ICD-9 and ICD-10 codes. Patients were excluded if they had been previously diagnosed with an antimicrobial-associated infection (i.e. Clostridium difficile) within the year prior to visit date. Clinical decision support and education was developed and provided to the clinical providers at PCHC’s pediatrics and walk-in clinics. The primary outcome is a composite definition of inappropriate use of antimicrobials per current guidelines defined as unnecessary administration of an antibiotic, incorrect dosing, incorrect duration of prescribed therapy, or incorrect coverage of infection. Secondary outcomes will include hospital admissions within 30 days post visit, a return visit to PCHC clinic for same diagnosis within 90 days post visit, and microbiological culture and susceptibility.

Poster Title: Evaluating the impact of the new opioid dose limits mandated by the state of Maine on provider-specific treatment plans for pain management

Primary Author: Shilpa Nair, Penobscot Community Health Care, ME; Email: snair@pchc.com

Additional Author(s):
Felicity Homsted
Kristopher Ravin
Morgan Harper
Nicholas Michaud

Purpose: In 2015 Maine reported 272 deaths attributed to drug overdose, 57 percent of which involved opioids. In response to this growing epidemic, a bill was signed into law (Chapter 488,) limiting opioid prescriptions from exceeding an aggregate of 100 morphine milligram equivalents (MMEs) daily. Patients receiving prescriptions in excess of 100 MMEs were given time to taper to meet this requirement. This study aims to identify prescription opioids exceeding 100 MMEs, and to track their respective taper schedules to assess compliance with the law and its impact on patient outcomes.

Methods: This study was submitted to an internal clinical review committee for approval. The electronic medical record within a Federally Qualified Health Center was utilized to identify patients who had been prescribed opioids between May 2016 and August 2016, excluding patients in hospice care, an exception status per Chapter 488. The following prescription information was collected: drug, strength, directions, date written and responsible provider. Aggregate daily MMEs were calculated per patient and categorized as below 100 MMEs, between 100 and 299 MMEs, and 300 MMEs or above. Providers and clinical coordinators were alerted as to which of their patients fell into these designated categories and their recommended taper schedules to achieve compliance with the law. Providers also received a summary of the law, appropriate alternatives to opioids for optimal pain management, and patient education handouts about the law and opioid medications. The implementation of taper schedules will be assessed in order to gauge compliance with the law by January 1, 2017. The reviewers will classify each patient’s care as compliant with Chapter 488, noncompliant
with Chapter 488, or an appropriate exception as defined in Chapter 488. Premature death rates will be collected in order to evaluate the impact of the law on patient outcomes.

Poster Title: Implementation of a hepatitis C virus screening process and treatment protocol to provide affordable access to care and identify barriers to treatment

Primary Author: Kathryn Cunniff, Penobscot Community Health Care, ME; Email: kcunniff@p chc.com

Additional Author (s):
Melissa Carr
Caitlin Morrow
Felicity Homsted

Purpose: According to the American Association for the Study of Liver Diseases, there are an estimated three to four million people in the United States infected with HCV. New drugs are expanding treatment options. Without a protocol in place 280 cases were documented in the electronic medical record with primary care based treatment initiation for 6 patients in the past year. Implementing a screening process and treatment protocol will create increased access to care. Providing treatment in the primary care setting will reduce the risk of hepatocellular carcinoma, all-cause mortality, and provide a public health benefit to reduce rates of transmission.

Methods: All at risk patients over the age of 18 presenting to primary care providers will be offered a hepatitis C virus (HCV) screening test. Patients will first be tested for the HCV antibody. Patients with a positive HCV antibody test will be referred for a HCV ribonucleic acid (RNA) supplemental test to determine if an active viral load is present. An RNA positive test means an active HCV infection is present. All patients testing positive for HVC will be referred to pharmacy for insurance coverage verification and determination of further testing requirements pre-treatment. A referral to an infectious disease specialist participating in collaborative practice will be done to determine the appropriate treatment regimen. Patients testing positive will receive vaccination against hepatitis A and B if indicated. For patients with cirrhosis a pneumococcal vaccine will be recommended. Patient education and interventions by the pharmacist will be aimed at reducing progression of liver disease and preventing transmission.
Once a treatment regimen is established, patients will begin therapy and pharmacy will track the patient’s progress and provide medication education and information. The number of identified cases, the number of patients who receive treatment, and the number of patients who reach a sustained virologic response will be measured during the course of this study.

Poster Title: Impact of pharmacy-filled medication box service on adherence rates and prescription refill volumes

Primary Author: Charles Gregor Derupe, Penobscot Community Health Care, ME; Email: cderupe@pchk.com

Additional Author(s):

Purpose: The effects of non-adherence to medications account for 26% of hospital admissions and 20% of adverse drug events outside of a medical practice. Non-adherence also impacts the health system financially, as it limits the number of eligible scripts that are filled. This study will analyze the impact of pharmacy-filled medication box services on medication adherence rates for high-risk patients and on pharmacy revenue through enhanced refill rates.

Methods: Patients are recruited through a referral process from providers and care managers who identify high-risk patients for medication non-adherence. Upon referral, the pharmacy will obtain consent to dispense the referred patient’s medications in a weekly pill box, organizing medications administered in the morning, noon, and in the evening. Pill boxes will be filled by either a pharmacy technician or a pharmacist with a final quality assurance check by a pharmacist. To facilitate the filling process, the patient’s medications will also be synced with the goal to dispense all of their medications on the same day. At each subsequent fill, the quantity of medications left in the pill box will be recorded to assess for medication adherence rates and identify opportunities to address medication adherence barriers. Patients will be followed for 6 months from the initiation of their participation in the study. Comparison of fill rates and associated revenue will be performed. Documentation of increased pharmacy revenue resulting from new patients without prior medication fills at PCHC pharmacies will also be documented and analyzed.

**Primary Author:** Nicholas Michaud, Penobscot Community Health Care, ME; **Email:** nmichaud2@une.edu

**Additional Author(s):**
Chelsea Magee

**Purpose:** Our organization is a Federally Qualified Health Center with four in-house pharmacies, the pharmacies currently capture approximately 20% of all prescriptions written by the organizations providers. Additionally, 90% of prescriptions filled at our pharmacies are written by our providers. Given these numbers there is a significant opportunity to increase the prescription capture rate through internal marketing. This initiative focused on increasing internal prescription retention to support and grow the free services available to the community including prescription assistance, homeless shelter, and clinical pharmacy services.

**Methods:** This study included all patients at our organization who received an electronic prescription from one of our providers. The initial data collected includes pharmacy location where prescription was sent, patients preferred pharmacy as listed in the electronic medical record, pharmacy encounters, and revenue. After the interventions are implemented, the data will be reviewed to assess the impact of each intervention. Interventions will include targeted provider education and patient focused marketing of pharmacy services. Informing providers about the positive economic impact the pharmacy has on funding the organization’s free services and the advantages to using an integrated pharmacy to patient safety. Patient education and advertising will inform patients of discount drug programs, increased safety, prescription assistance programs, and improved of access through the in house pharmacies. Each quarter, interventions falling under one of the two previous categories will be implemented with a subsequent evaluation of percentage of prescriptions retained as a primary end point. Secondary end points include, pharmacy encounters, revenue changes and service enhancements added.

**Submission Category:** Ambulatory Care  

**Submission Type:** Research-in-Progress  

**Session-Board Number:** 12-015  

**Poster Title:** An Interdisciplinary approach to reducing hospital readmissions by performing a home visit post hospital discharge  

**Primary Author:** Matthew Christie, Penobscot Community Health Care, ME; **Email:** mchristie@pchc.com  

**Additional Author (s):**  
Beth Kelly  

**Purpose:** Patients are often readmitted to the hospital within 30 days of discharge for treatment of the same condition for which they were originally admitted. This negatively impacts patients’ overall health as well as the health care system due to its costly process. Many patients are discharged from the hospital with medication discrepancies/errors, no follow up appointment with PCP, and/or are not set up with necessary services. This organization has developed a program to mitigate many of these challenges and reduce unnecessary hospitalizations as well as costs to the health care system.  

**Methods:** A pharmacist and a registered nurse visit homes of recently discharged from the hospital within 72 hours of discharge. The pharmacist performs a medication reconciliation at the patient’s home, counsels the patient on their medications and special devices (inhalers, injections, etc). The nurse performs a physical assessment, connects them with needed services (home health, transportation, etc), and makes sure the patient has a follow up appointment with their PCP within 7 days of discharge. After the patient is seen, the nurse or pharmacist performs a follow up phone call 7 days after the initial home visit to assure all interventions/services have been provided to the patient. Each patient will be monitored for 2 months and will be tracked for hospital readmissions.

**Submission Type:** Descriptive Report

**Session-Board Number:** 12-016

**Poster Title:** Use of target specific oral anticoagulants in dental procedures

**Primary Author:** Irene Madrigal, Penobscot Community Health Center, ME; **Email:** okinawagirl@me.com

**Additional Author(s):**

**Purpose:** There currently are no evidence-based practice guidelines on how to manage dental patients on the target specific oral anticoagulants (TSOACs). These agents are becoming a popular choice because they don’t require any monitoring, there are few drug interactions and they possess a predictable pharmacokinetic profile. There is a concern of thrombotic complications if these agents are abruptly discontinued. However, if the agents are continued there is a concern of prolonged bleeding during dental extractions or surgery. This study was undertaken to determine if the risk of discontinuing TSOACs outweigh the risk of bleeding.

**Methods:** A literature search of PubMed and Embase (January 1, 1988- May 31, 2016) was conducted to find studies of patients who are on TSOACs. Only English articles were searched. Dental procedures included the following: single or multiple dental extractions, single or multiple dental implants, bone grafting, dentoalveolar surgeries and osteotomies. Keywords included apixaban, rivaroxaban, edoxaban, dabigatran and anticoagulants. The Boolean operator “AND” was used to search for the following terms and was combined with the names of the TSOACs: oral surgical procedures, maxillofacial surgery, dental extraction and dental surgery. The search excluded articles pertaining to vitamin K antagonists, IV direct thrombin inhibitors and antiplatelet agents. A total of 52 articles were found pertaining to dental procedures and anticoagulants. Of these, 43 focused on dental procedures and TSOACS. This search revealed 3 case studies, 6 clinical prospective cohort studies and 2 retrospective cohort studies, 9 expert opinion articles, 14 review articles and 9 meta-analysis on the topic. The review articles discussed the pharmacology, pharmacokinetics, drug interactions, monitoring, and the side effect profile of the oral anticoagulants in dental patients.

**Results:** The strength of the literature was poor in that they did not consider all important outcomes and the conclusions were based on a small population of patients. Furthermore, the articles did not specify if any other medications were taken that might have interacted with the
TSOACs. The author recommendations varied. Some authors recommended to hold the TSOACs 24-48 hours prior to dental procedures depending on renal function, the complexity of the dental procedure or if the patient had comorbidities for increased bleeding. However, other authors recommended to continue with the TSOACs and to manage any localized bleeding with either tranexamic acid, aminocaproic acid, topical hemostatic agents or with mechanical compression. Expert opinions varied depending on whether the provider was a general dentist or a specialist such as an oral maxillofacial surgeon, endodontist or prosthodontist.

**Conclusion:** There are no evidence-based guidelines as to how to manage patients on TSOACs who will undergo dental procedures. However, most of the literature concluded that interruption of the TSOACs is unnecessary for patients undergoing routine procedures such as teeth extractions involving less than three teeth. These studies did not include patients who might have conditions that predispose them to bleeding, such as alcoholism, renal failure, liver failure, and hematologic disorders. In the absence of these risk factors, dental practitioners should continue TSOACs because the risk of death from thromboembolism is greater than the risk of bleeding.
**Submission Category:** Practice Research/ Outcomes Research/ Pharmacoconomics

**Submission Type:** Research-in-Progress

**Session-Board Number:** 12-017

**Poster Title:** Effectiveness of a medication synchronization program on proportion of days covered (PDC) scores and Medicare Part D medication-related adherence metrics

**Primary Author:** Brooke Cowles, University of New England College of Pharmacy/Martin's Point Health Care, ME; Email: bcowles@une.edu

**Additional Author(s):**
Kenneth McCall
Rose Mary Coyle
Moira O'Toole

**Purpose:** The Centers for Medicare and Medicaid Services as a part of their star ratings program evaluate medication adherence. Three of these medication-related adherence metrics apply to statins, renin angiotensin aldosterone system antagonists, and noninsulin diabetes medications. To aid in being compliant with these adherence metrics, community pharmacies are implementing medication synchronization programs. The objective of this study is to determine if proportion of days covered (PDC) scores improved after a patient was enrolled in a medication synchronization program, specifically if the scores of statins, renin angiotensin aldosterone system antagonists, and noninsulin diabetes medications will improve.

**Methods:** This observational, cohort study includes subjects who were members of a Medicare Advantage prescription drug plan and who participated in a medication synchronization program at the plan’s preferred pharmacy. Patients will be identified by their proportion of days covered (PDC) score, if they were taking at least one of the three groups of medications analyzed by the Centers for Medicare and Medicaid Services, and had at least two fills after being enrolled in the medication synchronization program. Patients who were not enrolled in the program but met all other criteria will serve as the control group. An adherence report will be generated from the plan’s claims data and will be retrospectively analyzed. Before analysis, data will be de-identified and each patient will have a random identifier. The primary endpoints for this study include the percentage change in the final PDC score from 2015 to 2016, the percentage change in PDC from quarter one and quarter two (January through June) 2016 prior to enrollment in the program to quarter three and quarter four (July through December) 2016 after enrollment in the program, and the percentage change of PDC from quarter one (January
through March) 2016 to quarter one 2017. In addition, associated medical costs will be evaluated before and during the intervention period. This study has been approved by the Institutional Review Board.

**Poster Title:** Hospital preparedness for the new joint commission antimicrobial stewardship standard: a survey study  

**Primary Author:** Mohammed Abdulwahhab, Ascension, MO; **Email:** mohammed.abdulwahhab@ascension.org  

**Additional Author (s):**  
Nisha Bhide  
Lynn Eschenbacher  
Roy Guharoy  
Mohamad Fakih  

**Purpose:** Approximately 23,000 people die each year in the United States from infections. Antimicrobial stewardship can help prevent the development of multidrug-resistant organisms and reduce unnecessary drug use and costs. The Joint Commission (TJC) announced a new Medication Management (MM) standard for hospitals, critical access hospitals, and nursing care centers. Standard MM.09.01.01 addresses antimicrobial stewardship and becomes effective January 1, 2017. The purpose of this survey is to assess hospital preparedness for the new The Joint Commission antimicrobial stewardship program standard.  

**Methods:** A MM.09.01.01 medication management standard compliance survey was developed by a multi-disciplinary team including pharmacy and infectious disease physician leaders. The survey creation utilized key elements from the new TJC antimicrobial stewardship medication management standard. The survey was created in the Zarca survey tool and sent to participants via an e-mail link. The survey was sent to all the antimicrobial stewardship pharmacists at Ascension Health and to directors of pharmacy at additional selected sites across the United States. The Ascension facility results will be compared to the non-Ascension facilities that participate in the survey. Results and descriptive statistics between the two groups will be reported following completion of data collection.

Poster Title: Rasburicase utilization at an academic pediatric hospital

Primary Author: Stephanie Duehlmeyer, Children's Mercy Hospital, MO; Email: srduehlmeyer@cmh.edu

Additional Author(s):
Ashley Duty
Christopher Klockau

Purpose: The purpose of this study is to evaluate the adherence to the current Children’s Mercy Hospital guideline for rasburicase use. Children’s Mercy Inpatient Pharmacy spent approximately $27,000 on doses of rasburicase dispensed in the last year. Investigating and characterizing patients receiving rasburicase will allow for determination if the clinical practice guideline is being utilized. Adherence to the guideline will provide insight into future areas of cost reduction.

Methods: This study has been submitted and approved with the Institutional Review board. This is a retrospective chart review of patients who received rasburicase at Children’s Mercy Hospital between July 1st, 2012 and July 30th, 2016. The following data will be collected: patient age (years), patient weight (kg), patient height (cm), patient gender, date/time of admission, date/time of discharge, nursing unit where drug was administered, medical service, diagnosis, documented allergies, findings (scans +/- physical exam) reflective of lymphadenopathy, organomegaly or abdominal/thoracic/mediastinal masses, rasburicase dose (mg), rasburicase administration date/time, rasburicase stop date/time, rasburicase order sentence and comments, rasburicase indication, allopurinol dose (mg), allopurinol administration date/time, allopurinol stop date/time, allopurinol route (IV or PO), concurrent medications (including pre-medications/fluids and medications to treat any adverse events), dialysis – yes or no, and the following lab values; serum uric acid, serum creatinine, serum phosphorus, white blood cell count, lactate dehydrogenase. The data will be analyzed using descriptive statistics (mean, median, and standard deviation) to characterize the information collected.

Poster Title: Utilization of Nebulized Antibiotics at Children's Mercy Hospital

Primary Author: Alexander Milligan, Children's Mercy Hospital, MO; Email: apmilligan@cmh.edu

Additional Author(s):
Diana Yu
Claire Elson

Purpose: Tobramycin and aztreonam are the only FDA indicated nebulized antimicrobials. Additionally, they are only approved in the cystic fibrosis (CF) patient population for eradication and chronic utilization, leading to increased off-label use of these agents and other antimicrobials. By characterizing the use of nebulized antimicrobials, we will be able to determine the patient populations associated with their use, the frequency of their use, and the associated indications of their use.

Methods: This study has been approved by the Institutional Review Board. A query of inpatient nebulized antibiotic orders will be performed to generate a list of potential candidates. The following data will be collected: patient age, gender, ethnicity, allergies, nebulized antibiotic name, order sentence and comments, and duration of therapy. A chart review will be performed to extract the following data: Pertinent past medical history, prescribing service, indication for nebulized antibiotic, concurrent systemic antibiotics, and documented adverse drug reactions to the prescribed nebulized antibiotic (e.g. bronchospasm, anaphylaxis). All data will be recorded without patient identifiers and maintained confidentially. Data will be analyzed to determine if a quality improvement plan is warranted at our institution.

Poster Title: Establishment and effects of appropriate opioid use (AOU) guidelines in the emergency department

Primary Author: Kaitlin Krisik, Christian Hospital, MO; Email: kkk1224@bje.org

Additional Author(s):
Leah Ogle
Karen Scott

Purpose: The national opioid epidemic has placed much emphasis on reducing opioid utilization. Christian Hospital currently has the busiest emergency department in the Saint Louis, Missouri area, but does not have opioid guidelines in place. The objective of this study is to establish Appropriate Opioid Use (AOU) guidelines, and to determine if implementation of the guidelines improves appropriate opioid prescribing in the emergency department.

Methods: The study will be submitted to the Institutional Review Board for approval. The electronic medical record will identify all patients who visited the emergency department from February 22 - April 7, 2016 and from February 22 - April 7, 2017. All patient charts within this timeframe will be reviewed for the study. The primary endpoints include the percentage of patients receiving opioid and non-opioid analgesics during their emergency department visit and the percentage of opioid and non-opioid prescriptions upon discharge from the emergency department. The secondary endpoints include the total cumulative dose of opioid in morphine milligram equivalents (MME) per emergency department visit, total daily dose of opioid in MME prescribed at discharge from the emergency department, and the percentage of each administrative route of opioid administration in the emergency department. The following data will be collected: age, gender, opioid (name, dose, route), cumulative MME during emergency department visit, use of non-opioid analgesics, type of pain, pain scale and severity, indication for analgesic, diagnosis, discharge analgesic prescription, MME, day supply and seven-day readmission rate. Data will be collected and stored in an encrypted Microsoft Excel spreadsheet. The data collection key will be destroyed once all data is collected, leaving only the master that will be untraceable back to the patient.

**Poster Title:** Pharmacist-directed warfarin protocol dosing compared to practitioner warfarin dosing

**Primary Author:** Tiffany Kiehna, Christian Hospital, MO; **Email:** txk1226@bjc.org

**Additional Author(s):**

**Purpose:** Christian Hospital implemented a new pharmacist directed warfarin protocol service in February 2016. The objective of this study is to assess how successful the pharmacy department is compared to other practitioners at reaching and maintaining therapeutic International Normalized Ratios (INRs).

**Methods:** The study will be submitted to the Institutional Review Board for approval. The electronic medical record will identify patients who received warfarin prescribed by physicians and other practitioners from April, 1st 2015 to January 31st 2016 as well as patients who received warfarin from “pharmacy per protocol” from April 1st, 2016 to January 31st 2017. Patient charts will be reviewed to track the primary and secondary endpoints. The primary endpoints include days to reach therapeutic INR in new-start warfarin patients and patients out of INR goal range upon admission/pharmacy referral as well as days within therapeutic INR in new-start patients and patients previously on warfarin. The secondary endpoints include adverse events (thrombus or bleed), supratherapeutic INRs, and percentage of patients who did not receive a therapeutic INR during his or her hospital stay. The following data will be collected age, sex, ethnicity, first available weight, indication for warfarin therapy, dose of warfarin at home, INR on admission through discharge, bridge therapy utilized, prescribing clinician of pharmacy referral, adverse events, number of days on warfarin, vitamin K doses administered, fresh frozen plasma administered, INR upon discharge, possible interacting medications, discontinuation of dosing service by clinician, and first 6 days of new-start warfarin doses. All patient data will be kept electronically in an encrypted computer file and made untraceable to the patient.

Poster Title: Impact of alvimopan on gastrointestinal recovery time following open ventral hernia repair procedures

Primary Author: Sara Wirth, CoxHealth, MO; Email: sara.wirth@coxhealth.com

Additional Author(s):
Matthew Simpson
Kris Jones
Chelsea Landgraf
Jason Pelletier

Purpose: Alvimopan, a peripherally-acting opioid antagonist, is FDA-approved to accelerate time to gastrointestinal recovery following surgeries that include partial bowel resection with primary anastomosis. Alvimopan has been shown to accelerate recovery of gastrointestinal function and reduce hospital length of stay in clinical trials for several types of abdominal surgeries, but data is limited in hernia repair procedures. The purpose of this study is to evaluate the impact of alvimopan on gastrointestinal recovery time, hospital length of stay, and associated hospital costs following open ventral hernia repair with component separation procedures in a community hospital.

Methods: This study will be submitted to the Institutional Review Board for approval. This retrospective cohort study will compare outcomes in adult patients who underwent open ventral hernia repair with component separation procedures and either received alvimopan (alvimopan group) or did not receive alvimopan (control group). Eligible patients will be identified from CoxHealth South surgery department records for patients with billing for open ventral hernia repair with component separation procedures. Data will be collected through retrospective chart review, including doses of alvimopan administered, time to first stool or flatus output following surgery, diet orders, ambulation orders, nasogastric tube placement or removal, hospital length of stay, associated hospital costs, perioperative opioid administration, patient age, gender, body mass index, and comorbidities. All data will be recorded without patient identifiers and maintained confidentially. Statistical analysis will compare mean time to return of bowel function, hospital length of stay, and associated hospital costs between the alvimopan and control groups.

Poster Title: Pharmacist impact on information exchange and collaboration management of a clinic formulary system.

Primary Author: Margaret Ladlie, CoxHealth, MO; Email: margaret.ladlie@coxhealth.com

Additional Author(s):
Sarah Billings
Cassie Heffern

Purpose: There is minimal guidance on assessing the impact of pharmacist intervention on the formulary management in an outpatient setting. The objective of this study is determine overall difference in drug spend of a high cost medication before and after pharmacist collaboration at a large multi-office outpatient clinic. Other secondary objectives include evaluating the difference in evidence-based prescribing habits, overall utilization of the selected high cost medication, and overall difference in quantity of high cost medication ordering before and after pharmacist collaboration on formulary management.

Methods: This study will be submitted to the local Human Research Protection Committee at CoxHealth. The top five highest cost medications purchased for the clinic will be reviewed for realistic opportunities for cost savings at the multi-office clinic. One medication will be selected to implement formulary management processes based on which has the greatest potential for cost savings and utilization of evidence-based medicine. Once finalized, these processes will be presented to the CoxHealth Evidence Based Medicine committee, which is equivalent to the outpatient therapeutics committee, to be approved. A standardization process will be established for approving the medication use through inventory and education measures. To review effectiveness of intervention, the selected medication use will be reviewed pre- and post- pharmacy intervention. Subjects will be identified by a running report of the high cost medication administered in the clinic for three months one year prior to intervention to avoid potential bias, as well as three months post intervention. Subject data pertinent to the objectives will be collected via electronic chart review. Financial information will be collected via the pharmacy department buying team.

Submission Type: Research-in-Progress

Session-Board Number: 12-025

Poster Title: Evaluation of clinical pharmacist performed comprehensive medication reviews for members of a health-system based Medicare plan

Primary Author: Ashley Evans, CoxHealth, MO; Email: ashley.evans@coxhealth.com

Additional Author(s):
Stefanie Hawkins
Cassie Heffern
Karrie Derenski

Purpose: Medicare Advantage plans that provide prescription coverage are required to establish Medication Therapy Management programs. Health-system pharmacists working in primary care clinics are well positioned to impact a health-system based plan. The primary objective of this study is to assess and evaluate the impact of face-to-face comprehensive medication reviews performed by a pharmacist through tracking pharmacist interventions by category, acceptance rate, and cost savings or cost avoidance. The secondary objectives are to evaluate the change in patient proportion of days covered, prescription drug plan costs, and hospital admissions and emergency department or urgent care visits.

Methods: This study will be submitted to the institution Human Research Protection Committee for approval. Pharmacists will perform comprehensive medication reviews at primary care offices. Pharmacists will review patient medications, gather additional history, and provide medication-related education. Pharmacists will document relevant findings and recommendations in the electronic medical record. Primary care providers will be notified of recommendations via the electronic medical records and/or verbal follow-up. Pharmacists will record the types and acceptance rates for these recommendations. Cost savings or cost avoidance associated with those recommendations will be calculated. Investigators will use health plan prescription claims data to calculate proportion of days covered and medication costs before and after the intervention. Additionally, investigators will review the electronic medical record for hospital admissions and emergency department or urgent care visits before and after the intervention. Per patient changes in 90-day proportion of days covered, annualized medication costs, and 30 and 90-day hospital admissions and emergency department or urgent care visits will be analyzed using Student’s t-test. Changes in the
proportion of patients with a proportion of days covered greater than or equal to 80%, with a hospital admission at 30 and 90-days, and with emergency department visit or urgent care visit at 30 and 90 days will be analyzed using chi-squared or Fisher’s Exact test depending on event incidence.

Session-Board Number: 12-026

Poster Title: Effect of quetiapine on total ventilator time and intensive care unit length of stay in trauma patients

Primary Author: Lance Schneider, CoxHealth, MO; Email: ronald.schneider@coxhealth.com

Additional Author(s):
Livia Allen
Karrie Derenski
Chelsea Landgraf

Purpose: Quetiapine is used off-label for treatment of delirium and subsequent reduction of ventilator time and length of stay in intensive care unit (ICU) patients. Evidence remains weak in this population, but quetiapine’s various mechanisms of action may make it an effective choice to improve these outcomes by decreasing agitation and use of benzodiazepines. The purpose of this study is to evaluate the effect of quetiapine on total ventilator time and intensive care unit length of stay in trauma patients. Secondary objectives include hospital length of stay, lorazepam equivalents use, dexmedetomidine use, and rescue therapy use with haloperidol and olanzapine.

Methods: This study is currently under review by the institutional review board. It will be a retrospective, cohort study on ICU trauma patients at a community hospital from August 1, 2014 to August 1, 2016. Trauma patients age 18 years and older admitted to the ICU for greater than 72 hours will be eligible for inclusion. Study group patients must also have received at least one dose of quetiapine. Patients who meet the requirements will be placed into one of four groups: received quetiapine and ventilated, received quetiapine and not ventilated, did not receive quetiapine and ventilated, and did not receive quetiapine and not ventilated. Patients with a history of irreversible cognitive dysfunction (e.g. dementia), antipsychotic or benzodiazepine treatment prior to admission, or treatment with a scheduled antipsychotic other than quetiapine during ICU stay will be excluded. Randomization of patients will be performed using a random number generator. Patient demographics, primary and secondary outcome measures will be collected for analysis. A statistical T-test will be performed for all outcome measures.

**Poster Title:** Impact of admission pharmacy services on patient care transitions in a community hospital setting

**Primary Author:** Lauren Fox, CoxHealth, MO; Email: lauren.fox@coxhealth.com

**Additional Author(s):**
Elizabeth Englin
Karrie Derenski
Chelsea Landgraf
Jason Pelletier

**Purpose:** Admission services within a hospital consist of creating or updating a patient’s home medication regimen and comparing it to the current medications started by the provider with the goals of avoiding inconsistencies and reducing adverse effects. Previous studies have shown the majority of medication errors are due to an inaccurate medication history. Additional studies have demonstrated a reduction in errors and improved outcomes with pharmacy involvement in this process. The objective of this study is to assess the impact of pharmacy-led admission medication history and reconciliation on patient care transitions in a community hospital setting on a medical-surgical unit.

**Methods:** This study will be submitted to the Institutional Review Board for approval. The hospital computer system will be used to identify patients that were seen by a clinical pharmacist performing medication histories and reconciliations on a specific medical-surgical unit of the hospital during a nine-month time frame. A chart review will be performed for each patient to obtain the following data: total number of home medications; number of medication history discrepancies sub classified as additions, removals or changes; total number of discrepancies per patient; number of recommendations made to providers and associated provider acceptance rate. Chart review will also be utilized to collect 30-day emergency department visits as well as 30-day and 90-day readmissions. Medication discrepancies will be evaluated for potential harm using the Institute for Safe Medication Practices’ List of High-Alert Medications in Acute Care Settings. Readmission, emergency department rates and Hospital Consumer Assessment of Healthcare Providers and Systems scores will be compared to scores during the same time-frame one year prior to the study period when pharmacy services were
not implemented. Cost savings will be analyzed using the Medication at Transitions and Clinical Handoffs’ Financial Model for Cost Savings equation. All data will be password protected and stored on restricted personal drives of the investigators.

**Poster Title:** Appropriateness of antibiotic prescriptions in patients diagnosed with a urinary tract infection in an outpatient, non-clinic setting

**Primary Author:** Scott Wuebbels, CoxHealth, MO; **Email:** scott.wuebbels@coxhealth.com

**Additional Author(s):**
- Kerrie Derenski
- Chelsea Landgraf
- Melissa Steenhoek
- Jason Pelletier

**Purpose:** The primary objective of this study is to evaluate the appropriateness of empiric antibiotics (drug, dose, and duration) in adult patients with a diagnosed community-acquired urinary tract infection discharged from a regional health system’s emergency departments and urgent care facilities. The secondary objective of this study is to create an antibiogram(s) detailing local antibiotic sensitivity to common urinary pathogens.

**Methods:** This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients with ICD-9 diagnosis code 599.0 for urinary tract infection, who were prescribed antibiotics and discharged from a regional health system’s emergency departments and urgent care facilities during the study period. The following data will be collected: patient age, gender, complicated vs uncomplicated urinary tract infection [as defined by male gender, age greater than 65 years old, indwelling catheter, diabetes, immunocompromised (such as HIV or chronic steroid use), antibiotic use within 1 month, renal failure], health conditions, signs and symptoms documented in the medical record (temperature greater than 100.4°F, pyuria, dysuria, flank pain, suprapubic heaviness), vital signs, serum creatinine, calculated creatinine clearance, white blood cell count, antibiotic(s) administered while in the emergency department or urgent care, antibiotic(s) prescribed by the provider (including drug, dose, frequency, and duration), location of emergency department or urgent care, allergies, and urine culture sensitivities. The reviewer will rate each antibiotic prescription as appropriate or inappropriate based on the 2010 Infectious Diseases Society of America Urinary Tract Infection guidelines and other related study recommendations. Culture
and sensitivity data from urine specimens submitted to Cox Microbiology department(s) from each emergency department or urgent care will be analyzed for the secondary objective.

**Poster Title:** Effect of a Pharmacist Driven Inpatient Medication Therapy Management Protocol on Glycemic Control in the Critically Ill

**Primary Author:** Shelbie McCoy, CoxHealth, MO; Email: shelbie.mccoy@gmail.com

**Additional Author(s):**
Livia Mackley  
Karrie Derenski  
Jenni Catlin

**Purpose:** Hyper and hypoglycemia impact morbidity, mortality, and healthcare cost. Impaired healing, infection, coma, and death are potential negative outcomes of glucose imbalance. Tight blood glucose control is beneficial and creates an opportunity to improve quality of life. Medication Therapy Management (MTM) provides education, counseling, and improved medication adherence. Pharmacist led MTM programs provide continuity of care, cost savings, and revenue but minimal data exists in hospitalized patients. This study aims to assess the impact of a pharmacist driven MTM program on glycemic management in the critically ill.

**Methods:** The primary objective of this prospective observational single center study is to assess the impact of pharmacist intervention on time to goal blood glucose levels from the initial blood glucose > 180 mg/dl to achieving goal < 180 mg/dl and the time maintained at goal. Secondary objectives include the frequency of hyperglycemia, hypoglycemic events, and ICU length of stay when comparing pre and post protocol change. This study is under review by the Institutional Review Board. Medical records of patients who were admitted to Medical, Cardiac, Neurology, Trauma, and Step Down units and received MTM services will be reviewed. All patient information will be gathered using data charted during MTM services performed in the electronic medical record. Data will be collected on enrolled subjects after MTM services have been completed and the MTM consult discontinued for > 1 week. Patients included are > 18 years old, admitted > 48 hours and MTM services provided within 24 hours of consultation. Patients are excluded if MTM services were performed during a separate admission, death during admission or transition to comfort care occurs, primary admission due to diabetic keto acidosis or requiring intravenous insulin upon admission, or endocrinology consultation.

Poster Title: Impact of pharmacist-provided comprehensive medication review (CMR) for patients receiving oral chemotherapy treatment

Primary Author: T. Mark Egbuka, CoxHealth, MO; Email: tmegbuka@gmail.com

Additional Author(s):
Ryan Baker
Lyndall Calhoun

Purpose: Patients receiving intravenous chemotherapy are monitored closely for adverse effects and efficacy of therapy, in addition to safeguarding adherence. For the oral chemotherapy patient, it is more difficult for physicians to monitor medication adherence and toxicity. Additionally, a lack of safety checks may lead to medication errors and decreased efficacy. Currently, CoxHealth Ferrell Duncan Clinic (FDC) Oncology does not utilize a pharmacist in the management of oral chemotherapy patients. The purpose of this study is to assess the impact of pharmacist-provided comprehensive medication reviews (CMR) on outcomes for patients receiving oral chemotherapy.

Methods: This study will be submitted to the Cox College/CoxHealth Human Research Protection Committee for approval. Patients will be identified by FDC Oncology providers on the basis of being on an oral chemotherapy regimen. After the patient consents to involvement in this study, the patient will be asked to complete a survey prior to the initial comprehensive medication review (CMR) in order to assess comprehension and comfortability with their oral chemotherapy regimen. Following survey completion, a CMR will be conducted for each patient entering the study. All CMR findings and interventions/recommendations will be communicated directly to the providers for review. Patients will be asked to complete a second survey following the conclusion of the study period or oral chemotherapy regimen, whichever occurs sooner. The following data will be collected: oral chemotherapy agent, type of cancer, number of drug interactions, dose adjustments, medications added or removed from patient’s medication list, number of provider communications for interventions, and survey data. All data will be recorded without patient identifiers and maintained confidentially. Adverse event, medication adherence, and intervention acceptance rates will be calculated. Statistical analysis
will assess patient satisfaction, intervention type and acceptance rate of pharmacist interventions.

Poster Title: Pharmacist education and post-discharge follow-up: Reducing 30-day readmission rates in post-myocardial infarction patients in a community hospital

Primary Author: Grant Florer, Mercy Hospital - Joplin, MO; Email: gflorer@gmail.com

Additional Author(s):

Purpose: Hospital readmissions contribute to increased patient morbidity and rising health care costs, and many hospitals are at risk for reduced payments due to excessive numbers of readmissions. The purpose of this study is to measure the impact that pharmacists can have on readmission rates for post-myocardial infarction (MI) patients in a 240 bed acute care, community-based hospital through medication reconciliation, inpatient education, and timely follow-up upon discharge.

Methods: This study will be submitted to the Institutional Review Board for approval or exemption. This will be a single-center prospective study in patients admitted to a community hospital for myocardial infarction. The electronic medical record will be used to determine baseline readmission rates, and all patients identified upon admission for or with a new diagnosis of MI (both STEMI and NSTEMI) during a six-month timeframe between November 2016 and May 2017 will be included. A pharmacist will provide education for all discharge medications for post-MI treatment recommended by the American College of Cardiology/American Heart Association, as well as comprehensive medication reconciliation upon admission or prior to discharge. The final component will include face-to-face (when feasible) or telephone follow-up within 72 hours of discharge to ensure the patient was able to pick up new medications. The primary outcome will be the number of readmissions for cardiovascular disease related co-morbidities in less than 30 days.

Poster Title: Evaluation of initial dosing of unfractionated heparin in obese patients with venous thromboembolism or acute coronary syndromes

Primary Author: Brady Lewis, Mercy Hospital Joplin, MO; Email: bradywlewis@gmail.com

Additional Author(s):

Purpose: A 240 licensed-bed acute care hospital uses weight-based protocols to dose heparin in the treatment of active deep vein thrombosis, pulmonary embolism, and acute coronary syndromes. These protocols utilize maximum bolus dosing and infusion rates that may provide suboptimal time to therapeutic anticoagulation in obese patients. The purpose of this study is to evaluate if using these current dosing protocols in obese patients delays achieving therapeutic levels of anticoagulation compared to nonobese patients.

Methods: This study will be submitted to the Institutional Review Board for approval or exemption. The electronic medical record system will identify patients who had received heparin per the institutional treatment protocols. The following data will be collected: patient age, gender, anticoagulation therapy prior to admission, height and weight on admission, heparin bolus dose and infusion rates, and antifactor Xa heparin assay (anti-Xa HA) levels. Patients will be divided into a nonobese population and an obese population. A time-to-event analysis for achievement of therapeutic anti-Xa range will be assessed. Appropriate statistical analysis will be conducted. All data will be recorded without patient identifiers and maintained confidentially.

Results: N/A (research in progress)

Conclusion: N/A (research in progress)
Purpose: Unfractionated heparin (UFH) is frequently prescribed to treat patients diagnosed with deep vein thrombosis (DVT) or pulmonary embolism (PE). UFH is most commonly monitored by activated partial thromboplastin time (aPTT), which measures multiple factors of the intrinsic and common coagulation pathway. Anti-factor Xa, however, is a direct measure of UFH activity. This facility recently revised protocols to monitor UFH with anti-factor Xa levels. The primary purpose of this study is to determine if the new protocol impacted the time to therapeutic anticoagulation. Additional measures will include number of labs drawn, patient length of stay, and patient safety.

Methods: This study will be submitted to the institutional review board for approval. The facility electronic health record will be used to find all patients 18 years of age and older diagnosed with a DVT or PE who received heparin as initial treatment between July and October 2016 and were monitored with anti-factor Xa levels. These patients will be compared to those who were monitored with aPTT levels for an equal number of study days prior to July 2016, the date of this institution’s protocol change. The following data will be confidentially collected and maintained for each patient: age, gender, primary diagnosis, indication for unfractionated heparin (DVT or PE), initial dose of heparin, time from drug initiation to first level drawn, type of level measured, time to therapeutic anticoagulation, number of monitoring labs drawn until therapeutic, presence of adverse events, length of stay from initiation of heparin, and number of pertinent labs drawn. Patient information will be recorded without patient identifiers. Chi-squared and descriptive statistics will be utilized to assess data collected. The results will be used to support a preferred monitoring parameter for UFH.

Results: N/A
Conclusion: N/A

Poster Title: Conventional versus facility protocol dosing of unfractionated heparin for thromboprophylaxis in patients >100 kg

Primary Author: Kelsey Johnson, Mercy Hospital Springfield, MO; Email: kelsey.johnson@mercy.net

Additional Author(s):
Cynthia Sutherland
Carla Zeilmann

Purpose: Obese patients are two to three times more likely to develop a venous thromboembolism (VTE) than normal weight patients. When used for the treatment of VTE, unfractionated heparin (UFH) is dosed based on patient weight; however, when used prophylactically, the CHEST guidelines recommend the use of fixed doses. The primary objective of this study is to quantify the safety of conventional dosing of thromboprophylaxis of UFH versus a weight based protocol in patients >100 kg based on the presence of bleeding or bruising. Secondary purposes include determining differences in efficacy and safety profiles between various body mass index (BMI) categories.

Methods: Patients will be identified using the hospital electronic health record. Inclusion criteria will be any patient greater than 100 kg in weight who is at least 18 years of age and received UFH as initial chemical thromboprophylaxis. Study groups will include patients prior to and following the implementation of the facility dosing protocol. The following data will be collected for each patient: age, sex, weight, height, BMI, dose, hemoglobin, platelets, and signs of bleeding or bruising as noted in provider or nursing documentation. All data will be recorded without patient identifiers and maintained confidentially. Chi-squared and descriptive statistics will be used to analyze the data. This study has been granted an exemption from the institutional review board based on its retrospective nature.

Results: N/A

Conclusion: N/A
**Purpose:** A previous study conducted at this institution revealed the vancomycin dosing protocol achieved initial steady-state therapeutic vancomycin trough goals in 30 percent of neonates. As a result, the protocol was modified to increase this percentage. The primary purpose of this study is to validate the modified protocol by measuring the percent of therapeutic steady-state trough levels in neonates dosed per modified protocol compared to those dosed per initial protocol. Secondary outcomes include assessing contributing clinical cofactors in neonates with non-therapeutic troughs, microbiology to validate safe area under the curve to minimum inhibitory concentration, and incidence of vancomycin-induced acute renal failure.

**Methods:** This observational, single-center retrospective chart review will be conducted from the time frame of July 1, 2015 through September 30, 2016. This study will be submitted to the Institutional Review Board for approval. Inclusion criteria are patients admitted to the level III b neonatal intensive care unit who are less than 2 months postnatal age and received vancomycin with a steady-state trough level measured no earlier than prior to the fourth dose. Exclusion criteria include neonates not dosed per protocol at 12.5 mg per kg per dose every 8 or 12 hours based on postnatal age, subsequent trough levels in a single patient, inappropriately drawn trough levels, therapy started at another facility, neonates who were anuric, or neonates with cystic fibrosis. Chi square test will be used to analyze the primary outcome.

**Results:** To be determined

**Conclusion:** To be determined

**Poster Title:** Evaluation of apixaban for appropriate dosing, indication, and safety in a community hospital

**Primary Author:** Michelle Wang, Missouri Baptist Medical Center, MO; Email: mxw1231@bjc.org

**Additional Author (s):**
Melissa Green
Anastasia Armbruster
Katie Tellor

**Purpose:** Apixaban, a direct factor Xa inhibitor, is approved by the Food and Drug Administration for prevention of stroke and systemic embolism in the setting of nonvalvular atrial fibrillation and treatment of venous thromboembolism. Apixaban’s ease of use, wide range of indications, and compelling safety and efficacy data make it an attractive anticoagulant. Since its addition to hospital formulary, a large number of patients have received apixaban for various indications. The purpose of this study will be to characterize the use and evaluate the appropriateness of apixaban at a community hospital with regards to indication, dosing, and safety.

**Methods:** A retrospective chart review will be conducted evaluating patients receiving therapeutic doses of apixaban from January 1, 2013 to June 30, 2016. Data will be collected at a community hospital in Saint Louis, Missouri. Patients 18 years of age or older who received at least two treatment doses of apixaban, including patients treated for off-label indications, will be evaluated. Patients with subsequent admissions will be evaluated for each hospital stay. Patients will be excluded if weight or serum creatinine was not documented during the hospital admission being assessed. Patients receiving apixaban for venous thromboembolism prophylaxis as well as for secondary venous thromboembolism prevention will also be excluded. Characterization of prescribing patterns that will be evaluated include appropriate dose based on indication and patient demographics. Safety outcomes include composite incidences of major, clinically relevant, and minor bleeding.

Poster Title: Evaluation of an inpatient sotalol initiation order-set within a large health-system

Primary Author: Stacy Cassat, Saint Luke’s Hospital, MO; Email: scassat@saint-lukes.org

Additional Author(s):
Charles Hayes
Sana Grover
Sanjaya Gupta

Purpose: Package inserts (PIs) for sotalol products recommend initiating sotalol under heart rhythm monitoring and waiting at least three days between dose escalations. Our health-system created a standardized sotalol initiation order-set. It includes options for more rapid dose up-titration or higher initial dosing. To our knowledge, no studies have evaluated inpatient sotalol dosing protocols that differ from the recommendations of the PIs. The purpose of this project is to evaluate inpatient sotalol initiation within the health-system after the implementation of the order-set.

Methods: Data will be gathered through retrospective review of inpatient medical records for patients who were started on sotalol therapy in the health-system after the implementation of the Sotalol Initiation Order-set (January 2016 to March 2017). Inpatient records will be limited to those who were started on sotalol using the order-set. Inpatient records for those who were on sotalol prior to admission will not be included.
The primary objective is to evaluate the length of stay for inpatients initiated on sotalol. Secondary outcomes will include therapy discontinuation during protocol, adverse reactions (Torsade de Pointes, QTc prolongation, new ventricular tachycardia, bradycardia, hypotension) and protocol compliance.
Data collection forms will not contain Protected Health Information and will be kept confidentially. IRB approval or exemption will be obtained for this project.

Poster Title: Evaluation of gentamicin dosing protocol in the neonatal intensive care unit

Primary Author: Abigail Mott, Saint Luke's Hospital, MO; Email: abigail.mott91@gmail.com

Additional Author(s):
Kimberly Day
Melissa Ruddle
Jacob Michalski

Purpose: Gentamicin is commonly used in the NICU. Various dosing strategies are available and based on gestational age, post-natal age, weight, post-menstrual age or a combination. Our health-system has used a dosing protocol that used weight categories to determine dosing and designed to achieve a trough below 2 mcg/mL. More recent literature recommends a trough below 1 mcg/mL. In January 2016, we modified the gentamicin protocol to reflect dosing provided in NeoFax. The purpose of this study is to compare how often target drug levels are achieved comparing our original neonatal gentamicin dosing protocol and the newly adopted empiric dosing strategy.

Methods: This study will be performed in a total of four NICUs, one level II, two level IIIa and one level IIIb NICU, all within our health-system. This study was approved by the Institutional Review Board as a quality improvement project. All patients admitted to the NICU during the study period who had both a gentamicin trough and peak plasma level drawn will be included in the study. Patients will be excluded if their levels were not obtained in timing with our guideline and could not be extrapolated using Sawchck-Zaske kinetics. Subjects will be identified in retrospective fashion using a reporting function in the electronic medical record. Demographics, gentamicin dosing specifics, culture results, lab results and clinical disposition will be collected through the electronic medical record. This study will look at target drug level attainment comparing our original gentamicin protocol to the new dosing protocol. The goal trough is below 1 mcg/mL and the goal peak is 5-12 mcg/mL, depending on the organism's reported minimum inhibitory concentration when known. Secondary endpoints include the incidence of nephrotoxicity, ototoxicity and clinical cure rate defined as microbial clearance in repeat cultures, stabilization of leukocytes, and/or provider’s assessment of infectious resolution.

**Poster Title:** Fixed versus variable dosing of four factor prothrombin complex concentrate for the reversal of warfarin-related non-intracranial bleeding  

**Primary Author:** Angelika Cyganska, Saint Luke's Hospital, MO; **Email:** acyganska@saint-lukes.org  

**Additional Author(s):**  
Joseph Blunck  

**Purpose:** Kcentra is a four factor prothrombin complex concentrate (4F-PCC) used for warfarin reversal in patients with acute major bleeding. The current FDA labeled variable dosing regimen is determined by patient weight and initial INR value. There have been studies assessing the safety and efficacy of fixed lower doses of prothrombin complex concentrate that have resulted in similar clinical outcomes as compared to the variable dosing regimen. After assessment of cost effectiveness and implementation of a fixed dose protocol, this study will analyze the safety and efficacy of fixed versus variable dosing regimens.  

**Methods:** This study will be submitted to the Institutional Review Board for approval. A list will be obtained from the blood bank of patients who received four factor prothrombin complex concentrate over the course of three years. These patients will be used as the control group for the prospective study portion. This data will also be analyzed to assess the cost effectiveness of the implementation of a fixed dose protocol. Kcentra dispensing will be moved from the blood bank to the pharmacy starting January 1st. Data will be collected from the electronic medical record of patients meeting inclusion criteria after implementation of the fixed dose protocol. Patients will receive a fixed dose of either 1000 or 1500 units based on initial INR. An INR will be drawn thirty minutes after infusion and will determine whether a second dose of Kcentra will be given. Physicians will also assess clinical signs and symptoms of bleeding and use clinical judgment to determine the need for a second dose. As patients are treated with 4F-PCC, the primary investigator will look at chart data to obtain necessary information. Data will then be analyzed and compared to the control group for the primary and secondary endpoints. The primary endpoint is the proportion of patients reaching a post-infusion target INR of less than 2.0.

Poster Title: Impact of an integrated approach to antimicrobial stewardship with rapid diagnostics in a multi-hospital health system

Primary Author: Shelby Shemanski, Saint Luke's Hospital, MO; Email: sshemanski@saint-lukes.org

Additional Author(s):
Nick Bennett
Sarah Boyd
Cindy Essmeyer
Donna Buchanan

Purpose: Antimicrobial overuse significantly burdens health care systems, accentuating the value of antimicrobial stewardship programs. In 2015, the Antimicrobial Stewardship Program (ASP) was launched at Saint Luke’s Health System (SLHS) concurrently with two new rapid diagnostic microbiology technologies which dramatically decrease time from culture collection to pathogen identification (ID). The aim of this study is to determine if integrating ASP personnel with rapid ID technologies results in improved outcomes for patients who had positive blood cultures during their hospitalization.

Methods: The study was supported through the SLHS Innovation Center and was deemed exempt by the Investigational Review Board. Previously, microbiology staff would call positive blood culture results to the floor nurse, who then contacted the attending physician. A new process change was adopted in June 2016, which consists of microbiology staff communicating positive blood culture results to an ASP member or other SLHS pharmacist. The pharmacist is expected to interpret the results, analyze local antibiograms, assess patient-specific information and subsequently relay that information to the appropriate physician. The goal of this process change was to leverage the expertise of the ASP members or SLHS pharmacists to maximize outcomes for patients, streamline communication, and decrease unnecessary antimicrobial use. In addition, the process change minimizes nurse interruptions which allows them to devote more time to their patients. Process and outcome measures for patients after the start of this process will be compared to a pre-intervention group who had positive cultures between August-December in the years 2013 and 2014. Primary outcomes include time to appropriate
therapy and optimal antimicrobial therapy. Secondary outcomes are numerous, but focus on clinical, process, and fiscal impacts of the updated blood culture communication process.

**Results:** Data collection currently ongoing at time of abstract submission.

Poster Title:
Assessing albumin use in intradialyic patients

Primary Author: Blake Baumann, Saint Luke's Hospital, MO; Email: blakewbaumann@gmail.com

Additional Author(s):
Scott Aldridge
Mark Woods

Purpose: Currently there are unclear indications and evidence for the appropriate use of albumin in intradialyic patients. The objective of this study is to evaluate the usage of albumin for intradialyic patients experiencing intradialyic hypotension (IDH) at Saint Luke’s Hospital and identify areas for improvement for albumin utilization during dialysis.

Methods: This study will be submitted to the Institutional Review Board for approval. A literature search will be conducted for recommendations for treatment of intradialyic hypotension (IDH). This study is a retrospective observational analysis. A drug utilization report from an electronic medical record will be used to identify all doses of albumin administered during dialysis from 3/1/2016 to 9/1/2016 at Saint Luke’s Hospital. The electronic medical record will be used to collect following data: percentage of patient dialysis sessions in which albumin was used, the percentage of dialysis sessions in which crystalloids were used, hemodynamic interventions used prior to giving albumin, mean dose of albumin used, mean systolic blood pressure and mean arterial pressure prior to albumin administration and the time from start of dialysis to albumin administration. All information gathered will maintain patient confidentiality.

**Poster Title:** Optimizing medication distribution through use of EHR medication messages

**Primary Author:** Michael Starling, Saint Luke's Hospital, MO; **Email:** mstarling22@gmail.com

**Additional Author(s):**
Jeffrey Little

**Purpose:** Pharmacy is frequently contacted for questions regarding medication dispensing and distribution of patient doses. The vast majority of patient doses are dispensed and distributed in accordance with pharmacy workflow. However, unanticipated difficulties do occur, resulting in unintended stock-outs of unit based automated dispensing cabinets and misplacement of delivered medications. This quality improvement project is designed to improve the medication use process.

**Methods:** Recently, Saint Luke’s implemented “missing dose” medication messages within the electronic health record to enhance nursing communication to pharmacy regarding missing medications. This communication allows the pharmacy to prioritize these medication requests and distinguish them from medication refills which are sent via the “request dose” message, and also allows for aggregation of missing dose data to look for trends and investigate possible solutions. The purpose of this quality improvement project is to improve internal processes regarding pharmacy medication distribution at Saint Luke’s Hospital. This project aims to improve pharmacy medication distribution by obtaining data generated by the use of these medication messages, analyzing trends, and making process improvements.

We will look to identify trends based on medication, hospital unit or period of day. We will then look to make changes based on identified trends and improve the medication use process, medication distribution workflow, and ultimately decrease the frequency of missing medications. Baseline data included will be the frequency of medication messages in the “missing medication” category. Collaboration with nursing unit managers is essential to promote proper use of the “missing medication” identifier on nursing units. Within this data we will stratify based on specific medication, hospital unit or period of day. Outcomes from this project will ideally improve pharmacy distribution practices and improve pharmacy-nursing collaboration.

Poster Title: Utilizing an electronic health record to improve pneumococcal vaccination rates

Primary Author: Theresa Lockwood, Saint Luke's Hospital, MO; Email: tlockwood@saint-lukes.org

Additional Author(s):
Jill Robke
Mark Woods

Purpose: The Centers for Disease Control and Prevention's Advisory Committee on Immunization Practices (ACIP) recommends vaccination of patients at risk for invasive pneumococcal disease. Indications for vaccination include age and certain underlying medical conditions. The purpose of this study is to improve pneumococcal vaccination rates.

Methods: A forcing function will be developed and integrated into the electronic health record that will alert the nurse that the patient has an active order for a pneumococcal vaccine that needs to be administered prior to discharge. Data collected from the electronic health record server will include: patient age, medication administration record (MAR) status, vaccine billing code, and reimbursement amount. Random sampling will be done to assess the current electronic screening algorithm that is being used. A chart review will be completed and pneumococcal vaccine orders will be classified as either appropriate or inappropriate depending on the patient’s indication.

**Poster Title:** Pharmacist interventions in the emergency department and associated medication error prevention and cost avoidance

**Primary Author:** Lynsee Lanners, Saint Luke's Hospital, MO; **Email:** llanners@saint-lukes.org

**Additional Author(s):**
Stephanie Burton
Tyler Barnes
Lindsay Massey

**Purpose:** The role of an emergency department pharmacist is crucial in medication safety as pharmacists are known to optimize medication therapy. The primary objective of this project is to describe medication error prevention associated with pharmacist interventions in the emergency department, and the secondary objectives are to evaluate cost avoidance associated with each type of intervention and assess the number of interventions associated with pharmacist order review.

**Methods:** Pharmacist interventions will be documented in the electronic medical record, EPIC software, by using a customized intervention that will be designed for use by pharmacists only in the emergency department. The intervention (I-vent) has customizable fields for pharmacists to fill out relating to each intervention made. When a pharmacist makes an intervention the name of the I-vent will be Emergency Department and there will be an option to click on subtype and a list of categories will be available to choose from. Examples of subtypes include therapeutic recommendation, adverse drug event prevented, drug incompatibilities, medication error prevented, clarifying medication histories, formulary interchange, dosage adjustment, toxicology, clarifying allergy information, and drug-drug or drug-disease interactions. Based on the type of intervention made there will be a field of the I-vent for the pharmacist to put whether the intervention was accepted, and a value category to associate the cost avoided with each intervention. All data extracted from the I-vent will be recorded without patient identifiers. An I-vent report will be generated into an EXCEL spreadsheet. The data will be used to describe medication error prevention and evaluate cost avoidance associated with different types of I-vents documented by pharmacists in the emergency department.

**Poster Title:** Evaluation of parenteral calcitonin in hypercalcemia treatment at a community hospital  
**Primary Author:** Kari Righter, Southeast Hospital, MO; **Email:** kari.arellano@yahoo.com  
**Additional Author (s):**  
Karen Woomer  
Donald Moore  

**Purpose:** Hypercalcemia is a laboratory abnormality that can present with renal, neurological, and cardiac symptoms. Common etiologies of hypercalcemia include malignancy and primary hyperparathyroidism. Aggressive hydration and bisphosphonate therapy are mainstays of hypercalcemia treatment. Calcitonin inhibits osteoclast resorption and can quickly lower serum calcium until the onset of bisphosphonate therapy. Calcitonin use should be reserved for patients experiencing symptomatic hypercalcemia and limited to 48 hours of treatment due to tachyphylaxis. The purpose of this medication use evaluation is to assess parenteral calcitonin use at a community hospital.  

**Methods:** A retrospective, single center chart review was performed at a 266-bed community hospital. Using the electronic medical record, all patients who received at least one dose of parenteral calcitonin between the dates 01/01/13 and 08/01/16 were reviewed. No patients were excluded for any reason in this analysis. Patient demographics collected include age, weight, gender, hypercalcemia symptoms, serum corrected calcium, and creatinine clearance. Data collected pertaining to the use of calcitonin incudes indication, dose, duration, prescriber service, and use of other hypercalcemia treatments, such as intravenous hydration and bone modifying agents. The primary end point was the utilization of calcitonin for symptomatic hypercalcemia. Secondary endpoints include dose appropriateness and duration of calcitonin as well as calcitonin use in relation to other hypercalcemia treatment modalities. Descriptive statistics will be applied to analyze primary and secondary endpoints.

Poster Title: Drug usage review for nonionic iodinated contrast media in cardiac catheterization procedures.

Primary Author: Jessica Brinkmeyer, Southeast Hospital, MO; Email: jkbrinkmeyer@gmail.com

Additional Author(s):
Susan Boswell
Nicole Allcock

Purpose: Iodinated contrast agents (ICA) are used for opacification of vascular structures in cardiac catheterization procedures. There are two nonionic ICAs on formulary, Visipaque™ (iodixanol) and Omnipaque™ (iohexol). Iodixanol is costlier and utilized more often compared to iohexol. The purpose of this drug usage review is to apply a newly developed ICA screening questionnaire to patients that underwent a cardiac catheterization procedure where iodixanol was utilized, and to use the results to identify patients that could have safely and appropriately received iohexol. Comparative cost savings will be calculated to support implementation of screening questionnaire prior to ICA administration for cardiac catheterization.

Methods: Patients must have received iodixanol to be included in this retrospective drug usage review. Patients in whom the amount of contrast was not documented will be excluded. Data will be gathered from electronic medical records. The following data will be collected: patient age, gender, race, weight, height, dose and type of contrast, allergies, if patient received additional hydration, serum creatinine pre- and post- ICA, glomerular filtration rate, metformin use, history of asthma, multiple myeloma, diabetes mellitus, cardiovascular disease (angina, congestive heart failure, severe aortic stenosis, primary pulmonary hypertension, severe cardiomyopathy), and chronic kidney disease. No patient identifiers will be recorded on data collection sheet. Patient medical record number cross-reference list will be kept in a password protected excel document. Descriptive analysis will be performed to determine the primary outcome of the percentage of patients who could have received iohexol instead of iodixanol, and the associated cost savings. Secondary outcomes will use descriptive analysis to determine the average amount and cost of iodixanol used and wasted per procedure, and if an average amount of iohexol can be determined for various procedures.

**Poster Title:** An evaluation of antibiotic administration time in febrile neutropenic patients  
**Primary Author:** Melissa Bien-Aime, SSM HEALTH SAINT LOUIS UNIVERSITY HOSPITAL, MO;  
**Email:** melissa.bien-aime@ssmsluh.com

**Additional Author(s):**  
Susan Woelich  
Janet Laquet  
Ashley Reller

**Purpose:** Over 80% of neutropenic patients with hematologic malignancies receiving chemotherapy will develop fever that can often be associated with infection. IDSA recommends urgent administration of an antipseudomonal antibiotic in every febrile patient with neutropenia. SSM Health Saint Louis University Hospital’s Institution Specific Protocol states that an antipseudomonal antibiotic should be initiated within 1 hour of fever spike in a neutropenic patient. The objective of our study is to conduct an institutional quality measure analysis of initial antipseudomonal antibiotic administration time in patients on the hematology or bone marrow transplant services who developed febrile neutropenia during their admission.

**Methods:** This study is a retrospective chart review of patients aged 18 years or older with hematologic malignancy or post blood marrow transplantation, an absolute neutrophil count (ANC) of less than 500 cells/mm3, and a fever greater than 38 degrees Celsius. Previous studies have been conducted to assess antibiotic administration in febrile neutropenic patients but were more inclusive of patients admitted through the emergency department or a clinic. This study will be excluding patients admitted through the emergency department or clinic, have a solid malignancy, or received an antibiotic escalation prior to fever. The primary outcome of this study is to assess adherence to institution specific protocol of initiating an antipseudomonal antibiotic within 1 hour of fever spike. Secondary outcomes will include adherence to institutional specific protocol of obtaining cultures during the initial assessment, sources of the delay in initiation of an antipseudomonal antibiotic, and death from infection during admission. Demographics on sex, age, malignancy, temperature, ANC, respiratory rate, pulse, blood pressure, and antibiotic ordered will be collected. Other data points on the number of cultures, death during admission, time of fever, cultures, antipseudomonal antibiotic
administered, pharmacy verification timing, and the use of other antibiotic administrations will also be collected. This study will be submitted to the St. Louis University Institutional Review Board for approval.

**Poster Title:** Time is of the essence; evaluation of treatment courses when vancomycin is dosed every 18 hours.  

**Primary Author:** Daphne Goewey, SSM Health St Mary's Hospital, MO; **Email:** daphne.goewey@ssmhealth.com  

**Additional Author(s):**  
Davina Dell-Steinbeck  
Krista Harry  

**Purpose:** The purpose of this study is to examine the patient population that has required a dosing interval of every 18 hours to validate this dosing regimen and see if recommendations can be made for initiating a dosing interval of every 18 hours based on patient characteristics.  

**Methods:** This study has already been submitted to and approved by the internal review board. The electronic medical record system will be used to identify adult patients who have received intravenous vancomycin administered every 18 hours. All adult patients between the ages of 18 and 89 who received a dose of intravenous vancomycin administered every 18 hours between August 1, 2013 and July 31, 2016 will be eligible for inclusion. Patients over the age of 89, those on hemodialysis, those who are pregnant, patients receiving continuous infusion vancomycin therapy, patients whose vancomycin troughs were not monitored, and subsequent visits of patients who were previously on q18 vancomycin dosing will be excluded. For the purposes of assessing primary and secondary outcomes the following patient data will be gathered: disease indication, gender, age, creatinine clearance, weight, race/ethnicity, vancomycin trough levels, number of vancomycin doses received, and milligrams of vancomycin in each dose. All data will be collected without patient identifiers and will remain confidential. Analysis will be conducted using descriptive statistics. The primary outcome will be number of patients subtherapeutic, therapeu, and supratherapeutic after receiving q18 vancomycin dosing based on trough levels. Secondary outcomes will include: number of patients who were mildly (21-25), moderately (26-30), or severely (>30) supratherapeutic based on trough levels and toxicity associated with vancomycin use.

**Poster Title:** Evaluation of an argatroban protocol regarding efficacy, safety, and appropriateness of use

**Primary Author:** Sarah Cook, SSM Health St. Mary’s Hospital, MO; Email: sarah.cook@ssmhealth.com

**Additional Author(s):**
Brian Rodden
Davina Dell-Steinbeck

**Purpose:** Over one year ago, the SSM Health St. Louis Network implemented a new argatroban dosing protocol with the intention of improving safety and efficacy outcomes associated with argatroban use. The purpose of this retrospective chart review is to evaluate the use of argatroban at five hospitals within the SSM Health St. Louis Network in order to assess its efficacy, safety, and appropriateness of use.

**Methods:** IRB approval was obtained in September 2016. The electronic medical record system will be queried to identify all patients aged 18 or older within the five included hospitals who received argatroban between August 1, 2015 and July 31, 2016. All individuals with an aPTT goal within the protocol defined range will be included. The primary investigator will collect the following data from the patients’ medical records: medical record number, age, diagnosis for argatroban use, baseline lab values (aPTT, PT, INR, AST, ALT, albumin, SCr, BMI), dosing nomogram used (standard for BMI less than 30, standard for BMI greater than or equal to 30, critical care/hepatic impairment), initial argatroban dose, time to goal aPTT, whether or not aPTT was supratherapeutic prior to goal, number of dose adjustments to attain goal aPTT, dose at goal, deviations from protocol, and adverse effects related to bleeding and thrombosis. Descriptive statistics will be utilized to analyze the data so they can be compared to safety and efficacy endpoints reported in primary literature. The primary efficacy endpoints will be time to goal aPTT and rate of new or extended thrombosis. The primary safety endpoint will be the rate of major bleeding as defined by the International Society on Thrombosis and Haemostasis. Compliance rates with the protocol, including appropriate nomogram selection and average number of deviations from protocol, will also be assessed.

Poster Title: Evaluation of tranexamic acid in trauma patients receiving massive transfusion at an academic medical center

Primary Author: Melissa Gaul, SSM Saint Louis University Hospital, MO; Email: melissa.gaul@ssmsluh.com

Additional Author(s):
Julia Alexander
Stacy Revelle
Carl Freeman
Brian Draper

Purpose: Trauma patients are at an increased risk of coagulopathy and hyperfibrinolysis, and approximately one third of trauma-related in-hospital deaths can be attributed to hemorrhage. Tranexamic acid has a proven mortality benefit in these patients, though it has not been specifically studied in patients requiring massive transfusion. Additionally, previous studies have not included thromboelastography as a measure of fibrinolysis to guide use of tranexamic acid. This study will attempt to evaluate the use, efficacy, and safety of tranexamic acid in patients requiring massive transfusion at an academic Level 1 trauma center.

Methods: This retrospective study has been submitted to the Institutional Review Board for approval. The primary outcome will be administration of tranexamic acid in massive transfusion according to the defined clinical parameters of the CRASH-2 trial: heart rate greater than 110 beats per minute or systolic blood pressure less than 90 mmHg. Additionally, thromboelastography will be included to measure fibrinolysis. The secondary outcomes will be mortality and adverse effects in patients receiving tranexamic acid versus those who did not. Patients aged 18-89 years old for whom massive transfusion protocol was activated from October 2013 through October 2016 will be included. Patients receiving tranexamic acid for indications other than trauma and those with preexisting clotting disorders will be excluded. A list of trauma patients for whom massive transfusion protocol was ordered will be obtained from hospital blood bank records, and will be separated into patients who received tranexamic acid versus those who did not. Data points collected will include patient demographic data (age, sex, prior anticoagulant or antiplatelet therapy), injury characterization (trauma type, incidence
of traumatic brain injury, Glasgow Coma Score, injury severity score, heart rate, systolic blood pressure, temperature, blood pH, LY30 value on thromboelastography), timing of tranexamic acid administration, incidence of various interventions (blood, fresh frozen plasma, cryoprecipitate, prothrombin complex concentrate, factor VII, surgical intervention, and patient outcomes (30 day mortality, vascular occlusive events).

Session-Board Number: 12-052

Poster Title: Effect of inhaled epoprostenol on clinical outcomes for refractory hypoxemia in patients with acute respiratory distress syndrome

Primary Author: Rosanna Yuen, SSM Saint Louis University Hospital- PGY-2 Critical Care Pharmacy, MO; Email: rosanna.yuen@ssmsluh.com

Additional Author (s):
Robert Sbertoli
Elizabeth Gau

Purpose: Acute respiratory distress syndrome (ARDS) is a life threatening lung injury that has been primarily managed by supportive interventions such as mechanical ventilation utilizing low tidal volume and prone position. Inhaled epoprostenol is a pulmonary vasodilator that has been proposed as a salvage therapy in patients with refractory hypoxemic ARDS. The current available studies with epoprostenol have focused on measuring surrogate outcomes such as improvement in oxygenation. The objective of this study is to determine if there is a difference in days of mechanical ventilation and other clinical outcomes in patients with ARDS receiving inhaled epoprostenol versus standard care.

Methods: A retrospective cohort study utilizing electronic medical record will be performed on patients with a diagnosis of ARDS utilizing inhaled epoprostenol or standard of care from October 2014 to August 2016. Patients between 18 to 89 years of age admitted to intensive care units who require mechanical ventilation with a PaO2/FiO2 150 mm Hg or lower and receive at least 4 hours of inhaled epoprostenol will be included. Patients who received any dose of inhaled nitric oxide or had documented intracranial hemorrhage will be excluded from this study. The primary outcome is mechanical ventilator-free days. Secondary outcomes include change in PaO2/FiO2 ratio, in-hospital mortality, ICU length of stay and rebound hypoxemia. This study will be submitted to the local Institutional Review Board for approval.

Poster Title: Influence of diastolic dysfunction on renal insufficiency in acute decompensated heart failure treated with intravenous loop diuretics

Primary Author: Patrick Baldwin, SSM-Saint Louis University Hospital, MO; Email: patrick.g.baldwin@gmail.com

Additional Author(s):
Michael Daly
Joseph Van Tuyl

Purpose: Approximately half of patients admitted with acute decompensated heart failure (ADHF) have heart failure with preserved ejection fraction (HFrEF). Dosing strategies of intravenous (IV) loop diuretics in ADHF were studied in patients with heart failure with reduced ejection fraction (HFrEF) and have not been robustly studied in patients with HFpEF. Patients with diastolic dysfunction require higher ventricular filling pressures to maintain cardiac output. Current diuretic strategies may decrease stroke volume and cause worsening renal function (WRF) in HFpEF. This study will assess the effect of diastolic dysfunction on WRF in ADHF requiring IV loop diuretics at an academic medical center.

Methods: Using International Classification of Disease (ICD) codes and the electronic medical record, a retrospective chart review will examine the hospital course of patients admitted for ADHF with HFrEF (ejection fraction less than 40 percent) and HFpEF (ejection fraction greater than or equal to 50 percent). Inclusion criteria include age at least 18 years, administration of IV loop diuretics within 24 hours of admission, and a primary admission diagnosis of ADHF. Baseline demographics, comorbidities, echocardiographic parameters, and medications will be collected at the time of admission. Data collected will include loop diuretic doses, serum creatinine, weight, and urine output from admission through 72 hours. This study has been submitted to the Institutional Review Board for approval. All data will be collected without identifiers for confidentiality. The primary endpoint is the incidence of WRF defined as an increase in serum creatinine of 0.3 mg/dL or greater within 72 hours of hospital admission. This endpoint will be compared between patients with HFrEF and HFpEF. Secondary endpoints will include changes in weight and total urine output over 72 hours. A pre-specified post-hoc analysis will compare the
incidence of WRF among patients with HFrEF to patients with advanced stages of diastolic dysfunction.

Poster Title: Validation of a bivalirudin adjustment algorithm in pediatric patients

Primary Author: Caitlyn Luecke, St. Louis Children’s Hospital, MO; Email: cxm0649@bjc.org

Additional Author(s):
Jennifer Wolff
Kara Kniska
Christopher McPherson

Purpose: This retrospective chart review is being conducted to evaluate the validity of the bivalirudin adjustment algorithm currently utilized at St. Louis Children’s Hospital for target level attainment in pediatric patients.

Methods: Study procedures were approved by the Institutional Review Board of Washington University in St. Louis. Patients who received bivalirudin continuous infusion for anticoagulation at St. Louis Children’s Hospital (SLCH) between January 1, 2010 and July 15, 2016 were identified using the St. Louis Children’s Hospital electronic medical record. Retrospective chart review of such patients will be conducted to evaluate the validity of the bivalirudin adjustment algorithm currently utilized at SLCH. Charts will be evaluated for bivalirudin course including the documented reason for use of bivalirudin, initial bivalirudin dose, bivalirudin dose adjustments and duration of treatment as well as monitoring parameters at baseline and throughout bivalirudin course including D dimer, complete blood counts, activated clotting time, activated partial thromboplastin time, prothrombin time, thromboelastography studies and documentation of bleeding. These data will be evaluated to determine the validity of the currently utilized bivalirudin adjustment algorithm for target level attainment and incidence of complications.

Poster Title: Evaluation of an oral posaconazole dosing regimen in pediatric patients less than 12 years of age

Primary Author: Kristin Bettger, St. Louis Children’s Hospital, MO; Email: kxb1226@bjc.org

Additional Author(s):
Miranda Nelson
Christopher McPherson

Purpose: Posaconazole use for treatment and prophylaxis of invasive fungal infections presents many challenges in the pediatric population less than 12 years old due to lack of universally accepted dosing recommendations, increased pharmacokinetic variability, and increased difficulty in obtaining target trough concentrations. The current dosing recommendation at St. Louis Children's Hospital is 9 mg/kg/dose with a maximum dose of 200 mg. The purpose of this study is to determine the percentage of pediatric patients less than 12 that were able to reach target trough levels with the current dosing strategy utilized.

Methods: This study is a retrospective chart review of patients less than 12 years of age that received posaconazole oral suspension at St. Louis Children’s Hospital between June 2006 and June 2016. Patients will be identified using the electronic medical record system. Patient information collected will include demographics, posaconazole regimen and trough concentrations, hepatic enzymes before and after therapy, and concomitant medications. Descriptive statistics will be utilized to evaluate the primary outcome of percentage of patients receiving posaconazole therapy that achieve target trough concentrations with the current dosing strategy. The Mann-Whitney U test and Fisher’s exact test will be used to compare differences in continuous and binomial variables, respectively, between patients who achieved target trough concentrations and those who did not.

**Poster Title:** Retrospective evaluation of the impact of group education classes on glycemic control

**Primary Author:** Kacie Kuehn, St. Louis College of Pharmacy and St. Louis County Department of Public Health, MO; **Email:** kacie.kuehn@stlcop.edu

**Additional Author (s):**
Justinne Guyton

**Purpose:** Patients with low health literacy benefit from individual diabetes management including education. There is a gap in current literature on the glycemic effects of group diabetes education classes. The St. Louis County Department of Public Health (DPH) serves a primarily indigent population of patients at risk for low health literacy. The clinical pharmacy team has initiated a group diabetes education class that includes general diabetes knowledge, checking blood sugar, and medication adherence counseling. The objective of this study is to determine if group diabetes education class in addition to standard of care reduced A1c compared to standard of care alone.

**Methods:** This study will be submitted for Institutional Review Board approval. The primary outcome of this study is change in hemoglobin A1c from baseline. Patients will be manually identified if they are English speaking adults at least 18 years of age with type 1 or type 2 diabetes, a recent A1c, and a medication therapy services referral to the clinical pharmacy team at the DPH between September 1 and December 31, 2016. Patient data will be separated based on past attendance at a group diabetes education class between September 1 and December 31, 2016 and those that did not attend any education classes. Patients will be excluded if they attended a diabetes education class at an outside facility or if they have a pre-existing diagnosis of severe cognitive impairment. The following data will be collected: hemoglobin A1c in the 3 months prior to the class, A1c 3 months post class, satisfaction with care received, age, gender, race, height, weight, diabetes type, diabetes regimen, Newest Vital Sign score, REALM-SF score, highest level of education achieved, duration of diabetes, history of hypertension, dyslipidemia, coronary artery disease, and diabetes complications, alcohol use, and tobacco use.

**Poster Title:** Evaluating the impact of pharmacist intervention in osteoporosis management  

**Primary Author:** Brandi Bowers, St. Louis College of Pharmacy/Mercy Hospital, MO; **Email:** brandi.bowers@stlcop.edu  

**Additional Author(s):**  
Shefali Barot  
Amy Drew  

**Purpose:** The American Association of Clinical Endocrinologists osteoporosis guidelines identify patients with high fracture risk as candidates for antifracture therapy. However, rates of antifracture therapy initiation and continuation in high-risk patients are consistently identified as inadequate in literature, leading to economic and clinical sequelae. Pharmacist intervention has been shown to increase patients’ osteoporosis knowledge and compliance with clinical guidelines in small populations and over short study periods. The objective of this retrospective study is to evaluate the impact of pharmacist intervention on antifracture therapy initiation rates in a larger cohort of high-risk patients in a family medicine clinic over eight years.  

**Methods:** This study will be submitted to the Mercy Hospital St. Louis and St. Louis College of Pharmacy Institutional Review Boards for approval. The primary outcome of this study is the difference in rates of initiation or continuation of antifracture therapy in female patients over 65 years of age with high fracture risk managed with pharmacist intervention versus those managed by physicians without pharmacist intervention. Secondary outcomes include measures of compliance with osteoporosis guidelines including percent of patients initiated on therapy after fracture and rates of vitamin D and calcium supplementation; measures of efficacy including change in bone mineral density and classification as osteoporotic or osteopenic; and measures of patient adherence including duration of potential exposure and discontinuation rates at six, twelve, and twenty-four months. Patients with a dual-energy x-ray absorptiometry (DXA) scan between June 1, 2008 and June 1, 2016 will be identified by the electronic medical record system, and patients’ study group will be determined by the presence or absence of pharmacy referral at the time of first DXA. Data collection will include baseline demographics; DXA date and results for initial DXA and each subsequent DXA; documented FRAX scores; height and weight; current medications and problem list at time of DXA; vitamin D
and thyroid-stimulating hormone levels within twelve months prior to DXA; alcohol and tobacco use; and antifracture therapy refill authorization history.

**Poster Title:** Single-institution comparison of four-factor prothrombin complex concentrate versus fresh frozen plasma

**Primary Author:** Teri McElheny, St. Louis College of Pharmacy/Mercy Hospital St. Louis, MO; Email: teri.mcelheny@stlcop.edu

**Additional Author(s):**
Matthew Korobey
Carmen Smith

**Purpose:** Four-factor prothrombin complex concentrate (4-FPCC) emergently reverses warfarin-induced coagulopathy by increasing vitamin K-dependent coagulation factors VII, IX, X, II, and proteins C and S. It is thought to be as effective as fresh frozen plasma (FFP) with fewer side effects. While the approved 4-FPCC in the United States has been compared to FFP in randomized controlled trials, it has not been evaluated in a real-world scenario. The purpose of this study is to further knowledge about the efficacy and safety of 4-FPCC and its use in clinical practice by comparing it to FFP.

**Methods:** This study will be submitted to the Institutional Review Board for approval. The study will be a retrospective cohort analysis of patients 18 years or older who received 4-FPCC or FFP for the reversal of warfarin-induced coagulopathy from August 1, 2013 through November 30, 2016. Patients who received 4-FPCC will be identified through a previously developed study registry. Patients who received FFP will be identified via electronic medical records and randomly matched with patients who received 4-FPCC within the same time period. The primary outcome will be the percent of patients who achieve an INR of less than or equal to 1.3 at 30 minutes after completion of 4-FPCC or FFP infusion. Secondary outcomes include length of hospital stay, number of units of packed red blood cells required within 48 hours of administration of 4-FPCC or FFP, vitamin K administration, and the change in INR from baseline to next INR draw. Safety outcomes that will be assessed are volume status within 24 hours after administration of 4-FPCC or FFP, incidence of thrombotic events, and incidence of transfusion related acute lung injury within 48 hours after administration. Chi-square or Fisher’s exact test will be used for all categorical data and Student t-test or Mann-Whitney U for parametric and nonparametric data, respectively.

Poster Title: Impact of an interdisciplinary pharmacist-driven weight loss service: a pilot study

Primary Author: Sara Twillmann, St. Louis College of Pharmacy/Mercy Hospital St. Louis, MO;
Email: sara.twillmann@stlcop.edu

Additional Author(s):
Jamie Pitlick

Purpose: Weight loss has several beneficial effects. Even a loss of five percent can improve overall health outcomes. The American Heart Association/American College of Cardiology guidelines recommend an initial weight loss goal of five to ten percent within six months using a comprehensive lifestyle program focused on diet modification and exercise. If that weight loss goal is not met in six months, pharmacotherapy may be warranted. Limited literature is available assessing interdisciplinary weight loss services combining the work of pharmacists and dieticians. This study will help to determine the effect of an interdisciplinary, pharmacist-driven weight loss service compared to standard care.

Methods: This study will be submitted to the Institutional Review Board for approval. This study will compare two cohorts of patients with a body mass index (BMI) greater than 27 kg/m2 with at least one co-morbid condition or greater than 30 kg/m2. One group is managed by an interdisciplinary healthcare team, including a pharmacist; the other group is receiving standard weight loss care. The primary outcome is to determine the percent change weight loss in each group at six months. Using ICD-10 codes and referrals to the pharmacist-driven weight loss program at the Mercy Hospital outpatient clinic, adult patients who meet BMI eligibility will be identified via electronic medical records. Patients will be matched according to timing of follow-up office visits. The following data will be collected: age, gender, weight, height, race, smoking status, blood pressure, dietician visit history, hemoglobin A1c, lipid panels, thyroid stimulating hormone, and medications or co-morbidities that may affect weight or metabolism. Data will be collected retrospectively from each office visit in both groups. If patients in the pharmacist-driven group have not met their five percent weight loss goal in six months, pharmacotherapy with lorcaserin or liraglutide may be initiated. Due to clinic policy, only patients in the pharmacist-driven group are eligible to receive pharmacotherapy.

**Poster Title:** Developing a pilot study for evaluating appropriate sodium polystyrene sulfonate use with a hyperkalemia order set

**Primary Author:** Zachary Mueller, St. Louis College of Pharmacy/Mercy Hospital St. Louis, MO; **Email:** zachary.mueller@stlcop.edu

**Additional Author (s):**
Andrew Crannage

**Purpose:** No consensus guidelines exist to assist practitioners in treating hyperkalemia. Many medications can induce hyperkalemia, including several that have long-term morbidity and mortality benefits. Sodium polystyrene sulfonate, a cation-exchange resin, is a common treatment option for elevated potassium. The inappropriate use of sodium polystyrene sulfonate may lead to potassium over correction, electrolyte disturbances, other serious adverse effects, and death. The objective of this study is to determine if the utilization of a hyperkalemia order set impacts the appropriate use of sodium polystyrene sulfonate.

**Methods:** This study will be submitted to the appropriate Institutional Review Boards for approval prior to commencement. Patients who received a dose of sodium polystyrene sulfonate will be identified from the electronic medical record and Vigilanz software. Study subjects will comprise two groups: those who received treatment from the hyperkalemia order set and those who received treatment not from an order set. The primary outcome will be the absolute difference in the proportion of patients with appropriate sodium polystyrene sulfonate between the two groups. Appropriate use will be defined as potassium level greater than or equal to 5.5 mEq/L prior to administering sodium polystyrene sulfonate for patients with no contraindications to use, including: hypokalemia (less than 3.5 mEq/L), history of hypersensitivity to polystyrene sulfonate resins, and/or obstructive bowel disease. Data including, age, sex, race, creatine clearance, potassium, sodium, blood glucose, magnesium, temperature, heart rate, blood pressure, respiratory rate, oxygen saturation, weight, electrocardiogram, height, body mass index, dose of sodium polystyrene sulfonate, medications that affect potassium, disease states, length of stay, mortality, and symptoms will all be collected.

Poster Title: Outpatient management of low-risk venous thromboembolism (VTE) in patients presenting to a Level I trauma center in an urban emergency department

Primary Author: Kerra Cissne, Truman Medical Center, MO; Email: kerra.cissne@tmcmd.org

Additional Author(s):
Tony Huke
Jeremy Hampton

Purpose: Novel oral anticoagulants (NOACs) are approved for the treatment of acute deep venous thrombosis (DVT) and pulmonary embolism (PE), yet patients are typically admitted to the hospital even when treated with the single oral agents rivaroxaban and apixaban. The purpose of this study is to establish screening criteria for patients presenting to the emergency department with low-risk venous thromboembolism and to create a protocol for outpatient treatment. Patients will be followed to determine rates of major bleeding and subsequent hospital admission secondary to complications arising from therapy. This study will also assess predicted annual cost savings for decreased unnecessary admissions.

Methods: A protocol will be developed to identify patient presenting with pulmonary embolism or deep venous thrombosis classified as low-risk and eligible for outpatient treatment. This will be based on the pulmonary embolism severity index (PESI) criteria and provider assessment. The protocol will identify relevant clinical and social factors that may preclude outpatient management. Physicians will be provided guidance regarding recommended options for initial therapy with attention being given specifically to the patient’s individual financial, social and payer source situation. This protocol will be submitted to the Institutional Review Board at Truman Medical Centers for corporate use and will be converted to an electronic order set for utilization during routine order entry. Providers will be educated on this process, and will be provided with the opportunity to ask questions. Patients will be referred to the anticoagulation clinic for follow up care. Patients will be monitored for reported major bleeding or admission to hospital. A retrospective review will be conducted to determine how many patients from January 1, 2016 to August 1, 2016 would have been eligible for outpatient treatment. This will be annualized to predict a cost-savings for unnecessary admissions.

Conclusion: N/A
**Submission Category:** Critical Care  

**Submission Type:** Research-in-Progress  

**Session-Board Number:** 12-062  

**Poster Title:** Evaluation of the appropriate use of an evidence-based pain and agitation order-set in the intensive care unit  

**Primary Author:** Brear Neff, Truman Medical Center, MO; **Email:** brear.neff@tmcmed.org  

**Additional Author(s):**  
Erin Pender  
Catherine Korte  
Muhammad Javed  

**Purpose:** In 2013 the Society of Critical Care Medicine (SCCM) released a guideline for the management of pain, agitation, and delirium in adult intensive care unit (ICU) patients. In order to provide optimal patient care and reduce adverse events it is essential that the SCCM guideline is followed accordingly. In 2015 an order-set aligned with the current SCCM guideline was implemented at Truman Medical Center. Even when armed with the information present in the literature and an order-set, multiple barriers may inhibit appropriate use. The purpose of this study is to assess adherence to this order-set and identify areas of improvement.

**Methods:** This study is pending approval of the Institutional Review Board at Truman Medical Center (TMC). This is a retrospective study based on data collected from routine hospital records at TMC over a 6-month period of time. Patients will be included if greater than or equal to 18 years old and mechanically ventilated in the ICU greater than 24 hours. Patients will be excluded if they require a deep level of sedation when mechanically ventilated (e.g. targeted temperature management, neuromuscular blockade, elevated intracranial pressure, status epilepticus). The primary endpoint will assess adherence to the order-set by evaluating the use of valid monitoring tools in conjunction with the pharmacologic interventions made. Adherence will be defined as meeting all the primary endpoints 100 percent of the time. The researcher’s hypothesis of this study is that valid monitoring tools and pharmacologic interventions supported by the evidence-based order-set are not being used as directed by the order-set. Secondary endpoints include evaluating areas of improvement by assessing the number of times a different pain scale outside of the order-set was used as well as determining the number of times a sedative medication not a part of the order-set was used. Additional
secondary outcomes include evaluating the impact of the order-set on clinical outcomes including ICU length of stay and length of ventilator days.

**Poster Title:** Implementation and evaluation of a novel vancomycin dosing protocol for morbidly obese patients in an academic medical center

**Primary Author:** Kathryn Burnett, Truman Medical Centers, MO; **Email:** kathryn.burnett@tmcmd.org

**Additional Author(s):**
Sayo Weihs
Tony Huke

**Purpose:** Due to increasing rates of obesity, alternate dosing recommendations are needed in order to provide adequate vancomycin therapy to patients that are morbidly obese. Traditional dosing strategies often result in subtherapeutic vancomycin trough concentrations. Morbidly obese patients have altered pharmacokinetics resulting in increased clearance of vancomycin and increased volume of distribution. There have been different dosing strategies that have been evaluated, but there is still a need for more research on this topic. The objective of this study is to determine the safety and efficacy of a novel vancomycin dosing strategy in morbidly obese patients.

**Methods:** This study will be submitted to the Institutional Review Board for approval. This will be a retrospective study comparing patients meeting inclusion criteria from December 2015 until March 2016 for baseline group and from December 2016 until March 2017 for post dosing strategy implementation group. The following data will be collected: patient age, gender, weight, height, serum creatinine, white blood cells, temperature, vancomycin dose, dose frequency and vancomycin trough concentrations. Ideal body weight, adjusted body weight and creatinine clearance using the Cockcroft-Gault equation will be calculated based on collected data. Patients that will be included must be at least 18 years of age, must have consulted for pharmacy to dose vancomycin, at least one vancomycin trough concentration drawn during maintenance dosing, and ideal body weight percentage of >137%. Patients will be excluded if they have a calculated creatinine clearance of less than 25 ml/min, patients receiving any type of dialysis, unsteady renal function, acute kidney injury, and if vancomycin therapy was initiated at an outside facility. All data will be recorded without patient identifiers and maintained confidentially.

Poster Title: Developing the framework to bill for inpatient pharmacist medication therapy services in an urban acute-care academic center

Primary Author: Samantha Gripka, Truman Medical Centers, MO; Email: samantha.gripka@tmcmed.org

Additional Author(s):
Lauren Mishler
Tony Huke

Purpose: Pharmacists currently have authorization to bill for outpatient cognitive services through medication therapy management (MTM) programs. Contrarily, reimbursement for inpatient pharmacist cognitive services is not yet a nationally established practice. With potential pharmacist “Provider Status” designation in the future, constructing the framework and workflow for inpatient reimbursement will enable inpatient pharmacists to perform, to document, and to bill for services, such as medication reconciliation, and to calculate projected potential reimbursement.

Methods: Researchers will seek approval from the Institutional Review Board. Researchers will build progress note templates containing all of the required elements for documentation and for potential billing into the current electronic medical record (EMR) system. With guidance and approval from the Finance and Compliance Departments, progress notes will link to time-based billing codes. Medication reconciliation will occur, regardless of patient payer status, and will be initiated by physician consult or through the current protocol. Medication lists will be verified utilizing at least two sources to meet The Joint Commission standards. Researchers will contact commercial payers in attempts to establish reimbursement fees. Once the framework is completed, the transitional care pharmacist will begin documenting interventions and interactions with patients using the newly created electronic form. Data collection will analyze the number and types of interventions completed, payer sources, and the amount of potential and actual reimbursement. This data can help project future revenue potential. Additionally, researchers will track other pharmacist cognitive consults and determine the scale of potential revenue generation if this framework is applied to services that are not yet recognized by private payers. One common barrier is lack of pharmacist provider status. The templates for
billing for additional services will be developed in the event that pharmacists are recognized and are able to bill as individual providers.

Sayo Weihs
Tony Huke

**Purpose:** Due to an increased understanding of pharmacodynamic and pharmacokinetic concepts, along with growing rates of antimicrobial resistance, the dosing strategies of many common antibiotics have been evaluated and modified in order to enhance efficacy, limit adverse effects, and reduce unnecessary drug exposure. Several institutions have adopted these alternative dosing methods for meropenem, using more frequent but lower dosing to maximize pharmacodynamic target attainment. The purpose of this study is to assess the clinical and economic outcomes of an alternative meropenem dosing strategy of 500 mg intravenous every 6 hours as compared to traditional methods of dosing.

**Methods:** This retrospective analysis to be submitted for IRB approval will involve adult patients, age 18 years or older, and receiving meropenem for at least 3 days for an appropriate indication. Patients who are pregnant, needing 2 g every 8 hour dosing (cystic fibrosis, febrile neutropenia, or meningitis), or receiving a dose that is too low for their renal function for at least 1 day will be excluded. The analyzed timeframe will be after implementation, October 2016 through January 2017, compared to the same timeframe from the previous year. The following information will be collected by the research team: age, gender, body temperature, meropenem indication, meropenem dosing and duration, concomitant antibiotics, serum creatinine, white blood cell count, use of steroids or antipyretics, seizure incidence, and microbiologic data, if available. Baseline APACHE II scores will also be calculated. The primary end-point for investigation will be meropenem-related length of stay (days from initiation of meropenem until discharge). Secondary outcomes analyzed will include days to normalization of white blood cell count (white blood cell count between 4000 and 10,800 cells per cubic millimeter), and days to normalization of temperature (body temperature below 100.4 degrees Fahrenheit). A cost analysis and a safety analysis of seizure rates between the two groups will
also be conducted. All patient-related data will be de-identified and recorded on a Microsoft Excel spreadsheet.

 Poster Title: Improving care for open-heart surgery patients: decreasing time in the intensive care unit. Retrospective analysis of transitioning patients on stable norepinephrine infusion to telemetry unit.

 Primary Author: Bradley Bingham, Mosaic Life Care - Heartland Regional Medical Center, MO; Email: bradley.bingham@mymlc.com

 Additional Author(s):
 Robert Zink
 Stephanie Lager
 Megan Baumann
 Sara Mills

 Purpose: The purpose of this study is to compare patients who underwent open-heart surgery before and after the use of non-titrated norepinephrine infusions outside the intensive care unit (ICU).

 Methods: A retrospective chart review will be conducted. Outcomes will be compared between the cohort of patients receiving norepinephrine post open-heart for a period of two years prior to lifting the restriction of norepinephrine infusion to the ICU (11/5/10 - 11/5/12) to the cohort of patients receiving norepinephrine post open-heart in the four years since the Pharmacy and Therapeutics committee approved transition of patients receiving a stable rate of norepinephrine to the cardiovascular telemetry unit (11/6/12 - 1/1/16). The primary outcomes will be combined complications directly related to norepinephrine infusion (incidence of hypotension, acute kidney injury, extravasation) and readmission to the ICU. Secondary outcomes to be evaluated include will include 30-day mortality, 30-day readmission to the hospital, days to discharge post-operation, incidence of post-operative atrial fibrillation, survival to discharge and post-operative wound infection.

 Results: In progress.

 Conclusion: In progress.
Purpose: The integration of information technology into hospital pharmacies not only assists with more comprehensive patient assessments and follow-ups, but also helps advance the efficiency of the Antimicrobial Stewardship Program. The objective of this study is to evaluate how well pharmacists can integrate VigiLanz software into their daily clinical activities. The study will also monitor how often software activations result in pharmacist initiated antimicrobial de-escalation or change of therapy in the event of a mismatched organism and antimicrobial agent.

Methods: Education on utilization of VigiLanz will be given to each pharmacist. A one page reference will be provided. A competency will be completed within 3 months by the clinical pharmacists to evaluate their ability to appropriately utilize the software and to ensure continuity between users. In addition, all mismatched organism and antimicrobial agent activations and subsequent interventions will be compiled and evaluated for a period of time after VigiLanz is initiated. Components to be analyzed will include: whether the activation was appropriate, if the pharmacist made any suggestions to the provider, if any pharmacist recommendation was accepted by the provider resulting in a change of antimicrobial therapy, and if a change was already completed by the physician prior to a pharmacist intervention. By evaluating VigiLanz activations and the correlating intervention rate, we can modify and improve the activations triggered by the software to aid in the efficiency of the clinical pharmacists.

Poster Title: Delirium rates in the intensive care unit: An evaluation of mechanically ventilated patients sedated with intravenous ketamine versus dexmedetomidine

Primary Author: Karin Zepf, Billings Clinic, MT; Email: kzepf@billingsclinic.org

Additional Author(s):
Jason Potts
Dax Rice
Michelle Blair
Melanie Townsend

Purpose: Delirium has been associated with sedative use in the intensive care unit (ICU) and has an adverse effect on patient outcomes, including a 3-fold increase in mortality. Previous studies have found that intravenous (IV) dexmedetomidine causes less delirium than midazolam and propofol when used for sedation. However, dexmedetomidine can cause significant hypotension and bradycardia. Ketamine is an alternate sedative with fewer cardiac effects, but its impact on delirium is not well understood. The objective of this study will be to determine the rates of delirium in mechanically ventilated ICU patients receiving continuous IV infusions of dexmedetomidine or ketamine for sedation.

Methods: This single-center, retrospective cohort study will assess the rates of delirium in mechanically ventilated patients who are sedated with ketamine versus dexmedetomidine in a mixed medical-surgical ICU. Included patients will be adults admitted to the ICU for greater than or equal to 24 hours, mechanically ventilated for greater than or equal to 24 hours, receive either IV ketamine or dexmedetomidine as the only continuous infusion sedative for greater than or equal to 24 hours, and have at least 1 Confusion Assessment Method for the ICU (CAM-ICU) screening documented in the electronic medical record during the infusion. Exclusion criteria includes pregnancy or lactation, allergy to ketamine or dexmedetomidine, and a positive CAM-ICU screening before ketamine or dexmedetomidine was initiated. The primary outcome will be rate of delirium, defined by a positive CAM-ICU screen while on the ketamine or dexmedetomidine infusion. Secondary outcomes will include ICU length of stay, days on mechanical ventilation, time to onset of delirium, and duration of delirium (as defined by
positive CAM-ICU scores). Prior to initiation, the study will be submitted to the local institutional review board for approval.

**Poster Title:** Impact of a standardized patient referral process for pharmacist-provided collaborative drug therapy management on access to and quality of care in a primary care clinic

**Primary Author:** Presley Legerski, Billings Clinic, MT; **Email:** plegerski@billingsclinic.org

**Additional Author(s):**
Shannon Puckett
Jeff Freund
Melanie Townsend
Jacki Ulishney

**Purpose:** Collaborative drug therapy management (CDTM) by pharmacists increases patients’ access to high quality care and improves medication-related outcomes using a team-based approach. Comprehensive medication management (CMM) is the process by which this care is delivered and includes assessment of medications by indication, effectiveness, safety, and adherence. The values of providing CMM in the medical home include improved clinical outcomes, increased attention to medications, and saved physician time. The purpose of this study is to increase patient access to care after implementation of a standardized patient referral process to an ambulatory care pharmacist for management of hypertension and diabetes mellitus.

**Methods:** In this prospective, single-center study, a standardized patient referral process will be developed to identify patients who have not met therapeutic goals for diabetes mellitus or hypertension. Patients will be included if they have a hemoglobin A1c greater than or equal to 9 percent or a blood pressure greater than or equal to 150/90 mmHg and attended at least one appointment with a Billings Clinic primary care provider (PCP) during the study period. Patients in the intervention group must also be referred to the primary care pharmacist using the standardized referral process. Patients will be excluded if their PCP is a resident physician. Patients meeting eligibility criteria will automatically be scheduled with the pharmacist to receive CDTM. Patients will then make subsequent appointments with the pharmacist until target hemoglobin A1c and blood pressure goals are met. The primary outcome is the percentage of patients who attended their first appointment with the pharmacist. The secondary outcomes include provider satisfaction with the standardized patient referral
process, patient satisfaction with their care, change in hemoglobin A1c levels, change in blood pressure values, and percentage of patients who do not show up for their appointments. As a quality improvement initiative, approval from the local institutional review board will not be needed prior to initiation.

**Poster Title:** Assessment of venous thromboembolism rates following elective total knee and total hip arthroplasties in patients receiving prophylactic twice daily aspirin

**Primary Author:** Annie Kraatz, Billings Clinic, MT; **Email:** akraatz@billingsclinic.org

**Additional Author (s):**
Cynthia Gary
Melanie Townsend

**Purpose:** Patients who undergo high-risk orthopedic procedures including total knee arthroplasty (TKA) and total hip arthroplasty (THA) are at an increased risk of venous thromboembolism (VTE) following surgery. Cumulative baseline rates for symptomatic deep vein thrombosis and pulmonary embolism for the first 35 days post-op are 2.8% and 1.5%, respectively. The optimal medication for VTE prophylaxis is still debated and data regarding the role of aspirin in VTE prophylaxis is inconsistent. The purpose of this study is to determine VTE rates in patients who underwent elective TKA or THA and who received aspirin 325mg twice daily for VTE prophylaxis following surgery.

**Methods:** This retrospective, single-center cohort study will investigate the rates of VTEs that occurred within 60 days of elective TKA or THA in adult patients receiving aspirin 325 mg orally twice daily for 6 weeks. Patients who were pregnant or breastfeeding, or received a TKA or THA secondary to trauma will be excluded. The primary outcome is the percentage of patients who experienced VTEs following their elective TKA or THA while receiving prophylactic aspirin. Secondary outcomes include rates of symptomatic DVTs and PEs, time to VTE in patients experiencing an event, major bleeding within 60 days post-hospital discharge, rates of VTEs with other prophylaxis regimens, and 60-day all-cause mortality. Prior to initiation, the study will be submitted to the local institutional review board for approval.

**Poster Title:** Formalization of an antimicrobial stewardship program in a small community hospital

**Primary Author:** Alexa Lockwood, Bozeman Health Deaconess Hospital, MT; **Email:** alexalockwood33@gmail.com

**Additional Author(s):**
Nicole Bolton  
Mark Winton  
Jean Carter

**Purpose:** Inappropriate or unnecessary use of antimicrobials has a detrimental impact on the health care system and patient care. Antimicrobial stewardship programs (ASPs) strive to improve patient care through optimization of infection treatment while reducing adverse effects and antimicrobial resistance associated with anti-infective misuse. The IDSA/SHEA developed guidelines for forming ASPs, but data is limited for ASP implementation in small community hospitals. The purpose of this project was to formalize an ASP in a small community hospital then determine the initial impact of ASP pharmacists’ interventions on patient outcomes and costs.

**Methods:** The formalization process began with a gap analysis of the hospital’s antimicrobial program; practice gaps in the hospital were identified by reviewing IDSA/SHEA guidelines for development of an ASP and comparing elements of formalized programs to the hospital. This was followed by the development of a fully integrated, multi-pharmacist ASP service. The impact was studied with an IRB-approved single group pre-post design. Retrospective pre-ASP data were pulled from 2012-2013 patient records; prospective post-ASP data were collected for March 1 to June 30, 2015. Analyses included descriptive and comparison statistics.

**Results:** No significant differences in age, percent of patients on antimicrobials, or LOS were found between the pre and post groups. During the four-month study periods, significant decreases in DDD/1000 patient-days ranged from 4.6% (p=0.12) for all antimicrobials to 30.2% (p < 0.001) for the 18 most frequently used parenteral antimicrobial products. For all units except nursery, vancomycin and piperacillin/tazobactam DDD/1000 patient-days decreased by
63% (p < 0.001) and 36% (p < 0.001), respectively. Mean antibiotic charges per patient-day decreased from $10.44 to $3.09 (p < 0.001) and $18.04 to $11.29 (p < 0.001) for vancomycin and piperacillin/tazobactam, respectively. Pharmacist interventions increased from 58 in 2012/2013 to 160 in 2015. De-escalation of therapy was the most common intervention in both time periods.

**Conclusion:** Within four months of implementation in a small, community hospital, a formalized ASP program with pharmacists significantly decreased the DDD/1000 patient-days for parenteral antimicrobials and average vancomycin and piperacillin/tazobactam charges per patient-day but did not appear to impact the length of stay.
Purpose: According to the Centers for Disease Control and Prevention (CDC), the prevalence of binge drinking in Montana in 2015 was approximately 25%. Furthermore, in 2014, Montana had the second highest rate of alcohol-related deaths in the country. It is imperative that healthcare professionals are able to appropriately treat acute alcohol withdrawal syndrome. The purpose of this study is to evaluate this institution’s alcohol withdrawal management protocol in comparison to treatment guidelines and other institution’s current practices. Interventions made will be prospectively examined to determine if the changes result in fewer admissions to an intensive care unit (ICU).

Methods: Initially, adherence of the protocol to current treatment guidelines will be evaluated. During phase I, data will be collected retrospectively and analyzed for all patients with an admission diagnosis of alcohol withdrawal syndrome from January through June, 2016. Patients will be included if they are greater than 17 years of age with an admission diagnosis of alcohol withdrawal syndrome in the specified time frame. Patients with a concurrent diagnosis of polysubstance overdose will be excluded. Data will be collected via a clarity report and will include age, date of birth, gender, hospital admission areas (emergency department, medical floor, ICU), initial blood alcohol level, CIWA-Ar scores including dates and times recorded, and benzodiazepine administration, including medications, doses, dates, and times. Information found in phase I will be utilized in phase II to evaluate adherence to the protocol and assess potential interventions and education points. A six-month prospective evaluation of outcomes following potential interventions and education will be conducted from November 2016 through April 2017 utilizing the same inclusion/exclusion criteria and data as phase I.

**Poster Title:** Evaluation of antimicrobial stewardship standards recently implemented within a community hospital.

**Primary Author:** Rob VanTreese, Bozeman Health Deaconess Hospital, MT; **Email:** vantjerr@gmail.com

**Additional Author (s):**
Nicole Bolton
Mark Winton
Jennifer Schultz
Amanda Woloszyn

**Purpose:** Overuse and inappropriate prescribing of antibiotics has long been recognized for contributing to microbial resistance and emergence of adverse outcomes. Antimicrobial Stewardship (AMS) has been defined by the Infectious Diseases Society of America (IDSA) as “coordinated interventions designed to improve and measure the appropriate use of agents by promoting the selection of optimal drug regimen including dosing, duration of therapy, and route of administration”. The objective of this study is to evaluate AMS components demonstrated to improve patient outcomes, as evidenced by peer reviewed literature and incorporation into accreditation standards, recently implemented within a community hospital.

**Methods:** A preliminary evaluation using a published Centers for Disease Control and Prevention (CDC) checklist was conducted to assess baseline modalities in place and to identify opportunities to foster more robust AMS. Strategies to improve prescribing habits were identified through literature review. Two evidence-based approaches were selected for implementation that complement existing ASP: a prospective feedback/decision tool, and a structured reassessment/antibiotic timeout after 72 hours of empiric broad spectrum antibiotic use. Data will be collected from patients admitted to the medical floor to determine acceptance rates of recommendations, physician adherence with antibiotic timeouts, and days of therapy of antimicrobial use.

**Poster Title:** Assessment of QTc interval monitoring in hospitalized patients receiving medications with known risk of torsades de pointes

**Primary Author:** Erica Rhein, Providence St. Patrick Hospital, MT; **Email:** erica.rhein@providence.org

**Additional Author(s):**
Teresa Stanley
Carla Federici

**Purpose:** Many medications commonly used in the hospital setting can cause QTc interval prolongation and have known risk of torsades de pointes when used at therapeutic doses. Therefore, monitoring of QTc at baseline, after initiation, and with dose adjustments of these medications is necessary to detect prolongation. The objective of this study is to investigate prescriber recognition of these pro-arrhythmic medications and subsequent initiation of appropriate QTc interval monitoring.

**Methods:** Patients who have received at least one dose of one or more QTc interval prolonging medications with known risk of torsades de pointes (Tdp) as identified by CredibleMeds.org will be identified prospectively using the electronic medical record. The data collected will include patient age, sex, admitting service, length of stay, medication(s) with risk of Tdp, duration of therapy, baseline ECG, repeat ECG(s), telemetry, and QTc measurement(s). QTc prolongation will be defined as QTc > 500 ms and/or an increase of > 60 ms from baseline. Patients admitted or followed by cardiology will be analyzed separately. Based on risk factors for QTc prolongation, patients will be divided into stratified risk groups to assess if there is a relationship between patient risk for QTc prolongation, prescribing of QTc prolonging medications, and monitoring of QTc.

Poster Title: Correlation of anti-factor Xa and activated partial thromboplastin time for monitoring continuous intravenous unfractionated heparin infusion.

Primary Author: Lucas Schonsberg, Providence St. Patrick Hospital, MT; Email: lucas.schonsberg@providence.org

Additional Author(s):

Purpose: Historically, activated partial thromboplastin time (aPTT) has been used to monitor anticoagulation by continuous intravenous unfractionated heparin (UFH) infusions. Anti-factor Xa (anti Xa) assay has emerged as an alternative laboratory measure for UFH infusion monitoring. The purpose of this study is to compare aPTT and anti Xa laboratory measures for monitoring intravenous UFH infusions at this Institution.

Methods: Patients included in the study had a diagnosis of known or suspected deep vein thrombosis, pulmonary embolism, or acute coronary syndrome and orders for continuous UFH infusion with pharmacy managed dosing, monitoring, and dosing adjustments. UFH dosing was based upon current Institution protocol, which utilizes aPTT as the laboratory marker to base dosing adjustments. Prospectively, staff pharmacists requested anti Xa assays to be added to the same blood specimen as the aPTT. Patients served as their own controls due to completing both aPTT and anti Xa laboratory measures on each blood specimen. The primary outcome will be the percentage of anti Xa values correlating with aPTT values within the desired therapeutic range. Secondary outcomes include time to therapeutic anticoagulation, time within the desired therapeutic range, number of blood draws per patient, and comparison of cost between anti Xa and aPTT.

**Purpose:** The objective of this pilot is to evaluate the impact of a pharmacist working collaboratively with the primary care team. This pilot will provide an assessment of how a pharmacist could be utilized in a family practice clinic to positively impact patient outcomes using pre-specified quality metrics, extend providers, and improve patient and provider satisfaction.  

**Methods:** This study will be prospective in design. The pilot pharmacist will work closely with providers, nurses, and office staff in a pod of a family practice clinic. The pilot pharmacist will perform various elements of the proposed workflow including: reviewing and identifying patients at high risk for medication adverse effects, completing medication reconciliations, extensive medication educations, comprehensive medication management discussions, communicating with other providers of the patient’s care, and assisting in a pneumonia vaccine outreach. The pharmacist will also complete any additional tasks as requested during this pilot. Metrics assessed can be divided into three main categories: Safety and Quality, Provider’s Perspective, and Pharmacy Specific. Safety and Quality metrics may include those set forth by NCQA and CMS. Provider’s perspective will be assessed subjectively and objectively. Pharmacy specific metrics are related to billing codes and pharmacist utilization and interventions in the clinic.

**Primary Author:** Shea Fanning, St. Peter's Hospital, MT; **Email:** shea.fanning@gmail.com  

**Additional Author(s):**  
Thomas Richardson  
Brad Hornung  
Heidi Simons  
Starla Blank  

**Purpose:** When pharmacists perform medication reconciliation, there is an opportunity to assess patient understanding of medications and educate patients about their medications while simultaneously reconciling the medication list. The objective of this study is to determine the impact of pharmacist led medication reconciliation on patient satisfaction scores pertaining to communication about medications when pharmacists participate in patient education while reconciling the medication list.  

**Methods:** One full time equivalent pharmacist will be designated to medication reconciliation and education services. Due to staff limitations, this pharmacy service will not be available on weekends. Newly admitted patients will be identified daily by running an admission report generated by the electronic medical record system. Patients discharging from the hospital will be identified by following physician discharge orders. Priority for medication reconciliation and education will be given to patients with a high risk for readmission as determined by a risk stratification tool developed by coders. Data collection will occur over a three month period. The following data will be collected both during admission and discharge medication reconciliation: number and type of discrepancies identified by pharmacists, number and type of educational interventions made by pharmacists, and time required for services provided. Patient satisfaction scores related to communication about medications, and thirty day readmission rates will also be collected after implementation of the pharmacist led medication reconciliation and education service. Average number of discrepancies per patient, interventions per patient, and time required per patient will be calculated.

Poster Title: Implementing computerized provider order entry for total parenteral nutrition in a neonatal intensive care unit

Primary Author: Riley Grubbs, St. Vincent Healthcare, MT; Email: riley.grubbs@sclhs.net

Additional Author(s):
Elizabeth Monson
Andrew Schuelke
JoEllen Maurer

Purpose: By implementing computerized provider order entry (CPOE), the project authors intend to promote safer and more efficient ordering of total parenteral nutrition (TPN) orders for the neonatal population. Risk of error occurs during the TPN ordering process, because orders require input of multiple parameters involving complex information. As possible errors, TPN orders may contain incorrect calculations, missing data, hyperosmolar contents, illegible handwriting, and out of range values for micronutrients or macronutrients. CPOE may reduce risk of ordering error through utilization of functions such as automated calculations, required data fields, and hard limits for out of range values.

Methods: The study design will be presented to the Institutional Review Board. For the intervention, an informatics pharmacist will implement a computerized order form for total parenteral nutrition (TPN) orders. Acting as a clinical decision support system, the computerized TPN order form will automatically detect when certain values are out of range such as osmolarity, electrolyte contents, macronutrient contents, bag volume, and infusion rate. The computerized order forms also have capability to perform calculations for parameters such as infusion rate and TPN volume.

The prospective, observational study will include all TPN orders written for patients in the neonatal intensive care unit (NICU). To determine whether the intervention results in an 85 percent relative reduction in TPN orders with an error, the sample must contain 252 orders (126 orders in each arm of the study) to meet 80 percent power. Power calculations assume a 5 percent risk of Type I error and a 20 percent risk of Type II error. A chi-squared statistical test will be used to determine whether the intervention results in a significantly decreased error rate. Authors will use a one-tailed t-test to determine if the intervention results in decreased
time from when a neonatologist completes a TPN order to when a pharmacist acknowledges a TPN order.

**Results:** Not applicable.

**Conclusion:** Not applicable.

Session-Board Number: 12-079

Poster Title: Diltiazem versus verapamil in the prevention of arterial spasm during transradial access for coronary procedures: A non-inferiority trial

Primary Author: Clark Vowell, St. Vincent Healthcare, Billings, MT, MT; Email: clark.vowell@sclhs.net

Additional Author(s):
Stacy Emmett
William Knopf
JoEllen Maurer

Purpose: The radial artery is becoming a common alternative site to the femoral artery in cardiac catheterization procedures due to earlier mobilization, fewer vascular complications and increased patient satisfaction. The most common adverse effect for radial access compared to femoral access (previous standard of care) is a significant increase in radial artery spasm (RAS) due to smaller vessel diameter. RAS is also the most common cause of transradial access failure. This study will investigate the efficiency of diltiazem versus verapamil to prevent arterial spasm when added to a radial artery cocktail of heparin and nitroglycerin in patients who undergo cardiac catheterization.

Methods: This study will be submitted to the investigational review board (IRB) for approval and will target the inpatient population who are scheduled to receive non-emergent cardiac catheterization. At the time of initial visit with the cardiology nurse practitioners, patients will have the procedures explained by the providers and the nurse practitioners will obtain consent for the procedure itself followed by the optional consent for this study. Exclusion criteria is defined by previous calcium channel blocker therapy, severe systolic heart failure (defined as LVEF < 20 percent), and a negative Barbeau’s test at the time of the procedure. Patients will receive either diltiazem 12.5 mg or verapamil 2.5 mg in normal saline that will be administered through the radial artery as part of a cocktail (heparin 2500 units + nitroglycerine 200 mcg + investigational drug) to prevent RAS. The medical staff performing the catheterization will be blinded to the study drug and will record vital signs immediately prior to administration and five minutes afterwards. The primary endpoint is defined as radial artery spasm (resistance during catheter maneuver, inability to freely manipulate the catheter, or
difficulty in removing the catheter with the presence of forearm pain during the procedure). Secondary endpoints include change in post-administration blood pressure and heart rate, burning after administration of the study medication, and failed radial artery access.

**Poster Title:** Emergency department pharmacist interventions in a small, rural hospital

**Primary Author:** Chaundra Sewell, The University of Montana Skaggs School of Pharmacy, MT; Email: chaundrasewell@gmail.com

**Additional Author(s):**
Ann Oberlander
Kevin Cady

**Purpose:** The emergency department (ED) is an area of high patient volume with a wide array of illnesses and acuity. These factors put patients in the ED at high risk for medication errors and other misadventures. An emergency medicine pharmacist (EMP) can play a key role to prevent medication errors and optimally manage medications.

**Methods:** This study aims to identify areas where an EMP can have a positive impact on the functioning of an ED in a small, rural hospital. A pharmacist will be decentralized to the ED for 8 hours a day, Monday through Friday, for two 4-week long rotations separated by a period of time to pilot an EMP role. During this time the pharmacist will conduct med reconciliations when requested by a physician, answer drug information questions, and assist the ED staff with other tasks related to medication management. All interventions made by the EMP will be tracked using a computer program. The data on interventions will then be quantified into number of interventions, amount of time spent on interventions, and projected cost-savings for the hospital. Comparisons will be made between the two rotations separated in time, to determine if and how the role of the EMP evolves.

Poster Title: Retrospective Drug Dosing Evaluation of Vancomycin in Obese Patients

Primary Author: Tiffany Tierney, The University of Montana Skaggs School of Pharmacy Community Medical Center, MT; Email: ttierney@communitymed.org

Additional Author(s):
Doug Allington
Michael Rivey

Purpose: Vancomycin is often a drug of choice for use in patients with suspected or proven infection due to susceptible gram-positive organisms. The target trough concentration for the drug depends on the type of infection. Unfortunately, the ideal dosing of vancomycin in the obese populations is not clearly defined to achieve the desired target concentrations in order to optimize efficacy and minimize toxicity. The purpose of this drug utilization evaluation (DUE) was to gain a better understanding of vancomycin dosing in obese populations defined as a body mass index (BMI) ≥30 kg/m2.

Methods: Vancomycin monitoring sheets from the pharmacy-managed pharmacokinetic service were used to identify patients for data collection. Patients were included in the retrospective DUE if they had both an initial vancomycin trough concentration prediction as well as a subsequent analysis based on single serum concentration; the Kinetidex® program was used for analysis. Electronic health records (EHR) were used to collect or verify information. Patients were excluded for any of the following reasons: missed dose(s) or dose change(s) prior to trough level draw; adjustments to initial prediction due to serum creatinine changes (prior to level draw); and initial dose given at a different institution prior to Community Medical Center admission.

Poster Title: Impact of a pharmacist-led medication safety committee on adverse drug events and reporting measured by a modified Global Trigger Tool-based report.

Primary Author: Colin Williams, Lovelace Medical Center, NM; Email: colin.williams@lovelace.com

Additional Author (s):
Henry Ofori
Jacob Hurt
Jarren Garrett
Jamie Glasgow

Purpose: Adverse drug events are a serious problem, resulting in significant morbidity and mortality and billions of dollars in healthcare costs annually. It is estimated that only 10-20 percent of adverse drug events are voluntarily reported. The Institute for Healthcare Improvement developed the Global Trigger Tool as a way to monitor rates of adverse drug events without relying on voluntary reporting. This study aims to quantify the rates of high priority adverse drug events and rates of voluntary reporting, before and after the implementation of a pharmacist-led medication safety committee in a 318-bed acute care hospital.

Methods: This study will utilize a quasi-experimental design and will be submitted to the Institutional Review Board for approval. Patients over the age of 18 who are admitted to Lovelace Medical Center during the study period of July, 2016 through February, 2017 will be included in the analysis. A pharmacist-led committee will be created to implement medication safety interventions and process improvements. Baseline data will be collected retrospectively for the period prior to the implementation of the medication safety committee and prospectively thereafter. We will use a report adapted from the Global Trigger Tool to identify all patients who have a blood glucose measuring less than 50 mg/dL, elevated International Normalized Ratio greater than 6, Partial Thrombin Time greater than 100 seconds, or who are given dextrose, glucagon, vitamin K, protamine sulfate, or naloxone during the study period. Investigators will review the charts of all patients identified by the trigger report using a standardized chart review protocol in order to determine if the patient experienced a high
priority adverse event (severe hypoglycemia, hemorrhage, or oversedation with opioids requiring reversal). Rates of serious adverse drug events and rates of voluntary reporting over the study period will be trended using descriptive statistics. The event and reporting rates before and after the implementation of the medication safety committee will be analyzed using Chi-Square.

Poster Title: Effect of a pharmacist-driven antimicrobial stewardship bundle on hospital-associated Clostridium difficile infection rate in an acute care hospital

Primary Author: Jamie Stocker, Lovelace Medical Center, NM; Email: jamie.stocker@lovelace.com

Additional Author(s):
Ryan Urih
Gregory Nelcamp
Jamie Glasgow

Purpose: According to the Center for Disease Control and Prevention, Clostridium difficile is the most frequently reported hospital-acquired pathogen. The organism causes 337,000 infections and 14,000 deaths every year in the United States. Additional health care costs related to this hospital-acquired infection are estimated at $4.8 billion for acute care facilities, reinforcing the importance of reducing Clostridium difficile infections. The objective of this study is to reduce hospital-acquired Clostridium difficile infections in an acute care hospital following the implementation of a pharmacist-driven antimicrobial stewardship bundle.

Methods: This study will be submitted to the Institutional Review Board for approval. There will be retrospective and prospective components surrounding implementation of the intervention, following quasi-experimental design. Retrospective data in patients with a diagnosis of hospital-acquired Clostridium difficile infection from February to July of 2016 include: patient age, gender, antibiotics, proton pump inhibitor use, duration of antibiotic use, antibiotic indication, admission diagnosis, and length of stay. The intervention is implementation of a pharmacist-driven antimicrobial stewardship bundle starting October 2016. The bundle consists of three components: pharmacists will verify appropriate indication for all proton pump inhibitor orders, recommend an infectious disease consult for patients receiving piperacillin-tazobactam or carbapenem for seventy-two hours and forty-eight hours, respectively, and perform an antibiotic time-out per protocol for patients receiving forty-eight hours of empiric antibiotic therapy consisting of targeted antibiotics. The time-out will consist of a thorough review of patients receiving forty-eight hours of cefepime, ceftriaxone, ciprofloxacin, levofloxacin, or piperacillin-tazobactam. When appropriate, pharmacists will recommend de-escalation or
discontinuation of antibiotics to the prescriber. Pharmacists will record their recommendations on a standardized collection sheet for data analysis. The Clostridium difficile infection rate will be analyzed prospectively using the same parameters as the retrospective analysis. Additional data includes rate of prescriber acceptance of pharmacist recommendations from October 2016 to March 2017. Statistical analysis method will be Chi-Square.

**Poster Title:** Impact of a pharmacist-led transition of care program at a community hospital and family medicine center on readmission rates

**Primary Author:** Candace Mims, Memorial Medical Center, NM; **Email:** candace.mims@lpnt.net

**Additional Author(s):**
Patrick Leung
Davena Norris

**Purpose:** Hospital readmissions impose a large burden on the health care system. Studies have estimated that 47 percent of readmissions are preventable and 38 percent of all hospital readmissions are medication-related. Pharmacists have the unique set of skills, knowledge, and training to complete accurate medication reconciliation, reduce medication errors, and improve patient adherence. The purpose of this study is to determine if a pharmacist-led transitional care program will reduce readmission rates, medication errors, and adherence to post-discharge follow up visits at a 199-bed hospital for patients followed by a family medicine center.

**Methods:** This study will be submitted to the Institutional Review Board for approval as a single-center, pre- and post- implementation of a transition of care program that will utilize historical controls to determine the benefits of the program. Patients admitted to a community hospital who plan to follow up at the Family Medicine Center for their primary care will be recruited to enroll in the study. Patients eligible for the study will receive a phone call within 48 hours of discharge, which will focus on assessing the patient’s health status, medication comprehension and adherence, and coordination of appointments. High-risk patients will be scheduled for an appointment with the PGY1 pharmacy resident for comprehensive medication management; this appointment will be in addition to the hospital follow up visit scheduled with their primary care physician but at no additional cost to the patients.

The primary outcome of the study will be the rate of inpatient readmissions for the family medicine service within 30 days of hospital discharge. Secondary outcomes will be medication errors avoided and the percentage of patients who attend the follow-up visit with their providers. A subgroup analysis will be performed on the patients who are scheduled for a pharmacist clinic visit to determine any potential benefits for high-risk individuals.

**Poster Title:** Medication regimen complexity and hospital readmissions in a rural healthcare system

**Primary Author:** Kristina Lantis, Presbyterian Healthcare Services, NM; Email: klantis@phs.org

**Additional Author(s):**
Ranee Runnebaum
Lori Prater

**Purpose:** Medication non-adherence can result in poorer outcomes for patients, including preventable hospital readmissions and increased utilization of emergency department services, and ultimately increased cost to the healthcare system. This increased utilization of hospital and emergency services can be especially difficult in resource-constrained rural settings. The Medication Regimen Complexity (MRC) index has been proposed as a tool to predict a patient’s potential for an adverse drug event and hospital readmission. The objective of this study is to determine whether MRC can be used to predict readmissions among patients in a rural healthcare delivery system.

**Methods:** This study will utilize a retrospective cohort design and will be submitted to the Institutional Review Board for approval. The electronic medical record will be used to identify patients admitted over a 12-month period to five regional medical centers in rural New Mexico. The discharge MRC score will be calculated for all patients using the MRC Data Capture Tool developed by the University of Colorado. In addition to the MRC score, data will be collected on patient age, sex, admission diagnosis, insurance provider, Charlson comorbidity index score, medication count, emergency department utilization and hospital readmissions. All data will be collected and stored anonymously and will be maintained securely. The association between unplanned readmissions within 90 days and discharge medication regimen complexity will be assessed. The study will also look at the association between medication regimen complexity and utilization of emergency services within 90 days from discharge.

Poster Title: Appropriateness of Empiric Piperacillin/Tazobactam in Suspected Infected Pleural Effusions and Diabetic Foot Infections

Primary Author: Jennifer Overman, Presbyterian Healthcare Services, NM; Email: joverman@phs.org

Additional Author(s):
Justin Schmetterer
Craig Nelson

Purpose: Piperacillin/tazobactam is a broad spectrum intravenous antibiotic with activity against gram-positive, gram-negative and anaerobic bacterial species, including Pseudomonas aeruginosa. The objective of this study is to determine the appropriateness of empiric piperacillin/tazobactam by evaluating the prevalence of Pseudomonas aeruginosa isolates from adult inpatients with either a suspected infected pleural effusion or a diabetic foot infection and the frequency of empiric piperacillin/tazobactam therapy. If our patients have a low rate of Pseudomonas aeruginosa infection, we are hopeful this will be a powerful tool that our antibiotic stewardship team can use in their continued efforts at reducing unnecessary piperacillin/tazobactam utilization.

Methods: This study will be submitted to the Institutional Review Board for approval. This will be a retrospective analysis involving data collection from patient charts including demographics, patient diagnosis (utilizing ICD-9 and ICD-10 codes), microbiology results, and antimicrobial use. The primary outcome is determination of the incidence of Pseudomonas aeruginosa infection and the frequency of piperacillin/tazobactam therapy. Secondary endpoints include evaluation of pleural fluid for appropriate microbiological and chemical analysis to distinguish between transudative and exudative effusions and frequency of antibiotics given prior to culture and bone biopsy in patients with diabetic foot infections.

Poster Title: Cost and hemoglobin A1C outcomes of medication therapy management (MTM) services provided by advanced-practice pharmacists

Primary Author: Brandi Bowman, Presbyterian Healthcare Services, NM; Email: bbowman2@phs.org

Additional Author(s):
Rochelle Fliethman
Stacey Dalton
April Sherard
Rob Rangel

Purpose: Medicare Part D programs are required to offer medication therapy management (MTM) services to a defined subset of their beneficiaries. These services consist of an annual comprehensive medication review with a qualifying provider, with the goal of optimizing therapeutic outcomes and reducing adverse events with medication use. Insurers may utilize their own personnel to conduct these visits, or can contract with outside personnel. This study seeks to evaluate the MTM services provided for a specific insurer by a group of pharmacists, termed Pharmacists Clinicians (PhCs) that hold advanced practice licenses allowing prescriptive authority.

Methods: This retrospective pre-post study will be submitted to the Institutional Review Board. Patients were targeted for inclusion in the MTM program in 2015 if they had been diagnosed with at least 2 eligible chronic disease states, were on at least 6 medications from eligible classes, and met cost criteria. Patients will be considered for inclusion in the study if they met the above criteria and completed an MTM visit with a PhC in 2015. Patients will be excluded from the study if they had previously completed an MTM visit with a PhC. The study will compare outcomes of interest in patients in the year prior and the year after their MTM visit. The primary outcomes will be the cost of medication to the insurer and to the patient for each patient. Secondary outcomes will include the cost of medications in pre-specified classes to the insurer and to the patient. In the subgroup of patients with a diagnosis of Type 2 Diabetes, an interrupted time-series will be used to compare hemoglobin A1C in the year prior and the year
after the MTM visit. Finally, each of the interventions made by the PhCs will be categorized based on a pre-specified classification scheme. All data will come from the electronic medical record, the insurer’s prescription claims database, and the insurer’s MTM documentation database.

**Poster Title:** Comparison of blood pressure in diabetic patients managed by pharmacist clinicians in a collaborative care model versus patients managed without pharmacist clinician collaboration.  

**Primary Author:** Austin Ballew, Presbyterian Healthcare Services, NM; **Email:** aballew@phs.org  

**Additional Author (s):**  
Rochelle Fliethman  
Robert Rangel  

**Purpose:** New Mexico requires the additional training of pharmacists to be certified as Pharmacist Clinicians (PhCs) who are given prescriptive authority by the state boards of medicine and pharmacy. Presbyterian Healthcare Services utilizes 17 PhCs in outpatient ambulatory care clinics for various disease states. PhCs manage multiple comorbidities in single patients; however, outcomes are reported through primary care physician outcomes without measuring pharmacist interventions directly. The objective of this study is to compare clinical control of blood pressure in diabetic patients who are managed by PhCs with patients who are managed without PhC collaboration.  

**Methods:** This study is designed under the guidelines of the Institutional Review Board and will be submitted for approval. The study will be a retrospective cohort study. Medical coding and diagnosis codes along with problem list history will identify all patients with disease state diagnosis of type one and type two diabetes mellitus. Patients who had two or more visits with a PhC or non PhC between the dates August 2014 and August 2016 will be identified. Excluded patients will include pregnancy during study period and patients who do not meet the visit criteria. Data to be collected are: patient age, gender, height, weight, glycated hemoglobin, blood glucose, systolic blood pressure (SBP), diastolic blood pressure (DBP), total cholesterol, low density lipoprotein, high density lipoprotein, triglycerides, serum creatinine, and medications. All data reviewed will be recorded in compliance with institution protected health information regulations. Descriptive as well as inferential statistics will be used to analyze the data to make a conclusion about the patient outcomes.

Poster Title: Rates of pneumocystis jiroveci pneumonia with and without prophylactic trimethoprim-sulfamethoxazole in Non-Hodgkin Lymphoma

Primary Author: Justin Zacharias, University of New Mexico - Health Sciences Center, NM; Email: justinjzbny@gmail.com

Additional Author(s):
Lisa Anselmo
Anton Sanchez
Carla Walraven
Scott Roach

Purpose: Not all lymphoma patients meet criteria for pneumocystis jiroveci pneumonia (PJP) prophylaxis. In addition, the risk status for PJP for common Non-Hodgkin Lymphoma (NHL) regimens such as R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, prednisone) is not entirely conclusive. The objective of this study is to determine if there is a difference in rates of PJP with and without prophylactic trimethoprim-sulfamethoxazole (TMP/SMX) in patients with NHL. Secondary outcomes will determine if there is a difference in rates of admission due to febrile neutropenia (FN), acute kidney injury (AKI), and differences in length of stay (LOS) between the two groups for FN.

Methods: The study has been submitted to the Institutional Review Board for approval. This retrospective cohort analysis will evaluate adult patients with a diagnosis of NHL who started and completed ≥ 1 cycle of chemotherapy from 1/1/2010–8/31/2016. Exclusion criteria include pediatric patients (< 18 years), not on chemotherapy, in patients receiving PJP prophylaxis (not receiving TMP/SMX all throughout chemotherapy), and patients that cannot be on TMP/SMX prophylaxis (e.g., allergy). Diagnosis of NHL will be identified by business intelligence (BI) reports. Patients with NHL who received prophylactic TMP/SMX will be identified using electronic medical record medication reports and verified by BI reports. Rates of PJP, admission due to FN, AKI, and difference in LOS between the two groups for FN will be determined by ICD-9 &10 codes via BI reports. Demographics variables to be collected include patient identification numbers, age, sex, and race/ethnicity. The a priori level will be 0.05 with a power of 80%. Demographic data will be summarized using descriptive statistics. Categorical variables
with nominal data looking at rates of PJP, rates of admission due to FN, and AKI will be described as frequencies and analyzed using a Chi-square test with a 95% confidence interval (CI). Continuous variables, such as mean LOS for FN admissions, will be analyzed using the student t-test. Multiple logistic regression will be used for the multivariate analysis.

**Poster Title:** Evaluation of acceptance rates of interventions made by pharmacists in a call center versus pharmacists with prescriptive authority providing face-to-face disease state management

**Primary Author:** Jessica Kerwin, University of New Mexico College of Pharmacy, NM; **Email:** jkerwin27@gmail.com

**Additional Author(s):**
Gretchen Ray
Melissa Roberts
Melanie Dodd
Larry Georgopolous

**Purpose:** This study aims to evaluate acceptance rates of interventions made by pharmacists working in a medication therapy management (MTM) call center setting compared to a pharmacist clinician (PhC) with prescriptive authority. Furthermore, the types of medication related problems identified and recommended intervention to resolve the problem will be analyzed to evaluate differences in interventions made by the pharmacists in each practice setting. With this information, the clinical impact of pharmacists in various practice settings will be better understood, the quality of the intervention and rate of acceptance can be analyzed, and opportunities for additional interventions by pharmacists can be identified.

**Methods:** This study will be submitted to the Institutional Review Board for approval. Patients seen by pharmacist clinicians in a primary care setting and patients evaluated by MTM call center pharmacists will be targeted for inclusion into the study. Intervention data is currently entered into an electronic intervention form located inside the electronic medical record (EMR) for each patient evaluated by an MTM call center pharmacist as well as patients seen by a pharmacist clinician in a primary care setting. Interventions entered between July 2016 and December 2016 will be analyzed. Data will be collected from a de-identified database of interventions made by MTM pharmacists and pharmacist clinicians in a primary care setting. Data collected will include the patient age category and gender but will not include any identifying information about the patient. The medication-related problem identified by the pharmacist will be categorized into one of four categories for analysis. Further information to
be collected will include disease state involved, drug involved, and acceptance status of the recommendation made.

**Session-Board Number:** 12-091

**Poster Title:** From cefazolin in vitro susceptibility to clinical use of cephalexin: Could we be wrong?

**Primary Author:** Jacob Kesner, University of New Mexico Health Sciences Center, NM; **Email:** jmkesner@salud.unm.edu

**Additional Author(s):**
Renee-Claude Mercier

**Purpose:** First generation cephalosporins, including cefazolin and cephalexin, are frequently prescribed as treatment for Gram-negative bacterial infections. Although cefazolin susceptibilities are often reported, testing for cephalexin is not routinely performed by most laboratories and cannot be interpreted accurately as no guidelines are provided by the Clinical and Laboratory Standards Institute. Providers regularly extrapolate cefazolin susceptibilities to use of cephalexin in practice as the former has historically been viewed as a surrogate marker, despite previous literature indicating that Enterobacteriaceae susceptibilities may differ. This study aims to determine the magnitude of difference, if any, that exists for Enterobacteriaceae susceptibilities to cefazolin and cephalexin.

**Methods:** Clinical isolates of Escherichia coli, Klebsiella pneumoniae, and Proteus mirabilis will be obtained from urine or blood cultures of patients receiving care at the University of New Mexico Hospital. Collection will occur from January 2015 through December 2016 at TriCore Laboratories. Isolates from patients under 18 years of age, and those identified as ESBL producers will be excluded. Approximately 350 combined isolates of E.coli, K.pneumoniae, and P.mirabilis will be collected. All isolates collected will have antimicrobial susceptibilities generated by the BD Phoenix Automated Microbiology System. Minimum inhibitory concentrations (MIC) will be determined for all isolates by broth microdilution (BMD) methods for both cefazolin and cephalexin. Two primary comparisons will then be made. First, differences between cefazolin and cephalexin MICs will be observed. If a difference is identified, the magnitude of difference will then be determined using time-kill studies mimicking clinical concentrations. Secondly, for cefazolin, comparisons will be made between the MICs determined by the BD Phoenix and BMD. Discrepancies observed for these comparisons will be defined as either first or second degree errors, depending on which testing
methods were used and which cephalosporin was resistant. Each of these comparisons will be made for all isolates as a whole, single isolates, and prespecified subgroups of isolates. Isolates will be stored at -80 degC and subbed twice prior to antimicrobial susceptibility testing.

**Poster Title:** Once daily versus twice daily enoxaparin for venous thromboembolism treatment in cancer patients

**Primary Author:** Katherine Fuller, University of New Mexico Hospital, NM; **Email:** kfuller@salud.unm.edu

**Additional Author (s):**
Allison Burnett
Lisa Anselmo
Bernadette Jakeman
Stephanie Malecki

**Purpose:** Cancer patients are at increased risk for both venous thromboembolism (VTE) and bleeding complications. National guidelines recommend using low molecular weight heparin (LMWH) for VTE treatment in cancer patients. Dalteparin is the only FDA approved LMWH for VTE treatment in cancer patients. No randomized controlled trials have investigated enoxaparin once versus twice daily for VTE treatment in this population. The objective of the study is to compare the safety and efficacy of enoxaparin 1 mg/kg twice daily versus enoxaparin 1.5 mg/kg/day for the treatment of acute VTE in cancer patients.

**Methods:** This retrospective, single-center, observational study has been submitted for Institutional Review Board approval. The study will include actively treated cancer patients 18 years and older prescribed enoxaparin 1 mg/kg twice daily or 1.5 mg/kg/day for acute VTE treatment at a regional academic cancer center from 2012-2016. All patients must have a follow-up within 6 months of enoxaparin initiation. Patients with active hemorrhage or fibrinolytic therapy within 3 days prior, a CrCl less than or equal to 30 mL/min, eye, spinal, or CNS surgery within the prior month will be excluded from the study. The primary outcome is the incidence of clinically relevant (major and non-major) bleeding within 30 days of enoxaparin initiation. Secondary outcomes include the incidence of clinically relevant bleeding and/or thrombosis at 3 months and 6 months, and a composite outcome of recurrent thrombosis and death. Patients who change enoxaparin dosing strategies will be excluded from secondary outcomes analysis. Data will be analyzed using descriptive statistics, a Chi-square test, and independent t-test.

**Poster Title:** Impact of administration time of tranexamic acid in urban trauma patients

**Primary Author:** Elizabeth Tencza, University of New Mexico Hospital, NM; **Email:** elizabeth.tencza@gmail.com

**Additional Author (s):**
Preeyaporn Sarangarm
Deba Rihani

**Purpose:** CRASH-II showed that adult trauma patients receiving tranexamic acid (TXA) less than three hours from time of injury decreased mortality compared with those receiving TXA between three and eight hours of injury, or not at all. The objective of this study is to compare use of blood products in adult, urban trauma patients whom receive TXA closer to time of injury versus those receiving TXA further from time of injury.

**Methods:** Adult trauma patients receiving 1 gram TXA within the first eight hours of emergency department admission will be retrospectively identified via automated dispensing cabinet, electronic medical record (EMR) and state trauma registry data. Only first admissions will be included for patients with multiple trauma-related admissions. Patients without information regarding type of injury will be excluded. Pre-hospital data collected from the trauma registry will include: injury severity score, type and time of injury, transport time, medications, cardiopulmonary resuscitation, vitals and Glasgow Coma Scale. Hospital data collected from the EMR will include: age, sex, ethnicity, initial labs, total TXA dose and time of first administration, factor product use, blood products and fluids used in the first 24-hours of admission, anticoagulation status at the time of admission, intensive care unit (ICU) and hospital length of stay, thrombotic events, emergent surgery within the first 24-hours, and patient disposition. All data will be de-identified on coded data sheets prior to data analyses. The primary outcome will evaluate 24-hour blood product usage from time of patient arrival by time from injury to TXA administration. Secondary outcomes will include mortality from blood loss, all-cause mortality, thrombotic events, and ICU and hospital length of stay. Data analyses will include descriptive statistics and chi-square and t-test for categorical and continuous variables, respectively. This study will be submitted to the Institutional Review Board for approval.

Poster Title: Evaluation of fixed-dose 4-factor prothrombin complex concentrate for emergent reversal of warfarin

Primary Author: Greta Astrup, University of New Mexico Hospital, NM; Email: gastrup@salud.unm.edu

Additional Author (s):
Shannon Rankin
Deba Rihani
Allison Burnett

Purpose: Published literature suggests that a fixed-dose PCC may be efficacious in managing warfarin-associated hemorrhage. In October 2016, our institution conducted a pilot, quality improvement project, utilizing a fixed dose of 1500 units of 4-factor PCC (4FPCC) for all patients requiring emergent warfarin reversal for a life-threatening bleed or need for urgent/emergent surgery. The purpose of this evaluation is to determine the efficacy of fixed-dose 4FPCC in reducing the International Normalized Ratio (INR) to less than or equal to 1.5 among warfarin patients with need for urgent or emergent anticoagulation reversal.

Methods: This evaluation will be submitted to the Institutional Review Board for approval. Electronic medical records will be reviewed to retrospectively identify patients 18 years of age and older who received a fixed 1500 unit dose of 4FPCC for urgent/ emergent warfarin reversal starting October of 2016. Exclusion criteria include: patients with no INR data available, or if the post-4FPCC INR is drawn greater than 3 hours after administration. The following data will be collected: age, weight, gender, pre- and post- treatment INR, patient location, concomitant antithrombotics, and indication for anticoagulation and reversal. We will determine timing of 4FPCC ordering, verification, delivery, and administration, concomitant vitamin K use, and time to repeat INR. We will evaluate the use of 4FPCC rescue doses for patients not achieving target INR or clinical hemostasis, or among patients whom a lower target INR is desired, per provider discretion. We will also evaluate confirmed thrombotic events occurring less than or equal to and greater than 72 hours after 4FPCC administration, and time to resumption of anticoagulation if applicable. The primary outcome is the proportion of patients who achieve an INR equal to 1.5 or less with a single fixed dose of 1500 units of 4FPCC. Secondary outcomes
include medication turnaround times, attainment of target INR or clinical hemostasis, use of rescue doses, thrombotic events, and cost savings.

Poster Title: Correlation between spontaneous bacterial peritonitis prophylaxis and 90-day hospital readmission rates

Primary Author: Laura Gonzalez, University of New Mexico Hospital, NM; Email: lauracg@salud.unm.edu

Additional Author (s):
Carla Walraven
Paulina Deming

Purpose: The American Association of the Study of Liver Diseases recognizes that spontaneous bacterial peritonitis (SBP) antibiotic prophylaxis is key in preventing recurrent SBP infections. The purpose of this study is to assess whether patients who were treated for an SBP infection were discharged with recommendations for SBP prophylaxis and determine their 90 day hospital readmission rate.

Methods: This study will be submitted to the Institutional Review Board for approval. This is a retrospective review of adult patients aged 18 and older admitted to an academic medical center between January 1, 2015 and June 30, 2016 and treated for SBP. The Vizient™ database will be utilized to identify patients who received an ICD-9 or ICD-10 code for “percutaneous abdominal drain.” Pregnant women or patients who were treated for SBP or had the paracentesis procedure performed at an outside institution will be excluded from the study. The electronic medical records of the patients will be retrospectively reviewed using Cerner®. Data to be included: demographics (i.e. age and gender), drug allergies, weight, pharmacological treatment of SBP, primary hospital treatment team, fluid culture results, baseline laboratories to calculate MELD score including serum sodium, serum creatinine, albumin, serum bilirubin, International normalized ratio (I.N.R.), need for dialysis, antibiotic recommended for SBP prophylaxis, admission, discharge and readmission rates within 90 days following their initial SBP hospitalization. All patient information will be de-identified and presented in aggregate.

Poster Title: Evaluation of peri-procedural antithrombotic management at a large, academic teaching hospital: Time to burn the bridge?

Primary Author: Jessica Garcia, University of New Mexico Hospitals, NM; Email: jgarci02@salud.unm.edu

Additional Author(s):
Allison Burnett
Patricia Marshik
Leslie Sanchez
John Togami

Purpose: Historically, peri-procedural bridging strategies have been employed to prevent thromboembolic complications in warfarin patients requiring temporary interruption of therapy for invasive procedures. This practice is based on expert consensus, biologic rationale and pharmacokinetics of anticoagulants rather than robust clinical trial data. Recent studies have demonstrated that the practice of peri-procedural bridging significantly increases the incidence of bleeding without reducing thromboembolic events. As a result, many institutions have modified their peri-procedural antithrombotic management. The objective of this study is to evaluate peri-procedural antithrombotic management strategies before and after protocol changes were implemented at our institution.

Methods: This study is a single-center, retrospective, pre-post observational study. The primary outcome is the proportion of patients receiving bridging therapy pre- and post-intervention. Secondary outcomes are incidence of clinically relevant bleeding and thromboembolic complications up to 30-days following the index procedure and proportion of patients with other complications. Patients will be identified using our outpatient anticoagulation peri-procedural database and further screened for inclusion utilizing the electronic health record. Patients are included if they are ≥ 18 years of age, prescribed warfarin therapy, underwent an invasive procedure at our institution requiring temporary warfarin interruption during the specified intervention periods, and were followed at the hospital’s outpatient anticoagulation clinic for ≥3 months prior to and 30 days after the index procedure. Patients will be excluded if their invasive procedure occurred outside our institution. Data collected will include: age,
gender, race, weight, anticoagulation indication, CHADS2VASc score, hypertension, thrombotic and bleeding risk stratification, time in therapeutic range (TTR), ethanol abuse, smoking status, renal function, liver disease, malignancy, antiplatelet therapy, last INR and complete blood count before index procedure, number of days warfarin and antiplatelet therapies were held prior to index procedure, use of bridging versus no bridging, dose of parenteral anticoagulant, number of parenteral anticoagulant doses prior to procedure, type and duration of procedure, procedural setting, time to first post-procedure anticoagulant dose and antiplatelet dose.

Poster Title: Identifying risk factors of potentially preventable 30-day readmission among patients with a human immunodeficiency virus diagnosis

Primary Author: Gregory Hadlock, University of New Mexico Hospitals, NM; Email: ghadlock@salud.unm.edu

Additional Author(s):
Kelli Moreles
Bernadette Jakeman
Larry Pineda

Purpose: Healthcare costs have been growing at unsustainable rates for governments and healthcare systems. The 30-day readmission rate is a commonly used measure of hospital quality and is used by the Center for Medicare and Medicaid Services to adjust reimbursement rates of hospitals. Certain patient groups have higher rates of 30-day readmission, including patients with human immunodeficiency virus (HIV) infection. However, not all readmissions are preventable. The objective of this study is to determine the incidence and risk factors of potentially preventable readmissions (PPR) among HIV infected patients with a 30-day readmission at our institution.

Methods: This study will be a retrospective cohort study of HIV infected patients with a PPR and those without with a PPR from 1/1/2012 – 12/31/2014. Patients will be selected if they have an HIV diagnosis, were admitted to our institution for any cause, and were readmitted within 30 days of the index admission. PPR will be identified by chart review of electronic medical records. PPR will be defined as a readmission for a recurrence or continuation of the index admission reason, an acute decompensation of a chronic problem present at the index admission date, and a complication (including surgical) related to treatment received during the index admission. To determine risk factors of PPR, demographic, social, and clinical characteristics will be collected and analyzed using univariate and multivariate regression to assess an association with PPR. Two reviewers will assess for PPR. Discordant assessments of PPR will be evaluated by a third reviewer. Prior to data collection, this study will be submitted to the our Institutional Review Board for Approval. All patient data will be de-identified to maintain confidentiality.

**Poster Title:** Implementation of pharmacist led medication reconciliation and education in the emergency department; a pilot project at a small, Planetree community hospital

**Primary Author:** Diana Flounders, Alliance Community Hospital, OH; **Email:** dtopp@neomed.edu

**Additional Author (s):**
Christopher Shelby
Patrick Divoky
Dustin Carneal

**Purpose:** Readmission rates for chronic diseases are elevated and it can be partially contributed to noncompliance or misunderstanding about medications. In addition, medication lists for patients may be incomplete or outdated compared to the patients’ current regimen. Therefore, the objective of this study is to examine the effectiveness a pharmacist has on medication reconciliation and education in the Emergency Department (ED) by examining readmission rates at 30 and 90 days post initial visit.

**Methods:** This study has been submitted to the Institutional Review Board for approval. Upon patient admission to the ED, the pharmacist will complete a medication reconciliation with the patient and provide medication counseling. Upon conclusion of the visit, patients that are leaving with a new prescription or diagnosis of a chronic disease will be counseled by the pharmacist. In addition, the pharmacist will provide a follow up phone call for patients 48-72 business hours after the initial visit to review changes, answer questions, and reinforce education topics. Daily ED activity reports will be collected via the hospital’s electronic medical record system (EMR), Meditech, to evaluate the patients the pharmacist was able to counsel and those patients that were either missed or were admitted to the ED when the pharmacist was not available. Readmission rates will be examined at 30 and 90 days post initial visit to examine if the patients that received counseling by the pharmacists had lower readmission rates compared to those patients that did not receive counseling. Other information that will be collected include the number of pharmacist interventions, number of patients that left the ED without being seen, number of Outcomes MTM™ opportunities for patients, age, number of
medications on admission, number of medications on discharge, and number of medications that are scheduled compared to as needed.

Poster Title: Enhanced medication awareness in hospice patients through a medication perception survey and individualized patient and caregiver education: a pharmacist-led initiative.

Primary Author: Jennifer Ward, Alliance Community Hospital, OH; Email: jward@neomed.edu

Additional Author(s):
Christopher Shelby
Patrick Divoky

Purpose: Pharmacists are trained to provide effective symptom management through optimization of therapy while minimizing adverse effects to patients in all care settings. The objective of this study is to survey hospice patients and caregivers to provide individualized education for appropriate symptom control as symptoms progress during their hospice tenure. Education will focus on patient centered care strategies to enhance symptom control by empowering appropriate medication administration.

Methods: All patients enrolled in Alliance Community Hospice between November 1st and December 31st will be included in the survey regardless of terminal diagnosis, comorbid conditions, or location of hospice care. Information will be obtained through the electronic medical record. Specialized hospice nurses will be utilized to obtain consent as well as initial and follow-up medication related survey responses from patients and their caregivers. All data will be de-identified and contained within a secure location with the locked pharmacy department. The initial survey will ask the responders to evaluate their confidence in medication knowledge, their current symptom control and topics of concern regarding their care. A patient/caregiver meeting will be arranged by the pharmacist during which education will be given on all medications with an emphasis on patient or caregiver identified areas of concern and as needed medications. Any additional concerns identified by the pharmacist will be communicated to the hospice care team. Follow-up surveys will be sent at two and ten weeks following education to assess how perceptions and symptom control were impacted. Descriptive statistics will be used to evaluate changes in patient and caregiver medication perception. Secondary results will include a comparison of surveys in different hospice
locations, between caregivers and patients, as well as between initial administration and 10 week follow-up. All interventions made will be recorded.

**Poster Title:** Analysis of a consult agreement in a federally qualified health center (FQHC): a pharmacist-physician approach to managing uncontrolled diabetes

**Primary Author:** Brittany Harbert, Aultman Hospital, OH; **Email:** brittany.harbert@aultman.com

**Additional Author(s):**
Megan Crissinger
Roger Musa

**Purpose:** The addition of a pharmacist to an interprofessional healthcare team can improve patient care and satisfaction. As of 08/31/2016, the Ohio revised code 4729.39 for consult agreements between physicians and pharmacists was revised. The revision permits pharmacists to expand their scope of practice and provide optimal patient care services in collaboration with physicians. The purpose of this study is to evaluate the successful implementation of a consult agreement within the family practice clinic of a newly developed FQHC. The primary outcome is patient and physician satisfaction following pharmacist-directed patient care.

**Methods:** This retrospective study will evaluate the integration of a pharmacist into the healthcare team in order to optimally manage diabetic patients. Care provided by the pharmacist will fall under the scope specified within the newly contracted consult agreement and occur during the months of November 2016 to March 2017. Inclusion criteria consist of age ≥ 18 years, type 2 diabetes mellitus, and a hemoglobin A1c ≥ 9%. The clinical pharmacist can modify diabetic therapy and order blood and urine tests as specified within the protocol section of the consult agreement. Each patient will be asked to complete a 10-item paper satisfaction survey evaluating the care provided by their clinical pharmacist. Physicians will also be requested to complete a 12-item assessment evaluating the service. Secondary outcomes will be measured by the number and types of interventions made by the pharmacist as well as clinical efficacy represented by A1C reduction. Other data collected will include: baseline demographics, medications, and co-morbid conditions. This study has been submitted to the Institutional Review Board for approval.

**Poster Title:** Analysis of the incidence of hypoglycemia upon initiation of tramadol

**Primary Author:** Tiffany Kneuss, Aultman Hospital, OH; **Email:** tiffany.kneuss@aultman.com

**Additional Author(s):**
Lacey Davis

**Purpose:** The use of tramadol has steadily increased worldwide since its approval. While there are many well-studied safety concerns with tramadol such as risk of seizure, sedation, respiratory depression, and serotonin syndrome, tramadol continues to be perceived and utilized as a “safer” option than other opioid analgesics. In addition to known safety concerns, there are many lesser known safety concerns associated with tramadol including risk of hypoglycemia. The purpose of this study is to analyze the incidence of tramadol-induced hypoglycemia, including time to development of hypoglycemia, number of hypoglycemic events per patient, and severity of the blood glucose decrease.

**Methods:** A 24-month retrospective chart review will be performed comprised of patients receiving post-acute care between August 2014 and August 2016 in a rehabilitation and transitional care unit facility. Patients eligible for analysis include all patients 18 years of age and older with tramadol initiated within the last 30 days. Patients with and without diabetes and/or anti-diabetic medications will be included in analysis. Exclusion criteria include use of tramadol as a home medication (prescription within the last 6 months), inability to determine the initiation date of tramadol, concurrent codeine use, and use of the extended-release formulation of tramadol. Data will be collected via electronic medical records and will include age, sex, initiation date of tramadol, all blood glucose levels during post-acute care stay, number of hypoglycemic events per patient, number of tramadol doses received prior to hypoglycemic event, number of days since initiation of tramadol at time of hypoglycemic event, potentially confounding medical conditions and medications, and renal function based on a calculated creatinine clearance. The study protocol has been submitted to the Institutional Review Board (IRB) for approval.

Poster Title: The ONESCOP study: effect of a neurohospitalist, stroke coordinator, and pharmacist (ONESCOP team) on acute ischemic stroke metrics and patient outcomes

Primary Author: Rebecca Prewett, Aultman Hospital, OH; Email: rprewettpharmd@gmail.com

Additional Author(s):
Scott Perry
Jennifer Brackman
Brianna Coss

Purpose: As a primary stroke center, the institution relies on an interdisciplinary team to provide acute ischemic stroke care. During regular business hours, this team includes a neurohospitalist, stroke coordinator, and pharmacist (ONESCOP team). This project seeks to determine if the presence of the ONESCOP team impacts acute ischemic stroke metrics (time to treatment-critical events within the emergency department) and patient outcomes (length of stay, readmissions, mortality) when compared to off-hours stroke coverage. The primary outcomes are door to needle (alteplase (t-PA) administration) time and length of stay.

Methods: A retrospective chart review will be performed for all subjects presenting to the emergency department (ED) under a stroke alert from January 1, 2015 to August 31, 2016. In order to be included in data analysis, subjects must have an ED stroke alert activated and had an ischemic stroke. Subjects will be excluded if their stroke was hemorrhagic, symptoms were determined to be from a cause other than stroke, presentation was more than 4.5 hours since last known well, or tPA was administered before arrival. Data will be analyzed in two groups based on whether the full ONESCOP team participated in the acute stroke care of the subject. Analyzed data will include door to tPA decision time, time from completed computed tomography scan to tPA decision, number of eligible subjects who received tPA, number of tPA eligible subjects with documented refusal of consent, door to needle time, time from tPA decision to administration, 90 day mortality, time to mortality (within 90 days), 90 day stroke-related readmission, time to readmission (within 90 days), and length of stay. All data will be tested for normality, and the appropriate statistical tests will be used to determine if there is a difference in outcomes between subjects who received acute ischemic stroke care from the ONESCOP team and those treated by off-hours providers.

**Poster Title:** Cost avoidance strategy with oritavancin  

**Primary Author:** Corey Groff, Aultman Hospital, OH; **Email:** cgroff@neomed.edu  

**Additional Author(s):**  
Thomas Bonsall  
Scott Perry  

**Purpose:** The objective of this study is to determine cost-avoidance, in dollars, 30-days post treatment using oritavancin in eligible patients with cellulitis administered in the emergency department (ED) against the average cost of admission for patients with cellulitis. Using cost-avoidance as an outcome allows real-world assessment of whether treating patients with oritavancin has reduced healthcare costs. By assessing if cost-avoidance was achieved with oritavancin, the potential exists to increase its utility in the outpatient setting and prevent healthcare spending.  

**Methods:** This study was submitted to the Institutional Review Board for approval. Patients presenting to the emergency department (ED) will be categorized based on drug protocol to be eligible to receive oritavancin infusion. Patients identified as potential candidates by ED team and if insurance coverage is validated, patients may receive oritavancin if decision to treat is made. Primary outcome will be cost-avoidance. Secondary outcomes will measure admission rate, patient satisfaction, and reimbursement percentage from third-party payers. The following data will be collected from the electronic medical record: third party billing information, reimbursement decision/amount from third party, status of coverage, thirty-day admission data following infusion, age, race, sex, race, principle diagnosis, and laboratory reports. All data will be collected and de-identified, and private health information will be stored in a password protected document. The data will remain on an encrypted and secure laptop that will be in the possession of the PI. No other investigator will have full-access to patient information. Patients who received oritavancin will be followed-up to determine cost to patient and health system. Cost-avoidance will be determined by analyzing reimbursement versus previous year average cellulitis cost of admission.

Poster Title: Impact of pharmaceutical bedside deliveries on 30 day readmission rates in a community hospital

Primary Author: Marcus Bergman, Blanchard Valley Hospital, OH; Email: mberman@bvhealthsystem.org

Additional Author(s):
Kristin Spangler
Tenna Rhonemus
Michael Leifheit

Purpose: Blanchard Valley Hospital offers counseling by a pharmacist prior to discharge. It has been a goal to counsel patients about their medications in order for the patient to be educated and understand their medications. The goal is to reduce complications with medications and improve patient compliance in order to reduce 30 day readmission rates. Limiting readmission is critical to the overall well-being of the patient and ensures reimbursement. The objective of this study is to evaluate the impact of pharmaceutical bedside deliveries on 30 day readmission rates as well as detecting additional benefits from this pharmacy delivery program.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients who have received medication bedside delivery counseling. The following data will be collected: patient age, disease state, admit date, bedside delivery participants, readmission date, location of stay within the hospital, and the medications on which the patient is discharged. The study will be conducted at a single center. It includes patients greater than or equal to 18 years of age, who participated in the bedside delivery program at Blanchard Valley Hospital located in Findlay, Ohio. The study will be looking at collected data from January 1, 2015 to December 31, 2016. Patients who were placed on the pediatric, labor and delivery floors, and surgery patients will be excluded. Patients discharged through the program only on pain medications and laxatives were also excluded. The primary outcome of this study consist of the pharmaceutical bedside delivery service impact on 30 day readmission rates. Secondary outcomes: types of medications delivered through the bedside delivery service, growth of the bedside delivery service, income the service brings to the
outpatient pharmacy, and trends in medication communication scores as reported through the Press Ganey Patient Survey.

Poster Title: Implementation of a pharmacist driven oral chemotherapy counseling service in an outpatient cancer care center

Primary Author: Brian Joslin, Blanchard Valley Hospital, OH; Email: bjoslin@bvhealthsystem.org

Additional Author(s):
Joshua Cain
Michael Leifheit

Purpose: As oral chemotherapy drugs are being used more frequently it is important that patients receive effective counseling in order to ensure they are able to use the drug in a safe and effective way. Patients who receive their oral chemotherapy from a mail order pharmacy or directly from a medical office often do not get the opportunity to speak to a pharmacist in person to address questions and concerns they may have regarding their oral chemotherapy. The purpose of this service is to provide patients with the opportunity to receive counseling by a pharmacist about their oral chemotherapy.

Methods: This study will be submitted to the Institutional Review Board for approval. This service will be offered to patients who are prescribed oral chemotherapy by their oncologist at Armes Family Cancer Care Center (AFCCC) in Findlay, Ohio. Both patients who have taken oral chemotherapy prior and those who are new to oral chemotherapy will be offered this service. A pharmacist will provide counseling to patients receiving oral chemotherapy via an outside pharmacy. Patient age, gender, diagnosis, time on oral chemotherapy, and oral chemotherapy agents prescribed will be assessed at baseline. Counseling sessions will last approximately 15 minutes and will include dosing, indication, storage, adverse effects and how to manage them. Patients will be given an opportunity to ask the pharmacist questions; the category of questions will be recorded. They will receive handouts that will summarize key information covered during the counseling session. Patients will be contacted for follow-up via telephone by the pharmacist who conducted the initial education 4 weeks after their initial oral chemotherapy counseling session. Information collected at follow-up will include effectiveness of counseling, patient compliance, frequency and management of adverse effects. Questions or concerns the patient may have at follow up will be addressed and the categories of questions
asked will be recorded. All data will be recorded without patient identifiers and maintained confidentially.

Session-Board Number: 12-107

Poster Title: Management of refractory status epilepticus at a children's hospital

Primary Author: Melissa Kincaid, Cincinnati Children's Hospital Medical Center, OH; Email: melissa.kincaid@cchmc.org

Additional Author(s):
Lisa Garrity
Andrea Chamberlain
Katrina Peariso
John Taylor

Purpose: Midazolam and pentobarbital are commonly used as continuous infusion anesthetics for the management of refractory status epilepticus (RSE). While these agents provide effective seizure control, they are associated with several adverse effects, such as hypotension requiring vasoactive agents, respiratory depression, and infection, which may have a negative impact on morbidity and mortality. The purpose of this study is to describe the efficacy and safety of continuous pentobarbital and midazolam infusions for the management of RSE at a children's hospital.

Methods: This study is an Institutional Review Board-approved retrospective chart review evaluating patients who were admitted to a children's hospital for the management of RSE from January 2010 to December 2015. Patients who received midazolam and/or pentobarbital as continuous infusion anesthetics for the treatment of RSE will be identified using the electronic medical record. The primary objective of this study is to describe the efficacy of continuous infusion anesthetics as determined by the rate of successful resolution of RSE; successful resolution will be defined as either discontinuation of continuous infusion anesthetics or discharge from the intensive care unit to a non-intensive care unit. The secondary objectives are to assess the intensity of hemodynamic intervention required and the rates of adverse effects associated with the use of continuous infusion anesthetics. Data to be collected include baseline characteristics, RSE treatment utilized including continuous infusion anesthetics rate and duration, use of antiepileptic medications at time of RSE resolution, non-pharmacologic interventions and immunotherapy. The intensity of hemodynamic intervention required will be evaluated using data collected regarding the vasoactive agents used for
hemodynamic support. This data includes which agent was used, duration of vasoactive therapy, as well as maximum and average daily infusion rates. Adverse effects including ileus, bloodstream infections, ventilator-associated pneumonia and acute kidney injury will also be collected.

Poster Title: Efficacy of capped rasburicase dosing for management of tumor lysis syndrome in oncology patients at a pediatric institution

Primary Author: Arathi Lambrix, Cincinnati Children's Hospital Medical Center, OH; Email: arathi.pillay@cchmc.org

Additional Author (s):
Jennifer Townsell
Jennifer Mangino
Adam Lane

Purpose: Rasburicase is a recombinant urate-oxidase inhibitor indicated for management of hyperuricemia associated with tumor lysis syndrome (TLS). A single fixed dose of rasburicase has shown to effectively normalize uric acid levels in adult patients experiencing TLS. Due to the high cost associated with rasburicase therapy, an institutional guideline for capping and rounding down rasburicase doses has been implemented at a pediatric institution. This retrospective review will evaluate the efficacy of capped and rounded doses, as well as the associated cost savings.

Methods: This retrospective chart review was approved by the Institutional Review Board to evaluate oncology patients who received rasburicase between December 1, 2014 and September 1, 2016. Patients will be identified by the electronic medical record and included if diagnosed with an oncologic malignancy requiring rasburicase for TLS management. The primary objective of the study is to evaluate the efficacy of capped or rounded doses of rasburicase in normalizing uric acid levels. The study will evaluate rates of repeat rasburicase dosing, rates of acute kidney injury, prescribing patterns and associated cost savings. Data to be collected includes serum uric acid, potassium, phosphate, creatinine, total white blood cells, and the rasburicase doses administered. Cost savings will consider both the dose administered and any drug wasted. Descriptive statistics will be used to characterize data regarding rasburicase efficacy and to evaluate cost savings and prescribing adherence. We hypothesize that a capped dose of rasburicase is efficacious in normalizing uric acid levels for the management of TLS in oncology patients.

Poster Title: Chloral hydrate utilization in a pediatric medical center

Primary Author: Maria Sellas, Cincinnati Children's Hospital Medical Center, OH; Email: msellas15@gmail.com

Additional Author (s):
Joshua Courter
Tamara Hutson

Purpose: Chloral hydrate is a sedative hypnotic agent that has been utilized for centuries. Despite its widespread and historical use, chloral hydrate is not currently approved by the United States Food and Drug Administration. However, institutions are able to compound chloral hydrate preparations for use. Current dosing guidelines recommend a maximum daily dose of 2,000 mg in pediatric patients. The objective of this evaluation is to assess the rates and outcomes of patients who receive total daily doses of chloral hydrate greater than the recommended 2,000 mg.

Methods: This is a quality improvement drug utilization evaluation conducted at a tertiary care pediatric medical center. Patients with orders for chloral hydrate from August 2015 – August 2016 will be identified utilizing the electronic medical record. The orders for chloral hydrate will be evaluated for total single dose, potential maximum cumulative dose in 24 hours, and total dose administered to the patient in 24 hours. Vital signs, including heart rate, systolic blood pressure, respiratory rate, and oxygen saturation, will be collected on those patients who received doses greater than 2,000 mg. A cost analysis of chloral hydrate will be completed. Following analysis of the data, strategies for prevention of exceeding the recommended dosing will be evaluated and recommended to the institution for implementation.

Results: n/a

Conclusion: n/a
Purpose: Benchmarking is a method for comparison to determine the value and effectiveness of pharmacy services. The Cleveland Clinic Department of Pharmacy measures dispenses, interventions, order verification, and automated drug cabinet refills. The department does not have an optimal infusion center operational productivity tool. Workflow throughout the department is not generalizable; therefore, it cannot accurately assess mixed skill workload – pharmacists and technicians alike – currently. Traditional productivity metrics (e.g. doses dispensed, admissions, patient days, revenue) are nonexistent or provide too little detail within this setting. Of the aforementioned metrics, dispenses are most universal to apply within the ambulatory infusion setting.

Methods: Data was electronically captured based on orders processed through the ambulatory oncology setting including hazardous and non-hazardous medications. Based on current workflow, inpatient and outpatient orders (both processed within the ‘chemo pharmacy’) were reviewed in productivity metrics. The metric defining the variability of the workload itself was weighted dispense type as it was the best representation of a mixed skill workflow. After conducting workflow process mapping, discrete measurable steps were assessed and evaluated within the day-to-day operations. Operational components of interest included pharmacist verification activities and technician compounding activities. Production data from September 1, 2014 – August 31, 2015 was sampled for assigning relative value units (RVU) respective to time to normalize workload into a common unit (i.e. one hour) and to relate work demand in a highly variable setting (e.g. chemotherapy infusion center). RVUs were assigned and delineated by cognitive and distributive activities for pharmacists and technicians, respectively. In addition to data from September 2015 – August 2016, the Delphi method will be utilized to verify...
assigned RVUs. The intent of this research-in-progress is to develop a productivity tool to retrospectively measure workload involving time to review, verify, reconstitute, admix, and deliver chemotherapeutic agents.

Poster Title: Evaluation of an electrolyte replacement protocol in critically ill patients at a community hospital

Primary Author: Melody Smith, Cleveland Clinic Medina Hospital, OH; Email: msmith12@neomed.edu

Additional Author (s):
Michelle Poole
Andrea Pallotta

Purpose: Electrolyte imbalances in critically ill patients have been positively correlated with increased morbidity and mortality. Although the use of electrolyte correction protocols has become more common in critical care settings, minimal data exists pertaining to the safety and efficacy of these protocols. Recently, Cleveland Clinic Medina Hospital has developed a nursing-driven electrolyte replacement protocol for patients in the intensive care unit (ICU), which targets hypokalemia, hypomagnesaemia, and hypophosphatemia. This study will evaluate the safety and efficacy of the new protocol.

Methods: This retrospective chart review will consist of inpatients at Cleveland Clinic Medina Hospital admitted to the intensive care unit between April 1, 2015 through October 31, 2015 (pre-protocol period) and April 1, 2016 through October 31, 2016 (post-protocol period). Patients at least 18 years old who received electrolyte replacement during the pre-protocol period, and received electrolyte replacement from the protocol order set in the post-protocol period, will be included. Per protocol, patients who experienced the following during ICU stay will be excluded: serum creatinine greater than 2 milligrams per deciliter, dialysis, rhabdomyolysis, diabetic ketoacidosis, anuria, or weight less than 40 kilograms. The primary efficacy outcome will be to compare the proportion of measured values of serum potassium concentration within the desired range (3.5 to 5.0 milliequivalents per liter) the morning after potassium replacement during the pre-protocol period versus the post-protocol period. Secondary outcomes will include assessment of magnesium and phosphate concentrations the morning after replacement, the average time to replacement, the incidence of cardiac arrhythmias during ICU admission, in-hospital mortality, as well as nurse and physician
satisfaction measured with an anonymous survey. Chi-squared and Student t-test will be utilized in the statistical analysis, as appropriate.

**Poster Title:** Impact of pharmacist-driven post-discharge medication reconciliation on 30-day readmission rates: a retrospective chart review.

**Primary Author:** Meredith Martin, Cleveland Clinic Medina Hospital, OH; **Email:** martinm4@ccf.org

**Additional Author (s):**
Brandon Mottice
Allison Naso
Samantha Loutzenheiser

**Purpose:** Medication discrepancies have the potential to prolong hospital length of stay and lead to increased utilization of other healthcare resources, including increased emergency department visits and hospital readmissions. Medicare readmissions within thirty days of discharge have been estimated to cost approximately $17.4 billion a year, which represents substantial implications for both patients and the entire health care system. The objective of this study is to determine the impact on 30-day readmission rates from pharmacist-led post-discharge medication reconciliations.

**Methods:** This study is a randomized, retrospective chart review of patients discharged from Cleveland Clinic Medina Hospital to skilled nursing facilities (SNFs) and long term acute care facilities (LTACs). The primary outcome is readmission to a Cleveland Clinic inpatient facility within thirty days of discharge. Secondary outcomes include number and type of medication discrepancies, drug interactions, interventions requiring physician contact, and average time of phone call. Daily discharge reports will be evaluated to identify patients discharged to SNFs and LTACs. All patients discharged to a SNF or LTAC will be randomized equally into two groups: patients who will receive post-discharge medication reconciliation and patients who will not. The nursing facility will be contacted to conduct a medication reconciliation within three days of discharge for those patients randomized into the intervention group. The following baseline data will be collected from the electronic medical record: patient age, gender, number of scheduled medications, length of stay, and primary discharge diagnosis. The number of medication discrepancies, drug interactions, interventions requiring physician contact, and length of the phone call will be documented. A medical record review will be completed to
determine readmission rate to a Cleveland Clinic inpatient facility within thirty days of discharge. All data will be recorded in a secure database to maintain patient confidentiality. This study will be submitted to the Institutional Review Board for approval.

Poster Title: Valproic acid induced hyperammonemia: Incidence, clinical significance, and treatment management

Primary Author: Elisa Baddour, Fairview Hospital, OH; Email: baddoue@ccf.org

Additional Author(s):
Ashley Tewksbury
Tuan Trinh

Purpose: Valproic acid induced hyperammonemia poses several clinical challenges in psychiatric medicine. The reported incidence of this adverse effect varies widely across the literature. Furthermore, many practitioners order ammonia levels and treat hyperammonemia in asymptomatic patients although studies suggest this practice is unnecessary and can lead to diagnostic confusion. The purpose of this study is to evaluate the clinical implications of monitoring ammonia levels in potentially asymptomatic patients.

Methods: This study will be submitted to the Institutional Review Board for approval. The primary objective is to determine the incidence of hyperammonemia in psychiatric patients on valproic acid with at least one ammonia level drawn during admission. The secondary objectives are to evaluate the incidence of symptomatic hyperammonemia and to evaluate the incidence and efficacy of various treatments for hyperammonemia. Patients will be retrospectively identified through a database query from June 2011 to June 2016. Patients will be included if they were admitted to a psychiatric unit, received at least one dose of valproic acid, and had at least one ammonia level drawn during admission. Exclusion criteria include a diagnosis of cirrhosis at admission. Data will be extracted from a shared electronic medical record and uploaded into a secured collection database. Collected data points will include demographic information, diagnosis, symptoms of hyperammonemia, ammonia levels drawn during admission, and treatment modality chosen. Hyperammonemia will be defined as greater than 47 micromoles per liter. Symptomatic hyperammonemia will be defined based on symptoms, such as lethargy and altered mental status. Only patients with multiple ammonia levels drawn will be used to assess efficacy of treatment modalities. The ammonia levels will be trended during admission, and the treatment modality will be deemed successful if the ammonia level was within normal range (17 to 47 micromoles per liter) at discharge.

Poster Title: Dosing of enoxaparin in morbidly obese individuals: A retrospective cohort

Primary Author: Michael Czupryn, Fairview Hospital, OH; Email: czupryn@ccf.org

Additional Author(s):
Cristal Exline

Purpose: Studies investigating the pharmacokinetics of non-standard doses of enoxaparin in a morbidly obese population have had mixed results, and there is a paucity of evidence analyzing thrombosis and bleeding risk in this population. The primary objective of this study is to evaluate incidence and risk of major bleeding between different enoxaparin dosage strategies in patients weighing greater than or equal to 120 kilograms receiving treatment doses of enoxaparin.

Methods: This study will be submitted to the Institutional Review Board for approval and will be completed using patient electronic medical records from a shared medical record system for all hospitals within the health system. Patient data will be extracted for three community hospitals from the past five years. Patients will be included in the primary analysis if they received enoxaparin with the intent of full anticoagulation for more than 24 hours, weighed greater than or equal to 120 kilograms at the time of treatment, and had outcomes data documented throughout the course of therapy. Data will be collected for patients with a creatinine clearance less than 30 milliliters per minute (including dialysis patients) and pregnant patients for the purposes of an ad-hoc subgroup analysis, but this data will be excluded from the primary analysis. Patients less than 18 years of age, patients with no creatinine or weight data, and patients with documented heparin induced thrombocytopenia will be excluded. The incidence of primary outcomes occurring within seven days of therapy will be compared between patients receiving an enoxaparin dose less than 0.9 milligrams per kilogram twice daily and greater than or equal to 0.9 milligrams per kilogram twice daily and also between patients weighing greater than or equal to 150 kilograms and less than 150 kilograms.

Poster Title: Reducing readmissions through pharmacist-led chronic obstructive pulmonary disease (COPD) education at a rural, community hospital

Primary Author: Kyle Weslosky, Firelands Regional Medical Center, OH; Email: kyle.weslosky@firelands.com

Additional Author(s):
Darla Gaiser
Rachael Macko
Nicole Wetoskey
Jeff Kelley

Purpose: Centers for Medicare and Medicaid Services (CMS) expanded their Hospital Readmissions Reduction Program (HRRP) in 2015 to include chronic obstructive pulmonary disease (COPD). Consequently, hospitals can be penalized up to 3% for high thirty-day readmission rates for Medicare beneficiaries, by CMS standards, with a diagnosis of COPD, further incentivizing hospitals to focus on implementation of programs to decrease readmissions. The goal of this study is to reduce the thirty-day readmission rates of patients with COPD through pharmacist-led education about COPD.

Methods: The study will be submitted to an institutional review board for approval. Thirty-day all-cause readmission rates for the COPD patients enrolled in the study will be compared to the national average. Upon discharge from the hospital and referral to the Firelands Regional Medical Center (FRMC) Center for Coordinated Care (FCCC), patients will be identified for inclusion in the study if they meet the following criteria: patients with primary discharge diagnosis of COPD, COPD exacerbation, or primary discharge diagnosis of respiratory failure with a secondary diagnosis of COPD, and enrollment in Medicaid or Medicare for at least thirty days post-discharge. Exclusion criteria will include: under 18 years old, learning disabilities, primary language other than English, patients discharged against medical advice (AMA), transferred to another acute care facility, discharged to long-term care facilities, those to receive home health care, and patients with planned readmissions according to the CMS algorithm. Patients meeting inclusion criteria will be assigned to receive usual care through FCCC alone or in combination with pharmacist-led COPD education within fourteen days of
discharge. The primary outcome to be measured is thirty-day readmission rates of COPD. Secondary outcomes include: pre- and post-test scores regarding COPD disease and medication knowledge, patient satisfaction survey scores, ninety-day readmission rates compared to the national average, and comparison to FRMC COPD readmission rates from the year prior to study implementation.

**Results:** To be determined.

**Conclusion:** To be determined.
Purpose: Medication reconciliation is an interactive process with patients in which the most accurate medication list is obtained with the intent to optimize pharmaceutical care and reduce medication errors. Providers face many challenges when trying to complete medication reconciliations including patients’ knowledge of medications as well as time limitations. Devoting one person, such as a trained pharmacy technician, to the role of documenting accurate medication histories can eliminate redundant efforts and save clinicians time. After completion of this study, the hospital hopes to devote a pharmacy technician to perform medication reconciliations in the emergency department (ED).

Methods: This study will be submitted to an institutional review board for approval. Prospective review will include tracking the time spent and medication reconciliations completed for selected patients in the emergency department during peak admission times. This data will be used to assess the efficiency of completing medication reconciliation by pharmacists and pharmacy interns and the consequent reduction of nursing time. Conducting this research will also help with development of a standard process to train and implement pharmacy technician involvement in medication reconciliation. Patients will be identified in the ED by the triage level and selected if they are likely to be admitted. Exclusion criteria will include patients that will not be admitted. Patients meeting inclusion criteria will have their medication reconciliation performed by either a pharmacist or pharmacy intern. Through literature search, standards will be established regarding what should be documented on a patient’s home medication list on admission with a goal to compile the most accurate
medication list and improve patient safety. The primary outcome measured will be efficiency at which medication reconciliation can be completed by pharmacy staff. Secondary outcomes that will be measured include a cost analysis of implementing a pharmacy technician to conduct medication reconciliation and assessing improvement in accuracy and completeness comparing current practice to post implementation of pharmacy involvement.

**Results:** To be determined.

**Conclusion:** To be determined.

**Poster Title:** Retrospective evaluation of proton pump inhibitor appropriateness within a small teaching hospital

**Primary Author:** Matthew Walker, Grandview Medical Center, OH; **Email:** matthew.walker@khnetwork.org

**Additional Author(s):**
Jessica Tyler
Nicholas Wolters

**Purpose:** Recent literature suggests an association between proton pump inhibitor (PPI) use and serious adverse effects such as increased risk for infection (pneumonia, clostridium difficile diarrhea), vitamin deficiencies, and myocardial infarction. In addition, inappropriate prescribing patterns for PPIs have been identified with nearly two-thirds of PPIs prescribed in many studies having no clear indication. The objective of this study is to assess the prescribing patterns for PPIs at a small teaching hospital and to gauge how effective pharmacy interventions are in limiting PPI use in accordance with acceptable guidelines.

**Methods:** This study is submitted to the local Institutional Review Board for approval. The electronic medical record system (EPIC) through a willow report will be used to identify all patients ≥18 years old admitted to Grandview Medical Center after July 1, 2015 who are either newly started on a PPI or continued from an outpatient setting. A thorough chart review will be conducted to assess the appropriateness of the patient’s PPI therapy, by first looking at and collecting factors such as: Indication, prior to admission medications, concurrent medications, age, admitting diagnosis, past medical history, ventilator status/days, length of stay, patient clinical status and lab values specifically INR, PTT, and platelets. The appropriateness of PPI therapy is then determined by comparing these factors to FDA approved indications, and current evidence-based literature. Both appropriate and inappropriate prescribing data will be collected. All data will be recorded without patient identifiers and kept confidential.

**Results:** N/A

**Session-Board Number:** 12-118

**Poster Title:** Analysis on the efficacy of intravenous versus oral antibiotic therapy in intravenous drug abusers with Staphylococcus aureus bacteremia

**Primary Author:** Tyler Jauss, Grandview Medical Center, OH; **Email:** tyler.jauss@khnetwork.org

**Additional Author(s):**
Julia Landis
Jack Bernstein

**Purpose:** While the incidence of illicit intravenous drug abuse is on the rise in the United States, an increased number of patients are presenting to hospitals with Staphylococcus aureus bacteremia with potential development into life-threatening endocarditis. Few studies have analyzed the success of oral antibiotic regimens in managing these infections at the time of discharge. The purpose of this study is to evaluate treatment success through analysis of the reinfection and readmission rates of intravenous versus oral outpatient antibiotic therapy in active drug abusers presenting to Grandview Medical Center with Staphylococcus aureus bacteremia.

**Methods:** This study will be submitted to the Kettering Health Network IRB board for approval. A retrospective search using EPIC software program will be performed to identify active drug abusers admitted to Grandview Medical Center from January 1, 2015 through December 31, 2016. Patients will be included in our study if two positive blood culture results of Staphylococcus aureus bacteremia are confirmed with or without endocarditis diagnosis. Personal health information will be delineated for each patient, and baseline characteristics such as age, sex, weight, and comorbid conditions will be recorded in a Microsoft Excel file that will only be accessible on Grandview’s campus. Along with baseline characteristics, patient’s culture results, antibiotic regimens, and therapy duration will be recorded. A follow-up chart review through Kettering Health Network will occur at ninety days from discharge to determine if these patients were readmitted to any of the network hospitals for Staphylococcus aureus bacteremia or endocarditis. An attempt will be made to contact the patient individually to determine if his or her oral antibiotic therapy was successful or if reinfection did occur. Results from the chart analysis and patient communication will then be recorded and analyzed. Cure rates for oral therapy will be calculated and compared to those for patients discharged on
intravenous therapy. The results of the study will then be released once the study is complete and finalized.

Poster Title: A comparison of the safety and efficacy of facilitated intubation (without paralytics) and rapid sequence intubation (with paralytics)

Primary Author: Taylor Roberson, Grant Medical Center (OhioHealth), OH; Email: taylor.roberson@ohiohealth.com

Additional Author(s):
Grant Walliser
Michelle Pershing
Christy Collins

Purpose: Rapid sequence intubation (RSI) involves administration of induction agents and neuromuscular blocking agents (NMBA). An alternative method of intubation called facilitated intubation (FI) does not utilize NMBAs. Advantages exist in performing RSI, including blunting physiologic response to laryngoscopy and impairing reflexes to prevent aspiration. However, using NMBA comes with risk because protective reflexes are removed, a concern in difficult airways due to potential for “can’t intubate, can’t ventilate” situations. Therefore, some practitioners elect to perform FI, allowing risk for aspiration and laryngospasm. The interest of this study is to compare safety and efficacy of RSI and FI at this institution.

Methods: This study will be submitted to the Institutional Review Board for approval. The proposed study is a retrospective, single-center chart review evaluating adult patients who underwent intubation for acute respiratory failure or inability to protect the airway at OhioHealth Grant Medical Center. I will examine the safety and efficacy of two types of intubation: rapid sequence intubation (RSI) utilizing neuromuscular blockade (NMB) and facilitated intubation (FI) without the utilization of NMB. The primary endpoint is to examine the unadjusted incidence of cumulative adverse events (such as more than one intubation attempt, traumatic intubation, aspiration, progression to airway emergency) associated with RSI and FI, overall and by provider type. Secondary analyses will include an attempt to identify contributing features affecting adverse event rates, such as patient demographics/co-morbid conditions or provider type. Additionally, we will describe the in-hospital mortality, length of stay, service line, provider type, pharmacist participation, intubation indications and number of first attempt intubations. Patient data will be collected via electronic medical records at my...
institution. Other data to be collected includes: patient age, gender, weight, medications utilized, and medication doses.

Poster Title: Implementation of a multifaceted pharmacy-led medical education to reduce asymptomatic bacteriuria treatment rates within an emergency department

Primary Author: Dan James, Grant Medical Center (OhioHealth), OH; Email: daniel.james@ohiohealth.com

Additional Author (s):
Lauren Lopez

Purpose: Asymptomatic bacteriuria (ABU) is a common occurrence that represents colonization as opposed to infection yet is often inappropriately treated with antibiotics. This inappropriate treatment frequently begins within the Emergency Department (ED) as a reaction to an abnormal urinalysis (UA) which is often subsequently continued as an inpatient regimen. The unnecessary use of antibiotics leads to an increased risk for multidrug resistant bacteria, Clostridium difficile infection, and avoidable healthcare costs. Thus the purpose of this quality improvement project was to evaluate the effects that a pharmacy-driven multifaceted educational intervention has on the rates of inappropriately treated ABU within a single-center ED.

Methods: We are conducting an educational quality improvement project at a single-center ED to reduce the rates of inappropriately treated ABU. The targeted audience for this education includes ED nurses, midlevel practitioners, and physicians. The education will consist of two components: an algorithm for appropriately evaluating an abnormal UA and an informative handout on ABU. The handout and algorithm will be communicated to the targeted audience using three different approaches: in-person discussions, emails, and general distribution within the ED. The education will be pharmacy-led but will be in collaboration with antimicrobial stewardship and ED personnel. This education will be implemented over a time period of one month. In order to evaluate the effectiveness of this quality initiative we will determine the pre- and post-intervention rates of inappropriate treatments through a retrospective chart review. Patients who were ordered prespecified antibiotics for a urinary tract infection (UTI) indication within the ED who had an abnormal UA will be included. Patients will then be filtered according to the presence or absence of documented UTI signs or symptoms. If UTI signs or symptoms are not documented, the patient will be recorded as having ABU and being inappropriately treated
with an antibiotic regimen. The primary outcome will be the difference in the frequency of inappropriately treated ABU after implementation of the educational intervention as compared to before implementation.

Poster Title: Pharmacists’ Evaluation of Apixaban Dosing for Atrial Fibrillation

Primary Author: Matthew Delisle, Hillcrest Hospital, OH; Email: delislm@ccf.org

Additional Author(s):
Frank Rigelsky
Sandra Axtell

Purpose: Apixaban, a direct oral anticoagulant (DOACS), has a different dosing regimen for each of its FDA indications, which can lead to potential dosing errors. The primary objective of this study was to identify the incidence of pharmacist documented interventions and appropriateness of pharmacist assessments for apixaban prescribed orders pertaining to atrial fibrillation. Secondary objectives include the following: (1) utilization of the order panel with the correct indication and dose; (2) the incidence of pharmacist led apixaban education to patients; and (3) prescriber adherence to apixaban dosing guidelines.

Methods: A retrospective chart review of 100 patients receiving apixaban in a 500-bed community hospital from January 2016 to May 2016. Inclusion criteria consisted of patients admitted to the hospital receiving apixaban for atrial fibrillation. Patients that received apixaban for other indications were excluded. Patients that received apixaban for atrial fibrillation were identified using a report generated from electronic medical records. Twenty patients per month were randomly chosen during the specified timeframe. Number of pharmacists’ renal function interventions were recorded for patients receiving apixaban. The criteria for an accurate apixaban dosing assessment was a pharmacist intervention for renal function assessment and an apixaban dose correction, if the dose was incorrect. Incidence of pharmacist led education and the effectiveness of the apixaban ordering panel were also analyzed. Institutional review board was obtained prior to conducting the study and descriptive statistics were used to analyze the data.

Results: The baseline demographics of the patients in this study included the following: median age 79 years; patient age over the age of 75 (66%); median weight (75.7 kg); prior TIA (17%); heart failure (22%); diabetes (29%); hypertension (88%); mean CHADS2 (2.4); CHADS2 score 1 (21%); CHADS2 score 2 (35%); CHADS2 score ≥3 (42%); and CHADS2-VASc (4.26). The apixaban
5mg was ordered for 65 patients, while the apixaban 2.5mg dose was ordered for 35 patients. The primary objective of pharmacist documented interventions was 82% and appropriateness of pharmacist interventions was 78%. The incidence of pharmacist documented interventions for new apixaban orders was 74%. The results of the secondary objectives are the following: utilization of the order panel with the correct indication and dose (98%); incidence of pharmacist led apixaban education to patients (62%); and the prescriber adherence to apixaban dosing guidelines (90%). When an incorrect order occurred in the study, pharmacists changed the apixaban dose according to protocol 30% of the time and followed up with a physician 10% of the time to verify a dose. A pharmacist missed an intervention 60% of the time when the order was incorrect.

**Conclusion:** Overall, pharmacists were successful in documenting renal dose interventions and making the correct decision regarding the prescribed apixaban dose. For patients with atrial fibrillation, utilization of the apixaban ordering panel was an effective tool for selecting the appropriate dose by providers.

Submission Type: Evaluative Study

Session-Board Number: 12-122

Poster Title: Evaluation of aztreonam utilization at a large community teaching hospital.

Primary Author: Kim Walker, Hillcrest Hospital, OH; Email: walker4@ccf.org

Additional Author(s):
Nathan Wirick

Purpose: The purpose of this study was to identify potential opportunities for improvement in aztreonam utilization. Aztreonam was recently added to several new order sets at our institution, and we wanted to retrospectively review its use. The primary objective assessed patients that received aztreonam for a documented penicillin or beta-lactam allergy, a history of penicillin or beta-lactam tolerance, and the duration of aztreonam use.

Methods: Evaluation included all patients admitted to Hillcrest hospital between January 1, 2015 and June 22, 2016 who were at least 18 years of age and received at least one dose of aztreonam during the admission. Descriptive statistics were used to evaluate the primary objective as well as multiple secondary objectives. Secondary objectives included the distribution of aztreonam orders by provider type, infectious disease consultation during admission, the proportion of patients without documented penicillin or beta-lactam allergies, and the proportion of patients with a documented history of penicillin or beta-lactam tolerance. Encounters were assessed by chart review in the Epic electronic medical record. Collected variables included reported allergies, antibiotic use history, chief complaint, admission diagnosis, culture data, and all antibiotics administered during the encounter. All patient information was de-identified prior to analysis. IRB approval was obtained for this study.

Results: One hundred and thirty four encounters met the inclusion criteria for the time period. Of these, three patients received aztreonam without a previously documented history of penicillin or beta-lactam allergy. Ninety-seven patients had a previously documented history of penicillin or beta-lactam tolerance or received a penicillin or beta-lactam during the admission. Of the remaining 34 patients, 18 received aztreonam for less than 24 hours and two eventually had microbiological results that would not have been treatable with aztreonam. Final review suggests initial prescribing could potentially be modified in 89% of these patients. Infectious
disease was consulted in 66.4 percent of encounters with aztreonam discontinued in 87.6 percent of those instances. Of the 44 positive cultures in the study group, 17 were gram-negative organisms that may have been treatable with aztreonam.

**Conclusion:** Evaluation of the use of aztreonam over an 18 month period shows that 89 percent of aztreonam orders were for patients who did not have a penicillin or beta-lactam allergy, had documented tolerance to penicillin or beta-lactams, or continued for less than 24 hours of treatment. The findings indicate an opportunity may exist to improve the utilization of aztreonam within our institution.

**Session-Board Number:** 12-123  

**Poster Title:** Comparison of Clostridium difficile infection (CDI) rates in antimicrobial regimens for diverticulitis  

**Primary Author:** Bethany Sibbit, Kettering Medical Center, OH; **Email:** bgssibbit@cedarville.edu  

**Additional Author (s):**  
Amanda Hipsher  
Aleda Chen  
Kin Chan  
Casey Garman  

**Purpose:** Clostridium difficile infection (CDI) is one of the most costly yet preventable nosocomial infections and has potential for substantial morbidity and mortality. In 2017, CDI rates will negatively impact an institution’s Medicare reimbursement, adding an even greater impetus for CDI prevention. The objective of this study is to assess the CDI incidence related to diverticulitis treatment in regimens containing metronidazole versus those without and evaluate the clinical relevance of antimicrobial selection.  

**Methods:** This retrospective chart review will be submitted to the Kettering Health Network (KHN) Institutional Review Board (IRB). Using the appropriate ICD-9 and ICD-10 codes, the electronic medical record will be used to identify patients who received at least 48 hours of antimicrobials for diverticulitis. The following data will be collected: patient age, gender, antimicrobial agent(s) used, dosage, duration of therapy, Clostridium difficile polymerase chain reaction (PCR) results, blood pressure, temperature, heart rate, complete blood count (CBC), diagnostic imaging, length of stay, nursing unit location, surgical and/or infectious disease consultation with or without intervention, use and duration of vasopressors, and 30-day readmission, if applicable. Provider documentation will be assessed to determine appropriativeness of inpatient and discharge antimicrobial selection as well as appropriate treatment of CDI when it occurred according to the Infectious Diseases Society of America (IDSA) treatment guidelines. All data will be collected and de-identified to maintain patient confidentiality. CDI rates will be compared between regimens containing metronidazole and those without. The clinical impact of CDI will be assessed through length of stay, the need for
vasopressor support, transfer to an intensive care unit, or necessity of surgical intervention. Analysis will be conducted using descriptive statistics, unpaired t-tests for parametric data or continuous variables, Mann-Whitney-U for nonparametric variables, and chi-squared for binary variables.

**Results:** Not applicable

**Conclusion:** Not applicable

Poster Title: Retrospective analysis of antimicrobial selection and timing for treatment of febrile neutropenia

Primary Author: Jonathan Wilkie, Kettering Medical Center, OH; Email: jonathan.wilkie@ketteringhealth.org

Additional Author(s):
Kin Chan
Rachel Henderson
Amanda Hipsher
Casey Garman

Purpose: This study was designed to assess adherence to current Infectious Disease Society of American guidelines regarding appropriate selection and timing of antimicrobial agents for treatment of febrile neutropenia and its impact on patient outcomes. IDSA febrile neutropenia treatment guidelines emphasize the importance of proper selection and timely administration of antimicrobial agents for improved outcomes in this patient population. An additional purpose of this study is to determine possible risk factors for inappropriate treatment of febrile neutropenia, defined as deviation from current IDSA guideline recommendations.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will distinguish patients with a diagnosis of febrile neutropenia with or without a documented temperature greater than or equal to 38 degrees Celsius (100.4 degrees Fahrenheit). Prior to submission, patient identifiers will be removed from data to preserve confidentiality.

Patient-specific data to be collected include: age, weight, gender, serum creatinine, complete blood count with differential, absolute neutrophil count, reported and measured temperatures, time of initial fever, cancer diagnosis and central line access. Admission-related data to be gathered: hospital admission time and type (via emergency department or direct admission), presence of infectious disease physician consult and admitting physician specialty. Treatment-specific data to be obtained include: antimicrobial, antipyretic and colony stimulating factor medications received and specific administration times, antimicrobial agent order priority, timing, verification and administration, type, timing and results of microbiologic cultures drawn.
Estimated creatinine clearance will be calculated using the Cockcroft-Gault formula. Time intervals between admission, initial fever, antimicrobial order, order verification and antimicrobial administration will be calculated. Physician documentation and treatment course will be analyzed for proper selection and timely administration of antimicrobial agents. Microbiologic culture results and temperature readings will be evaluated to determine if proper escalation and de-escalation of therapy occurred. Treatment courses will be categorized as “adherent” or “non-adherent” based on IDSA treatment guidelines.

Poster Title: Effect of patient medication counseling by a pharmacist at hospital discharge on patient satisfaction survey results in a community hospital setting

Primary Author: Katie Tourjee, Lima Memorial Health System, OH; Email: tourjeek@findlay.edu

Additional Author (s):
Jeremy Ebert
Karen Kier

Purpose: Hospital pharmacists are beginning to provide patient discharge counseling as a way to improve patient satisfaction, lower readmission rates, and improve medication adherence in the transitions of care. Many hospitals utilize the Centers for Medicare and Medicaid Services (CMS) Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey in order to assess patient satisfaction. The purpose of this study is to determine the effect that medication counseling by a pharmacist prior to discharge has on the results of the medication-related questions in the CMS HCAHPS survey scores on the cardiac stepdown unit.

Methods: The study will be submitted to IRB for approval. It is a historical control, interventional study with retrospective and prospective review of CMS HCAHPS scores for medication-related questions. The first intervention will be a continuation of the current process of a pharmacist performing medication reconciliation at discharge. The second will be an intervention to provide medication discharge counseling to patients on the cardiac stepdown unit. Areas addressed will include which prior medications should be continued and which should be stopped, as well as which medications are new and their indication. This reviewed list will be provided to the patient for reference. Inclusion criteria for the study are patients 18 years of age or older who speak English and are being discharged from the stepdown unit to return home or to an assisted living facility in which the patient will manage his/her own medications. Patients will be excluded if they are pregnant/breastfeeding, are being discharged to hospice/nursing home where they will not manage their own medications, or if they are being transferred to a tertiary care center. The primary outcome is CMS HCAHPS survey results on the cardiac stepdown unit. A paired t-test will be used to analyze the pre-post HCAHPS results. Descriptive statistics will be used to analyze demographic data and medication interventions. A power calculation determined a sample size of 35 per group.

**Poster Title:** Impact of utilizing rapid pathogen identification with pharmacist intervention on time to appropriate antimicrobial agents

**Primary Author:** Amanda Lanker, Lima Memorial Health System, OH; **Email:** a-lanker@onu.edu

**Additional Author(s):**
Brittany Bates
Karen Kier

**Purpose:** Mortality is higher for patients with bloodstream infections that receive inadequate initial antimicrobial therapy. Current laboratory practices for incubation, identification, and obtaining sensitivity results of offending organisms can take 3-5 days or longer. The latest Infectious Disease Society of America guidelines recommend the use of rapid diagnostic testing along with the intervention of antimicrobial stewardship programs. The objective of the study is to determine if pharmacist intervention with real-time results from rapid identification of microbes from positive blood cultures decreases the time to appropriate antimicrobial agents.

**Methods:** This is a historical controlled, multi-phase, interventional study. The primary outcome will be the time in hours to appropriate antimicrobial agents. Other outcomes to be measured include overall days of therapy, length of stay, days of broad-spectrum antimicrobials given, and recommendations accepted. Three comparator arms of patients with positive blood cultures will be included in the study. Group one will include patients prior to implementation of rapid diagnostic testing, group two will include patients after implementation, and group three will include patients after implementation plus pharmacist intervention. The Biofire FilmArray® (Biofire Diagnostics; Salt Lake City, Utah) blood culture identification (BCID) panel will be used by hospital laboratory services to identify the pathogens isolated from blood cultures. Pharmacists will be alerted of positive BCID panel results in real-time. Data to be collected includes name, age, creatinine clearance, white blood cell count, temperature, drug allergies, antimicrobials regimen, and microbiology results. All personal identifiers will be saved on secure network computers and eliminated before sending data to other investigators. Treatment algorithms will be created for the pathogens that can be identified by the BCID panel. Inferential parametric statistics (ANOVA) will be used for continuous data while
nonparametric statistics will be used to analyze categorical data. A power calculation identified a sample size of 35 per group. This study will be submitted for IRB approval.

Poster Title: Establishing a long-acting injectable antipsychotic clinic at a community hospital

Primary Author: Tuan Trinh, Lutheran Hospital-Cleveland Clinic, OH; Email: trinht2@ccf.org

Additional Author (s):
Ashley Tewksbury

Purpose: Long-acting injectable (LAI) antipsychotics have demonstrated clinical benefits in the treatment of psychiatric patients, including reducing risk of relapse and re-hospitalization. These clinical benefits are especially important for schizophrenic patients because of their low medication adherence and high rate of re-hospitalization. One current challenge to providing these benefits is that there are few pharmacist-led LAI clinics even though pharmacists are among the most accessible healthcare providers. In Ohio, pharmacists are recently permitted to administer LAIs to patients. This project aims to establish an outpatient LAI clinic under a collaborative practice agreement between pharmacists and psychiatrists at a community hospital.

Methods: The outpatient LAI clinic will be established to provide LAIs for behavioral health patients with the needs for these medications with the goals of optimizing patient adherence, minimizing hospital readmission rates, and reducing associated costs. In this clinic, psychiatric clinical pharmacists will provide the injections, laboratory monitoring, medication counseling, and therapy adjustments. The PGY2 resident will develop a collaborative drug therapy management (CDTM) agreement, which will define the pharmacists' scope of practice and include detailed protocols for drug administration, laboratory ordering and monitoring, therapy adjustments, and patient follow-up services. The protocols will specify pharmacist training requirements, pharmacist peer review process, and periodic quality assessment of the services provided. The practice agreement will adhere to all the laws and rules established by the Ohio State Board of Pharmacy to allow clinically trained pharmacists to provide LAIs to patients. The practice agreement and protocols will be presented to the Pharmacy and Therapeutics (P&T) Committee for approval after the psychiatrists have the opportunity to make suggestions and modifications. Once the P&T committee approves the practice agreement and relevant protocols, they can be implemented provided that the other components of the LAI clinic, such as space, pharmacist training, and drug acquisition process are ready.

Poster Title: Integrating an interdisciplinary approach to medication reconciliation for transitions of care in a family practice department of a rural healthcare system

Primary Author: Alexandra Dimit, Marshall University/Holzer Health System, OH; Email: adimit@holzer.org

Additional Author(s):
Brittany Riley
Sarah Meucci

Purpose: Reducing readmission rates following acute care hospitalization continues to be an area for improvement in the healthcare system. Following the 2010 Affordable Care Act, the Centers for Medicare and Medicaid began an initiative to improve readmission rates nationwide. Pharmacists are trained to address the concerns about patient safety and efficacy pertaining to medication use. Studies have shown that readmission rates and overall healthcare costs can be reduced when pharmacists are actively involved in post-discharge planning. This study will evaluate the impact of including a pharmacist in an interdisciplinary approach to medication reconciliation on 30-day readmission rates relative to current methods.

Methods: This nonrandomized, single-center study will be submitted to the Institutional Review Board for approval. Holzer Health System ambulatory pharmacy services will collaborate with Holzer Family Practice to provide pharmacist-led medication reconciliation to patients recently discharged from the hospital. Patients seen between September 2016 and March 2017 are eligible to participate in this study provided that they are at least eighteen years old, and not discharged to a nursing facility or long-term care rehabilitation facility. During a scheduled, post-discharge appointment with the patient’s primary care provider, a pharmacist will perform medication reconciliation. The medication reconciliation will include reviewing medication profiles, disease state and medication education, identification of any gaps in care, adherence issues, therapeutic duplications, medication errors, adverse reactions, or drug interactions. Once the medication reconciliation is complete, the pharmacist will discuss any concerns, recommendations, or opportunities for intervention with the physician. Patients will be monitored for thirty days after discharge for potential readmissions. Readmission rates of patients who have had a pharmacist perform their medication reconciliation will be compared
to readmission rates from September 2015-March 2016 for the family practice department, and the average 30-day readmission rates for Holzer Health System and the United States.

**Poster Title:** Impact of a medication assistance program  

**Primary Author:** Samantha Hartings, Mary Rutan Hospital, OH; **Email:** s-hartings.1@onu.edu  

**Additional Author (s):**  
Karen Kier  
Christina Myers  

**Purpose:** In 2010, the Logan County Census reports approximately 15% of the population below the poverty line. The 2014 Small Area Health Insurance Estimates (SAHIE) estimates nearly 11% of Logan County occupants are uninsured. Improving medication access could have a potentially significant impact on frequent flyer emergency department visits and hospital readmission rates. The purpose of this study is to assist participants in acquiring their medications either free or at a discounted cost through manufacture programs and discounts.  

**Methods:** All eligible patients will be identified by emergency department and hospital personnel. Pharmacy will receive a referral and a pharmacy technician will set up an appointment to collect the participant’s medication list, identify eligible medications, and acquire the necessary demographic information, such as a W-2 form, social security statement, disability benefit verification statement, and a bank statement/check stub to meet the requirements of the manufactures’ programs. A pharmacist will counsel the patient on their medication(s) and provide an index card with important prescription information. The pharmacist will perform a medication review and then contact the participant’s health provider to obtain his/her signature or make therapeutic substitution recommendations regarding medications that are ineligible and a new prescription when required. After receiving the signed application back from the provider, the pharmacy will complete the application and, if approved, the medications will be shipped directly to the patient. The primary outcome variable will be number of patient interventions identified. Secondary outcome variables will include emergency department and hospital readmission, dollar value of medication acquired, and patient satisfaction. Descriptive statistics will be used for the primary outcome variable with inferential statistics for readmission and patient satisfaction.

Poster Title: Prescribing patterns of direct oral anticoagulants within an academic medical center

Primary Author: Aimrie Ream, Mercy Health, OH; Email: aream@mercy.com

Additional Author(s):
Lisa McIntyre
Deidre Rohaley

Purpose: Direct oral anticoagulants (DOAC) are an increasingly popular alternative to warfarin. In 2012, an internal drug utilization evaluation (DUE) of rivaroxaban revealed areas for improvement in regards to physician prescribing and pharmacist monitoring of rivaroxaban. Two additional DOAC medications have since been approved, apixaban and edoxaban. The purpose of this evaluation is to assess current DOAC prescribing patterns at an academic medical center for commercially available DOAC medications, identify if previous knowledge gaps have been successfully addressed, and identify potential areas for process improvement. Additionally, safety outcomes will be reviewed.

Methods: Once approval is received from the Institutional Review Board, patients will be identified through use of the electronic health record (EHR). A report generated by the EHR will include all patients during January 1, 2016 – June 30, 2016 for whom an order was placed for DOAC therapy (dabigatran, apixaban, edoxaban, or rivaroxaban). The pharmacy resident will perform a retrospective chart review of these patients to include only patients that were newly started on one of the specified agents. The following data will be collected: age, gender, actual body weight, allergies, drug, indication, dose, renal and liver function tests, prescriber, medical unit, expected length of treatment, concomitant medications (to identify drug interactions), contraindications, adverse events, and whether inpatient pharmacy education was provided to the patient. Up to three months post-discharge will be reviewed to assess 30-day readmission rate, discontinuation rates, and adherence (proportion of days covered will only be calculated for patients that utilize one of the medical center’s outpatient pharmacies in the local area). Data analysis will include descriptive statistics. Confidentiality will be maintained, as patient identifiers will not be used in data collection. Upon completion of the DUE, hospital units with
the highest number of prescriptions issued will be targeted for recruitment of patients into a new anticoagulation clinic service where pharmacists monitor DOAC therapy.

Poster Title: Evaluation of inpatient tolvaptan use in a 338-bed hospital with post-evaluation prescriber education and assessment

Primary Author: Megan Foreman, Mercy Health - Regional Medical Center, LLC, OH; Email: mmforeman@mercy.com

Additional Author(s):

Purpose: Tolvaptan is a vasopressin antagonist FDA-approved to treat hypervolemic and euvoletic hyponatremia. The average price of treatment is around $1,200, which represents significant cost for both the hospital and the patient. The objective of this study is to evaluate the usage of inpatient tolvaptan treatment and design institution-specific education to guide tolvaptan usage.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record will be used to identify patients who received tolvaptan during their inpatient stay. Data gathered from patient profiles will include the following: gender, demographics, etiology of hyponatremia, baseline serum sodium, tolvaptan dosing regimen, sodium levels at discontinuation of therapy, prior and/or concomitant treatment of hyponatremia, and prescriber name/specialty. Prescriber documentation will also be examined to determine if reasons for selecting tolvaptan therapy were recorded. Following completion of the drug use evaluation, institution-specific prescriber education will be created to guide tolvaptan usage. Assessment of education provided to prescribers will consist of a questionnaire determining if education has changed their practice.

**Poster Title:** Evaluation of a pharmacist-led medication reconciliation and discharge program in a psychiatric population

**Primary Author:** Jerome Pasquale, Mercy Health - St. Charles Hospital, OH; **Email:** jpasquale@mercy.com

**Additional Author (s):**
Lauryl Kristufek

**Purpose:** Psychiatric patients are at an increased risk for medication discrepancies due to polypharmacy, poor adherence, and comorbid disease states. Currently there is no pharmacist-led medication reconciliation program upon admission or medication counseling upon discharge. Although medications are reconciled upon admission and discharge counseling is provided, a pharmacist is not involved in these processes. The objective of the study is to evaluate if a pharmacist-led medication reconciliation and discharge education program results in a decrease in the overall number of medication discrepancies, an increase in medication appropriateness, and improvement in a discharge education survey score.

**Methods:** This single center pilot study will be conducted at the Behavioral Health Institute located on the hospital’s campus. All patients admitted to unit C or D of the Behavioral Health Institute will have a medication reconciliation review conducted as soon as possible after admission by the researcher. This up-to-date medication list will be compared with the list derived from the current nursing led process and any discrepancies between the two lists will be noted. Also, the researcher will meet with patients 1 to 2 days prior to discharge and discuss their home medication regimen. A survey will be administered prior to medication education and after education to determine if there was any improvement in the patient’s understanding of key aspects of their medication regimen including: name, indication, dose, frequency, and possible side effects of each medication. The primary objectives are the overall number of medication discrepancies found, change in medication appropriateness index scores, and improvement in discharge medication education survey scores. The secondary objectives are classification of the medication discrepancies found, overall cost avoidance from preventing medication errors, and documentation of dual-antipsychotic usage at discharge with proper justification in compliance with HBIPs 5.

Poster Title: Comparison of vancomycin regimens and resultant trough concentrations in a pediatric population

Primary Author: Derek Gyori, Mercy Health St. Vincent Medical Center, OH; Email: djgyori@mercy.com

Additional Author (s):
Deidre Rohaley
Kathryn Kleckner

Purpose: The Infectious Diseases Society of America currently recommends a vancomycin dose for pediatric patients of 40 mg/kg/day divided every six hours for minor infections and 60 mg/kg/day divided every six hours for more complicated infections. Recent studies have shown the current dosing strategies are not consistently achieving the recommended target vancomycin troughs of 10 to 20 mcg/mL for minor infections and 15 to 20 mcg/mL for complicated infections. The objective of this study is to evaluate initial and subsequent vancomycin dosing regimens to compare the frequency of therapeutic trough levels and nephrotoxicity in pediatric patients.

Methods: A single center, retrospective chart review will be conducted after approval from the Institutional Review Board. Subjects between the ages of 29 days to 17 years admitted to the general pediatrics or pediatric intensive care units who received intravenous vancomycin from September 1, 2013 to August 31, 2016 will be identified via the electronic medical record. For inclusion, a subject must have received more than three vancomycin doses and had a trough level drawn one hour prior to vancomycin. Neonates, subjects receiving vancomycin via continuous infusion or without a documented trough concentration, and subjects with a history of renal replacement therapy will be excluded. The following data will be collected: demographic information, admitting service, past medical history of cystic fibrosis, burn, or cancer, recent antimicrobial therapy, type of infection and pathogen, initial and subsequent vancomycin regimens, vancomycin trough levels including timing in relation to doses, renal function measures, and concomitant nephrotoxic medications. Initial intravenous vancomycin doses will be categorized as 40 to 45 mg/kg/day or 60 mg/kg/day and the percent of subjects who reached a target vancomycin trough level will be compared. Secondary analysis of dose
adjustments, doses stratified by age group and admitting service, common dosing intervals, and nephrotoxicity will be assessed. Data will be analyzed using descriptive statistics, Chi-square or Fisher’s exact test, and student’s t-test as appropriate.

Poster Title: Pharmacist management of vancomycin dosing in the critical care unit of an acute care urban hospital

Primary Author: Rachel Gresko, Mercy Medical Center, OH; Email: rachel.gresko@cantonmercy.org

Additional Author (s):
Matthew Reale
Kyle Sobecki

Purpose: Vancomycin is a glycopeptide antibiotic with effective coverage against Gram-positive bacteria. When given intravenously, there is a potential for harmful adverse events including nephrotoxicity and ototoxicity. Monitoring trough concentrations allows clinicians to minimize adverse effects, while ensuring efficacy. Pharmacist management of vancomycin therapy in a hospital setting can provide an increased frequency of therapeutic troughs, in addition to added patient safety. The primary objective of this study is to assess the number of therapeutic first troughs obtained from pharmacist managed vancomycin compared to non-pharmacist vancomycin management. The ultimate goal of this research is to implement a hospital-wide pharmacy-to-dose vancomycin protocol.

Methods: Pharmacy will manage all vancomycin dosing and monitoring for patients admitted to the intensive care unit (ICU) during the month of November 2016. Management includes ordering appropriate initial vancomycin doses, measuring and assessing troughs, making dosing adjustments, monitoring cultures, and providing recommendations for changes in therapy when necessary. Data collected from current patients will be retrospectively compared with patients who were prescribed vancomycin in the ICU in November 2015. The primary outcome of the study is percentage of troughs therapeutic at first draw. Secondary measures of this study will include percentage of subtherapeutic troughs (< 10 mcg/mL) and percentage of supratherapeutic troughs (>20 mcg/mL). Inclusion criteria for this study include patients with an initial vancomycin consult while in the ICU and patients admitted to the ICU from the emergency department with no more than 1 dose of vancomycin administered. Exclusion criteria include patients started on vancomycin outside of the ICU, hemodialysis patients, pregnant patients, and patients with orders for oral vancomycin therapy.

Poster Title: Implementation of two follow-up interactions between a pharmacist and patient after hospital discharge to reduce 30-day readmission rate

Primary Author: Gregory Hauler, Mercy Medical Center, OH; Email: gregory.hauler@cantonmercy.org

Additional Author(s):
Sunita Patel

Purpose: In 2011, there were approximately 3.3 million adult 30-day hospital readmissions, resulting in $41.3 billion in hospital costs. Of all 30-day readmissions, the majority occurs within 15 days of hospital discharge. Pharmacists are integral in providing medication education, improving adherence, preventing medication errors, and identifying adverse events that may contribute to readmissions. The primary objective of this study is to evaluate the impact of pharmacist involvement in the hospital follow-up appointment and subsequent phone call on 30-day readmission rate. Secondary objectives include adherence score, number of accepted and total pharmacist interventions, time spent with patient, patient satisfaction, and physician satisfaction.

Methods: This study will be submitted to the Institutional Review Board for approval. This is a descriptive study that will be conducted from October-December 2016 in the Mercy Ambulatory Care Clinic (ACC). Patients discharged from the Medical Teaching Service are scheduled for a hospital follow-up appointment within ten days in the ACC. The pharmacist will contact the patient prior to their scheduled appointment to serve as a reminder call and inform the patient to bring in all of their medications. At the hospital follow-up appointment, the patient will meet with the pharmacist prior to meeting with the physician. During this interaction, the pharmacist will complete a medication history/reconciliation. Additionally, the pharmacist will assess adherence via the 4-item Morisky Medication-Taking Adherence Scale (MMAS), provide adherence/medication counseling, and identify pharmacist interventions. Patients will also be given an optional, anonymous survey to assess satisfaction with the pharmacist. The interaction will be documented in the patient’s electronic medical record and the findings will be reiterated to the patient within seven days after the appointment via telephone. The physicians will be given an optional, anonymous survey to assess satisfaction.
with the pharmacist. The following data will be collected: age, gender, ethnicity, admitting diagnosis, discharge date, emergency department visits, co-morbidities, number of medications, adherence score, pharmacist interventions, patient and physician satisfaction via survey, and the time spent with patient during the appointment.

Poster Title: Impact of emergency medicine pharmacists on follow-up of positive microbiological culture results

Primary Author: Geetika Bajpai, Mercy St. Vincent Medical Center, OH; Email: gbajpai@mercy.com

Additional Author(s):
Todd Gundrum
Rachel Leis
Alison Paplaskas
Jenifer Sze

Purpose: Urinary tract infections (UTIs) and skin and soft tissue infections are commonly diagnosed infections in the emergency department (ED), with bacteremia being less common. The 2010 Infectious Diseases Society of America guideline for the management of acute uncomplicated cystitis and pyelonephritis states that empiric antibiotic selection should be based on local and national antibiograms. However, the isolated pathogens are not always susceptible to the antimicrobial regimen prescribed at discharge from the ED. This can lead to therapy failure, ED revisits and hospitalizations. The objective of this study is to assess the impact of a pharmacist led ED culture follow-up program.

Methods: Pending institutional review board approval, a retrospective chart review will be conducted and will include patients discharged from the ED with a positive urine, blood, abscess or wound culture from August 1, 2015 to August 1, 2016. Patients will be excluded if they had asymptomatic bacteriuria, contaminated urine culture, or were hospitalized. A pharmacy report will identify interventions made through the culture follow-up program. The overall number of interventions that the pharmacist made and the method of follow-up will be recorded. A further analysis of the positive urine cultures that required a pharmacist intervention will be conducted. The empiric antibiotic regimen prescribed at discharge will be classified as optimal, appropriate or inappropriate. Optimal therapy is defined as a urinary isolate susceptible to the empiric antibiotic therapy and is a preferred therapy. The preferred antibiotic list is based on the local and national antibiograms. Appropriate therapy is defined as a urinary isolate susceptible to the empiric antibiotic therapy and is not a preferred therapy.
Inappropriate therapy is a urinary isolate not susceptible to the empiric antibiotic therapy, not discharged on an antibiotic, or discharged on an antibiotic that is not used to treat a UTI. A sub-group analysis will compare the ED revisit rate within 30 days for urinary tract infections prior to and post the culture follow-up program.

Poster Title: Use of dalbavancin as an alternative to traditional agents for the treatment of acute bacterial skin and skin structure infections (ABSSSI)

Primary Author: Dustin Freshwater, MetroHealth Medical Center, OH; Email: dustinf1224@gmail.com

Additional Author (s):
Nina Naeger-Murphy
Michelle Hecker
Mark Pangrazzi

Purpose: Dalbavancin is a lipoglycopeptide antimicrobial given as a one-time intravenous (IV) dose for the treatment of ABSSSI. The advantages of dalbavancin are one time dosing, no therapeutic drug monitoring and potential avoidance of hospital admission. The disadvantages of dalbavancin are high cost and potential overuse in settings where less expensive options exist or antimicrobial therapy is not warranted. The primary objective of this study is to determine the number (%) of patients with an ABSSSI diagnosis admitted to a level 1 trauma center who would have qualified for dalbavancin treatment using predefined use criteria.

Methods: The study will be submitted to the Institutional Review Board for approval. This is a prospective chart review of adult patients admitted to a level 1 trauma center with a primary diagnosis of cellulitis (ICD10 L03) and/or local skin and soft tissue infections (ICD10 L08.9). Inclusion criteria are presence of greater than or equal to 2 local signs/symptoms of complicated ABSSSI and greater than or equal to 1 systemic sign or complicating factor requiring IV therapy. The following data will be collected from the electronic medical record: patient age, gender, ethnicity, hospital unit and service, antibiotic allergies, length of stay, local symptoms and signs of infection, temperature, laboratory results (including white blood cell count, vancomycin levels, microbiology results), antibiotic therapy, adverse effects related to antibiotic therapy, peripherally inserted central catheter placement, need for surgical intervention, development of deep seated infection during hospitalization related to ABSSSI, intravenous drug use, contraindication to linezolid oral therapy and 30 day readmission. Patients will be classified as qualifying for dalbavancin if they meet all of the following criteria: requirement of IV therapy for at least 3 days but less than 14, no gram negative or anaerobes
isolated, no need for operative interventions, linezolid therapy contraindicated, and no need for hospital management of other comorbidities. All data will be de-identified and maintained confidentially. Descriptive statistics will be utilized to analyze results.

Poster Title: Clinical and humanistic outcomes of face-to-face and telehealth warfarin management: a retrospective, crossover study

Primary Author: Rachel Maxwell, MetroHealth Medical Center, OH; Email: r-maxwell@onu.edu

Additional Author(s):
Julie Baron
Matthew Schneiderman
Christina Wadsworth

Purpose: Health systems are rapidly expanding to offer ambulatory services, including warfarin-management, throughout surrounding communities. This can lead to various warfarin-management approaches with lack of standardization from site to site. This study will evaluate clinical and humanistic outcomes of warfarin management via face-to-face and telephone encounters to determine how well patients are clinically managed in each setting; as well as how satisfied patients are with telehealth care. This information may help guide health-systems to decide which services to offer and which patients may benefit from telehealth or face-to-face encounters.

Methods: This study will be approved by the institutional review board prior to commencement. The population includes about 165 patients transitioning from two satellite anticoagulation clinics to the Medication Management Clinic (MMC) for warfarin management. Patients must be 18 years or older, taking warfarin, and managed by one of the two satellite clinics at least six months prior to transitioning to MMC. Patients will be excluded if warfarin is discontinued during the study period, patient is home INR testing, or if the patient uses the face-to-face clinic instead of telehealth more than 25% of the time. RedCap software will be used for retrospective data collection including; demographics, indication, goal INR range, use of chronic NSAIDs or antiplatelet medications, encounter type, INRs, number of procedural interruptions, and hospitalizations/emergency room visits stratified by primary diagnosis and bleed type per BARC score (Bleeding Academic Research Consortium). Data will be collected from six months prior to transitioning to MMC through six months following the transition. Design: Non-inferiority, retrospective crossover. Primary outcome: time in therapeutic range
(TTR) calculated via the Rosendaal method. Secondary outcomes include extreme INR level (INR \geq 4.5 or INR)

Poster Title: Impact of pharmacist led disease state management of patients with diabetes in primary care clinics

Primary Author: Benjamin Pontefract, MetroHealth Medical Center, OH; Email: bpontefract@metrohealth.org

Additional Author (s):
Benjamin King
Cynthia Brucato

Purpose: Current literature demonstrates the positive impact of clinical pharmacists in primary care clinics on hemoglobin A1c (HbA1c). However, there is limited information detailing the effects of a clinical pharmacist in a primary care clinic on patient satisfaction and medication adherence. In addition, the financial viability of a pharmacist in this setting has yet to be fully explored. The objectives of this study are to contribute to existing literature on pharmacists’ effect on diabetes control, patient satisfaction, patient adherence, and sustainability.

Methods: This study is pending Institutional Review Board approval. This study is a prospective chart review with patient survey comparing clinical pharmacist disease state management of diabetes mellitus under a collaborative practice agreement to usual care. Patients will be identified as members of the control or intervention group utilizing reports within the electronic medical record (EMR). Demographic data will be collected from their index visit: age, gender, height, weight, body mass index, race, and duration of diabetes. Clinical data will be collected every three months starting with the index visit: hemoglobin A1c (HbA1c), number of medication doses missed in the week prior to clinical pharmacist visit, number of office visits, and presence of statin therapy. Another report within the EMR will be used to gather the total revenue of the clinical pharmacy services over a six month period of time. Once during the study period, intervention patients will be given the opportunity to complete an optional, anonymous, abbreviated version of the Clinicians and Group Consumer Assessment of Healthcare Providers and Systems survey in order to determine patient satisfaction with the clinical pharmacy services.

**Poster Title:** Evaluating the impact of a pharmacist on guideline directed medical therapy in patients with reduced ejection fraction heart failure

**Primary Author:** Adam Ingram, MetroHealth Medical Center, OH; **Email:** aingram@metrohealth.org

**Additional Author (s):**
Megan Valente
Mary Ann Dzurec

**Purpose:** The current heart failure guidelines emphasize the use of guideline directed medical therapy, which includes recommendations to titrate specific medications shown to reduce morbidity and mortality to target doses reflected in published literature. This pilot study aims to investigate the impact of a pharmacist-run, outpatient heart failure management clinic on patients’ heart failure outcomes and healthcare related costs.

**Methods:** This is a retrospective electronic chart review pending approval from the Institutional Review Board. Patients who were referred to the pharmacist-run, outpatient heart failure management clinic will be considered for inclusion. The primary endpoint is the average time (number of weeks and number of visits) to achieve individualized target doses of guideline-indicated medications. Beta-blocker titration will be evaluated within the secondary endpoints: percentage of patients titrated to target doses, reasons for inability to fully titrate, and the percentage of patients with a left ventricular ejection fraction of 35 percent or greater after maximal beta-blocker titration. Additional secondary endpoints include the total and per-visit revenue generated as well as the change in average number of all cause and heart failure-specific hospital admissions and emergency department visits. Data will be stratified into two patient groups; those whose medications were partially titrated and those whose medications were not titrated at the time of enrollment into the clinic. Data reviewed will include demographic characteristics, New York Heart Association functional class, baseline and post-titration ejection fraction, dates and number of visits, reasons for inability to titrate beta-blockers, as well as number and type of hospital admissions and emergency department visits. Analysis of continuous variables will be completed using a Wilcoxon signed rank test. All other endpoints will be reported using descriptive statistics.

Poster Title: Implementation of FilmArray blood culture identification panel: Assessment of time to appropriate antimicrobial therapy and subsequent impact on patient outcomes

Primary Author: Kaylee Wentworth, Mount Carmel West Hospital, OH; Email: kaylee.wentworth@mchs.com

Additional Author(s):
Theresa Koski
Katrina Reynolds
Andrew Caputo

Purpose: The FilmArray Blood Culture Identification (BCID) panel identifies 24 organisms and 3 antibiotic resistance genes in approximately 1 hour. Previous studies suggest that early detection of the pathogen positively impacts patient outcomes. In addition, rapid identification may reduce the amount of time spent treating contaminants and improve time to optimal therapy. The purpose of this study is to analyze the effects of the FilmArray BCID panel on appropriate antimicrobial use, including duration of vancomycin therapy, and patient outcomes.

Methods: This retrospective chart review will be submitted to the Institutional Review Board for approval. The hospital informatics system will be used to identify patients with positive blood cultures for contaminants or methicillin-sensitive Staphylococcus aureus (MSSA). Patients will be excluded if they have positive blood cultures for pathogens other than contaminants or MSSA, or if they expire or transfer to palliative care within 24 hours of the positive culture. Antimicrobial utilization and patient outcomes will be compared pre- and post-implementation of the FilmArray BCID panel. Data to be collected from electronic medical records include patient age, gender, drug allergies, serum creatinine, concomitant nephrotoxic agents, duration of vancomycin therapy, time of positive and identified blood cultures, time of appropriate antimicrobial initiation, Charlson Comorbidity Index (CCI), and Pitt bacteremia score. Patient data will be de-identified for confidentiality. Time to appropriate antimicrobial therapy and patient length of hospital stay will be the primary outcomes of the study. Secondary outcomes will include length of intensive care unit (ICU) stay, time to negative blood culture, adverse drug events, 30-day mortality, and total hospital cost.

**Poster Title:** Pharmacist initiated intervention in sepsis management in the emergency department

**Primary Author:** Nicole Pavlik, Mount Carmel West Hospital, OH; **Email:** nicole.m.pavlik@gmail.com

**Additional Author(s):**
Katrina Reynolds
Virginia Ruef
Ryan Schell
Jocelyn Owusu-Yaw

**Purpose:** The purpose of this research project is to improve patient care, compliance with the sepsis bundle, and quality measures set forth by Center for Medicare and Medicaid Services (CMS) by implementing pharmacist driven early intervention in patients presenting to the emergency department (ED) with sepsis. The primary outcome is time to antibiotic administration, thus complying with the 3-hour sepsis bundle and 1-hour septic shock recommendations. Secondary outcomes include overall sepsis bundle compliance, fluid resuscitation, and empiric antibiotics. The overall goal is to improve adherence to standard of practice in the management of septic patients.

**Methods:** The pharmacists will identify patients to initiate an intervention by evaluating each patient’s Systemic Inflammatory Response Syndrome (SIRS) criteria. If the patient has at least 2 SIRS criteria, the pharmacist will go to the bedside and assist in the initial evaluation of the patient with the nurse. If there is a high likelihood of infection or sepsis is suspected, the pharmacist will discuss the evaluation of the patient with the physician and make an antibiotic recommendation based on the patient's presentation and history. Data will be collected on all patients at least 18-years of age who are coded with unspecified septicemia on admission. Patients will be placed into two separate groups; group one will be patients that the ED pharmacist initiated an intervention on and group two will be the control group of patients who presented when the ED pharmacist was not present due to variable staffing hours. Data will be collected through retrospective chart review and also in real time by the ED pharmacists during the initial intervention. In addition, the antibiotics recommended by the ED pharmacist will be
assessed to determine the appropriateness based on the presenting source of sepsis and will also be evaluated for appropriate coverage once culture results are available. This project has recently been approved by the Institutional Review Board for the health system.

Poster Title: Impact of Antibiotics on Readmission Rates in Pediatric Patients with Asthma Exacerbations and Viral Infections

Primary Author: Yejin Choi, Nationwide Children's Hospital, OH; Email: jane.choi@nationwidechildrens.org

Additional Author (s):
Lindsay Landgrave

Purpose: Respiratory viruses promote bacterial infections through different mechanisms. Secondary bacterial infections following a viral infection with rhinovirus or influenza have been well described. Co-infection in patients with asthma increases risk of hospital readmission due to an asthma exacerbation. However, establishment of a bacterial etiology in pediatric patients is challenging due to the limitations associated with performing a bronchoaveolar lavage (BAL) and obtaining sputum specimens in children. The objective of this study is to determine whether patients with asthma who are viral positive on admission are less likely to be readmitted for an asthma exacerbation after antibiotic utilization.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify pediatric patients aged 2 to 18 years with a hospital admission due to an asthma exacerbation found to be viral positive through a respiratory viral panel. The following data will be collected: patient age, gender, admission date, discharge date, readmission within 30 and 60 days for an asthma exacerbation, emergency department (ED) or urgent care (UC) visit within 30 and 60 days for an asthma exacerbation and antibiotic use including route and duration. If available, results of a BAL or sputum culture will be collected. All data will be recorded without patient identifiers and maintained confidentially. Average length of stay will be calculated.

Poster Title: Evaluation of dexamethasone versus prednisone/prednisolone for acute asthma exacerbations at a pediatric hospital

Primary Author: Brett Leja, Nationwide Children's Hospital, OH; Email: brett.leja@nationwidechildrens.org

Additional Author(s):

Purpose: The primary objective of this study is to determine if dexamethasone (DEX) (given either enterally or intravenously (IV)), is superior or inferior to oral prednisone (PRED) or prednisolone (PREDN) in the inpatient, non-intensive care unit (ICU) setting for asthma. Secondary objectives are to perform a medication use evaluation of enteral and IV DEX in inpatient non-ICU patients with a primary diagnosis of asthma at my institution.

Methods: Outcomes were evaluated by completing a retrospective chart review via the electronic medical record from 01/01/2016 to 06/30/2016 in patients aged 2 to 18 years with a primary, admitting diagnosis of asthma. Data was organized into two study cohorts: (1) patients who received DEX and (2) patients who received PRED or PREDN. The primary outcome was comparison of asthma related hospital readmission rates, emergency department (ED) visits, or urgent care (UC) visits within 7 days of hospital discharge. Other outcomes included length of stay (LOS) and evaluation of asthma controller (initiation or continued) during the hospital admission.

Poster Title: Inhaled vancomycin for suppression of methicillin-resistant staphylococcus aureus in cystic fibrosis patients

Primary Author: Michelle Robosky, Nationwide Children’s Hospital, OH; Email: michelle.robosky@nationwidechildrens.org

Additional Author(s): Kimberly Novak

Purpose: Lung damage secondary to chronic infection is the leading cause of morbidity and mortality in cystic fibrosis (CF) patients. Prevalence of methicillin-resistant Staphylococcus aureus (MRSA) has nearly tripled in recent years. Detection of MRSA in the respiratory tract has been associated with worse lung function, decreased survival, and an increased risk of poor recovery of baseline lung function post-pulmonary exacerbation. No inhaled antibiotics are currently approved for suppression of MRSA in CF patients. Inhaled vancomycin as localized treatment avoids the nephrotoxicity and ototoxicity associated with systemic vancomycin. This study aims to evaluate safety and efficacy of off-label inhaled vancomycin therapy.

Methods: This study is designed as a retrospective, single-center drug use evaluation of off-label aerosols compounded using vancomycin for injection. Institutional review board approval will be obtained to review inhaled vancomycin use in pediatric and adult CF patients who received at least one dose of this therapy between October 1, 2008 and September 30, 2016. Electronic medical record data will be analyzed for improved pulmonary function test outcomes, reduced hospitalizations, reduced need for oral and intravenous antibiotics, and patient-reported intolerance or side effects. Additionally, patient-specific information including: age, sex, race, body mass index, CF genotype and concomitant medications including antistaphylococcal therapies and additional inhaled antibiotics will be collected. Culture data for sputum, endotracheal tube, bronchoscopy, and sinus samples will be evaluated for appropriateness of vancomycin selection as well as changes in MIC. Data will be reported using descriptive statistics.

**Poster Title:** Evaluation of blood cholesterol management in HIV-positive patients within an outpatient immunodeficiency clinic

**Primary Author:** Gregory Sneed, Nationwide Children's Hospital, OH; **Email:** gregory.t.sneed@gmail.com

**Additional Author(s):**
Kristen Lamberjack

**Purpose:** The American College of Cardiology and American Heart Association (ACC/AHA) Guideline on the Treatment of Blood Cholesterol to Reduce Atherosclerotic Cardiovascular Risk in Adults established a correlation between elevated blood cholesterol and cardiovascular risk. The guideline provided recommendations for the initiation of statin therapy in patients within four major statin benefit groups, but did not address specific patient populations with increased cardiovascular risk. The primary objective of this study is to determine provider compliance with the ACC/AHA guideline within an outpatient immunodeficiency clinic for HIV patients, and to quantify statin eligibility of this high-risk patient population.

**Methods:** A retrospective chart review of patients with HIV will be conducted to evaluate the appropriateness of statin therapy by providers within an outpatient immunodeficiency clinic, based upon the ACC/AHA Guideline on the Treatment of Blood Cholesterol to Reduce Atherosclerotic Cardiovascular Risk in Adults. The chart review will examine gender, age, race, total cholesterol, systolic blood pressure, smoking history, diabetes diagnosis, and hypertension treatment. This information will be input into the ASCVD Risk Estimator provided by the American College of Cardiology to obtain a recommendation for statin therapy. This recommendation will be compared to the actual prescribing record for the patient. If the prescribing record does not comply with the recommendation, documentation will be reviewed to determine if the prescriber provided rationale for their decision. The chart review will also evaluate the efficacy and safety of each patient’s regimen based upon percentage decrease in low-density lipoprotein and patient-reported side effects that led to drug discontinuation.

**Results:** The final results will be presented at ASHP Midyear Clinical Meeting & Exhibition.
Conclusion: The conclusion will be presented at ASHP Midyear Clinical Meeting & Exhibition.

**Poster Title:** Evaluation of drug waste associated with white-bagging for an outpatient gastroenterology (GI) infusion clinic at a pediatric hospital.

**Primary Author:** Kriss Petrovskis, Nationwide Children's Hospital, OH; **Email:** kriss.petrovskis@nationwidechildrens.org

**Additional Author (s):**
Patrick Collins
Vinita Pai
Marjorie Neidecker
Michael Storey

**Purpose:** White-bagging is the process by which an outside pharmacy ships medication on behalf of a patient to a health-system pharmacy for administration. The process is sometimes used by payers as a drug cost-containment strategy, though it carries significant operational, regulatory, safety and fiscal implications for health-system pharmacies, including creation of drug waste. The purpose of this study is to quantify drug waste associated with white-bagging infliximab for GI infusion clinic patients and identifying causes of waste. This study will serve as a baseline analysis for a quality improvement initiative to reduce drug waste associated with white-bagging.

**Methods:** This is a single-center retrospective analysis. All patients receiving intravenous infliximab from January 1, 2016 through September 30, 2016, white-bagged from an outside pharmacy will be included. Exclusion criteria include any white-bagged product received for a patient who was not scheduled for an infusion during the study period. Demographic data to be collected include patient name, age, weight and gender. Infliximab dose, quantity received, arrival date, infusion date, amount of drug wasted and reason for waste will be evaluated. Drug waste will be categorized as excess supply, expiration or partial vial. Excess supply waste is drug shipped but never administered to a patient. Expiration waste is drug that expires before it can be used. Partial vial waste is defined as drug discarded from a partially used vial. If waste cannot be associated with one of the categories, it will be noted as an outlier and categorized as miscellaneous waste. The study will include 27 patients and 110 unique infusion clinic visits. Descriptive statistics will be applied to analyze the data. This study is exempt from Institutional
Review Board approval, per the institution's IRB-041-02 Determination of Human Subject Research Protocol, which categorizes this study as a Quality Improvement/Quality Assurance project.

**Poster Title:** Assessing physician perceptions of credentialing and privileging pharmacists in a free-standing pediatric institution

**Primary Author:** Kasandra Chambers, Nationwide Children's Hospital, OH; **Email:** kdchambers3@gmail.com

**Additional Author(s):**
Sonya Sebastian
Kimberly Novak
Abi Clark
Karl Kappeler

**Purpose:** In 2012, the Centers for Medicaid and Medicare Services (CMS) updated its definition of “medical staff” to include nonphysician practitioners. This allows for pharmacists to obtain and exercise clinical privileges within their health-systems. To acquire such privileges, pharmacists must abide by the same credentialing and privileging policies as other nonphysicians set forth by the medical staff. Physician engagement is crucial in obtaining these privileges. Few pediatric institutions have implemented this practice. The purpose of this study is to assess physician perceptions of credentialing and privileging pharmacists within a free-standing pediatric institution prior to implementing a credentialing and privileging process.

**Methods:** A steering committee comprising of pharmacists in different practice areas will review the current literature and compile a list of target areas to implement pharmacist privileges. Based on this list, an electronic survey will be developed to assess physicians’ perceptions on privileging pharmacists to perform these functions independently. The survey will also assess physician awareness of pharmacist capabilities, using examples of privileges pharmacists may have at other institutions. The survey will also be used to inform physicians of the changes to the CMS definition of medical staff. The survey will be distributed to all prescribers, including residents, fellows, nurse practitioners, and attending physicians in the inpatient and ambulatory environments. The data will be analyzed to determine which functions may be feasible to implement initially within our institution.

**Results:** Baseline results will be presented at the 2016 ASHP Midyear Clinical Meeting.

Poster Title: Strategies for prevention of dexmedetomidine withdrawal in a pediatric intensive care unit

Primary Author: Kelsey Fink, Nationwide Children’s Hospital, OH; Email: kelsey.fink15@gmail.com

Additional Author(s):
Brittany Shutes
Samantha Gee
Joseph Tobias
Cheryl Sargel

Purpose: Dexmedetomidine is increasingly used for sedation in the pediatric intensive care unit (PICU). There are limited reports regarding the prevalence and prevention of dexmedetomidine withdrawal upon abrupt discontinuation of continuous infusions. Various discontinuation and weaning strategies exist and include abrupt discontinuation, gradual reduction of infusion rate, and transition to enteral clonidine. The objective of this drug utilization evaluation is to describe the various weaning strategies for dexmedetomidine and compare incidence of withdrawal between strategies employed. Efficacy of initial clonidine taper, measured by need to modify the initial weaning plan, will also be analyzed.

Methods: Inclusion criteria are: all patients < 18 years of age admitted to the PICU from January 1, 2014 to September 1, 2016 with concomitant use of non-invasive positive pressure ventilation and dexmedetomidine continuous infusion for more than 24 hours. Exclusion criteria are: patients with a history of congenital heart disease, tracheostomy, home continuous positive airway pressure (CPAP) or bidirectional positive airway pressure (BiPAP), arrhythmia or use of heart rate altering medications, invasive mechanical ventilation, receiving vasoactive medications, received racemic epinephrine while on dexmedetomidine, or received other continuous sedation. Data will be collected retrospectively from the electronic medical record. Time points captured for each patient include: pre-dexmedetomidine; dexmedetomidine dose-escalation from initiation to peak dose; and dexmedetomidine weaning from peak dose to discontinuation or initiation of enteral clonidine. For those patients receiving clonidine, additional time points include: transition from first clonidine dose to dexmedetomidine.
discontinuation, and tapering of enteral clonidine. Post treatment data will be collected for 24 hours after dexmedetomidine discontinuation and 48 hours after clonidine discontinuation. For each interval, average withdrawal assessment tool (WAT-1) scores and sedation scores, as well as maximum and minimum heart rates will be analyzed. Blood pressure and heart rate at 30 minutes, 1, 2, and 4 hours after peak dexmedetomidine dose will also be collected. Descriptive statistics will be used to analyze and present the findings of our use evaluation.

Poster Title: Effectiveness of a pharmacist-led tobacco cessation mobile health clinic in a rural setting

Primary Author: Colin Frank, Ohio Northern University Raabe College of Pharmacy/ONU HealthWise, OH; Email: c-frank@onu.edu

Additional Author(s):
Amy Fanous
Michael Rush
Karen Kier
BreAnne Meinzer

Purpose: Tobacco use is the leading cause of preventable death in America. Although there has been significant improvement in lowering the rates of tobacco use, rural areas continue to have a greater rate of tobacco use. This is due to limited treatment options from a lack of access to healthcare services and a low socioeconomic status. The potential exists that pharmacists practicing in a rural mobile health clinic could effectively eliminate these barriers. The purpose of this study is to determine the effectiveness of a pharmacist providing tobacco cessation services through a mobile health clinic in an underserved rural setting.

Methods: The study is IRB approved. Current tobacco users will be recruited from rural communities to participate in the study. Participants will be required to have an initial appointment at a mobile health clinic event where data will be collected on tobacco use, past medical history, current medications, and vital signs. At the initial visit, participants will choose a quit date and select whether they will use nicotine replacement therapy, prescription medications, or counseling alone. Additionally, participants will be asked to complete a survey assessing the effectiveness of various tobacco cessation marketing strategies, reasons for starting tobacco cessation, and perceived barriers to tobacco cessation. Participants will receive a phone call follow up on their set quit date followed by appointments at weeks 1, 4, 8, and 12 weeks of therapy either by a phone call or an on-site follow up. At each appointment, participants will be assessed on tobacco use, symptoms of nicotine withdrawal, and side effects of medications. The primary outcome variable will be the percent of patients who have not used any tobacco products after 12 weeks. Descriptive statistical measures will be used to
evaluate demographic data as well as secondary outcomes variables from the survey data. Patient documentation will be securely stored at the primary clinic site. Data utilized in the study will be de-identified and stored in a password protected spreadsheet.

Poster Title: Evaluating enoxaparin dosing for venous thromboembolism prophylaxis in low body weight patients

Primary Author: Daniel Dybdahl, OhioHealth Grant Medical Center, OH; Email: daniel.dybdahl@ohiohealth.com

Additional Author(s):
David Robinson
Grant Walliser

Purpose: It is hypothesized that low body weight patients receiving enoxaparin for venous thromboembolism (VTE) prophylaxis have an increased bleeding risk and require a dose reduction. The literature supporting this hypothesis is limited to studies observing anti-factor Xa levels. However, studies have not yet assessed the risk of bleeding. As a result, there is a lack of guidance for providers to decide when to reduce the dose of enoxaparin based on body weight. The objective of this study is to evaluate the impact of enoxaparin dosing on major and minor bleeding events in patients who weigh less than 45 kg.

Methods: This study was submitted to the Institutional Review Board for approval. The study is a retrospective, single-center review of patients at least 18 years of age with an actual body weight of less than 45 kg receiving enoxaparin therapy (enoxaparin 40 mg daily, 30 mg twice daily, or 30 mg daily) for VTE prevention between March 1, 2015 and September 30, 2016. Patients with a creatinine clearance (CrCl) of less than 30 mL/min and patients receiving oral anticoagulants were excluded from the study. The primary objective is to determine whether different enoxaparin doses correlate with changes in the incidence of major and minor bleeding. Major bleeding is defined as a hemoglobin drop of at least 2 g/dL in 24 hours, a transfusion of at least one unit of packed red blood cells, bleeding into a critical site (e.g., intracranial, intraocular, retroperitoneal, intraarticular, pericardial, or intramuscular with compartment syndrome), or bleeding leading to death. Minor bleeding is defined as overt bleeding not meeting the criteria for major bleeding (e.g., gastrointestinal bleeding, hematuria, hematemesis, or hematochezia). Secondary objectives include comparing the incidence of VTE, defined as a diagnosis of deep venous thrombosis (DVT) or pulmonary embolism (PE), and
performing subgroup analyses to determine the risk of major and minor bleeding events based on service line, age, gender, body mass index (BMI), and CrCl.

**Session-Board Number:** 12-152  

**Poster Title:** Patient satisfaction and understanding of medication therapy after participation in discharge pharmacy services  

**Primary Author:** Andrew Zurlinden, OhioHealth Marion General Hospital, OH; Email: andrew.zurlinden@ohiohealth.com  

**Additional Author(s):**  
Kenneth Launder  

**Purpose:** Hospital discharge can be a hectic time for patients and has a large impact on the patient experience as well as patient wellbeing. Studies show that patients have poorer outcomes and increased hospital readmissions as a direct result of inadequate hospital discharge education due to medication discrepancies, poor patient education, and non-compliance. Pharmacist involvement in the hospital discharge process has shown to increase patient compliance and understanding of medication regimens as well as reduce medication errors and discrepancies. This study looks to determine patients’ overall satisfaction and understanding of medications after utilization of pharmacy-led discharge services at a community hospital.  

**Methods:** This quality improvement project is pending IRB-exempt status and consists of surveying patients prior to discharge from inpatient medical units. This study is designed to determine the value of the current discharge pharmacy services in place at a community hospital. Each day during the two month study period, patients due to be discharged from the hospital will be approached by the discharge pharmacy staff and offered discharge pharmacy services. Such services include medication and disease state education as well as providing the first fill of all new or changed medications from the patient’s hospitalization. Regardless of participation in the discharge pharmacy service, patients will be provided a patient satisfaction survey to complete and return to their nurse before leaving the hospital. This patient survey was created to identify satisfaction with pharmacy-provided education and the patient-perceived understanding of the provided education. Participation is voluntary and no patient-specific information will be reported to the study investigators. Results of the surveys will be compared between patients that used the discharge pharmacy and those that did not. The overall impact of the pharmacy services will be evaluated.

**Poster Title:** Cost impact of pharmacist intervention in a community inpatient behavioral health unit: a pilot study

**Primary Author:** Rachel Kerns, OhioHealth Marion General Hospital, OH; **Email:** rachel.kerns@ohiohealth.com

**Additional Author(s):**
Arvinder Kaur
Erica Wibberley
Heidi Trautwein

**Purpose:** Admission to a behavioral health unit is associated with significant costs. Existing studies focus on reducing overall cost of admission versus the cost of medications associated with treatment. The current staffing model at Marion General Hospital does not involve significant pharmacy collaboration with providers in the behavioral health unit. Increased pharmacist monitoring of psychiatric medications should reduce side effects, duplicate therapy and optimize patient care. The primary endpoint of this study is to evaluate the total cost reduction of inpatient medications in the behavioral health unit after establishing a dedicated pharmacy presence.

**Methods:** A retrospective chart review was conducted on patients 18 years of age and older, who were admitted to a 26-bed acute inpatient psychiatric unit at a community hospital. Included patients were required to have a primary diagnosis of depression/anxiety, schizophrenia/schizoaffective disorder, or bipolar disorder. Exclusion criteria included patients younger than 18 years old or admitted to a medical unit. The pre-intervention time period was June 1, 2016 to July 31, 2016 and the pharmacy involvement occurred from August 1, 2016 – September 30, 2016. During the pharmacy intervention period, a pharmacy resident and an Advanced Pharmacy Practice Experience student were dedicated to reviewing behavioral health patient profiles and making medication recommendations as needed to reduce polypharmacy. The cost of each psychiatric medication will be evaluated and multiplied by the total number of administrations for each patient. Trends will also be assessed between the study groups, including psychiatric diagnoses, types of psychiatric medication, number of psychiatric doses administered, number and types of pharmacy interventions, length of stay and comorbidities.

Poster Title: Validation of a Targeted Antibiotic Algorithm for Multiplex-PCR Blood Culture Identification (BCID) Results Based on Suspected Source of Infection

Primary Author: Jordan DeWitt, OhioHealth Riverside Methodist Hospital, OH; Email: jdewitt10@gmail.com

Additional Author (s):
Tara Fisher
Tamara McMath
Christine Collins

Purpose: Rapid diagnostic tests are changing the way that medical providers start and change therapy for patients with a multitude of conditions. Multiplex polymerase chain reactions (PCR) utilized for pathogen identification in blood cultures allow clinicians to tailor antimicrobial therapy in a shorter amount of time compared to traditional cultures and sensitivities, which may provide final results at 48-72 hours from collection. The purpose of this project is to validate an algorithm based on multiplex-PCR blood culture identification results stratified by suspected infectious source.

Methods: This study was a retrospective chart review approved by the Institutional Review Board. Charts were reviewed for patients admitted to 4 critical care units at a tertiary community medical center between June 1, 2016 and August 31, 2016. Patients were included if they were greater than 18 years of age and had a blood culture result with a pathogen identified via multiplex-PCR. Patient charts were reviewed for blood culture collection date and time, multiplex-PCR result date and time, suspected source of infection, empiric antimicrobial selection, proposed algorithm antibiotic, and final sensitivities to each. All data was stored without patient identifiers and maintained confidentially by the primary investigator. Collected data was analyzed to validate and compare actual empiric antimicrobial selection with algorithm guided antibiotic selection in regards to final culture sensitivity. Data was also used to assess over and/or under coverage based on all final culture sensitivities.

**Session-Board Number:** 12-155

**Poster Title:** Pharmacist intervention of asymptomatic bacteriuria: an antimicrobial stewardship program

**Primary Author:** Adam Smith, OhioHealth Riverside Methodist Hospital, OH; **Email:** adam.smith@ohiohealth.com

**Additional Author(s):**
Tara Fisher
Ashraf Kittaneh

**Purpose:** Asymptomatic bacteriuria is oftentimes inappropriately treated with antimicrobial therapy. Current guidelines and primary literature exhibit evidence supportive of recommendations to withhold antimicrobial therapy unless the patient is either pregnant or undergoing a urologic procedure. Despite the evidence to support withholding therapy, this condition is commonly mistreated leading to antimicrobial resistance, increased financial burden to the patient and the healthcare system, as well as unwanted adverse effects from the antimicrobial therapies selected. The objective of this study is to determine the impact of pharmacist intervention on management of antimicrobial therapy in patients with asymptomatic bacteriuria and urinary tract infections.

**Methods:** This study was approved by our Institutional Review Board. This is a prospective, interventional study with data collection via a 24 hour urinalysis report and chart review within an electronic health record. Patients who are admitted to a general medicine unit, on antimicrobial therapy and have a urinalysis analyzed within the past 24 hours will be included. The pharmacist will review the medical record for appropriateness of therapy and contact the physician with recommendations. The primary outcome is the proportion of inappropriate antimicrobial therapy to the number of successful pharmacist interventions. A successful intervention is defined as a recommendation made to the provider that is accepted and implemented. Types of interventions include discontinuation of therapy due to a lack of indication for treatment, placement of a stop date on appropriate therapy or de-escalation of therapy. De-escalation is defined as narrowing antimicrobial coverage or transitioning the route from intravenous to oral. A secondary outcome of this study is the number of treatment days saved as a result of pharmacist intervention. Data points collected will include: medical record
number, age, gender, antimicrobial agent and dose, urinalysis and urine culture results, source of infection and number and type of intervention.

Session-Board Number: 12-156

Poster Title: Evaluation of a Virtual Pharmacy-Led Medication Reconciliation Pilot Program

Primary Author: Margaret Oser, OhioHealth Riverside Methodist Hospital, OH; Email: maggie.ozer@ohiohealth.com

Additional Author(s):
Michele Holley
Stuart Beatty
Bella Mehta

Purpose: Patients experience many transitions within the healthcare system, creating a constantly evolving medication list. Because of these frequent changes that occur, ensuring accurate medication reconciliation is of utmost importance to prevent medication errors and adverse drug events. Multiple studies have looked at the accuracy of medication reconciliations conducted by pharmacy technicians as compared to nursing and have found favorable results with pharmacy technicians. There is little research surrounding telepharmacy models for medication reconciliation, which could be useful for expanding these programs. The study will compare the accuracy of virtual medication reconciliation to in-person medication reconciliation as conducted by pharmacy personnel.

Methods: This is a retrospective, multi-center chart review of a virtual pharmacy medication reconciliation pilot program conducted at OhioHealth Grady Memorial Hospital (GMH) by technicians and pharmacists from two free-standing emergency departments – OhioHealth Westerville Emergency Care Center (WECC) and OhioHealth Pickerington Emergency Care Center (PECC). The pilot included patients over 18 admitted from the emergency departments (ED) at WECC, PECC, and GMH over a 60-day period. The in-person group will be comprised of patients at WECC and PECC, while the virtual group will include those from GMH. In the virtual pilot, pharmacy staff at WECC or PECC was contacted by the nursing staff when a patient was being admitted and deemed appropriate for medication reconciliation at GMH. When pharmacy personnel was ready to speak with the patient, they contacted the nursing staff to transport the virtual communication technology into the room. Once the technology was ready, pharmacy personnel interviewed the patient/family. Pharmacy staff documented
the encounter in the EMR after conducting the interview and updating the list for physician review.

The specific aims of the study are to determine if there is a clinically significant difference in accuracy between the in-person and virtual group, compare the capture rate across sites and the average time spent on medication reconciliation to evaluate workflow implications, and satisfaction of the physicians, nursing, and pharmacy staff with the process.

**Session-Board Number:** 12-157

**Poster Title:** Tolerability of aerosolized versus intravenous pentamidine for Pneumocystis Jirovecii Pneumonia prophylaxis in immunosuppressed pediatric patients

**Primary Author:** Kelsey Brown, Rainbow Babies and Children's Hospital, OH; **Email:** kelsey.brown@uhhospitals.org

**Additional Author (s):**
Michael Reed
LeAnne Moore
Jignesh Dalal
Melissa Makii

**Purpose:** At a pediatric academic children’s hospital, pentamidine is a commonly used alternative for Pneumocystis Jirovecii Pneumonia (PJP) prophylaxis when the drug of choice, sulfamethoxazole-trimethoprim, is not tolerated due to adverse reactions. Pentamidine is an antifungal medication that is administered aerosolized or intravenously. Current evidence has shown efficacy of aerosolized and intravenous formulations as PJP prophylaxis, but there is a lack of literature comparing tolerability between the two administration routes. The primary objective of this study is to determine the tolerability of aerosolized versus intravenous pentamidine for PJP prophylaxis in immunosuppressed pediatric patients.

**Methods:** This retrospective study will be submitted to the local Institutional Review Board for approval. The study will assess the incidence and types of adverse reactions associated with pentamidine prophylaxis in immunosuppressed pediatric patients over the past 3 years, from January 1, 2014 to January 1, 2017. Study variables will be retrieved from the electronic medical record (EMR). The following data will be collected: patient gender, ethnicity, age, patient weight, allergy history, location of administration, primary diagnosis, concurrent medications (if applicable), cycle of chemotherapy (if applicable), days from transplant (if applicable), pentamidine dose, dosage form, frequency, infusion duration, pre-medications, immunosuppressive therapy, type of reaction, history of sulfamethoxazole-trimethoprim use, number of pentamidine doses before reaction, absolute neutrophil count (ANC), and Immunoglobulin E serum concentrations. The information for each reaction will be categorized for both administration routes and compared relative to the collected variables focusing on
dosage, route, use of concurrent immunosuppression, and the reaction(s). Non-parametric statistics and frequency analysis will be used to assess differences between the two routes of administration. Linear regression will be used to evaluate the variable(s) to determine if there is any association with a greater likelihood of route-induced reaction.

Poster Title: Evaluation of customization from standard total parenteral nutrition (TPN) for patients admitted to a level IV neonatal intensive care unit (NICU)

Primary Author: Catherine Hobart, Rainbow Babies and Children's Hospital, OH; Email: catherine.hobart@uhhospitals.org

Additional Author (s):
Jaime Marasch
Michael Reed
Jacquelyn McClary

Purpose: TPN is an intervention used to support the nutritional needs of patients that are unable to receive adequate enteral nutrition. Currently, five standard TPN formulations are utilized by the NICU. Patients’ age and weight dictate which standard formulation is used to provide nutrition. A need has been identified to assess the rate of customization from standard formulations. Deviation from standard formulations are driven by patient specific electrolyte laboratory values. The objective of this study is to describe the frequency at which the calcium and phosphorous concentrations are customized in standard TPN formulations for patients located in the NICU.

Methods: This descriptive study will be a single site, retrospective evaluation of all patients receiving TPN in the NICU from January 1, 2015 until August 31, 2016. Patients will be included from the first day of TPN therapy until discontinuation. A subgroup analysis for patients weighing less than 1500 grams will be completed. Data will be collected from the electronic medical record (EMR), TPN compounding machine, and pharmacist documented errors upon order and product verification. Data collection will include patient age, weight, standard TPN duration, custom TPN duration, dose of calcium and phosphorous administered from the TPN each day, composition of the daily TPN, and pertinent laboratory values. Descriptive statistics will be utilized to analyze data. Additionally, this study will assess secondary outcomes impacting patient safety such as error rates associated with customization of TPNs. After completing the analysis, reconsideration of standard formulations may occur to ensure 80% of TPN formulations prescribed are standard with 20% or less customized.

**Poster Title:** Validation of a weight-based unfractionated heparin (UFH) protocol comparing activated partial thromboplastin time (aPTT) to the antifactor xa assay: a case-control study

**Primary Author:** April Downey, Riverside Methodist Hospital, OH; **Email:** april.downey@ohiohealth.com

**Additional Author (s):**
Mark Friedman  
Brian Peifer  
Tamara McMath  
Christy Collins

**Purpose:** Since first described in 1953, there has been substantial clinical experience with aPTT monitoring for UFH; however, limitations have been identified. The aPTT is subject to preanalytic and biologic factors including time of blood sampling, the reagent, and coagulopathies affecting aPTT results. The antifactor Xa, however, works by quantifying the functional activity of heparin providing better estimates of the actual heparin concentration while not impacted by the preanalytic and biologic factors. This study will help to determine the efficacy and safety of transitioning to the antifactor Xa monitoring for patients receiving continuous heparin infusions at a large tertiary community hospital.

**Methods:** The study is a single-center prospective, and future retrospective, case-control study comparing monitoring parameters for UFH infusions. Patients will be enrolled from October 1, 2016 through December 30, 2016 and followed until heparin therapy is discontinued. Study authors will consent 30 patients prospectively for the antifactor Xa group. Patients with new UFH orders will be referred to the primary investigator (PI) by order verification pharmacists. For patients that meet inclusion criteria the PI will contact the ordering physician and, following approval, obtain informed consent from the patient. After UFH initiation, antifactor Xa levels will be evaluated by pharmacy and infusion rates adjusted using the institution's established weight-based protocol adapted for antifactor Xa levels. The aPTT control group will be identified retrospectively to match the antifactor Xa group based on location (intensive care or general medicine) and protocol (Venous Thromboembolism, Stroke, Mechanical Valve, and Cardiac/Arterial). Patients will be excluded if less than 18 years of age, breastfeeding or
pregnant, unable to give informed consent, UFH use for any other protocol not listed, and patients on oral factor Xa inhibitors. The two groups will be compared to identify a difference in average time to therapeutic window, number of lab draws required to obtain a therapeutic level, proportion of patients who reach therapeutic level within 24 hours, average time within therapeutic window, and safety outcomes such as bleeding.

**Poster Title:** Analysis of time to antibiotic administration in adult febrile neutropenic patients in a hospital emergency department  

**Primary Author:** Christopher Walczak, Riverside Methodist Hospital, OH; **Email:** walczak.11@osu.edu  

**Additional Author(s):** Teresa Meier  

**Purpose:** In cancer patients with chemotherapy-induced neutropenia, fevers may be the only indicator of a severe infection due to the reduced signs and symptoms of an inflammatory response. The American Society of Clinical Oncology (ASCO) recommends that febrile neutropenic patients should receive initial doses of empiric antibiotics within 1 hour of triage. Therefore, the objective of this study is to determine the current time to antibiotic administration (TTA) in febrile neutropenic patients who present to the emergency department. This information will be ultimately used to optimize empiric antibiotic administration and decrease TTA.  

**Methods:** This study has been submitted and approved by the institutional review board. It is a retrospective chart review of cancer patients age 18 or older who initially presented to the emergency department (ED), were recently treated with chemotherapy, and have laboratory confirmed febrile neutropenia [absolute neutrophil count (ANC) of less than 1000 cells/mm3, and a fever with a temperature greater than or equal to 38.0°C] between May 1, 2015 and August 31, 2016. Data points that will be collected include determining average time intervals leading up to antibiotic administration (from ED registration to being seen by a physician, blood draws, antibiotic order placement, antibiotic order placement to pharmacist verification, and pharmacist verification to administration). Other outcomes of interest will include proportion of patients that utilized the febrile neutropenia order set, hospital length of stay, and inpatient deaths in patients that met the treatment goal of 60 minutes or less and those who did not.

**Poster Title:** Impact of implementing charge on administration into an outpatient infusion center

**Primary Author:** Laura Stasiak, Southwest General, OH; **Email:** lstasiak@swgeneral.com

**Additional Author(s):**

**Purpose:** Patient wait times and turnover time in outpatient infusion centers are often negatively impacted by the delay in medication administration due to the need for order clarifications, which is especially prevalent in oncology infusion centers with chemotherapy orders. The purpose of this study is to evaluate the effect of implementing a charge on administration process into this outpatient infusion center. The hypothesis is that by introducing this new workflow, the time from patient arrival to first chemotherapy administration will be decreased, improving turnover time and decreasing patient wait times.

**Methods:** Chemotherapy orders will be completed by physicians and sent to the pharmacy for patients scheduled in the infusion center the following day. One of two pharmacists working in the infusion pharmacy will review the orders for all patients the day prior to arrival. If clarifications are needed, the pharmacist will contact the physician and get the order clarified before entering it into the system. Once the patient arrives for his or her scheduled appointment the following day, the pharmacy will compound the medication(s) from the order that has already been verified. The medication will be scanned at the patient's bedside, allowing the patient to be charged directly on administration. To assess the effect of this new workflow, patient charts will be reviewed and compared before implementation and after implementation of this process. The primary outcome is time from patient arrival to administration of first chemotherapy medication. Secondary endpoints that will be assessed include time to first pre-medication and time between first pre-medication and first chemotherapy medication to assess confounding variables between the data sets. The daily patient load, daily nursing staffing, and daily pharmacy staffing will also be used in order to compare patient charts on similar days to reduce confounding variables. This project has already been approved through the Institutional Review Board and has been deemed as a process improvement project, not human research.
Results: Data collection to occur in October and results to be presented at the conference.

Conclusion: To be presented at the conference.

Poster Title: Impact of pharmacist-led medication history overnight in a community hospital

Primary Author: Sabrina Allen, Southwest General Health Center, OH; Email: sallen@swgeneral.com

Additional Author(s):

Purpose: Current literature demonstrates the positive impact that pharmacists can have on medication histories, however, there is significant research lacking in the benefit of twenty-four hour coverage in the emergency department. When pharmacy staff is not available, the task of medication history typically falls to nursing. The objective of this study is to quantify medication history errors occurring overnight, and validate the need for twenty-four hour pharmacist coverage.

Methods: This prospective quality improvement study is pending Institutional Review Board for approval. The electronic medical record (EMR) will identify patients that have been admitted overnight, and a pharmacist will conduct a new medication history within forty-eight hours of admission. The pharmacist will collect medication histories by using the patient, family members, available medications lists, and external sourcing from pharmacies. Information obtained that would not be available at the original time of the medication history will not be included. All data will be recorded without patient identifiers and maintained confidentially. Discrepancies in the medication history will be documented on a daily monitoring form. Errors identified will include incorrect dosage, incorrect frequency, inactive medications listed, and missing medication. Potential adverse drug events will also be reviewed, which is defined as harmful or potentially harmful medication discrepancies.

Poster Title: Collaborative practice between a community hospital and extended care facility utilizing a transitions of care pharmacist

Primary Author: Kailey Stough, Southwest General Hospital, OH; Email: kstough@swgeneral.com

Additional Author (s):
Dave Ferris
Rebecca Margevicius
Kaylee Adams

Purpose: Patients transferred from hospitals to extended care facilities (ECF) are at risk for errors in transitions of care (TOC) due to lack of communication between facilities. Specific patient populations identified at this institution as experiencing errors in TOC are those being transferred on IV antibiotics and those diagnosed with heart failure being transferred for rehabilitation services. The purpose of this collaborative practice between a community hospital, TOC pharmacist, and ECF is to improve the transition of patients going from hospital to ECF with IV antibiotics or for rehabilitation as part of the heart failure bundled payment program.

Methods: In order to improve the transition period for patients on IV antibiotic therapy, the inpatient antimicrobial stewardship pharmacist and the TOC pharmacist identify patients to be discharged to the ECF. Once identified, a form is completed and faxed to the supplying pharmacy handling all medication orders for the ECF. The form consists of pertinent information related to IV antimicrobial therapy, such as start date, total duration of therapy, labs, and cultures. The purpose of the IV antibiotic form and subsequent follow-up by the TOC pharmacist at the ECF is to improve the transfer of orders for IV antibiotics, prevent delays in therapy, ensure appropriate dosing, and prevent unnecessary antibiotic exposure. The TOC pharmacist also works to improve the transition period for heart failure patients that are newly enrolled in the bundled payment program at the hospital. Upon identification of potential bundled payment patients, the TOC pharmacist provides medication education prior to transfer to ECF. Once transferred to ECF for rehabilitation, the TOC pharmacist performs an admission medication reconciliation and then daily monitoring of patients for signs and symptoms of
worsening heart failure. Finally upon discharge from the ECF, the TOC pharmacist provides medication education to the patient and family during a discharge care conference with other members of the healthcare team and encourages follow-up with the tele-health nurse at home.

**Results:** The collaborative practice between the hospital and ECF was established in early September and thus far only a small portion of patients have been identified and evaluated; however, positive results have been observed within that portion of patients. Since initiation, about fifty percent of IV antibiotic patients going to the ECF have been identified, which amounts to about 10 patients. Appropriate documentation sent to ECF has resulted in correct stop dates and decreased delays in antimicrobial therapy upon transfer. Currently a report is being generated with pharmacy and IT at the hospital to increase the number of patients identified. Daily communication between the TOC pharmacist and the ECF staff occurs regarding weight measurements of the heart failure bundled patients and also any additional questions or concerns with either the heart failure or IV antibiotic patients. Prior to this collaboration, heart failure patients were not being monitored for weight changes daily; however, now small changes in weight can be addressed with the physicians and nurse practitioners earlier. Also, two heart failure patients were provided discharge education before leaving the ECF and reported not only being satisfied with the service, but also felt prepared to care for themselves at home.

**Conclusion:** Currently the collaboration between the community hospital and the ECF has been successful in improving transitions of care for specific patient populations utilizing a TOC pharmacist. Positive impacts have been seen in both heart failure patients and patients on IV antimicrobial therapy. In addition to current efforts the team from both the hospital and the ECF are working to create a collaborative practice agreement between the TOC pharmacist and physician staff at the ECF. The collaborative practice agreement will help to empower the TOC pharmacist to provide an even greater impact on patients residing in the ECF.

**Submission Category:** Infectious Diseases  
**Submission Type:** Research-in-Progress  
**Session-Board Number:** 12-164  
**Poster Title:** Conducting a targeted multimodal antimicrobial stewardship protocol in patients with or at high risk for developing Pseudomonas aeruginosa pneumonia  
**Primary Author:** Travis Macek, St. Elizabeth Youngstown Hospital, OH; **Email:** tpmacek@mercy.com  
**Additional Author (s):**  
Dawn Miller  

**Purpose:** The 2016 IDSA guidelines for implementation of antimicrobial stewardship along with newly published Hospital and Ventilator-associated Pneumonia guidelines recommend alternative dosing strategies for broad-spectrum beta lactams and proper identification of patients at high risk for multi-drug resistant (MDR) gram negative organisms. The objective of this study is to determine if length of IV anti-pseudomonal therapy can be decreased by implementing a pharmacist-driven antimicrobial stewardship program aimed at providing institution-specific appropriate double coverage to high risk patients, optimizing beta-lactam dosing to improve pharmacodynamics, and providing recommendations for appropriate duration of antibiotics in patients with Pseudomonas aeruginosa pneumonia.  

**Methods:** This study is Institutional Review Board approved. It is a before after study to investigate the impact of a clinical pharmacist facilitated antimicrobial stewardship program on duration of IV anti-pseudomonal antibiotics in hospitalized patients with Pseudomonas pneumonia. The electronic medical record will be utilized to identify patients with respiratory cultures having been drawn within the previous 24 hours. Patients will be screened for the necessity of double anti-pseudomonas coverage by assessing antibiotic use within the previous 90 days. Other patients that will receive a recommendation for double coverage include those with septic shock and those with increased risk of mortality. Patients will be followed until culture results are obtained, and therapy narrowed if appropriate. Patients will be included in the study if they have a positive Pseudomonas respiratory culture. Beta-lactam administration will be optimized by providing extended infusion cefepime and piperacillin/tazobactam at doses recommended by the HAP and VAP guidelines if indicated. A Monte Carlo simulation may be run to ensure probability of target attainment of 90% on select patients. Patients will be
followed daily by a clinical pharmacist. When patients meet clinical criteria for resolution, and after at least 7 full days of treatment, a call will be made to the physician recommending discontinuation of anti-pseudomonal therapy. If the recommendation is not accepted, an additional call will be made on days 10 and 14.

**Poster Title:** Effect of pharmacist education on methylnaltrexone prescribing habits

**Primary Author:** Keith Pohlman, St. Rita’s Medical Center, OH; **Email:** kapohlman@mercy.com

**Additional Author (s):**
Suzanne Marques

**Purpose:** St. Rita’s Medical Center utilizes methylnaltrexone three to four times more frequently than any other institution within the Mercy Health System for the treatment of opioid-induced constipation (OIC). This may be due to inappropriate prescribing habits stemming from a lack of understanding of the OIC treatment algorithm and the pharmacokinetics of methylnaltrexone. The primary objective of this study is to determine the effect health care professional education has on the appropriate use of methylnaltrexone.

**Methods:** This study has been approved by the Institutional Review Board at St. Rita’s Medical Center. Patients who received a dose of methylnaltrexone for OIC from November 1st, 2015 through February 29th, 2016 will be reviewed through a retrospective drug utilization evaluation for appropriateness of use. All patient data will be de-identified. Doses of methylnaltrexone will then be classified as either appropriate or inappropriate. Methylnaltrexone doses considered to be appropriate will meet all of the following criteria: patient was taking an opioid regimen; there is no documentation of a bowel movement for at least 48 hours prior to methylnaltrexone use; patient was receiving a stimulant laxative in combination with a stool softener, osmotic laxative, or magnesium salt for three days prior to methylnaltrexone use; and a bowel movement was recorded after the first dose of methylnaltrexone to indicate patient response prior to receiving any subsequent doses. Physician, pharmacist, and nursing education will be performed in October 2016. Another drug utilization evaluation will then be performed from November 1st, 2016 through February 28th, 2017 to assess the effect this education has on appropriate methylnaltrexone use. This assessment will adhere to the same parameters that were previously mentioned.

**Poster Title:** Decreasing duration of antimicrobial therapy in patients with hospital-acquired pneumonia at St. Rita’s Medical Center

**Primary Author:** David Jordan, St. Rita's Medical Center, OH; **Email:** djordan2@mercy.com

**Additional Author(s):**
Jessica Walles

**Purpose:** The Infectious Disease Society of America (IDSA) and the American Thoracic Society (ATS) recently published updated guidelines regarding the management of adults with hospital-acquired pneumonia in July 2016. The primary objective of this study is to decrease the total duration of antimicrobial therapy for hospital-acquired pneumonia for inpatients at St. Rita’s Medical Center from November 1, 2016 to February 28, 2017 compared to duration of therapy from November 1, 2015 to February 29, 2016.

**Methods:** This study was submitted to the Institutional Review Board and was approved on September 19, 2016. Adult patients who develop pneumonia at least 48 hours after admission to St. Rita’s Medical Center will be selected and analyzed for inclusion into this study. Information from the patient chart will be reviewed, and the following data will be collected: duration of antimicrobial therapy in the hospital, duration of antimicrobial therapy at discharge, time to de-escalation of antimicrobial therapy, and if discharge medication reconciliation was performed by a clinical pharmacist. This data will be recorded in a spreadsheet where the patients will be de-identified. The data collected will include a patient assigned number and the unit in which the patient resided while at St. Rita’s Medical Center. Physicians and pharmacists will be educated on the updated guidelines through clinical pearls, flyers, and newsletters. The data from November 2015 to February 2016 will be compared to the data from November 2016 to February 2017 to see if the duration of antimicrobial therapy in patients with hospital-acquired pneumonia has decreased.

Poster Title: Alert fatigue reduction: The impact of dosage alert changes in a large health system

Primary Author: Rachel Muhlenkamp, St. Rita’s Medical Center, OH; Email: rmuhlenkamp@mercy.com

Additional Author(s):
Nathan Ash
Kristi Ziegenbusch

Purpose: Alert fatigue is a known and prevalent issue in today’s technology oriented healthcare field. The primary objective of this study is to reduce the number of dosage alerts provided to ordering users. The secondary objective of this study is to improve physician and pharmacist perception of alerts within the system.

Methods: Institutional Review Board approval has been obtained for this study. Dose alerts registered throughout the entire health system during a defined two day period will be collected by the electronic record application coordinator. The five medications that most frequently register dose alerts will be evaluated for appropriateness related to the specific patient’s characteristics by the researcher. Additionally, the ten most frequently fired alerts that have been identified through the use of the ‘Inaccurate Warning” option during alert override will be evaluated by the researcher for appropriateness. Through a series of predetermined channels, all alerts that are determined to be firing inappropriately by the researcher will be addressed and modified when possible. The change in the number of alerts will be determined through percent change data before and after intervention. These numbers will also be compared to the average number of alerts displayed to EPIC users in general. To evaluate the changes perceived by physicians and pharmacists, a pre and post-intervention survey will be distributed to the hospitalists and pharmacists of one facility within the health system. Follow-up will occur with as many of both parties that can be reached to review actual interventions made after the post-intervention survey has been distributed and the deadline for survey submission has been reached.

Poster Title: Evaluation of the safety and economic impact of an antibiotic allergy protocol in a tertiary medical center

Primary Author: Frances Shuk Kwan Fu, Summa Health- Akron Main Campus, OH; Email: fuf@summahealth.org

Additional Author(s):
Paula Politis
Susanna Petiya
Thomas File

Purpose: Approximately, 8% of the population is reported to have a penicillin allergy in the United States. Among patients who report an antibiotic allergy, only 10% have a true IgE-mediated hypersensitivity reaction. Antibiotic allergy protocols maybe a helpful tool to determine if patients have a IgE-mediated reaction. Using a step-wise approach protocol to assess patients with a history of penicillin allergy can prevent the misuse of antibiotics and reduce resistance. The goal of this project is to develop and implement a safe and valid assessment tool to determine patient’s antibiotics allergy status and reduce the antibiotics cost for the hospital.

Methods: Patients will be screened for Beta-lactam antibiotic allergies in the electronic medical record. Once patients are identified, pharmacists will perform a face-to-face or telephone interview with either patients or family members. Pharmacists will be using a standardized medication allergy assessment form, which is developed by the department of Pharmacy to determine patient allergy status. Pharmacists will not change patient’s allergy record in the electronic medical record without the confirmation of penicillin skin test or physician consultation. Pharmacists will then make recommendations to the prescriber based on clinical guidelines, protocols and local antibiotic resistance patterns. The primary investigator of the study will create the allergy assessment form and will be heavily involved in patient interviews and making recommendations. The patient will be followed for clinical outcomes and adverse reactions up to seven days beginning on first day of transitioning to Beta-lactam antibiotics. Primary outcome measures are the number of patients with listed Beta-lactam allergy that tolerated Beta-lactam antibiotics after evaluation, and the percentage changes in antibiotics
prescribed after pharmacist’s recommendation. Secondary outcomes included cost reduction, length of antibiotic treatment, mortality rate, hospital length of stay and incidences of C.difficile infection, acute kidney injury, gastrointestinal symptoms and infusion-related reactions.

**Poster Title:** Effectiveness and safety of twice daily versus thrice daily subcutaneous unfractionated heparin for venous thromboembolism prophylaxis at a tertiary medical center

**Primary Author:** Meghan Sorgi, Summa Health System- Akron Campus, OH; **Email:** meghan.wilson213@gmail.com

**Additional Author(s):**
Seth Bauer
Simon Lam
Heather Torbic

**Purpose:** The American College of Chest Physicians’ guidelines for the prevention of venous thromboembolism (VTE) recommend low-dose unfractionated heparin (LDUH) as an option to prevent VTE in patients at increased risk. The guidelines do not provide a recommendation with regards to twice daily (BID) versus thrice daily (TID) LDUH because there is a lack of head-to-head trials comparing these dosing frequencies. Meta-analyses evaluating safety and effectiveness of BID and TID dosing did not include trials that directly compared the two. Due to the lack of direct comparisons, our study evaluated the effectiveness and safety of LDUH dosed BID versus TID.

**Methods:** The institutional review board approved this retrospective study under expedited review. This cohort evaluated 5,000 patients, age 18 years or older, admitted to the tertiary medical center who received subcutaneous LDUH BID or TID for VTE prophylaxis between July 31, 2015 and September 30, 2015. Patients who received low molecular weight heparin or fondaparinux, or both BID and TID dosing of LDUH for at least 48 hours during admission, and those treated with therapeutic anticoagulants for a duration greater than 48 hours before initiation of LDUH were excluded. Data collected included patient demographics, risk factors for VTE and bleeding, hospital length of stay, missed doses of LDUH, and incidence of VTE and major and minor bleeding as identified by ICD-9 codes. For the univariate analysis, nominal data was evaluated using Chi-Square and Fisher’s Exact Test, and continuous data was analyzed with ANOVA. Patients were matched using propensity score matching and multivariable logistic regression analysis was performed for the primary outcome. The primary outcome was the
Results: A total of 4,188 patients were included for analysis. In the full analysis, the primary outcome of VTE occurred in 0.71% of patients who received LDUH BID compared to 0.77% of patients who received LDUH TID (p = 0.85). The secondary outcome of major bleed occurred in 0.71% of patients in the BID arm compared to 0.77% of patients in the TID arm (p = 0.85), and minor bleed was seen in 2.3% compared to 1.9% of patients in the BID and TID arms respectively (p = 0.52). For the matched cohort, VTE occurred in 1.4% of BID patients and 2.1% of TID patients (p = 0.32). Major bleed occurred in 0.36% of BID patients and 0.52% of TID patients (p = 0.7), while a minor bleed was seen in 3.4% of BID patients and 2.1% of TID patients (p = 0.13). The multivariable analysis within the matched cohort demonstrated that both personal history of VTE (OR 1.3482; 95% CI 0.4949-2.2016; p = 0.002) and weight (OR 0.0089; 95% CI 0.0006-0.0172; p = 0.035) were independently associated with an increased risk of VTE.

Conclusion: This study did not demonstrate a difference in effectiveness or safety between BID and TID dosing of LDUH for the prevention of VTE. Several patient characteristics were noted to be significantly different between the two treatment groups, which suggests these patients may have differed in regards to overall VTE risk. Future evaluation with a larger cohort and subgroup analyses will allow better investigation of these differences.

Poster Title: Retrospective review of the comparative effectiveness between antipsychotics used to treat intensive care unit-related delirium

Primary Author: Kimberly Perkins, The Christ Hospital, OH; Email: kimberly.perkins@thechristhospital.com

Additional Author(s):
Shannon Gray
David Frey
Kathryn Martin
Charles Scharfenberger

Purpose: Delirium in critically ill patients contributes to prolonged hospital and intensive care unit (ICU) length of stay as well as increased mortality. Many antipsychotic medications have been studied in clinical trials to evaluate their effectiveness in treating ICU-related delirium; however, results have been inconclusive. The objective of this retrospective chart review is to examine the comparative effectiveness of ICU delirium resolution among antipsychotic medications. Secondary outcomes include time to resolution of delirium, length of stay, use of mechanical ventilation, and mortality.

Methods: A single-center retrospective chart review will be performed at a large, community teaching hospital evaluating patients admitted to the medical, cardiovascular, or surgical intensive care units (ICUs) between January 2015 and December 2016. Medications to be included are haloperidol, risperidone, valproic acid, olanzapine, quetiapine, and ziprasidone. Patients eligible for inclusion must be 18 years or older, admitted to the ICU for greater than 72 hours, and have received an included study medication. Patients must have a negative Confusion Assessment Method for the ICU (CAM-ICU) score at admission followed by a positive score during hospitalization in the ICU. Patients with a history of psychiatric illness that are restarted on home therapy (involving one or more of study medications) within 48 hours of ICU admission will be excluded. Additionally, patients will be excluded if pregnant or received valproic acid for management of seizures. Data will be collected via electronic medical records. Data to collect includes: demographic data; prior medical history; prior to admission medications; admission location; CAM-ICU scores; baseline QTc; APACHE score; evidence of

Resident Poster Abstracts
metabolic acidosis; urea concentration at admission; sedative used if on mechanical ventilation; time to onset of delirium; signs and symptoms documented by medical staff; any psychiatric consults; discharge disposition; and documentation supporting delirium subtype (hypoactive, hyperactive, or mixed). For study medications: name, dose, frequency, route, and length of therapy will be recorded.

**Poster Title:** Evaluation of pharmacy interventions in an academic outpatient transition of care clinic

**Primary Author:** Alexandra Ting, The Christ Hospital, OH; **Email:** alexandra.ting@thechristhospital.com

**Additional Author(s):**
Molly Webster  
Alissa Lee  
Rebecca Shaffer

**Purpose:** Pharmacist interventions in a patient’s transition between levels of care have been proven to directly impact clinical outcomes through the identification of medication-related problems. The Transition of Care (TOC) Clinic was established in November of 2015 in an effort to improve continuity of care for patients recently discharged from the hospital. The purpose of this study is to evaluate the impact of pharmacist interventions made in the TOC Clinic on the rate of hospital readmissions and emergency department visits.

**Methods:** This is an IRB-approved, single-center, retrospective study of Internal Medicine Clinic patients who were discharged from the hospital medicine service between November 1st, 2014 and October 31st, 2016. Patients will be divided into pre- and post-implementation periods of the TOC Clinic (November 1st, 2014 through October 31st, 2015 and November 1st, 2015 through October 31st, 2016). Patients will be excluded if they were not discharged home. Additionally, patients in the post-implementation group will be excluded if they were not scheduled for a TOC appointment following discharge or were not seen by a pharmacist at their appointment. Data will be collected from electronic medical records and will consist of baseline demographic information; hospital, emergency department visit, and clinic visit information; and pharmacy interventions categorized into medication therapy management, safety, non-compliance, and miscellaneous interventions. Data collection is in progress. The primary endpoint of this study is the difference in composite rate of 30 day readmissions and emergency department visits before and after the establishment of the Transition of Care Clinic. Secondary endpoints include rate of 60 day readmissions and emergency department visits before and after implementation, rate of death at 30 and 60 days after discharge,
frequency of phone calls to healthcare providers, and characterization of pharmacy interventions made in this clinic. Baseline characteristics and readmission rates will be analyzed for significance utilizing the chi-squared test.

**Poster Title:** Outcomes of an inpatient pharmacist-led discharge intervention on medication-related problems post-discharge

**Primary Author:** Marissa Guillen, The Good Samaritan Hospital of Cincinnati Ohio, OH; **Email:** guillenm@findlay.edu

**Additional Author (s):**
Stacy McCoy
Lauren Gilmer
Colin Fitzgerrel

**Purpose:** Pharmacist involvement in transitional care management of medications has led to decreased medication discrepancies post-discharge, improved communication among health care providers, and reduction of medication-related hospital readmission rates. While pharmacists may contribute to aiding patients in their transition from hospital to home, the role of the pharmacist in this area of practice is not well-defined. Currently, Good Samaritan TriHealth Hospital has no formal process in place to evaluate changes in a patient’s medications prior to discharge. The purpose of this study is to evaluate the impact of an inpatient pharmacist-led discharge intervention on the incidence of medication-related problems post-discharge.

**Methods:** This study will be submitted to the TriHealth Institutional Review Board for approval. “High risk” patients for readmission will be identified from the medical resident internal medicine service for inclusion in the study. “High risk” patients are defined as patients who meet any of the following criteria: 1) discharged on 3 or more new medications not listed on the home medication list prior to admission; 2) discharged on a new high-alert medication; 3) admitted for treatment of uncontrolled symptoms of 2 or more of the following chronic disease states: diabetes mellitus (types 1 or 2), chronic heart failure, hypertension, or COPD, and were not initially diagnosed with the disease state upon the admission being studied; 4) admitted with 10 or more documented maintenance prescription or over-the-counter medications prior to admission (excluding nursing home patients). The study group will receive a pharmacist-led intervention prior to discharge consisting of a face-to-face interview with the patient to assess barriers to medication adherence, provide medication education, and creation of a patient-
specific medication plan in collaboration with the physician. The control group will receive the current standard of care prior to discharge. All patients will be evaluated for outcomes of medication-related problems via phone calls at 3, 14, and 30 days post-discharge. Other outcomes of consideration include severity of potential adverse effects, and reduction in 30-day all-cause readmission rates.

**Poster Title:** Cost analysis and length of stay associated with linezolid versus vancomycin use in methicillin-resistant Staphylococcus aureus pneumonia in a regional health organization

**Primary Author:** Eric Place, The Good Samaritan Hospital of Cincinnati, Ohio, OH; **Email:** eric_place@trihealth.com

**Additional Author(s):**
Thomas Imhoff
Colin Fitzgerrel

**Purpose:** Core elements warranting this project as timely and relevant include the recent price reduction in direct drug cost of linezolid, increasing occurrence of elevated vancomycin MIC, and IDSA pneumonia guidelines parring vancomycin and linezolid with considerations for patient-specific factors. Economic analyses to date have extrapolated data from RCTs as opposed to real world data with actual utility. Value in this project will be derived from awareness of recent usage, clinical outcomes, and cost of treatment between the medications. Additionally, data derived from this study may have implications on current practice and necessitate further discussion

**Methods:** This is an IRB approved retrospective cohort review with the primary goal of comparing overall cost of treatment and length of stay for patients diagnosed with pneumonia and treated with linezolid or vancomycin. Secondary outcome measures include clinical success and failure, adverse drug events, duration of antibiotic therapy, ancillary service costs, and all-cause mortality. Data from patient records and cost histories for the TriHealth health system of Cincinnati, Ohio will be accessed utilizing EPIC, Premier QualityAdvisor, and Data Warehouse. Participant records from January, 2015 to March, 2017 will be analyzed and compared for treatment of confirmed or presumed MRSA pneumonia. The linezolid group will be identified through QualityAdvisor generated reports, and the vancomycin comparative cohort will be randomly selected through 1:1 risk stratification classification. Subject balance will be established by use of 3M risk scoring and give consideration to whether or not the patients were mechanically ventilated, treated in the ICU, or diagnosed with HCAP versus HAP/VAP as these factors independently contribute to costs. Data to be viewed, recorded, and analyzed include patient demographics, location of treatment, diagnoses, comorbidities, concurrent
medications, hospital-administered medications, method of ventilation, renal function, dialysis status, radiology and microbiology findings, other important laboratory results including procalcitonin, and permanent medical record information detailing clinical outcomes. Primary and secondary endpoints will be analyzed between groups using appropriate statistical tests.

Poster Title: Impact of pharmacist intervention on Primary Care 10 (PC10) measures in primary care practices

Primary Author: Laine Vicarel, The Health Management Group - St. Rita's Medical Center, OH;
Email: lainealexa@gmail.com

Additional Author(s):
Debra Parker
Staci Dotson

Purpose: Primary Care 10 (PC10) metrics established for St. Rita’s Professional Services (SRPS) assess quality of care for outpatient practices. Practices not meeting standards are seeking methods to do so. Literature supports the incorporation of pharmacists within healthcare teams. This study seeks to determine the impact of pharmacist intervention on two PC10 measures: blood pressure control and pneumonia vaccination status. This information will provide supporting evidence to current literature and may provide insight for practices to improve PC10 scores. It may also build a foundation to perform a future return on investment to assess the utility of pharmacists in outpatient practices.

Methods: This is a descriptive, prospective cohort of patients seen between October 15, 2016 and March 31, 2017 in two of the SRPS outpatient practices. There are three study arms: blood pressure control, pneumonia vaccination status, and diabetes clinic referral. Patients will be included in the appropriate study arm if they meet the following criteria: adults at least 18 years old, blood pressure of greater than or equal to 140/90, are a candidate for pneumococcal vaccination, and have an A1c greater than nine percent. Patients will be excluded if they are pregnant or receiving hospice care. The appropriate data will be collected for patients within each study arm and progress notes will be documented, by the pharmacist, in the electronic medical records at each patient visit. Pharmacist intervention will be in accordance with the Eighth Joint National Committee guidelines and Centers for Disease Control recommendations. The primary outcome will be described as the score for the PC10 measures, blood pressure control and pneumonia vaccination status, during each month of the study period. The secondary objective will be described as the proportion of patients with an A1c greater than nine percent who accept a diabetes clinic referral and the reasons for declining such a referral.
This study will be submitted to the Institutional Review Board for approval and informed consent will be obtained from all study participants.

**Poster Title:** Impact of a pharmacist-led transitions of care model in patients with a primary admission diagnosis of congestive heart failure exacerbation

**Primary Author:** Olivia Huprich, The Jewish Hospital, OH; Email: ohuprich@mercy.com

**Additional Author(s):**
Kim Pharris
Cathy Jenkins

**Purpose:** There has been a nationwide spotlight on readmission rates in heart failure patients since Congress enacted the Hospital Readmissions Reduction Program. Transitional-care programs have been implemented in hospitals across the country to improve outcomes in the transition between the inpatient and outpatient settings. However, the types of interventions that reduce readmission rates are not well established. A number of studies have demonstrated pharmacist involvement significantly reduces heart failure readmission rates. The purpose of this study is to identify the impact of pharmacist-led interventions on 30-day readmission rates in patients admitted with a primary diagnosis of congestive heart failure exacerbation.

**Methods:** The study population will include patients admitted to The Jewish Hospital’s cardiology group in November 2016 with a primary diagnosis of congestive heart failure exacerbation. Patients will be identified according to their primary admission diagnosis in the electronic medical record. Within 48 hours of admission, patients in the intervention group will have home medications reconciled with the medication list in the electronic medical record by a pharmacy intern, pharmacy resident, clinical pharmacist, or staff pharmacist. Patients will be followed peripherally by the pharmacy resident throughout the duration of hospitalization who will aim to optimize adherence with guideline based therapy. At discharge, the resident will reconcile the physician’s discharge summary with the after visit summary and the discharge medication orders. The resident will provide discharge counseling and offer to fill and deliver the patient’s new medications to their bedside through the hospital’s MedstoBeds service. Finally, the resident will ensure the patient has an appointment for outpatient follow-up within 7-10 days after discharge. The resident will also follow-up via telephone with the patient within 3 days of discharge to ensure there are no acute issues with medications or changes in overall clinical status.

Poster Title: Vancomycin dosing in obese patients: a retrospective case-control study

Primary Author: Mallory Houtchens, The Jewish Hospital - Mercy Health, OH; Email: mhoutchens@mercy.com

Additional Author (s):
Holly Lawhorn

Purpose: Currently there is no standardized guideline or clear recommendation for dosing vancomycin in obese patients (body mass index of at least 30 kilograms per meter squared). Infectious Diseases Society of America recommendations for empiric vancomycin dosing often do not result in therapeutic vancomycin troughs in obese patients, and can result in inadequate dosing. Reaching a therapeutic vancomycin trough sooner ensures that patients are being treated at the minimally effective concentration. This study’s aim is to determine if our institution’s current efforts in dosing vancomycin in the obese population is sufficient by comparing our success rates with that of non-obese patients.

Methods: This study will be a single-center case-control retrospective chart review of at least 120 cases and 60 controls who received at least three doses of vancomycin. Cases will be matched with controls based on type of infection and goal trough, comorbidities, age, presence of other nephrotoxic medications, and presence of baseline renal dysfunction. The electronic medical record will be used as the source of patient data. The primary outcome is the time to therapeutic vancomycin trough in hours. Secondary outcomes include length of stay, initial vancomycin trough level, development of acute renal dysfunction, length of time between first dose and first trough drawn in hours, and dose of vancomycin. The following data will be collected: patient age, gender, height, actual and ideal body weights, body mass index, past medical history, infection being treated with corresponding vancomycin trough goal, timing of drawn vancomycin levels, renal function, and other nephrotoxic agents used concomitantly with vancomycin. A clinically significant difference between groups has been defined as a time to target vancomycin trough difference of at least 24 hours.

Poster Title: Sub-dissociative ketamine for analgesia in the emergency department (ED)

Primary Author: John DeLeon, The Toledo Hospital and Toledo Children's Hospital, OH; Email: john.deleon@promedica.org

Additional Author(s):
Korin Calkins
Kristen Thomas
Michael Rudoni

Purpose: Ketamine is a general anesthetic approved for procedural sedation with hypnotic, amnestic, and analgesic properties. Evidence exists that support the use of sub-dissociative ketamine in patients in the ED setting for analgesia as an adjunct to traditional agents. An institution-specific clinical protocol was developed to standardize administration of sub-dissociative ketamine in adult patients who present to the ED with acute moderate to severe pain not relieved by opiate analgesics. The purpose of this study is to determine the efficacy and safety of sub-dissociative ketamine use based on an institution-specific protocol.

Methods: This single-center, non-randomized, retrospective study will be submitted to the Institutional Review Board for approval. Adult patients 18 years or older presenting to the ED with acute moderate to severe pain not relieved by opiate analgesics will be included. The exclusion criteria will include pregnancy, weight less than 49 kg or greater than 115 kg, systolic blood pressure (SBP) less than 90 mmHg or greater than 180 mmHg, heart rate (HR) less than 50 or greater than 150 beats per minute, and respiratory rate less than 10 or greater than 30 breaths per minute. The following data will be collected: patient age, gender, weight, SBP, diastolic blood pressure (DBP), HR, respiratory rate, pain scores, ketamine dose administered, concomitant medications, and reported adverse medication events. All data will be recorded without patient identifiers and maintained confidentially. The primary outcome of the study will evaluate efficacy of the protocol by measuring differences in pain scores, heart rate, and blood pressure before and after ketamine administration. The secondary outcome will evaluate any adverse effects and reactions observed after ketamine administration.

**Poster Title:** Assessing appropriate use of aztreonam

**Primary Author:** Malihe Hosseini, The Toledo Hospital/Toledo Children's Hospital, OH; **Email:** malihe.hosseini@promedica.org

**Additional Author(s):**
Cynthia Dusik
Armisha Desai

**Purpose:** The monobactam structure of aztreonam makes cross reactivity with beta lactam allergies unlikely; therefore, it is primarily used when a beta lactam allergy is present. Currently, the only approved indication of aztreonam at our institution is for aerobic gram negative infections in patients with documented allergic reactions to beta lactam antibiotics. The purpose of this quality improvement project is to assess the appropriate use of aztreonam based on our institutional guidelines.

**Methods:** This is a single center, retrospective chart review that will be approved by the Institutional Review Board. All adult patients that received at least one dose of intravenous aztreonam between 01/01/2015 through 12/31/2015 will be included. Pediatric patients and patients on inhaled aztreonam will be excluded. The following data will be collected: age, sex, documentation of beta lactam allergy, aztreonam dose and frequency, duration of therapy, prescriber, and documentation of successful administration of penicillin or cephalosporin antimicrobials one year prior to aztreonam therapy. Beta lactam allergies will be defined as follows: Severe (anaphylaxis, difficulty breathing, tongue swelling, seizure, or allergic interstitial nephritis), moderate (rash or hive) or beta lactam allergy with no reaction listed. The primary objective of this project is to quantify the number of patients that received aztreonam appropriately based on our institutional guidelines.

Poster Title: Evaluation of PlasmaLyte on intraoperative acidosis in patients who undergo cardiopulmonary bypass

Primary Author: Kyle Bailey, The University of Toledo Medical Center, OH; Email: kyle.bailey.kappapsi@gmail.com

Additional Author (s):
Jessica Pakulski
Mark Bonnell
Vincent Mauro
Thomas Schwann

Purpose: Fluid management plays an important role in patients undergoing cardiopulmonary bypass. Normal saline (NS) has a pH of 5.4 and an unbalanced electrolyte profile (Na 154 mEq/L and Cl 154 mEq/L) compared to human serum. Hyperchloremic acidosis is currently a concern with NS administration. PlasmaLyte contains electrolyte concentrations and pH similar to serum (Na 140 mEq/L, Cl 98 mEq/L, acetate 27 mEq/L, gluconate 23 mEq/L, K 5.0 mEq/L, Mg 3.0 mEq/L, pH 7.4). The objective of this study is to compare the incidence of acidosis between patients receiving PlasmaLyte and NS intraoperatively when examining final intraoperative arterial blood gas values.

Methods: This study will be submitted to the Institutional Review Board for approval. The Society of Thoracic Surgeons database will identify patients who have undergone cardiothoracic surgery requiring cardiopulmonary bypass at UTMC. The following data will be collected: patient age, gender, weight, height, comorbid conditions, type of surgery, duration of surgery, time on cardiopulmonary bypass, postoperative length of stay, intraoperative fluid balance, 24-hour fluid balances, arterial blood gases, systolic blood pressures, central venous pressures, amounts of bicarbonate administered, amount of albumin administered, basic metabolic panels, lactates, serum osmolalities, intubation duration, vasopressor duration, mortality, new-onset atrial fibrillation, and acute renal failure. Base excess less than -2 will be used to define acidosis on the last intraoperative arterial blood gas. Appropriate statistical tests will be performed. Differences in postoperative length of stay, duration of vasopressors, time to
extubation, in-hospital mortality, 30-day mortality, incidence of new-onset atrial fibrillation, and acute renal failure will also be compared between groups.

Poster Title: Effect of a sedation protocol revision on sedative use in the medical intensive care unit (MICU)

Primary Author: Sebastian Al-Saiegh, The University of Toledo Medical Center, OH; Email: sebastian.al-saiegh@utoledo.edu

Additional Author (s):
Kellie Buschor

Purpose: Patients in the intensive care setting requiring mechanical ventilation often receive sedatives to manage their pain, anxiety, or agitation. Studies have identified sedative medications as risk factors for extended mechanical ventilation duration, intensive care unit length of stay, and increased incidence of ventilator-associated events (VAE). This project aims to evaluate the impact of daily sedation interruption (DSI) and education on sedative use in the MICU at an academic medical center. The primary endpoint compares sedative use after implementing an automatic DSI and educating physicians and nurses. Secondary endpoints include evaluating effects on VAEs, pain scores, and MICU length of stay.

Methods: A retrospective chart review will be conducted pre- and post-sedation protocol implementation. All patients over 18 years of age, admitted to the MICU at an academic medical center, and mechanically ventilated from August 1, 2013 to November 30, 2014 (pre-implementation) and December 1, 2015 to May 31, 2016 (post-implementation) will be included. Exclusion criteria include: pregnant patients, those whom life-sustaining support was withdrawn or expired within 48 hours of admission, those patients using sedatives for purposes other than sedation, and those remaining in the MICU after the study’s stop date. An electronic medical record system will be used to retrieve the following patient data: name, medical record number, age, sex, height, weight, hospital admission date and diagnosis, MICU admission date and diagnosis, MICU and hospital length of stay (LOS), duration on mechanical ventilation, Acute Physiology and Chronic Health Evaluation (APACHE II) score, Riker Sedation-Agitation Scale (SAS) scores, pain and agitation scores, sedatives and opioids administered, neurologic diagnostic studies, ventilator-associated events, self-extubations, re-intubation, and survival to discharge. This project has been submitted for Institutional Review Board approval. Appropriate statistical analyses will be used to define primary and secondary objectives.

**Poster Title:** Impact of a continuous local anesthetic pain ball on post-operative pain in kidney transplant recipients

**Primary Author:** Eric Betka, The University of Toledo Medical Center, OH; **Email:** eric.betka@utoledo.edu

**Additional Author(s):**
Lindsey Eit niear  
Jorge Ortiz  
Samantha Spetz  
Paul Samenuk

**Purpose:** A multi-modal approach for the management of post-operative pain utilizing local anesthetic wound infiltrations, such as the ON-Q pain ball, has gained momentum over the last decade. This multi-modal approach has proven to be efficacious for reducing post-operative opioid consumption and opioid-related complications in procedures involving the abdominal wall. However, data are controversial in regards to this multi-modal approach for renal transplant (RT) recipients. The objective of this study is to determine the effectiveness of a continuous wound infusion of local anesthetic in the reduction of post-operative opioid consumption compared to traditional post-operative pain management in RT recipients.

**Methods:** This retrospective cohort study was approved by the Institutional Review Board at The University of Toledo Medical Center (UTMC). Patients 18 years and older admitted to UTMC from July 1, 2006 through July 30, 2016 with an International Classification of Diseases (ICD) 9 or 10 code correlating to end stage renal disease or kidney transplantation will be screened for inclusion into the study. Eligible patient will have undergone kidney transplantation during the specified time period. The following data will be collected: age, gender, type of post-operative pain management regimen, type of transplant, post-operative pain scores, and post-operative opioid requirements. The primary endpoint will be the cumulative opioid consumption in intravenous morphine equivalents at 24, 48, and 72 hours following transplantation. Secondary outcomes will include the difference in post-operative pain scores (24, 48, and 72 hours), hospital length of stay, surgical wound infections, and a subgroup analysis of recipients of living donor versus deceased donor transplants.
**Results:** Data collection in progress.

**Conclusion:** To be determined.

Poster Title: Compliance with surviving sepsis guidelines: correct timing of antibiotics at presentation

Primary Author: Courtney Hochman, UH Regional Hospital Richmond Campus, OH; Email: courtney.hochman@uhhospitals.org

Additional Author (s):
Patricia Tumbush

Purpose: The surviving sepsis campaign recommends that broad spectrum antimicrobial therapy be initiated within the first hour of presentation in patients with septic shock or severe sepsis without septic shock. Many articles have been published showing benefit to overall mortality with the initiation of empiric therapy in a timely manner. The initiation of broad spectrum antimicrobial therapy is found in the three hour bundle of the campaign. The purpose of this medication-use evaluation is to determine if there is variance in the recommended initiation within one hour of recognition of septic shock or severe sepsis without septic shock at our institution.

Methods: At our institution, an order set has been developed with guidance of the surviving sepsis campaign. It contains definitions of sepsis, severe sepsis, and septic shock. This order set includes the option to select from recommended broad spectrum antibiotics. When these orders are selected there is a special designation for immediate need for these medications and it appears in red as a stat order in the pharmacy queue. This research evaluates patients with a diagnosis of sepsis from January to August 2016. The actual administration time of broad spectrum antibiotics from the time of presentation is the primary outcome. This data will be analyzed in comparison to the time of presentation with septic shock or severe sepsis without septic shock. Additional information that will be analyzed includes: if blood cultures were drawn pre- or post-antibiotic administration, appropriate antibiotic use, if antibiotics were deescalated appropriately based on cultures, lab results, vital signs, order time, and time of presentation to the emergency department, and patient demographics. This data will be used to determine time to administration of empiric antimicrobial therapy in relation to a patient presentation with sepsis.

Poster Title: Evaluation of prothrombin complex concentrate guideline compliance at a large academic medical center

Primary Author: Brian Lauer, University Hospitals Cleveland Medical Center, OH; Email: brian.lauer2@uhhospitals.org

Additional Author(s):
Jason Makii

Purpose: For the reversal of warfarin associated intracranial hemorrhage and major bleeding with an INR > 1.4, it is recommended to use intravenous vitamin K (5-10 mg) along with 4-factor PCC over the use of vitamin K and either 3-factor PCC or FFP. The current procedure at University Hospitals Cleveland Medical Center is to use PCC for life-threatening intracranial/spinal cord hemorrhage associated with warfarin or for reversal of serious bleeds associated with oral anticoagulants with hematology consult. The purpose of this study is to evaluate the compliance with the use of PCC with respect to the institutions reversal guidelines.

Methods: This study was submitted to the Institutional Review Board for approval. This retrospective cohort study will take place from January 1st, 2015 to December 31st, 2015 including all patients receiving PCC for reversal of severe/life threatening bleeding or within the operating room. Patient’s electronic medical records will be reviewed for the necessary data variables. Individuals will be stratified according to indication for PCC. The estimated sample size will be approximately 100 patients. Variables to be collected include: age, race, admitting diagnosis, location where PCC was administered, indication for PCC, hematology consultation recommendations, dose of PCC administered, coagulation markers, documented hemostasis 12 hours post administration, hemoglobin/hematocrit at baseline and 24 hours post administration, documented thrombosis within 7 days of administration, charting documentation of dose administration, concomitant administration rates of alternative reversal agents (vitamin K, fresh frozen plasma, idarucizamab, rFVIIa, platelet transfusion), and imaging studies demonstrating hemorrhage. The primary endpoint is the compliance rate with reversal guidelines defined as guideline approved indication and guideline recommended dose for the specified indication.

Poster Title: Evaluation of the efficacy of bivalirudin and argatroban titration nomograms in an institutional heparin induced thrombocytopenia and thrombosis syndrome guideline

Primary Author: Lindsey Rayhill, University Hospitals Cleveland Medical Center, OH; Email: lindsey.rayhill@uhhospitals.org

Additional Author(s):
Robert Barcelona
Jessica Traeger

Purpose: The primary goal of this medication use evaluation is to evaluate the efficacy of the bivalirudin and argatroban titration nomograms in a heparin-induced thrombocytopenia and thrombosis syndrome (HITTS) guideline at University Hospitals Cleveland Medical Center. The guideline is intended to be used in patients with a high suspicion for HITTS or patients with HITTS confirmed by laboratory results. This study will also assess documentation of heparin allergy in patients with HITTS and the safety of and adherence to the institutional guideline.

Methods: This study will be submitted to the Institutional Review Board for approval. Data will be collected retrospectively from the institution’s medical record. Adult patients who received bivalirudin or argatroban through the HITTS order set from July 1, 2015 to June 30, 2016 will be included. Patients will be excluded if they received bivalirudin or argatroban for less than 48 hours, received bivalirudin or argatroban for indication other than suspected HITTS, have a known history of HITTS, or if the work up for HITTS was initiated at an outside hospital. Data to be collected includes: baseline platelet count, platelet nadir, time from heparin initiation to platelet nadir, 4 T’s score, heparin platelet factor 4 enzyme assay results, serotonin release assay results, use of bivalirudin or argatroban, duration of direct thrombin inhibitor (DTI) therapy, activated partial thromboplastin time levels, titration of DTI, units of blood transfused, documentation of heparin allergy, and length of hospital stay. Data will be collected and maintained in REDCap™, a secure database.

Results: N/A

Conclusion: N/A
Purpose: Tumor lysis syndrome is a life-threatening emergency characterized by a group of metabolic derangements due to abrupt release of intracellular contents following lysis of malignant cells. Hyperuricemia associated with malignancy can result in acute kidney injury or even death. Rasburicase is a recombinant urate oxidase enzyme FDA-approved for treatment of hyperuricemia associated with malignancy. Rasburicase converts uric acid to an inactive soluble metabolite allantoin which can be excreted through the urine. The primary objective of this study is to evaluate the adherence to the rasburicase use guidelines and order set at UHCMC for management of hyperuricemia associated with malignancy.

Methods: This study is in the process of being submitted to the Institutional Review Board for approval. The design of the research is a single-center, retrospective chart review of adult patients 18 years and older who received at least one dose of rasburicase for hyperuricemia associated with malignancy during an inpatient hospitalization at UHCMC from August 1st, 2015 through July 31st, 2016. Information collected includes: patient demographics (patient, age, sex, weight), hospital location, oncologic diagnosis, hematology consult, date of last cytotoxic chemotherapy dose, therapies used prior to rasburicase administration (allopurinol, hydration), dosage and frequency of allopurinol, length of time on allopurinol, documentation of allopurinol allergy, indication for rasburicase use, rasburicase dose, repeat dosing, administration time for rasburicase, uric acid levels and other lab values (potassium, phosphorus, calcium) prior to and following rasburicase use, time drawn for lab values, number of uric acid levels per patient, and G6PD status. Data will be extracted using the electronic medical record and pharmacy databases. Data collection for this study will take place at UHCMC and will be maintained in REDCap™, a secure database.

**Poster Title:** Carbapenem drug-use evaluation at a large, academic medical center

**Primary Author:** Derek Michalski, University Hospitals- Cleveland Medical Center, OH; **Email:** derek.michalski@uhhospitals.org

**Additional Author(s):**
Riane Ghamrawi
Constantine Tsigrelis

**Purpose:** The broad-spectrum activity of carbapenems has led to their overuse in certain clinical situations, which has led to an increase in the development of multi-drug resistant organisms that are difficult to treat and associated with higher rates of mortality. In order to ensure ertapenem, meropenem, and other select antimicrobials are used appropriately, the institution’s Antimicrobial Stewardship Program designed specific usage criteria to optimize antimicrobial therapy. The primary objective of this drug-use evaluation is to determine if the current use of carbapenems (meropenem and ertapenem) within the institution is in accordance with these Antimicrobial Stewardship Program usage guidelines.

**Methods:** This drug-use evaluation is a prospective, descriptive, single-center chart review. The hospital’s electronic medical record and an add-on clinical decision support system will be utilized to identify hospitalized patients greater than or equal to 18 years old who have received at least one dose of ertapenem or meropenem between October 15, 2016 and March 1, 2017 at the study site pending Institutional Review Board approval. The primary objective will be assessed by determining the proportion of patients that were initiated on a carbapenem and meet at least one usage criteria that is listed in the institutional antimicrobial stewardship usage guidelines. In order to assess the study objectives, the following data will be collected: patient age, date of birth, gender, allergy to beta-lactam antibiotics, primary location, service (medical or surgical), drug-related factors, previous antibiotic exposure to select anti-pseudomonal antibiotics, concomitant antimicrobial therapy during carbapenem therapy, infection-related factors, extended-spectrum beta-lactamase (ESBL) producing organism or AmpC beta-lactamase producing organism on culture in past twelve months, and if infectious disease consult was obtained. All data will be de-identified to ensure patient confidentiality.
Descriptive statistics will be utilized to analyze the collected data and proportions will be used to identify adherence rates to the institution’s guidelines.

Poster Title: Comparison of adherence to manufacturer dosing recommendations with apixaban, dabigatran, and rivaroxaban therapy

Primary Author: Brittany Snyder, University Hospitals Geauga Medical Center, OH; Email: brittany.snyder2@uhhospitals.org

Additional Author(s):
Mate Soric

Purpose: Among the non-warfarin oral anticoagulants, differences in manufacturer recommended dosing strategies may lead to inconsistencies in adherence to dosing guidelines between agents. This study will compare the relative incidence of adherence to manufacturer recommended dosing strategies for apixaban, dabigatran, and rivaroxaban in the treatment of atrial fibrillation.

Methods: A retrospective chart review spanning the dates of 1/1/2013-9/30/15 will be performed. This study will use records from a large integrated health system and will include patients at least 18 years of age receiving apixaban, rivaroxaban, or dabigatran with a diagnosis of non-valvular atrial fibrillation and admitted as inpatient or observation status for at least 24 hours. Exclusion criteria include treatment for deep vein thrombosis (DVT), pulmonary embolism (PE), secondary prevention of recurrent DVT or PE, or postoperative thromboprophylaxis. The primary outcome is the incidence of inappropriate dosing for apixaban, rivaroxaban and dabigatran therapy. Additional data to be collected include age, sex, cardiology consult, history of thrombotic events, concomitant use of p-glycoprotein and CYP3A4 inhibitors, race, serum creatinine, age group (18-50, 51-79, or 80 years of age and older), and HAS-BLED score (hypertension, abnormal renal and liver function, history of stroke or bleeding, labile INRs, elderly, history of drugs or alcohol abuse). A logistic regression model will be developed to identify predictors of prescribing patterns that are inconsistent with manufacturer recommendations. A total study population of 200 will be required to meet power.

Purpose: The prescribing of antipsychotics in patients that have Parkinson's disease has been associated with a marked increase in mortality. A recent cohort study of the Veterans Health Administration reported that antipsychotic use was associated with more than twice the hazard ratio compared to nonuse in patients with Parkinson's disease. The objective of this study is to evaluate the prevalence of and factors that are associated with prescribing antipsychotic medications in patients with Parkinson's disease in an outpatient population.

Methods: This national cross-sectional study will use data from the National Ambulatory Medical Care Survey (NAMCS) from 2008 through 2013. This study will be submitted to the Institutional Review Board for approval. Upon IRB approval, data sets for the years 2008 through 2013 of the NAMCS will be obtained through the Centers for Disease Control and Prevention website. The de-identified data sets will be combined and evaluated to include patients that are at least 65 years old with diagnosis of Parkinson's disease. Patients who have a diagnosis of bipolar disorder, schizophrenia, Lewy body dementia or secondary Parkinsonism will be excluded from the study. The primary outcome will be the rate of antipsychotic prescribing, as well as the classification of the antipsychotic prescribed, in patients who have Parkinson's disease. Multivariate logistic regression will be used to identify variables that may be associated with prescribing antipsychotics in this patient population, including: patient demographics, payer type, co-morbid conditions and prescriber characteristics.

**Poster Title:** High-dose methylprednisolone utilization in the emergency department and continued steroid use upon hospital admission.

**Primary Author:** Leah Schomburg, University Hospitals Richmond Medical Center, OH; **Email:** leah.schomburg2@uhhospitals.org

**Additional Author (s):**
Natasha Niemeyer

**Purpose:** At our institution, the use of high-dose methylprednisolone is common for exacerbations of respiratory conditions such as asthma or chronic obstructive pulmonary disease. Based on literature, it appears that lower doses of steroids may be as effective as higher doses in the exacerbation of these conditions and result in less adverse effects. The goal of the medication-use evaluation is to determine the appropriateness of steroid doses in the emergency department to optimize patient outcomes and minimize adverse effects by influencing prescribing practice if necessary.

**Methods:** The electronic medical record will be used to identify patients who received high-dose methylprednisolone intravenously in the emergency department. This review will evaluate patients from September 2015 to September 2016. In addition to general patient information, the following data points will be collected for each patient: indication for steroid use, steroid dose ordered in the emergency department, steroid ordered and dose continued upon admission, and presence or absence of post-steroid use hyperglycemia. Steroid utilization will be assessed for appropriateness based on indication, available guidelines, and recommendations for steroid use in the diagnosed medical condition. Cost comparisons between steroid dose and route of administration will also be evaluated. After determining the common prescribing practices for high-dose intravenous methylprednisolone in the emergency department, assessment regarding the appropriateness of these trends will be concluded. Education on recommended steroid use and dosing can be provided if necessary.

**Poster Title:** Implementation and results of an ED pharmacist-led antimicrobial stewardship program in a community hospital

**Primary Author:** Carly McKenzie, University Hospitals St. John Medical Center, OH; **Email:** carly.mckenzie@uhhospitals.org

**Additional Author(s):**
Kathryn Koliha
Rachana Patel
John Remchick

**Purpose:** The importance of antimicrobial stewardship programs (ASPs) has been emphasized by The Joint Commission (TJC), who issued a 2016 standard requiring hospitals to have an ASP including a pharmacist. According to Bartlett et al. (AJHP 2014), antimicrobial cost per discharge decreased by $23.38 and cost per inpatient-day decreased by $4.27 with a pharmacist-led ASP. At University Hospitals St. John Medical Center (UHSJMC), an ED pharmacist makes empiric and outpatient antibiotic therapy recommendations by reviewing culture and sensitivity reports. This retrospective review is to determine the number, type and cost savings of interventions made by the UHSJMC ED pharmacist.

**Methods:** Patients seen in the ED between the dates of 7/6/2016 through 9/21/2016 were identified using our electronic medical record system (EMRS). The ED pharmacist performs a chart review of each patient, assesses the need for antimicrobials and makes an appropriate recommendation for empiric therapy. Similarly, the ED pharmacist performs a chart review of discharged patients based on daily culture and sensitivity reports. The ED pharmacist reviews and documents pertinent diagnoses, previous antibiotics and antibiotics prescribed at discharge. The pharmacist then determines the appropriateness of drug therapy and intervenes when necessary to adjust antibiotic therapy for outpatients. A retrospective review of this process was performed to determine the number, type and cost savings of interventions made by the ED pharmacist.
Results: From July 7, 2016 - September 21, 2016, we identified 257 interventions made by the ED pharmacist. Of the 257 interventions, a total of 161 antibiotic therapies were recommended. The pharmacist reviewed 174 culture and sensitivity (C&S) reports for patients recently discharged and 32 antimicrobial recommendations were made based on the C&S results. Additionally, the pharmacist reviewed 129 patient profiles, including past culture and sensitivities, current symptoms, allergies and medications, and was able to provide recommendations for empiric antibiotic therapy in the ED.

Conclusion: Traditionally, pharmacists institute changes in antibiotic therapy for patients admitted to the hospital through narrowing of broad-spectrum therapy or IV to PO conversions. Having a pharmacist in the ED allows early intervention, cost savings, and decreased workload for future practitioners. Over a two-month period, the UHSJMC ED pharmacist made 257 interventions with a total of 161 antimicrobial recommendations. Our study fulfills TJC standards and supports previous studies showing that pharmacist-led ASPs improve patient safety, decrease risk of antibiotic resistance, and provide cost savings for the hospital.
Purpose: Here we report a case of supratherapeutic INR ≥ 8.0 with no active bleeding associated with econazole 1% topical cream application in a patient previously stable on warfarin therapy. The patient was an 88-year-old Caucasian male with a history of deep vein thrombosis/pulmonary embolism maintained on chronic warfarin therapy. He presented to our pharmacist-based outpatient Anticoagulation Monitoring Service for follow-up with a point-of-care INR exceeding the upper limit of detection. Notably, the patient had been stable at a target INR of 2.0 – 3.0 for the past three months. When asked about any recent changes in medication, the patient discussed initiating econazole 1% cream, an imidazole antifungal typically used to treat seborrheic keratosis, applied once daily. Per physician instructions the patient stated he was applying the econazol 1% cream over large portions of the chest, neck, and back. He denied changes to other medications, diet, or consumption of alcohol, cranberry, pomegranate, or grapefruit. The patient’s subjective report did not indicate any alternative cause for elevated INR. Econazole was discontinued, warfarin was held, and oral phytonadione 2.5 mg was ordered for same-day administration. At follow-up one day later, the INR fell to 3.2 and the patient was advised to restart warfarin. Three days later the patient presented with a supratherapeutic INR of 5.0 with no active bleeding, which was attributed to cranberry juice ingestion. INR returned to therapeutic levels eight days after econazole was discontinued. A retrospective analysis using the Drug Interaction Probability Scale (DIPS) tool to assess the relationship between econazole and warfarin adverse effect (elevated INR) indicated there was a probable association for causality. Although a handful of previous case reports have documented a similar interaction between topical imidazoles and warfarin, more data is necessary to determine the safety of combining these agents and appropriate dosing to minimize warfarin toxicity. Pharmacists and other healthcare providers involved in
Anticoagulation Monitoring Services must cautiously assess patients receiving these medications concurrently, as this unlikely yet dangerous interaction may be easily overlooked.

Poster Title: Comparison of Narrow versus Broad Spectrum Antibiotics in Elderly Patients with Acute Exacerbations of Chronic Obstructive Pulmonary Disease

Primary Author: Kayla Joyner, University Hospitals-Geauga Medical Center, OH; Email: kjoyner@neomed.edu

Additional Author(s):
Mate Soric

Purpose: Acute exacerbations of chronic obstructive pulmonary disease (AECOPD) are associated with significantly increased morbidity, mortality, and health-care cost. To date, no study has specifically targeted broad versus narrow spectrum antibiotics in elderly patients hospitalized with AECOPD. However, the prevalence of chronic obstructive pulmonary disease (COPD) is 3 times higher in patients 65 years and older than those 40 to 64 years old. The purpose of this study is to compare outcomes of elderly patients receiving broad versus narrow spectrum antibiotics during a hospitalization for AECOPD.

Methods: A retrospective observational study will be performed using electronic medical records of patients >65 years old admitted with a primary diagnosis of AECOPD or a primary diagnosis of acute respiratory failure and a secondary diagnosis of AECOPD. The planned primary outcome of the study is a composite of mechanical ventilation within 48 hours of admission, transfer to intensive care status after 48 hours of admission, readmission within 30 days for COPD exacerbation, oxygen saturation less than 90% on room air and increased oxygen requirements from baseline after 48 hours. Secondary outcomes include individual components of the primary outcome, hospital length of stay, 10-day and 90-day readmission for AECOPD, all-cause 30-day and 90-day readmission, and clinical decompensation after 48 hours based on systolic blood pressure, respiratory rate, heart rate, oxygen saturation, and increased supplementary oxygen needs. Safety outcomes to be analyzed include Clostridium difficile associated diarrhea and reported adverse reaction to study medications. Data to be collected and analyzed will include patients baseline demographics, risk factors for multidrug resistant bacteria, home medications, concomitant hospital treatments, and antibiotics used.
**Results:** Results are pending data collection and will be presented at the Ohio Pharmacy Residency Conference.

**Conclusion:** Conclusions are pending data collection and will be presented at the Ohio Pharmacy Residency Conference.

**Poster Title:** Comparison of standard vs extended durations of antimicrobial therapy for hospital-acquired pneumonia

**Primary Author:** Khang Nguyen, University of Toledo Medical Center, OH; **Email:** khang.nguyen@utoledo.edu

**Additional Author (s):** Sarah Petite

**Purpose:** Hospital-acquired pneumonia is one of the most common nosocomial infections, accounting for up to 13% of healthcare-associated infections. The Infectious Diseases Society of America recommends a 7 day duration of antimicrobial therapy for hospital-acquired pneumonia; however, this recommendation is based on low quality evidence. The majority of evidence supporting this recommendation is from ventilator-associated pneumonia clinical trials. The objective of this study is to determine the difference in clinical cure rate for patients with hospital-acquired pneumonia treated with less than or equal to 8 days versus those treated with greater than 8 days of antimicrobial therapy.

**Methods:** This retrospective cohort study has been approved by the University of Toledo Medical Center Institutional Review Board and data is currently being collected. Patients will be included if they are 18 years or older, have a diagnosis of hospital-acquired pneumonia with 1 sign or symptom of pneumonia and received at least 72 hours of antimicrobial therapy. Patients will be excluded if they have community acquired pneumonia on admission, are pregnant, have cystic fibrosis, are immunocompromised, or received effective antimicrobial therapy for greater than 24 hours during the 72 hours prior to diagnosis of hospital-acquired pneumonia. Data describing baseline characteristics, antimicrobial therapy, and clinical cure and failure will be collected. The primary outcome will be the clinical cure rate at day 28 in patients treated with less than or equal to 8 days (standard duration) versus patients treated with greater than 8 days of antimicrobial therapy (extended duration). Secondary outcomes will include 30-day hospital readmission rates, mortality rates, hospital length of stay and rate of Clostridium difficile infection in patients treated with standard versus extended duration of antimicrobial therapy.

**Results:** N/A
Conclusion: N/A

Poster Title: Identifying perceptions of adherence in Human Immunodeficiency Virus (HIV)-positive through individual elicitation interviews.

Primary Author: William Kirsch, University of Toledo Medical Center, OH; Email: william.kirsch@utoledo.edu

Additional Author(s):
Joan Duggan
Eric Sahloff

Purpose: Near-perfect adherence with antiretroviral therapy is associated with virological suppression and immunological recovery in patients with Human Immunodeficiency Virus (HIV). However, a meta-analysis estimated that only 55% of the HIV population in North America achieve optimal adherence rates. Therefore, the objective of this study is to identify themes and predictors of adherence by evaluating perceptions of HIV-positive patients. The themes and predictors identified will be used to develop a brief survey that can prospectively predict adherence in treatment-naïve HIV-infected individuals.

Methods: The study will be submitted to the health-system’s Institutional Review Board for approval. HIV-positive patients, 18 years and older receiving care at the HIV outpatient clinic will be identified by a third party through review of the electronic medical record system and clinic-based software. Patients will be selected based on “expected” adherence (based on previously identified risk factors for adherence) and actual adherence (based on current viral loads) with four groups being identified – expected/adherent, expected/non-adherent, not expected/adherent, and not expected/non-adherent. Five to ten subjects will be selected for each group. Data collected will include the following: age, gender, race, education, income, and most recent viral load. Individuals meeting inclusion into the study will be invited to participate in an individual elicitation interview conducted by a trained interviewer. Following consent, the sessions will follow a structured interview format using predetermined questions related to the Health Belief Model and patient perceptions of disease state, social support, and medication management. Subjects’ responses will be noted, audio recorded, and subsequently transcribed. The data derived from these sessions will be de-identified and remain confidential. Themes will then be extracted and summarized from the transcribed recordings. Responses will be
compared between adherent and non-adherent participants. From this, factors that influence the likelihood to be adherent to antiretroviral therapy will be determined.

**Poster Title:** Analysis of potentially inappropriate medication (PIM) use in the older adult population at an academic medical center

**Primary Author:** Niketa Patel, University of Toledo Medical Center, OH; **Email:** niketa.patel@utoledo.edu

**Additional Author (s):**
- Julie Murphy
- Rachel Rarus

**Purpose:** Research suggests that the use of potentially inappropriate medications (PIMs) is associated with severe harm and high economic costs in the elderly. The aim of the Beers Criteria, updated in 2015 by the American Geriatrics Society, is to reduce inappropriate medication use in the elderly. The purposes of this study are to 1) determine the prevalence of and types of PIMs used in the older adult population at an academic medical center from January 1, 2016 through June 30, 2016, and 2) assess the prevalence of and categorize the adverse events due to PIMs.

**Methods:** The health-system’s Institutional Review Board approved this study. The electronic medical system will identify patients 65 years of age and older admitted to the non-intensive care unit inpatient setting. The two new categories added to the 2015 Beers criteria will be used to identify PIMs, that include: potentially clinically important non-anti-infective drug-drug interactions that should be avoided in the elderly and non-anti-infective medications that require dose adjustments in elderly patients with varying degrees of kidney impairment. Baseline characteristics such as gender, age, weight, height, hospital admission date, reason for admission, new medications initiated during the admission, serum creatinine, creatinine clearance, length of stay, home medication list and hospital medication list during admission will be collected. Adverse events will be defined as medication side effects that may be associated with patient’s hospital admission or an adverse event during hospitalization. Any documentation in the medical record of an adverse event to a medication will also be considered in this definition. Medical records of patients who are identified to have a drug interaction will be evaluated using the Drug Interaction Probability Scale (DIPS) and the Naranjo scale as applicable and will be used for evaluating the probability of adverse drug reaction. The
Wilcoxon rank-sum test and the independent student’s t-test will be used for statistical analysis. Results will be considered statistically significant when alpha < 0.05.

Poster Title: Implementation of Matrix-Assisted Laser Desorption/Ionization Time-of-Flight (MALDI-TOF) and Antimicrobial Stewardship Intervention at an Academic Medical Center

Primary Author: Sarah Elhalis, University of Toledo medical Center, OH; Email: sarah2731@gmail.com

Additional Author (s):
John Macko
Heather Byrd
Claudiu Georgescu
Kelli Cole

Purpose: Blood stream infections (BSIs) are associated with increased morbidity and mortality in hospitalized patients. Prompt organism identification is vital for optimizing antimicrobial therapy in patients with BSI and decreasing antimicrobial resistance. To help improve treatment of BSIs, several rapid diagnostic tests (RDT), such as the Matrix-Assisted Laser Desorption/Ionization Time-of-Flight, have been developed. Studies have shown that RDTs along with antimicrobial stewardship improve time to effective therapy and have a positive impact on patient outcomes, including mortality. The objective of this study is to assess the impact of this combined approach on the management of BSIs at our institution.

Methods: Single-center, pre-post quasi-experimental study awaiting IRB approval including all patients treated for documented BSI at our institution between January 1, 2015 and December 31, 2016. Patients will be excluded if they were transferred from an outside hospital with a documented BSI or had blood cultures that grew Mycobacterium species, Nocardia species, anaerobic organisms, or filamentous fungi. Outcomes will be compared between pre- and post-MALDI-TOF implementation groups. Primary endpoint of time to effective antimicrobial therapy is defined as time from blood culture draw to administration of the first antimicrobial with known susceptibility per microbiology report. Secondary endpoints: time to optimal antimicrobial therapy, 30-day readmission and all-cause mortality, hospital and intensive care unit (ICU) length of stay following blood culture positivity, and recurrent bacteremia within 30 days of discontinuation of antimicrobial therapy. All statistical analyses will be performed using SPSS software.

Poster Title: Assessment of Glycemic Control in Diabetic Patients While Unable to Eat

Primary Author: Joseph Huenecke, University of Toledo Medical Center, OH; Email: joseph.huenecke@utoledo.edu

Additional Author (s):
Natalie Tuttle
Sarah Petite

Purpose: Hypoglycemia in the general medicine ward is associated with increased in-hospital mortality, length of stay, and 1-year mortality. Previous evidence demonstrated half of identified hypoglycemic events were associated with decreased caloric intake without a medication change. The 2016 American Diabetes Association treatment guidelines recommend a basal plus correction regimen for diabetic patients that are unable to eat (NPO) in the noncritical care setting. In the perioperative period, the guidelines recommend full doses of long-acting insulin and half doses of morning insulin NPH. Other treatment guidelines do not provide specific recommendations for the inpatient management of patients with reduced caloric intake.

Methods: This is an Institutional Review Board-approved retrospective cohort study. Adult patients admitted to a noncritical care setting with type II diabetes, prescribed outpatient basal insulin, received at least one basal insulin injection while inpatient, and were NPO during their admission will be included. Patients will be excluded if they have diabetic ketoacidosis, hyperosmolar hyperglycemic state, hypoglycemia on admission, received corticosteroid therapy, received total parenteral nutrition, cardiovascular surgery, type 1 diabetes, or are pregnant. Data describing baseline characteristics, diabetic therapy and blood glucose control will be collected. The primary outcome is the difference in hypoglycemic events, defined as a blood glucose less than 70 milligrams per deciliter, between patients with a greater than or equal to fifty percent or less than fifty percent reduction in home basal insulin dose while NPO. Secondary outcomes include comparing glycemic control, defined as a blood glucose between 70 and 180 milligrams per deciliter, severe hypoglycemic events, hyperglycemic events, administration of glucose or dextrose, hospital length of stay, hospital complications and inpatient total daily dose of insulin between both groups.

Poster Title: Identification and management of sepsis: who does it better?

Primary Author: Marwa Amer, University of Toledo Medical Center, OH; Email: marwa.amer@utoledo.edu

Additional Author(s):
Kellie Buschor
Kelli Cole
Martin Ohlinger

Purpose: In October 2015, the Centers for Medicare and Medicaid Services (CMS) implemented a national core measure addressing the management of patients with sepsis and septic shock. In response to this, the University of Toledo Medical Center (UTMC) created a task force charged with ensuring compliance with this measure including a sepsis order set, and collaboration with rapid response teams. Despite this, the implementation of them may vary depending on the location. The objective of this study is to compare adherence to the core measure between patients who present with sepsis in the emergency department (ED) versus those who are already hospitalized.

Methods: This retrospective cohort study was submitted to the Institutional Review Board at the UTMC for approval. Patients 18 years and older admitted with sepsis, severe sepsis, and septic shock between January 1, 2016 and June 30, 2016 will be included. Patients will be excluded for age less than 18 years, pregnant, patient admitted with other types of shock including cardiogenic shock, hemorrhagic shock, and anaphylactoid reaction, and patients admitted / transferred from outside hospital. Patients’ medical records will be evaluated to retrieve the 3 hours and 6 hours bundle components. The 3 hours bundle includes measuring lactate level, obtaining blood cultures prior to antibiotics, administering broad spectrum antibiotics, administering 30 mL/kg crystalloid. The 6 hours bundle includes applying vasopressors for hypotension not responding to initial fluid resuscitation, repeating a focused exam, assessing volume status, and re-measuring lactate. The primary outcome will be the incidence of adherence to CMS core measure. Secondary outcomes will include risk factors for non-adherence to CMS core measure components and the level of practitioners’ baseline knowledge “will be assessed by administering a survey for UTMC employees”, the length of
hospital and ICU stay, 30-day hospital mortality rate, and the average time of first antibiotic dose. Appropriate statistical analyses will be used to define primary and secondary objectives.

**Poster Title:** Association between tacrolimus levels and graft loss in renal transplant patients  
**Primary Author:** Jelena Radan, University of Toledo Medical Center, OH; **Email:** jelena.radan@utoledo.edu  
**Additional Author(s):**  
Lindsey Eitniear  
Mariann Churchwell  
Jorge Ortiz  

**Purpose:** Success associated with kidney transplants is attributable to calcineurin inhibitors (CNIs), specifically tacrolimus, and their ability to reduce acute rejection rates and improve overall graft survival. Trough levels are closely monitored as to remain in the recommended reference range to minimize adverse effects. Specific CNIs trough values that minimize patients risk of acute or chronic rejection, have not been specifically identified. Therefore, the objective of this study is to evaluate the effect of tacrolimus trough concentrations following kidney transplant on long term graft loss.

**Methods:** This retrospective cohort study was submitted to the Institutional Review Board at the University of Toledo. Patients 18 years and older who underwent a renal transplant between Oct 1, 2006 to July 31, 2016, received alemtuzumab induction therapy, and tacrolimus and mycophenolate maintenance therapy at University of Toledo Medical Center are eligible for inclusion. Patients will be excluded if they were treated with agents other than tacrolimus, mycophenolate and prednisone for long term immunosuppression, those pregnant or breast-feeding, documented allergy to any agent in the post-transplant protocol, patients without at least 50% available outpatient labs and those without a one year tacrolimus level. Tacrolimus concentrations at 12 months will then be stratified into quartiles and compared. Kaplan-Meier curves will be used to analyze the probability of graft loss over time. The primary endpoint is to compare the incidence of death-censored graft failure based on tacrolimus trough concentrations. Secondary endpoints include the incidence of acute rejection episodes, and adverse outcomes including new onset of diabetes mellitus, hyperlipidemia, and opportunistic and surgical site infections over the first twelve months post-operatively. A planned sub-group analysis of deceased versus live donor transplant will be done on all outcomes.

**Poster Title:** Implementation of an antimicrobial restriction policy: is the “paper” more persuasive?

**Primary Author:** Lisa Hayes, University of Toledo Medical Center, OH; **Email:** lisa.hayes2@utoledo.edu

**Additional Author (s):**
Claudiu Georgescu
Russell Smith
Kelli Cole

**Purpose:** Antibiotic stewardship (AS) is defined as “coordinated interventions designed to improve and measure the appropriate use of antibiotic agents”. Among the many types of interventions that can be implemented in order to help accomplish this goal, the Infectious Diseases Society of America (IDSA) has recommended the use of pre-authorization and prospective audit and feedback (PAF) as core interventions to improve antibiotic prescribing practices. The objective of this study is to examine the impact of implementation of a pre-authorization method in the form of a restrictive antimicrobial policy on prescribing patterns at an academic medical center compared to PAF alone.

**Methods:** Single-center, pre-post quasi-experimental study awaiting IRB approval including all patients admitted to the University of Toledo Medical Center between January 1, 2015 and December 31, 2016 who received at least one dose of either linezolid, meropenem, or micafungin. Patients who were readmitted in the study period and received additional doses of study drug will have their subsequent admissions excluded. Outcomes will be compared between the pre- and post-implementation groups. The primary endpoint is rate of meeting hospital-approved criteria for use; this will be assessed at 24 hours, 48 hours and greater than or equal to 72 hours based on currently approved hospital policy standards. Secondary endpoints include the rate of meeting clinical criteria for use, incidence of C. difficile, hospital length of stay, total days of antibiotic therapy, and antimicrobial cost (adjusted for cost differences over the study period). Additional outcomes, to ensure the policy has not led to additional patient harm, include in-hospital and 30-day all-cause mortality.

Poster Title: Assessing the impact of pharmacist discharge medication reconciliation and heart failure education in reducing 30-day readmission rates

Primary Author: Masseeh Rahman, Asante Rogue Regional Medical Center, OR; Email: masseeh.rahman@asante.org

Additional Author(s):
Shane VanHandel
Deborah Sanchez

Purpose: Heart failure patients who are non-compliant to their medications and/or do not have the proper resources available are at a higher risk of being readmitted to the hospital, carrying a very high cost-burden. The purpose of the study is to evaluate the impact of utilizing the heart failure core measure guidelines in combination with pharmacist-driven discharge medication reconciliation and patient bedside medication counseling and education to reduce 30-day hospital readmission rates in the heart failure population. Our goal is to further identify areas where pharmacists can intervene and help the hospital avoid financial penalties related to 30-day readmissions.

Methods: This study has been submitted to the Institutional Review Board for approval. The electronic medical record system (EPIC) will identify patients who are admitted to the heart center at our institution with a primary diagnosis of acute on chronic heart failure exacerbation, with an ejection fraction of less than or equal to 40 percent. The unit base pharmacist will evaluate the patient medication list, and will provide heart failure and discharge medication to the patients, with a focus on medication adherence. These recommendations will be centered on the 2016 ACC/AHA/HFSA Focused Update on New Pharmacological Therapy for Heart Failure guidelines. This pharmacist intervention period will span 3 months (December 1, 2016 – February 28, 2017), and data from this span will be reviewed to rate compliance of treatment and interventions with respect to heart failure guidelines. All data will be recorded without patient identifiers and maintained confidentially. The results will be linked to readmission rates during this span, and will be compared to readmission rates during a similar time period last year, helping to assess the impact of pharmacist intervention in reducing readmission rates at our institution.

Poster Title: Benefits of rapid microbiologic tests and automated pharmacy alerts to optimize pharmacy-driven antibiotic stewardship

Primary Author: Gregory Dimont, Asante Rogue Regional Medical Center, OR; Email: gregory.dumont@asante.org

Additional Author(s):
Immanuel Ijo
Matthew White
Tim Peterson
Kirsten Schutte

Purpose: The goal of antibiotic stewardship is to optimize clinical outcomes related to antibiotic use, decrease healthcare costs associated with infections, and minimize antibiotic resistance. New technology to expedite bacterial identification and antibiotic susceptibility testing plays an important role in optimizing antibiotic therapy. This study was designed to evaluate the clinical impact of implementing rapid microbiological tests and automated pharmacy alerts on pharmacy-driven antibiotic stewardship in the Intensive Care Unit (ICU).

Methods: A retrospective, observational study will be performed at Asante Health System, Oregon. Inclusion criteria will be patients in the Intensive Care Unit receiving antibiotic therapy involving pharmacy recommendations and positive rapid microbiological tests, specifically matrix-assisted laser desorption/ionization time-of-flight mass spectrometer (MALDI-TOF) and VITEK 2 for rapid microbial identification and susceptibility, and rapid polymerase chain reaction (PCR) tests for methicillin-resistant Staphylococcus aureus (MRSA) detection. Exclusion criteria include patients without documented pharmacy intervention and positive rapid microbiological tests suggesting contamination or colonization rather than true infection. Primary outcome measures will be inpatient days of antibiotic therapy and time between laboratory receipts of collected specimens and initial pharmacy antibiotic recommendations. Secondary outcome measures will be time from specimen receipt to initiation of empiric antibiotics, time from specimen receipt to initiation of pathogen-directed antibiotics, and time from pharmacist recommendation to change from empiric to pathogen-directed therapy. Blood samples will be analyzed using MRSA PCR, MALDI-TOF, and VITEK 2, while respiratory cultures
will be analyzed using the latter two microbiological tests. Data collection will span over three time intervals for comparison: pre-rapid microbiological tests (January to March 2015); post-rapid tests/pre-pharmacy alerts (January to March 2016); and post-rapid tests/post-pharmacy alerts (January to March 2017). Clinical guidelines on interpreting rapid microbiological tests will be developed to assist prescribers in antibiotic selection. This study was approved by the Southern Oregon Institutional Review Board.

Poster Title: Evaluating the effect of recent intravenous drug abuse on vancomycin dosing

Primary Author: Songlin Cai, Asante Rogue Regional Medical Center, OR; Email: songlin.cai@asante.org

Additional Author(s):
Immanuel Ijo
Somnath Ghosh
Tim Smith
Matthew White

Purpose: The potential effect of recent intravenous drug abuse (IVDA) on vancomycin dosing regimen is unclear. The primary objective of this study is to determine the average maintenance dose of vancomycin required for individuals with recent history of IVDA to achieve therapeutic trough range of 15 to 20 mg/L compared to the required mean dose for patients without recent history of IVDA. Secondary outcomes will be the mean initial trough at steady state and the mean time between initial pharmacy vancomycin dosing per protocol and first reported therapeutic trough at steady state.

Methods: This study has been approved by the Institutional Review Board. The electronic medical record system will be used to identify patients who have received intravenous vancomycin and have had positive drug tests for methamphetamine, opiate or cocaine. Additional chart review will be done to confirm a history of IVDA. Patients who are under the age of 18, over the age of 65, has body mass index (BMI) greater than 30 kg/meter squared, and those with creatinine clearance less than 60 ml/min will be excluded. A registry will be created to track and collect information on patients who meet these criteria between January 1, 2013 and January 1, 2017. The results will be compared to a patient population with similar demographics, but without a recent history of IVDA. Statistical t-tests will be applied to analyze the outcomes. It is estimated a sample size of 22 will provide the study with 80 percent power, assuming there is a 20 percent difference in vancomycin dosing between the control and study groups. Three separate subgroup analysis will be done for patients with positive drug tests for methamphetamine, opiate, and cocaine to stratify the data.

Poster Title: Development and implementation of managed care pharmacist-led opioid tapering initiative in a rural healthcare coordinated care organization

Primary Author: Cassandra Miller, CareOregon, OR; Email: millerc@careoregon.org

Additional Author(s):
Melissa Brewster

Purpose: There has been a dramatic increase in drug overdose and hospitalization due to prescription opioids in the United States. The CDC guidelines for chronic pain recommend keeping patients' opioid dose as low as possible since the relative risk of death significantly increases when opioid dose exceeds 50 mg per day morphine equivalent dose. Lack of prescriber knowledge remains a significant barrier impeding successful implementation of a population based opioid reduction plan. This study aims to improve primary care provider opioid prescribing and reduce opioid use across the covered population. We will achieve this aim through a focused provider education intervention.

Methods: Needs assessments will be conducted at Columbia Pacific CCO (CPCCO) network clinics. Providers at participating CPCCO network clinics managing at risk members will complete the pre-survey instrument to assess their current knowledge level of opioid management topics, identify barriers to safe opioid management, and rank the opioid management topics in order of importance. Managed care pharmacists will assist providers by providing each clinic with tailored opioid management education series in the form of in-person seminars, webinars, workshops, and reference guides. Providers at participating clinics will complete the post survey to assess change in knowledge after education intervention. The pre and post intervention survey of provider knowledge self-assessment will be analyzed for each participating clinic. The number of at risk members at each CPCCO network clinic pre-intervention will be compared with number of at risk members post intervention. At risk members are defined as 18 years of age and greater, filled opioids for 90 consecutive days or longer, and MED over 50 mg averaged over 90 days.

**Poster Title:** Using medication burden to stratify patient complexity and coordinate pharmacist involvement in team-based care

**Primary Author:** Andrew Hibbard, CareOregon, OR; **Email:** hibbard@careoregon.org

**Additional Author(s):**
Zachary Rosko
Mike Fite'
Carl Stevens

**Purpose:** Effective enrollment, engagement, and risk stratification is imperative for any population health management strategy taking place within a patient centered medical home (PCMH). In a PCMH clinic population consisting mainly of empaneled managed Medicaid members, we are seeking a new way to efficiently identify patients who may benefit from active disease-state management intervention(s), and to prioritize them to maximize program impact with existing resources. This exploratory data analysis aims to discover data elements that alone or in combination have an association with high utilization and are able to capture patients with multiple chronic conditions.

**Methods:** This retrospective, exploratory, data mining analysis will examine existing claims data to track one year of service utilization and outcomes from 8/10/2015 through 8/9/2016. Pre-specified decision trees will be used to categorize variables of importance and examine the association to the primary outcome, all-cause health care utilization costs. Secondary endpoints will attempt to determine the accuracy of the variables to reliably capture patients with uncontrolled diabetes, hypertension or dyslipidemia, and identified as having multiple chronic conditions. First we will compute raw associations of the variables by placing the results of the data pipeline in contingency tables, followed by adjustments that involves matching for baseline controls. At each step the data pipeline likelihood ratios will be calculated as well as confidence intervals using logistical regression and use a significance cutoff of p-value of less than 0.05. Our hypothesis is that patients identified as taking five or more medications (defined as 2 or more Generic Product Identifier character 12 prescription fills within the study period) will be a highly associated to the purposed outcome variables. This project was approved by Western IRB on 9/23/2016.

**Poster Title:** Contraceptive opportunities in females of childbearing age in a primary care clinic providing family planning services for a low-income or underinsured population

**Primary Author:** Pamela Chukwuleta, CareOregon Ambulatory Care Pharmacy, OR; **Email:** chukwuletap@careoregon.org

**Additional Author(s):**
Zach Rosko

**Purpose:** In Oregon about 50 percent of pregnancies are unintended; of these 52 percent did not use any contraceptive methods. As such, the Oregon Health Authority developed an incentive-driven quality measure for provision of Effective Contraceptive Use in females of childbearing age. Initial steps in providing contraceptive services to females of childbearing age is screening for pregnancy intentions. The One Key Question is a screening tool for primary care to improve documentation of counseling for contraception. The purpose of this project is to increase documentation of contraceptive method or counseling in adult females of childbearing age in our FQHC clinics.

**Methods:** The Western Institutional Review Board has decided that this project is exempt. This is an observational, cohort, process improvement study utilizing a retrospective chart review in adult females’ ages 18 through 50 years old. Females documented as pregnant during the year or incapable of becoming pregnant will be excluded. The One Key Question (OKQ) is a screening tool with the goal of providing appropriate preventative or prenatal planning. The retrospective chart review will identify rate of documentation of OKQ. Based on the results of the chart review, a process for documentation of the OKQ will be determined for implementation. The process will aim to create a workflow that identifies opportunities for contraceptive services and streamline the method for consistent provider documentation. A chart review of the post implementation period (approximately 4 months) will be performed. The baseline percentage of OKQ documentation will be compared to the post implementation percentage of documentation for visits with a primary care provider. Data collected will be de-identified to report results by primary care provider and age. The outcome of this project is to increase documentation of contraceptive methods or counseling for females patients of childbearing age utilizing the OKQ screening.

Poster Title: Evaluation of treatment with dabigatran in patients previously prescribed warfarin with a time in therapeutic range less than 50%

Primary Author: Jenna West, Kaiser Permanente Health Plan of the Northwest, OR; Email: jenna.west02@gmail.com

Additional Author(s):
Megan Meis
Taben Main
Tanya Ramsey

Purpose: Patients on warfarin with a time in therapeutic range (TTR) of less than 50% are at risk of poor outcomes and require frequent monitoring. Dabigatran has been shown to be non-inferior to warfarin for the prevention of venous thromboembolism (VTE) in patients with non-valvular atrial fibrillation (NVAF). The purpose of this program is to develop criteria to transition select patients with TTR less than 50% from warfarin to dabigatran. The primary outcome is adherence and tolerance to dabigatran.

Methods: Patients on warfarin for the prevention of VTE with NVAF and a TTR of less than 50% will be eligible for this study. Patients will be assessed for treatment with dabigatran based on inclusion and exclusion criteria. Pharmacists will transition eligible patients from warfarin to dabigatran using an anticoagulation collaborative drug therapy agreement. The dabigatran group will be compared to a group of patients managed on warfarin with a TTR less than 50%. The primary outcome will be adherence and side effect monitoring at one month for patients on dabigatran. The secondary outcome will be safety monitoring for major bleeding or clotting events. This study is exempt from review by the Institutional Review Board.

Poster Title: Effect of a clinical pharmacy intervention plus mailing or mailing alone compared to usual care on zolpidem deprescribing among older adults

Primary Author: Louis Kouch, Kaiser Permanente Northwest, OR; Email: louis.j.kouch@kp.org

Additional Author(s):
Jennifer Kuntz
Daniel Christian
Corinne Johnson
Tanya Ramsey

Purpose: The American Geriatric Society recommends against prescribing sedative hypnotic medications, including zolpidem, in patients 65 years and older. Although these drugs may pose more risk than benefit to older patients, they may be prescribed without a clear plan for discontinuation. The aim of this study is to compare the rate of zolpidem discontinuation from a pharmacist intervention plus mailing or mailing alone to usual care.

Methods: To qualify for enrollment, health care plan members 64 years and older received a total of at least two, but no more than three, zolpidem dispenses in the past year. Exclusion criteria include: less than six months of health plan enrollment; a dispense quantity of six tablets or less per prescription; palliative care or hospice enrollment; long-term care or skilled nursing facility residence; active cancer care; and co-prescribing of an antipsychotic medication, a cholinesterase inhibitor, or memantine. A total of 150 patients will be randomized (1:1:1) to three arms: 1) those receiving a signed letter from the prescriber and an educational brochure; 2) those receiving a signed letter from the prescriber, an educational brochure, and follow-up telephone contact with a pharmacist; or 3) usual care (control). With 50 patients in each intervention arm, we will have 80% power to detect a similar difference in the discontinuation rates between each intervention group and the usual care group. The primary endpoint is the rate of discontinuation of zolpidem at six months in each arm. The secondary objective is to qualitatively assess the barriers and facilitators to implementation and success of the interventions. This study is exempt from review by the Institutional Review Board.

**Poster Title:** Effectiveness of a pharmacy diabetes management clinic implementing a provider – pharmacist warm hand-off referral process to recruit patients and demonstrate improved clinical outcomes

**Primary Author:** Luis Gonzalez, Oregon State University College of Pharmacy, OR; **Email:** ldgonzalez6288@gmail.com

**Additional Author(s):**
Jennifer Davis
Cathy Zehrung
Sarah Thomas
Michal Mingura

**Purpose:** There are well documented therapeutic and safety outcomes-based data representative of the positive effect that pharmacists have in the treatment and prevention of chronic disease states, including diabetes mellitus. Collaborative diabetes clinics managed by pharmacists have demonstrated positive clinical outcomes compared to patients whose diabetes is managed solely by a Primary Care Provider (PCP). The purpose of this research is to evaluate the effectiveness of an interdisciplinary method of recruitment to enroll patients within a Federally Qualified Health Center (FQHC) into a Pharmacy Diabetes Management Clinic (PDMC), and assess the clinical outcomes of patients co-managed by a pharmacist and PCP.

**Methods:** The institutional review board approved this study. This is a prospective cohort and data analysis study. Diabetic patients who were enrolled into Yakima Valley Farmworkers Clinic – Salud Medical Center (SMC) PDMC using a provider – pharmacist warm hand off referral method of recruitment will be compared to patients managed solely by an SMC PCP. Uncontrolled type 2 diabetic patients with a hemoglobin A1C% ≥ 9 charted in their medical records within twelve months of recruitment will be included. A total target number of 80 patients will be consented and stratified according to HbA1C subgroup: (1) 9 – 9.9%; (2) 10 – 10.9%; (3) 11 – 11.9%; (4) ≥ 12%. Information collected using medical charts at baseline and at three and six months of receiving diabetes care will include; percentage change in HbA1C, range and average of self-monitoring blood glucose (SMBG) levels, frequency of HbA1C testing, and patient self-reported adherence to prescription medications. A modified intent-to-treat
analysis will be performed and the last observation carried over method will be used to account for missing values at the end of the study. The investigators will analyze the data to discover statistical trends and correlations between participant characteristics and study endpoints. The data will be reported in aggregate form.

Poster Title: Evaluating utilization and policy variances of antivirals for hepatitis C in the Oregon Medicaid program

Primary Author: Kim Vo, Oregon State University/Oregon Health and Science University College of Pharmacy, OR; Email: kimv@ohsu.edu

Additional Author (s):
Melissa Smith
Daniel Hartung
Megan Herink

Purpose: Each of Oregon’s 16 Coordinated Care Organizations (CCOs) set qualifying factors for authorizing approval of different medications for those in the Medicaid program. The treatment for hepatitis C has drastically changed with the approval of all oral direct acting antiviral (DAA) regimens. One of the major barriers to widespread treatment with DAAs is the significant financial burden for the CCOs. Therefore, each CCO has implemented criteria to prioritize treatment to those with more advanced disease. The purpose of this analysis is to characterize how the variability of authorization criteria amongst the CCOs impacts utilization of DAAs.

Methods: This is a descriptive observational analysis. Consent will be requested from each CCO to include their DAA prior authorization (PA) criteria. The CCO name will not be tied to the criteria. To control for frequent PA changes, criteria from January 2015 and 2016 will be obtained. The preferred DAA(s) and individual components within the criteria will be included. At a minimum, the following components required for approval will be collected and compared: fibrosis stage, HIV co- infection, prescriber type, and drug and alcohol abuse or use. A utilization trend analysis will be performed using aggregate claims data. This will be quantified as prescriptions filled per enrolled member per month. Additionally, total denied and paid claims will be quantified for each CCO. Approval from the local Institutional Review Board is pending.

**Poster Title:** Impact of diagnostic uncertainty: distinguishing acute decompensated heart failure and community acquired pneumonia

**Primary Author:** Melissa Smith, Oregon State University/Oregon Health and Science University College of Pharmacy, OR; **Email:** msmit6h@gmail.com

**Additional Author(s):**
Kim Vo
Jacqueline Verlinich
Harleen Singh
Jessina McGregor

**Purpose:** In heart failure (HF) patients, distinguishing between acute decompensated heart failure (ADHF) and community acquired pneumonia (CAP) is challenging due to similarities in presentation and imaging. Delays in accurate diagnosis may lead to adverse outcomes; however early initiation of simultaneous treatment for both ADHF and CAP may lead to excess medication use and increased risk for drug-associated adverse effects. Our objective is to describe the diagnostic work-up, management, and outcomes of HF patients presenting to the Veterans Affairs Portland Health Care System (VAPORHCS) with symptoms consistent with either ADHF or CAP.

**Methods:** A retrospective cohort study of HF inpatients and outpatients presenting with symptoms consistent with either ADHF or CAP; patients will be excluded if neither ADHF nor CAP are included in the differential diagnoses. Data will be collected on patient demographics, comorbidities, visit type, imaging, laboratory tests, medications, chief complaint, and primary diagnosis. The proportion of patients receiving diagnostic testing and/or pharmacologic treatment consistent with ADHF and CAP will be summarized. The frequency of 30-day readmission and emergency department visits will be compared between patients with diagnostic uncertainty (those treated for ADHF and CAP) versus those without (those treated only for ADHF or CAP). This project has been approved by the Institutional Review Board.

Poster Title: Impact of a pharmacist-managed COPD service utilizing spirometry on patient-related outcomes

Primary Author: Katie Steele, Pacific University Ambulatory Care/Academia PGY2 Residency Program, OR; Email: ksteele@pacificu.edu

Additional Author (s):
John Begert
Jennifer McElravey
Kris Marcus
Brigg Turner

Purpose: Appropriate management of COPD is necessary in order to reduce exacerbations and hospitalizations. Previous literature has demonstrated value in having pharmacists involved in COPD patient care. This study will seek to compare pharmacist-managed COPD patients at the Virginia Garcia Memorial Health Center (VGMHC) Beaverton clinic to patients receiving usual care at other VGMHC clinic locations. Usual care at VGMHC is defined as having a referral placed to pulmonology. Spirometry data will be utilized to categorize disease severity and to ensure therapy is consistent with guideline recommendations and our clinic standards of care.

Methods: In January 2014, the Virginia Garcia Memorial Health Center (VGMHC) Beaverton clinic began a pharmacist-managed spirometry clinic for management of asthma and COPD patients. This service is not available at the other VGMHC clinics; instead, asthma and COPD patients are managed at the discretion of their provider who can refer patients to pulmonologist as warranted. Our study will be a retrospective chart review of all patients at VGMHC clinics who had a diagnosis of COPD as of January 2013, excluding patients with asthma or congestive heart failure comorbidities. We will identify all COPD exacerbations (composite of ED visits, hospitalizations, physician visits, and corticosteroid prescriptions) that occurred from January 2013 to January 2014 (one year prior to implementation of the pharmacist-managed spirometry), as well as those that occurred from January 2014 to January 2015 (one year after implementation of the pharmacist-managed spirometry service). We will then utilize this data to compare the rate of COPD exacerbations for patients seen in the Beaverton clinic to the rate
of COPD exacerbations for patients at all other VGMHC clinic sites in order to demonstrate the impact of the clinical pharmacy spirometry service on COPD management.

Poster Title: Impact of pharmacist performed screening on the diagnosis of depression in diabetic patients

Primary Author: Joselyn Benabe, Pacific University School of Pharmacy, OR; Email: jbenabe@pacificu.edu

Additional Author (s):
Bridget Bradley
Brigg Turner

Purpose: Studies have shown depression is associated with an increased risk of diabetes and inversely diabetes is associated with an increased risk of depression. The American Diabetes Association recommends screening for psychological stresses. Depression screening was implemented into clinical pharmacy workflow at Virginia Garcia Memorial Health Center in February 2016. Patients who screen positive on PHQ-9 (score greater than 10) are referred by clinical pharmacy to their provider for management of depression. The objective of this study is to determine the impact of incorporating depression screening with the PHQ-2/9 into the clinical pharmacy workflow on the identification of patients with depression.

Methods: This is a retrospective study of patients with diabetes at Virginia Garcia Memorial Health Center who were screened with the PHQ-2/9 to assess for depression. Patients will be divided into two cohorts based on time; pre-intervention period from January 31, 2015 to January 31, 2016 and post-intervention period from February 1, 2016 to January 31, 2017. The primary outcome will be to assess the composite of an increase or addition of antidepressant, new diagnosis of depression/anxiety, referral to behavioral health, mental health or to the psychiatric-mental health nurse practitioner. The study will be submitted to the Institutional Review Board at Pacific University for approval.

**Poster Title:** Impact of targeted discharge counseling on heart failure patients with increased readmission risk: effect on readmission rates  

**Primary Author:** Marta Stueve, PeaceHealth Sacred Heart Medical Center, OR; **Email:** marta.stueve@pacificu.edu  

**Additional Author(s):**  

**Purpose:** Since the implementation of the Value Based Purchasing and the Affordable Care Act, heart failure readmission rates have received increased scrutiny. Not only are hospital readmission rates utilized to calculate federal reimbursement dollars, this information is now publicly available on the Center for Medicare and Medicaid (CMS) website for hospital comparison. The objective of this study is to determine the impact of targeted, in-depth discharge counseling for heart failure patients on hospital-wide heart failure readmission rates.  

**Methods:** This study will be submitted to the Institutional Review Board for approval. A report will be generated in the electronic health record to determine the readmission risk of a heart failure patient using: number of prior admissions, Charleston Comorbidity index score, income metrics, polypharmacy index, minority status, age status, presence of diabetes and/or chronic obstructive pulmonary disease (COPD), admission from the emergency department and presence of end-stage renal disease. The top 20% of heart failure patients with the highest risk for readmission as determined by the metric will be given discharge counseling by the pharmacy resident, in conjunction with the hospital’s heart failure educator. Barriers to medication adherence will be identified and referred to social work as needed. All patient data will be recorded confidentially. Data will be collected for a three-month period, and a readmission rate for the top 20% of heart failure patients will be calculated. This data will be compared to data from the previous quarter, as well as the corresponding quarter from the previous

Poster Title: Pharmacist-driven glycemic management in post-operative patients

Primary Author: Steven Barton, PeaceHealth Sacred Heart Medical Center, OR; Email: barton59501@yahoo.com

Additional Author(s):

Purpose: Hyperglycemia in post-operative patients is detrimental to the healing process. The objective of this study is to determine if pharmacist management of insulin dosing can reduce the incidence of hyperglycemia in this patient population and lead to improved outcomes.

Methods: This study will be submitted to the Institutional Review Board for approval. The pharmacist located in the satellite on the surgery floor will be responsible for management of blood glucose levels in general surgery post-operative patients located on their floor. They will follow a basic protocol developed to utilize basal, prandial, and correction-scale insulin to maintain patients’ blood glucose level between 100 and 180 mg/dL. The data collected during a three-month pilot period will include incidence of hypoglycemic events, incidence of blood glucose over 180 mg/dL, incidence of surgical site infections, and length of stay. This will be accomplished by monitoring the electronic health records of patients referred to this clinical service.

Poster Title: Hypoglycemia rates among inpatients receiving insulin

Primary Author: Christopher Lin, Providence Health and Services at Providence Portland and Providence St. Vincent Medical Centers, OR; Email: christopher.lin@providence.org

Additional Author(s):
Cole Southworth
Luetta Jones
Elizabeth Stephens

Purpose: Insulin is often utilized to meet recommended glycemic control standards during inpatient care. However, insulin has an increased risk for hypoglycemia and its associated symptoms and effects. Hypoglycemia is one of the most common adverse drug events among hospitalized patients, and is associated with increased morbidity, mortality, hospital length of stay, and cost. This study aims to monitor the prevalence of hypoglycemic events in patients receiving insulin therapy during admission to a large metropolitan medical center, and to identify, transform, and evaluate modifiable medical practices to reduce the incidence of hypoglycemic events.

Methods: Retrospective data collection and analysis will be employed to perform a single-hospital study on hypoglycemia rates. Patients admitted during the study period who received at least one dose of insulin prior to a hypoglycemic blood glucose reading (defined as less than or equal to 50 mg/dL) will be evaluated. Exclusions will include emergency department patients, day surgery patients, and patients experiencing a hypoglycemic episode prior to or without receiving insulin during their inpatient admission. Electronic reporting tools and manual chart review will be utilized to identify patients and the following data: patient age; gender; medications prior to admission; blood glucose and other pertinent laboratory values; medication administration information; intake and output information; admission length of stay; admission diagnosis; significant medical history; and nursing unit location. Data analysis will be performed to evaluate the clinical context, timing, type, and dose(s) of insulin given in relation to the hypoglycemic events; factors (medications, comorbidities, medical conditions) that may have increased hypoglycemia risk; and possible modifiable factors and related interventions that may decrease hypoglycemia rates. Interventions will be formulated based on
data analysis and implemented mid-study. Post-implementation data collection and analysis will be performed to re-evaluate hypoglycemia rates and intervention efficacy. Patient identifiers will not be retained. This study will be submitted to the Institutional Review Board for approval.

Poster Title: Development of a pharmacist-driven oral oncology neutropenia management protocol for a system-wide specialty pharmacy

Primary Author: Jacqueline Benjamin, Providence Health and Services at Providence Portland and Providence St. Vincent Medical Centers, OR; Email: benj577@usc.edu

Additional Author (s):
Yam Peggy
Martina Akeson
Cody Sorenson

Purpose: Specialty pharmacy is a growing area that focuses on high-touch, high-cost medications indicated for complex disease states. Oral oncology agents represent a significant proportion of these therapies. These agents are attractive to both prescribers and patients due to ease of administration; however, unprecedented barriers exist to their acquisition compared to their traditional intravenous counterparts. Cost of therapy remains high which contributes to patient nonadherence, along with other factors such as adverse effects. Neutropenia is a serious adverse effect of several oral oncology agents and if inappropriately managed, can lead to increased patient harm, decreased outcomes, and increased healthcare costs.

Methods: This study will be submitted to the Institutional Review Board for approval. A neutropenia management protocol will be developed that will allow specialty pharmacists of a large health-system to collaborate with prescribers in the clinical management of patients receiving certain oral oncology agents. This protocol will entail the pharmacists to proactively review patients charts and collaborate with prescribers to decrease the incidence of neutropenia in this patient population. Determining which oral oncology agents to include in the protocol will be based on the agent’s risk of neutropenia (considering both published data and historical data) and based on dispense volume and propriety to dispense. A retrospective observational cohort study will be conducted that will include a control group (patients who received a qualifying oral oncology agent prior to protocol development) and an intervention group (patients who received agent after protocol development). The protocol is currently in development and will entail pharmacists checking labs for neutropenia and markers of infection and contacting prescribers when these outlined criteria are met to assist in guiding therapy. All
data will be obtained without patient identifiers and confidentiality will be maintained. The primary endpoint will be a reduction in the rate of neutropenia. Secondary endpoints will include a reduction of rate of healthcare consumption (number of hospitalizations, emergency department visits, prescriber office visits), reduction of infection rates, and increased adherence rates.

Poster Title: Evaluation and impact of antibiotic use on Clostridium difficile rates

Primary Author: Abdul Ghorbandi, Providence Health and Services at Providence Portland and Providence St. Vincent Medical Centers, OR; Email: asghorbandi@gmail.com

Additional Author(s):
Catherine Baker
Jarrod Brubaker

Purpose: Antibiotic use is a well-established risk factor for Clostridium difficile-associated diarrhea (CDAD). However, ambiguity exists regarding antibiotics associated with highest risks of new-onset and recurrent CDAD. Implementation of strategies to reduce use of high risk antibiotics is an essential step in prevention of CDAD. It has been estimated that 30 percent reduction in antibiotic utilization will result in 26 percent decrease in Clostridium difficile rates. The objective of this study is to evaluate baseline medication use data to identify opportunities to improve medication use and clinical practice for reduction of Clostridium difficile rates.

Methods: This study will be submitted to the Institutional Review Board for approval. The study will commence with evaluation of Clostridium difficile rates within the medical centers. Upon assessment of hospital-wide Clostridium difficile rates, a retrospective analysis of patients diagnosed with CDAD will be conducted. This analysis will elucidate antibiotic utilization in patients with CDAD and risk factors contributing to the development of CDAD. Collection of pertinent patient data will include white blood cell count, percentage of bands, presence or absence of fever, watery diarrhea (3 or more loose stools in 24 hours), positive stool test for Clostridium difficile or toxins, time to positive stool test, pseudomembranous colitis on histopathology or colonoscopy, time from admission to onset of symptoms or risk factors for CDAD, previous and current antibiotics use (indication, route, duration, appropriateness), length of stay, hospital floor admission, and comorbidities. By means of this data, areas for improvement in clinical management of CDAD and interventions to reduce rates of Clostridium difficile will be discovered and reported.

Poster Title: Impact of oritavancin on prevention of hospitalization through an infectious disease physician-led cellulitis treatment pathway

Primary Author: Travis Yesiki, Providence Health and Services at Providence Portland and Providence St. Vincent Medical Centers, OR; Email: travis.yesiki@providence.org

Additional Author (s):
Scott Smorra
Jarrod Brubaker
Paul Sehdev

Purpose: The Center for Disease Control estimates that each year there are over three million emergency department visits for cellulitis and abscess in the United States. The majority of patients receive outpatient treatment. However, nearly ten percent of all hospital admissions are for acute bacterial skin and skin structure infections (ABSSSI), creating a costly economic burden. The objective of this study is to compare rates of hospitalization and cost-saving implications in patients with ABSSSI's that were treated with oritavancin vs standard therapy.

Methods: This study will be submitted to the Institutional Review Board for approval. A quasi-experimental study will be conducted at a 523 bed tertiary, teaching hospital. A protocol for oritavancin use in the emergency department or clinical decision unit will be implemented within an infectious disease physician-led cellulitis treatment pathway. The electronic health record system will be used to identify patients who were treated with standard therapy prior to implementation of the oritavancin protocol, but would have met criteria for oritavancin. At the conclusion of this study, data will be used to calculate rates of 30-day readmission or emergency department visits for patients treated with oritavancin vs patients treated with standard therapy. Average cost per patient in the group treated with oritavancin will be calculated using cost of the drug, administration, and emergency department visit. Average cost per patient in the group treated with standard therapy will be calculated using cost per number of days they are hospitalized. The following data will be collected: patient age, gender, Body Mass Index (BMI), ABSSSI characteristics, antibiotics given, location in hospital for treatment, length of stay (LOS), reported adverse medication events, and treatment post-discharge. All data will be recorded without patient identifiers to maintain confidentiality.

Poster Title: Development, implementation, and evaluation of an oral glucose gel protocol within a mother baby nursery unit

Primary Author: Emmalee Thornton, Providence Health and Services at Providence Portland and Providence St. Vincent Medical Centers, OR; Email: emmalee.thornton@providence.org

Additional Author (s):
Michael Garcia

Purpose: Hypoglycemia is a common metabolic problem in neonates, with a normal transient decline in blood glucose concentration at birth. Currently neonates with hypoglycemia are often admitted to the neonatal intensive care unit (NICU) for intravenous (IV) dextrose. The goal of this study is to implement an oral glucose gel protocol within the mother baby nursery unit to decrease the number of neonates requiring transfer to the NICU for IV placement and IV dextrose infusion. Successful protocol implementation would enable the neonate to remain with the mother and reduce stress and infection risk by avoiding IV line placement.

Methods: This study will be submitted to the Institutional Review Board for approval. The study design is a retrospective quasi-experimental review of the implementation of an oral glucose gel protocol in a mother baby nursery unit. The eligible neonatal population will be greater than or equal to 35 weeks gestational age, less than 4 hours old, at either high risk for neonatal hypoglycemia (large for gestational age, intrauterine growth restriction, small for gestational age, maternal diabetes or less than 37 weeks gestational age, perinatal stress or Apgar score of less than or equal to 6 at 5 minutes of life) or symptomatic (apnea, decreased muscle tone, poor suck, temperature instability, jitters, pallor/diaphoresis), and have a blood glucose concentration of 25 – 45 mg/dL. A retrospective chart review of neonates admitted to the NICU for hypoglycemia for one year prior to implementation of the protocol will be conducted to determine how many neonates could have been trialed with the protocol, and possibly prevented admission to the NICU. Following protocol implementation, data will be recorded in a retrospective manner to audit protocol utilization and identify the number of NICU admissions for hypoglycemia. The primary outcome will be to determine if the oral glucose gel
protocol was successful by comparing the number of NICU admissions for hypoglycemia prior- and post- protocol implementation.

**Poster Title:** Corticosteroids in acute respiratory distress syndrome: Patterns of utilization within the intensive care unit

**Primary Author:** Elizabeth Levins, Providence Health and Services at Providence Portland and Providence St. Vincent Medical Centers, OR; **Email:** elizabeth.levins@providence.org

**Additional Author(s):**
Holly Furushima
Carl Riddick

**Purpose:** Acute Respiratory Distress Syndrome (ARDS) is a pulmonary complication of critical illness. Its hallmark is the development of acute hypoxic respiratory failure with sudden onset of diffuse lung injury and the presence of bilateral pulmonary infiltrates. The literature regarding the use of corticosteroids in this disease are conflicting and no general consensus has been reached. The objective of this study is to evaluate the use of corticosteroids in the Intensive Care Unit (ICU) in relation to patient specific outcomes in order to guide future practice.

**Methods:** This study will be submitted to the Institutional Review Board for approval. A retrospective cohort study will be conducted at a 523 bed tertiary, teaching hospital. The electronic medical record system will be used to identify patients that were admitted to the Intensive Care Unit (ICU) and either presented with, or later diagnosed as having Acute Respiratory Distress Syndrome (ARDS). Patients will be evaluated based on prescriber preference to utilize corticosteroid therapy post diagnosis of ARDS. The following data will be collected: patient age, weight (actual and adjusted), past medical history, day of treatment initiation from diagnosis, medication used, dose and elected taper duration. Average daily ventilator settings will also be recorded to assess patient’s response to the treatment modality prescribed as well as any adverse reactions incurred from steroid therapy. Additional interventions, such as neuromuscular blockers, inhaled nitrous oxide and extracorporeal membrane oxygenation (ECMO) will be recorded if pursued. A composite outcome of mortality, length of stay (LOS) and days on ventilator after diagnosis will be used to assess patient outcomes in regards to recovery. All data will be stored on a secure server, accessible only by password and will be recorded without patient identifiers to maintain confidentiality.

Poster Title: Concomitant use of vancomycin and piperacillin-tazobactam and the risk of acute kidney injury

Primary Author: Peter Hoang, Providence Health and Services at Providence Portland Medical Center, OR; Email: peter.hoang@providence.org

Additional Author(s):
Brent Footer

Purpose: Emerging literature suggests that acute kidney injury (AKI) occurs more frequently in patients receiving combination therapy of vancomycin and piperacillin-tazobactam (PT), than patients treated with vancomycin alone. The primary objectives of this study are to determine the rate and describe the severity of AKI at a not-for-profit hospital with 483 licensed beds amongst patient who received concomitant vancomycin and PT for greater than 2 days. Secondary objectives include the identification of risk factors for AKI amongst the study cohort.

Methods: This will be a retrospective study utilizing data from the EPIC electronic medical records. All data will be de-identified and maintained confidentially. Patients will be included if they are 18 years of age or older and were co-administered vancomycin and PT for greater than or equal to 2 days with a baseline serum creatinine of less than or equal to 1.4 milligrams per deciliter (mg/dL) between 11/15/2015 and 7/14/2016. Included patients must have vancomycin and PT started within 24 hours of each other. In order to evaluate the rate and severity of AKI, we will use the risk, injury, failure, loss, and end-stage kidney disease (RIFLE) criteria. In order to examine risk factors for AKI, a case control study design will be used in which cases will be defined as patients with AKI and controls defined as patients without AKI. Variables to be collected include admission source, demographics, comorbidities, intensive care unit stay, relevant laboratory parameters, microbiology data, concomitant nephrotoxic agents, vancomycin loading dose, and the dose and duration of vancomycin and PT.

**Poster Title:** Development and implementation of a pharmacist lead glycemic control program on an inpatient post-surgical spine and orthopedic unit

**Primary Author:** Bonnie Jiron, Providence Medford Medical Center, OR; **Email:** bonnie.jiron@providence.org

**Additional Author(s):**
Michael Lanning
Herbey Lumbreras

**Purpose:** Hyperglycemia occurs in a significant percentage of hospitalized patients. Improved glycemic control leads to reductions in hospital complications, length of stay, and mortality. Despite the potential benefits of improved glycemic control patients admitted to hospitals may not receive optimal glucose management. Expanding the roles of nonphysician health professionals, such as pharmacists, will be central to the success of new healthcare delivery models in optimizing quality and providing timely evidence-based medicine. The aim of this study is to determine the impact pharmacists have on inpatient glycemic control when consulting on glucose management as part of an Inpatient Glycemic Team.

**Methods:** A six month, prospective pilot study is planned. The Inpatient Glycemic Team will be lead by pharmacists and diabetes educators, and include hospitalists, nurses and other practitioners. Patients admitted to the spine and orthopedic recovery unit will be identified through an Epic report that will be manually generated by a pharmacist and dietician each morning. This report will include patients that have blood glucose readings greater than 180 milligram per deciliter or less than 70 milligram per deciliter. Pharmacists will request to consult on glucose management from the attending practitioner. Consult will involve pharmacists ensuring that patients are on correct order sets, dosing insulin if indicated, and monitoring laboratory parameters. Pharmacists and dieticians will generate a report within Epic to track those patients being consulted on and their glucose control. The Glycemic Team will provide in-service education to pharmacists, hospital medical staff, and nursing staff. Pharmacists will provide patient education in coordination with diabetic educators. Overall, blood glycemic management will be compared before and after implementation of the Glycemic Team intervention. Data will be analyzed to report the number of consults made by pharmacists,
compliance with glycemic order sets, the amount of time patients are euglycemic in order to identify any impact the establishment of an Inpatient Glycemic Team had on glycemic control. Investigational Review Board approval will be submitted for this study.

Poster Title: Management of side effects of oral oncology therapies with side effect management kits provided by a specialty pharmacy

Primary Author: Joshua Loesche, Providence Milwaukie Hospital, OR; Email: joshua.loesche@providence.org

Additional Author(s):
Austin Ewing

Purpose: Side effects of oral oncology therapies can decrease patient quality of life and decreased adherence which can potentially lead to lack of efficacy and potentially require escalation in step-wise therapies. This in turn can lead to an increase of overall healthcare consumption. The objective of this study is to determine if the severity of side effects of oral oncology therapies can be mitigated with pharmacy-provided side effect management kits.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record will identify patients currently receiving an oral oncology therapy with a side effect targeted for pharmacy management (constipation, stomatitis, dermatologic reactions). The patients will be supplied with pre-assembled kits by the pharmacy, and will be provided counseling for use of the kit to manage the most common side effects that may occur during therapy. Patients will receive routine follow up by the pharmacy. Information such as the number of times kit items were used, number of missed doses due to side effects, patient-reported adherence, and patient reported quality of life will be collected through in-person or telephone assessment. All data collected will be recorded without patient identifiers and will be maintained confidentially. Data collected from patients following the use of pharmacy-provided side effect management kits will be compared to data collected prior to the implementation of the kits.

Poster Title: Development and implementation of a pharmacist driven antimicrobial urine culture follow up program at a rural community hospital

Primary Author: Amy Tzou, Providence Newberg Medical Center and Providence Milwaukie Hospital, OR; Email: amy.tzou@providence.org

Additional Author(s):
Carol Keller

Purpose: Pharmacists in the emergency department (ED) have been utilized to enhance the level of care in acute settings, particularly in antimicrobial stewardship efforts. Despite being one of the leading indications for ED antibiotic prescribing, urinary tract infections (UTI) are often discharged on empiric therapy. Urine cultures and sensitivities with subsequent patient follow-up are necessary to provide better targeted care, but place additional burden on ED providers. ED pharmacists can help facilitate and potentially shorten time sensitive urine culture review and patient follow up to provide appropriate antimicrobial therapy modification.

Methods: This study will be submitted to the Institutional Review Board for approval. A single-hospital retrospective review of electronic medical records will be used to identify ED patients for whom urine cultures were obtained and subsequently discharged on antibiotics. Patients under the age of 18 or hospitalized after ED presentation will be excluded. The following data will be collected: time to review culture (days); time to review sensitivities (days); negative/positive culture; source of culture; organism and count; antibiotics prescribed; whether empiric antibiotics were appropriate (according to sensitivities); time to patient contact. Pharmacist intervention will be implemented mid-study and will include urine culture follow-up and appropriate patient contact. Additional data regarding if physician consultation was required will be collected alongside post-intervention data. Pre and post surveys for provider satisfaction will be provided to ED physicians to evaluate perceived availability and time commitment for urine culture review. Data analysis will evaluate median time to chart review; median time to patient contact if therapy modification warranted; percentage of appropriate empiric UTI antibiotic therapy; and potential cost-savings for the hospital system.

**Poster Title:** The role of antimicrobial prophylaxis in patients with head and neck cancer undergoing radiation and/or chemotherapy  

**Primary Author:** Alina Jaeger, Providence Portland Medical Center, OR; Email: alina.jaeger@providence.org  

**Additional Author (s):**  
James Connelly  
Samuel Jacobson  
Rom Leidner  

**Purpose:** Patients undergoing chemoradiation for head and neck cancer often experience mucositis, which increases the risk for infection. The National Comprehensive Cancer Network does not currently have strong recommendations regarding the use of antimicrobial prophylaxis in patients with head and neck cancer. Since there are no guidelines, the use of antimicrobial prophylaxis is often provider dependent. The objective of this study is to determine the effect of prophylactic antimicrobials on the incidence of infection in patients undergoing radiation and/or chemotherapy for head and neck cancer in an outpatient setting.  

**Methods:** This study will be submitted to the Institutional Review Board for approval. Patients who have received chemoradiation for head and neck cancer between July 2013 and July 2016 will be identified by the electronic medical record system. Individuals who are 18 years of age or older, diagnosed with head and neck cancer, undergoing radiation and/or chemotherapy, and seen for treatment in an outpatient oncology network will be included in the study. The exclusion criteria will include the occurrence of an infection that can be attributed to an extraneous cause unrelated to cancer or chemoradiation. Patients will be organized into two cohorts, those who received prophylactic antimicrobials, and those who did not. Demographic data includes patient age, sex, primary diagnosis/location of cancer, type of chemotherapy agent(s) used, and type of antimicrobial(s). Outcomes data includes early discontinuation of antimicrobials, occurrence of infection, hospital admission, length of hospitalization, and occurrence of mucositis. Recorded data will not include any patient identifiers and will be maintained confidentially. Chi-square tests will be used to assess nominal data, which includes the incidence of infection, hospitalization, occurrence of mucositis and discontinuation of
antimicrobials between cohorts. Student’s t-test will be used to assess duration (days) of hospitalization.

Poster Title: Appropriateness of antimicrobial prescribing: antimicrobial stewardship across transitions of care

Primary Author: Justin Bachman, Providence Portland Medical Center, OR; Email: justin.bachman@providence.org

Additional Author (s):
Brent Footer

Purpose: Inappropriate antimicrobial prescribing has a significant impact on both individual and public health. This coupled with the emergence of increasing antimicrobial resistance has resulted in a recent focus on antimicrobial stewardship. Antimicrobial stewardship has traditionally focused on hospitalized patients while largely ignoring the fact that the majority of patients complete their antimicrobial course after discharge. A recent study found that 53% of analyzed patients discharged on antibiotics were prescribed an inappropriate antimicrobial regimen. The objective of this study is to evaluate current discharge oral antibiotic prescribing practices for appropriateness and identify common factors that may be leading to inappropriate prescribing.

Methods: This is a retrospective cohort study and will be submitted to the Institutional Review Board for approval. The electronic medical record system will be used to identify patients treated with antimicrobial agents discharged from the medicine units, who were subsequently prescribed oral antimicrobial agents at the time of discharge to finish the treatment course. Of patients identified the following data will be collected if available: patient age, gender, type of infection, inpatient antimicrobial agents, inpatient treatment duration, discharge antimicrobial agents, outpatient treatment duration, antimicrobials within the past 90 days, past medical history, inpatient unit, discharging physician, presence of an infectious disease physician consultation, serum creatinine, liver function tests, collected culture results including Gram stain, organism, and sensitivities. Provider documentation in the electronic medical record will be reviewed for reasoning of discharge antimicrobial selection. All data will be recorded without patient identifiers and maintained confidentially. Antimicrobial selection, dose, and duration will be compared to local and Infectious Diseases Society of America guidelines to
determine appropriateness. All deviations from recommended guidelines deemed inappropriate will be documented and categorized either as indication, dose, or duration.

**Poster Title:** Transitions of care: Evaluating pharmacy impact on high-risk patients

**Primary Author:** Catherine Behret, Providence Portland Medical Center, OR; **Email:** catherine.behret@providence.org

**Additional Author (s):**
Luetta Jones

**Purpose:** Maintaining and communicating accurate patient medication information is recognized as a National Patient Safety Goal by the Joint Commission that is pertinent to all healthcare settings. Accurate medication information is critically important in patients with an increased risk of readmission related to disease state or high-risk medications. The purpose of this project is to develop workflow to support targeted pharmacy involvement in transition of care for inpatients with heart failure or with newly initiated oral anticoagulants. Outcomes to be evaluated include 30-day readmissions and Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) scores.

**Methods:** The study design is a retrospective study of patients with heart failure or new start oral anticoagulants in two large tertiary hospitals. Patient identification will occur through the use of the medical record and a heart failure readmission risk complexity scoring tool. The electronic medical record will identify all inpatients receiving pharmacy documented transition of care services including collection of admission medication list, patient education and discharge medication list review. Readmission rates between patients who received transition of care pharmacy services will be compared to all patient readmissions. Patients excluded from readmission analysis include patients with planned readmissions, who leave against medical advice or expire, or who are discharged to another acute facility or hospice facility. Data collection will include patient age, gender, nursing unit, and discharge disposition. HCAHPS scores for medication and discharge communication scores will be obtained. Patient identifiers will not be retained. This study will be submitted to the Institutional Review Board for approval.

Poster Title: Evaluation of once daily versus three times daily metronidazole for postoperative treatment of perforated appendicitis in pediatric patients

Primary Author: Henry Tran, Providence Portland Medical Center, OR; Email: henry.tran@providence.org

Additional Author(s):
Sara Clark
Cynthia Hankins

Purpose: Perforation of the appendix is an indication for multiple days of intravenous antibiotics postoperatively. Numerous treatment approaches have been shown to be effective in reducing the incidence of wound infection and intra-abdominal abscess formation. The objective of this study is to compare once daily metronidazole dosing to three times daily metronidazole.

Methods: This study will be submitted to the Institutional Review Board for approval. The study will be a retrospective chart review of pediatric patients who received either metronidazole once daily or three times daily between September 2014 through September 2016 after appendectomy surgery. Patients will be separated into two groups: those who received 30 milligrams per kilogram metronidazole once daily and those who received 30 milligrams per kilogram metronidazole divided three times daily. Both groups will also have received ceftriaxone 50 milligrams per kilogram. Patient’s age, weight, sex, maximum temperature and white blood cell count prior to antibiotics are recorded through chart review. In addition, pre-operative antibiotics, operative technique and complications during operation will be recorded. The primary objectives of postoperative length of stay and number of patients who had abscess formation will be compared between the two groups. Secondary outcomes of total duration of intravenous antibiotics, total dose and cost of antibiotics, time to afebrile, time to oral intake and tolerability will also be investigated.

**Poster Title:** Evaluation of thromboembolic and major bleeding events in patients prescribed oral anticoagulants managed in an ambulatory care setting  

**Primary Author:** Patricia Chaffey, Providence Portland Medical Center, OR; Email: patricia.chaffey@providence.org  

**Additional Author(s):**  
Charmaine Hunt  
Janice Belknap  
Wendy Eckhart  
Judy Perkins  

**Purpose:** Current studies show that direct-acting oral anticoagulants (DOACs) are associated with fewer and less severe bleeding complications compared to warfarin. Optimal use of DOACs is complicated by the lack of assays to measure the magnitude of anticoagulation effects associated with their use. Furthermore, patient outcomes as a result of prescribing DOACs deviating from the approved labeled indication and dose is not fully characterized. The objective of this study is to determine if a pharmacist led anticoagulation clinic results in better patient outcomes in terms of reduced thromboembolic and major bleeding events in patients prescribed warfarin or DOACs.  

**Methods:** This study will be submitted to the Institutional Review Board for approval. Electronic medical records will be utilized to identify patients prescribed oral anticoagulants presenting to the emergency department or admitted inpatient with a diagnosis of a thromboembolic or major bleeding event. The following data will be collected: patient age, gender, ethnicity, oral anticoagulant prescribed, indication for anticoagulation, dose of oral anticoagulant, anticoagulant start date, length of treatment, enrollment in an anticoagulation clinic, concurrent medications potentially increasing bleeding risk, history of bleeding, prior thromboembolic event, CHADS2 scores, CHA2DS2-VASc scores, HAS-BLED scores, serum creatinine, and creatinine clearance. Provider documentation will be reviewed to determine if there is a reason for patients prescribed a dose of an oral anticoagulant that deviates from the food and drug administration (FDA) approved labeled indication. All data will be collected and reported without the use of patient identifiers and will be maintained confidentially.
Percentage of major bleeding and thromboembolic events observed will be calculated. This data will be reviewed by a team of pharmacists to determine the incidence of thromboembolic and major bleeding events amongst patients on oral anticoagulants managed by an anticoagulation clinic or other clinician. The reviewers will rate each patient’s oral anticoagulant indication and dose as appropriate per FDA labeled indication, inappropriate per FDA labeled indication but clinically appropriate, or inappropriate per FDA labeled indication and clinical status.

**Poster Title:** Safe Opioid Prescribing for Emergency Department Discharge Patients

**Primary Author:** Randi Agata, Providence Portland Medical Center, OR; **Email:** randiagata@gmail.com

**Additional Author(s):**
Luetta Jones

**Purpose:** Approximately 47,000 drug overdose deaths occurred in 2014, with over half of these deaths involving an opioid (including prescription opioids and heroin). National research has found that 39 percent of all opioids prescribed, administered, or continued come from the emergency department (ED). The objective of this study is to evaluate discharge opioid prescribing in the Emergency Department and identify opportunities to decrease the quantity and potency of opioids prescribed.

**Methods:** The design is a retrospective study of opioid prescribing in the emergency departments of eight hospitals. Data from the electronic medical record will be used to identify patients 18 years of age and older, who have been discharged from the emergency department with an opioid prescription. Study exclusions are ED visits resulting in a hospital admission, ED patients that leave without being seen or formally discharged and ED transfers to another hospital. Data to be collected includes patient age, chief complaint upon presentation in the ED, name of the medication prescribed upon discharge including its strength (dose) and formulation, and quantity prescribed. Trends in ED discharge opioid prescribing will be compared across hospitals and interventions to improve safe prescribing practices identified and implemented. Patient identifiers will not be retained. This study will be submitted to the Institutional Review Board for approval.

Poster Title: Efficacy of dementia medications in controlling behavior symptoms and reducing use of psychotropic medications in ElderPlace patients

Primary Author: Monica Dougherty, Providence St. Vincent Medical Center, OR; Email: monica.dougherty@providence.org

Additional Author(s):
Sharon Leigh
Kaitlyn Wilson
Maureen Nash

Purpose: Adults with dementia experiencing behavioral and psychological symptoms of dementia (BPSD) can be distressing for patients and creates challenges for caregivers. Psychotropics are used off label to treat BPSD, though these medications have safety concerns, creating the need for safer and more effective therapies. Studies suggest acetylcholinesterase inhibitors (AChE-Is) and memantine may be beneficial to treat BPSD. The objective of this continuation study is to determine the effectiveness of these medications in treating BPSD, and analyze the use of psychotropics in patients started on dementia medications in dementia patients enrolled in a Program of All-Inclusive Care for the Elderly (PACE).

Methods: This study is an extension of previous work completed by a PGY-1 Pharmacy Resident, and will be submitted to the Institutional Review Board for approval. Inclusion criteria consists of patients with a dementia diagnosis initiated on an AChE-I and/or memantine. During this study period, the clinical pharmacist team will be alerted of new orders for dementia medications. The Pharmacy Resident or Clinical Pharmacist will conduct a Neuropsychiatric Index (NPI) with the patient’s caregiver to assess severity of BPSD. In addition, use of psychotropic medications will be evaluated at baseline. A follow-up NPI and psychotropic medication use will be conducted at three months post-initiation to analyze change in BPSD. In patients that have already had an NPI conducted at three months in the original study portion, a follow-up NPI and psychotropic medication use will be conducted at six months or greater than six months post-initiation of dementia medications. Data will be collected via electronic medical record (EMR) review. The following data will be collected: dementia diagnosis type, SLUMS scores, NPI scores, dementia and psychotropic medications, date of initiation or
discontinuation and reasons for discontinuation of all medications. A subgroup analysis of the change in NPI, and change of psychotropic medications, will be completed in three patient groups: AChE-Is only, memantine only, and combination of both. All data will be recorded without patient identifiers and maintained confidentially.

**Poster Title:** Appropriateness of proton pump inhibitor utilization in an integrated health-system

**Primary Author:** Benjamin Vermillion, Providence St. Vincent Medical Center, OR; **Email:** benjamin.vermillion@providence.org

**Additional Author (s):**
Cathy Baker
Jarrod Brubaker

**Purpose:** The use of proton pump inhibitors (PPIs) has increased despite concerns for over-prescribing, associated adverse events, and increased costs. The aim of this study is to assess appropriateness of PPI prescribing and identify opportunities to align practice with evidence-based guidelines.

**Methods:** This study will be submitted to the Institutional Review Board for approval. Electronic reporting systems will be used to identify PPI orders. Aggregate data will be analyzed to characterize our study population and to determine PPI utilization trends. Medical record review will be conducted on a subpopulation to further characterize PPI prescribing practices including compliance with evidence-based guidelines. The pre-determined indications include duodenal ulcer disease, erosive esophagitis, gastroesophageal reflux disease (GERD), Zollinger-Ellison syndrome, pathologic gastric hypersecretion, helicobacter pylori as part of triple therapy, acute and recurrent upper gastrointestinal bleeding, and stress ulcer prophylaxis. In addition, data will be assessed to identify predictors in PPI prescribing patterns, opportunities to improve prescribing practices, potential adverse events, and cost implications.

Poster Title: Implementation of a total parenteral nutrition (TPN) pharmacy protocol and standardization of safety practices in accordance with the American Society of Parenteral and Enteral Nutrition

Primary Author: Cody Weidenhaft, St. Charles Health System, OR; Email: crweidenhaft@stcharleshealthcare.org

Additional Author (s):
Tyler Larson
Rachel Seitz

Purpose: TPN is defined by the Institute for Safe Medication Practices (ISMP) as a high-alert medication, carrying a heightened risk to cause significant patient harm when used in error. Roughly only 58% of organizations have protocols in place to protect from medication errors associated with TPN. ASPEN currently makes recommendations within four areas: prescribing and communication of the physician order, order review and verification, compounding of TPN, and the administration of TPN. The purpose of this study is to evaluate current TPN workflow within a hospital system and identify necessary adjustments to ensure alignment with ASPEN safety recommendations.

Methods: IRB will be submitted for this study. Pharmacists will be given the opportunity to take a pre-survey assessing their current knowledge of both safety and clinical aspects of TPN. The survey will include questions on laboratory value monitoring, appropriate indications and contraindications for TPN, safety surround the TPN workflow, and their current personal comfort level with making electrolyte adjustments to TPN preparations. The data gathered from the survey will help to generate pharmacist education sessions in which appropriate clinical and safety applications of TPN will be presented. An assessment of TPN workflow at SCHS will be performed and compared to the 2014 safety recommendations from ASPEN. A TPN medication use evaluation will be performed using retrospective, de-identified chart data from 30 different patients within the past year. The information gathered will be used to promote the initiation of both a TPN per pharmacy protocol and the revamping of TPN workflow to include many new safety precautions that SCHS has not yet initiated.

Poster Title: Technician checking validation program (TCVP) at a central Oregon hospital

Primary Author: Alexander Miller, St. Charles Health-System, OR; Email: asmiller@stcharleshealthcare.org

Additional Author(s):
Tyler Larson
Rachel Seitz

Purpose: The technician checking validation program (TCVP) is a tool that permits hospital pharmacists to focus on clinical matters while a certified technician performs distributive tasks. The objective of this study is to evaluate the impact of the TCVP on workflow and to develop the processes used to implement a pilot program at St. Charles Medical Center (SCMC).

Methods: This study will be sent to the Institutional Review Board for approval. Baseline time spent by pharmacists checking automated dispensing cabinet medication refills will be collected over the course of a week with a timer. An anonymous survey, given to technicians and pharmacists, may be used to assess baseline attitudes toward roles in the inpatient pharmacy, as well estimate the possible personal impact of the TCVP at St. Charles. Policies and procedures will be developed and implemented per the requirements set by the Oregon Board of Pharmacy (OBOP) that meet all necessary criteria for the TCVP as laid out in Oregon law OAR 855-041-5100. A proposal will be developed and approval for the program will be obtained from the state board of pharmacy. Eligible staff will be identified and validated to participate in the program, and appropriate training will be completed with the intent of developing TCVP-certified technicians at SCMC. Quality assurance will be recorded in the form of documentation of medication checking errors discovered during the pilot program. Progress assessments will be conducted at designated intervals. The scope of practice of a validated checker will be described, such as types of included medications and a list of “high-risk” medications to be excluded. Finally, the overall impact of the TCVP on pharmacy workflow will be assessed by examining time spent on distributive or cognitive tasks.

**Submission Type:** Research-in-Progress  

**Session-Board Number:** 12-238  

**Poster Title:** Evaluation of fluoroquinolone prescribing for acute sinusitis, acute bronchitis, and uncomplicated urinary tract infections at a Community Health Center  

**Primary Author:** Hoang Phan, Virginia Garcia Memorial Health Center, OR; **Email:** hphan@vgmhc.org  

**Additional Author (s):**  
Edward Saito  
Sarah Deines  

**Purpose:** A recent FDA warning has advised restricting the use of fluoroquinolone antibiotics for the treatment of acute bronchitis, acute sinusitis, and uncomplicated urinary tract infections (UTI) when other treatment options are available. This restriction was issued due to an observed increase in the risk of side effects involving the nerves, joints, and tendons in patients receiving systemic fluoroquinolones. Since fluoroquinolones are not recommended as first-line agents in acute sinusitis, acute bronchitis, or uncomplicated urinary tract infections, the aim of this project is to evaluate the appropriateness of fluoroquinolone prescribing at Virginia Garcia Memorial Health Center.

**Methods:** This is a retrospective medication use evaluation of the fluoroquinolone drug class at Virginia Garcia Memorial Health Center. ICD-9 and ICD-10 codes will be used to identify patients with a diagnosis of acute sinusitis, acute bronchitis, or uncomplicated urinary tract infections who were also prescribed a fluoroquinolone from January 1, 2015 to December 31, 2015. A review of the electronic medical record will evaluate medication use history and clinical outcomes. Specific areas of review include allergies, microbiology results and history of antibiotic use or hospitalization in the past 3 months. Appropriateness of prescribing will be evaluated based on current (Infectious Diseases Society of America, American College of Physicians, and Centers for Disease Control and Prevention) treatment guidelines. Inappropriate prescribing is defined as the use of a fluoroquinolone for acute sinusitis, acute bronchitis, or uncomplicated urinary tract without contraindications to a recommended first-line agent.

**Poster Title:** Evaluation of the prescribing practices of tricyclic antidepressants in adults 65 years and older at a federally qualified health center  

**Primary Author:** Hannah Noh, Virginia Garcia Memorial Health Center, OR; **Email:** hnoh@vgmhc.org  

**Additional Author (s):**  
Samantha Flores  
Bridget Bradley  

**Purpose:** The 2015 Beers Criteria identifies tricyclic antidepressants (TCAs) as potentially inappropriate medications (PIMs) in adults 65 years and older due to their ability to cause sedation and orthostatic hypotension. The general recommendation is to avoid the use of tricyclic antidepressants in this population unless no safer alternatives are available. The objective of this medication use evaluation is to describe the rate of TCA prescribing and indications for use in older adults at Virginia Garcia Memorial Health Center (VGMHC). VGHMC is a federally qualified health center which provides care to patients through a patient centered medical home model.  

**Methods:** This study will be submitted to the Institutional Review Board at Pacific University for approval. An existing internal report that includes data pulled from the electronic medical record consists of patients 65 years of age or older who are currently on a tricyclic antidepressant between May 1, 2014 and April 30, 2016 will be utilized. The following is also included in the data report: patient age, name and dose of the prescribed tricyclic antidepressants, and associated diagnosis for which the tricyclic antidepressant was prescribed. All data for evaluation will be recorded without patient identifiers and stored securely and confidentially. Chart review will be completed to fill in missing indications. The rate of tricyclic antidepressant prescribing and indications for use will help determine focus areas for provider education to improve the safety of tricyclic antidepressant prescribing practices at VGMHC in the future.  

**Results:** N/A
Conclusion: N/A
