Danielle Massee
Chelsea Bast
Agnes Zajac

Purpose: Neuromuscular blocking agents, such as rocuronium, vecuronium and succinylcholine, are widely used in surgical practice to facilitate intubation and ensure optimal skeletal muscle relaxation. Until recently neuromuscular blockade (NMB) reversal was accomplished through the use of the acetylcholinesterase inhibitor, neostigmine. Sugammadex, a modified gamma cyclodextrin, has shown to effectively reverse moderate to profound rocuronium or vecuronium-induced NMB and reduce the time to neuromuscular function recovery. The purpose of this project is to evaluate safety, efficacy and potential cost savings following the formulary addition of sugammadex at our health system.

Methods: A retrospective review of the intra-operative records will be conducted to identify patients who underwent a surgery requiring reversal of neuromuscular blockade with sugammadex or neostigmine. Efficacy of NMB reversal will be assessed by evaluating appropriateness of the dose administered compared to patient’s weight, NMB level (defined as moderate block, profound block or rapid sequence intubation block) and time between surgical closure and extubation. Safety of sugammadex will be assessed based on the need for re-intubation in the post-anesthesia care unit (PACU) and incidence of adverse drug effects, such as post-operative nausea and vomiting, compared to neostigmine use. A cost evaluation will be conducted based on the sugammadex vial volume used in relationship to the dose required and a change in utilization of rocuronium compared to succinylcholine since sugammadex formulary approval.

Poster Title: Hypophosphatemia management optimization in a large health-system

Primary Author: Milan Patel, Yale New Haven Hospital, CT; Email: milan.patel@ynhh.org

Additional Author (s):
Michael Liu
Myroslava Sharabun
Nilesh Amin

Purpose: Hypophosphatemia, defined as serum phosphate less than 2 milligrams per deciliter, can result in severe clinical sequelae including respiratory failure, seizures, and mortality. With increasing costs for intravenous sodium and potassium phosphate, a guideline on appropriate usage was implemented in our computerized provider order entry system (CPOE) at the health-system in 2014. The primary outcome is to determine adherence rate to our guideline, and across the health-system if it were to be applied.

Methods: Electronic medical records of 150 patients that received intravenous sodium and potassium phosphate from July 1, 2015 to December 31, 2015 are being reviewed. Exclusion criteria include those who have creatinine clearance less than 30 milliliters per minute, documented acute kidney injury, chronic kidney disease, on a dialysis modality, or on parenteral nutrition. Our guideline defines that intravenous phosphate is warranted if serum phosphorus is less than 2 milligrams per deciliter, and the patient cannot tolerate oral supplementation. Decision to use sodium phosphate versus potassium phosphate depends on serum potassium level. Intravenous sodium phosphate is the preferred choice of repletion, but if serum potassium is less than 4 milligrams per deciliter then intravenous potassium phosphate is recommended. The guideline states for both intravenous forms of phosphate 15 millimoles is recommended, unless the patient’s weight is 70 kilograms or more, in which case 21 millimoles is the preferred dose. Percentage of non-adherence is defined as any deviation from the guideline, which includes when oral supplementation is the preferred method of repletion. Other examples of non-adherence are wrong product, wrong dose, or wrong frequency order. Evaluation of the current data is underway, and if the data shows a reduction of inappropriate use by 50%, then an optimized guideline on phosphate repletion will be implemented across the health-system to improve patient care while reducing overall hospital costs.

Poster Title: Cardiac stress testing agent selection: a retrospective assessment of adherence to drug use guidelines

Primary Author: Jessica Cunio, Yale New Haven Hospital, CT; Email: jessica.cunio@ynhh.org

Additional Author(s):
Julie D'Ambrosi
Constance Cholewczynski
Myla Anderson
Nilesh Amin

Purpose: Recently, the American Society of Nuclear Cardiology updated its guideline detailing pharmacologic stress agents utilized in cardiac stress testing; however, there remains no standardization for agent selection. In 2013, one of three hospitals in a large health system implemented a guideline for pharmacologic stress testing agent selection, categorizing patients into risk strata for potential adverse events. This strategy for cost-effective agent selection between adenosine, regadenoson, and dobutamine was not adopted at the additional institutions. The purpose of this review is to retrospectively assess compliance to this guideline at the initial institution and standardize agent selection across the entire health system.

Methods: Patients undergoing cardiac stress testing will be reviewed from the period of March 1, 2016 to June 30, 2016. Information collected will include chosen stress agent, weight, BMI, COPD diagnosis, asthma diagnosis or inclusion of bronchodilator or steroid inhalers to treat these diseases in active medication list, systolic and diastolic blood pressure at time of testing, and an allergy or intolerance history to any of the pharmacologic agents. This data will be used to determine the appropriate stress agent that should have been chosen based on the current drug use guideline. The primary endpoint is to assess guideline compliance for agent selection at the initial institution. A secondary endpoint will be to assess agent selection at other institutions within the health system against these guidelines. These results will be utilized to estimate cost-savings across the health-system. A safety analysis will be completed to review adverse events secondary to use of these agents. Additionally, a subgroup safety analysis will be completed specifically looking at percentage of adverse events in the adenosine group.
stratified by weight/BMI, as the dosing of this agent is currently based on total body weight. All primary and secondary study outcomes will be analyzed using descriptive statistics.

Poster Title: Expanding the practice advancement initiative (PAI) through implementation of optimized pharmacy resident practice

Primary Author: Courtney DesJardins, Yale New Haven Hospital, CT; Email: courtney.desjardins@ynhh.org

Additional Author(s):
Amber Castle
Elizabeth Cohen
Kimberly Boothe

Purpose: The Practice Advancement Initiative (PAI) aims to advance the health and well-being of patients by optimizing the role of pharmacists in providing direct patient care. Our institution has expanded the pharmacy residency program with the goal of decreasing the pharmacist to patient ratio. This allows for better patient care. The purpose of this study is to increase the level of clinical pharmacy services consistently provided by pharmacists to enhance the patient care experience and improve patient safety, using interventions as a surrogate marker.

Methods: This is a single-center, retrospective study using descriptive statistics. Data will be collected to determine the total amount of interventions documented in the electronic health record by PGY-1 and PGY-2 pharmacy residents and clinical pharmacists. Baseline data will be from July 2015 to July 2016, at which point we expanded the residency class. With this increase in residents, the hospital also optimized twenty consistent resident run service rotations, and focused on setting and standardizing expectations for resident accountability. Resident preferences were maintained through strategic scheduling. Data from August 2016 to October 2016 are expected to reflect these changes. Interventions made by pharmacy interns, students, pharmacy technicians, and foreign pharmacists will be excluded from this study. Examples of high priority interventions that will be tracked include intravenous to oral conversion, patient counseling, medication reconciliation, renal dose adjustments, and drug level monitoring. The primary endpoint for this study is the number of high priority interventions documented by pharmacists before and after our practice changes. Secondary endpoints include resident-specific interventions, the number of medication errors and adverse events reported by pharmacists, the pharmacist to patient ratio, number of medical teams with a
dedicated/rounding pharmacist, and hourly order verification volume per pharmacist. Data and insights from this retrospective study period will be utilized to drive continuous quality improvement to optimize the resident practice.

Poster Title: Implementation of a health system-wide IV sodium bicarbonate infusion utilization guideline

Primary Author: Erica Liu, Yale-New Haven Hospital, CT; Email: erica.liu@ynhh.org

Additional Author(s):
Stephanie Cotugno
Gurinderpal Doad
Michael Liu
Nilesh Amin

Purpose: Sodium bicarbonate is an alkalinizing agent used for a wide array of indications, including treatment of acid-base disorders, severe diabetic ketoacidosis, and toxicological overdoses. Inappropriate utilization of IV sodium bicarbonate infusions may lead to suboptimal therapeutic outcomes and excessive expenditure, all of which may be exacerbated during a national drug shortage. The purpose of this drug use optimization project is to streamline IV sodium bicarbonate infusion utilization to improve cost-effective measures through the development and implementation of a health system-wide guideline.

Methods: A multi-center retrospective chart review will be conducted on all patients ordered for IV sodium bicarbonate infusion during hospital admission. Data will be collected over a period of six months between August 2015 to January 2016. Data collection will include indication, concentration, duration of therapy, and laboratory values including arterial pH and serum bicarbonate level. Exclusion criteria will include pediatric patients in addition to patients receiving IV sodium bicarbonate infusion for contrast-induced nephropathy, high-dose methotrexate therapy, or hyper-CVAD treatment. A total sample size of 150 patients will be selected via randomization. A pharmacist will then review, analyze, and assess all IV sodium bicarbonate infusions for appropriateness of therapy based on one of the center’s criteria for usage. An updated, health-system wide, evidence-based guideline will then be implemented to assist in the ordering and administration of IV sodium bicarbonate infusion when indicated.

Poster Title: Standardizing the medication procurement process in the ambulatory clinic setting

Primary Author: Elise Mangione, Yale-New Haven Hospital, CT; Email: elise.mangione@ynhh.org

Additional Author(s):
Mariel Pereda
Nilesh Amin

Purpose: Ambulatory clinic sites associated with our large academic medical center have two methods for ordering and replenishing medications: directly from our contracted wholesaler or from the pharmacy department. Our lack of a standardized process for clinics in ordering medications is inefficient and can result in duplication of orders filled and unnecessary work. The purpose of this project is to standardize the ordering process for ambulatory clinics and utilize our current technologies and resources to minimize or eliminate the manual ordering of medications.

Methods: A complete list of roughly two hundred ambulatory clinics serviced by the pharmacy department will be obtained. An assessment will be conducted to determine the current method of medication ordering and storage at each clinic. For clinics with an automated dispensing cabinet (ADC), an assessment of current medications stored in the cabinet will be conducted to ensure appropriateness based on the patient populations serviced at the clinic. Additionally, an assessment will be conducted to confirm all medications stored in the clinic are in the ADC and not in other unsecured locations. Clinics without an ADC will be granted access to inventory management software. This software will split individual orders to route to our contracted wholesaler or manual pick from our central pharmacy carousel based on the amount of medication being requested. These process changes will allow for clinic ownership of inventory management, while simplifying individual ordering methods. Successful implementation will be measured by a reduction in the number of manual orders specifically by telephone, fax and ordering sheet.

**Poster Title:** Implementation of a Pediatric Satellite Pharmacy Within a Large Health System: A Failure Mode and Effects Analysis

**Primary Author:** Shannon Giddens, Yale-New Haven Hospital, CT; **Email:** shannon.marie.giddens@gmail.com

**Additional Author (s):**
Michelle Rychalsky
Catherine McGeary
Sarah Kelly

**Purpose:** A large academic health system pharmacy department has approved plans to build a technologically advanced, just-in-time dispensing pediatric and women's services satellite pharmacy including use of an IV workflow system and carousel technology. The purpose of this study is to identify best practices for establishing multiple technologies in a pediatric and women’s services satellite pharmacy with risk mitigation through application of a failure modes and effects analysis.

**Methods:** This prospective evaluative study is a continuous quality improvement initiative that will take place over the course of the satellite building time. The current medication distribution process will be assessed and mapped. A failure modes and effects analysis will identify potential risk points within the current processes. A failure detection scale using an adapted version of previously published scales will be applied to determine high risk elements. A risk priority number will be assigned to each process to quantify likelihood of occurrence, detection, and severity of impact. Proactive strategies, involving multidisciplinary healthcare professionals, will be generated to ensure integration of multiple technologies within the just-in-time dispensing satellite pharmacy for this special population.

Poster Title: Evaluate the efficacy of pneumococcal vaccine in immunized population two years before and after immunization regarding hospitalization and ICU admission due to respiratory tract infection

Primary Author: Ahmed El-bardissy, Hamad Medical Corporation, Doha, Qatar., Doha, Qatar;
Email: aelbardissy@hamad.qa

Additional Author(s):
Rana Moustafa
Zainab Jassim
Dina Elgaily
Hani Abdel Aziz

Purpose: Pneumococcal vaccine is recommended by different national and international institutions for high risk populations as elderly (over 65 years), the young, and those with underlying health problems, such as chronic obstructive pulmonary disease, diabetes mellitus, congestive heart failure, and sickle cell anemia. More than 90% of pneumococcal infections can be prevented by a single pneumococcal vaccine, which protects against 23 different types of streptococcus pneumonia bacteria. The purpose of this study was to evaluate the real effects of pneumococcal vaccine in regards to the number of medical ward and intensive care unit (ICU) admissions due to pneumonia post vaccination.

Methods: The institutional review board approved this retrospective study. Men and women 18 years and above who were eligible for vaccination and actually received the pneumococcal vaccine between June 2012 and June 2013 were reviewed for any respiratory tract infections that caused admission to a medical ward or ICU two years before and two years after vaccination. Patients under 18 years old and congestive heart failure patients were excluded. Data for 161 patients were collected retrospectively by reviewing patients’ charts for demographics, comorbidities (smoking, chronic kidney diseases (CKD), diabetes (DM), asthma, chronic obstructive pulmonary disease (COPD), and hypertension (HTN)), microbiological
laboratory data, X-rays, respiratory panel, and empirical antibiotics treatment (especially Azithromycin and respiratory fluoroquinolones). The primary goal was to evaluate the rate of hospitalization to medical wards and ICUs. Secondary aims included the evaluation of the efficacy of pneumococcal vaccine in different age groups and different comorbidities.

Results: The study included 161 patients; those from 64–85 composed the dominant age group at 52%. Diabetic patients composed 57%, HTN 70%, and COPD/asthma 44.7%. The rate of hospitalization due to respiratory tract infection was significantly reduced within two years after vaccination: 71% to 39% (P less than 0.05). There was a trend towards lower ICU admissions However, the results did not achieve statistical significance (P greater than 0.05).

In diabetic patients there was a decrease in hospitalization and ICU admission (70.7% to 37.0% ,P less than 0.05; and 14.1% to 12% P greater than 0.05, respectively) In HTN patients, the difference between hospitalization and ICU admissions was (71.7% to 39.8% P less than0.05;and 12.4% to 13.3% P greater than 0.05 respectively)while in COPD/asthma there was also a difference in hospitalizations and ICU admissions (75% to 36.1%, P greater than 0.05; and 11.1% to 8.3%, P greater than 0.05, respectively).

Conclusion: Pneumococcal vaccine decreased hospitalizations due to respiratory tract infections. The clinical significance of these findings must be determined in larger long-term clinical trials, especially on ICU admission.

**Poster Title:** Medication waste analysis using barcode scanning technology in a large community hospital

**Primary Author:** Kevin Davis, 33400, FL; Email: kevin.davis@flhosp.org

**Additional Author(s):**
Heath Jennings
Justin Simon
Jason Newberry

**Purpose:** Pharmaceutical waste can make a large impact on the cost of care for health systems. Within a large hospital, there are many areas for medication waste due to IV room, compounded medication expirations, and loss of product during inpatient transitions. Medication waste can be difficult to track in a large hospital due to the variety of sources of waste that can be generated. The purpose of this project was to complete an analysis of medication waste at a large community hospital. A technician inpatient transitions of care process to reduce medication waste utilizing an electronic system was also created.

**Methods:** A pre-intervention analysis of medication waste was conducted. The sources for waste included automated dispensing cabinet expirations and returns, patient-specific doses, and IV room waste. A waste analysis tool was utilized in order to document medications returned to central pharmacy. Reason for waste was also included in order determine the source of the waste. Data was analyzed in order to determine waste reduction strategies. A technician pilot was also conducted in order to determine the impact of an inpatient transitions of care program on waste reduction. Upon patient transfer, technicians moved all patient-specific medications to the new patient unit automated dispensing cabinet. An analysis was conducted on the pilot program in order to determine the impact on direct product cost and labor costs.

**Poster Title:** Evaluating hydromorphone use in the emergency department and the pharmacist’s influence on prescribing practices

**Primary Author:** Austin Greanias, Aventura Hospital and Medical Center, FL; **Email:** austin.greanias@hcahealthcare.com

**Additional Author (s):**
Harry Marcelin
Debbie Zock

**Purpose:** Pain management is a significant concern in patients who present to the emergency department. Optimal pain management takes into consideration patient-specific factors, such as opioid naivety, adverse effect profile, allergies, pain source, and pain scale. Variability in prescribing practices exists for pain management in an acute-care setting. The objective of this study is to evaluate the use of hydromorphone in the emergency department and determine its appropriateness.

**Methods:** This study is a retrospective data review conducted at a 407 bed teaching hospital located in an urban setting. This project is currently pending Institutional Review Board approval. Data collection will be conducted via review of hydromorphone orders in a randomly sampled 100 patients. After data evaluation has concluded, the findings will be shared with the medical staff. A one-month “washout” period will take place during this education phase. Post education, data will be collected via the same strategy to determine effectiveness of the intervention.

**Poster Title:** Review of the use of dexmedetomidine in adult patients in the intensive care unit (ICU)

**Primary Author:** Liane Horiuchi, Baptist Hospital of Miami, FL; **Email:** lianeh@baptisthealth.net

**Additional Author (s):**
Heidi Clarke

**Purpose:** To create a database that describes the current prescribing patterns of dexmedetomidine at Baptist Hospital of Miami. This database will be used to evaluate the use of dexmedetomidine in adult patients in the ICU and to assess prescribing criteria.

**Methods:** A random sample of 50 adult ICU patients prescribed dexmedetomidine between January 1, 2016 and June 30, 2016 will be evaluated to assess appropriate prescribing criteria compared to the package insert. Adverse events, such as bradycardia, hypotension, arrhythmias, and acute kidney injury that require interventions from dexmedetomidine will also be evaluated. This research will be used to develop a protocol for dexmedetomidine in hopes to standardize its use and decrease the likelihood of potential adverse events.

Poster Title: Retrospective review of complete joint replacement patients stratified by prophylactic anticoagulation received

Primary Author: Jonathan Kline, Baptist Hospital of Miami, FL; Email: jonathank@baptisthealth.net

Additional Author(s):
Robert Wilkinson
Heidi Clarke

Purpose: To reveal prescribing patterns of deep vein thrombosis (DVT) prophylaxis among orthopedic surgeons for patients undergoing total knee replacement or total hip replacement. Patients included in the study will be stratified by therapeutic class of the prophylactic agent received post-surgery. There is no current guideline implemented at Baptist Hospital of Miami for selection of a prophylactic agent but is instead based off the prescriber’s clinical judgement on a case-by-case basis. The goal is that through evaluating the bleeding, DVT, and infection complications post-surgery, prescribers can assess the efficacy and safety of each prophylactic agent among specific patient populations.

Methods: Retrospective chart review of 120 patients who underwent either a total hip replacement (THR) or total knee replacement (TKR) during a twelve-month period beginning July 1st 2015 and ending June 30th 2016. Patients will be randomly selected and classified by the type of surgery performed and the therapeutic agent received for DVT prophylaxis. Sixty TKR patients and sixty THR patients will be included in the study. For each type of surgery, patients will be further organized into three groups of twenty patients, classified by type of therapeutic agent received. The three categories for therapeutic agents include aspirin, low molecular weight heparin, or novel oral anticoagulant. Data collection will include patient demographics, risk factors for bleeding and thrombosis, details of surgery, post-operation complications, and all-cause readmission within thirty days of surgery. After data collection is completed, prescriber’s will be able to review specific patient populations and compare the outcomes based upon the type of therapeutic agent received.

Poster Title: Evaluating pharmacy technician satisfaction and processes at a tertiary academic medical center

Primary Author: Neill McNatt, Bayfront Health - St. Petersburg, FL; Email: neill.mcnatt@bayfronthealth.com

Additional Author(s):
Jason Hernandez
Kara White
Matthew Wilkinson

Purpose: A community hospital currently does not have a standardized pharmacy technician training program for its employees. Pharmacy technician satisfaction historically has been low especially in regards to initial training which has led to low retention rates of new employees. By creating a standardized pharmacy technician training program and having participants complete an engagement and satisfaction survey, the goal is to facilitate an improved pharmacy technician program that will increase engagement, satisfaction, and retention.

Methods: A community hospital is currently in the process of creating a new technician training program led by pharmacy leadership. After the two week initial training, the data will be prepared for analysis following export from a survey completed using SurveyMonkey. Frequency distributions will be tabulated for all relevant questions. Non-parametric tests along with median scores and ranges will be calculated, as appropriate. Correlation analysis via chi-squared test will be completed to determine relationships between 2 or more variables believed to be associated with one another.

**Poster Title:** Multi-Disciplinary Medication Assistance Program for Indigent Patients Suffering with Heart Failure  

**Primary Author:** Kyle Hejmanowski, Bayfront Health - St. Petersburg, FL; **Email:** kyle.hejmanowski@bayfronthealth.com  

**Additional Author (s):**  
Sarah Marker  
Gwendolyn Wantuch  
Matthew Wilkinson  

**Purpose:** To perform a data analysis of a multi-disciplinary medication assistance program currently offered as a new standard of care service at an institutional hospital. Analysis will determine the impact of medication assistance on 30-day hospital readmission rates for indigent patients suffering with heart failure. The program involves the skills of nurses, case management, and pharmacists working together as a team. The results of this standard of care service evaluation will be compared to previous readmission rates for similar indigent patients suffering with heart failure prior to program installation.  

**Methods:** Eligible patients include those that are suffering with heart failure who require furosemide, carvedilol, metoprolol, lisinopril, and/or losartan for long-term medication management. Case management verifies each patient has no financial resources available to afford discharge medications. Once patients are identified with heart failure and financial need they are enrolled into the program. After being consulted by case management, extensive education is provided to each patient by the pharmacist and heart failure coordinator for medication assistance and disease state management. Discharge planning to include physician follow-up and outpatient management scheduling by case management. Upon discharge each patient will receive a 30-day supply of their medications, free of charge, which includes furosemide, carvedilol, metoprolol, lisinopril, and/or losartan dependent upon their personalized drug therapy regimen. Follow-up and tracking by the heart failure coordinator and pharmacist will be performed with each patient via telephone 1-2 weeks after discharge. The study period includes eligible patients from August 1, 2016 to January 31, 2017. The target enrollment into the program during the 6-month pilot period is 50 patients. The results of this
program evaluation will be compared to previous readmission rates for an equal number of similar indigent patients suffering with heart failure prior to program installation from August 1, 2015 to January 31, 2016. The primary outcome of this study will be to compare 30-day hospital readmission rates between groups.

Poster Title: Extended Infusion Piperacillin/tazobactam Impact on Mortality and Length of Stay in Critically Ill, Obese Patients

Primary Author: Kalee Sullivan, Bayfront Health St. Petersburg, FL; Email: kalee.sullivan@bayfronthlth.com

Additional Author(s):
Ashley Lockwood
Matthew Wilkinson

Purpose: Current literature on extended infusion piperacillin/tazobactam has evaluated the mortality and length of stay of the severely critically ill with Acute Physiology and Chronic Health Evaluation II scores greater than or equal to 17 (APACHE). The objective of this study is to compare intermittent piperacillin/tazobactam versus extended infusion piperacillin/tazobactam effect on the mortality and length of stay in obese and non-obese critically ill patients.

Methods: The study is submitted to the Institutional Review Board for approval. Data will be collected from patients’ electronic medical records at a community hospital. The electronic medical record will identify intensive care unit (ICU) patients who received piperacillin/tazobactam infusion and generate a report. The following data will be collected: patient demographics, APACHE score, body mass index, length of stay, survival, antibiotics administered, loading dose administered, treatment duration, drug allergies, cultured organisms, minimum inhibitory concentration (MIC) values, and hospital costs. Data will be de-identified to protect confidentiality of information and stored in a secured database. An ANCOVA will be utilized to assess if weight confounds the comparison between intermittent and extended infusion piperacillin/tazobactam dosing. Categorical and continuous data will be compared via a Mann-Whitney U test. Data will be reviewed to assess if there is a difference between intermittent and extended infusion piperacillin/tazobactam on targeting MIC’s, length of stay, and mortality in the severely critically ill obese patient population.

Poster Title: Incidence of venous thromboembolism in hospitalized high risk patients: a retrospective cohort chart review

Primary Author: Matthew Stankowicz, Boca Raton Regional Hospital, FL; Email: mstankowicz@brrh.com

Additional Author (s):
Anderson Mabour

Purpose: Hospital-acquired venous thromboembolisms (VTE) are a concern for healthcare institutions because they can cause substantial morbidity and drastically increase healthcare costs. Despite aggressive prophylactic measures, patients with obesity, malignancy, or ICU admission remain at an increased risk of developing hospital-acquired VTE. This retrospective cohort chart review aims to discover the rate of hospital-acquired VTE development in high-risk patient populations at a 400 bed community hospital in order to develop a protocol for ideal dosing of pharmacologic prophylaxis in these patients.

Methods: After approval from the institution’s research committee, an electronic report will be generated to identify patients with an ICD-9 or ICD-10 code for deep vein thrombosis (DVT) or pulmonary embolism (PE) while in the hospital from January 1, 2015 to January 1, 2016. Obesity will be defined as a body mass index (BMI) greater than 30 kg/m2 or an actual body weight greater than 120 kg and 20% above the patient’s ideal body weight. Cancer patients will be identified by ICD-9 and ICD-10 codes for primary malignancies. Intensive care unit patients will be identified as having an admission to the medical ICU during the course of hospitalization. Charts will be reviewed for type of VTE prophylaxis, dose of pharmacologic prophylaxis, signs or symptoms of bleeding (defined by Hgb drop of > 1.5 g/dL in 24 hours or documented bleeding), and readmission within 90 days of discharge. Patients who develop a documented VTE within 2 weeks of surgery will be excluded. If patients are readmitted and developed another VTE they will be counted as 2 incidences.

**Poster Title:** Implementation and utilization of procalcitonin laboratory testing at a teaching community hospital

**Primary Author:** Jinal Choksi, Boca Raton Regional Hospital, FL; **Email:** jinalchoksi12@gmail.com

**Additional Author(s):**
Kristin Boyar
Barbara Hammer

**Purpose:** Procalcitonin (PCT) is a novel biomarker that has been studied in patients with sepsis and in lower respiratory tract infections (pneumonia, COPD exacerbation and bronchitis). PCT levels are elevated in bacterial infections and therefore can help differentiate between viral and bacterial infections. PCT guidance can aid in antibiotic stewardship by reducing antibiotic duration and promoting deescalating or discontinuing antibiotics. The objective of this study is to evaluate the utilization of PCT test that will now be available to order at our institution and assess any antibiotic changes and cost savings as a result of these levels.

**Methods:** The study population will include all the patients that have PCT level ordered over a two month period. A report will be generated on a daily basis for any patient that has an order for a PCT level. The following information will be collected for each patient: patient’s age, gender, location, physician ordering the lab, initial indication of antibiotics, starting antibiotics ordered, PCT level, number of PCT test ordered, days of antibiotic therapy and length of stay. The patient identifiers will be de-identified and all the data collected will be kept confidential. The physician will be instructed to follow the algorithm created for utilization of PCT levels although clinical judgement will be allowed. The impact of using PCT testing on overall management of the patient will be assessed and potential cost savings will be evaluated.

Poster Title: Utilization of visual stimulation tools and nursing to improve the effectiveness of patient education on hospital consumer assessment of healthcare providers and systems (HCAHPS) scores

Primary Author: Patricia Medina, Boca Raton Regional Hospital, FL; Email: pmedina@brrh.com

Additional Author(s):
Gwenesia Collins
Jade Montejo
Nicolle Waetjen

Purpose: Patient education is paramount in order to obtain positive patient outcomes. Many efforts have been tried and initiated in the hospital setting in order to find the most effective way to successfully deliver medication education. Examples of this include patient counseling and medication education booklets. However, there is limited information regarding the impact that these interventions may have on the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey. In this pilot pre-post interventional study, we will evaluate the impact that multiple visual tools provided simultaneously with patient counseling have on medication education, and HCAHPS scores.

Methods: This is a prospective, pre-post interventional pilot study that will be conducted between October 2016 to March 2017 at Boca Raton Regional Hospital, a not-for-profit, advanced tertiary medical center. The target population will be all patients admitted to the 4th floor within that time frame. The interventions will consist of multiple visual tools that will be combined with medication education in order to increase HCAHPS scores. These tools include medication education booklets, videos, word puzzles and placemats which will reinforce the standard patient education currently delivered by pharmacists, pharmacy students and nurses. Every tool used will be consistent in terms of content (descriptive graphics), colors and medication information. Nurses, pharmacy students or the pharmacist responsible of patient medication education will be in charge of distribution of the materials. The primary outcome is achieving the 80% percentile in the medication education related HCAHPS scores. Secondary outcomes will be related to usefulness of the interventions based on patients’ feedback, nurse’s workload, average change in HCAHPS scores and the difference in HACHPS scores between the
study group and the control. A questionnaire to assess patients’ feedback and nursing shadowing by pharmacy students will be performed to measure compliance by nurses in delivering materials and education. Statistical analysis assessing the differences in HCAHPS scores will be reported using descriptive statistics.

**Poster Title:** Implementation of a pharmacist-run clinical service at a medical health clinic affiliated with a non-profit organization and its potential impact on readmission rates

**Primary Author:** Ernesto Perez, Boca Raton Regional Hospital, FL; **Email:** epere050@gmail.com

**Additional Author(s):**
Nicolle Waetjen
Jade Machin
Gwenesia Collins

**Purpose:** Studies have shown that socioeconomic status can have a direct impact on the readmission rates of patients in underserved communities. Limited access to patient care and lack of financial assistance are among the leading causes of increased readmission rates. Recent data has demonstrated that the introduction of clinical pharmacy services to a healthcare system consistently increase cost savings and improve patient satisfaction and therapy outcomes. The purpose of this study is to determine if establishing a novel pharmacy-run service at a medical health clinic affiliated with a non-profit organization will impact the hospital’s readmission rates.

**Methods:** A pharmacy-run clinical service will be introduced to the Florida Atlantic University Medical Health Clinic affiliated with Boca Raton Regional Hospital, which is a non-profit organization. Pharmacists and pharmacist residents will work alongside physicians and medical residents, providing pharmacological expertise. Patient’s charts will be reviewed prior to their arrival and recommendations will be communicated directly to the physician or medical resident. Additionally, the pharmacy service will allow patients to visit the clinic for a one-on-one pharmacist consultation. After four months, a retrospective analysis will compare the 30-day readmission rates between patients who were seen by a pharmacist to patients who were not. Our target population will be uninsured patients and those primarily receiving benefit from Medicare. The primary outcome is the difference seen in readmission rates between patients who were exposed to the pharmacist-run clinical service to those that were not. Secondary outcomes include physician acceptance and refusal rates of pharmacist-made recommendations and patient satisfaction with the clinic and pharmacist counseling (pharmacy
services). Types of interventions may include but are not limited to: providing medication education to physicians, suggesting dosage adjustments, and recommending medication addition or discontinuation when applicable. Descriptive statistics will be used to evaluate the impact of the pharmacist-run clinical service.

Poster Title: Impact of an automated computerized provider order entry (CPOE) alert on generic dispensing rate (GDR) within an accountable care organization (ACO)

Primary Author: Abeer Kazimi, Broward Health, FL; Email: akazimi@browardhealth.org

Additional Author(s):
Jeannette Travis
Katy Lacknauth
Zaher Hajar

Purpose: Healthcare stakeholders have been concerned about the increasing cost of prescription drugs in the United States. The GDR is a standard metric used by pharmacy benefit providers to evaluate performance. Higher GDRs are associated with lower prescription drug costs. The purpose of this study is to determine the impact of using an automated alert in an outpatient setting as a tool to increase the GDR within an ACO.

Methods: This research is in progress and will be submitted to the Institutional Review Board for review. A prospective interventional design will be used. The study will be conducted within an ACO. During order signing, the prescriber will be presented with a custom visual alert displaying a recommendation to substitute the prescribed brand product with a generic therapeutic equivalent. The prescriber will have the option to accept this substitution or override it. A reason has to be selected if the alert is overridden. Based on a six months retrospective review of prescribing trends, a collaborative team elected to apply this alert to Crestor (rosuvastatin). The alert will recommend substituting Crestor with an equivalent dose of generic atorvastatin. GDR and total cost reduction will be the primary and secondary endpoints respectively. The endpoints will be collected for a duration of six months pre and post alert implementation and differences will be statistically analyzed. Descriptive analysis will be used to quantify prescriber alert override rates and associated reasons. All data will be recorded without patient identifiers and maintained confidentially.

Poster Title: Evaluation of meropenem, piperacillin/tazobactam, and ceftriaxone prescribing patterns in the pediatric setting of a large, tertiary care, teaching hospital

Primary Author: Alex Fechtmeyer, Broward Health Medical Center, FL; Email: afechtmeyer@browardhealth.org

Additional Author(s):
Jenny Martinez

Purpose: Antimicrobial stewardship programs have been implemented at hospitals across the country and have shown benefit in preventing antibiotic resistance, reducing costs, and reducing multi-drug resistant bacteria. 48 hour antibiotic timeouts have been utilized to ensure clinicians reevaluate the patient’s therapy and optimize treatment. Piperacillin/tazobactam, meropenem, and ceftriaxone are common broad-spectrum antibiotics used for empiric treatment and are ideal candidates for intervention. The aim of this study is to examine the prescribing patterns of piperacillin/tazobactam, meropenem, and ceftriaxone in the pediatric setting and determine if antibiotic therapy was optimized after 48 hours of empiric antibiotic therapy.

Methods: By utilizing a retrospective chart review for these medications we will be able to determine areas of improvement concerning antibiotic utilization. This will be accomplished by examining data using discern analytics and MedMined which extract data from the hospital’s computerized physician order entry system. The study will implement the following inclusion criteria: age between 3 months and 18 years, patient administered at least 3 doses of ceftriaxone, meropenem, or piperacillin/tazobactam, and was admitted to the hospital. Exclusion criteria include adult patients greater than 18 years of age and patients on prophylactic antibiotics. Patient charts will be selected from 10/1/2015 to 10/1/2016. Data collected from the patient chart will include labs, clinical status, microbiology cultures, and diagnosis. The chart review will examine appropriateness of therapy, duration, route, renal dosing, de-escalation, duplication of therapy, and dose optimization at the 48-hour timeout.

Poster Title: Evaluation of clinical pharmacist interventions in hospitalized human immunodeficiency virus-infected patients in an academic institution

Primary Author: Esther Garcia, Broward Health Medical Center, FL; Email: elgarcia@browardhealth.org

Additional Author (s):
Grace Heyaime
Jenny Martinez

Purpose: Patients with human immunodeficiency virus (HIV) transitioning to an inpatient setting are at a higher risk for medication errors because of the complexity of antiretroviral therapy (ARV) and a lack of clinicians with specialized training in HIV. A pharmacist-led HIV stewardship program in a hospital setting can improve patient outcomes and prevent medication errors. Broward Health Medical Center (BHMC) has a historically high HIV patient population, allowing pharmacists the opportunity to have an impact on these patients’ ARV regimens. The purpose of this study is to evaluate clinical interventions made by pharmacists to optimize ARV regimens in a hospital setting.

Methods: Adult patients, 18 years and older, with an HIV diagnosis admitted to our 714 bed facility, whose ARV regimens are continued during their inpatient stay, will be assessed on a daily basis by the clinical pharmacist per the standard of care at our institution. Additional patients included in this study will be those on ARV regimens for pre or post exposure prophylaxis. Patients on ARV medications solely for the treatment of Hepatitis B infection without an HIV diagnosis will be excluded. The pharmacist will monitor laboratory values and assess ARV regimens for completeness, appropriate administration, adequate opportunistic infection (OI) prophylaxis, drug-drug interactions, renal/hepatic dose adjustment, and contraindications. The pharmacist will intervene in the treatment of these patients whenever necessary in the same manner that pharmacists currently intervene in the care of these patients at our facility. Pharmacist interventions, as well as descriptive patient demographics such as age, gender, concomitant medical conditions (cardiovascular disease, cognitive dysfunction, thyroid dysfunction, renal/hepatic dysfunction, malignancies) and the reason for
admission will be recorded. The length of data collection period will be approximately 4 months.

Poster Title: Hypoglycemic events: A retrospective analysis of the risk factors and insulin regimens in hospitalized patients

Primary Author: Samantha Vickers, Broward Health Medical Center, FL; Email: svickers@browardhealth.org

Additional Author (s):
Luis Alfonso
Jenny Martinez

Purpose: Hypoglycemia is a major cause of morbidity and mortality in the hospital setting. Adequate glycemic control is important in order to improve patient outcomes and decrease complications and infections. Despite being highly discouraged, the use of sliding scale insulin alone to treat diabetic patients while in the inpatient setting is still employed in many hospitals. This practice has been associated with numerous hypoglycemic events, many of which could be prevented by the implementation of basal bolus insulin protocols. The purpose of this study is to evaluate incidences of hypoglycemia in hospitalized patients and related risk factors.

Methods: This is a retrospective study using the electronic medical record to identify patients who experienced a hypoglycemic event while receiving insulin therapy during their inpatient stay at Broward Health Medical Center. The patients must have received inpatient treatment at Broward Health Medical Center between February and July 2016, age 18 to 100, received an insulin regimen, and had blood glucose levels less than 50 mg/dL to be included in this study. The main variables collected will include age, sex, weight, height, inpatient unit, insulin regimen, timing of insulin administration, any oral diabetic medications, medications that can contribute to hypoglycemia or hyperglycemia, diagnosis, co-morbidities, renal function, type of diabetes, most recent A1C, number of hypoglycemic events, diabetic home medications, nutrition status, length of stay, and any surgeries within the past 72 hours. All data will be deidentified and be maintained confidentially. The primary study aim is to determine the appropriateness of their insulin regimen and to identify risk factors for these hypoglycemic events. A secondary aim is to examine if the number of hypoglycemic events increases the length of stay. Descriptive and inferential statistics will be conducted as necessary to meet the needs of the data.

Poster Title: Performance of a hospital vancomycin dosing and monitoring protocol

Primary Author: William Coyne, Broward Health Medical Center, FL; Email: wcoyne@browardhealth.org

Additional Author(s):
Jenny Martinez
Quyen Trinh

Purpose: Dosing and monitoring of intravenous vancomycin at Broward Health Medical Center is carried out using a protocol with predefined frequency adjustments based on renal function. The objective of this study is to determine the performance of this protocol with regard to accuracy in achieving therapeutic serum concentrations of vancomycin in non-dialysis adult patients.

Methods: The institutional review board at Broward Health Medical Center approved this retrospective observational study. Patients were identified using electronic medical records. Men and women from a single non-critical care nursing unit aged 18-100 years were included if they received intravenous vancomycin and had an available baseline creatinine and albumin level. Dialysis patients and those with less than 2 trough serum vancomycin levels were excluded. The following data was collected: age, sex, height, weight, admission and discharge date, indication, dose received, duration of treatment, serum trough concentrations, baseline creatinine and albumin, and culture information. All data was recorded without patient identifiers and stored securely. Actual serum concentrations of vancomycin will be compared to targeted goals. Patient factors such as weight, age, sex, renal function, and albumin level will be analyzed for correlation with dosing accuracy.

Poster Title: Four-factor prothrombin complex concentrate use in patients not receiving warfarin anticoagulation

Primary Author: Samantha Henningfield, Florida Hospital Altamonte, FL; Email: samantha.henningfield@flhosp.org

Additional Author(s):
Anna Shields
Lyndi McVey

Purpose: Four-factor prothrombin complex concentrate (Kcentra) is a coagulation factor replacement product indicated for the urgent reversal of acquired coagulation factor deficiency induced by warfarin. Kcentra has not been approved by the FDA for the reversal of non-warfarin anticoagulation; however, in life-threatening bleeds secondary to non-warfarin anticoagulation, Kcentra can be considered. A recent study also found Kcentra to have benefit in liver disease coagulopathy, but questions on dosing, safety and efficacy of the drug remain. An evaluation of the use of Kcentra was performed to assess appropriate utilization of this high-cost medication.

Methods: A retrospective chart review was performed to assess the use of Kcentra from November 30, 2015 to June 30, 2016. A report was generated to identify 100 patients for whom 125 doses of Kcentra were ordered for non-warfarin reversal indications within the Florida Hospital system. Upon approval of criteria by the Drug Utilization Review Committee, patient data was reviewed to evaluate the prescribing, dosing, dispensing, administration, and safety of Kcentra. The collected information included: patient demographics, indication, prescriber specialty, adherence to mandatory order entry form, dosing, administration, presence of contraindications, order to administration timeframe, occurrence of adverse events, and 28-day survival or hospital discharge.

Results: Kcentra was prescribed for the reversal of major or life-threatening bleeds associated with apixaban or rivaroxaban in 10% of cases and for non-warfarin reversal for the purpose of urgent surgery or invasive procedure in 4% of cases. The remaining 86% of cases involved reversal of hemorrhage not associated with anticoagulant medication, such as hemorrhage
related to surgery or hepatic dysfunction coagulopathy. Ordering physician specialties were surgery (74%), critical care (20%), emergency medicine (4%), and cardiology (2%). Time between Kcentra order entry and drug administration was collected to ascertain the level of emergency. Sixty-two percent of doses were administered within 30 minutes of order entry, 20% between 31 and 60 minutes, 13% between 61 and 120 minutes, and 5% at greater than 120 minutes. Repeat dosing of Kcentra is not indicated per package insert or available literature and 18% of patients received multiple doses per bleeding episode. Contraindications to Kcentra, namely heparin-induced thrombocytopenia and disseminated intravascular coagulation, were recorded in 7% of patients prior to drug administration. Deep vein thrombotic events occurred in 4% of patients after administration. Sixty-nine percent of patients achieved 28-day survival or hospital discharge.

**Conclusion:** Based on the results of this medication use evaluation, there is a high utilization of four-factor prothrombin complex concentrate for unapproved indications in the surgical setting and in patients not receiving anticoagulation. There is significant variability in prescribing that deviates from the recommended clinical practice concerning usage in non-emergent situations and administration of multiple Kcentra doses per bleeding episode. Opportunity exists to improve the appropriate utilization of Kcentra.

**Submission Category:** Drug-Use Evaluation/ Drug Information  

**Submission Type:** Research-in-Progress  

**Session-Board Number:** 9-090  

**Poster Title:** Medication use evaluation: Enoxaparin dosing in patients less than 50 kilograms  

**Primary Author:** José Leon-Burgos, Florida Hospital Celebration Health, FL; **Email:** atinuke.omolara@flhosp.org  

**Additional Author(s):**  
Atinuke Omolara  
Elizabeth Clements  
Lindsay Celauro  

**Purpose:** Low molecular weight heparin (LMWH) products, such as enoxaparin, are commonly used in the inpatient setting for prevention and treatment of venous thromboembolic events (VTE). Enoxaparin has a favorable pharmacokinetic profile; however, there is not enough information regarding the safety and efficacy of LMWH in extreme weights. The purpose of this medication use evaluation is to understand the safety and efficacy of enoxaparin in patients less than 50 kilograms receiving prophylactic or treatment doses for VTEs.  

**Methods:** This study was reviewed and approved by the Scientific Review Committee of the Florida Hospital (FH) Clinical Excellence and Research Department. A retrospective chart review will be performed to assess the use of enoxaparin in adults weighing less than 50 kilograms from January 1, 2016 through July 1, 2016. A clinical report with the eligible patients has been generated to include adults aged 18-99 years who are less than 50 kilograms and have received at least one dose of enoxaparin in the inpatient setting at one of the seven FH campuses. The following information will be collected: dose, indication, number of doses received, labs on admission (hemoglobin, hematocrit, platelets, serum creatinine), height, and weight. Anti-Xa levels will be collected if available. To monitor for adverse effects, platelets less than 100,000 units/ul, hemoglobin drop of greater than 2 g/dL, and creatinine clearance of less than 30 ml/min will be recorded. Provider documentation, including imaging studies, will be reviewed to determine whether a VTE episode occurred during hospital stay as well as mortality. A random number generator will be used to select 100 patient charts from the initial sample population. The data will be evaluated and the descriptive analysis performed will be presented to the FH Medication Use Evaluation Committee.

**Poster Title:** Medication use evaluation of rosuvastatin renal dose adjustment in patients with creatinine clearance less than 30 milliliters per minute not on hemodialysis

**Primary Author:** Ke'la Barnes, Florida Hospital Celebration Health, FL; **Email:** kaybarnes90@gmail.com

**Additional Author (s):**
Stephanie Cox
Julia Nickerson-Troy

**Purpose:** Statins are widely prescribed medications and commonly encountered in the hospital setting. While all statins do not require renal dose adjustment, the recommended maximum daily dose of rosuvastatin is 10 mg for creatinine clearances less than 30 milliliters per minute not on hemodialysis. As part of the hospital’s formulary, rosuvastatin is the therapeutic interchange for atorvastatin and simvastatin, which do not require renal dose adjustment. The objective of this study is to examine the use of the appropriate renal dose adjustment of rosuvastatin in patients with creatinine clearances less than 30 milliliters per minute during hospital stay and at discharge.

**Methods:** This retrospective analysis was approved by the hospital’s clinical excellence research group. The electronic medical record will be used to generate a de-identified report of all patients with at least one dose of rosuvastatin ordered during the month of June 2016. The total number of doses ordered at all seven campuses will be calculated to determine the total study population, which will then be used to determine the population size and percentage ordered at each campus. One hundred patients will be randomly selected from the total study population proportional to the campus percentage ordered. Patients will be included if a dose of rosuvastatin was received and had a creatinine clearance less than 30 milliliters per minute. Patients receiving hemodialysis during their stay will be excluded. The following data will be collected: dose of rosuvastatin administered, number of doses received, presence of therapeutic interchange, and statin name and dose prescribed at discharge. All available patients’ creatinine clearances throughout hospitalization will be assessed to determine if the correct dose was administered based on creatinine clearance. The Modification of Diet in Renal Disease and Cockcroft-Gault equations will be utilized to determine renal function.

**Poster Title:** Medication use evaluation of esmolol in septic shock

**Primary Author:** Amy Talana, Florida Hospital East Orlando, FL; Email: amy.talana@flhosp.org

**Additional Author(s):**
Jinjoo Lee
Joseph Trang

**Purpose:** Several studies have supported beneficial effects from esmolol in septic shock patients with tachycardia. Benefits included increases in stroke volume and perfusion to vital organs as well as decreases in mortality and fluid and vasopressor requirements. The objective of this study is to evaluate how esmolol is being used in septic shock patients and to identify opportunities for improvement in its medication use process.

**Methods:** As a quality improvement project, this study met criteria for Institutional Review Board exemption and was approved by the Drug Utilization Review Committee. Patients on esmolol between June 30, 2014 and June 30, 2016 will be identified via an electronic medical record report. Septic shock patients that received esmolol for at least 4 hours in the intensive care unit (ICU) will be reviewed for the following: hospital and ICU length of stay, duration of esmolol and vasopressors, vasopressor requirements, percentage of time within the order-specified heart rate goal and within the literature-supported heart rate goal of 80 to 94 beats per minute, adverse effects, use in contraindicated patients, and mortality. In addition, dosing strategies, use of hold parameters, and demographic data will be collected. Appropriateness of esmolol therapy duration and nurse-driven titration will be evaluated.

**Results:** N/A

**Conclusion:** N/A
Poster Title: Epoetin sliding scale and dose rounding: Determination of best practice deviations

Primary Author: Chelsea Rohrer, Florida Hospital East Orlando, FL; Email: chelsea.rohrer@flhosp.org

Additional Author(s):
Michael Geisel
Kelly Rafferty
Laura Mbionwu

Purpose: At Florida Hospital, epoetin is sometimes prescribed on a sliding scale based on hemoglobin levels to target patient-specific doses. There is no recommended dosing strategy for efficacy or reduction of risks associated with epoetin alfa. Manufacturers suggest using the lowest possible weight-based dose of 50-100 units/kg to prevent or reduce blood transfusions and maintaining that dose for at least four weeks before making therapeutic adjustments in 25% increments, unless to reduce the dose for side effects(1,2). The purpose of this medication use evaluation is to determine clinical and financial impacts of prescribing epoetin sliding scale.

Methods: Retrospective chart review of 100 adult inpatients receiving epoetin sliding scale regimen for renal dysfunction was performed. Data was collected for patient demographics, past medical history, indication, administration comments, doses received, dialysis schedule, laboratory information, occurrence of side effects, and concomitant medications. The epoetin sliding scale doses received and their associated costs were compared with that of the recommended weight-based dose for each patient. Incidence of side effects, proper indication, contraindications, and abnormal laboratory values were analyzed.

Results: Of 100 patients prescribed epoetin sliding scale, 66 patients received a total of 159 doses. Orders included sliding scale doses as low as 4,000 units and as high as 60,000 units. The average sliding scale dose was 229.4 units/kg. Doses were adjusted an average of 2.3 times over an average of 5.5 days. 49% of orders were continued until discharge even if patient no longer required subsequent doses. The average hemoglobin level on the day a dose was received was 8.72 g/dL; hemoglobin was above 11 g/dL within 24 hours of a dose in ten patients. Twenty-one patients with coronary artery disease and 22 patients with congestive
heart failure received doses. Eight patients received IV iron, three patients received PO iron and 20 patients required blood transfusions. The average cost of a sliding scale dose was $219.59 compared to the average weight-based dose cost of $84.99. Prescribing a weight-based dose could have potentially saved $324.26 per patient in drug cost alone.

**Conclusion:** There is no evidence to support or refute the use of epoetin sliding scale. However, the variability in prescribing patterns, potential for increased risk of side effects due to elevated doses, and potential for cost savings with weight-based dosing regimens suggests that there is little utility for epoetin sliding scale regimens.

Poster Title: Evaluation of erythropoietin stimulating agents on hemoglobin level in critically ill patients with acute kidney injury

Primary Author: Heather Johnson, Florida Hospital Orlando, FL; Email: heather.johnson@flhosp.org

Additional Author (s):
Otsanya Ochogbu

Purpose: Epoetin alfa (EPO) was selected for a medication use evaluation in the intensive care setting due to routine observation of use of EPO for treating anemia due to acute kidney injury (AKI) in critically ill patients. This is an unapproved indication with current literature unable to support use in this patient population. As there are substantial costs and adverse effects associated with use of EPO, it is prudent to retrospectively evaluate the use of EPO for treatment of anemia in the critically ill patient with AKI to establish a risk-benefit profile.

Methods: This is a retrospective chart-review conducted across intensive care units (ICU) within a multihospital system. Adult patients admitted to ICUs from 6/30/2013 to 6/30/2016 who received a dose of EPO with a concurrent diagnosis of acute kidney injury defined by AKIN criteria were included. Patient charts were reviewed for exclusion criteria including chronic kidney disease or unwillingness to receive blood products. Baseline demographics and the following endpoints will be collected; hospital/ICU length of stay, pertinent past medical history including: hypertension, venous thromboembolism, seizure, cancer, and myelodysplastic syndrome, dose of EPO, serum creatinine and urine output, renal replacement therapy initiation, hemoglobin levels, transfusion requirements, iron studies and iron repletion therapy. The primary outcome is to determine the impact of EPO on hemoglobin levels in patients with AKI. Secondary outcomes include determining influence on transfusion requirements and incidence of adverse events, while establishing the frequency of EPO use in this population.

**Poster Title:** Medication use evaluation of ceftazidime/avibactam and ceftolozane/tazobactam use in a large community hospital system

**Primary Author:** Carlos Jimenez, Florida Hospital Orlando, FL; **Email:** carlos.jimenez2@flhosp.org

**Additional Author (s):**
Lauren Hunt

**Purpose:** Ceftazidime/avibactam (C/A) and ceftolozane/tazobactam (C/T) are both non-formulary antimicrobial agents that are newly approved for the treatment of multi-drug resistant gram negative infections. The use of C/A and C/T was broadly evaluated with the primary objective of assessing utilization. Secondary objectives include appropriate dosing, adverse events, cost analysis, and potential for future clinical pharmacy interventions including infectious diseases consults. Based on the findings and supportive evidence, the intent of this medication use evaluation will be to create criteria for use.

**Methods:** This quality improvement project has been determined by our organization to be exempt from Florida Hospital IRB approval criteria as it is non-human subject research and follows our organization’s patient safety work product guidelines. A retrospective chart review was performed on all patients greater than 18 years old who received C/A or C/T between 09/01/2015 and 08/31/2016 while admitted within the Central Florida Hospital System. Data collected from the electronic medical record include: patient demographics (gender, weight, length of stay, admission to ICU, mechanical ventilation usage, readmission, history of cystic fibrosis), renal function, usage of C/A or C/T, duration of therapy, dosing interval, indication, use of extended-infusion administration, broad spectrum antibiotic use 90 days prior to admission, number of doses given, duration of therapy, microbiological data (including MIC data for C/A and C/T), placement of infectious disease consult, and prescriber information.

**Results:** Data collection has begun and results will be presented at the Midyear clinical meeting.

**Conclusion:** Research in progress.

Poster Title: Evaluation of pharmacy-directed vancomycin dosing per institution guideline in a large community hospital

Primary Author: Meghan Bloxam, Florida Hospital Orlando, FL; Email: meghan.bloxam@flhosp.org

Additional Author (s):
Natasa Occhialini
Nicholas Edmonds

Purpose: Vancomycin is a highly utilized antimicrobial agent in internal medicine patients. This agent requires dosing within a narrow therapeutic index to achieve clinical effectiveness and avoid adverse effects. Patient-specific variables affect the dosing regimen required to achieve therapeutic concentrations. Our institution guideline uses actual body weight and renal function to determine initial dosing recommendations, however other population-based kinetic calculations may be useful for effective dosing strategies. The frequency in which therapeutic vancomycin concentrations were achieved through use of the pharmacist-directed dosing guideline was undetermined. The purpose of this study was to evaluate pharmacist-directed dosing of vancomycin per institution guideline.

Methods: This quality improvement project was determined by our organization to be exempt from IRB approval criteria as it was non-human subject research and followed our organization’s patient safety work product guidelines. The primary outcome was the frequency in which therapeutic vancomycin concentrations were achieved through compliance with pharmacist-directed dosing standards set by the institution guideline. A retrospective chart review was conducted over a period of 3 months for eligible patients who received pharmacy-directed vancomycin dosing per institution guideline. Eligible patients included those over the age of 18 years old who were admitted to an internal medicine unit within our institution, received at least 4 doses of vancomycin, and had at least one measured vancomycin concentration. The study population was narrowed to include approximately 100 eligible patients. The hospital electronic medical record was used to identify and randomize eligible patients and for all data collection.

**Poster Title:** Evaluation of venous thromboembolism prophylaxis in orthopedic patients within a large community hospital system

**Primary Author:** Tina Wang, Florida Hospital Orlando, FL; **Email:** tina.wang@flhosp.org

**Additional Author (s):**
Larry Diamond
Michelle Thomas

**Purpose:** Orthopedic surgery is considered a high risk factor for VTE. A medication use evaluation was completed in order to assess for appropriate use of VTE prophylaxis agents, such as enoxaparin, heparin, fondaparinux, and rivaroxaban, in orthopedic patients undergoing either hip arthroplasty (THA) or total knee arthroplasty (TKA). The primary objective was to assess for appropriateness of utilization including dosing and duration. The secondary objective included readmission rates and complications related to VTE prophylaxis, such as VTE or bleeding. The potential for future direction is to create a protocol for VTE prophylaxis in our orthopedic patients.

**Methods:** This quality improvement project has been determined by our organization to be exempt from FH IRB approval criteria as it is non-human subject research and follows our organization’s patient safety work product guidelines. A retrospective chart review will be conducted for approximately 100 eligible patients who received VTE prophylaxis with any of the following: enoxaparin, heparin, fondaparinux, and rivaroxaban between 09/01/2015 and 09/01/2016. Data collected from the electronic medical record include, but not limited to: patient demographics, medication, dose, timing of initiation, duration of therapy, directions, type of surgery, renal function, and complete blood count.

**Results:** Data collection has began and results will be presented as ASHP Midyear Clinical Meeting 2016.

**Poster Title:** Implementation of a relative value unit system to predict pharmacy technician workload

**Primary Author:** Fernando Blanco, Florida Hospital Orlando, FL; **Email:** fernando.blanco@flhosp.org

**Additional Author (s):**
Craig MacDonald
Jonathan Girnys
Melissa Hupfer

**Purpose:** The healthcare landscape continues to remain in flux as it transitions from a fee-for-service to a value-based reimbursement model. Pharmacy departments face mounting financial pressures to reduce their cost structures and are tasked with determining the appropriateness of allocated departmental staffing resources. A relative value unit (RVU) system can be applied by hospital pharmacy departments to better determine the allocation of resources and improve efficiency. The purpose of this study was to create and implement a relative value unit system to capture pharmacy technician workload in order to guide staffing decisions by hospital pharmacy departments.

**Methods:** This is a single center quality improvement initiative evaluating pharmacy technician workload between October 2016 and February 2017. Time-motion studies will be used to create the RVU system by analyzing the time spent in seconds per activity and standardizing to the lowest common value. The mean time necessary to perform a task will be used for each activity by means of twenty direct observations, determining the average time required to complete the task, and establishing a standard deviation to the mean measurement. Once standardized, the numeric value assigned to each activity is known as an RVU. Workload is determined by multiplying the RVU by the volume, or frequency, for the particular activity. The mean frequency of reported tasks will be identified for each activity through use of available reports. The outcome is the average number of RVU’s per hour worked by a productive technician. A correlation analysis will be used with the goal of identifying a relationship between RVU’s and the hospital’s volume metrics (e.g. census, projected admissions) as well as
workload metrics (e.g. doses dispensed, orders verified, doses charged) to allow the department to objectively and consistently adjust staffing levels based on expected workload.

Poster Title: Evaluation of venous thromboembolism (VTE) prophylaxis in patients with chronic liver disease at a large community medical center

Primary Author: Jill Mendoza, Florida Hospital Orlando, FL; Email: jill.mendoza@flhosp.org

Additional Author(s):
Larry Diamond

Purpose: Chronic liver disease patients often have coagulopathies resulting in elevated INR, thrombocytopenia, and anemia, routinely excluding these patients from receiving chemical venous thromboembolism (VTE) prophylaxis. Studies showed that patients with rate of coagulopathies are not protected against VTE. A medication use evaluation was completed to assess current use of heparin, enoxaparin and fondaparinux in chronic liver patients. The primary objective was to assess the rate of chemical VTE prophylaxis. Secondary objectives included bleeding events, coagulopathies, and readmission. The potential for future direction is to identify VTE prophylaxis at our institution and modify the screening process for these patients.

Methods: This quality improvement project has been determined by our organization to be exempt from Florida Hospital Institutional Review Board approval criteria as it is non-human subject research and follows our organization’s patient safety work practice guidelines. A retrospective chart review was conducted for eligible patients with chronic liver disease from September 1st, 2015 to September 1st, 2016, and have received VTE prophylaxis with any of the following agents: heparin, enoxaparin and fondaparinux. Patients were identified based on their diagnosis-related group code on admission. Data collected from electronic medical records included, but was not limited to: patient demographics, anticoagulant use (if any), dose, duration of therapy, readmission rates, complete blood count, values to assess renal function, and requirement of blood transfusion(s).

Results: Data collection has begun, results will be presented at the 2016 ASHP Midyear Clinical Meeting

Conclusion: N/A

Poster Title: Evaluation of tolvaptan use in heart failure patients in a large community hospital

Primary Author: Sienna Smith, Florida Hospital Orlando, FL; Email: sienna.smith@flhospital.org

Additional Author(s):
Ruti Dwivedi
Danielle Honein
Kristie Zappas
Melissa Royero

Purpose: Patients presenting to the hospital with heart failure exacerbation are often fluid overloaded. Due to hypervolemia, they can have severe hyponatremia and are at risk for having active cognitive symptoms. Tolvaptan, a vasopressin antagonist, may be considered to improve sodium concentration due to its mechanism of excretion of free water. The primary objective of this study is to evaluate for appropriateness of utilization of tolvaptan according to our institution’s order set. Secondary objectives will include rate of sodium correction, instances of subsequent hypernatremia, and subsequent diagnoses of osmotic demyelination syndrome.

Methods: This quality improvement project has been determined by our organization to be exempt from FH IRB approval criteria as it is non-human subject research and follows our organization’s patient safety work product guidelines. A retrospective chart review will be conducted for eligible patients who received tolvaptan between 09/30/2015 to 09/30/2016. Eligible patients include those over the age of 18 years old admitted to Florida Hospital Orlando with a heart failure diagnosis. Data collected from electronic medical record includes: patient demographics, prescriber specialty, dose, frequency, duration of therapy, number of doses administered, utilization of required tolvaptan order set, patient-met criteria of tolvaptan order set, contraindications to tolvaptan, sodium levels before tolvaptan administration, sodium levels at subsequent six, twelve, and twenty-four hour intervals after tolvaptan administration, subsequent diagnoses of osmotic demyelination syndrome, and any interventions for sodium overcorrection or rapid correction.

Results: Results of this study are pending data collection.
Conclusion: Conclusions of this study are pending data collection.

**Poster Title:** Medication use evaluation of ertapenem in the surgical patient population of a large community hospital

**Primary Author:** Ravi Bacchus, Florida Hospital Orlando, FL; **Email:** ravibacchus22@gmail.com

**Additional Author(s):**

**Purpose:** Ertapenem is a carbapenem antibiotic indicated for prophylaxis of the surgical site following colorectal surgery and is used off-label to treat other surgical site infections. Per the Clinical practice guidelines for antimicrobial prophylaxis in surgery, ertapenem is a recommended antibiotic in colorectal surgery prophylaxis and is also included in the IDSA SSTI Guidelines. Within our institution, prescribing of ertapenem is restricted to infectious diseases specialists and colorectal surgeons. A medication use evaluation was completed to assess for utilization of ertapenem in the surgical patient population including perioperative use. The primary objective assessed appropriateness of utilization including indications and directions.

**Methods:** This quality improvement project has been determined by our organization to be exempt from FH IRB approval criteria as it is non-human subject research and follows our organization’s patient safety work product guidelines. A retrospective chart review was conducted for eligible patients who received ertapenem between August 1, 2016 and September 30, 2016. Eligible patients included those over the age of 18 years old within our hospital. A randomly generated list narrowed the study population to approximately 100 of all eligible patients. Data collected from electronic medical record included: patient demographics, prescriber specialty, surgical site infections, length of stay, hospital readmissions, dose, directions, indication, days of therapy on ertapenem, total days on antibiotics, previous inpatient antibiotics within the same admission, admission/discharge dates, date medication initiated/discontinued, number of doses administered, risk factors for multidrug-resistant organisms, antibiotic use in transitions of care, antibiotic single-use doses, and perioperative antibiotic doses.

**Results:** Results of the study are pending data collection.

**Conclusion:** Conclusions of the study are pending data collection.

**Poster Title:** Medication use evaluation of phytonadione for coagulopathy reversal in patients with liver disease

**Primary Author:** Michele Wiltse, Florida Hospital Orlando, FL; **Email:** mwiltse180@gmail.com

**Additional Author(s):**
Philip Morrison

**Purpose:** Patients with liver disease frequently present with significant coagulopathies including an elevated PT/INR. Practitioners seek to reverse elevated PT/INR in anticipation of invasive procedures with the use of phytonadione. However, controversy exists over the effectiveness of phytonadione in this patient population. A medication use evaluation was completed to assess for appropriate use within our hospital system. The primary objective was to characterize the degree of reversal (PT/INR) of phytonadione administration in liver disease patients. The secondary objectives included delay in procedure due to insufficient PT/INR reversal, degree of reversal with concomitant use of reversal agents, and occurrence of adverse effects.

**Methods:** This quality improvement project has been determined by our organization to be exempt from FH IRB approval criteria as it is non-human subject research and follows our organization’s patient safety work product guidelines. A retrospective chart review was conducted for eligible patients who received phytonadione within the past year. Eligible patients included those over the age of 18 years old within our hospital system. A randomly generated list narrowed the study population of all eligible patients to identify 100 unique patients for analysis. Data collected from electronic medical records included: patient demographics, prescriber information, admission/discharge dates, procedure type, type of liver disease (MELD-Na and/or Child Pugh Score), date/time medication initiated, date/time of procedure, dose /route (oral, SC, IV)/number of doses administered, use of concomitant reversal agents (FFP/PCC/platelets/desmopressin), PT/INR (baseline and after administration), adverse effects (infusion reactions, bleeding and/or clotting), length of stay, readmissions, cost, and concurrent use of other medications that may affect PT/INR (antibiotics, etc).

**Results:** Results are pending as this is research in progress
Conclusion: N/A
Submission Category: Drug-Use Evaluation/ Drug Information

Poster Title: Medication use evaluation of nebulized budesonide and formoterol in medical intensive care unit patients in a large community hospital

Primary Author: Weishi Wang, Florida Hospital Orlando, FL; Email: weishi.wang@flhosp.org

Additional Author(s):
Deron Baker
Kristie Zappas

Purpose: Budesonide, an inhaled corticosteroid, and formoterol, a long acting beta agonist, are both indicated for asthma and COPD. These medications have to be administered by certified respiratory therapist (CRT) in the intensive care unit (ICU). The primary objective of this retrospective analysis is to assess the utilization of nebulized budesonide and formoterol in medical ICU patients based on labeled indications and previous outpatient use. The secondary objective is to assess financial impact of these medications on patients who did not meet criteria for use including CRT time spent for administration and costs of the medications.

Methods: This quality improvement project has been determined by our organization to be exempt from International Review Board (IRB) approval criteria as it is non-human subject research and follows our organization's patient safety work product guidelines. A retrospective chart review will be conducted for approximately 100 eligible patients who received nebulized budesonide and formoterol during their inpatient hospital stay. Eligible patients include those over the age of 18 years old and admitted into the medical ICU. Data collected from electronic medical records include: patient demographics, dispensing areas, prescriber information, dose, indications, directions, previous home inhalers, therapeutic interchange information, admission/discharge dates, date medication initiated/discontinued, type of dispense, number of doses administered, inpatient transfer information, and concomitant use of inhalers. The percentage of the patients who met the dispensing criteria will be calculated and analyzed.

Results: Pending data collection.

Conclusion: N/A due to pending data collection.
**Submission Category:** Quality Assurance/ Medication Safety  

**Submission Type:** Evaluative Study  

**Session-Board Number:** 9-104  

**Poster Title:** Fentanyl Transdermal Patch Utilization in Post-Cardiac Surgery  

**Primary Author:** Rebekka Adamson, Florida Hospital Orlando, FL; **Email:** rebekkaadamson@gmail.com  

**Additional Author(s):**  

**Purpose:** Though utilization of the fentanyl transdermal system is contraindicated for the management of postoperative pain, utilization remains common among postoperative cardiothoracic surgery patients at our institution. The goal of this study is to evaluate the utilization, safety, and effectiveness, of the fentanyl transdermal system in this patient population.  

**Methods:** This medication-use evaluation will be submitted for approval by the Institutional Review Board. Postoperative cardiothoracic surgery patients will be included in the analysis if a fentanyl transdermal patch was applied during their postoperative hospital stay. The electronic medical record will be utilized to perform the retrospective chart review and gather all relevant data. Patient demographics, including whether the patient was opiate-naïve at admission, surgical procedure performed, and history of drug abuse or misuse will be collected. All medication order characteristics, including order duration (number of patch applications), and dose ordered will be recorded. Efficacy will be assessed via pain scores, including maximum pain score recorded in the first 24 hours after patch application, and whether the patients’ pain score goals were met in the first 12 and 24 hours. Additional orders for pain medications (including NSAIDs, short-acting opioids, muscle relaxers) while receiving a fentanyl patch will be investigated, as well as the use of any “as-needed” pain medications while a fentanyl patch is applied. Safety will be assessed by investigating the following events: use of naloxone, new constipation medication orders after patch application, falls, altered mental status or reintubation, and incidence of respiratory depression. Additional information will be gathered on whether a patient receives a fentanyl patch within 24 hours of discharge or receives a prescription for a fentanyl patch at time of discharge.

**Poster Title:** Evaluation of belatacept use in renal transplant patients transitioned from calcineurin inhibitors in a large community medical center

**Primary Author:** Jennifer Elfman, Florida Hospital Orlando, FL; **Email:** jennifer.elfman1@gmail.com

**Additional Author (s):**
Lauren Lasater

**Purpose:** Belatacept is a fusion protein composed of the Fc fragment of the human IgG1 immunoglobulin, a molecule crucial in the activation of T-cells through the co-stimulation, therefore blocking T cell activation. Current standard of care regimens include calcineurin inhibitors (CNIs) which can lead to nephrotoxicity and deterioration of kidney function. Belatacept is an option for non-CNI based immunosuppressant regimens. The purpose of this study was to evaluate indications and dosing regimens in kidney transplant patients transitioned from CNI based therapies to belatacept. Future direction for this research is to create a protocol for use.

**Methods:** This quality improvement project has been determined by our organization to be exempt from IRB approval criteria as it is non-human subject research and follows our organization’s patient safety work product guidelines. In this retrospective single center study, data was gathered on all patients identified via discern analytics who received belatacept between September 2013 and September 2016. The data collected from electronic chart review included: patient demographics, weight, epstein barr virus status, renal biopsy results, dosage, frequency, baseline and post transition serum creatinine trends, acute rejection, graft loss, adverse side effects, and death.

**Results:** N/A

**Conclusion:** N/A

**Poster Title:** Medication evaluation of antimicrobial use for kidney and urinary tract infections diagnosed throughout a large community hospital system  

**Primary Author:** Xavier Torres, Florida Hospital Orlando, FL; **Email:** torres.xavier9@gmail.com  

**Additional Author(s):**  
James Priano  
Jennifer Elfman  

**Purpose:** Urinary tract infections (UTI) are one of the most frequently encountered infections in the community hospital setting. Assessing the antimicrobial practices may help set a focus for future clinical pharmacy interventions that will improve patient outcomes and prevent adverse effects including the development of antimicrobial resistance. Therefore, a medication use evaluation will be completed to assess for utilization of antimicrobials for the management of kidney and UTI within our hospital system.  

**Methods:** This quality improvement project has been determined to be exempt from IRB approval criteria as it is non-human subject research and follows our organization’s patient safety work product guidelines. A retrospective chart review will be conducted for eligible patients who received antimicrobials between August 1, 2016 and August 31, 2016 for the indication of kidney and urinary tract infection. Eligible patients include females over the age of 18 years old treated for this indication either at the outset or during their stay as inpatients. A randomly generated list will narrow the study population to approximately 100 eligible patients. The primary objective is to quantify the duration and selection of antibiotic treatment for this indication. assess for appropriateness of utilization including empiric and subsequent management pre- and post-culture results, respectively. Secondary outcomes assessed will include length of stay, adverse events, comparison to current guideline recommendations, and onset of Clostridium difficile during the same admission. Data collected from electronic medical records will include patient demographics, admission and discharge dates, antibiotics ordered, date medication initiated and discontinued, number of doses administered, previous antibiotic use in the previous 90 days, and microbiological data.

**Poster Title:** Cost-saving potential for bivalirudin using percutaneous coronary intervention (PCI) clinical pathway

**Primary Author:** Lauren Nienas, Florida Hospital Orlando, FL; **Email:** lauren.nienas@flhosp.org

**Additional Author(s):**

**Purpose:** Bivalirudin and unfractionated heparin (UFH) are two antithrombotic agents utilized during percutaneous coronary intervention (PCI) to prevent thrombus formation. Head-to-head trials offer conflicting data on the preferred agent in terms of ischemic and bleeding events. Contemporary trials suggest UFH to have reduced in-stent thrombosis incidence compared to bivalirudin, which may have a reduction in bleeding events. Additionally, bivalirudin comes at an increased cost compared to UFH. The study purpose is to identify patients appropriate for UFH use and estimate projected cost-savings associated with the reduced bivalirudin utilization through a PCI clinical pathway implementation.

**Methods:** This retrospective, observational study will be submitted to the Institutional Review Board for approval. The electrical medical record system will identify patients and include acute coronary syndrome (ACS) admissions who received bivalirudin during PCI. All patient identifiers will be removed to maintain confidentiality. Patients will be excluded if they have a history of heparin-induced thrombocytopenia, age greater than 75 years old, or a high risk of major bleeding (greater than 5%). Inclusion and exclusion criteria were designed based on a proposed clinical pathway to select patients who received bivalirudin but were appropriate to receive UFH. Cost-analysis will be performed to estimate the potential cost savings associated with implementing this pathway and increasing UFH in PCI. Collected data points include age, gender, weight, ACS classification, access site, stent type, concurrent anticoagulants and antiplatelet medications (aspirin, P2Y12 inhibitors, or glycoprotein IIb/IIIa inhibitors), bivalirudin infusion duration, periprocedural intra-aortic balloon pump utilization, and post-procedure hematocrit. Patients will also be assessed for 30-day readmission and post-procedure ischemia or bleeding event incidence.

**Poster Title:** Medication use evaluation of eltrombopag post hematopoietic stem cell transplantation (HSCT) in a large community hospital

**Primary Author:** Angela Boyd, Florida Hospital Orlando, FL; **Email:** angela.boyd@flhosp.org

**Additional Author (s):**
Jan Nelson
Shayna Smith

**Purpose:** Eltrombopag is a thrombopoietin receptor agonist which stimulates platelet production. An innovative use of eltrombopag has been reported in the treatment of thrombocytopenia post-hematopoietic stem cell transplantation. The prescribing practice of eltrombopag, within this specific patient population, will be identified to standardize use and improve patient care as well as add to current literature. The primary objective is platelet count greater than or equal to 50x10^9/L for 7 consecutive days without platelet transfusions. Secondary objectives include time from transplant to initiation of eltrombopag, dose modification strategy, duration of therapy, adverse events, and cost to the hospital system.

**Methods:** This quality improvement project has been determined by our organization to be exempt from FH IRB approval criteria as it is non-human subject research and follows our organization’s patient safety work product guidelines. A retrospective chart review was conducted for eligible patients who received eltrombopag between September 30, 2014 through September 30, 2016. Eligible patients include those 18 years of age or older who underwent HSCT. Due to the relatively small study population, all patients meeting eligibility were included in the analysis. Data collection from electronic medical record includes: patient demographics, platelet count, platelet transfusion date(s), date medication initiated/discontinued, dose/titration schedule, disease indication for transplant, transplant conditioning regimen, transplant type/date, liver function (ALT, AST, t.bili), and development of bone marrow fibrosis.

**Poster Title:** Development of a pharmacy service productivity tool within a community hospital  

**Primary Author:** Mary Munchalfen, Florida Hospital Orlando, FL; **Email:** mary.munchalfen@outlook.com  

**Additional Author (s):**  
Jonathan Girnys  

**Purpose:** The current economic environment challenges healthcare organizations to provide financial justification to the ever-increasing costs in healthcare. The use of a pharmacist productivity metric tool would serve to guide pharmacy leadership towards the appropriate use of pharmacist resource acquisition and allocation. The objective of this study is to design a tool used to determine a minimum set of productivity standards applicable to the delivery of pharmacy services within an organization in an effort to optimize patient care and reduce costs.  

**Methods:** A single-center, observational analysis of pharmacist workload productivity will be performed assessing pharmacist relative value units. The relative value unit method will serve as an internal benchmarking assessment. Each activity performed by a pharmacist will be assigned a relative value unit. Pharmacist relative value unit activities will range from medication order verification to a variety of clinical pharmacy interventions. Time standards including time-to-verify, time-to-complete, and time-to-response metrics of pharmacist activities performed will be collected. Time standards will be validated by an expert panel and weighted based upon medication acuity. The productivity metric tool would provide real-time data on a variety of distributive and clinical pharmacist responsibilities.  

**Results:** N/A

**Poster Title:** Medication use evaluation of pantoprazole continuous infusion

**Primary Author:** Bibidh Subedi, Florida Hospital Orlando (Orlando Campus), FL; Email: bsubedi23@ufl.edu

**Additional Author (s):**
Ramy Girgis
Eric Pyles

**Purpose:** Proton pump inhibitors (PPIs) are utilized for gastrointestinal (GI) bleeding prophylaxis in patients who have nonvariceal GI bleed. Current recommendation is to infuse PPIs for a duration of 72 hours and then transition to intermittent dosing. In practice however, PPI infusions are continued beyond 72 hours, potentially increasing the risks for adverse events. This study sought to analyze pantoprazole infusion usage in seven affiliated community teaching hospitals.

**Methods:** A retrospective analysis of 100 patients who received pantoprazole infusion was conducted in seven affiliated community teaching hospitals. The efficacy outcomes included bleeding cessation, documented re-bleeding, or death. Safety outcomes included documented clostridium difficile infection, pneumonia, or hypomagnesemia. Additional data collected were patient’s age, gender, pertinent past medical history, pertinent home medications, presenting symptoms, service ordering pantoprazole infusion, indication for usage, duration of therapy, concomitant therapy, step down therapy, ICU length of stay, and hospital length of stay.

Session-Board Number: 9-111

Poster Title: Assessing utilization of an updated smoking cessation order set in a community hospital health system

Primary Author: Stephanie Hughes, Florida Hospital-Celebration Health, FL; Email: stephanie.hughes@flhosp.org

Additional Author(s):
Elizabeth Powell
Ruthan Tattersall

Purpose: A smoking cessation order set in the electronic order entry system was recently updated. This update included providing nicotine dosing and combination regimens consistent with current guidelines. Prior to this update, an order set existed; however, it had to be actively searched for. This recent update now includes a trigger (alert) to suggest utilizing the order set when a smoker (> 10 cigarettes per day) is identified. This study may provide data to determine if the order set is being used and whether it should be changed from suggested to mandatory for identified patients who smoke.

Methods: This retrospective chart review has been approved by the hospital’s clinical excellence research group for quality assurance. A report from the electronic medical records system will be generated on patients who were identified as smokers from August 5, 2015 to August 5, 2016. The data fields for this report include financial identification number, unit/room number, attending physician, smoking documentation indicator (whether patient reported smoking at admission when health history was obtained), smoking cessation order set indicator (whether order set was used or not), and orders generated for nicotine replacement outside the order set. Nicotine replacement therapy options available on formulary include nicotine patch (14 mg and 21 mg) and nicotine gum (2 mg and 4 mg). Systematic random sampling will be used to select 150 patients for this evaluation. Patient-specific data will be secured at all times. This data will be used to assess the utilization of the order set and nicotine replacement therapy. This may help determine if the currently suggested order set trigger should become a mandatory trigger for patients who smoke. Other areas to be assessed include adverse events from nicotine therapy, prescriber trends, and if referral to an outpatient
community resource for smoking cessation is documented upon discharge. Data will be presented to the hospital system to show trends and areas for improvement.

Poster Title: Interdisciplinary population management in an integrated delivery network (IDN) targeting Medicare diabetes members and the effect on clinical outcomes and quality metrics.

Primary Author: Myla Ross, Health First Health Plans, FL; Email: myla.ross@health-first.org

Additional Author(s):
Nancy Youssef
Jason Dickey

Purpose: The Medicare Star Rating System is an important tool used by members and the healthcare industry to evaluate the quality of care provided by health plans. Health plans are awarded for 5 star ratings with increased resources and flexibility within the industry. This flexibility allows a health plan to provide high quality care and optimize system and member resources. A multimodal management of Medicare type 2 diabetics is necessary for better clinical outcomes and will have a positive impact on the Plan’s quality metrics.

Methods: Permission will be obtained from the plan’s ethics committee. We will identify our Medicare members diagnosed with type 2 diabetes. These members will benefit from a diabetic care plan that includes appropriate disease state management based on the American Diabetes Association guidelines (2016). Members will be identified by a risk stratification tool using clinical and socioeconomic information, provider referrals, chart reviews, comprehensive health assessments (CHAs), provider scorecards, and self-referrals. Pharmacists will provide in-person and/or telephonic medication therapy management and disease management reviews to ensure guideline driven therapy. Pharmacists will also identify and address barriers to adherence and close care gaps. The Plan’s interdisciplinary team, including clinical care coordinators, case managers, social workers and providers will work with the pharmacists to provide members diabetes education, financial information and follow up to assure adequate treatment and resources during a transition of care. Clinical and quality outcomes will be measured. These include A1c, blood pressure, guideline adherence and care gaps closed. Care gaps include statin therapy, annual eye exams, blood pressure control and kidney disease monitoring. Medication adherence will be measured using pharmacy claims data. We will use the electronic medical record (EMR) for member information and notification to providers. We
will document interventions in a spreadsheet and analyze the data accordingly. The interdisciplinary team will have a positive impact on all of the plan’s diabetic quality metrics.

**Poster Title:** Impact of an interdisciplinary team managed protocol on hospital readmissions for heart failure

**Primary Author:** Rizwan Khaliq, Health First Health Plans, FL; **Email:** rizwan.khaliq@health-first.org

**Additional Author (s):**
Nancy Youssef
Jeveire Moore

**Purpose:** Heart Failure (HF) affects nearly 5 million Americans nationwide and has an estimated yearly cost of $30.7 billion. Although HF medication therapy has improved significantly, an estimated 24% of members are readmitted within 30 days. Our interdisciplinary team consisting of pharmacists, case managers, providers and social workers will work on a multimodal approach within our integrated delivery network to reduce our hospital readmission rates.

**Methods:** The plan’s ethics committee will be asked for approval to conduct research. Members will be identified through our embedded pharmacists program, risk stratification of hospital admissions, pharmacy claims, medication therapy management (MTM) referrals, and medical claims. The American College of Cardiology/American Heart Association (ACC/AHA) and the New York Heart Association (NYHA) guidelines will be used to evaluate the member’s therapeutic regimen. Medication adherence will be measured throughout the study period with pharmacy claims. Pharmacists will reconcile medications during a member’s transition of care by educating members and making clinical recommendations to providers. Transitions of care include going from hospital to home, hospital to long term care facilities, and physician office to home. Acceptance or denials of recommendations will be tracked in order to determine their effectiveness. Heart Failure kits will be utilized to evaluate key components of disease management. Clinical outcomes and hospital readmission rates will be measured. Outcomes to be measured include abnormal weight increases, symptoms reported, and medication adherence.

**Submission Type:** Research-in-Progress  

**Session-Board Number:** 9-114  

**Poster Title:** Assessment of multidisciplinary intervention in prevention of hospitalization of members with COPD.  

**Primary Author:** Jelena Cusanelli, Health First Health Plans, FL; **Email:** jelena.cusanelli@health-first.org  

**Additional Author (s):**  
Nancy Youssef  

**Purpose:** Chronic Obstructive Pulmonary Disease is associated with high risk of mortality, high death rates, and significant burden on healthcare. Inappropriate use of inhalers, low literacy, and non-adherence are major factors contributing to hospitalizations. The Plan recognizes the importance of multidisciplinary approach in COPD management. Identification of barriers to disease state education and early intervention is a key to eliminating COPD readmissions. The Plan’s goal is to develop strategies and evaluate the effects of an interdisciplinary team that is using a multi-modal approach to reduce COPD readmission rates.  

**Methods:** The Plan’s Ethics Committee will be asked for approval to conduct a research. Members will be identified by the medical and pharmacy claims, MTM referrals, embedded pharmacist clinics, health fairs, and risk stratification reports. Our interdisciplinary team consists of clinical care coordinators, case managers, providers, respiratory technicians, and pharmacists. Member disease management will be provided at every encounter. Members will receive education for appropriate breathing technique, use of durable medical equipment, and use of inhalers and nebulizers to ensure appropriate delivery of medications. Smoking cessation and transition of care will be essential parts of our intervention. We will monitor members’ adherence to the therapy and assess the need for financial assistance to remove the economic barrier. Home visits and phone calls will be made to ensure all members’ needs are met, including transportation and safety concerns. We will evaluate clinical outcomes and any care gaps that need to be closed. Clinical outcomes and medication adherence rates will be measured. These include medication adherence, carbon monoxide levels, and symptom control using simple survey. To prevent further exacerbations and complications, members will be
encouraged to get seasonal flu and pneumonia vaccines done as soon as they get stable, if that was done previously. We will document all interventions in a spreadsheet and analyze the data accordingly.

**Poster Title:** Investigating the pharmacokinetics and dosing of vancomycin in intravenous drug abusers: the Flor-lvDA trial

**Primary Author:** Varun Vohra, Holmes Regional Medical Center, FL; **Email:** varun.vohra@health-first.org

**Additional Author(s):**
Joseph Bratsch
Ted Heierman
Heather McCormick-Morrison
Michael Sanchez

**Purpose:** Renewed interest in vancomycin in the intravenous drug abuse (IVDA) population has warranted a thorough investigation into the pharmacokinetics and potential need for more aggressive dosing requirements. Despite the paucity of available literature on the subject, studies have reported increased vancomycin clearance thereby necessitating adjusted dosing requirements to achieve and maintain consistent therapeutic concentrations in this patient population. The primary outcome of this study is to determine whether patients with active or reported history of IVDA require clinically significant differences in vancomycin dosing compared to non-IVDA.

**Methods:** This study was approved by the institutional Ethics Committee and consisted of a retrospective chart review from September 1, 2015 through September 1, 2016. Patients were identified using a manual chart review of all adult patients 18 years or older who received IV vancomycin with at least one serum trough level obtained during this time period. A 2:1 case-control study was performed evaluating patients with documentation of physician-confirmed IVDA and non-IVDA. Exclusion criteria consisted of patients with unstable renal function, defined as a serum creatinine (Scr) increase of 0.3 mg/dL or more in 24 hours, and creatinine clearance (CrCl) less than 30 ml/min. The following data was collected: patient age, height, weight, gender, renal function, doses of vancomycin administered and dosing intervals, serum vancomycin levels, indication for therapy and the offending agents, if specified. As a result of more observed aggressive dosing regimens, the frequency of nephrotoxicity, defined as an
increase in SCr 0.5 mg/dL or greater than 50% from baseline in 48 hours, was also assessed. All data will be collected without patient identifiers and maintained encrypted and confidential.

**Poster Title:** Implementation of a pharmacy-driven protocol to discontinue proton pump inhibitors in patients without a clinically appropriate indication.

**Primary Author:** Brittany Grant, Holmes Regional Medical Center, FL; **Email:** brittany.grant@health-first.org

**Additional Author(s):**
Michael Sanchez  
Joseph Bratsch  
Jay Pauly  
Andrew Sirois

**Purpose:** Proton pump inhibitors (PPI’s) are widely prescribed in the hospital setting, often times without an appropriate indication for use. The use of these agents does not come without consequences; there is a 3-fold increased risk of Clostridium difficile infection with PPI use, as well as an increased risk of pneumonia. A pharmacy-driven protocol was implemented at our institution in order to decrease the unnecessary utilization of PPI’s. The purpose of this study is to assess the appropriate use of these medications before and after implementation of the protocol.

**Methods:** A retrospective chart review will be conducted before and after implementation of this pharmacy-driven protocol, with 150 patients included in each group. Patients 18 years of age and older who are admitted into the hospital and received more than one dose of pantoprazole will be included in this study, utilizing data from a one-month time period before and after implementation of the protocol. This study was reviewed and approved by our Ethics Committee. The indication for use will be assessed in all patients. Appropriate conditions for use include the following: duodenal or gastric ulcer, gastroesophageal reflux disease, Barrett’s Esophagus, Zollinger Ellison Syndrome, history of a gastrointestinal bleed within 1 year, peptic ulcer disease, erosive gastritis, Helicobacter pylori infection, dual antiplatelet therapy, concomitant scheduled non-steroidal anti-inflammatory drugs, or meeting criteria for stress ulcer prophylaxis. The following data will also be collected: medication dose, route and frequency; total doses received and days of therapy; development of C. difficile infection or pneumonia; and medication continuation upon discharge. In addition, the post-implementation
group will be assessed for appropriate discontinuation by pharmacy when an appropriate indication is not documented. A pharmacist may discontinue use of these medications in patients not meeting the above criteria, unless it is a patient’s home medication as documented on admission medication reconciliation, in which the physician will be contacted to consider discontinuation.

**Poster Title:** Impact of Pharmacist-conducted Discharge Counseling on Readmissions of Patients with Chronic Obstructive Pulmonary Disease

**Primary Author:** Steffi Stephen, Holy Cross Hospital, FL; **Email:** ss1820@nova.edu

**Additional Author(s):**
Lucas Beeler
Alissa Fuller

**Purpose:** Since October 2012, the Hospital Readmission Reduction Program requires CMS to reduce payments to hospitals with excess readmissions. Patients admitted for Chronic Obstructive Pulmonary Disease (COPD) have had the most readmissions in Holy Cross Hospital, a non-profit community teaching hospital that is located in Fort Lauderdale, Florida. The objective of this study is to determine if pharmacists can reduce the percentage of COPD admissions that were readmitted within 30 days in a non-profit community teaching hospital through pharmacy conducted discharge counseling.

**Methods:** This study will compare the 30-day all cause readmission rate for COPD patients receiving pharmacist discharge counseling to the historical readmission rate of COPD patients prior to initiation of pharmacist discharge counseling. Before patients are discharged, the pharmacist will collect information from the patients. This includes: demographics, COPD medical history, smoking status, chronic oxygen therapy status, and a COPD patient knowledge survey to be completed by the patient. The patient will then be given education on their COPD disease state, information about their COPD medications prescribed upon discharge, and administration technique for their inhalers. Discharge counseling will be tailored to each patient based on identified knowledge gaps or deficiencies (smoking cessation, inhaler technique, side effect management, disease education, etc.) Two days after discharge, the patient will receive a follow-up phone call by the pharmacy resident to see if they made an appointment with a physician for COPD care, if they received their COPD medications, and if they are using proper inhaler technique. At the end of the study, the average number of COPD readmissions per month will be calculated and compared to historical data using the Chi-squared test.

**Submission Category:** Pain Management  

**Submission Type:** Research-in-Progress  

**Session-Board Number:** 9-118  

**Poster Title:** Assessing the adherence of the American Pain Society’s (APS) Post-Operative Pain Management Guidelines in exploratory laparotomy surgery patients at a community hospital  

**Primary Author:** Navdeep Kaur, Homestead Hospital, FL; **Email:** navdeepk@baptisthealth.net  

**Additional Author (s):**  
Winifred Pardo  
Sarah Amofah  

**Purpose:** This study will assess provider adherence of two recommendations from the 2016 post-operative pain management recommendations of the American Pain Society, specifically, recommendations number 14 and 15: 1) Provision of acetaminophen and/or nonsteroidal anti-inflammatory drugs (NSAIDs) as part of multimodal post-surgical analgesia, and 2) Ensuring that either a stool softener or laxative are prescribed to patients for the prevention of opioid-induced constipation.  

**Methods:** This retrospective, single center, observational study, will use chart reviews of patients who underwent an exploratory laparotomy procedure from January 1, 2016 to June 30, 2016. Exclusion criteria are: Age younger than 18 years and patients who had contradictions to NSAIDs and APAP.  
The following data will be collected: medical record number, age, gender, date of admission, presence or absence of orders for opioids, acetaminophen, and/or NSAIDs, and the number of doses administered. Outcome measures will be: 1) Proportion of charts with both opioid and APAP or NSAIDS ordered; 2) The proportion of days out of the total length of stay in which NSAIDs and APAP were administered concurrently with opioids; the proportion of patients who also received a stool softener or laxative while they were on opioids.

Poster Title: Clinical institute withdrawal assessment for alcohol-revised protocol implementation in a community hospital

Primary Author: Edlyn Hwang, Indian River Medical Center, FL; Email: edlyn.hwang@irmc.cc

Additional Author(s):
Matthew Lambie
Jeni McGuire

Purpose: Nationally, alcohol use is present in 40% of ED visits, and 8% of them experience alcohol withdrawal syndrome (AWS). AWS treatment is mainly benzodiazepines (BZD), where dosing should be guided to provide safe and effective treatment. The Clinical Institute Withdrawal Assessment for Alcohol-revised (CIWA-Ar) assessment is used to determine when to administer BZDs; however, dosing protocols vary amongst institutions. Recently, Indian River Medical Center updated their dosing protocol to reduce its complexity and improve adherence. The aim of the study is to evaluate a quality improvement initiative and determine the safety and efficacy of the new protocol.

Methods: At the institution, Indian River Medical Center, there will be a change in the CIWA-Ar based alcohol withdrawal protocol in October 2016. Data results would be obtained through retrospective chart review through the electronic medical record system. The following data will be collected: patient age, gender, race, past medical history, social history, home medications, length of stay, number of cases transferred to the intensive care unit (ICU), number of seizures, duration of BZD, total cumulative dose of BZD, and daily dose of BZD. All data will be recorded without patient identifiers and maintained confidentially. Patients admitted with documented alcohol withdrawal symptoms or alcohol-related diagnoses and CIWA-Ar protocol ordered during January 2016 to March 2016 (pre-protocol) and to January 2017 to March 2017 (post-protocol). Exclusion criteria include any prior conditions that would interfere with the treatment of alcohol withdrawal, such as hypersensitivity to BZD and benzyl alcohol.

Poster Title: Comparison of efficacy and cost-effectiveness of filgrastim, tbo-filgrastim, and filgrastim-sndz in patients with cancer receiving myelosuppressive chemotherapy and patients with severe chronic neutropenia

Primary Author: Megha Patel, Indian River Medical Center, FL; Email: megha.patel@irmc.cc

Additional Author(s):
Matthew Lambie
Carp Daniel

Purpose: Colony-stimulating factors such as filgrastim, tbo-filgrastim, and filgrastim-sndz act on hematopoietic cells and stimulate proliferation, differentiation, and some endcell functional activation. These medications are important for patients who are myelosuppressed or are experiencing febrile neutropenia. The objective of this study is to compare the efficacy and cost-effectiveness of filgrastim, tbo-filgrastim, and filgrastim-sndz.

Methods: This study will be submitted to the Institutional Review Board for approval. Indian River Medical Center (IRMC) used filgrastim and tbo-filgrastim over different two-year spans in the past and is currently using filgrastim-sndz. The electronic medical record system will be used to identify patients who were administered filgrastim, tbofilgrastim, and filgrastim-sndz for myelosuppressive chemotherapy and severe chronic neutropenia. The following data will be collected: patient age, gender, ethnicity, white blood cell trends, absolute neutrophil count trends, IV anti-infective use, incidence of bone pain, incidence of nausea, length of stay, and hospital costs. Six months of utilization data will be collected and reviewed for each of filgrastim, tbo-filgrastim, and filgrastim-sndz. The data from the three medications will be organized and compared using Microsoft Excel to find statistics showing how they compare on efficacy and cost-effectiveness.

**Poster Title:** Costs associated with continuous naloxone infusion in pediatric patients receiving continuous or patient-controlled analgesia opioid therapy

**Primary Author:** Meghan Roddy, Johns Hopkins All Children's Hospital, FL; **Email:** meghan.roddy90@gmail.com

**Additional Author(s):**
Bernard Lee
Megan Allen
Emi Onuki

**Purpose:** Opioid therapy in pediatric patients is often complicated by side effects: nausea, vomiting, constipation and pruritus. Previous studies have examined the effectiveness of low-dose continuous naloxone infusion to mitigate opioid-induced pruritus while preserving adequate pain control. Currently, inpatients initiated on continuous or patient-controlled analgesia (PCA) opioid therapy consistently receive empiric, concurrent low-dose continuous naloxone infusions resulting in significant costs incurred to the institution. The purpose of this medication-use evaluation was to assess the frequency of inefficiencies associated with and other attributable costs to the use of low-dose continuous naloxone.

**Methods:** A retrospective medication-use evaluation was conducted for low-dose continuous naloxone infusions in patients on continuous or PCA opioid therapy over the second and third quarters of 2016. The electronic medical record was utilized to identify patients who received continuous naloxone infusions. Data collected included but were not limited to: patient demographics, service/provider, opioid used and start/stop time, duration of naloxone infusion, dose titrations, unused naloxone quantities dispensed/wasted and use of adjunct medications. Patients were excluded for indications of respiratory depression and other opioid toxicity management.

**Poster Title:** Evaluation of intravenous allopurinol use in a pediatric hospital  

**Primary Author:** Haley Grunwald, Johns Hopkins All Children's Hospital, FL; **Email:** hgrunwa1@jhmi.edu  

**Additional Author(s):**  
Amanda Memken  

**Purpose:** Tumor lysis syndrome (TLS) is a life-threatening oncological emergency most commonly seen in tumors with a high proliferative rate, large tumor burden, or high sensitivity to cytotoxic therapy. Appropriate prophylactic measures and treatment of TLS is necessary to reduce the risk of serious and potentially fatal complications. Allopurinol, a xanthine analog available in oral and intravenous (IV) formulations, is used to prevent and treat TLS. Given the recent cost increase of the IV product, this medication use evaluation was designed to assess current usage, create appropriate usage criteria, and evaluate the potential cost savings of implementing the usage criteria.

**Methods:** The electronic medical records of 31 patients who received allopurinol IV between July 1, 2014 and June 30, 2016 will be reviewed. The following demographic information will be collected: patient age, gender, height, weight, and tumor type. Additional data to be collected includes: dose strength, dose frequency, total number of doses received, NPO status, WBC count, uric acid, lactic dehydrogenase, basic metabolic panel, and urine output prior to the start of therapy. All data will be analyzed to determine if patients meet the proposed criteria for use. Criteria for use will be defined as patients unable to receive rasburicase or patients at intermediate or high risk of developing TLS who are NPO or unable to tolerate oral allopurinol.

Poster Title: Compliance with antimicrobial restriction criteria at a pediatric institution: a medication usage evaluation

Primary Author: Talia Papiro, Johns Hopkins All Children's Hospital, FL; Email: tpapiro1@jhmi.edu

Additional Author(s):
Katie Namtu

Purpose: Antimicrobial restriction is an effective strategy for antimicrobial stewardship. Antimicrobial agents with restrictive criteria include vancomycin, ciprofloxacin, and levofloxacin. Implementation of restrictive criteria for antimicrobials reduces use of inappropriate antibiotics and leads to significant cost savings. The impact of pharmacist involvement in monitoring prescriber compliance to restrictive criteria is unknown. This medication usage evaluation was developed to assess utilization of restricted antimicrobials and to evaluate pharmacist impact on compliance with restriction criteria at a pediatric institution.

Methods: Patients who received more than 48 hours of therapy with vancomycin, ciprofloxacin, or levofloxacin from January 1, 2016 through June 30, 2016 will be included for analysis. The following data will be collected: antimicrobial agent, route of administration, patient care unit, microbiology, and indication for use. To ensure compliance with restriction criteria, documentation by pharmacy, infectious diseases, and antimicrobial stewardship will be reviewed. Data will be analyzed for overall utilization and compliance with antimicrobial restriction criteria. Results will be presented to the antimicrobial stewardship, pharmacy and therapeutics, and medical executive committees.

Poster Title: Evaluation of Initial Fluid Resuscitation in Critically Ill Septic Patients

Primary Author: Brittany Petrosky, Lakeland Regional Health, FL; Email: brittaby22@gmail.com

Additional Author(s):
Michael Semanco
Rebecca Anderson
Lauren Morata

Purpose: Sepsis is a severe inflammatory response to infection, frequently associated with hypovolemia and vasodilation. Affecting millions annually and increasing in incidence, mortality is approximately one in four. Timeliness of appropriate therapy after initial identification influences patient outcomes. The purpose of this evaluation is to assess the utilization and timing of initial fluid resuscitation in critically ill septic patients. Primary outcomes include time from Sepsis Alert to initiation of fluid administration and time from fluid initiation to completion of resuscitation. Secondary outcomes include primary outcomes stratified to location at time of alert and amount of fluid administered within six hours.

Methods: This evaluation is approved by the Institutional Review Board. Patients admitted and discharged between June 1, 2014 and June 30, 2016 will be screened in reverse chronologic order from a report of all patients with a Sepsis Alert. Inclusion criteria include adult patients (> 18 years) with an admission order or transfer to the intensive care unit (ICU) for presumed sepsis within six hours of the Sepsis Alert. Exclusion criteria include trauma patients, pregnant or immediately postpartum women, and location in an ICU at the time of Sepsis Alert. A data tool was created to aid with collection and documentation of baseline characteristics including: basic demographics (age, gender, and weight), location at time of Sepsis Alert (ED or acute care floor), requirement of vasopressor(s), fluid administered (crystalloid type and bolus amount per hour for initial six hours after sepsis identification), and fluid timing (time from Sepsis Alert to fluid initiation and time from initiation to completion of resuscitation fluids). Descriptive statistics will be used to analyze primary and secondary outcomes.

Poster Title: Evaluation of the management of pulmonary embolism in the emergency department

Primary Author: Somer Harvey, Lakeland Regional Health, FL; Email: somer.harvey@mylrh.org

Additional Author(s):

Purpose: Acute pulmonary embolism (PE) affects approximately 300,000 patients in the United States each year and is divided into three types: massive, submassive, and low-risk. The 2016 CHEST Guidelines provide recommendations for anticoagulation, thrombolysis, and catheter embolectomy specific for each of the PE types and risk of bleeding. Although the guidelines do not provide recommendations on timing, earlier treatment has been associated with improved outcomes. The goal of this medication use evaluation is to describe the current acute management of pulmonary embolism including anticoagulation, thrombolysis, and catheter embolectomy in our emergency department.

Methods: This single center, retrospective, cohort evaluation has been approved by the Institutional Review Board. Patients with a discharge diagnosis of pulmonary embolism will be consecutively screened in reverse chronological order. Patients who expired in the emergency department will be excluded. The following data will be collected: age, gender, weight, pertinent past medical history, vital signs, laboratory markers, length of stay, type of PE, method of PE diagnosis, time to therapy, dosing of anticoagulants and thrombolitics, and indication for thrombolitics and catheter embolectomy. Indications for thrombolitics and catheter embolectomy will be determined in accordance with recommendations from the 2016 CHEST Guidelines. A goal of 30 patients with each of the three types of PE will be targeted, for a total of 90 patients. Descriptive statistics will be used to report the population characteristics and to evaluate therapy.

Poster Title: Re-evaluation of total parenteral nutrition utilization at a tertiary care hospital

Primary Author: Nathan Greenfield, Lakeland Regional Health, FL; Email: nathan.greenfield@mylrh.org

Additional Author(s):
Georgia Keriazes
Katie Maples

Purpose: In December 2013, total parenteral nutrition (TPN) utilization at Lakeland Regional Health (LRH) was evaluated. Based on the American Society for Parenteral and Enteral Nutrition (ASPEN) guidelines, it was determined that 50% of patients were inappropriately initiated on TPN. Lack of baseline protein-calorie malnutrition was found to be the primary cause. Subsequently, an algorithm for TPN use was developed and educational inservices were provided to dietitians, nurses, pharmacists, and physicians. The primary objective of this study is to re-evaluate the utilization of TPN in accordance with current ASPEN guidelines and the LRH algorithm for TPN initiation.

Methods: This retrospective chart review was approved by the Institutional Review Board. Patients 18 years of age and older who were admitted and discharged between January 1st and June 30th 2016 and initiated on TPN will be included. Patients will be excluded if admitted on chronic TPN. Data collection will include: age, gender, indication for TPN, hospital day of initiation, whether it was initiated in the ICU, and duration of TPN. The primary outcomes include proportion of patients with appropriate indication and timing of TPN based on LRH protocol. Appropriate TPN indications include: enteral nutrition intolerance or contraindication, severe malnutrition, and major upper GI surgery. Appropriate timing is defined as initiation after seven days of being unable to meet at least 60% of energy or protein needs. Secondary outcomes include the primary outcome stratified based on initiation in the ICU compared to the acute care floor as well as duration of TPN therapy.

Poster Title: Timing of Antibiotic Administration in Critically Ill Septic Patients

Primary Author: Kelsey Lubbers, Lakeland Regional Health, FL; Email: kelsey.lubbers@mylrh.org

Additional Author(s):
Rebecca Anderson
Michael Semanko
Kayla Montgomery

Purpose: Sepsis is the primary cause of death related to infection. Literature demonstrates as each hour passes between recognition of sepsis-related hypotension and administration of effective antimicrobials, a patient’s survival to discharge decreases by 12%. The primary objective will evaluate antimicrobial administration for diagnosis of sepsis, severe sepsis, or septic shock in accordance with identified evidence-based criteria. The secondary objective is to determine the delay in antimicrobial administration, if present, and to identify areas for improvement in clinical practice.

Methods: This is an Institution Review Board approved single center, retrospective, cohort evaluation at Lakeland Regional Health. Patients admitted and discharged between June 1, 2014 and June 30, 2016 will be screened for inclusion in reverse chronological order. Up to 100 adult patients with a diagnosis of sepsis, severe sepsis, or septic shock admitted or transferred to the ICU within six hours of sepsis identification will be included. Patients will be excluded for the following reasons, pregnancy, trauma, and sepsis alert triggered in the ICU. The outcomes will be analyzed and reported using descriptive statistics.

**Poster Title:** Evaluation of N-acetylcysteine Use for Acetaminophen Poisoning

**Primary Author:** Antonia Fawaz, Lakeland Regional Health, FL; **Email:** antonia.fawaz@mylrh.org

**Additional Author (s):**
Jennifer Montero

**Purpose:** Acetaminophen (APAP) is one of the most commonly used medications for pain and fever. The antidote of choice for treating an APAP poisoning is N-acetylcysteine (NAC). APAP poisonings account for approximately 23,000 courses of NAC given annually. Lakeland Regional Health (LRH) utilizes the FDA approved dosing regimen for NAC as an established protocol in the Emergency Department for APAP overdose. However, no protocol currently exists to guide continued monitoring and NAC administration for admitted patients. The purpose of this evaluation is to describe NAC use in APAP overdose at LRH and identify patients eligible for early discontinuation of NAC therapy.

**Methods:** This single center, retrospective cohort evaluation has been approved by the Institutional Review Board. Informed consent has been waived. Patients will be identified from a usage report of intravenous and oral NAC. Patients admitted and discharged between January 1, 2012 and June 30, 2016 will be screened in reverse chronological order until 100 patients are included. Patients will be included if they received NAC for suspected or proven acute or chronic APAP overdose. Those patients presenting greater than 8 hours after acute ingestion will be excluded. All data will be collected from the hospital electronic medical record database and de-identified to protect patient privacy. Primary outcomes include proportion of patients eligible for early discontinuation of NAC and time from NAC initiation to meeting eligibility criteria for early discontinuation. Secondary outcomes include common causes for continuing therapy beyond a pre-specified time frame, common causes for discontinuing therapy before a pre-specified time frame, and eligibility for oral NAC in those receiving intravenous therapy. Descriptive statistics will be utilized to report the results of primary and secondary outcomes.

Poster Title: Evaluation of the safety and efficacy of fluoroquinolones use at a teaching hospital

Primary Author: Marlene Calix, Larkin Community Hospital, FL; Email: mc1293@nova.edu

Additional Author (s):
Estela Trimino
Aridia Acosta
Alex Gonzalez

Purpose: Fluoroquinolones are utilized as first-line agents in different types of infections due to their broad-spectrum of activity and convenient dosing regimens. However, the overutilization of this antimicrobial class has increased the incidence of resistance, adverse effects, and therapeutic failures. The objective of this study is to evaluate the utilization of fluoroquinolones at a teaching hospital.

Methods: A retrospective review was conducted to evaluate the use of the fluoroquinolones. This study was approved by the appropriate committee of the hospital. The evaluation included patient demographics, appropriateness of therapy, dosing, concurrent therapies, and adverse events during a period of three months. Currently, the hospitals does not have an active antimicrobial stewardship program and there are no restrictions or specific guidelines on fluoroquinolone use. Clinical pharmacists are assigned to make antibiotic recommendations regarding appropriate dosing, identified drug interaction, and adverse reactions. The results of this evaluation will identify strategies to optimize therapies, implement an antimicrobial stewardship team with the focus of de-escalation of therapy, and improve patient outcomes.

**Poster Title:** Daptomycin utilization in a multicenter community healthcare system for the treatment of gram-positive infections

**Primary Author:** Ashley Cubillos, Lee Health, FL; **Email:** ashley.cubillos@leememorial.org

**Additional Author(s):**
Isabelle Gallagher
Harrison Bachmeier

**Purpose:** Daptomycin, a cyclic lipopeptide antimicrobial agent, has become a popular treatment option for resistant gram positive infections, including endocarditis, bone and joint, and skin and skin structure infections. Compared to alternative agents with similar spectra of antimicrobial activity, daptomycin is a substantial drug expenditure for hospitals and health systems. The aim of this drug use evaluation is to clarify the current daptomycin prescribing patterns within the Lee Health system’s acute care hospitals, in order to provide a basis for guiding clinicians in choosing the most appropriate therapy for patients presenting with complicated or resistant gram positive infections.

**Methods:** This retrospective chart review will include patients receiving daptomycin for any indication within Lee Health's four acute care hospitals. A total of 200 patients, 50 from each hospital, will be included. Patients who are younger than 18 years of age, or who received fewer than 3 doses of daptomycin, will be excluded. Data collected on each patient will include length of stay, age, sex, weight, creatinine clearance, indication for daptomycin, daptomycin dose, ordering physician's service, presence of infectious diseases service consult, vancomycin allergy and reaction if applicable, rationale for switching from other gram positive antibiotic therapy to daptomycin if applicable, previous and concomitant antibiotics, bacterial culture results, minimum inhibitory concentration (MIC) of vancomycin for cultured Enterococcus or Staphylococcus, length of daptomycin therapy, opportunities for streamlining antibiotic therapy based on cultures and any streamlining actions taken, creatinine phosphokinase (CPK) levels at initiation and end of daptomycin therapy, and overall clinical success or failure with daptomycin. Statistics for each observational data measure will be descriptive in nature only.

**Results:** Not applicable
Conclusion: Not applicable

**Session-Board Number:** 9-131  

**Poster Title:** Utilization of dexmedetomidine in critically ill patients in a community health-system  

**Primary Author:** Karina Esquivel, Lee Health, FL; **Email:** karina.esquivel@leememorial.org  

**Additional Author (s):**  
Mallory Fiorenza  
Michael Walsh  

**Purpose:** Sedation with dexmedetomidine allows patients to be more arousable without the risk of respiratory depression. Current FDA-approved indications for dexmedetomidine include: sedation of non-intubated patients prior to and during surgical or other procedures and sedation of mechanically ventilated intensive care unit (ICU) patients for duration of less than 24 hours. In practice, dexmedetomidine use extends beyond these FDA-approved indications. The purpose of this medication use evaluation is to assess if dexmedetomidine is being utilized appropriately at our institution for the indications of sedation, alcohol withdrawal syndrome (AWS) and perioperative therapy in cardiac surgery.

**Methods:** A retrospective chart review will be conducted in patients 18 years and older, who were admitted to any of the ICUs within a community health-system and received dexmedetomidine for at least 4 hours in February and March of 2015 and 2016. The following data will be collected: demographics, ICU location, specialty group, indication for dexmedetomidine per chart documentation, duration of dexmedetomidine, administration of dexmedetomidine bolus, dexmedetomidine dosing, Richmond Agitation-Sedation Scale (RASS) and Clinical Institute Withdrawal Assessment for Alcohol (CIWA) scores achieved during dexmedetomidine use as applicable, presence and duration of other sedation infusions (propofol, benzodiazepines, opioids), presence of a neuromuscular blocker infusion during dexmedetomidine use. The reviewers will classify dexmedetomidine use as appropriate if the following criteria is met: use for sedation of mechanically ventilated patients for up to 5 days with a maximum dose of 1.5 mcg/kg/hr; use for AWS for up to 5 days with a maximum dose of 1.5 mcg/kg/hr and concomitant use of benzodiazepines as indicated per AWS protocol; use as a perioperative adjunct after cardiac surgery for a duration of 24 hours or less. The
appropriateness of dexmedetomidine use will be compared between the 2015 and 2016 groups.

Poster Title: Utilization analysis of the pneumococcal vaccine in a multicenter community healthcare system

Primary Author: Christina Martin, Lee Health, FL; Email: christina.martin@leememorial.org

Additional Author(s):
Edgar Turner
Sandy Estrada

Purpose: The CDC approximates one million U.S. adults are hospitalized with pneumococcal disease each year. Although many different organisms can cause pneumonia, the pneumococcal vaccinations target multiple serotypes of the most common bacterial cause of pneumonia, Streptococcus pneumoniae. In 2015 the CDC expanded the approved indications of the 13-valent pneumococcal conjugate vaccine (PCV13) to include high-risk adults age 19-49, increasing the targeted population for the prevention of pneumococcal disease in the community. The objective of this study is to determine if the ordering and administration of the pneumococcal vaccines within our health system are in accordance with recommended guidelines.

Methods: A retrospective chart review was performed at our multi-centered acute care community health system to identify adult patients admitted between November 2015 and April 2016 eligible to receive either PCV13 or PPSV23. A list including patients age 19-64 who met high-risk criteria and all patients over age 65 was generated using our electronic medical record system (Epic). One hundred patients from each group were randomly selected for inclusion. Once selected, the electronic medical record was reviewed to determine if the patient met Lee Health, and accordingly, CDC inclusion and/or exclusion criteria to receive either PCV13 or PPSV23 based on their age, vaccination history, and past medical history. Data collected included age, sex, admission site, length of stay, high-risk factor for those 19-64, vaccine duplication or omission, readmission for pneumonia or COPD within 6 months, and previous outpatient clinic visit within the previous 6 months. Patients were excluded from the study if they were under age 19, pregnant, missing data points, receiving chemotherapy, refused vaccination when indicated, had a vaccine allergy, bone marrow transplant within the past 12 months, previously immunized, or had an organ transplant during admission.
Opportunities for outpatient pneumococcal vaccination in the six months preceding admission were assessed by reviewing patient chart notes. This study was approved by our Institutional Review Committee. Descriptive statistics were used for data analysis.

**Poster Title:** Treatment of acute bacterial skin and skin structure infections (ABSSSI) in the outpatient setting: clinical and economic outcomes from a real-world multi-center study of oritavancin

**Primary Author:** Edgar Turner, Lee Health, FL; **Email:** edgar.turner@leememorial.org

**Additional Author(s):**
Sandy Estrada  
Shannon Armstrong  
Annmarie Galli  
Dino Delaportas

**Purpose:** At a mean admission cost of 8000 dollars per visit, significant interest exists to avoid unnecessary admission for the treatment of ABSSSIs. The mean cost of a seven day course of daptomycin in the outpatient setting is 4,150 dollars. Oritavancin is a once-only dose intravenous (IV) antibiotic which may allow avoidance of hospital admission and reduce costs, but little is known about clinical and economic outcomes in the outpatient setting. The purpose of this study was to evaluate the clinical and economic outcomes of patients treated with oritavancin in the hospital outpatient infusion setting.

**Methods:** This was an institutional review board approved multi-center retrospective chart review conducted at 6 US hospitals. Patients 18 years of age or older who received outpatient oritavancin from 1/1/2015 to 1/31/2016 were included if they had not been discharged from the inpatient setting within the previous 24 hours. Clinical success (cure or improved) was assessed at 5-30 days. Economic evaluation encompassed medication cost and healthcare resource utilization (HRU), including subsequent hospital admission, antimicrobials and antimicrobial administration, diagnostic testing and surgical procedures. Economic data was collected from index diagnosis to 30 days post oritavancin administration.

**Results:** 115 patients met all inclusion criteria. The mean age was 59.7 and 64 percent were female. Overall 93 percent of patients had at least 1 comorbidity; most common were hypertension (53 percent), diabetes (22.6 percent) and hyperlipidemia (20.9 percent). Mean BMI was 36.1 kilogram per square meter. 60 percent of patients had prior oral or IV antibiotic
treatment. All patients returned home after treatment. Success rate was 99.1 percent, with 1 patient requiring additional antibiotics due to inadequate treatment response. A total of seven (6.1 percent) patients were admitted to a hospital within 30 days of outpatient treatment, of which three (2.6 percent) were infection-related. No patient required discontinuation of therapy due to adverse event. Mean cost of outpatient administration of oritavancin was estimated to be 3,162 dollars.

**Conclusion:** Results of this study suggest that outpatient treatment with oritavancin is highly safe and effective. Economic data collected during this study indicate that oritavancin treatment involves fewer resources and is less expensive than inpatient or alternative outpatient treatments for ABSSSI. Treatment with oritavancin in the outpatient infusion setting may allow for effective treatment of ABSSSI without hospital admission, peripherally inserted central catheter line utilization or multiple daily visits in the infusion or home-health setting for patients requiring intravenous antimicrobial therapy.
**Submission Category:** Preceptor Skills

**Submission Type:** Research-in-Progress

**Session-Board Number:** 9-134

**Poster Title:** Implementation of a preceptor development program in a community health system

**Primary Author:** Marcus Silva, Martin Health System, FL; **Email:** marcus.silva@martinhealth.org

**Additional Author(s):**
Julianne Beacom
Kelly Dutra
Jennifer Prete

**Purpose:** Teaching is an important part of being a pharmacist. Throughout the doctor of pharmacy curriculum, students are given opportunities to learn from practicing pharmacists who serve as preceptors. However, many pharmacists have not received formal education in preceptorship. While it may not be necessary for pharmacists to be trained as teachers, teaching principles can be applied in any learning environment, including experiential rotations. This project involves the design and implementation of a structured preceptor development program for pharmacists to improve their preceptor skills.

**Methods:** This project will be submitted to the institutional review board for approval. Content will be provided through three modules that each include readings, videos, and supplemental activities. Each module will be designed to require approximately one hour to complete, but assumes completion will be done over small blocks of time. This design will accommodate the pharmacists involved in direct patient care by not impeding workflow. Each module will focus on a core area of preceptorship. Pharmacists will access the program through a third-party website that provides continuing education, a platform that is already in place for the delivery of required institution-specific continuing education. Introduction to the program will be provided via in-services that include discussions about the program, why it is being undertaken, potential benefits to be gained, and requirements for completion. The project will include two assessments. The first will occur prior to beginning and assess baseline characteristics. Results will be utilized to help tailor content to pharmacist needs and interests. The second will occur after completion and assess perception of the program. Results will be analyzed to help improve future preceptor development initiatives. For both assessments, participants will be surveyed using closed-ended multiple choice and matrix questions, as well as open-ended free
response questions to capture additional relevant information. Data collection, analysis, and summary will be done through SurveyMonkey.

**Results:** N/A

**Conclusion:** N/A
Purpose: Propofol is a widely used sedative in intensive care units (ICU) due to its pharmacokinetics and ease of titrating. While propofol use is common, one of its major adverse effects is hypotension. These effects can be so severe that vasopressors become necessary for the survival of the patient. This retrospective review will evaluate the use of propofol in patients in the ICU and emergency room to determine correlations between the average dose of propofol requiring vasopressor initiation. Patient-specific demographics will be evaluated to determine any significant risk factors increasing the incidence of propofol-induced hypotension requiring the use of vasopressors.

Methods: A retrospective, cohort study will be conducted at Martin Health System. Patients must meet the inclusion criteria of sepsis, severe sepsis, or septic shock diagnosis, and have been maintained on continuous infusion propofol for a minimum of 12 hours. Exclusion criteria are patients less than 18 years of age, patients who were on sedative (benzodiazepines, ketamine) infusions, or analgesic (fentanyl, morphine) infusions simultaneously with propofol. The patient list will be generated by completing a report of patients with specific ICD-9 codes for sepsis, severe sepsis, and septic shock, and cross referenced with a report of propofol continuous infusion use within a four year time period. Patient demographics, comorbidities, prior to admission prescriptions for benzodiazepines, and other patient-specific factors will be collected. The primary outcome will be the incidence of hypotension requiring vasopressor initiation. Secondary outcomes will include average propofol dose, average duration of infusion, hospital and ICU lengths of stay. Mean medication doses, length of stays, and duration of vasopressor therapy will be compared using Student’s t-tests. Nominal data will be compared using Pearson’s chi-square. P-values less than 0.05 will be considered statistically significant. Statistical analysis will be completed utilizing SPSS version 12.

**Poster Title:** Clinical impact of a rapid diagnostic blood culture identification panel in the treatment of bacteremia in a community health system  

**Primary Author:** Anthony Kennedy, Martin Health Systems, FL; **Email:** ak828@nova.edu  

**Additional Author (s):**  
Aileen Martinez  
Moti Ramgopal  

**Purpose:** Rapid diagnostic tests are quickly becoming a critical tool for Antibiotic Stewardship Programs (ASPs) to design quick and efficacious antibiotic regimens to better serve their respective patient populations. This single center study will focus on the use of blood culture identification panels (BCID) in order to streamline empiric therapy for those patients identified as having bacteremia. In turn, data from this study will be analyzed in order to determine the effects of rapid diagnostic tests on hospital stay, readmission rates, mortality, and time to optimal therapy.  

**Methods:** Patients included in this study are those with confirmed cases of bacteremia. Through the use of a multiplex polymerase chain reaction (PCR) system, organism identification will be obtained in a mere fraction of the time utilized by traditional culturing methodologies. Results will then be conveyed to point of care physicians and infectious disease pharmacists directly in order to decrease the time to optimum antibiotic therapy. This study will focus on data pre and post implementation of the institution’s rapid diagnostic device and the relevant protocols designed to take advantage of the expedited cultures and sensitivities. The study population prior to the implementation of the rapid diagnostic device will serve as the study control. The primary outcome of this study is to measure the time needed to obtain streamlined antibiotic therapy; this will be measured in the time in hours needed for empiric therapy to be changed to optimal therapy. Secondary outcomes will assess for changes in hospital stay, mortality, hospital readmission, and the costs associated with treating patients with bacteremia.  

**Results:** N/A
Conclusion: N/A
**Submission Category:** Infectious Diseases

**Poster Title:** Evaluation of a computerized physician order entry system on selecting guidelines-directed adult empiric antibiotic therapy for skin and soft tissue infections  

**Primary Author:** Benjamin Duong, Memorial Hospital Miramar, FL; **Email:** bqduong25@gmail.com  

**Additional Author (s):**  
Matthew Sherman  
Pujan Dave  
Matthew Curran  
Fabio Vogel  

**Purpose:** Memorial Healthcare System developed a computerized adult empiric antibiotic therapy order set for providers to select guidelines supported antimicrobials. The order set promotes the selection of optimal antimicrobial drug selection, dose, duration of therapy, and route of administration based on a patient’s diagnosis, risk factors for resistance and admitting presentation. This order set, however, continues to be under-utilized. This study evaluates the difference in prescribing trends for adult patients admitted with skin and soft tissue infections after the implementation of the order set has been completed when compared to the same time frame the previous year.  

**Methods:** A retrospective electronic health records (EHR) review was conducted between October 2014 and February 2015 identifying patients admitted for skin and soft tissue infections at an acute care community hospital. The primary intervention will be hospital wide in-services for healthcare providers on the adult empiric antibiotic therapy order set, which will be conducted over a 14-day period prior to data collection. After the education period, the records of patients admitted for skin and soft tissue infections will be prospectively evaluated on the compliance of the order set. Data that will be collected includes but not limited to: demographic variables, initial antibiotic selected, dose, duration of therapy, route of administration, length of stay, and prior antibiotic use. The results will be compared to data collected from a retrospective chart review of the same patient population within the same time frame one year prior to the intervention. The primary endpoint is the appropriate selection of empiric antibiotic based on the order set. The secondary endpoints are length of
stay, antibiotic defined daily doses per 1000 patient days, costs of antibiotics, and readmission rates.

**Poster Title:** Evaluation of the accuracy of a sepsis alert and the effects on readmission rates, mortality and antibiotic appropriateness

**Primary Author:** Carolina Gutierrez, Memorial Hospital Pembroke, FL; **Email:** cargutierrez@mhs.net

**Additional Author(s):**
Ira Schatten
Jon Francisco
Sandra Adeife

**Purpose:** Severe sepsis and septic shock are responsible for significant morbidity and mortality in the United States accounting for more than 250,000 annual deaths. Early recognition, although sometimes challenging, is crucial to reduce mortality and costs. The Surviving Sepsis Campaign was created to reduce mortality by standardizing care based on data from clinical trials, however, despite the availability of evidence-based guidelines, mortality rates have increased. The objective of this quality improvement initiative is to assess the accuracy of a sepsis alert used to identify potentially septic patients, in addition to the effects on appropriateness of antibiotics, readmission rates, and mortality.

**Methods:** A sepsis alert is fired for further review by clinicians via the electronic health record when a patient has two abnormal vital signs (temperature above 38 °C or below 36.1 °C, HR bpm above 90, RR over 20 rpm, systolic blood pressure below 90 mmHg, and oxygen saturation below 90%). Upon further review, the clinician answers additional screening questions to detect sepsis. We will evaluate the appropriateness of antibiotics administered to patients identified as septic, and will compare outcomes, such as morbidity and mortality following implementation of this alert and prior to initiation of this alert. The time period evaluated will be 6 months for each group. Chart reviews will be performed using a standardized data collection tool. Patients with ICD-9/ICD-10 codes of sepsis will be reviewed for readmission rate, mortality, and antibiotic appropriateness (susceptibility and timing). A random retrospective analysis of 585 patients in whom the sepsis alert fired will be reviewed for presence of sepsis based on ICD-9/ICD-10 codes and appropriateness of antibiotics in order to potentially streamline the number of false positive alerts that fire. The primary outcomes to be
evaluated will be 30 day readmission rates and mortality rates for septic patients, and antibiotic appropriateness of patients in which the sepsis alert was triggered.

**Poster Title:** Implementation of a pharmacist-driven antibiotic stewardship best practice initiative to decrease incidence of healthcare-associated Clostridium difficile infections

**Primary Author:** Omama Sabir, Memorial Hospital West, FL; **Email:** omamasabir@gmail.com

**Additional Author(s):**
Diana Andrade
Veronica Sherman
Alexandra Rivera
Dorinda Segovia

**Purpose:** Clostridium difficile infection (CDI) rates are on the rise and contribute significantly to mortality and cost of care. Antibiotic exposure is the single most modifiable risk factor for developing C. difficile infections. Currently, our facility, Memorial Hospital West, does not have a consistent practice for antibiotic surveillance as recommended by the Infectious Diseases Society of America (IDSA) guidelines. The intent of this study is to utilize dedicated pharmacists to conduct antibiotic surveillance using IDSA Antibiotic Stewardship Program (ASP) guideline recommendations to optimize antibiotic therapy for patients and decrease risk for developing healthcare-associated C. difficile infections (HA-CDIs).

**Methods:** This study has been exempt by the Institutional Review Board. A pharmacist-driven antibiotic stewardship will be initiated at our facility. The surveillance program involves daily review of antibiotics, defined as clindamycin, fluoroquinolones, cephalosporins, carbapenems, amoxicillin and ampicillin, that are highly associated with CDIs. Pharmacists will utilize a report to identify all adults on the aforementioned high risk antibiotics for greater than or equal to two days. Patient charts will be reviewed for appropriateness of antibiotic therapy. Physicians will be contacted with interventions that meet the following criteria: streamlining antibiotic therapy, assigning a duration of therapy, discontinuing antibiotic(s) and/or proton pump inhibitors (PPIs), if appropriate. All pharmacist interventions will be documented in patient charts. The following data will be collected: patient age, gender, race, past medical history, immunosuppressive state, previous hospitalization and antibiotic exposure, prior CDI, active PPI order, antibiotic(s), indication for antibiotic(s), total days of therapy, pharmacist intervention, physician response, physician specialty and if patient developed CDI. All patient identifiers will
be de-identified and kept confidential. Primary outcome of this study is to reduce the number of HA-CDIs at our facility where number of pre and post-intervention HA-CDIs will be compared. Descriptive analysis will be used to evaluate secondary outcomes which will be number of pharmacist interventions that were accepted or rejected by physicians and total number of days on any high risk antibiotic(s).

**Poster Title:** Impact of an infectious disease call service on antimicrobial stewardship: A retrospective quality analysis

**Primary Author:** Jeana Kett, Memorial Regional Hospital, FL; **Email:** jkett@mhs.net

**Additional Author(s):**
- Corey Frederick
- Carla Hawkins-Smith
- Margaretta Kearson

**Purpose:** The role of pharmacists in antimicrobial stewardship programs is well documented. Pharmacists play a key role by promoting optimal use of antimicrobial agents, reducing transmission of infections, and coordinating educational seminars. The implementation of an infectious disease call service pharmacist can potentially play an integral role in the acclimation of the upcoming Joint Commission Standards for Antimicrobial Stewardship, specifically to improve optimal antibiotic use and initiation of a tracking program. The purpose of this quality analysis is to investigate the effectiveness of a pharmacist driven infectious disease call service on patient outcomes and cost avoidance related to antimicrobial prescribing practices.

**Methods:** A six month prospective, single center pilot study was conducted by a pharmacy resident to evaluate the interventions and outcomes of a pharmacist driven infectious disease call service. Advertisement of the service occurred with a kickoff event at the pharmacy monthly staff meeting, monthly emails, and word of mouth. The kickoff event included an introduction to the program, an infectious disease personalized Instagram frame, and flyers that were distributed to all pharmacists. The service was available from 0700-1600 Monday-Friday. The service was managed by a pharmacy resident two weeks out of the month and the Infectious Disease Clinical Coordinator for two weeks out of the month. An infectious disease clinical pharmacist was assigned to the pharmacy resident for guidance throughout the study period. A data collection sheet was maintained on a shared drive to capture documentation of the call and was updated within 24 hours of any call. The data sheet included a brief synopsis of the question/case, answer/intervention provided, time spent on call, whether intervention was accepted, and the intervention type. Intervention types were classified into the following categories: adverse effects, dosing optimization, drug interactions, de-escalation, antimicrobial
coverage, pharmacokinetic (PK) monitoring, proper utilization, and other. Analysis of results included call volume, acceptance rates, intervention types, and average time span per call to evaluate the effectiveness of a pharmacist driven infectious disease call service.

Poster Title: Management of Sickle Cell Pain in the Emergency Department in Adult Sickle Cell Vaso-occlusive Crisis

Primary Author: Zhen Zhang, Memorial Regional Hospital, FL; Email: zzhang@mhs.net

Additional Author(s):
Dina Dumercy
Margaretta Kearson
Carla Hawkins Smith
Jennifer Mourafetis

Purpose: Acute sickle cell vaso-occlusive crisis (VOC) is the hallmark of sickle cell disease (SCD). Pain is the most common reason for sickle cell patient admission to the Emergency Department (ED). The National Institutes of Health (NIH) expert panel suggested pain management should be prompt and individualized among patients with sickle cell disease (SCD). The objective of the study is to evaluate the current pain management in sickle cell VOCs and to identify priority areas of intervention.

Methods: This retrospective single center analysis will be conducted in a tertiary hospital in south Florida. A report of sickle cell VOC admissions will be requested and the electronic medical records will be reviewed. The current management of sickle cell VOCs involves use of intravenous "as requested" (PRN) opioids within a sickle cell order set. Outcome of current sickle cell VOC management will be evaluated and used to identify priority areas for future intervention. Data regarding demographics, pain scale, pain management, appropriate continuation of home medications such as long acting opioids and hydroxyurea will be collected retrospectively. Additionally, inpatient length of stay, pain scale reduction, and 30-day readmission rate will also be described.

**Poster Title:** Effect of clinical pharmacy specialist intervention on metabolic markers in patients receiving long-acting antipsychotic injection therapy

**Primary Author:** Samantha Themis, Memorial Regional Hospital, FL; Email: spthemes@gmail.com

**Additional Author(s):**
Alberto Augsten
Claudia Vicencio
Clara Alvarez Villalba
Madeline Camejo

**Purpose:** Metabolic syndrome is a cluster of symptoms that increases an individual’s risk of developing chronic diseases such as diabetes and cardiovascular disease. Early recognition and management of symptoms can prevent the development of these diseases. The risk for metabolic syndrome is increased in patients with severe mental illness. The purpose of this study is to assess the impact of a clinical pharmacy specialist-managed long-acting antipsychotic injection clinic on metabolic parameters, emergency room visits and hospitalizations. The clinic’s primary design focus is on improving patients’ overall wellness through a collaborative treatment approach.

**Methods:** Patients who currently receive long acting injection antipsychotic therapy by psychiatric providers at the outpatient behavioral health clinic will be referred to the pharmacist-run long acting therapy (LAT) clinic. At the first visit, the clinical pharmacy specialist will collect demographic and medical information including allergies, past medical history and current medications. The patient will have labs ordered, including fasting glucose and a lipid panel, within 1-2 weeks of the initial visit. During each visit, the patient’s vitals will be taken and waist circumference will be measured. In addition, the clinical pharmacy specialist will complete an evaluation and management session. This process will include interviewing the patient and assessing the patient’s understanding of their medication regimen including potential side effects and their lifestyle choices. In addition, the efficacy, response, adherence and side effects will be evaluated using validated scales. The clinical pharmacy specialist will provide education to the patient on any aspect of their medication regimen and/or lifestyle choices as
appropriate. The clinical pharmacy specialist may contact the primary care and/or psychiatric provider to make recommendations regarding the patient’s medication regimen if necessary. All visits will be documented and co-signed by the patient’s psychiatric provider to ensure continuity of care.

Poster Title: Evaluation of fixed dose enoxaparin on safety and efficacy for venous thromboembolism (VTE) prophylaxis in acutely ill morbidly obese patients: A retrospective analysis.

Primary Author: Pamela Ijeoma, Memorial Regional Hospital, FL; Email: pamela1.ijeoma@gmail.com

Additional Author (s):
Simon Leung
Charmaine Wilson
Carla Hawkins

Purpose: Morbid obesity, defined as body mass index (BMI) greater than 40 kg/m2, is associated with a two-fold risk of developing venous thromboembolism (VTE). Morbidly obese patients have been underrepresented in all VTE prophylaxis clinical trials. Consequently, there is limited data to assess appropriate low molecular weight heparin (LMWH) dosing for VTE prophylaxis in acutely-ill morbidly obese patients. Fixed dose LMWH may not provide ideal VTE prophylaxis in morbidly obese patients. The objectives of this study are to assess hospital acquired VTE rates and clinical outcomes of morbidly obese patients receiving enoxaparin 40 mg subcutaneously (SQ) once daily for VTE prophylaxis.

Methods: This is a retrospective chart review conducted on all morbidly obese patients admitted to a community based, 800-bed hospital from July 1, 2015 to July 1, 2016. The study will begin once institutional review board approval is received. The study population will be limited to inpatients with BMI greater than 40 kg/m2, with a length of stay greater than 48 hours, who received VTE prophylaxis with enoxaparin 40 mg SQ once daily. Exclusion criteria include renal impairment defined as creatinine clearance less than 30mL/min using Cockcroft-Gault equation adjusted for lean body weight, therapeutic anticoagulation on admission, active bleeding on admission, platelet count less than 100,000 per microliter, active cancer, known hypersensitivity to unfractionated heparin or LMWH, thrombophillic disorders, admission under trauma or surgical services and patients with VTE diagnosis on admission. The endpoints of this study include hospital acquired VTE rates and incidence of bleeding. Based on previous literature, the VTE incidence rates for prophylaxis and placebo in medically ill non-obese
patients are 5.5 and 14.9 percent, respectively. We can assume the incidence of VTE in obese patients is at least twice that of the general population. Assuming an attrition rate not to exceed 20 percent, a sample size of 200 will be required to achieve 80 percent power, with an alpha level equal to 0.05. Descriptive statistics will be used to analyze the data.

Poster Title: Impact of pharmacist-facilitated multidisciplinary approach to accelerate prior authorization times for high cost specialty medications to assist in transition of care

Primary Author: Levi Morris, Memorial Regional Hospital, FL; Email: rx.levimorris@gmail.com

Additional Author(s):
Madeline Camejo
Marlaine Mance
Sheila Ader
Carla Hawkins Smith

Purpose: The discovery of human genome mapping has paved the way to new drugs tailored to specific patient populations. The research and development process associated with these medications often leads to a higher cost. The unavailability of generics also equates to higher drug acquisition costs for these medications. Insurance companies may cover the costs of medications, but unaffordable co-payments may remain. This may result in delayed treatment or prescription abandonment. The purpose of this study is to evaluate prior authorization time, co-payment costs, and patient’s access to specialty prescriptions when a pharmacist is an integral part of the prior authorization process.

Methods: Pharmacists play an integral role in treatment recommendations and disease management for cardiac patients. Cardiology-trained pharmacists in both the inpatient and outpatient setting are involved in the prior authorization process when a cardiologist have identified patients as candidates for specialty medications through the use of diagnosis specific guidelines. During admission or once discharged patients may be referred to the cardiac clinic for treatment or follow up care. During the clinic visit, the cardiologist may decide to place a patient on a medication which requires patient enrollment, consent and/or prior authorization. The cardiac clinic is a unique facility that has a cardiology-trained pharmacist in place to process prior authorizations. Information often needed to complete enrollment and /or prior authorization includes demographic information, insurance information, diagnosis, and previously trialed and failed medications. Data will be collected by utilizing monthly Epic reports. Information from these reports will identify patients newly initiated on specialty medications. Identified patients insurance information will be recorded. Other recorded
information includes time to completion of prior authorization, supplemental information required for prior authorization, co-payment, and hospital readmission. A telephone interview will be conducted with readmitted patients to identify potential obstacles to medication access and adherence. Patients unable to afford their medication will be evaluated for enrollment eligibility in patient assistance programs or foundation grant access.

**Poster Title:** Pharmacists’ evaluation of surgical site infections (SSI) and antimicrobial stewardship: A retrospective quality analysis

**Primary Author:** Bradley Rogers, Memorial Regional Hospital, FL; **Email:** brogers@mhs.net

**Additional Author(s):**
Corey Frederick
Margaretta Kearson
Carla Hawkins Smith

**Purpose:** Surgical site infections (SSIs) occur in approximately 2% of all surgical procedures and account for 20% of all healthcare-associated infections (HAI). A diagnosis of a SSI extends a patient’s length of stay approximately 9 days and increases healthcare costs by approximately $20,000 per admission. SSIs most often occur within 30 days of procedure between post-operative days five and ten. The primary objective of this study is to evaluate trends and risk factors for patients diagnosed with SSI within 30 days of surgery.

**Methods:** This study is a retrospective quality analysis of patients who developed a SSI following a surgical procedure. A list of patients classified with a SSI within 30 days following surgery will be generated from a hospital database. Parameters to be analyzed include: type of surgical procedure, antibiotic selection, timing of dose prior to procedure, completion of antibiotics within 24 hours of anesthesia end time, intra-operative re-dosing, colonization with microorganisms, age, diabetes, smoking, steroid use, malnutrition, obesity, and length of preoperative stay.

Poster Title: Impact of a standardized methadone weaning protocol and withdrawal assessment tool for iatrogenic opiate withdrawal in pediatric patients

Primary Author: Ryan Walters, Memorial Regional Hospital/ Joe DiMaggio Children's Hospital, FL; Email: rwalters@mhs.net

Additional Author (s):
Michael Izquierdo
Juan Carlos Rodriguez
Joanie Spiro Stevens
Leyner Martinez

Purpose: Pediatric patients exposed to long-term opiate infusions are at risk of developing iatrogenic opioid dependence and withdrawal symptoms, potentially increasing patient morbidity and increasing intensive care unit length of stay. Methadone is an ideal weaning agent due to its long half-life and high oral bioavailability and has been used extensively at our institution for weaning. Lack of a standardized protocol resulted in variability in methadone dose and therapy duration. The purpose of this study is to quantify the impact of a standardized methadone weaning protocol and implementation of a validated withdrawal assessment tool on weaning duration and incidence of withdrawal.

Methods: This study will be submitted to the institutional review board for approval. A standardized methadone weaning protocol was developed and implemented as an order set in the electronic health record (EHR) to maximize adherence to the protocol. This protocol was developed at a 224 bed free standing community children’s hospital, for use in pediatric intensive care unit patients. Additionally, the withdrawal assessment tool (WAT-1), a validated scoring tool for evaluating iatrogenic withdrawal in pediatric patients, will be implemented to objectively assess withdrawal symptoms during methadone treatment. Patients who were exposed to morphine or fentanyl continuous infusions greater than 5 days and have no baseline neurological deficit or methadone intolerance will be included in the study population. Investigators will retrospectively review outcomes for pediatric patients who have been prescribed methadone for weaning opiate infusions pre and post protocol implementation. The outcome of the protocol will be evaluated by comparing total number of days on methadone...
and number of morphine bolus doses administered for withdrawal symptoms pre and post implementation. Data will be collected by running EHR usage reports to identify patients on the methadone protocol. The following will be collected post protocol implementation and will be compared to available data prior to protocol implementation; duration of methadone exposure, administration of morphine boluses for withdrawal, WAT-1 scores and concomitant sedative administration.

Poster Title: Evaluation of physician-led oral chemotherapy management within a large health-systems outpatient cancer center

Primary Author: Racquel Reese, Memorial Regional Hospital/Memorial Cancer Institute, FL; Email: racquelreese@gmail.com

Additional Author(s):
Shanada Thomas
Irene Borrero
Dina Dumercy
Jorge Garcia

Purpose: The use of oral chemotherapy has increased over the past decade. It is estimated that more than 25 percent of the antineoplastic agents in development will be orally administered. The oral route of chemotherapy administration is desirable to patients due to ease of administration and potentially fewer office visits. However, safety issues exist, such as limited resources to monitor adherence and toxicity. The primary objective of this study is to evaluate the current practice of primarily physician-led management of oral chemotherapy based on prescribing recommendations and published guidelines and identify whether gaps in care exist that could impact patient outcomes.

Methods: This analysis is a retrospective chart review that will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients who received an oral antineoplastic medication for a minimum of three consecutive months between January 1, 2015 and June 30, 2016. Prescriptions must be written by an institution-employed oncologist. Patients will be included if they are at least 18 years of age and receiving oral chemotherapy for an oncology indication. Patients will be excluded if they are younger than 18 years of age, have orders prescribed for a non-oncology indication, are a bone marrow transplant recipient, are taking hormonal therapies or medications that are part of a risk evaluation and mitigation strategies program. A report will be generated utilizing the electronic medical record system. An excel spreadsheet will be created to store de-identified information. Patient demographic information will be assessed and the following data will be collected and evaluated: indication, dosing, administration instructions, appropriate labs, frequency of
monitoring, dose adjustments, major drug interactions, toxicities, documented patient education and informed consent, and adherence to follow-up appointments. Data will be analyzed using descriptive statistics.

Poster Title: Retrospective evaluation of inpatient to home health care (HHC) carbapenem transition after computerized process restructure in a community hospital

Primary Author: Beatriz Hernandez, Mercy Hospital, a campus of Plantation General Hospital, FL; Email: beatriz.hernandez3@hcahealthcare.com

Additional Author(s):
Janelle Berg
Marta Benitez
John Lamarque

Purpose: Patients receiving meropenem, who require continued treatment at home, are switched to ertapenem for its once daily dosing convenience. A HHC criteria for patient transition is to give one dose of ertapenem while the patient is hospitalized. However, patients may receive more than one dose, especially if their discharge is held. As a result, ertapenem use has increased steadily over the past year. The clinical manager and informatics pharmacist implemented an order strategy to help avoid unnecessary ertapenem utilization. The objective of this study is to assess the impact of the newly implemented process for patients transitioning to HHC.

Methods: This process evaluation will be submitted to the institutional review board (IRB) for approval. A retrospective chart review will be performed using the electronic medical record (EMR). Patient data will be censored and will be recorded without identifiers. A data inquiry will be requested and generated for the inclusion of patients in this study. Inclusion criteria: patients 18 years and older, admitted during the second or third quarter of 2016, transitioned to HHC, who received at least one dose of ertapenem. Exclusion criteria: patients not discharged on ertapenem to HHC. The following data will be collected for each quarter: number of ertapenem patients discharged to HHC, total number of ertapenem doses administered to these patients, number of patients discharged to HHC who received more than one ertapenem dose and total number of unnecessary ertapenem doses. In addition, the number of times the new order strategy was used will be collected for the third quarter. Appropriate statistics will be used to analyze the information. For the study period the number of unnecessary ertapenem doses given before and after the implementation of the new process will be
translated to a monetary value. The primary outcome measure will be the change in ertapenem doses utilized from the second to the third quarter.

Poster Title: The utilization of icatibant in treating angiotensin-converting enzyme inhibitor (ACE-inhibitor) induced angioedema

Primary Author: Marie Barnicoat, n/a, FL; Email: mbarnico@gmail.com

Additional Author(s):
Shelby Gaudet

Purpose: This case series illustrates the utilization of icatibant to treat angiotensin-converting enzyme inhibitor (ACE inhibitor) induced angioedema at a community based hospital between December 2015 through November 2016. Patient 1 is a 62 year old African-American female with a past medical history significant for hypertension, gout, and atrial fibrillation who presented with angioedema. At the time of admission she was on hypertension therapy with lisinopril/hydrochlorothiazide 20/12.5 mg daily. In the emergency room, she was given single doses of famotidine 20 mg IV, methylprednisolone 125 mg IV and diphenhydramine 50 mg IV. The patient had little improvement in her condition after one hour. She was then given a subcutaneous injection of 30mg of icatibant. A documented improvement in edema occurred 20 minutes after administration. The patient was then admitted to the intensive care unit for monitoring and was continued on oral diphenhydramine and intravenous methylprednisolone. Patient had no further documented incident or complications and was discharged from the hospital after a one day stay.

Patient 2 is a 56 year old Caucasian male with a past medical history significant for atrial fibrillation, chronic obstructive pulmonary disease, hypertension, hyperlipidemia who was transferred to our facility with suspected angioedema and/or anaphylaxis. At the time of admission, he was on hypertension therapy with lisinopril 10 mg daily. Prior to transfer, the patient received diphenhydramine 25mg IV, epinephrine 0.3mg IM, famotidine 20mg IV with mild resolution of swelling. Upon arrival to our ED, the patient received a subcutaneous injection of 30mg of icatibant and had marginal, continued improvement in swelling. Patient was admitted to our step down unit for 24 hours of monitoring. Patient had no further documented incident or complications and was discharged from the hospital after a one day stay.
Patient 3 is a 49 year old African-American female with a past medical history significant for hypertension. At the time of admission, her hypertension therapy consisted of lisinopril 20 mg daily and hydrochlorothiazide 25 mg daily. In the emergency room, she was given single doses of diphenhydramine 25 mg IV, famotidine 20 mg IV, methylprednisolone 125 mg IV, glycopyrrolate 0.2 mg IV. She was then given a subcutaneous injection of 30mg of icatibant. Patient was admitted and placed in PCU for 24 hours of monitoring and was continued on methylprednisolone 60 mg IV q 6 hours, diphenhydramine 50 mg IV q 6 hours, and famotidine 20 mg IV. Patient had no further documented incident or complications and was discharged from the hospital after a one day stay.

Patient 4 is a 53 year old African American male with a past medical history significant for hypertension and schizophrenia. Patient presented to the ED with complaint of facial and throat swelling which began a day prior to admission. Upon admission, the patient’s hypertension therapy consisted of lisinopril 40 mg daily, amlodipine 5 mg daily. In the emergency room, patient received methylprednisolone 125 mg IV once, famotidine 20 mg IV, diphenhydramine 50 mg IV, hydralazine 10mg IV. Patient received icatibant 30 mg SQ which resulted in a significant relief of symptoms shortly after. Patient had no further documented incident or complications and was discharged directly from ED department after a 2 hour ED admission.

Data collection is ongoing and future utilization will be included in final case series presentation. Overall, from this evaluation the use of icatibant at our facility expedited the time of resolution of symptoms and decreased our length of stay from angiotensin-converting enzyme inhibitor (ACE inhibitor) induced angioedema compared to standard therapy.

Poster Title: Incidence of hyponatremia with the use of vasopressin in pediatric patients with shock

Primary Author: Nian Chang, Nicklaus Children's Hospital, FL; Email: nian.chang@mch.com

Additional Author(s):
Helen Lee
Sharineen Roy
Amber Taylor
Weize Wang

Purpose: Vasopressin is used to help manage severe hypotension in patients with vasodilatory shock as adjunct therapy with catecholamines and for refractory shock. Consequently, a potential serious adverse effect of vasopressin is retention of free water followed by a decrease in serum sodium levels. Vasopressin has a low volume of distribution. Therefore, higher incidences of hyponatremia are expected in pediatric patients and underweight adults. The purpose of this study is to review the incidence of hyponatremia in pediatric patients admitted to the cardiac, neonatal, and pediatric intensive care unit (ICU) with vasodilatory shock following administration of vasopressin.

Methods: The study protocol has been approved by the Institutional Review Board. This will be a retrospective evaluation of pediatric patients who received vasopressin in an intensive care setting within a four-year timeframe. The Research Analytics and Data team at Miami Children’s Research Institute will search the electronic data warehouse for patients who were diagnosed with an ICD 9 or 10 code for shock. Using the electronic medical record system, baseline characteristics of the following will be collected: age, gender, weight, and height. Serum sodium concentrations will be noted as follows: baseline, lowest level during therapy, and at 6 hours, 12 hours, and 24 hours after discontinuation of vasopressin. Serum sodium levels less than 135 mEq/L will be classified as hyponatremia, and severe hyponatremia will be classified as levels less than 130 mEq/L. Serum sodium levels before and during vasopressin therapy will be compared. The medication administration record will be reviewed to determine a relationship between incidence of hyponatremia and dose of vasopressin or length of treatment at the time of lowest sodium level. All recorded data will be de-identified to protect patient confidentiality.

Poster Title: Development of transitions of care pharmacist services for high-risk medical patients in a tertiary community hospital discharge unit

Primary Author: Paul Boylan, Nova Southeastern University College of Pharmacy, FL; Email: pboylran@nova.edu

Additional Author(s):
Sara Eltaki
Margaretta Kearson
Madeline Camejo

Purpose: The Centers for Medicare and Medicaid Services implemented the Hospital Readmissions Reduction Program to incentivize institutions to reduce preventable readmissions by implementing payment penalties if indexes exceed national rates. National average 30-day readmission rates for high-risk conditions, including pneumonia, heart failure, chronic obstructive pulmonary disease, and acute myocardial infarction are approximately 20%. Similar rates are observed within a large, acute care facility in South Florida. The purpose of this project is to implement a pharmacist-driven transitions of care (ToC) service in a discharge unit for high-risk patients and to improve readmission rates.

Methods: An interdisciplinary team of stakeholders, including pharmacy administration, nursing management, clinical effectiveness supervisors, and a PGY-2 ToC resident, collaborated in July 2016 to institute programs and processes to reduce preventable readmissions. High-risk Medicare beneficiary admissions were captured for fiscal year 2015 – 2016. During this time, 670 patients were admitted and 120 of those patients with the previously-specified medical conditions were readmitted with 30-days of discharge. Previous workflow involved discharging patients from various medical and surgical units throughout the hospital. Case management was the primary service who provided post-discharge telemanagement. The team of stakeholders determined that pharmacist services, including discharge medication counseling and telemanagement, were underutilized.

Results: A pharmacist-driven, interdisciplinary ToC service was developed in order to triage and coordinate high-risk patients’ discharge. Health information technologies and electronic
medical record systems were developed to identify subjects at risk for readmission. In the discharge unit, subjects meet with a pharmacist who performs medication reconciliation, offers pharmacotherapeutic counseling, ensures post-discharge medication access, facilitates pill box planning, and arranges follow-up provider appointments. Verbal and written education is subject specific. Within 72 hours following discharge, the pharmacist provides telemanaged care to the subject at home. Pharmacist-driven ToC interventions continue for 30 days following discharge.

**Conclusion:** Project investigators and key project stakeholders established a pharmacist-driven discharge service by means of interdisciplinary collaboration. Continuous quality improvement analysis evaluates both the successes and areas for improvement of this program. With the implementation of the program, there is an expectation for high-risk readmissions to decrease. Additional interdisciplinary education is necessary for continuity of the program.

Poster Title: An evaluation of the initiation and use of sacubitril/valsartan in an inpatient heart failure population: A retrospective observational study

Primary Author: Tara Kuhn, Palm Beach Atlantic University, FL; Email: kuhn.tara2@gmail.com

Additional Author(s):
Krisy Thornby
Victoria Scott
Robert Thornby
Amy Henneman

Purpose: Sacubitril/valsartan, an angiotensin receptor-neprilysin inhibitor, was found to be superior to enalapril in reducing the risks of death and hospitalization for heart failure in the PARADIGM-HF study. This novel therapy has currently only been studied in the outpatient setting and only 0.7% of patients were classified as NYHA class IV and < 25% NYHA class III. Although only patients in the outpatient setting were included in the pivotal trial, institutions may receive formulary requests for maintenance/initiation of therapy. The objective of this study was to determine if sacubitril/valsartan has a potential role in heart failure management in the inpatient setting.

Methods: This study was approved by the Palm Beach Atlantic University Institutional Review Board. A retrospective observational study was performed via electronic chart review of all patients with a primary diagnosis of heart failure from two community hospitals (327 & 233 beds). The study outcome was number of hospitalized heart failure patients that would be appropriate candidates for initiation of sacubitril/valsartan therapy based upon drug labeling, guidance from the ACC/AHA/HFSA focused update on new pharmacologic therapy for heart failure, and inclusion criteria from the PARADIGM-HF study. Statistical significance was determined using Chi Square Test of Proportions. Secondary outcomes include number of patients with an order for sacubitril/valsartan who were appropriate candidates, number of patients with an order for sacubitril/valsartan who were not appropriate candidates, readmission within 90 days, length of stay, NYHA classification, compliance with 36-hour washout period for patients maintained on an ACE inhibitor, and number of patients who received a dose of sacubitril/valsartan while in the hospital.
Results: N/A

Conclusion: N/A
Purpose: Mental health disorders are difficult to treat and include avoidance of undesirable side effects when selecting an appropriate antipsychotic agent. Second generation antipsychotics are more frequently prescribed than first-generation due to perceived improved tolerability. However, some second generation antipsychotics have been associated with metabolic side effects such as weight gain, increase in lipids, blood glucose and hypertension. Pharmacist-provided comprehensive medication management for psychiatric patients has been shown to be cost saving and beneficial for patients. The objective of this feasibility study is to determine the utility of a pharmacist managed metabolic syndrome clinic for indigent patients on second generation antipsychotics.

Methods: This study has been approved by the Palm Beach Atlantic University Internal Revenue Board. This is a pilot study conducted at the Community Health Center; a free clinic that serves the indigent population of West Palm Beach, FL. Beginning September 2016 patients at the Community Health Center scheduled to be seen by the clinic’s psychiatrist or mental health counselor or managed on antipsychotic medications will be screened for metabolic risk factors. Risk factors include hemoglobin A1C (HbA1C), random blood glucose, weight and blood pressure by point of care testing or from patient charts. Patients with risk factors for metabolic syndrome will be referred to the pharmacist managed clinic at the Community Health Center. The pharmacist will review each patient’s current regimen and make recommendations for medication management. Pharmacological and lifestyle interventions will be made as necessary for risk factor management. The number of interventions made by the pharmacist will be
analyzed to determine the feasibility of a pharmacist managed metabolic syndrome clinic. The primary outcome of this study will be the number of interventions made. Secondary outcome will be the number of pharmacological and nonpharmacological interventions. A chi square series will be used to analyze data for both primary and secondary outcomes.

Poster Title: Implementation of a diabetic ketoacidosis and hyperosmolar hyperglycemic state protocol via computerized prescriber order entry (CPOE) in an acute care community hospital
Primary Author: Mercedes Fraga, Palmetto General Hospital, FL; Email: mbertot1@yahoo.com
Additional Author(s): Daphne Zeilinger
Mary Ibarra Diaz
Diana Reyes

Purpose: Diabetic Ketoacidosis (DKA) and Hyperosmolar Hyperglycemic State (HHS) are serious complications of diabetes mellitus associated with morbidity and mortality. DKA presentation includes uncontrolled hyperglycemia, metabolic acidosis, and increased ketone concentration. HHS is associated with severe hyperglycemia and hyperosmolality in the absence of ketoacidosis. Rapid and appropriate management of these emergencies is vital to improve patient outcomes and decrease mortality. Implementation of a disease specific protocol has been shown to significantly improve the management of DKA and HHS. The purpose of this study is to develop and implement a diabetic ketoacidosis and hyperosmolar hyperglycemic state protocol via computerized prescriber entry (CPOE).

Methods: Study will consist of a retrospective and prospective evaluation of patients admitted for the treatment of DKA and HHS. Patients admitted as a result of DKA and HHS will be identified using Cerner Millennium, an electronic medical record system. Appropriate and timely fluid replacement, correction of electrolyte imbalances, resolution of metabolic acidosis, and length of stay will be compared.

**Additional Author(s):**  
Mercedes Fraga  
Daphne Zeilinger  
Mary Ibarra-Diaz  

**Purpose:** Most patients who are discharged from an intensive care unit (ICU) recall unrelieved pain and anxiety as a prevailing experience during their ICU stay. In addition, the Joint Commission requires organizations to establish policies regarding proper pain assessment and treatment. The methods used to determine a patient’s level of pain, agitation, and presence of delirium are the Critical Care Pain Observation Tool (CPOT), Richmond Agitation Sedation Scale (RASS), and Confusion Assessment Method for the ICU (CAM-ICU), respectively. The purpose of this study is to evaluate the compliance and effectiveness of a pain, agitation, and delirium protocol implemented in an ICU.

**Methods:** This study will consist of two phases: Phase I will include a retrospective review of data collected prior to a pharmacist intervention, while Phase II will consist of a prospective review by a pharmacist. The primary outcome is to assess the compliance of a pain, agitation, and delirium protocol in the ICU. Secondary outcomes will evaluate ICU length of stay and risk factors for patients with acquired delirium during ICU stay.

Poster Title: Impact of matrix assisted laser desorption ionization time of flight mass spectrometry (MALDI-TOF MS) and antimicrobial stewardship on patient outcomes

Primary Author: Daniel Diaz, Palmetto General Hospital, FL; Email: danieldiaz06@gmail.com

Additional Author(s):
Mercedes Fraga
Daphne Zeilinger
Mary Ibarra-Diaz

Purpose: Matrix assisted laser desorption ionization time of flight mass spectrometry (MALDI-TOF MS) has allowed efficient and rapid identification of organisms. Compared to conventional techniques, MALDI-TOF MS has higher output and improvements in turnaround time and patient outcomes. Implementation of rapid identification techniques as part of antimicrobial stewardship has been shown to significantly improve time to optimal therapy and reduce hospital length of stay and total cost. The purpose of this study is to reduce time to optimal antibiotic therapy and length of stay in critical care units.

Methods: This study will consist of two phases. Phase I will include a retrospective review of patients empirically treated in critical care. Phase II will consist of a prospective assessment of MALDI-TOF MS utilization and real time antimicrobial stewardship intervention. Time of first appropriate antibiotic de-escalation dose, total time of antimicrobial therapy, and length of stay in critical care will be compared.

Poster Title: Implementation of a pharmacist-driven vancomycin dosing nomogram in hospitalized patients

Primary Author: Adam Harnden, PGY-1 Adult Sacred Heart Hospital Residency Program, FL; Email: adam.harnden@shhpens.org

Additional Author(s):
Lisa Scott

Purpose: Vancomycin requires careful dosing and monitoring to achieve therapeutic concentrations and avoid potential side effects such as nephrotoxicity and bacterial resistance. Prior to this study, vancomycin was dosed per pharmacists by a variety of methods at Sacred Heart Hospital. A vancomycin dosing nomogram and pharmacokinetic calculator were developed with the aim to standardize pharmacist dosing of vancomycin and increase percentage of patients achieving therapeutic troughs. The objective of this study is to evaluate the outcomes of implementation of a vancomycin dosing nomogram and pharmacokinetic calculator at a community hospital.

Methods: This study consists of analysis of patient outcomes prior to and after the implementation of a vancomycin nomogram and pharmacokinetic calculator. The primary outcome is percentage of patients with a steady state trough within a predetermined acceptable therapeutic range. The secondary outcome examines percentage of patients with therapeutic drug levels corresponding with dose regimens from the nomogram. A retrospective chart review was conducted on all adult patients who received at least three doses of vancomycin and had a level drawn. Patients are excluded if they were pregnant, had cystic fibrosis, or unstable renal function. Data collected included patient demographics, renal function, vancomycin administrations, and vancomycin drug levels. A comparative evaluation and statistical analysis will be made between the two cohorts.

Poster Title: Development and implementation of a chemotherapy induced nausea and vomiting protocol in a pediatric population

Primary Author: Quianna Harris, Sacred Heart Health System, FL; Email: quianna.harris@shhpens.org

Additional Author (s):
Chenita Carter
Jeffrey Schwartz

Purpose: Chemotherapy induced nausea and vomiting (CINV) can be an issue for pediatric patients experiencing the noxious therapy. Implementing a guideline-based CINV protocol that accounts for a regimen’s emetogenic potential and uses patient characteristics and condition is ideal. Evaluating the institution’s current chemotherapy orders presented the opportunity for enhancement. The Joint Commission Medication Management Standards and The Children’s Oncology Group (COG) Guideline on Prevention of Nausea and Vomiting due to Antineoplastic Medication in Pediatric Cancer Patients present valuable information on creating proper protocols. This project was designed to improve patient care, enhance patient safety, and become complaint with Joint Commission standards.

Methods: A medical team consisting of a pharmacy resident, pharmacist, and oncologist at a pediatric hospital will collaborate to change the current chemotherapy order sets by incorporating a standardized chemotherapy induced nausea and vomiting (CINV) protocol. Changes will be made based on The Children’s Oncology Group (COG) Guideline on Prevention of Nausea and Vomiting due to Antineoplastic Medication in Pediatric Cancer Patients, Joint Commission Medication Management Standards, and other pertinent research. Additionally, the use of a standard nausea scale to determine the severity of nausea will also contribute to improving patient care. Nurses will be assessed before and after implementing the new chemotherapy order sets using a survey on the ease of executing orders. The finished protocol will be submitted to the Pharmacy and Therapeutics (P&T) committee at the hospital for review and approval.

**Poster Title:** Assessing the Use of Stress Ulcer Prophylaxis in ICU Patients in a Community Hospital

**Primary Author:** Andrew Molinaro, Sacred Heart Hospital, FL; **Email:** andy.molinaro1@gmail.com

**Additional Author (s):**

**Purpose:** The use of stress ulcer prophylaxis in the intensive care unit population is common practice. The pharmacist has identified multiple patients who did not meet criteria to be on any type of stress ulcer prophylaxis during their stay in the ICU. The addition of unnecessary medications adds costs to the patient and to the hospital and takes time away from the pharmacist. The potential for drug interactions and side effects also increases when the patient is on additional medications. This drug-use evaluation was designed to gather objective data on the use of these medications in an ICU population.

**Methods:** The pharmacist will evaluate the drugs of all of the patients on two intensive care unit floors in the community hospital. Using updated guidelines in regards to stress ulcer prophylaxis, the pharmacist will collect information on each of the patients currently on a proton-pump inhibitor or H2-receptor antagonist. The patients who are on these medications will be assessed as to whether or not they have a proper indication to be on these medications according to the guidelines. This information will then be collected and documented accordingly in order to gather objective data on the use of these medications and if their use is warranted. A cost-savings analysis will then be performed. Using the information gathered, the pharmacist will then analyze the data to see if a new pharmacist protocol may be warranted in regards to the overuse of these medications.

Poster Title: Development and implementation of a pharmacy-driven HIV medication reconciliation process

Primary Author: Mike Turk, Sarasota Memorial Health Care System, FL; Email: john-turk@smh.com

Additional Author (s):
Lauryn Gazzia
Jamie Kisgen

Purpose: Medication reconciliation errors committed during transitions of care for HIV patients are well-described in the literature, with lack of pharmacist comfort with HIV medications cited as one of many reasons. Literature shows that Involving pharmacists with the medication reconciliation process has been shown to significantly lower these errors in the general patient population, and it further suggests that the most effective HIV-specific medication reconciliation interventions included pharmacists with training in infectious disease. Combining pharmacy-driven medication reconciliation along with pharmacy staff education targeting HIV therapy addresses both of these deficiencies in order to effectively reduce medication reconciliation errors.

Methods: A medication reconciliation process for HIV patients was implemented at an 819-bed community hospital in October 2016. This process targeted all admitted HIV patients at least eighteen years of age and with projected length of stay greater than forty-eight hours. As part of this process, pharmacy staff received education in HIV therapy. After implementation, a convenience sample of all patients admitted over a five-month period is to be analyzed by retrospective chart review. IRB approval will be obtained prior to data collection. Based on historical data, it is expected that a minimum of fifty patients will be included in this sample. Data to be collected includes patient demographics, number of medication reconciliations performed, number of HIV patients with an error requiring an intervention by a pharmacist, number of pharmacist interventions required, error types identified by pharmacists, and pharmacist time required to complete the medication reconciliation process. The primary outcome is the percent of HIV patients with an error requiring pharmacist intervention. Secondary outcomes include the number of pharmacist interventions required, the percentage
of HIV patients who received a medication reconciliation within 48 hours, the number and types of errors identified, time from admission to completion of the medication reconciliation, time from order entry to order correction, and length of time pharmacists dedicate to this process. Data will be analyzed by using descriptive statistics.

Poster Title: Implementation of Institute for Safe Medication Practices recommendations to prevent medication misadventures in hospitalized patients with Parkinson's disease

Primary Author: Frank Gentile, Sarasota Memorial Hospital, FL; Email: frank-gentile@smh.com

Additional Author(s):
Amy Giovino
Ashley Nazareno
Dean Sutherland

Purpose: Patients with Parkinson's disease (PD) rely on timely administration of their medications in order to lessen symptoms of tremor, rigidity, bradykinesia, and postural instability, and allow them to perform activities of daily living. While hospitalized, standard medication administration times often do not meet the needs of these patients. Additionally, some medications that are contraindicated in PD do not alert prescribers to potential harmful effects when ordered. The objectives of this study are to provide timely administration of PD medications and prevent inappropriate prescribing of contraindicated medications by implementing the pharmacy practice recommendations published by the Institute for Safe Medication Practices.

Methods: Institutional Review Board approval will be obtained prior to data collection. A retrospective chart review will be performed for all inpatients in the month of February 2016 and compared with the post-implementation group of February 2017. The three strategies being implemented are custom designed administration times for select Parkinson's disease (PD) medications, alerts for drug-disease state interactions in the computerized provider order entry (CPOE) system, and focused education provided to nursing and pharmacy staff. The primary outcome is a composite endpoint of number of missed doses and number of contraindicated medications ordered per visit. Other outcomes that will be assessed include reasons for missed doses, percentage of doses given late and number of contraindicated medications administered.

Poster Title: Pharmacy implementation of United States Pharmacopeia (USP) chapter in a large community hospital

Primary Author: Gary Houchard, Sarasota Memorial Hospital, FL; Email: gary-houchard@smh.com

Additional Author(s): Pam Lewis
Lisa Hymel
Rebecca Kisgen
Sandra Prenosil

Purpose: The risks associated with handling hazardous drugs have long been a concern in healthcare; however, published safety recommendations have not been universally adopted. United States Pharmacopoeia (USP) Chapter < 800> becomes effective July 1, 2018 and contains federally enforceable standards intended to create a safer working environment for personnel who handle these drugs. Although hazardous drug policies and procedures are currently in place at our institution, they do not meet all USP < 800> requirements. The objective of this project is to increase our compliance, focusing on the standards related to pharmacy practice.

Methods: This project, which is designed as a process improvement initiative, received Investigational Review Board exemption status. A gap analysis was performed to determine the hospital’s current compliance to USP < 800> requirements. Following completion of the gap analysis, a determination was made to address areas of non-compliance in phases, focusing on pharmacy-specific standards first. An inventory list of all hazardous drugs on formulary was then created which will be further classified and categorized according to the published recommendations from NIOSH (National Institute for Occupational Safety and Health). A risk assessment will be completed on select non-antineoplastic drugs to determine the risk of exposure through normal handling and use, based on the type of hazardous drug, dosage form, packaging, and manipulation, as defined by USP < 800>. Current hospital policies will then be revised to more clearly define the requirements for receipt, storage, manipulation, transportation, deactivation/decontamination, waste management, personal protective
equipment, and other factors related to the handling of each category of hazardous drug. Finally, pharmacy and nursing staff will be educated on the revised hazardous drug policies and procedures through interactive online modules and live presentations.

**Poster Title:** Implementation of a procalcitonin algorithm to reduce length of antimicrobial therapy in trauma intensive care unit patients

**Primary Author:** Raina Lad, Sarasota Memorial Hospital, FL; **Email:** raina-lad@smh.com

**Additional Author(s):**
Kirsten Busey
Eileen Shomo
Andre McMahon
Jamie Kisgen

**Purpose:** Procalcitonin (PCT) is a precursor to calcitonin that is produced by the C cells of the thyroid gland. PCT levels increase and decrease with the onset and resolution of bacterial infections, making it a useful biomarker in patients with suspected sepsis. PCT guided antibiotic de-escalation has been well studied in critically ill patients; however, data regarding the use of PCT in the trauma intensive care unit (ICU) is limited. The purpose of this study is to evaluate the impact of a PCT guided algorithm on antimicrobial use in trauma ICU patients with suspected sepsis.

**Methods:** This study will be submitted to the Institutional Review Board for approval prior to data collection. This retrospective study will compare pre and post-algorithm implementation patient groups. The primary outcome is length of antimicrobial therapy in trauma ICU patients with suspected sepsis. Secondary outcomes include hospital and trauma ICU length of stay. The electronic medical record and Trauma Registry will be used to identify patients who are admitted to the trauma ICU, meet sepsis criteria during admission, and receive antibiotics for at least 48 hours. Patients are excluded if they are neutropenic, immunosuppressed, given antibiotics for surgical prophylaxis, or diagnosed with infections that require long-term antimicrobial therapy (e.g. endocarditis, osteomyelitis, Mycobacterium tuberculosis, Pneumocystis jirovecii, Toxoplasma gondii). Patients in the post-algorithm implementation group must have at least one baseline and one follow-up PCT level appropriately drawn. Data collected will include the following: baseline demographics, length of stay, acute physiology and chronic health evaluation (APACHE) IV score, diagnosis, white blood cell count, blood urea nitrogen, temperature, serum creatinine, microbiology data, antibiotic(s) used, and duration of

**Poster Title:** Development and implementation of a vancomycin area under the curve/minimum inhibitory concentration ratio calculator and dosing protocol at a large community hospital

**Primary Author:** Megan Seddon, Sarasota Memorial Hospital, FL; **Email:** megan-seddon@smh.com

**Additional Author(s):**
Kevin Scorgie  
Sara Kutner  
Andre McMahon  
Jamie Kisgen

**Purpose:** The pharmacodynamic parameter that best predicts efficacy of vancomycin for serious Staphylococcus aureus infections is the 24-hour area under the curve/minimum inhibitory concentration (AUC/MIC) ratio. Current guidelines recommend targeting a vancomycin trough between 15-20 mcg/mL in order to achieve the goal AUC/MIC ratio of greater than 400. Recent literature suggests trough concentrations greater than 15 mcg/mL are associated with increased rates of nephrotoxicity and that the target AUC/MIC ratio may be achieved with serum trough levels between 10-15 mcg/mL. In order to improve the accuracy of AUC calculations, a peak-trough vancomycin dosing protocol will be implemented using a spreadsheet-based calculator.

**Methods:** This retrospective observational study will be approved by an institutional review board prior to data collection. A random sample of 100 adult inpatients will be included in the analysis. Inclusion criteria: receipt of pharmacy-dosed vancomycin using the new AUC-dosing method, treatment of moderate-severe infections caused by laboratory-confirmed Staphylococcus aureus for which susceptibility information is available, and at least one appropriately drawn peak and trough vancomycin concentration. Infections of the central nervous system, skin and soft tissue, and urinary tract will be excluded. Data to be collected includes patient demographics, baseline serum creatinine, infection type, vancomycin loading dose, initial maintenance dose, peak and trough vancomycin levels, and bacteria MIC. Ideal body weight, adjusted body weight, creatinine clearance, and area under the concentration-
time curve will be calculated. The primary outcome will be percent of patients who meet the AUC/MIC goal of greater than or equal to 400. Secondary outcomes will include: mean initial trough concentration in patients who meet the AUC/MIC goal compared with those who do not; correlation of two methods of AUC-estimation (previously validated equation vs. new computerized spreadsheet-based calculator method using population parameters) with patient's actual AUC; and percent of patients meeting AUC/MIC goal stratified by initial trough concentrations, age, weight, and indication.

Poster Title: Implementation of a multimodal initiative to decrease intravenous proton-pump inhibitor use in a large community hospital

Primary Author: Conner Mansfield, Sarasota Memorial Hospital, FL; Email: conner-mansfield@smh.com

Additional Author (s):
Anit Legare
Dave Jungst
Kenneth Hurwitz

Purpose: Proton-pump inhibitors (PPIs) are associated with an increased risk of adverse effects such as ventilator associated pneumonia and Clostridium difficile infections. Despite these risks, oral and intravenous (IV) PPIs continue to be used for stress ulcer prophylaxis (SUP) instead of H2 receptor antagonists (H2RAs). Intravenous PPIs cost significantly more than H2RAs and oral PPIs. They also carry additional risks associated with the administration of any IV medication. The use of IV PPIs should be limited to indications where they are preferred to alternative therapies. The objective of this study is to decrease IV PPI use at a large community hospital.

Methods: This study is subject to review by the hospital’s Institutional Review Board. The multimodal initiative will involve the development of a medical-staff approved order set for IV PPIs which requires prescribers to select an indication for using an IV PPI, the removal of IV PPIs from physician-specific order sets, and the education of pharmacy staff on the hospital’s automatic IV to oral conversion protocol. Prescribers will select from three indications when ordering an IV PPI: active gastrointestinal bleed, home medication while nil per os, and “other.” Currently, the hospital’s automatic IV to oral protocol is rarely utilized. It is often difficult for pharmacists to ascertain why an IV PPI was ordered. Attaching indications to IV PPI orders will facilitate pharmacist recognition of orders that are eligible for an IV to oral switch. Adult inpatients who receive at least one dose of an IV PPI using the order set will be included. Patients admitted to the hospital’s trauma or psychiatric services will be excluded. The primary outcome will compare the average duration of IV PPI therapy per 100 patient days during the study period to a historical control. Additional endpoints will include the percentage of IV PPI
orders transitioned to an oral PPI, the percentage of interventions accepted, and the financial impact of the initiative.

Poster Title: The influence of education on practitioners’ comfort in prescribing patient-specific hormonal replacement therapy: A study from the ACO Research Network, Services and Education (ACORN SEED).

Primary Author: Andrea Murzello, SimfaRose Pharmacy, FL; Email: am2059@nova.edu

Additional Author(s):
Cynthia Moreau
Stephanie Gernant

Purpose: Following the publication of the Women’s Health Initiative and its results on the long term risks and benefits of hormone replacement therapy (HRT), prescribing patient specific HRT has decreased. As a result, practitioners may fall into one of three groups in regards to their opinions of HRT: those who have decreased HRT prescribing due to concern from the WHI results, those who continue to prescribe HRT without concern, and those newly graduated who have been rarely exposed to HRT. If education that explained how proper patient-specific HRT could be safely prescribed, then practitioners may be more comfortable with such therapies.

Methods: A pharmacist in post-graduate residency within an independent compounding pharmacy in Southern Florida developed the intervention. The intervention, an in-service education, will be delivered to primary care practitioners within Nova Southeastern University’s practice based research network, The ACO Research Network, Services and Education (ACORN SEED). The in-service will include an introduction to hormonal replacement therapy (HRT), a background to women’s health and cycle changes, and the tools to prescribe. Prescriber participants will be surveyed twice, once immediately before the in-service, and once immediately after. The pre- and post-surveys will evaluate the practitioner’s opinions and comfort in prescribing patient specific HRT. Baseline characteristics of participants, including gender, practice specialty, and previous HRT education exposure will also be collected. The surveys will be further evaluated using descriptive statistics.

Results: Results of this study will be presented at the American Society of Health Systems Pharmacy Midyear 2016 Clinical Meeting.
Conclusion: Results of this study may show how patient-specific hormonal replacement therapy education could improve prescriber’s comfort in such therapies.

Poster Title: Analysis of empiric selection and utilization of vancomycin and piperacillin-tazobactam in the treatment of cellulitis

Primary Author: Michele Rondeau, South Florida Baptist Hospital, FL; Email: michele.rondeau@baycare.org

Additional Author(s):

Purpose: The objective of this study is to evaluate the appropriate empiric selection and utilization of vancomycin and piperacillin-tazobactam for the treatment of cellulitis. The results of this analysis will be used to reinforce the importance of an Antimicrobial Stewardship Program at our institution and to aid in changes in practice in order to improve therapeutic outcomes and decrease the risk for the development of multidrug resistant pathogens.

Methods: An IRB-approved retrospective chart review will be conducted in patients at our institution who received a primary diagnosis of lower extremity cellulitis between July 2014 and July 2016. Included patients must be greater than or equal to 18 years of age and have received the empiric antibiotic regimen consisting of both vancomycin and piperacillin-tazobactam. Patients will be excluded from the analysis if they have also received the diagnosis of a diabetic foot ulcer or have a concomitant infection other than a skin and soft tissue infection (SSTI) requiring the use of broad-spectrum antimicrobials. The first 100 patients meeting study criteria will be included in the evaluation. Data to be collected will include basic patient demographics, presence of systemic inflammatory response criteria, presence of immunosuppression, documentation of failed oral antibiotic therapy, presence of skin sloughing or bullae, history of multidrug resistant infections, and risk factors for methicillin-resistant Staphylococcus aureus infection. The overall appropriateness of the empiric regimen will be evaluated using the most current Infectious Diseases Society of America Practice Guidelines for the Diagnosis and Management of Skin and Soft Tissue Infections.

Poster Title: Assessment of intravenous iron sucrose use at a community-based hospital

Primary Author: Ada Jalice, South Miami Hospital, FL; Email: adaj@baptisthealth.net

Additional Author(s):
Mercedes Frias
Yarelys Garcia

Purpose: The standard of care for iron deficiency anemia is oral iron. Parenteral iron is reserved as first line for pregnant women, dialysis patients, patients who cannot tolerate/absorb oral preparations, or patients with unresolved bleeding. At Baptist Health South Florida (BHSF), an intravenous (IV) iron algorithm has been proposed to streamline the use of IV iron sucrose (Venofer®). This study aims to determine if patients who received Venofer® as first line therapy met the criteria of BHSF’s proposed algorithm, to assess if patients had baseline hemoglobin, transferrin saturation (TSAT), and ferritin levels, and to estimate the cost savings of the algorithm.

Methods: This is a single-centered, retrospective chart review of fifty adult inpatients treated with Venofer® as first line therapy for iron deficiency anemia during June 2016 and approved by BHSF’s Institutional Review Board. An electronic user data access report will be used to identify patients who meet the inclusion criteria. Patients younger than eighteen years of age, patients who were first treated with oral iron supplementation, and outpatients will be excluded from the study. Fifty patients will be selected at random to review their electronic medical records and determine if they were dialysis patients, pregnant women, gastric surgery patients, patients with gastrointestinal (GI) disorders, malabsorption syndromes, blood loss, or not tolerating oral intake. The fifty records will be reviewed to identify how many patients had baseline hemoglobin, TSAT, and ferritin levels. The potential cost savings of using oral iron therapy as first line therapy will then be calculated based on the total cost of Venofer® received by patients who did not meet criteria for first line use of Venofer®.

Poster Title: Evaluating the impact of pharmacist follow-up on discharge medications for stroke and transient ischemic attack patients

Primary Author: Devin Steiner, St. Anthony’s Hospital, FL; Email: devin.steiner@baycare.org

Additional Author (s):
William Braun
Timothy Bach

Purpose: It is recommended by stroke prevention and cholesterol guidelines that most patients with a diagnosis of stroke or transient ischemic attack should be started on aspirin and/or other antithrombotics, and statins. It has been observed in our institution that it is not uncommon for these patients to not be discharged on what medications the neurologists have recommended in their progress notes. When this occurs, patients are at an increased risk for being readmitted for subsequent ischemic events. The purpose of this study is to determine the impact of pharmacist follow-up on discharge medications for stroke or transient ischemic attack patients.

Methods: This study is designed as an observational study. Beginning in August 2016, a pharmacist-led service was introduced at our institution. For this service, pharmacists review the chart of every patient who is discharged with the diagnosis of stroke or transient ischemic attack to determine if the patient was discharged on the medications that the neurologist had recommended. Specifically the pharmacists will be reading progress notes to determine what the recommendation from the neurologists were and if there was any documented reason from the primary physicians that he or she disagreed. If a patient is not discharged on the recommended medications, and the primary physician did not document against the recommendation, follow-up with a physician will performed by the pharmacist. Data from before the implementation of this service will be compared to after its implementation to determine the percentage of patients that were discharged on the neurologists’ desired medications. The study population includes patients that are 18 years old or older who have had an admission during the study period with a diagnosis of a stroke or transient ischemic attack.

**Poster Title:** Evaluation of Clinical Pharmacist to the Post-ED visit Review of Discharge Cultures and Antimicrobial Regimens

**Primary Author:** Alexandria Hatzileris, St. Anthony's Hospital, FL; **Email:** alexandria.hatzileris@baycare.org

**Additional Author (s):**
- William Braun
- Mindy Durkin
- Clinton Holder
- David Ball

**Purpose:** Currently in our emergency department (ED), cultures obtained on discharged patients are reviewed in a central location by registered nursing staff. Current protocols require nursing staff to contact ED physicians for antimicrobial selection and orders. Due to the high work load burden of ED physicians, this often leads to a delay in communication and ultimately delay in treatment. Implementing a pharmacist driven antimicrobial selection protocol, pharmacy would be contacted to determine antimicrobial. By doing so, the hope is to reduce burden of ED physicians, work collaboratively with nursing staff and decrease time to treatment for the patient.

**Methods:** Conduct a retrospective observational study, observing time-to-treatment differences between nurse review of cultures with physician contact for antimicrobial management versus nurse review of cultures with pharmacist driven protocol for uncomplicated antimicrobial management, in discharged adult ED visits from October 2016 to October 2017. Time-to-treatment will be observed at an off-site call center associated with St. Anthony’s Hospital and other BayCare affiliates. Through implementation of a P&T approved, pharmacist driven antimicrobial selection protocol, pharmacists will now be contacted to determine antimicrobial selection for uncomplicated infections, such as urinary tract infections, skin and soft tissue infections and gastrointestinal infections. Pharmacists will then be responsible for ordering the medication and contacting the patient to inform them of culture results and counsel on therapy selected. Physicians will continue to be contacted for critical cultures, including positive blood and sputum cultures and for patients who have developed
additional or worsening symptoms since discharge. The analysis will be conducted to compare the pre- and post-implementation of the pharmacy service. Secondarily, the study will evaluate differences in antibiotic selection. Additionally, the study will evaluate the potential of billing for medication therapy management (MTM) services conducted by the pharmacists.

Poster Title: Evaluation of process efficiency of chemotherapy regimens requiring post-hydration
Primary Author: Kyle Jones, St. Joseph’s Children’s Hospital, FL; Email: kyle.jones@baycare.org
Additional Author(s):
Kimberly Perez
Samantha Schaefer

Purpose: Pediatric cancers place high financial and socioeconomic burdens on patients and their families. It has been observed at our institution that pediatric oncology patients treated with chemotherapy regimens requiring post-hydration may be having extended inpatient length of stays. The primary objective of this study is to examine the inpatient admission in selected patients, determine process changes that can be implemented, and if these changes result in a decrease in extended inpatient stays. Secondary objectives are to perform a cost savings analysis on the process changes implemented and determine the safety of advancing the administration times through a retrospective chart review.

Methods: This prospective/retrospective process improvement study will evaluate the efficiency and length of stay for chemotherapy patient admissions requiring post-hydration fluids at St. Joseph’s Children’s Hospital. A cohort of patients will be identified by their chemotherapy admission and each step of their inpatient process (admission, assessment, treatment initiation) will be timed. Next, a rapid cycle improvement strategy will be utilized to determine what processes in the inpatient admission can be improved. Once the changes have been implemented, identified patients’ charts will be retrospectively reviewed to determine the adherence to the modified processes and the efficacy of the implemented changes to reduce extended inpatient admissions. From there, a cost savings analysis will be utilized to determine the financial impact of modified process. For the retrospective arm of the study, patients who received chemotherapy requiring post-hydration between January 1st 2016 and July 1st 2016 will be identified. These patients’ charts will be reviewed to determine if length of stay was appropriate. The retrospective chart review will also include determining if chemotherapy administration times were advanced. Occurrence of drug specific toxicities communicated to the providers via phone calls, electronic communication, clinic visits, or inpatient readmissions
will be evaluated to determine safety of chemotherapy administration advancement compared to patients who had a normal administration schedule.

Poster Title: Evaluation of the effect of program introduction type in a transitions of care pharmacy program on 30-day hospital readmission

Primary Author: Lauren Briggs, St. Joseph’s Hospital, FL; Email: lauren.briggs@baycare.org

Additional Author(s):
Daryl Miller
Josephine Cheng

Purpose: Successful transitioning of patient care from inpatient to outpatient setting is important for improving patient outcomes and preventing hospital readmissions. BayCare Health System implemented a Transitions of Care pharmacy service in 2015, with a goal to reduce 30-day readmission rates and improve patient safety. The service focuses on continuity of care after discharge. The purpose of this study is to compare 30-day readmission rates of patients followed by the pharmacy service based on the type of program introduction. The study’s main objective is to evaluate the effectiveness of different introduction processes of the program in reducing 30-day readmission rates.

Methods: This study is a retrospective observational study that will be submitted to the Institutional Review Board for approval. BayCare’s Transitions of Care pharmacy service aims to reduce hospital readmission rates through three main pharmacist-patient interactions: an initial introduction, and two follow-up telephone calls at post discharge days 3-7 and day 21. This study will focus on three patient population groups, each defined by the type of program introduction process that was provided: an in-patient visit, BayCare’s Get Well Network Video (an educational tool introducing the program), or no initial introduction. The primary outcome of the study is all cause 30-day readmission to the same facility following inpatient admission. The secondary outcome of the study is the number of pharmacist-patient interactions completed for each type of initial introduction process. Only adult patients who are Medicare A/B beneficiaries with discharge disposition to home will be included. Oncology and hospice patients will be excluded. Data will be collected utilizing the program’s internal data tracking sheet and Cerner Electronic Medical Record. Data collection will include type of program introduction process, readmission within 30 days of discharge, number of pharmacist-patient
encounters completed (call completion rates), patient readmission risk, and patient demographics.

Poster Title: Implications of a hydromorphone dose interchange policy on pain management and patient safety at a large community hospital

Primary Author: Katelyn Sommerer, St. Joseph’s Hospital, FL; Email: katelyn.sommerer@baycare.org

Additional Author(s):
Syeda Kareem
Elizabeth Espinel

Purpose: Hydromorphone, a potent opioid agonist, comes with a Black Box Warning for risk of respiratory depression. As such, caution is advised when dosing hydromorphone in opioid-naïve versus opioid-tolerant patients. In the hospital setting, hydromorphone is commonly used in the management of acute pain. Challenges exist in balancing appropriate starting doses that both are safe and can adequately treat pain. This study aims to evaluate the effect of an initial intravenous hydromorphone dose reduction on pain control in opioid-naïve patients. Secondarily, this study will determine if incidence of adverse effects associated with hydromorphone toxicity is reduced following policy implementation.

Methods: This is a retrospective cohort study of opioid-naïve patients who received intravenous hydromorphone between January 2008 and December 2015. This surrounds the time that the hospital’s hydromorphone dosing interchange policy was implemented in August 2010. Patients at least 18 years of age with documented intravenous hydromorphone administration will be identified through the electronic medical record system. Data to be collected include: patient demographics, pain scores before and after intravenous hydromorphone administration, total daily dose of hydromorphone up to 72 hours or until dose escalation/opioid rotation, oxygen saturation, respiratory rate, and documented use of naloxone. Average percent reduction of pain scores and associated adverse effects of hydromorphone toxicity such as respiratory depression will be compared. All data will be de-identified and kept confidential. This study has been submitted to the Institutional Review Board for approval.

Poster Title: Pharmacist-driven Vancomycin Dosing and Monitoring Guidelines in Pediatric Patients

Primary Author: Kelsey Hyman, St. Joseph's Hospital, FL; Email: kelsey.hyman@baycare.org

Additional Author(s):
Catherine Storms
Maida Muratagic

Purpose: Pharmacokinetics in pediatric patients vary between age groups and individual clinical characteristics and as a result, there has not been an accepted standardized method of vancomycin dosing in this patient population. There has been a climb in vancomycin nephrotoxicity as vancomycin dosing increases to overcome resistance. The purpose of this study is to evaluate the safety and efficacy of a pharmacist-driven pediatric vancomycin dosing and monitoring guideline at St. Joseph’s Children’s Hospital and to identify any risk factors that may be associated with vancomycin-induced nephrotoxicity in the pediatric population.

Methods: This will be a retrospective and prospective cohort study to assess the safety and efficacy of a pharmacist-driven pediatric vancomycin dosing and monitoring guideline. Data for Group A [patients prior to the implementation of guidelines (March 2016-September 2016)] and Group B [patients after implementation of guidelines (October 2016-May 2017)] will be collected and compared. Patients will be eligible for inclusion in this study if pharmacy was consulted to dose, they are 1 month-18 years old, and have received vancomycin for more than 48 hours. Patients will be excluded if they meet one of the following criteria: less than 1 month or greater than 18 years old, pregnancy, cystic fibrosis patient, on extracorporeal membrane oxygenation, renal dysfunction prior to initiation of vancomycin therapy. The primary objective of this study is to assess the safety of the dosing guidelines. Secondary objectives are to assess the efficacy of the dosing guidelines and to identify the associated risk factors of nephrotoxicity in this patient population. Patient demographics, indication for vancomycin, values and trends of serum creatinine, creatinine clearance, urine output, infection markers and their trends, other nephrotoxic agents received, duration of vancomycin treatment, number and value of vancomycin troughs, day(s) to therapeutic trough goal, how often there was a dosage change,
and adverse drug reactions to vancomycin will be collected. This study was sent to Institutional Review Board for approval.

**Poster Title:** Evaluation of fixed dose four-factor prothrombin complex concentrate (4FPCC) for urgent warfarin reversal

**Primary Author:** Quynh Nguyen, St. Joseph’s hospital, Tampa FL, FL; **Email:** quynh.nguyen1@baycare.org

**Additional Author(s):**
Scott Dietrich
Joanna Caranante
Amanda Harmon
John Phillips

**Purpose:** To evaluate the efficacy, safety, and cost effectiveness of fixed dose four-factor prothrombin complex concentrate (4FPCC) regimen (1500 or 2000 units Kcentra) compared to standard dose regimen (package insert recommended doses).

**Methods:** This study is a retrospective chart review comparing patients who received fixed dosing of four-factor prothrombin complex concentrate (4FPCC) for emergent warfarin reversal (October 2016 to March 2017) to patients who received standard dosing of 4FPCC (October 2015 to March 2016) prior to the implementation of fixed dosing protocol. Collected data include demographics, warfarin and 4FPCC indications, timing and value of pre-treatment international normalized ratio (INR), timing and number of repeat doses of 4FPCC, additional reversal agents given, timing and value of post-treatment INR (first INR within 8 hours post-4FPCC therapy), and thrombotic events. Cost data for 4FPCC is calculated based on acquisition cost. Patients will be eligible for inclusion if on warfarin and received a dose of 4FPCC. Patients will be excluded if meeting one of the following criteria: trauma patients, age less than or equal to 18, received 4FPCC for non-warfarin reversal, no post-treatment INR, received fresh frozen plasma prior to 4FPCC administration. The primary endpoint of this study is proportion of patients who reached target INR (less than 1.4) within 8 hours post-4FPCC therapy. Secondary endpoints include proportion of patients who reached target INR in sub-populations of weight greater than 100 kg or pre-treatment INR greater than 7.5, thrombotic events up to 7 days post-therapy and cost comparison of different dosing regimens. This study was submitted to Institutional Review Board for approval.

**Poster Title:** Effects of atypical antipsychotics on hemoglobin A1c

**Primary Author:** Sarah Honaker, University of Florida College of Pharmacy, FL; **Email:** honaker41@marshall.edu

**Additional Author(s):**
Katherine Vogel-Anderson

**Purpose:** It is known that atypical antipsychotics are associated with an increase in hemoglobin A1c; this may increase the risk for the development of diabetes and other metabolic complications. The purpose of this study is to determine the relationship between the change in hemoglobin A1c and the antipsychotic drug prescribed, dose, and duration of therapy in an outpatient setting.

**Methods:** This study is submitted to the Institutional Review Board for approval. The electronic medical record system (Epic) will identify patients who are prescribed an atypical antipsychotic. We will conduct a retrospective chart review of patients prescribed an atypical antipsychotic since 2011. Patients are eligible for inclusion if they are assigned to a UF Health Internal Medicine provider and are prescribed any of the following atypical antipsychotics between January 1, 2011 through January 31, 2016: aripiprazole, asenapine, brexpiprazole, cariprazine, clozapine, iloperidone, lurasidone, olanzapine, paliperidone, quetiapine, risperidone, or ziprasidone. The following data will be collected: Age, gender, body weight, antipsychotic indication, dose and duration, baseline hemoglobin A1c, and co-morbid conditions. All data will be de-identified and recorded in the Research Electronic Data Capture software program (REDCap). Data will be stratified according to each antipsychotic drug prescribed. The change in hemoglobin A1c from baseline will be calculated. This data will then be statistically analyzed to assess whether there are any differences in hemoglobin A1c according to the antipsychotic prescribed.

Poster Title: Comparison of anesthetic delivery methods and opioid administration forty-eight hours after total knee replacement

Primary Author: Leany Capote, University of Miami Health Systems, FL; Email: lac254@med.miami.edu

Additional Author(s):
Marlene Delavalle
Ralf Gebhard

Purpose: At the University of Miami Hospital, there is a focus to reduce opioid use due to potential adverse reactions. Current practice allows for a variety of anesthetic administration methods in patients undergoing total knee replacement (TKR) surgery. The primary objective of this study is to compare the amount of opioids administered 48 hours after TKR in three arms: (1) patients anesthetized with a single injection into the adductor canal, (2) through a 48 hour catheter into the adductor canal, or (3) as a local infiltrate. Secondary objectives include length of stay (LOS) and adverse events potentially attributed to opioids.

Methods: This study will be submitted to the Institutional Review Board for approval. Patients who underwent a TKR at the University of Miami Hospital from October 1, 2015-September 1, 2016 will be identified using ICD 9 and ICD 10 codes. Approximately 45 medical records will be reviewed and further classified by anesthesia method. University of Miami Regional Anesthesia (UMRA) records will be utilized to identify method of anesthesia administration. Retrospective chart review through Innovian, Meditech and VigiLanz will serve to review non-opioid and opioid analgesic administration, as well as adverse events potentially attributed to opioid administration 48 hours after surgery. Home analgesic medications will be reviewed through Pyxis Connect. The following data will be collected: age, weight, height, body mass index (BMI), allergies, home analgesics, surgical procedure, anesthesia administration method, LOS, opioid administration, non-opioid analgesic administration, naloxone administration, and side effects potentially attributed to opioids 48 hours after surgery. All data will be recorded without patient identifiers. Total opioid administration will be converted to milligrams oral morphine equivalent. The total amount of postoperative opioids administered after each type of block will be compared to determine if one uses less or not.

Poster Title: Impact of medication adherence on hospitalization rates

Primary Author: Ayonna Tolbert, WellCare Health Plans, Inc., FL; Email: ayonnat@gmail.com

Additional Author(s):
Nathan Jakowski
Steven Walden
Stephen Jones
Kerri Petrin

Purpose: Adherence to maintenance medications is a vital component of chronic disease management. Medication non-adherence has been associated with disease progression, poor therapeutic outcomes, and an increase in overall healthcare costs. Hospitalization rates are one of the more costly outcomes. Managed Care Organizations track three primary therapeutic areas and report patient adherence rates for HMG-CoA inhibitors, renin angiotensin system antagonists, and oral diabetes medications to the Center for Medicare and Medicaid Services as part of their STAR rating. The purpose of this study is to determine if a relationship exists between adherence of these three medication classes and hospitalization rates.

Methods: A retrospective cohort study of patients who were continuously enrolled in a Medicare Advantage Prescription Drug (MAPD) plan from January 1, 2014 to December 31, 2015 is being conducted. Utilizing methodology developed by RxAnite, a predictive analytics and clinical services company, patients were classified as adherent or non-adherent based on prescription claims history of an HMG-CoA inhibitor, renin angiotensin system antagonist, or oral diabetes medication. A proportion of days covered value of greater than 80% is used to define medication adherence. Adjusting for member-level confounding differences, hospitalization rates will be compared between the adherent and non-adherent populations to determine if medication adherence significantly reduces the risk of a hospitalization. The relative risk of a hospitalization based on medication adherence will be presented along with the 95% confidence interval.

**Poster Title:** Impact of a pharmacist-driven stress ulcer prophylaxis protocol in a community hospital setting  

**Primary Author:** Megan Graham, West Florida Healthcare, FL; Email: ford.megan20@gmail.com  

**Additional Author (s):**  
Mina Ilia  
Ernie Cyr  
Jaclyn Chessher

**Purpose:** The overuse of proton pump inhibitors and histamine-2 receptor antagonists for stress ulcer prophylaxis has been linked to adverse effects, such as Clostridium difficile infections, pneumonia, bone fractures, and low magnesium levels; however, histamine-2 receptor antagonists are associated with fewer adverse effects than proton pump inhibitors. The purpose of this study is to assess the impact of a pharmacist-driven stress ulcer prophylaxis protocol in a community hospital setting with the primary aim of seeing a reduction in inappropriately used stress ulcer prophylaxis medications.

**Methods:** This retrospective and prospective study will be conducted in a 515 inpatient bed community hospital. Hospitalized adults who receive either a histamine-2 receptor antagonist or proton pump inhibitor will be considered for inclusion. Exclusion criteria include patients with an active upper gastrointestinal bleed or active peptic ulcer disease, receiving dual antiplatelet therapy or concurrent antiplatelet and anticoagulant therapy, solid organ transplant recipient, receiving Viokace via gastric feeding tube, and total gastrectomy. The pharmacist-driven stress ulcer prophylaxis protocol will be implemented on September 28, 2016. Therefore, data will be collected from September 28, 2015 through January 31, 2016 for the pre-implementation phase and from September 28, 2016 through January 31, 2017 for the post-implementation phase. All patient data gathered and assessed for study purposes will be de-identified. The primary outcomes to be measured include the ratio of proton pump inhibitors to histamine-2 receptor antagonists used throughout the facility, the amount of appropriately used versus inappropriately used stress ulcer prophylaxis medications, proton pump inhibitors and histamine-2 receptor antagonists use on general floors versus intensive care unit use, and the number of patients discharged on a
proton pump inhibitor or histamine-2 receptor antagonist. Secondary outcomes to be assessed before and after protocol implementation include stress ulcer prophylaxis cost, stress ulcer rates, Clostridium difficile rates, hospital-acquired pneumonia rates, and hypomagnesemia rates.

**Poster Title:** Evaluation of fixed versus variable dosing of prothrombin complex concentrates for emergency warfarin reversal in a community hospital setting

**Primary Author:** Maria Eduardo, West Florida Healthcare, FL; **Email:** maria.eduardo@hcahealthcare.com

**Additional Author(s):**
Richard Wilhoit
Charlton Dennison
Ernie Cyr

**Purpose:** Prothrombin complex concentrates (PCC), such as Kcentra, are used for emergency warfarin reversal due to their fast onset and ability to effectively achieve hemostasis. The CHEST Guidelines and AHA/ASA Guidelines recommend using PCC with vitamin K for warfarin-associated major bleeding. West Florida Hospital implemented a trial of fixed dosing of Kcentra in September 2016 replacing the variable dosing strategy. This change was made to streamline patient care and improve patient outcomes. The primary objective of this study is to evaluate the efficacy, safety, and cost effectiveness of fixed-dosed versus variable-dosed Kcentra for reversal of emergent bleed due to warfarin.

**Methods:** This prospective study will be conducted at West Florida Hospital in Pensacola, Florida. The study will compare the use of fixed-dosed Kcentra 1500 international units to variable dosing. Written informed consent is not necessary since data will be collected using the electronic record database. The variable dosing will be evaluated retrospectively from September 2015 through March 2016. The data for the fixed dosing will be collected prospectively from September 2016 through March 2017. All patient data gathered and assessed for study purposes will be de-identified. The primary efficacy endpoint of this study is to determine the time to Kcentra administration between fixed dosing and variable dosing, reversal of INR to less than 1.5, and achievement of hemostasis within 30 minutes of Kcentra infusion. The primary safety endpoint of this study is the occurrence of thromboembolic complications 7 days post Kcentra administration. A cost analysis will be conducted to determine the difference in treatment cost using variable dosing versus fixed dosing Kcentra and hospital length of stay.

**Poster Title:** Justification of expansion of hospital-based clinical pharmacy programs to ambulatory medication management services for continuity of care

**Primary Author:** Nydia Rivera-Berríos, West Kendall Baptist Hospital, FL; **Email:** nyvetterivera@gmail.com

**Additional Author(s):**
Ana López-Samblas
María Rojo-Carlo
Abby Marrero

**Purpose:** The benefit of post discharge pharmacy services in enhancing adherence, reducing medication related problems and preventing unnecessary readmissions is well established in the literature. Financial constraints make the expansion of pharmacy services challenging. The purpose of this project is to develop a framework to implement reimbursable post hospital discharge clinical pharmacy services.

**Methods:** Sources of reimbursement that can be utilized for pharmacist provided clinical services will be evaluated in order to identify programs that can support post hospital discharge Transition of Care services. The project will evaluate the different models of Transition of Care programs, Chronic Care Management and Medication Therapy Management services in order to create a framework of reimbursable services to include follow up phone calls and pharmacy clinic visits. Based on gathered information, the aim is to define which clinical pharmacy services will be better suited to support the needs of our patient population post hospital discharge. A business case will be developed to quantify the number of patients and types of services needed to support a self sustainable program. Patient recruitment is not a component of this project and no patient data will be collected, therefore IRB request for determination indicated that this study is exempt.

**Poster Title:** Prevalence and economic impact of patient reported penicillin allergy in a community hospital.

**Primary Author:** Loida Portalatin Perez, West Kendall Baptist Hospital
Miami, Florida
, FL; **Email:** loida.portalatin1@gmail.com

**Additional Author(s):**
Maria Perez-Arias
Ana Lopez-Samblas

**Purpose:** Penicillin allergy is the most common drug allergy reported in the United States with a prevalence of 10%. Vague allergy history may result in a patient being mislabeled as penicillin allergic. This often leads to the prescribing of a broader spectrum and more costly antibiotic. The purpose of this study is to quantify the prevalence of patient reported penicillin allergy in our population and evaluate if these patients had received beta-lactam antibiotics in past hospitalizations. In addition, the cost difference between the alternative antibiotic therapy prescribed due to the penicillin allergy history and the standard of care will be calculated.

**Methods:** This study will be submitted to the Institutional Review Board for approval. A retrospective chart review of patients reporting a penicillin allergy during their visit to the hospital during a 3-month period from June 1 to September 1, 2016 will be conducted. A computer generated report will be used to identify these patients. The report will include the patient’s medical record number, age, gender, ethnicity, allergy to penicillin, and antibiotic regimen during the study period hospital stay. Patients will be stratified by age, gender, and ethnicity to determine if there are any differences in prevalence among groups. The medical record number of the subjects will be used to perform a chart review in order to determine if the patient had received beta-lactam antibiotics during previous hospitalizations in our Health System and identify any untoward reactions described in the clinical notes. All data will be recorded without patient identifiers and maintained confidentially. The cost difference between the beta-lactam antibiotic considered the drug of choice and the alternative regimen received during the study period hospitalization will be calculated utilizing the patients’ length
of therapy. This calculation will be used to evaluate the cost incurred by treating patients with alternative therapy due to the proposed allergy to penicillin.

Poster Title: Impact of post-PCI pharmacy intervention on 30-day hospital readmission due to acute stent thrombosis

Primary Author: Sandra Martin, Winter Haven Hospital, FL; Email: sandra.martin@baycare.org

Additional Author (s):
Karin Thatcher
Karen Siegel

Purpose: Non-adherence to dual antiplatelet therapy (DAPT) is the leading cause of acute stent thrombosis (AST) following PCI procedures with stent placement. The purpose of this study is to determine if 30-day readmission rates due to AST are reduced for patients who receive a pharmacist-guided intervention following PCI stent placement compared to those who did not receive pharmacist intervention.

Methods: The study will be submitted to the Institutional Review Board for approval. This retrospective study will compare 30-day readmission rates due to acute stent thrombosis (AST) in patients who received a pharmacist-guided intervention versus patients who did not receive pharmacy intervention. The study group will be identified by generating a list of patients who have previous documentation of receiving post-PCI counseling at Winter Haven Hospital. The control group will consist of patients who underwent PCI stent placement at Morton Plant Hospital, a comparable BayCare System hospital. The control group will be identified by utilizing ICD-9 and ICD-10 codes, yielding a list of patients who underwent PCI-stent placement during the pre-specified time period. Randomization of the control arm will occur by selecting every other patient on the list to be analyzed for inclusion in the study. We will continue this method until we have matched the number of patients in the treatment arm one-to-one. The following data will be collected: date of PCI procedure, gender, age, coagulation labs upon admission, type of stent, previous history of stent placement, and patient specific DAPT regimen. AST readmission will be identified in both study groups by means of a chart review and ICD 9/10 codes. Any documentation of non-adherence to DAPT regimen will also be recorded.

**Poster Title:** Impact of pharmacist intervention on 30 day readmission rates of patients with chronic obstructive pulmonary disease  

**Primary Author:** Theresa Trindade, Winter Haven Hospital, FL; **Email:** theresa.trindade@baycare.org  

**Additional Author(s):**  
Erika Rugay  
Lacey Charbonneau  
Jovino Hernandez  

**Purpose:** In 2015, the Centers for Medicaid and Medicare Services (CMS) added chronic obstructive pulmonary disorder (COPD) to the list of core measures utilized for reimbursement. The objective of this study is to determine whether medication reconciliation and counseling at discharge will decrease 30 day hospital readmission rates of patients with chronic obstructive pulmonary disease (COPD).  

**Methods:** The protocol for the present study will be submitted to the Institutional Review Board (IRB) for approval. Between the months of November 2016 through January of 2017, patients with a primary diagnosis of COPD who are at moderate to high risk for readmission will be identified upon admission to the hospital. These patients will be followed through discharge. Upon impending discharge, medication reconciliation will be performed to identify discrepancies in the final medication list. Patients will also be counseled on their COPD medications prior to leaving the hospital. All patient information will be de-identified and information recorded including admission/discharge dates, length of stay, date of readmission if applicable and medication issues identified prior to discharge. A retrospective review of COPD readmission rates during the same time period the previous year will be conducted for comparison to results from the intervention.

Poster Title: Evaluation of aztreonam utilization in a tertiary care hospital

Primary Author: Kacie Clark, Wolfson Children's Hospital/Baptist Health, FL; Email: kacie.clark@bmcjax.com

Additional Author (s):

Purpose: Aztreonam, a monobactam antimicrobial agent, is commonly reserved for patients with β-lactam allergies requiring broad-spectrum gram negative coverage, including Pseudomonas. Due to increased resistance in gram-negative microorganism isolates and increased costs, antimicrobial stewardship programs have also begun to target aztreonam use in patient self-reported β-lactam allergies. Many hospitals restrict aztreonam to only to patients with anaphylactic reactions to β-lactams. The objective of this medication use evaluation was to assess utilization of aztreonam to aid in the development of Criteria for Use to be suggested to the hospital’s Pharmacy & Therapeutics (P&T) committee.

Methods: This medication use evaluation consisted of a retrospective chart review of 28 patients who received aztreonam orders while admitted to a tertiary care hospital. Orders were identified through a Drug Utilization Report from August 1, 2016 to August 31, 2016. Orders were included based on the following inclusion criteria: patients greater than or equal to 18 years old, admission to the tertiary care hospital, and at least one dose of aztreonam administered during admission. Data was accessed using electronic medical records and information was collected using a data collection form. Institutional Review Board approval was not required as this was considered a pharmacy performance improvement project. Data assessment points included allergy documentation history, inpatient locations, indication for use, desensitization attempts, de-escalation patterns following positive culture results, and cost. Aztreonam cost was assessed based on the dose and the number of doses administered to a patient.

Results: Eighty-nine percent of patients had a documented allergy to a β-lactam agent. Specified reactions to β-lactam agents were reported in only 43% of patients. The most commonly listed reaction was hives. Five patients were mechanically ventilated in the ICU while receiving aztreonam. The most common indication for aztreonam for antimicrobial therapy was
cellulitis or wounds (32%). Sixty-eight percent of patients had an Infectious Disease consult placed but only 43% had aztreonam prescribed by an Infectious Disease prescriber. Only 1 patient had desensitization preformed. Fifty-seven percent of patients had a positive culture during following initiation of aztreonam. Only 6 of 16 positive cultures had an identified gram-negative organism that would have the potential to be susceptible to aztreonam. Three patients were not de-escalated from aztreonam to a preferred agent following a positive culture result. De-escalation from aztreonam took on average 1 day following a positive culture result. Four patients were de-escalated from aztreonam without a positive culture result and this was consistently done by an Infectious Disease physician. The total cost of aztreonam based on acquisition cost of the drug from August 1, 2016 to August 31, 2016 was $9343.60.

**Conclusion:** Aztreonam Criteria for Use was presented to the P&T committee following the completion of this medication utilization evaluation. Aztreonam should be restricted to patients with verified severe β-lactam allergies (anaphylaxis, urticaria, or angioedema) requiring empiric gram-negative coverage. “Unknown reaction” for a patient-reported β-lactam allergy is not an indication for initiation of aztreonam and consultation with an Infectious Disease pharmacist can help aid in deciding an appropriate agent. Therapy should be transitioned to a preferred agent (e.g. fluoroquinolone) as soon as a positive culture result is available. Restriction of aztreonam will aid in both antimicrobial stewardship and cost savings.

**Poster Title:** Medication reconciliation service for paediatric ward and paediatric intensive care unit in a major acute hospital in Hong Kong

**Primary Author:** Chung Ping Chow, Princess Margaret Hospital, Hospital Authority, Hong Kong, Hong Kong; **Email:** terence_chowcp@yahoo.com.hk

**Additional Author (s):**
Vivien Ng
Chi Chung Harry Chiu

**Purpose:** Medication reconciliation has been identified as a major intervention to target and reduce the burden of medication discrepancies and medication errors during transitions in care. Unintended therapeutic changes are common, and suboptimal communication between healthcare providers at care transitions may subsequently result in medication errors. Moreover, these errors can be more vulnerable to children than adults. The aim of medication reconciliation on hospital admission is to improve medication safety by ensuring the medications prior to admission are prescribed appropriately on admission for the pediatric patients through obtaining a patient’s best possible medication list from various information sources by clinical pharmacist.

**Methods:** Medication reconciliation service is provided to patients admitted to the pediatric wards (an 18-bed general pediatric ward and a 7-bed pediatric intensive care unit) in the hospital since Dec 2015. The best possible medication list is reconciled by pediatric clinical pharmacist to include all medications that the patient is taking from hospitals and clinics under Hong Kong Hospital Authority, clinics under Department of Health, private institutions and clinics as well as over-the-counter medications, herbal medicines and traditional Chinese medicines. The clinical pharmacist would verify the medication list through interviews conducted with patients or care-givers if possible. Appropriate documents (e.g. latest Medication Administration Record from the previous wards or institutions) are consulted if necessary for transfer-in cases. The medication list is then compared with the current medications prescribed in the hospital. For any discrepancies found, the clinical pharmacist would investigate the cause of discrepancies based on the available clinical information. The pharmacist should consult the case medical officer for discrepancies if in doubt and provide
interventions if necessary. Patient’s medication compliance is checked during interviews to identify any potential admission due to drug non-compliance.

**Results:** During the period of Dec 2015 to Jun 2016, medication reconciliation was done for 558 patient admissions (495 general pediatric cases and 63 pediatric intensive care cases) in the hospital by pediatric clinical pharmacist. Among these admissions, 87 (15.6%) involved patients with chronic medication use prior to admission, 155 (27.8%) involved patients with short-term episodic medication use and the remaining 316 (56.6%) involved patients with nil medication prior to admission. Sixteen unintended discrepancies in 7 admissions were identified during the period, which accounts for 8.0% of admission cases with chronic medication use. The most common types of discrepancy were omitted medications (56.3%), followed by medications unintentionally ordered (37.5%) and orders with unclear preparation specified (6.3%). Sixteen interventions were provided to doctors and all of them were accepted with problems rectified. Nil medication compliance problems were identified.

**Conclusion:** An effective process for medication reconciliation can reduce medication errors and support safe medication use by patients. The results of the medication reconciliation service showed that unintended discrepancies can happen in pediatric patients during admission or other transitions of care. Pediatric clinical pharmacist can help to improve medication safety by reducing unintended discrepancies and solving the drug-related problems during transitions of care. These results support the expansion of the service to other pediatric ward units.

Poster Title: Diluted single-syringe administration of adenosine for the rapid conversion of supraventricular tachycardia (SVT) in the Emergency Department

Primary Author: Allyson Greenberg, Advocate Christ Medical Center, IL; Email: allyson.greenberg@advocatehealth.com

Additional Author(s):
Robert Moksycki
Neal Lyons
Rolla Sweis

Purpose: Adenosine administration for the conversion of SVT to normal sinus rhythm (NSR) has a reported success rate of ninety percent. The standard administration method involves undiluted adenosine given intravenously followed by a rapid bolus of normal saline. This method requires a coordinated effort during administration and is prone to error. Complications in administration may lead to decreased conversion rates. The objective of this study is to determine if administering a single syringe of diluted adenosine is non-inferior to the conventional two-syringe method in converting to NSR.

Methods: This will be a single-center, prospective, randomized, non-inferiority study for adult patients presenting to Advocate Christ Medical Center Emergency Department with stable SVT requiring adenosine administration. This study will be submitted to the Institution Review Board for approval. After the diagnosis of SVT is confirmed by a physician, patients will be randomized into the two-syringe control group or the single-syringe treatment group. The primary endpoint will be the percent of patients with successful conversion from SVT to NSR with the administration of adenosine as a single-syringe compared to the conventional two-syringe administration technique. Secondary endpoints include the requirement of repeat doses, administration errors, and adverse events. The following data will be collected: age, gender, weight, history of concomitant disease states, home medications, adenosine administration technique, number of adenosine doses, duration of procedure, reported adverse reactions, site of adenosine administration, and administration errors. Patients will be observed by a study investigator for 30 minutes following the administration of adenosine.

Poster Title: Comparison of phenytoin and levetiracetam for seizure prophylaxis in patients with a severe traumatic brain injury

Primary Author: Faaeq Yousaf, Advocate Christ Medical Center & Advocate Children’s Hospital, IL; Email: faaeq.yousaf@advocatehealth.com

Additional Author (s):
Lina Piech
Neal Lyons
Ellen Omi
Rolla Sweis

Purpose: The Brain Trauma Foundation recently released guidelines for the management of severe traumatic brain injury. These guidelines provided a level II recommendation for the use of phenytoin to decrease the incidence of early post-traumatic seizures (within 7 days of trauma). However, due to minimum adverse effects and drug interactions and the lack of required drug monitoring, levetiracetam has increasingly been utilized for seizure prophylaxis. There have been few studies conducted comparing the efficacy of phenytoin and levetiracetam. The objective of this study is to determine whether phenytoin or levetiracetam is more effective in reducing the incidence of early post-traumatic seizures.

Methods: This will be a retrospective, single center study performed at Advocate Christ Medical Center. The study will be submitted for approval to the Institutional Review Board. Adult patients with a Glasgow Coma Score (GCS) of 8 or less receiving phenytoin or levetiracetam following a traumatic brain injury confirmed with radiographic imaging will be evaluated. Patients with a history of seizures or previously taking antiepileptic medications and pregnant women will be excluded. The primary outcome of this study will be clinical and electroencephalogram (EEG) seizure rates within 7 days of severe traumatic brain injury. Secondary outcomes include late (7 days) seizure rates, mortality, and adverse drug reactions. The following data points will also be collected: length of stay (LOS), Injury Severity Score (ISS), GCS, weight, use of concomitant antiepileptic medications, dose of antiepileptics administered, use of hyperosmolar therapy, type of trauma, neurosurgical intervention, serum phenytoin
levels, and seizure onset. All data will be collected without patient identifiers and confidentiality will be maintained.

Poster Title: Phenobarbital front loading dose compared with low intermittent doses for benzodiazepine refractory severe alcohol withdrawal: a retrospective comparison

Primary Author: Kati Stegner, Advocate Christ Medical Center and Hope Children's Hospital, IL; Email: kati.stegner@advocatehealth.com

Additional Author(s):
Poorvi Shah
Rolla Sweis
Tabassum Hanif

Purpose: High variability exists in refractory alcohol withdrawal syndrome (AWS) management which has been defined as, patients requiring more than diazepam 40 mg or equivalent within one hour to achieve symptom control. Benzodiazepines remain the primary treatment for AWS. However, adjunct phenobarbital (PB) dose escalation strategies in ICU patients have shown significant reductions in the need for mechanical ventilation. The purpose of this study is to compare efficacy and safety outcomes of critically ill patients with AWS who were treated with a front loading PB protocol versus a PB low intermittent dosing protocol after benzodiazepines were ineffective for controlling symptoms.

Methods: The following study is a single-center, pre-post study conducted in patients 18 years and older admitted to the Medical Intensive Care Unit (MICU) of a large community teaching medical center requiring treatment for AWS. The study is pending Institutional Review Board approval. The study will include a retrospective efficacy and safety comparative analysis of two severe AWS protocols, requiring a Clinical Institute Withdrawal Assessment for Alcohol Scale (CIWA-Ar) greater than or equal to 20. The CIWA-Ar and Richmond Agitation and Sedation Scale (RASS) are utilized for symptom control assessments in non-intubated and intubated patients, respectively. Pre-arm low-intermittent PB dosing strategy includes a one-time bolus of 260mg IVP followed by PB 130 mg IVP every 15 minutes for 8 doses, maximum 1,300 mg of PB collected from January 2013 to July 2015. The post-arm includes a one-time 10 mg/kg PB loading dose IVPB over 30 minutes, collected from July 2015 to December 2016. The primary outcome is the time from phenobarbital administration to CIWA-Ar score less than 20. Secondary outcomes to be collected include ICU length of stay, respiratory failure,
complications of alcohol withdrawal, phenobarbital adverse effects, and readmission to ICU. The following data points will also be collected: concomitant amounts of sedative medications, serum PB levels, intubation rates, prior alcohol use, alcohol serum levels if available, and various laboratory data.

Poster Title: Incorporating student pharmacists in the admission reconciliation process at a community teaching hospital

Primary Author: Alen Landup, Advocate Illinois Masonic Medical Center, IL; Email: alandup2@yahoo.com

Additional Author (s):
Jodi Fugate

Purpose: Medication reconciliation is an important part of improving patient care when a patient transitions between different levels of care within a hospital system. Up to a quarter of all prescription medications taken by patients prior to admission are not recorded correctly within the electronic medical record. Student pharmacists can play an integral role in obtaining medication histories on admission and allow pharmacists to have more time to provide other clinical services. The objective of this study is to evaluate the impact of incorporating student pharmacists in the admission reconciliation process.

Methods: This study will be completed at a 408-bed academic medical center in the North side of Chicago over a six-week period between October 2016 and November 2016. A one-week run-in phase will be conducted to determine the average time for a pharmacist to conduct a medication history without student pharmacists. After the run-in phase, student pharmacists will be assigned to perform and document thorough medication histories. Students will screen for medication related problems and make recommendations to the pharmacist to optimize patient care. The accuracy of the medication histories obtained by student pharmacists will be reviewed by a clinical pharmacist. Patients admitted to the following units will be excluded from the study: neonatal intensive care, pediatrics, mother/baby, labor and delivery, rehabilitation, and psychiatric. The primary outcome will be to evaluate the accuracy of student pharmacist obtained medication histories. The secondary outcomes will be to evaluate the average pharmacist time to review a medication history completed by a student, percentage difference of completed medication histories pre- and post student involvement, total number of discrepancies observed (e.g. allergy clarification, incorrect dose, incorrect route, incorrect frequency, incorrect formulation, drug omission, prescribed OTC missed, drug addition,

Poster Title: Implementation of a pharmacist-run outpatient transitions of care clinic in an internal medicine clinic

Primary Author: Jenna Boznos, Advocate Illinois Masonic Medical Center, IL; Email: jenna.boznos@gmail.com

Additional Author(s):
Linda Tung

Purpose: The literature reports that as many as 49% of patients experience a preventable medication error post-hospital discharge, which may lead to serious adverse events and readmissions. The Affordable Care Act has enacted hospital penalties for readmissions within 30 days at the same site. Previous trials have shown decreased readmissions with pharmacist intervention at discharge. The objective of this project is to implement and evaluate the impact of a pharmacist–run outpatient Transitions of Care (TOC) clinic by optimizing patients’ medication therapy by empowering patients through education.

Methods: This project is a single site, quality improvement project conducted from December 1-December 31, 2016. It is a prospective analysis of outcomes of pharmacist managed TOC services combined with medical care provided by physicians compared to outcomes of standard medical care provided by physicians in a historical group. Patients will be scheduled for an appointment with the TOC pharmacist along with their first primary care physician visit post-discharge. Patients will be instructed to bring in all medications, which the pharmacist will review and compare to their hospital course and discharge list. Patient’s medication knowledge and adherence will be assessed during the visit. Additionally, the pharmacist will screen for medication related issues such as duplication, omission, drug interactions and inappropriate therapy then communicate recommendations with physician prior to patient’s visit to optimize therapy. All medications will be reviewed with the patient and the pharmacist will provide disease state and medication education to help empower patients to take medications correctly. The pharmacist will conduct a 2-week follow up phone call to the patient and administer a questionnaire similar to that completed at the visit to assess medication knowledge and adherence. The primary outcome will be 30-day hospital readmission rates of internal medicine clinic patients. Secondary outcomes will be collected for the prospective
group only and will include pharmacist interventions, patient knowledge of medications and adherence.

Poster Title: Evaluation of the hematologic effects associated with same-day pegfilgrastim therapy in children receiving myelosuppressive chemotherapy

Primary Author: Kevin Le, Ann and Robert H. Lurie Children's Hospital of Chicago, IL; Email: kle@luriechildrens.org

Additional Author(s):
Diana Wu

Purpose: Pegfilgrastim is a granulocyte-colony stimulating factor (G-CSF) that promotes neutrophil proliferation following myelosuppressive chemotherapy. In children, pegfilgrastim is indicated for the prevention of primary and secondary chemotherapy-induced neutropenia. However, it is not recommended to be administered within 24 hours after receiving chemotherapy. The activating effect of G-CSF on myeloid progenitor cells during this time can increase the risk of exposure to cytotoxic agents, which may result in prolonged neutropenia. The purpose of this study is to evaluate the hematologic safety of same-day administration of pegfilgrastim in children receiving chemotherapy.

Methods: This retrospective chart review has been approved by the Institutional Review Board. The electronic medical record database was queried for all courses of pegfilgrastim administered to children for the prevention of chemotherapy-induced neutropenia. Patients were excluded from the study if they possessed confounding conditions such as non-malignant myelosuppressive disorders, total body irradiation, or hematopoietic stem cell transplantation. Patients were also excluded if they received pegfilgrastim therapy within 14 days prior to chemotherapy. Pegfilgrastim administrations will be categorized as administered within 24 hours or greater-than 24 hours after myelosuppressive chemotherapy administration. The following variables will be collected: patient age, sex, race, ethnicity, weight, height, malignancy, chemotherapy regimen and administration time(s), and pegfilgrastim dose and administration time. The primary objective is to evaluate hematologic safety based upon hospitalizations due to febrile neutropenia following pegfilgrastim administration. Secondary objectives include evaluating the duration of neutropenia and assessing delays in chemotherapy. The incidence of intensive care unit admission and/or mortality will be collected to characterize the severity of hospitalization for febrile neutropenia. It was determined that a
sample size of 480 courses of pegfilgrastim administrations is required to detect a 10 percent difference in the incidence of febrile neutropenia between the comparison groups with 80 percent power.

Poster Title: Implementation of rapid diagnostic testing and treatment algorithm for rapid identification of gram positive cocci in the bloodstream

Primary Author: Katelyn Hoyt, Blessing Hospital, IL; Email: katelyn.hoyt@blessinghealthsystem.org

Additional Author (s):
Melissa Genenbacher
Andrea Chbeir

Purpose: Rapid diagnostic testing has been shown to decrease time to appropriate antibiotics, length of stay and mortality. Bauer, et al. demonstrated that rapid diagnostic testing has minimal impact on patient outcomes without an antimicrobial steward having an active role in result interpretation. The objective of this project is to evaluate the effectiveness of an antimicrobial stewardship pharmacists-driven treatment algorithm on time to optimal antimicrobial therapy.

Methods: The rapid diagnostic testing algorithm was designed to streamline antibiotic therapy based upon the resulting gram positive cocci. Upon gram positive cocci identification, the pharmacist will review the patient’s antimicrobial regimen. If a change is recommended, according to the algorithm, a call will be placed to provider. Primary outcome measures include time to targeted antimicrobial therapy defined as the time from initiation of initial empiric antibiotics to time the antibiotics were tailored to the resulting pathogen. Data collection will consist of 40 patients in the pre-intervention group using traditional organism identification and 40 patients in the post-intervention group using rapid diagnostic testing. Time to targeted antimicrobial therapy and hospital length of stay will be compared between the pre-intervention and post-intervention groups.

**Poster Title:** Optimization of P2Y12 receptor inhibitor selection for patients with ST elevation myocardial infarction (STEMI) in the emergency department

**Primary Author:** Allison Tenhouse, Blessing Hospital, IL; **Email:** allison.tenhouse@blessinghealthsystem.org

**Additional Author (s):**
Abby Dunker
Ryan Thurm
Melissa Genenbacher
Andrea Chbeir

**Purpose:** Current American Heart Association guidelines for patients with a diagnosis of ST elevation myocardial infarction (STEMI) recommend the use of an appropriate loading dose of a P2Y12 inhibitor prior to percutaneous coronary intervention (PCI). The current STEMI order set lacks the ability to select all recommended P2Y12 inhibitors at optimal doses. This study aims to improve patient outcomes by providing guideline-based therapy to STEMI patients. The objective of this study is to determine whether an updated STEMI order set increases utilization of guideline-based treatment in patients admitted to the emergency department with a diagnosis of STEMI.

**Methods:** This is a single center, retrospective, quality improvement study. The STEMI order set will undergo revisions in the fall of 2016 which will include the addition of updated P2Y12 loading doses. A medication use evaluation will be conducted to identify changes in P2Y12 inhibitor usage in the emergency department three months before and three months after implementation. The electronic medical record will identify patients who were admitted through the emergency department with a diagnosis of STEMI and received a loading dose of a P2Y12 inhibitor prior to PCI. The following data will be collected: age, gender, P2Y12 inhibitor ordered and dose administered. The primary outcome will be the use of a guideline recommended P2Y12 inhibitor loading dose before and after implementation of the order set. Secondary outcomes will examine the difference in usage of each individual P2Y12 inhibitor before and after the implementation of the new order set. A chi square test will be used to analyze demographic data as well as the primary and secondary outcomes.

Poster Title: Comparison of intravenous magnesium sulfate and oral mangesium L-lactate in adult hospitalized patients

Primary Author: Tyler Ludwig, Carle Foundation Hospital, IL; Email: tyler.ludwig@carle.com

Additional Author(s):
Matthew Pike

Purpose: Magnesium supplementation occurs frequently in the inpatient setting although there are currently no clearly defined guidelines for how much magnesium to supplement and whether to administer it orally or intravenously. This study will calculate the increase of serum magnesium following supplementation with either oral or intravenous magnesium in order to compare effectiveness between the two routes of administration.

Methods: This retrospective study will use the electronic medical record system to identify occurrences from January 1st, 2013 to January 1st, 2016 when patients under hospitalist care received magnesium supplementation with either intravenous magnesium sulfate or oral magnesium L-lactate. In order to be included within the study, each occurrence of supplementation must also have a documented serum magnesium level within 12 hours prior to the administration as well as another level between 6 to 24 hours after the administration. The dose, route, and frequency of magnesium supplementation will also be recorded from each occurrence. Other patient specific information to be collected includes age, sex, height, weight, and serum creatinine for the purpose of calculating estimated creatinine clearance using the Cockcroft-Gault equation. All patient data will be stored securely and confidentially on the health-system’s internal servers. Occurrences will be excluded if the patient is under 18 years old, has a creatinine clearance less than 30 milliliters per minute, takes magnesium supplements at home, or received both intravenous and oral magnesium supplementation within 24 hours. Average increase in serum magnesium will be calculated and compared between the different administration routes and doses. A student’s T-test will be used with an alpha level set at 0.05 to determine any statistically significant differences.

**Poster Title:** Evaluating factors contributing to unplanned readmissions for medication therapy management interventions in a community hospital

**Primary Author:** Ashley Shar, Carle Foundation Hospital, IL; **Email:** ashley.shar@carle.com

**Additional Author (s):**
Matthew Pike
Erica Stevens

**Purpose:** Unplanned hospital readmissions are common and costly and current risk scoring tools are not oriented towards clinical pharmacist interventions. The objective of this study is to evaluate the associations between medication-related parameters and unplanned 30-day, 3-month, and 6-month readmissions. The results from this study will be used to develop a practical prediction tool that identifies patients who may benefit from medication therapy management pharmacy services.

**Methods:** This retrospective, cohort study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients who were admitted to Carle Foundation Hospital between January 2013 and June 2016 for heart failure exacerbation, acute myocardial infarction, chronic obstructive pulmonary disease exacerbation, or pneumonia. Independent associations between each medication-related risk factor and 30-day, 3-month, and 6-month readmissions will be determined using bivariate and multivariate regression analysis. Medication-related risk factors will include specific diagnoses in past medical history, patient demographics, insurance information, number of medications on admission and at discharge, length of stay, time since last readmission, specific classes of medications on admission and discharge, number of pharmacies on file, social work consults, and if the patient is without a primary care provider on file. All patient identifiers will be removed prior to the analysis.

Poster Title: Impact of a pharmacist-run smoking cessation clinic on reduction in cigarette use
Primary Author: Nathan Mitchell, CPS/Mercy Hospital and Medical Center, IL; Email: nathan.mitchell@mercy-chicago.org
Additional Author(s):
Michael Mikrut
Vaishali Shah

Purpose: Cigarette smoking is the primary cause of preventable death and morbidity in the United States and is highly addictive. Smoking is linked to lung cancer, heart disease, and many other comorbidities. Between 1965 and 2014 over 20 million people died from smoking-related causes. Given the importance of smoking cessation on patient outcomes, the objective of this study is to evaluate the efficacy of a pharmacist-run smoking cessation clinic. The primary outcome is to determine the rate of cigarette use reduction in patients attending a smoking cessation clinic at a community teaching hospital.

Methods: This study is a retrospective cohort chart review of patients who attended Mercy Hospital’s outpatient smoking cessation clinic between July 2014 and August 2016. Patients will be evaluated through review of their electronic medical records. Patients will be included if they are at least 18 years of age, enrolled in the smoking cessation clinic, and completed two or more counseling visits with a pharmacist. Patients will be excluded if they are pregnant or had uncontrolled hypertension, arrhythmias, or other chronic diseases at the time of referral. Data collected will include percentage of patients who quit smoking, time to complete smoking cessation, number of visits to stop smoking, number of visits within the first three months, and predictive factors for quitting. A threshold of less than five cigarettes per day will be considered clinically significant; however, any reduction in cigarette use will be recorded.

Poster Title: Implementation of a pain scorecard and its impact on hospital-wide pain scale administration and reassessment timing compliance

Primary Author: Amanda Daniels, HSHS St. Elizabeth's Hospital, IL; Email: amanda.daniels@hshs.org

Additional Author(s):
Joshua Schmees
Julia Schimmelpfennig

Purpose: The objective of this study is to develop a pharmacy managed scoring tool to improve nursing compliance with as needed pain scale medication administrations and reassessment timing. The appropriate pain medication selection based on the patient’s reported pain level is critical in providing optimal patient care. Nursing interpretation of as needed pain qualifiers and relating the patient’s reported pain score is within the nursing scope of practice; however, many factors may limit compliance. Implementation of the scorecard allows for trending weekly pain scale administration and reassessment timing data to assess improvement in hospital-wide compliance.

Methods: After institutional review board approval, the data that will be collected from the electronic medical record system include as needed pain medication administrations, reported pain scores, and timing of reassessments. This information will be compiled into an electronic database that will be modified to allow for a summary scorecard to be sent to each nursing manager with the overall hospital-wide compliance, further broken down into department and user specific information. Compliance with as needed pain medication administrations and pain reassessment timing will be compared as pre- and post-scorecard implementation with pain scale compliance rates evaluated at six months.

**Poster Title:** Impact of provider education on methacillin-resistant Staphylococcus aureus nasal swabs and antibiotic de-escalation

**Primary Author:** Tyson Dietrich, HSHS St. John's Hospital, IL; **Email:** tyson.dietrich@hshs.org

**Additional Author(s):**
Natalie Tucker
Alexis Bylina
Brandi Strader
Anupam Verma

**Purpose:** To evaluate the influence of provider education regarding methacillin-resistant Staphylococcus aureus (MRSA) nasal swabs as an antimicrobial stewardship instrument to assist with the de-escalation of empiric vancomycin coverage in the intensive care unit (ICU). The primary outcome of the study is to assess the days of empiric vancomycin therapy after ICU providers receive live education regarding the negative predictive value of the MRSA nasal swab. Secondary outcomes will include positive and negative predictive values of MRSA nasal swabs at this institution, development of MRSA pneumonia, provider acceptance of the intervention, and patient mortality.

**Methods:** This is a quasi-experimental pilot study to assess the impact of provider education regarding MRSA nasal swab results and subsequent de-escalation of empiric vancomycin coverage. The initial phase of the study will consist of a retrospective electronic medical record review, from December 1, 2014 to February 28, 2015, to identify and gather data from ICU patients with pneumonia. This retrospective data will provide the institutions pre-education time to de-escalation of empiric vancomycin coverage. The intervention phase will focus on the education of ICU providers. Provider education will consist of live presentations of the literature regarding the predictive value of MRSA nasal swabs concerning MRSA pneumonia. The providers will receive a post-presentation survey to gauge their initial response to the education and assess the probability of implementing what they learned into practice. The final stage of the study will be collecting data prospectively, post-provider education from December 1, 2016 to February 28, 2017, to see if the education provided has any impact on empiric vancomycin de-escalation. Data collection will include baseline patient characteristics,

**Poster Title:** The impact of a nursing driven sedation protocol in mechanically ventilated intensive care unit patients

**Primary Author:** Kyle Dillon, HSHS St. John's Hospital, IL; Email: kyle.dillon@hshs.org

**Additional Author(s):**
Anna Stewart
Alexis Bylina

**Purpose:** The purpose of this study is to evaluate the impact of a nursing driven sedation protocol on outcomes of patients receiving mechanical ventilation. A previous institutional sedation protocol and drug utilization review found that patients who received sedation while mechanically ventilated had inappropriate documentation of both the medications utilized and associated sedation scores. A nursing driven sedation protocol was subsequently developed and implemented in July 2016 to improve utilization of sedative agents and improve patient outcomes. Additionally, this study will also evaluate compliance with the sedation protocol and nursing algorithms.

**Methods:** The retrospective study is currently pending Institutional Review Board approval. Patients mechanically ventilated in the Intensive Care Unit (ICU) from July 1, 2016 to January 31, 2017 will have a chart review performed to assess several factors related to the patient’s sedation. Baseline characteristics collected will include patient age, weight, gender, and admission date. Patients must be eighteen years or older receiving sedation while mechanically ventilated in a critical care area to be included. Patients undergoing targeted temperature management or receiving ventilation less than 24 hours will be excluded. The primary objectives will be length of ICU stay and duration of mechanical ventilation, both reported as average number of days. Data will then be compared to the previous institutional quality initiative to assess the impact of the newly implemented protocol. Secondary measures evaluated will include utilization of the sedation medication and sedation vacation order sets, documentation of Richmond Agitation Sedation Scale (RASS) goal and RASS scores, appropriateness of alterations in sedation agents (if applicable), and documentation of delirium assessments. Appropriateness of sedation agents and dosing alteration will be assessed based on a nursing algorithm for sedation developed as part of the protocol and according to the
ordered physician goal RASS score. In order to meet power of 80%, a total of at least 376 patients must be included in the review.

Poster Title: Assessing the efficacy of multimodal analgesia protocol in orthopedic surgical patients in a community hospital

Primary Author: Erielle Anne Espina, Ingalls Memorial Hospital, IL; Email: eespina@ingalls.org

Additional Author(s):
Alan Fisher
Laura Acevedo
Brandy Cooper-Kirby
Gregory Biedron

Purpose: Traditionally, high-dose opioids have been used to manage postoperative pain after joint reconstruction. Adverse effects of opioids can impair recovery, lead to medical complications, and potentially increase length of stay (LOS). The principal of multimodal analgesia therapy is to use interventions that target several steps of the pain pathway, allowing more effective pain control with fewer side effects. Recent literature suggests that multimodal analgesia protocols (MAP) decreases opioid consumption, increases patient satisfaction, and decreases LOS for orthopedic surgical patients. The objective of this study is to evaluate the efficacy and safety of a newly implemented MAP at Ingalls Memorial Hospital.

Methods: A single-centered, retrospective study was conducted to assess postoperative pain management for patients receiving protocol guided multimodal analgesia following orthopedic hip or knee surgery. Patients were included in this study if they were 18 years or older, had undergone total knee or total hip orthopedic surgery, and had normal renal function. A pre-implementation retrospective analysis was performed to obtain baseline pain score data, opioid consumption rates and adverse event reporting for postoperative orthopedic patients. The pre-implementation retrospective analysis was performed from September 1, 2016 to September 30, 2016. Following the implementation of the MAP, a retrospective chart review was performed for all total knee or total hip orthopedic surgery patients from October 1, 2016 to October 31, 2016. The following data was collected from all patients that met the inclusion criteria: patient age, gender, type of surgery, MAP was used, type and amount of opioids consumed, length of stay, numeric pain scores, adverse events from medications, and patient satisfaction. The primary outcome was the difference in total opioid consumption in morphine
equivalents. Secondary outcomes included the difference in numeric pain scores, adverse events related to opioids, and length of stay.

Poster Title: Prospective analysis of proper personal protective equipment (PPE) use in chemotherapy administration

Primary Author: John McNiff, Ingalls Memorial Hospital, IL; Email: jmcniff@mail.roosevelt.edu

Additional Author (s):
Laura Acevedo
Alan Fisher
Greg Biedron

Purpose: Although safe handling and administration of chemotherapy agents has improved nationwide over the years, a high number of oncology nurses are still contaminating treatment areas putting themselves as well as patients at risk. In response to this issue, the pharmacy department at a small community hospital with infusion centers has created a medication usage evaluation plan to help improve the safety of oncology nurses and patients. The purpose of this study will be to assess the proper use of PPE while oncology nurses are administering chemotherapy to cancer patients and making the necessary interventions to improve safety practices.

Methods: A multi-centered, prospective study of oncology nurses administering chemotherapy agents to cancer patients will be conducted. To ensure that the study will be up to current safety standards, a checklist was created based off of the 2016 OSHA Guidelines. Two pharmacists and one oncology nurse manager will evaluate the oncology nurses using this checklist. The checklist consists of: glove inspection, double gloving, using proper PPE, hand washing after removing gloves and PPE, proper donning and disposal of PPE and keeping beverages and food outside of the treatment area. The study will take place in three outpatient chemotherapy infusion centers as well as the oncology unit in the main hospital. After two months, the findings will be tallied from the checklists of all infusion centers. The primary outcome will be assessing the safety of the oncology nurses and patients using the tallies from all of the checklists. Secondary outcomes will be providing interventions (education, motivation and repetition) after the initial 2 months and evaluate again to assess for improvement in safety outcomes.

**Session-Board Number:** 9-203

**Poster Title:** Comparison of preventative strategies for contrast induced nephropathy in critically ill patients

**Primary Author:** Marissa Kamaryt, Jewel Osco Pharmacies and Midwestern University Chicago College of Pharmacy, IL; **Email:** mkamar@midwestern.edu

**Additional Author (s):**
Payal Gurnani
Nicholas Panos

**Purpose:** Contrast induced nephropathy (CIN) is a serious complication which may progress towards end-stage renal disease (ESRD) and require dialysis with prolonged hospital stay. There is a paucity of data describing the optimal preventative strategy for CIN in the critically ill patient. Therefore, the objective of this study was to compare the efficacy of normal saline (NS) to sodium bicarbonate (BC) with or without N-acetylcysteine (NAC) for the prevention of CIN in critically ill patients exposed to iodinated radiocontrast.

**Methods:** This was a single-center, retrospective, Institutional Review Board (IRB) approved study conducted in an urban tertiary care academic medical center. The primary outcome was the development of acute kidney injury (AKI), as defined by the RIFLE criteria, within 48 hours of radiocontrast administration. Secondary outcomes were the development of AKI requiring hemodialysis, intensive care unit (ICU) length of stay (LOS) and hospital LOS. Patients 18 years of age or older and receiving either NS or BC with or without NAC before and after iodinated radiocontrast administration were included in this study. Any of the following were considered exclusion criteria: a serum creatinine (Scr) greater than or equal to 8 mg/dL, ESRD, history of dialysis or hemofiltration, allergy to NAC, AKI, and pregnancy. Patients could not be included if they received iodinated radiocontrast within 10 days of the initial inclusion event. The initial IRB approved list of patients was screened for administration of radiocontrast during the three year study interval. Those patients identified as receiving radiocontrast during the study were further evaluated for receipt of one of four regimens to prevent CIN (NS, BC, NS plus NAC, and BC plus NAC).
**Results:** Seventy-three patients met inclusion criteria and were included in this analysis: 38 patients (NS group), 16 patients (BC group), 3 patients (NS plus NAC group), and 19 patients (BC plus NAC group). Baseline characteristics were similar among groups, with one exception. Baseline Scr was highest in the BC plus NAC group ($p = 0.04$). The incidence of AKI was similar among groups (10.5 percent, 6.3 percent, 0 percent, and 0 percent in the NS, BC, NS plus NAC, and BC plus NAC groups, respectively ($p = 0.281$)). In addition, there was no difference in the need for dialysis post-contrast administration ($p = 0.706$), ICU LOS and hospital LOS ($p/ICU = 0.67$, hospital = 0.96).

**Conclusion:** Our study concluded that NS was as effective as BC with or without NAC in the prevention of CIN in critically ill patients. Information gained from this study can guide agent selection of preventative CIN strategies in times of drug shortages and drug supply interruptions. Further studies are needed to validate this conclusion in specialized ICU populations.
Purpose: Platinum based antineoplastic agents are commonly used for the treatment of a variety of cancers. With the increased use of platinum agents, there is an increased risk of patients developing hypersensitivity reactions. Recently published literature suggests a higher incidence of hypersensitivity reactions when a patient is given greater than 7 cycles of carboplatin or 6 cycles of oxaliplatin. The purpose of this study is to identify a potential lifetime dose of carboplatin and oxaliplatin and to determine potential risk factors for these hypersensitivity reactions.

Methods: This is a retrospective chart analysis of all patients being treated with platinum agents from 2008 to 2016. This study will compare patients who developed a hypersensitivity reaction to a control group that did not develop a hypersensitivity reaction. All patients who received platinum based antineoplastic agents will be identified through Cerner computer system. Patients will be excluded if they meet one of the following criteria: less than 18 years of age, received greater than 9 cycles of oxaliplatin, received greater than 4 cycles of carboplatin, or transferred from an outside facility for continuation of care. Data to be collected and analyzed includes age, gender, weight, presence of preexisting allergies, indication for treatment, renal function, prior or current exposure to platinum containing agents, chemotherapy dosing regimen, presence of a hypersensitivity reaction, use of pre-medications for mitigation of treatment reactions, number of attempts or trials before determining treatment termination, and total dose of platinum agent received. Patients will further be categorized based on total dose received and evaluated for potential risk factors for development of hypersensitivity reactions. The primary outcome will be determined by the
average total dose at which the majority of patients experience a hypersensitivity reaction. Statistical methods to be determined.

Poster Title: Conversion of patients from insulin U-100 to U-500 and the effect on glycemic control

Primary Author: Dharti Patel, John H. Stroger, Jr. Hospital of Cook County, IL; Email: dhartipatel15@gmail.com

Additional Author (s): Sol Farias

Purpose: Insulin U-500 is prescribed frequently due to rising rates of insulin resistance. U-500 has safety issues and lacks consensus on the method of converting patients from U-100 to U-500, which may lead to under or over treatment. Common methods include 1:1 conversion of the total daily dose of U-100 to U-500 for patients with hemoglobin A1c (HbA1c) greater than or equal to 8 percent, and dose reduction of 10-20 percent for patients with lower initial HbA1c. This study will identify patients converted from U-100 to U-500 and evaluate the safety and efficacy on glycemic control in type 2 diabetic patients.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will be used to identify patients converted from insulin U-100 to U-500. The following data will be collected: age, gender, weight, onset of diabetes, glucose level, HbA1c and method of U-100 to U-500 insulin conversion. Chart and patient-reported hypoglycemia, defined as blood glucose less than or equal to 70 mg/dL, and hyperglycemia, defined as pre-prandial blood glucose levels greater than 130 mg/dL and postprandial blood glucose levels greater than 180 mg/dL, will also be identified. Provider documentation will be reviewed to determine if alternate etiologies of hypoglycemia and hyperglycemia can be identified. Once the data has been collected patients will be categorized by method of conversion and then compared by rates of hypoglycemia, in range blood glucose values, and hyperglycemia.

**Poster Title:** Implementation and evaluation of public health outreach events as resident teaching experiences

**Primary Author:** Alvin Godina, John H. Stroger, Jr. Hospital of Cook County, IL; **Email:** alvingodina@gmail.com

**Additional Author(s):**
Molly Rockstad

**Purpose:** Mitigating negative effects of health disparities is a goal of public health initiatives. Offering medication reviews through outreach events is one approach to achieve this goal. Such events may be ideal for pharmacy residents to gain additional teaching opportunities with the participation of fourth year pharmacy students. The objective of this study is to assess feasibility of implementing outreach events, and to evaluate their impact on the public through evaluation of interventions made, as well as through patient reported satisfaction of these events. There is also an opportunity to determine if a benefit exists in near-peer teaching.

**Methods:** Medication review events will be scheduled at least monthly in a hospital-based outpatient pharmacy. Prior to each event, residents will lead a topic discussion for students on conducting a medication review, providing an opportunity to answer questions. Patients who consent to a pre- and post-survey will be included in data analysis. Patients who do not consent can take part in this service yet will not be included in analysis. The pre-survey will assess number of medications, if the patient receives help with their medications, use of an adherence aid, ability to read prescription labels, and self-reported understanding of medications. During the review, students will document patient knowledge of the following information for each medication: indication, dose, instructions for use, and associated adverse effects. Patients will be educated on unknown information. Upon completing the review, the post-survey will again assess patient self-reported understanding of their medications as well as overall satisfaction with the event. Following each event the resident will debrief with students, answering questions or concerns. A survey will then be administered to gauge students’ experience with near-peer teaching. Resident preparedness and ability to answer questions, as well as student comfort level with said resident will be assessed.

**Poster Title:** Evaluation of continuous infusion anti-hypertensives in the intensive care unit

**Primary Author:** Elena Telebak, Loyola University Medical Center, IL; **Email:** elena.telebak@lumc.edu

**Additional Author(s):**
Erin Mancl
Athanasia Eleftheropoulos

**Purpose:** Hypertensive emergency is a category of hypertensive crisis defined as blood pressure (BP) greater than 180/120 mm Hg with end-organ damage. It requires intravenous anti-hypertensive therapy to lower the mean arterial pressure by 20-25 percent within 60 minutes, avoiding hypotension which may compromise organ perfusion. Postoperative hypertension in cardiac surgery also requires BP control, as it is associated with increased morbidity, myocardial ischemia, and postoperative bleeding. The main objective of this drug evaluation is to compare the efficacy, safety, and relative cost of continuous infusion clevidipine, nicardipine, nitroprusside, or labetalol when used for hypertensive emergency and postoperative cardiac surgery.

**Methods:** This is a retrospective chart review of patients receiving continuous infusion clevidipine, nicardipine, nitroprusside, or labetalol for treatment of hypertensive emergency and acute hypertension in cardiac surgery patients. Adult patients admitted to the intensive care units at our institution from May 1st, 2016 to June 30th, 2016 will be included. Patients who were initiated on therapy in a pre-procedural setting will be excluded. Demographic data collected will include age, weight, body mass index, and ordering service. Clinical outcomes to be assessed include average time required to achieve pre-specified BP goals, duration of therapy, and the incidence of hypotension and bradycardia. For each medication, the mean and the maximum dose received will be measured. Proper discontinuation of continuous infusion agents will be evaluated with successful conversion to an oral agent defined as transition without the requirement of a continuous infusion within 24 hours of conversion. A brief cost analysis will also be performed. Data will be analyzed using descriptive statistics.

**Poster Title:** Medication use evaluation of liposomal bupivacaine in bariatric surgery patients

**Primary Author:** Michelle Nguyen, Loyola University Medical Center, IL; **Email:**
michelle.nguyen508@gmail.com

**Additional Author(s):**
Natalie Prentice
Elizabeth Greenhalgh

**Purpose:** Liposomal bupivacaine (Exparel) is a novel, sustained release formulation of bupivacaine hydrochloride. Several clinical trials in colorectal surgery have demonstrated that infiltration with liposomal bupivacaine at the end of the procedure reduced post-operative pain, opioid use, and hospital length of stay. Liposomal bupivacaine was approved at Loyola University Medical Center, a 569-bed tertiary care hospital, for use in bariatric surgery in March 2016. The purpose of this medication use evaluation is to compare post-operative opioid usage and length of stay in bariatric surgery patients pre- and post-implementation of liposomal bupivacaine.

**Methods:** This is a retrospective cross-sectional analysis comparing 50 bariatric surgery patients who received liposomal bupivacaine intra-operatively between April and July 2016 to 50 similar patients who did not receive liposomal bupivacaine between December 2015 and February 2016. Information to be collected and compared includes patient demographics, comorbidities, length of stay, time to first post-operative opioid dose, mean post-operative pain scores, and cumulative post-operative opioid consumption in morphine equivalents.

**Results:** Data collection in progress

**Poster Title:** Efficacy of a pharmacist-driven warfarin protocol from early implementation to current practice  

**Primary Author:** Vishali Amin, Loyola University Medical Center, IL; **Email:** vpatel022@gmail.com  

**Additional Author(s):**  
Stephanie Bennett Wesling  
Candy Ng  

**Purpose:** Warfarin is challenging to dose and monitor due to its unpredictable effects on the international normalized ration (INR), drug interactions and narrow therapeutic index. Pharmacist-driven warfarin management has been shown to increase the number of therapeutic INRs and decrease the time needed to reach therapeutic goal. Though studies have analyzed the efficacy of warfarin dosing pre and post-implementation of a pharmacist-driven protocol, none have evaluated the impact on therapeutic outcomes after initiation. This study was designed to evaluate whether pharmacist achievement of therapeutic INR has improved since initial implementation of pharmacist-managed warfarin anticoagulation.  

**Methods:** A pharmacist-managed warfarin service was implemented for pharmacists to dose warfarin and monitor INR upon provider referral. To determine the efficacy of this protocol, we completed a retrospective chart review of 200 patients. We randomly selected 100 patients from April 2014 and May 2016, representing early implementation and current practice respectively. Age, gender, weight, baseline INR, need for INR reversal, reversal agent administered, primary service and hospital location were recorded. Patient charts were reviewed to determine whether the INR was within goal at consult, if patient was warfarin naive, anticoagulation indication, INR goal, parenteral anticoagulation, low vitamin K diet and whether the INR was within goal at discharge. INR chronology was collected daily. This included the date, INR, dose administered, whether INR was therapeutic, dose adjustment, need for INR reversal and reversal agent administered. The primary outcome measure was the percentage of patients with a therapeutic INR. Secondary outcomes included the incidence of an INR greater than 4 or less than 2, the incidence of rapid change in an INR (defined as an increase or
decrease greater than or equal to 0.5) and the incidence of clinically significant bleeding and thrombotic events.

**Poster Title:** Evaluating the appropriate continuation of outpatient highly active antiretroviral therapy upon hospital admission at an academic medical center

**Primary Author:** John Donaldson, Loyola University Medical Center, IL; **Email:** cdonaldson87@gmail.com

**Additional Author (s):**
Laurie Labuszewski
Evelina Lin

**Purpose:** Continuity of a patient’s highly active antiretroviral therapy (HAART) is imperative in preventing deleterious consequences, such as furthering the development of Human Immunodeficiency Virus (HIV) resistance. While rates of HIV resistance development are highly variable, it has been reported that even a 24 hour gap in coverage may increase resistance rates. Prior studies have found that HIV-associated medication error rates upon hospital admission may be as high as 30 percent. In this evaluation, we explore the appropriateness of HAART regimens for HIV patients upon admission to an academic medical center.

**Methods:** This evaluation is a retrospective chart review of HIV-positive patients on HAART who were admitted at a suburban, academic medical center from September 2015 to September 2016. A review of electronic medical records was performed to identify patient admissions and obtain the following data: age, gender, ethnicity, prior to admission HAART regimen, inpatient HAART regimen ordered upon admission, route of administration and time to resuming HAART. The objectives of this review were to assess HAART medication error rates upon admission, including delays in restarting therapy. Causes of delay in resuming HAART or inappropriate ordering of HAART were examined, including non-formulary medications, administration route barriers and prescribing errors. Descriptive statistics will be used to analyze data, and results will be presented in poster format.

Poster Title: Evaluation of the use of intravenous acetaminophen

Primary Author: Hailey Steuber, Loyola University Medical Center, IL; Email: hailey.steuber@lumc.edu

Additional Author(s):
Natalie Prentice
Whitney Chaney

Purpose: Intravenous (IV) acetaminophen is FDA approved for fever reduction and management of mild to moderate pain, and moderate to severe pain in conjunction with opioids. IV acetaminophen was removed from formulary at our institution in 2014 due increased cost and lack of clinical benefit compared to alternate therapies. IV acetaminophen may be ordered as a non-formulary agent in patients who cannot tolerate oral or rectal medications, and when opioids and nonsteroidal anti-inflammatory drugs are contraindicated. This evaluation will characterize use and identify if opportunity exists to correct inappropriate prescribing, optimize use, and decrease costs.

Methods: This retrospective chart review will evaluate 100 patients who had non-formulary orders placed, and received at least one dose of IV acetaminophen from August 2015 to August 2016. Patients will be identified and data will be collected using the electronic medical record. The following data will be collected: patient demographics, dosing parameters (creatinine clearance, weight, and liver function tests), dose, duration of therapy, ordering service, and type of surgery if applicable. In addition, the use of other analgesic and antipyretic medications concurrently and within 48 hours of IV acetaminophen will be evaluated. All data will be collected without patient identifiers and will be stored securely. Descriptive statistics will be used to analyze data, and results will be presented in a poster format. Data analysis will include assessment of appropriate dosing, monitoring, and indication with regards to inability to use alternate analgesics or antipyretics. Amount of use in patients where there was no contraindication to formulary agents will be evaluated to identify areas for process improvement.

Poster Title: Evaluating the efficacy of a weight adjusted dosing strategy for an unfractionated heparin nomogram

Primary Author: Bryan Menich, Loyola University Medical Center, IL; Email: bryan.menich@lumc.edu

Additional Author(s):
Abigail Cook
Stephanie Bennett Wesling

Purpose: The purpose of this study is to evaluate the efficacy of a weight adjusted dosing strategy for an unfractionated heparin (UFH) nomogram in achieving and maintaining a therapeutic activated partial thromboplastin time (aPTT) in patients on an UFH infusion.

Methods: This nomogram provides UFH dosing and laboratory monitoring instructions to nurses for patients requiring therapeutic anticoagulation for atrial fibrillation or acute coronary syndrome. An aPTT between 55 and 75 seconds is considered therapeutic for this nomogram. Patients were excluded from the study if they were less than 18 years old, managed with an alternate aPTT goal previously within the encounter, or received less than 24 hours of continuous infusion. Data collection for each patient includes baseline demographics, baseline aPTT, administration of initial and intermittent heparin bolus doses, duration of therapy, all aPTT values during therapy, reasons and duration of stoppage, and incidence of protocol deviation. The primary endpoint of this study is the time to first therapeutic aPTT. Secondary endpoints include the average percentage of time patients remained above, below, or within the therapeutic range and the average number of protocol deviations per patient. A total of 175 patients managed with the UFH nomogram were screened, and 100 patients met the study inclusion criteria. Data has been collected on 50 patients to date. Data collection and analysis is ongoing.

**Poster Title:** Assessment of the safety and efficacy of an inpatient pharmacist managed warfarin dosing protocol

**Primary Author:** Chris Mahaffey, Memorial Medical Center, IL; **Email:** csm11591@gmail.com

**Additional Author(s):**
Julie Downen
Ashlie Kallal
Manali Soni

**Purpose:** Implementing a pilot pharmacy warfarin dosing service at our hospital will provide valuable information as to the feasibility of a full scale implementation of the service in the future. This dosing service trial will allow pharmacy management to assess if a full scale version would 1) be physically feasible with the current resources, 2) result in improved efficacy and safety outcomes for the patient, and 3) result in cost savings for the hospital through pharmacy management of a high risk medication.

**Methods:** This study is currently under review by the Institutional Review Board as a quality improvement project. A pharmacy managed warfarin dosing protocol has been created and approved by the Pharmacy and Therapeutics committee which establishes the warfarin dosing guideline for the pharmacists. Patients who are referred to the warfarin dosing service will be assessed for inclusion into one of two treatment populations: new start warfarin therapy or maintenance warfarin therapy. Based on the inclusion and exclusion criteria for these two groups, patients will be case matched with patients who previously had their warfarin managed by a physician before the initiation of the dosing service trial. This will allow comparison of outcomes between pharmacist managed and physician managed warfarin therapy. The primary efficacy objectives for the new start warfarin group include time to therapeutic INR and percent time in goal INR range. The primary objective for the maintenance warfarin group is percent time in goal INR range. Secondary objectives include length of stay, readmission within 30 days, number of supratherapeutic INRs greater than or equal to 4, number of supratherapeutic INRs greater than or equal to 4 requiring reversal, and number of bleeding events requiring discontinuation of warfarin.

**Poster Title:** Comparison of nicardipine and clevidipine for the management of hypertension in acute stroke  

**Primary Author:** Zachary Rosenfeldt, Memorial Medical Center, IL; **Email:** rosenfeldt.zachary@mhsil.com  

**Additional Author (s):**  
Katelyn Conklen  
Don Ferrill  

**Purpose:** Rapid reduction to goal blood pressure (BP) reduces the risk of brain injury in acute stroke patients, however, there is a lack of evidence or guideline recommendation for a preferred antihypertensive agent. Clevidipine and nicardipine have both been studied as reliable agents for use in stroke, but no studies have compared these two directly. The purpose of this study is to evaluate the use of clevidipine and nicardipine for treatment of hypertension in patients with an acute stroke.  

**Methods:** This study will be submitted to the Institutional Review Board for approval. A retrospective chart review from 3/17/2015 to 9/30/2016 will identify patients 18 years and older with intracranial hemorrhage, acute ischemic stroke, and subarachnoid hemorrhage treated with nicardipine or clevidipine for blood pressure (BP) reduction. Patients will be excluded if on dialysis or diagnosed with traumatic brain injury or intracranial neoplasm. The following baseline characteristics will be collected: age, gender, ethnicity, Acute Physiologic and Chronic Health Evaluation (APACHE) score, Glasgow Coma Scale, stroke type, family history of stroke, transient ischemic attack, hypertension, blood pressure, heart rate, serum creatinine, computed tomography (CT) scans, electrocardiogram, and medications. Data will be recorded without patient identifiers and maintained confidentially. Co-Primary outcomes include achievement of the care team defined BP goal at 1 and 6 hours post therapy initiation. Secondary outcomes include: composite in-hospital death, 30 day readmission, rebleeds on 24 hour CT scan, conversion from ischemic to hemorrhagic stroke on 24 hour CT, and hematoma expansion in the hemorrhagic subset. The following data will also be collected: length of intensive care unit stay, length of hospital stay, time to goal BP, time spent in goal BP,
maximum and minimum systolic BP during treatment, BP range during treatment, the need for additional intravenous antihypertensives, and reported adverse effects.

Poster Title: Implementation of an antimicrobial stewardship order set for the treatment of Clostridium difficile infection in hospitalized patients

Primary Author: Sreya Patel, Mercy Hospital and Medical Center, IL; Email: spatel52008@gmail.com

Additional Author(s):
Katelyn Lappin
Michael Mikrut

Purpose: In 2011, half a million infections were caused by Clostridium difficile (C. difficile) in the United States. Approximately 83,000 patients experienced at least one recurrence and 29,000 expired within 30 days of the initial diagnosis. Treatment of Clostridium difficile infection (CDI) is based on clinical data and the patient’s history of CDI. Patients are often incorrectly stratified based on disease severity and inappropriately treated leading to recurrent infections. The purpose of this study is to identify discrepancies in the stratification and treatment of CDI in hospitalized patients before and after the implementation of a standardized antimicrobial stewardship order set.

Methods: This study will retrospectively evaluate compliance with Infectious Diseases Society of America (IDSA) guidelines on the prescribing of antimicrobials for CDI before and after the implementation of a C. difficile order set. Two patient groups will be retrospectively evaluated. The first group will be analyzed before implementation of the order set from May 1, 2016 to August 31, 2016. The second group will be analyzed after implementation of the order set from November 1, 2016 to February 28, 2017. Patients will be selected based on the date of the positive polymerase chain reaction (PCR) assay for C. difficile toxin. Patients will be included if they are greater than or equal to 18 years of age and have a new, confirmed clinical diagnosis of CDI with a positive PCR assay. Data collection will include: baseline demographics and characteristics, medication history, laboratory data, patient history of CDI, antibiotic regimen prescribed for the treatment of CDI, treatment outcomes, overall compliance with the order set, length of hospital stay, transfer to a higher level of care, colo-rectal surgery consult, infectious diseases consult, radiology studies, and probiotic use.

Poster Title: Medication administration through enteral feeding tubes: a quality improvement project

Primary Author: Katherine Wang, Mount Sinai Hospital, IL; Email: katherine.wang@sinai.org

Additional Author(s): Karen Trenkler
Dallas Schepers

Purpose: Administration of medications through enteral feeding tubes presents challenges to optimizing medication therapy. Poor administration practices have been linked to numerous patient care problems including clogging of feeding tubes, unpredictable drug-drug and drug-formula interactions, subtherapeutic drug levels, and patient death. In 2009, the American Society of Parenteral and Enteral Nutrition (ASPEN) released recommendations on administration of medications through feeding tubes. However, observational studies and nursing surveys have found that actual practice can significantly deviate from these recommendations. The initial step of this quality improvement project will assess current medication administration practices at this institution.

Methods: Nurses’ technique for administering medications through enteral feeding tubes will be evaluated during an initial observation period from August through September 2016. An automated report of patients on tube feedings will be used to identify patients for observation. In addition to the observation period, a survey will be used to assess pharmacists’ and nurses’ baseline knowledge of proper medication administration practices. Data will be reviewed in collaboration with dietary services to identify the need for policy and procedure revisions, development of educational materials, and other interventions, if needed.

**Submission Type:** Research-in-Progress

**Session-Board Number:** 9-217

**Poster Title:** Impact of ambulatory care pharmacy services on human immunodeficiency virus (HIV) patients with concomitant diabetes, hypertension, or both in a safety net clinic

**Primary Author:** Diebh Faraj, Mount Sinai Hospital Medical Center, IL; **Email:** diebh.faraj@sinai.org

**Additional Author (s):**
Sharon Sam
Thomas Yu

**Purpose:** Human immunodeficiency virus (HIV) as well as antiretroviral therapy have been associated with increased metabolic effects resulting in impaired glucose tolerance, insulin resistance, increased blood pressure and elevated lipids. In primary care clinics, studies have demonstrated improved blood pressure and hemoglobin A1c with ambulatory care pharmacy services. In addition, HIV ambulatory care pharmacists significantly improve medication adherence leading to immunologic and virologic suppression. The primary objective of this study is to evaluate the impact of an ambulatory care pharmacist on improving clinical outcomes of patients diagnosed with HIV and diabetes, hypertension or both in a low income urban community.

**Methods:** This study is a retrospective chart review of HIV patients with concomitant diabetes, hypertension or both from October 2014 to March 2017. This study will be submitted to the Institutional Review Board for approval. Historically, the infectious diseases clinic utilized physicians and case management services for medication counseling and adherence. In October 2015, pharmacy services were implemented to monitor and manage medication therapy. All patients 18 years of age and older with a documented diagnosis of HIV with diabetes or hypertension and were adherent to two or more clinic visits were included. The primary objective is to compare the number of HIV patients who achieve blood pressure and diabetes treatment goals before and after the implementation of an HIV ambulatory care pharmacist. The secondary objectives are to evaluate the correlation between virologic suppression and controlled diabetes, hypertension or both. Hemoglobin A1c and blood pressure goals will be in compliance with the American Diabetes Association and Eighth Joint National Committee (JNC...
8) guidelines. The following data will be collected: HIV RNA, CD4 count, patient demographics, hemoglobin A1c, blood pressure, and types of pharmacist interventions.

**Results:** Data collection ongoing

**Primary Author:** Matthew Dandino, Mount Sinai Hospital Medical Center, IL; **Email:** matthew.dandino@sinai.org

**Additional Author(s):**
Tejal Patel
Thomas Yu

**Purpose:** Transitions of care (TOC) pharmacists reconcile medication regimens to ensure medication accuracy and patient safety upon discharge. The primary objective of this research project is to evaluate two TOC pharmacists’ impact on the rate of patient readmission at a safety net hospital within the first 30 days post-discharge. Secondary objectives will look at interventions logged by a TOC pharmacist, and ability of the TOC pharmacist to reach the patient once discharged for follow-up at 7, 14, and 30 days.

**Methods:** This retrospective chart review will assess the impact of TOC pharmacists on 30-day readmission rates. Admitted patients who are counseled by the TOC pharmacist will be included into the study. The study will examine 30-day readmission rates with TOC pharmacists present compared to only having technician discharge services available. Electronic medical records (EMRs) will be used to collect data. Patients will be identified for the research project via clinical interventions logged in the hospital’s EMR. Data collection will include the following: TOC pharmacist interventions, the rate of readmission within the first 30 days post-discharge, and ability of a TOC pharmacist to reach the patient post-discharge at 7, 14, and 30 days.

**Poster Title:** Gentamicin utilization for Gustilo-Anderson type III open fractures in trauma

**Primary Author:** Tanya Abi-Mansour, Mount Sinai Hospital Medical Center, IL; Email: tanya.abi-mansour@sinai.org

**Additional Author(s):**
Marc McDowell
Kuntal Patel

**Purpose:** Open fractures are commonly encountered in the trauma population. The Eastern Association for the Surgery of Trauma (EAST) has addressed the need for prophylactic antibiotics for Gustilo-Anderson type I, II, and III open-factures. Aminoglycosides are recommended for additional coverage of gram-negative pathogens in type III open fractures. The 2011 EAST guidelines do not make a definitive recommendation on traditional versus extended-interval aminoglycoside dosing and no recent publications have addressed dosing strategies. The objective of this study is to compare the efficacy and safety of traditional aminoglycoside dosing versus extended-interval dosing as prophylaxis in patients with type III open fractures.

**Methods:** This is a single-center, retrospective cohort study in patients who presented to the emergency department from January 1, 2009 through October 31, 2015 with a type III open fracture requiring the use of gentamicin. A gentamicin utilization report was generated to identify patients for inclusion in the study. Patients who received traditionally-dosed gentamicin were compared to those who received extended-interval dosing. The primary efficacy outcome was surgical-site infection within 1 year of injury. The primary safety outcome was acute kidney injury.

**Results:** Data collection is currently in progress.

**Conclusion:** Data collection is currently in progress.

Poster Title: Safety and efficacy of inhaled nitric oxide in patients with acute respiratory distress syndrome

Primary Author: Min Kim, Mt. Sinai Hospital Medical Center, IL; Email: min.hakim@sinai.org

Additional Author(s):
Basirat Sanuth
Karl Wainwright
Maria Iliescu
Sameer Shah

Purpose: Acute respiratory distress syndrome (ARDS) is a clinical syndrome which can lead to respiratory failure and increased mortality. The management of ARDS consists of supportive care which includes treatment of underlying causes, prone positioning, mechanical ventilation and pharmacologic treatment. Inhaled nitric oxide (iNO) is a pulmonary vasodilator used in patients with severe hypoxemia. It has demonstrated significant improvement in oxygenation for a short period of time. The objective of this study is to review the safety and efficacy of iNO in adult medical intensive care unit patients with ARDS.

Methods: This is a retrospective, cohort study reviewing the use of iNO for patients admitted to the medical intensive care unit (MICU) between 2014 and 2016. The following data was collected via electronic medical record system: age, gender, weight, ICU and hospital length of stay, history of chronic respiratory disease, utilization of conventional therapy, vital signs, dose and duration of iNO, arterial blood gas, and mortality. The primary outcome measure is ventilator free days post-initiation of iNO. The secondary outcomes include change in partial pressure of oxygen in arterial blood (PaO2), PaO2/FiO2 ratio, mortality, and cost.

Poster Title: Effects of reduced monitoring of low-dose ketamine infusions

Primary Author: Christine Kim, NorthShore University Health System, IL; Email: ckim4@northshore.org

Additional Author(s):
Martina Novotny

Purpose: Low-dose intravenous (IV) ketamine infusions have been shown to be safe and effective for adjunctive analgesia in chronic pain, neuropathic pain, bone metastases, sickle cell disease, and post-operatively, especially in patients with opioid tolerance. The dissociative anesthetic properties of low-dose ketamine provide pain control without causing respiratory depression. The most common adverse effects of low-dose ketamine infusions include sedation, visual disturbances, and CNS excitation characterized by delirium, agitation, hallucinations, and vivid dreams. This medication use evaluation will focus on this institution’s expanded use of low-dose IV ketamine infusions without intensive care monitoring, and evaluate the effects of reduced monitoring.

Methods: This quality assurance evaluation is exempt from review by the Institutional Review Board. Through retrospective chart review all adults over 18 years of age who received low-dose IV ketamine infusions on general medical and surgical units between July 1, 2015 and June 30, 2016 will be identified. The following data will be collected: vital signs, duration of low-dose IV ketamine, requirements of change in acuity of care to an intensive care unit, discontinuation and dose reductions of ketamine due to intolerability of psychiatric adverse effects including delirium, agitation, hallucinations, irrational behavior, confusion, vivid dreams, and sedation, peak dose of ketamine received, and Richmond Agitation and Sedation Scale scores. The primary objective will be to evaluate whether patients receiving low-dose IV ketamine infusions require a change in acuity of care, defined as a transfer to the intensive care unit. Secondary objectives include evaluating hemodynamic changes during low-dose IV ketamine infusion and evaluating discontinuation of IV ketamine infusion due to psychiatric adverse effects. Descriptive statistics will be used to evaluate data.

**Poster Title:** Evaluation of continuous opioid infusion for post-operative pain management in infants

**Primary Author:** Quang Phan, NorthShore University Health System, IL; **Email:** qphan@northshore.org

**Additional Author (s):**

Pooja Shah

**Purpose:** Neonates in the intensive care setting undergo numerous painful procedures. Inadequately treated pain can lead to hemodynamic instability, neuro-developmental delays, and behavioral delays. Opioid therapy remains first line for systemic pain control, with concerns for tolerance, withdrawal, and developmental delays associated with its use. In January 2016, the American Academy of Pediatrics (AAP) recommended intravenous (IV) acetaminophen as an adjunct agent for systemic pain management and opioid requirements reduction. This evaluation will assess the continuous opioid infusion requirements prior to the addition of IV acetaminophen in June 2016; data collected will be used in a future analysis for comparison purposes.

**Methods:** This evaluation is exempt from review by the Institutional Review Board due to its scope as a quality assurance assessment. A descriptive, retrospective chart review will be conducted for infants from January 1st, 2014 - June 31st, 2016 who received continuous opioid infusion post-operatively. A patient list will be generated of all patients who received continuous opioid infusion, and the following data will be collected: gestation age, date of birth, birth weight, gender, surgical procedure, post menstrual age at time of procedure, cumulative opioid dose in the first 48 hours post-operation, overall dose for the entire duration of the therapy, and total duration of opioid therapy. The secondary endpoint is to evaluate the average N-PASS score in the first 48 hours post-operation. All patient data will be de-identified and maintained confidentially. Descriptive statistics will be used for analysis of data

**Poster Title:** Development and implementation of an antimicrobial stewardship program within a multisite health system

**Primary Author:** Jae Shin, NorthShore University HealthSystem, IL; **Email:** shin.jaer@gmail.com

**Additional Author(s):**
Jeff Thiel

**Purpose:** The Centers for Medicare and Medicaid Services (CMS) proposed new requirements for hospitals to implement an antimicrobial stewardship program (ASP) to help reduce inappropriate antimicrobial use and resistance. Multiple studies have demonstrated that an antimicrobial stewardship program could potentially reduce antibiotic use by 22-36 percent and produce an annual savings of approximately 200,000-900,000 dollars based on hospital size. Other benefits associated with a stewardship program include reduction in multi-drug resistant pathogens and Clostridium difficile infections. This project was initiated to determine the impact on antibiotic usage and cost savings from an antimicrobial stewardship program.

**Methods:** An interdisciplinary team consisting of three infectious disease (ID) physicians, one infectious disease pharmacist, two hospital administrators, pharmacy director, and a pharmacy resident worked together to develop a project plan to initiate an antimicrobial stewardship program. The physicians and pharmacist worked together to create a checklist of responsibilities based on the CMS proposal. After the responsibilities were complied, it was determined that 1.4 full-time equivalent (FTE) ID physicians, two FTE ID pharmacists, and a part-time data analyst were required to fulfill the CMS recommendations. The pharmacy resident’s role was to perform literature research and create a business plan to predict the potential costs and savings from initiating a stewardship program. After extensive literature search, it was concluded that there was a potential for a 15 percent cost savings in the first year. There was also potential for greater than one million dollars in overall savings in three years after incorporating costs for employees with benefits. In order to track antibiotic usage and potential savings, a retrospective analysis was initially conducted to determine the baseline of antibiotic use and expenditure. After the implementation period of six months, we plan to collect data within the same time period as the baseline data to determine the benefits of an
ASP. This project is exempt from the institutional review board as it is a performance improvement project.

Poster Title: Impact of perioperative administration of intravenous multiple electrolytes solution on postoperative hyponatremia in total joint replacement patients

Primary Author: Rachel Bruns, NorthShore University HealthSystem, IL; Email: rbruns@northshore.org

Additional Author(s):
Carol Heunisch

Purpose: Hyponatremia is associated with risk of perioperative morbidities in orthopedic surgical patients. In attempt to reduce occurrence of postoperative hyponatremia, a multiple electrolytes solution containing 140 milliequivalents per liter of sodium was selected to be administered perioperatively to orthopedic surgical patients in place of a fluid containing 130 milliequivalents per liter of sodium. The purpose of this review is to evaluate the incidence of postoperative hyponatremia in primary total knee or hip replacement patients before and after implementation of the multiple electrolytes solution protocol and to determine if an association exists between incidence of postoperative hyponatremia and duration of hospitalization.

Methods: This medication use evaluation qualifies as a quality assurance project and is exempt from Institutional Review Board approval. A retrospective chart review of patients at a community hospital aged 18 years and older who underwent primary total knee or hip replacement will be completed. Patients will be excluded if they have undocumented preoperative sodium levels and/or postoperative sodium levels within 48 hours following surgery. Patient lists will be generated from the electronic health record as a report. The following data will be collected: patient demographics, attending provider, ordering provider, authorizing provider, order number, order start and end dates, name of fluid and rate administered, time and date of fluid administration, discharge diagnosis, baseline serum sodium level, serum sodium levels on postoperative days one and two, admission and discharge dates, and time in days from postoperative day zero to discharge date. Postoperative hyponatremia will be defined as a documented serum sodium level less than 135 milliequivalents per liter within 48 hours following surgery. Inferential statistics will be used to
analyze data to determine if a difference in incidence of postoperative hyponatremia exists between groups.

**Results:** N/A

**Conclusion:** N/A
Purpose: Procedural sedation and analgesia (PSA) is used to produce amnesia, anxiolysis, and analgesia to help patients tolerate procedures. Ketamine is an antagonist of N-methyl-D-aspartate receptors in the central nervous system that produces analgesia and dissociation from external stimuli. These unique pharmacologic properties have made it a popular medication for PSA in both adult and pediatric patients. Potential side effects of ketamine include hypertension, hypotension, tachycardia, emergence delirium, and respiratory depression. This evaluation will assess compliance with documentation of monitoring parameters, adverse drug reactions, and dosing of ketamine for PSA in a community health system emergency department (ED) setting.

Methods: A retrospective chart review of patients who received ketamine in the four emergency departments of a community health system between July 1, 2013 and June 30, 2016 will be conducted. Patients who received ketamine in the ED will be randomized and 100 charts will be reviewed. This medication use evaluation is for quality assurance and is exempt from Institutional Review Board approval. Patients aged 3 months and older who received ketamine for PSA by intravenous or intramuscular route will be included. Patients who received ketamine by continuous infusion or for the indications of rapid sequence intubation or analgesia will be excluded. The following data will be collected: patient weight; age; type of procedure; ketamine dose(s) and route; other sedatives administered in addition to ketamine; monitoring parameters, including heart rate (HR), blood pressure (BP), respiratory rate (RR), oxygen saturation, Aldrete score, pain assessment, and loss of consciousness; timing of vital sign assessment and documentation; and adverse drug reactions, such as emergence delirium. The primary objective will be percentage of patients with complete assessment and documentation of monitoring parameters at specific times pre-, intra-, and post-procedure. Secondary
outcomes will evaluate adult and pediatric dosing, and adverse drug reactions, including changes in BP, HR, and RR. Descriptive statistics will be used to analyze the data.

**Results:** N/A

**Conclusion:** N/A

Poster Title: Impact of pharmacist intervention on intravenous acetaminophen use at a community health system

Primary Author: Hannah DeLuna, NorthShore University HealthSystem, IL; Email: hdeluna@northshore.org

Additional Author (s):
Amber Clouse

Purpose: In November 2010, the FDA approved the use of intravenous (IV) acetaminophen (Ofirmev) for pain and fever management. It is commonly used for patients who are unable to tolerate oral or rectal medications; however, its place in therapy is often questioned due to its high cost. Historical data from a four-hospital community health system suggests that use of IV acetaminophen remains high despite the implementation of an institutional guideline. The objective of this evaluation is to determine the impact of pharmacist-led intervention on IV acetaminophen use when compared to the historical data.

Methods: This evaluation is a quality assurance project exempt from review by the Institutional Review Board. Daily reports will be generated Monday through Friday from September 8, 2016 until November 2, 2016 to identify patients with orders for IV acetaminophen. Patients less than 18 years old will be excluded from review. Pharmacists assigned to patients who have received two or more doses of IV acetaminophen will determine whether its use is appropriate based on the institutional guideline and whether the prescriber should be contacted to recommend an alternative medication. A chart review will be conducted during this period, and the following data will be collected from the electronic medical record: age, gender, hospital, ordering provider service, total number of hours with nothing by mouth status while hospitalized, and number of IV acetaminophen doses administered. This data will be compared to existing data obtained from electronic reports from September 1, 2015 through August 31, 2016 by calculating the following: average number of IV acetaminophen doses administered per patient throughout the health system and for each hospital as well as the percentage of patients who received two or fewer doses of IV acetaminophen. Additionally, the average number and percentage of IV acetaminophen doses administered per patient for each service
will be calculated for the intervention group. Inferential statistics will be used to evaluate data collected for these indicators.

Poster Title: Evaluation of ferumoxytol utilization within a health system

Primary Author: Chelseaiwohi, NorthShore University HealthSystem, IL; Email: aiwohic@gmail.com

Additional Author(s):
Alice Kim

Purpose: Ferumoxytol is an iron salt used for the treatment of iron deficiency anemia in patients with chronic kidney disease (CKD). It is a high cost intravenous iron product that is frequently prescribed. The objective of this evaluation is to assess the utilization of ferumoxytol, by evaluating the number of patients receiving at least two doses of ferumoxytol treatment, the number of patients with an appropriate timing of 3 to 8 days between doses, and the number of patients being treated for the indication of CKD anemia within a health system.

Methods: A retrospective chart review of patients who received two or more doses of ferumoxytol between January 2015 to August 2016 from all hospital sites, outpatient clinics, and dialysis centers within a health system will be conducted. The electronic medical record system will be used to identify patients receiving 2 or more doses of ferumoxytol. The following data will be collected: medication name, medication dose, sex, age, ordering number, ordering date, authorizing provider, ordering service, patient care unit, site, dosing frequency, and indication for drug use. The primary indicator is defined as the percent of patients who received the appropriate number of doses, timing between doses, and indication of CKD anemia. Each component of the primary indicator will also be evaluated separately. Descriptive statistics will be used for this evaluation. This is a quality assurance evaluation, and is exempt for approval from Institutional Review Board.

Poster Title: Evaluation of the usage of epoetin alfa for inpatients with anemia of chronic kidney disease

Primary Author: Sarah Klembith, NorthShore University HealthSystem, IL; Email: sklembit@northshore.org

Additional Author(s):
Dipa Patel

Purpose: Erythropoiesis-stimulating agents (ESAs) are standard of care for treatment of anemia of chronic kidney disease (CKD). These agents have been associated with an increased risk of death, serious cardiovascular reactions, and stroke when administered to target hemoglobin (Hgb) levels greater than 11 grams per deciliter. Therefore, the lowest dose should be used. Currently, guidelines are not available for the use of ESAs for anemia of CKD in the inpatient setting. The objective of this medication use evaluation is to describe the usage of epoetin alfa in anemia of CKD for inpatients at a 4 hospital community health system.

Methods: This retrospective electronic chart review will include inpatients at least 18 years of age who received a dose of epoetin alfa for anemia of CKD between June 1, 2015 and May 31, 2016. The results will be used for quality improvement; therefore, the project is exempt from review by the Institutional Review Board. Data to be collected from medical records include: patient age, sex, actual body weight, hospital site, indication, initial dose administered, prescriber, dialysis schedule and type, Hgb level and date prior to initial epoetin alfa administration, and date and dose of previous outpatient epoetin alfa administration. The primary endpoint is the percentage of initial epoetin alfa orders given for an appropriate indication of anemia of CKD, at an initial dose of 20 to 100 units per kilogram, and with a Hgb less than 12 grams per deciliter. Secondary endpoints include percentage of initial epoetin alfa orders administered: at 20 to 50 units per kilogram, at 51 to 100 units per kilogram, to dialysis patients, to non-dialysis CKD patients, to patients with Hgb less than 12 grams per deciliter, and to patients who had a documented outpatient epoetin alfa dose administered within previous 7 days. Also, percentage of patients with the same epoetin alfa inpatient dose as outpatient dose received within previous 7 days. Descriptive statistics will be used to evaluate data.

**Poster Title:** Evaluation of tirofiban renal dosage adjustment in the inpatient setting at a four hospital community health system

**Primary Author:** Erik LaChance, NorthShore University HealthSystem, IL; **Email:** elachance@northshore.org

**Additional Author (s):**
Laura Nasca

**Purpose:** Tirofiban requires an adjustment of the maintenance infusion dose for patients with a creatinine clearance less than or equal to 60 milliliters per minute. Studies have shown a propensity towards bleeding in patients with renal dysfunction who received standard tirofiban maintenance infusions. The objective of this evaluation is to determine if the maintenance infusion rate was properly adjusted for patients with decreased renal function who were initiated on tirofiban.

**Methods:** A retrospective chart review will be conducted on all patients initiated on tirofiban as inpatients between November 1st, 2015 and July 31st, 2016. This evaluation will assess for quality assurance, therefore, it is exempt from Institutional Review Board approval. Patients aged 18 to 89 years with coronary indication with or without percutaneous coronary intervention (PCI) initiated on tirofiban will be included. The following data points will be collected via electronic medical record and manual chart review: Gender, hospital/location, date of birth, prescriber, medical record number, time given, indication, body weight, height, indication, serum creatinine, creatinine clearance, concurrent anti-platelet medications, and dose. The primary objective will assess if the tirofiban maintenance infusion dose was properly adjusted based on creatinine clearance. A secondary objective will determine the average duration of tirofiban infusion in minutes. Descriptive statistics will be used to evaluate the data.

**Poster Title:** Evaluation of a pharmacist-led initiative of intravenous levothyroxine use at a community health system

**Primary Author:** Kyle Brauer, NorthShore University HealthSystem, IL; **Email:** kbrauer@northshore.org

**Additional Author (s):**
Megan Britton

**Purpose:** Levothyroxine is available in intravenous (IV) and oral dosage forms. Oral dosage forms have shown to be more cost-effective than IV dosage forms due to difference in overall cost and decreased risk of cannula-related infections. IV doses are converted to oral based on the criteria of a functioning gastrointestinal tract, adequate absorption, and administration of other oral medications. This health system uses a 2:1 ratio when transitioning from an oral to IV route of administration. The objective of this evaluation is to assess the transition of IV levothyroxine to oral during a pharmacist-led initiative.

**Methods:** This prospective chart review will be exempt from review by the Institutional Review Board as it is a quality improvement project. All adult patients between September 16, 2016 and October 14, 2016 on Monday through Fridays with an active order for IV levothyroxine will be evaluated for transition to oral therapy based on the criteria of a functioning gastrointestinal tract, adequate absorption, and administration of other oral medications. Patients with a diagnosis of myxedema coma or patients determined to require IV levothyroxine via endocrinology recommendations will be excluded. Pharmacists in charge of patients deemed to have potential to transition to oral levothyroxine will be contacted via electronic health record messaging and prompted to evaluate patient for transition based on the above criteria. The following data will be collected: hospital name, hospital unit, number of IV levothyroxine doses that meet criteria for transition to oral therapy, number of IV levothyroxine doses transitioned to oral therapy, number of IV levothyroxine doses administered, number of IV levothyroxine doses prepared, and diet order. The primary objective of this review is to evaluate the percentage of IV levothyroxine orders transitioned to oral during a pharmacist-led initiative. The secondary objective of this review is to evaluate the waste associated with current IV levothyroxine preparation. Descriptive statistics will be used to analyze the data collected.

**Poster Title:** Post-operative pain in patients who received epidural or spinal anesthesia during total hip arthroplasty

**Primary Author:** Kayla Pearson, NorthShore University HealthSystem, IL; **Email:** kpearson@northshore.org

**Additional Author(s):**
Josie Klink

**Purpose:** As the population ages and obesity rates continue to rise, more joint arthroscopies are being performed. It is imperative that the safest and most efficacious forms of anesthesia are utilized. Previously, a community hospital used epidural anesthesia for THA procedures but transitioned to using only spinal anesthesia. This conversion was initiated as an opportunity for cost savings as well as potential improved patient outcomes in terms of ambulation, post-operative pain scores, and reduced adjunctive pain medication use. This evaluation will compare the effects of spinal versus epidural anesthesia have on these outcomes.

**Methods:** This evaluation is a quality improvement evaluation and is exempt from IRB review. A list of patients who have undergone a THA and received either epidural or spinal anesthesia will be generated using the electronic medical record system. The following data will be collected: patient age, gender, baseline analgesic medications taken prior to surgery (if applicable), date of surgery, surgery procedure type, type of anesthesia received, time anesthesia was administered, intra-operative steroid administration, baseline and post-op pain scores according to electronic health record, ability to stand within six hours of anesthesia injection, distance walked on post-op day zero (in feet), name of as needed pain medications and number of doses administered, surgeon, and drug costs of epidural and spinal anesthesia. The primary objective will be differences in total pain relief (TOTPAR) scores over each post-operative day for each anesthesia type. Results will be shared with the anesthesia and orthopedic surgery departments.

**Results:** N/A

**Conclusion:** N/A

Poster Title: Evaluation of appropriateness of meropenem use in a community health-system

Primary Author: James Kallander, NorthShore University HealthSystem, IL; Email: jkallander@northshore.org

Additional Author(s):
Jim Cha

Purpose: Antibiotic resistance is increasing globally. Inappropriate exposure to antimicrobials is the highest risk factor for the development of antibiotic resistance. Ensuring appropriate use of meropenem is crucial in keeping meropenem a viable treatment option for future use. An internal project conducted in 2016 at this community health-system showed a possible increase in meropenem utilization compared to previous years. The purpose of this medication use evaluation is to determine whether the initial order for meropenem at a four-hospital community health-system is appropriate based on local guidelines.

Methods: This is a retrospective chart review for quality assurance purposes and is exempt from IRB review. Meropenem use from July 1, 2015 to June 30, 2016, for all patients older than 18 years of age, admitted to the hospital will be collected. Fifty patient encounters will be reviewed from each of the four hospitals, randomly selected from all patients encountering receiving meropenem. Information obtained will include indication for meropenem, identification of prescriber’s specialty, ID consult before second dose, days of meropenem, days of total antibiotics within the hospital, and calculated creatinine clearance. The primary objective is to determine if the initial order for meropenem has been appropriate per criteria in local institution guidelines. Appropriate use is defined as meeting the dosing, indication, frequency and infectious disease (ID) consultation recommendations defined in the local guideline. Secondary objectives will include comparison of the four hospitals for appropriate use, days of therapy, and average days of meropenem use per antibiotic therapy days. Orders initiated in the emergency department will be reviewed for indication, dose, and ID approval. Descriptive statistics will be used to analyze the information.

Poster Title: Follow-up evaluation of appropriateness of initial edoxaban orders and prescriptions

Primary Author: Hardik Patel, NorthShore University HealthSystem, IL; Email: hpatel2237@gmail.com

Additional Author(s):
Izabela Wozniak

Purpose: Edoxaban is unique because it is contraindicated for atrial fibrillation in patients with a creatinine clearance greater than 95 milliliters per minute. An initial evaluation of edoxaban ordering was conducted for all inpatient orders and outpatient prescriptions after addition of edoxaban to formulary at this community health-system. Prescribers were contacted by letter regarding any orders that did not meet Food and Drug Administration (FDA) approved dosing criteria based on indication and renal function. This evaluation is a follow-up evaluation conducted to see if there was a change in ordering patterns after education was provided to prescribers.

Methods: A retrospective, electronic chart review is being conducted on all initial edoxaban orders for both inpatient orders and outpatient prescriptions between April 1, 2016 and September 30, 2016. This review is being completed for quality improvement purposes and, therefore, exempt from review by the Institutional Review Board. The primary objective of this evaluation is to assess if edoxaban was ordered appropriately based on indication specific FDA approved dosing criteria. A secondary objective is to examine the appropriateness of edoxaban stratified by indication of either atrial fibrillation or venous thromboembolism. Another secondary objective is to determine the date of the serum creatinine level that immediately preceded the edoxaban order, relative to the date of the initial order for edoxaban. All initial edoxaban orders within the prespecified time period will be evaluated. Descriptive statistics will be used to evaluate the data. The results of this evaluation will be submitted to committees within this health-system.

**Session-Board Number:** 9-234  

**Poster Title:** Evaluation of the impact of sugammadex on rocuronium and succinylcholine use  

**Primary Author:** Shayna Acance, NorthShore University HealthSystem, IL; **Email:** sacance@northshore.org  

**Additional Author(s):**  
Muriel Forbes  

**Purpose:** Sugammadex is a selective binding agent indicated for reversal of neuromuscular blockade induced by rocuronium or vecuronium. Neostigmine was the drug of choice for reversal prior to the availability of sugammadex. Sugammadex was added to the health system’s inpatient formulary in January 2016. Succinylcholine is an alternative option for neuromuscular blockade during surgical procedures; however, it does not have an established reversal agent. The purpose of this medication use evaluation is to assess the change in usage of rocuronium and succinylcholine after the addition of sugammadex to the health system’s formulary.  

**Methods:** This is a retrospective chart review of a random sample of patients who received succinylcholine or rocuronium during a surgical procedure before and after sugammadex was added to the inpatient formulary. The time period for the review is April 1 – August 31, 2015 and April 1 – August 31, 2016. This is a quality assurance review and is exempt from Institutional Review Board approval. A list of patients 18 years and older who received at least one dose of succinylcholine or rocuronium during a surgical procedure will be generated from electronic health records within the health system. Patients who received either medication for the purpose of rapid sequence intubation, had a contraindication to succinylcholine use, or who were enrolled in the neostigmine-sugammadex study will be excluded. The following data will be collected: patient age, date of surgery, type of surgery, patient location, and total number of administrations of rocuronium, succinylcholine, sugammadex, and neostigmine. The primary endpoint is to assess if there was a change in the usage of rocuronium and succinylcholine, while the secondary objective is to evaluate financial impact.  

**Results:** N/A

Poster Title: Evaluation of dose alerts within order sets at a community health system

Primary Author: Onchuma Kaenkumchorn, NorthShore University Health System, IL; Email: okaenkumchorn@northshore.org

Additional Author(s):
Jenny Szparkowski
Lynn Boecker

Purpose: Exposure to numerous alerts leads to desensitization of alerts, commonly known as alert fatigue. Related orders may be preconfigured as order sets to streamline order entry for a specific problem or diagnosis. The ideal configuration of order sets should produce minimal dosing alerts. An area of improvement for dose alerts was identified upon review of the organization’s electronic health record (EHR) optimization report. The purpose of this evaluation is to review the organization’s dose alerts originating from order sets and address the identified dose alerts contributing to alert fatigue.

Methods: This is a retrospective review of the most commonly encountered dose alerts involving ambulatory and inpatient order sets from the organization’s August 2016 monthly statistical alert report. Order sets with dose alerts that appeared fifty times or more in order entry from the August 2016 monthly statistical report were selected. Inclusion criteria consists of dose warnings from entered orders within the selected order sets that were canceled, overridden, or removed and appeared ten times or more within an order set. The dose alerts will be evaluated against reputable medication references and reviewed with a clinical taskforce. The possible action(s) for identified dose alerts contributing to alert fatigue include no change, database vendor warning change, suppression of interaction at medication level, or suppression of interaction at order set level. Any recommended changes to dose alerts will be brought to the organization’s Pharmacy and Therapeutics Committee for final approval prior to implementation.

Results: Results are currently in progress.
Conclusion: Conclusions are currently in progress. Final conclusions will be presented at the 2016 Midyear Clinical Meeting.

Poster Title: Timeliness of time-critical medication administration

Primary Author: Bridget Dolan, NorthShore University HealthSystem, IL; Email: bdolan@northshore.org

Additional Author(s):
Jennifer Szparkowski

Purpose: Compliance with timeliness of medication administration is important for patient safety and the effectiveness of therapy. Time-critical medications are defined as medications that an early or late administration of greater than thirty minutes may cause harm or negatively impact the intended therapeutic effect. This project focuses on a four hospital community health system’s administration of time-critical medications (antibiotics, anticonvulsants, and anticoagulants) and medications scheduled every six or eight hours. The project was designed to evaluate and improve the compliance, according to the health system’s administration policy, with meeting the one hour window of scheduled time from administration time of medications.

Methods: This retrospective chart review is deemed quality evaluation and is exempt from review by the Institutional Review Board. All patients who received scheduled doses of intravenous antibiotics, intravenous anticonvulsants, and/or any anticoagulants between May 1, 2016 and July 31, 2016 will be included. Any patients who received a scheduled medication every six or eight hours between May 1, 2016 and July 31, 2016 will also be included. The following data will be collected: medication name, therapeutic class, nursing unit, specific hospital, administration time, administration due time, number of every six hour and/or every eight hour scheduled dose given within twenty-four hours, held doses, rescheduled doses, missed doses that were not rescheduled, and missed doses that were rescheduled. Orders that are discontinued prior to twenty-four hours are excluded from the second objective. The primary objective is to evaluate compliance with the health system’s policy for administration of time-critical scheduled medications, defined as meeting the one hour window of scheduled time from administration time. The secondary objective is to evaluate the compliance of the every six- and eight- hour scheduled medications within a twenty-four hour period. Descriptive statistics will be used to evaluate compliance.

Poster Title: A community oncology center’s experience with immune checkpoint inhibitors

Primary Author: Laura Schmidt, NorthShore University HealthSystem, IL; Email: schmidt.l.ann@gmail.com

Additional Author(s):
George Carro
Abigail Harper
Wendy Hui

Purpose: Checkpoint inhibitors are changing the landscape of treatment in oncology. The first checkpoint inhibitor, ipilimumab (Yervoy®), was approved in 2011, followed by pembrolizumab (Keytruda®) and nivolumab (Opdivo®). The use of checkpoint inhibitors is growing rapidly as the FDA-approved and off-label uses for these medications broaden. Given the relative infancy of the use of checkpoint inhibitors, much information stands to be gained on their use in oncology, especially regarding toxicity. The purpose of this project is to explore a community oncology center’s experience with checkpoint inhibitors in order to draw observations on toxicity patterns and treatment impact.

Methods: A retrospective chart review will be conducted on patients who have received pembrolizumab, ipilimumab, and/or nivolumab from May 1, 2011 to July 31, 2016. This evaluation does not require Institutional Review Board approval because the findings will be used as a quality assurance measure. The following information will be collected: patient demographics, disease state, treatment information, and adverse event details. The primary objective of this evaluation is to assess this oncology center’s experience with checkpoint inhibitors, focusing on treatment toxicity and treatment impact in the clinical practice setting. The results will be presented using descriptive statistics utilizing a simple proportional analysis.

**Poster Title:** Evaluation of concentrated insulin use at a community healthsystem

**Primary Author:** Ryan Kinnavy, NorthShore University HealthSystem, IL; **Email:** rkinnavy@northshore.org

**Additional Author(s):**
Dipa Patel
Lisa Patel

**Purpose:** Concentrated insulin options provide the advantage of patient-specific tailoring of insulin therapy by reducing administration volumes and optimizing absorption kinetics. However, the differing concentrations of these formulations can create challenges during patient transitions of care. The purpose of this evaluation is to describe the usage patterns and appropriateness of currently available concentrated insulin products initially ordered during inpatient admissions at a community healthsystem. Results of this retrospective review will give insight into concentrated insulin prescribing practices and compliance with current institutional policy regarding concentrated insulin regular U-500 use.

**Methods:** This evaluation is a retrospective review of patients 18 years of age or older admitted to the hospital with an order for a concentrated insulin formulation including insulin glargine U-300, insulin regular U-500, insulin lispro U-200, or insulin degludec U-200 from August 1, 2015 to July 31, 2016. This evaluation will be used for quality improvement, and therefore, is exempt from IRB review. For all patients with a concentrated insulin product prescribed during an inpatient admission, data including insulin formulation, dose, frequency, ordering provider, administration instructions, use of patient’s own medication, and prior to admission dose and formulation will be gathered. The presence of an endocrinology consult, progress note documenting insulin regular U-500 dose, and method of insulin regular U-500 measurement will be collected to determine compliance with current institutional U-500 insulin regular policy. Appropriate use of concentrated insulin will be defined as compliance with current institutional U-500 insulin regular policy and conversion of concentrated insulin glargine and lispro to their respective formulary-preferred U-100 formulations. Descriptive statistics will be used for this evaluation.
Results: Results for this evaluation are to be determined.

Conclusion: Conclusions for this evaluation are to be determined.

**Poster Title:** Characterizing prescribing habits of direct oral anticoagulant (DOAC) in the emergency department

**Primary Author:** Jamie Nguyen, NorthShore University HealthSystem, IL; Email: jnguyen@northshore.org

**Additional Author(s):**
Anne Kaminski

**Purpose:** Recent studies show higher DOAC (apixaban, rivaroxaban, dabigatran, and edoxaban) prescription rates across clinical settings such as the emergency department (ED). To avoid potential bleeding complications, dosing should account for adjustments for drug-drug interactions and patient specific factors such as age, weight, and renal function. The purpose of this evaluation is to assess the appropriateness of new prescriptions for DOACs in patients discharged from the ED.

**Methods:** This Research-in-Progress is conducted on patients discharged from the ED with a new prescription for a DOAC from August 1, 2014 through August 31, 2016. This evaluation is exempt from review from the Institutional Review Board because it is conducted for quality improvement purposes. Patients are included if the date of the new DOAC prescription is the same as the ED discharge and the patient was discharged to home. Patients younger than 18 years of age or patients seen in the ED and admitted into the hospital are excluded. The primary objective of this evaluation is to assess the appropriateness of DOAC prescriptions in patients discharged from the ED based on recommended adjustments for age, weight, renal function, drug-drug interactions, and bridging requirements for each DOAC. The secondary objectives are to evaluate appropriate prescribing for each DOAC individually as well as to assess appropriate lab monitoring prior to these prescriptions being written. Descriptive statistics will be utilized to evaluate the data.

**Results:** To be determined

**Conclusion:** To be determined

Poster Title: Changes in provider prescribing practices for intravenous acetaminophen in pediatric patients

Primary Author: Amanda Penland, OSF Saint Francis Medical Center, IL; Email: amanda.m.penland@osfhealthcare.org

Additional Author(s):
Julie Kasap
Danny Mai

Purpose: Usage of intravenous acetaminophen is restricted at our institution due to the high cost relative to oral and rectal formulations. The primary objective of this study is to determine whether there has been an increase in usage of intravenous acetaminophen that falls outside of the Pharmacy and Therapeutics Committee approved criteria. The secondary objective is to determine if intravenous acetaminophen is consistently being administered outside of guidelines in certain patient populations or disease states. Subsequently, revisions may be made to the criteria for use guidelines based upon these findings.

Methods: This study will be submitted to the Institutional Review Board for approval. This study is a retrospective analysis of intravenous acetaminophen use at our pediatric hospital. The electronic medical record will be used to identify all patients who received intravenous acetaminophen between June 1st 2015 to August 31st 2015 or April 1st 2016 to June 30th 2016. All patients who received a dose of intravenous acetaminophen and were less than 18 years of age will be included in the study. Patients greater than 18 years of age and patients in the neonatal intensive care unit receiving intravenous acetaminophen for patent ductus arteriosus will be excluded. Patient data collected will include: patient age and weight, acetaminophen dosage, amount of time after operative procedure that the acetaminophen was administered (if applicable), number of doses given, indication for use (diagnosis/procedure), absolute neutrophil count (ANC), diet order at time of administration, admission diagnosis, and the authorizing user for the order. Each administration will be assessed to determine if it met the hospital’s criteria for use guidelines. The total number of administrations that fall outside of the criteria for use guidelines will be compared between the 3 month periods to assess for
trends in prescribing practices. Descriptive statistics will be utilized, as well as additional statistical analyses when applicable.

**Poster Title:** Hospital readmission rates for patients treated with ceftriaxone and azithromycin versus levofloxacin for community acquired pneumonia

**Primary Author:** Luke Piarowski, OSF Saint Francis Medical Center and Children’s Hospital of Illinois, IL; **Email:** luke.r.piarowski@osfhealthcare.org

**Additional Author (s):**
Timothy Murrey
Julie Giddens
Jessica Luebshaw

**Purpose:** The current Infectious Disease Society of America (IDSA)/American Thoracic Society (ATS) guidelines on the management of community-acquired pneumonia (CAP) recommend treatment with levofloxacin or the combination therapy ceftriaxone and azithromycin for patients being treated on a floor other than the intensive care unit (ICU). This study aims to determine if the combination therapy is superior to levofloxacin monotherapy based on thirty-day readmission rates of any cause. Secondary endpoints analyzed will include mortality within thirty days, reason for readmission, and adverse effects of patients discontinuing therapy.

**Methods:** This multi-center retrospective study will collect data from non-ICU patients admitted for CAP. The patients will be selected by the electronic health record by using an international classification of diseases (ICD) for CAP. The following data points will be collected: age, sex, length of stay, all-cause readmission within thirty days, time to readmission, total treatment length with each drug group, reason for discontinuing antibiotic, Clostridium difficile infection development, antibiotic regimen changed, duration of fever, mortality within thirty days, reason for readmission, adverse effects leading to discontinuation of treatment and congestive heart failure. Inclusion criteria are eighteen years of age or greater, CAP diagnosis, and receiving either the combination ceftriaxone and azithromycin or levofloxacin monotherapy within forty-eight hours of presentation. Exclusion criteria are ICU patients, less than eighteen years of age, pregnancy, prisoners, multi-drug resistant organism isolated in the past ninety days, antibiotic treatment for five or more days in the past ninety days, intravenous antibiotics within the past ninety days, chronic obstructive pulmonary disease, and immunocompromised patients. The program Crimson will be utilized to gather certain data
points, while the rest will be gathered with chart review. Certain data points will be assessed by the investigator including reason for discontinuing an antibiotic, side effects developed, and reason for readmission.

**Submission Type:** Research-in-Progress

**Session-Board Number:** 9-242

**Poster Title:** Evaluation of the efficacy and safety of prescribing practices for patient controlled analgesia in pediatric patients at a large academic children’s hospital

**Primary Author:** Cassandra Collins, OSF St. Francis Medical Center, IL; **Email:** cackama@gmail.com

**Additional Author (s):**
Julie Kasap
Jody Mallicoat

**Purpose:** Uncontrolled pain in pediatric patients can have serious and lifelong consequences. Patient-controlled analgesia (PCA) use in children is often challenging, mainly due to concerns for adverse events such as respiratory depression, excessive sedation, and nausea. The objective of this study is to determine if current prescribing practices of PCA are adequately controlling pain while maintaining patient safety in post-surgical patients or patients with sickle cell pain crisis. In addition, a comparison of strategies and their outcomes will be made between the two populations to assess if prescribing of PCA should be tailored by indication.

**Methods:** This study will be submitted to the Institutional Review Board for approval. This study will be a retrospective analysis of PCA ordering practices at a large academic children’s hospital. Patients will be included if they were 6-17 years of age and had an order for a morphine, fentanyl, or hydromorphone PCA between June 30th, 2015 and June 30th, 2016. Patients who were pregnant, had undocumented pain scores, or were on a PCA for indications other than post-surgical pain or sickle cell crises will be excluded. The following data will be collected: indication for PCA, age, weight, gender, PCA-ordering service, concurrent analgesic medications, PCA drug and settings (demand dose, lockout period, basal dose, and 4 hour lockout) at PCA initiation and at 8 hours of therapy. Efficacy measures will include: the number of demands, number of injections, and total amount of opioid received over 8 hours, patient pain score goals, and pain scores hourly up to 8 hours after initiation of PCA. Safety measures will include whether naloxone was administered, and if so, how many doses were given. Comparative analysis of initial dosing, total amount of opioid utilized, length of time to pain goal, and frequency of naloxone use will be performed. Data will be analyzed via descriptive statistics as well as additional statistical analyses, when applicable.

**Submission Type:** Evaluative Study  

**Session-Board Number:** 9-243  

**Poster Title:** Evaluation of phytonadione (vitamin k1) use for international normalized ratio reversal secondary to warfarin in a community hospital  

**Primary Author:** Anmol Chhabra, Palos Community Hospital, IL; **Email:** achhabra@paloshealth.com  

**Additional Author (s):** Andrera Quinn  

**Purpose:** Phytonadione (vitamin k1) is a therapeutic option to reverse elevated international normalized ratio (INR) secondary to warfarin. The American College of Chest Physicians define criteria for non-emergent and emergent INR reversal. They recommend use of oral phytonadione for non-emergent INR reversal and phytonadione via slow intravenous infusion for urgent INR reversal. Use of subcutaneous administration is not recommended due to erratic absorption. This analysis was designed to evaluate the prescribing practices for phytonadione and the subsequent impact on INR.  

**Methods:** A retrospective analysis, using the electronic medical record, was conducted in patients admitted to Palos Community Hospital in July 2016. Patients 18 years of age and older on warfarin therapy prior to admission who received at least 1 dose of phytonadione were included. Patients with documented hepatic failure and those without documented warfarin use prior to phytonadione administration were excluded. Documented appropriate indications for phytonadione included reversal for surgery, active bleed of any type, INR of 10 or greater, or documented concern for bleed development. Data points analyzed included overnight INR change, need for additional doses of phytonadione, and time to surgery post reversal. The overnight INR change was defined as the difference of the baseline INR (day 0) and INR post phytonadione dose (day 1). The need for additional phytonadione doses was further analyzed in obese patients (patients weighing greater than or equal to 135 percent of ideal body weight (IBW)). Time to surgery was identified through chart review. The administration routes were recorded for all patients.  

**Results:** Forty-one patients received 57 doses of phytonadione via subcutaneous (n equals 30), intravenous (n equals 14) and oral (n equals 13) routes of administration. Nine doses in 9
patients were administered without an appropriate indication documented. The median subcutaneous dose was 10 mg with a median day 0 INR of 2.85. Median overnight INR decrease was 1.1. Eight patients received repeat doses. Four of 10 obese patients required another dose. Median time to surgery was 37 hours. The median intravenous dose was 5 mg with a median day 0 INR of 2.75. Median overnight INR decrease was 1.3. One patient received a repeat dose. Zero of 3 obese patients required another dose. Median time to surgery was 28 hours. The median oral dose was 5 mg with a median day 0 INR of 2.7. Median overnight INR decrease was 1.2. Three patients received repeat doses. Three of 8 obese patients required another dose. Median time to surgery was 19 hours. Four patients received phytonadione via multiple routes. Two patients received an intravenous dose following a subcutaneous dose, 1 patient received an intravenous dose following an oral dose, and 1 patient received an oral dose following a subcutaneous dose.

**Conclusion:** Despite guideline recommendations, subcutaneous administration was selected for the majority of doses, resulting in lesser INR reversal. Repeated doses were more prevalent following initial oral and subcutaneous administrations compared to intravenous, regardless of patient weight. Subcutaneous administration correlated to the longest time to surgery. Although oral administration had the shortest time to surgery, several patients received more than 1 dose. Future actions include creation of an institution specific phytonadione guideline for use, recommending to default the primary parenteral route of administration to intravenous for emergent reversal, and providing hospital wide education of these changes.

**Submission Type:** Evaluative Study

**Session-Board Number:** 9-244

**Poster Title:** Evaluation of intravenous dual anaerobic coverage with piperacillin-tazobactam and metronidazole in a community hospital

**Primary Author:** Laura Lofky, Palos Community Hospital, IL; **Email:** lllofky@paloshealth.com

**Additional Author(s):**
Andrea Quinn

**Purpose:** Clinically unnecessary antimicrobial agents can lead to the development of increased resistance, expose patients to an increased risk of untoward effects and increase costs to the health care institution. Despite previous health care provider education, dual anaerobic coverage with piperacillin-tazobactam and metronidazole remains an ongoing practice. The anaerobic susceptibility of these agents approximates 100 percent and therefore using both agents in absence of clear indication may be redundant. This evaluation was designed to assess the prescribing practices and indications for dual anaerobic therapy and identify direct future educational initiatives at a community hospital.

**Methods:** A retrospective analysis using the electronic medical record (EMR) was conducted to evaluate concomitant intravenous dual anaerobic use with piperacillin-tazobactam and metronidazole in adult patients from July 2016 through August 2016 at Palos Community Hospital. Patients were included in the analysis if they received one or more doses of both antibiotics concomitantly. Patients with documented Clostridium difficile infection per positive PCR assay or suspected C. difficile infection per note documentation were excluded. Location of the initial dose (emergency department versus inpatient unit), the presence or absence of an infectious disease consult, indication for antimicrobial therapy, presence or absence of microbiological cultures and identified pathogen, when applicable, or documentation of no pathogen isolated, were recorded.

**Results:** A total of 60 patients received at least one dose of both agents. The location of initiation of dual anaerobic therapy was evenly split between patients in the emergency department (50 percent, n equals 30) and patients located in an inpatient unit (50 percent, n equals 30). The infectious diseases service was consulted for 28 percent of patients (n equals 17). Intra-abdominal infection (IAI) was the primary indication for therapy and the documented
source of infection for 90 percent of the patients (n equals 54). Cultures were not obtained in 27 percent of patients (n equals 16). Of the patients that had cultures obtained, no pathogen was isolated in 66 percent of patients (n equals 29). Of the 15 patient that had isolated pathogens, the most common pathogen isolated in 47 percent of patients (n equals 7) was Escherichia coli. Potentially resistant pathogens (e.g. Bacteroides species, Clostridium perfringens, and Actinomyces species) were not isolated in any patients with microbiological data.

**Conclusion:** Dual anaerobic coverage continues despite lack of guideline recommendations and patient specific clinical evidence to support its use. IAI was the most common indication for therapy. Of the 44 patients with microbiological data, more than half had no pathogen isolated and resistant pathogens were not isolated, indicating possible unwarranted exposure to antibiotics, adverse drug effects and increased healthcare costs. Future steps include implementing a targeted service line educational intervention, reviewing current order sets for unnecessary duplicative therapy, and enhancing provider and pharmacist awareness of potentially unnecessary dual anaerobic therapy via utilization of the antimicrobial stewardship scoring system in the EMR.
Poster Title: Evaluating the cost benefit of implementing extended infusion of cefepime within a 350-bed urban community teaching hospital.

Primary Author: Jelena Saric, Presence Health St. Joseph Hospital, IL; Email: jelena.saric@presencehealth.org

Additional Author(s):
Dharmesh Bavda

Purpose: Alternative dosing strategies have been employed by antimicrobial stewardship programs to combat escalating resistance patterns. One such example is extended infusion of β-lactam antibiotics to provide optimal time-dependent killing. Prolonged infusions of these antibiotics have been shown to maximize likelihood of antibiotic concentrations above the minimum inhibitory concentration of the pathogen, resulting in enhanced clinical outcomes and cost savings. The objective of this study will be to evaluate the economic benefit after implementation of cefepime as an extended infusion in comparison to the standard 30-minute infusion at the same interval.

Methods: This study will undergo an expedited review by the hospital’s Institutional Review Board. Monthly utilization reports will be generated three months prior to and after implementation of extended infusion cefepime. A retrospective chart review will be conducted for patients on cefepime. Data to be collected from electronic health record include indication of use, number of doses administered and duration of therapy, infusion time, and culture results. A standard wholesale acquisition cost will be used to calculate total cost of cefepime 1 gram and 2 grams vials. Total drug expenditures will be compared between pre and post implementation of extended infusion cefepime.

Results: N/A

Conclusion: N/A

**Poster Title:** Pharmacist-driven education to increase adherence to evidence-based headache guidelines in the Emergency Department (ED).

**Primary Author:** Neil Schroeder, Presence Saint Joseph Hospital - Chicago, IL; **Email:** neil.schroeder@presencehealth.org

**Additional Author (s):**
Richard Wenzel

**Purpose:** The objective of this study is to determine to what degree pharmacist directed education to physicians and nurses in the ED can impact the use of opioids and migraine specific medications in patients with a diagnosis of headache or migraine. The study will also attempt to determine the impact education will have on physicians prescribing migraine specific medications for headache or migraine.

**Methods:** The study will be Institutional Review Board approved. The electronic medical record system will be used to compile 90-day retrospective data of patients who presented to the ED with chief complaint of headache per international classification of diseases 9 code. Baseline data will include: age, gender, history of headache, any current medications indicated for migraine, and any opioid medications. Exclusion criteria will include patients under the age of 18 years old, pregnancy, secondary headache (as defined by the International Headache Society), and documented contraindications to non-opioid headache medications. Next, three 15-minute in-service presentations directed towards physicians and nurses in the ED will be conducted. A handout summarizing the American Headache Society ED treatment recommendations will be provided at each in-service. Physician and nurse attendance will be collected. The 90-day data will be collected after the last in-service to determine the impact on physician medication selection for treatment of headache in the ED.

Poster Title: Effect of pharmacist verification on fluoroquinolone orders in the emergency department

Primary Author: Monica Dutridge, Presence Saint Joseph Medical Center, IL; Email: mndutridge92@gmail.com

Additional Author(s):
Kayla Collins
Nicole Costa

Purpose: The Food and Drug Administration (FDA) recently released safety alerts regarding appropriate indications for fluoroquinolone use. In patients who have other treatment options available for acute bacterial sinusitis, bronchitis, and uncomplicated urinary tract infections, the risk of serious side effects outweighs the benefit of fluoroquinolone use. Based on the FDA’s safety communication and trends in the study institution’s antibiogram, fluoroquinolones were removed from auto-verification in the emergency department’s (ED) automated dispensing cabinets. The objective of this study is to determine the effect on time to administration and appropriate empiric therapy after implementation of required pharmacist verification of ED fluoroquinolone orders.

Methods: This study will be submitted to the Institutional Review Board for approval. A data surveillance system will be used to identify all fluoroquinolone orders originating in the ED for a three month period both prior to and after the implementation of required pharmacist verification. The data collected will include: time of order entry, time of nurse acknowledgement, time of verification, time of administration, antibiotic indication, and fluoroquinolone dosing. The primary outcome of this study will be to determine the effect of pharmacist verification on time to administration. The secondary outcome of this study will be to observe if pharmacist verification improves appropriateness of empiric therapy. If time to administration does not prove to be significantly delayed and empiric therapy choice proves to be more appropriate, this data could be used to support the eventual removal of all antibiotics from auto-verification in the ED automated dispensing cabinets.

Poster Title: Effect of fluoxetine on motor recovery after acute ischemic stroke

Primary Author: Meredith Manning, Presence Saint Joseph Medical Center, IL; Email: meredith.manning2@presencehealth.org

Additional Author(s):
Annette Elens

Purpose: Stroke is one of the leading causes of disability worldwide, with two-thirds of surviving patients left with persistent motor deficits. Physical therapy has been shown to reduce functional deficits, but additional strategies are needed to improve outcomes and promote restoration of patients' normal pre-stroke function. Multiple small studies have shown selective serotonin reuptake inhibitors to be successful in this role, but this strategy has not been widely incorporated into practice. The objective of this study is to determine whether the addition of fluoxetine to physical therapy further improves functional outcomes in ischemic stroke patients.

Methods: This study will be submitted to the Institutional Review Board for approval. Patients will be eligible for enrollment in the study if they are 18 years or older with an acute stroke and a baseline modified Rankin Scale (mRS) score of 3 or more. Patients taking any antidepressant medication at the time of admission will not be eligible. Patients will receive either standard physical therapy alone or physical therapy in combination with fluoxetine 20 mg daily for 3 months. The following data will be collected: patient age, gender, past medical history, current medications, reported adverse events, mRS scores, National Institutes of Health Stroke Scale (NIHSS) scores, Patient Health Questionnaire (PHQ)-2 scores, and PHQ-9 scores for those with a positive depression screen on the PHQ-2. Patient progress will be monitored with repeated mRS, NIHSS, and PHQ-2/9 scores on Days 0, 30, 60, and 90. The primary outcome of this study will be the mean change in mRS score from Day 0 to Day 90. Secondary outcomes will include the mean change in NIHSS and PHQ-2/9 scores from Day 0 to Day 90 and adverse events attributable to fluoxetine use reported at any time during the treatment period.

Poster Title: Implementation of pharmacist-driven beta-lactam allergy verification

Primary Author: Humera Syed, Presence Saint Joseph Medical Center, IL; Email: humera.syed@presencehealth.org

Additional Author(s):
Allie Mahalik
Nicole Costa

Purpose: One aim of antimicrobial stewardship is reducing unnecessary broad-spectrum antibiotic exposure, which is often driven by patient-reported allergies. The Centers for Disease Control and Prevention (CDC) reports that among patients who self-report allergies, only 10-15% have a true allergy confirmed by a positive skin test. Due to reliance on patient self-reported allergies and a lack of restriction policy, aztreonam use at the study institution exceeds the national average. The objective of this study is to determine if pharmacist-driven verification and intervention of penicillin allergy reactions decrease the inappropriate use of aztreonam.

Methods: This study will be submitted to the Institutional Review Board for approval. Retrospective data from May 2016 to July 2016 will be collected for all inpatient aztreonam orders at the study institution. Pharmacists will be educated on how to address aztreonam orders in the absence of documented beta-lactam allergies or allergy reactions. Prospective data will also be collected from October 2016 to December 2016 following the implementation of the pharmacist-driven intervention. Data collected will include: patients’ beta-lactam allergies and respective reactions, antimicrobial indication, culture results, and appropriateness of aztreonam use. The primary outcome of this study will be to determine if pharmacist-driven documentation of beta-lactam allergy reactions correlates to a decrease in inappropriate aztreonam use.

Poster Title: Value of a clinical pharmacist on multi-disciplinary behavioral health rounds

Primary Author: John Littler, Presence Saints Mary and Elizabeth Medical Center, IL; Email: john.littler@presencehealth.org

Additional Author (s):
Maryam Farid-Mohseni
Ahoo Sammak

Purpose: Pharmacists have been shown to improve patient safety, decrease adverse drug events, and reduce overall length of stay when participating in medicine rounds. The impact of pharmacists on behavioral health rounds has yet to be demonstrated. Behavioral health is a growing field for pharmacy because many psychiatric medications have complicated properties not understood by other healthcare professionals. Additionally, provision of psychiatric care often involves multiple medications that require adjustments to achieve optimal effects. The purpose of this study is to investigate the role of the clinical pharmacist in the behavioral health unit, particularly when rounding with a team of psychiatrists.

Methods: This study will include a retrospective review of the interventions made by pharmacists on behavioral health rounds over a four month period (August to December 2016). Each day, a clinical pharmacist rounds with one of the psychiatrist-based teams in the behavioral health units and documents interventions made. Each intervention will be reviewed and classified by type, including dose optimization, adverse drug event prevention, and duplicate therapy avoidance. Interventions will be reviewed for acceptance by the physician. The documented interventions will be compared to the interventions documented for that physician’s patients from August to December 2015, before clinical pharmacists began participating in behavioral health rounds. The primary outcome of this study will be physician-accepted pharmacist interventions. Secondary outcomes for this study will include cost savings and adverse drug events prevented by pharmacist interventions on rounds.

**Poster Title:** Pharmacist involvement in discharge medication reconciliation

**Primary Author:** Carmen Kotfisz, Presence Saints Mary and Elizabeth Medical Center, IL; **Email:** carmen.kotfisz@presencehealth.org

**Additional Author (s):**
Andrea Beshalske
Julie Foglio
Erin Quinn
Diana Mekhiel

**Purpose:** Medication reconciliation is recognized as an important tool for the prevention of medication discrepancies and subsequent patient harm at care transitions. It is one of the more challenging aspects of inpatient care, and its accuracy is vital to patient safety. Pharmacists have a role in medication reconciliation to improve patient safety and avoid excess costs through identification of medication errors. The purpose of this retrospective review at Presence Saints Mary and Elizabeth Medical Center (PSMEMC) will be to assess the impact of pharmacist intervention during the discharge medication reconciliation process on medication discrepancies from the medical inpatient units.

**Methods:** This retrospective patient chart review will examine the number and type of medication discrepancies between an intervention group and a control group. Patients will be included if they are discharged from a medical inpatient unit (5th – 8th floor at PSMEMC) by the family medicine service or a private attending physician. Patients will be excluded if they leave against medical advice or are discharged to hospice or another healthcare facility. The intervention group will include patients discharged from January through April 2016 who had their medication reconciliation reviewed by a pharmacist at discharge. The control group will include patients discharged from January through April 2015, prior to the implementation of pharmacist medication reconciliation review at discharge. We hope to collect data from 100 patients in both the intervention group and control group, giving a total of 200 patients in this study. The intervention will include four components: (1) discharge medication lists prepared by the attending physician within the electronic hospital record (EHR); (2) pharmacist review of the discharge medication list to identify potential errors and discrepancies; (3) discussion
between the pharmacist and physician to correct discharge prescriptions as needed; and (4) patient counseling with education about their discharge medication list.

**Poster Title:** HIT or miss: Assessing appropriateness of testing for heparin induced platelet aggregation

**Primary Author:** Brandle Blakely, Presence St. Joseph Medical Center, IL; Email: brandle.blakely@presencehealth.org

**Additional Author (s):**
Katherine Allen-Koncar

**Purpose:** Heparin-induced thrombocytopenia (HIT) presents as an immune mediated response in which autoantibodies formed are directed against a complex of heparin and platelet factor 4. A score can be calculated and used to estimate the likelihood of heparin-induced platelet aggregation (HIPA). Appropriate assessment of HIPA can prevent unnecessary drug therapy changes to non-heparin products that may increase therapy costs and risk of complications. The objective of this study is to determine if pharmacist involvement in HIPA assessments decreases inappropriate testing and use of non-heparin anticoagulants.

**Methods:** This study will be submitted to the Institutional Review Board for approval. An analysis of a positive enzyme-linked immune-absorbent assay (ELISA) will be used to determine if ordering for serotonin release assay (SRA) was appropriate. ELISA will also be examined to determine if a switch to non-heparin anticoagulants was indicated. Education will be provided to clinical pharmacists regarding assessments of HIPA scores. Post-education, pharmacists will be involved in HIPA assessment and provide recommendations to physicians regarding appropriate therapy modifications. Chart reviews will be conducted to determine appropriateness of HIPA testing based on individual scores for a three-month period both prior to and after implementation of pharmacist intervention. The information for collection and review will include: ELISA, SRA results, platelet count, dates of prior heparin exposure, 4Tscore, length of stay, and evidence of bleeding/thrombus during treatment.

**Poster Title:** An evaluation of intravenous immunoglobulin at Rush University Medical Center

**Primary Author:** Sonam Patel, Rush University Medical Center, IL; **Email:** sonam_patel@rush.edu

**Additional Author (s):**
Ishaq Lat
Joshua DeMott

**Purpose:** Intravenous Immunoglobulin (IVIG) is used as a replacement therapy for immunodeficiencies, but the exact mechanism of action for specific disease states is unknown. Adverse events related to kidney injury (AKI) have been noted with all forms of IVIG, but more commonly attributed to those products high in sucrose content, such as Carimune. The objective of this study was to characterize the use and safety of IVIG at Rush University Medical Center (RUMC).

**Methods:** This investigation was a single center, retrospective study that looked at all orders placed for Gammagard and Carimune between January 1, 2016 – June 30, 2016. All administered medications were evaluated for indication, IVIG product, dose, number of doses, baseline creatinine clearance, baseline serum creatinine (SCr), peak SCr during inpatient admission, history of renal transplant, anaphylactic reaction, ordering medical service, compliance with RUMC guidelines, and if the patient experienced acute kidney injury based on the Acute Kidney Injury Network (AKIN) criteria. Data was analyzed using descriptive statistics.

**Results:** A total of 125 patients and 326 administered doses of IVIG were evaluated, with neurology accounting for 67% of all IVIG products prescribed. Approximately 10% of patients experienced an adverse drug event which was defined as acute kidney injury or anaphylaxis. Thirty three percent of patients experiencing AKI received Carimune (n= 88), while 67% of patients experiencing AKI received Gammagard (n= 37).

**Conclusion:** Regardless of which IVIG product was used, both products were associated with acute kidney injury. Therefore, IVIG products should be used with caution and renal function
should be closely monitored. This finding is contrary to the prevailing notion that Carimune is more likely than Gammagard to induce AKI.

Poster Title: Evaluation of prednisone 40 mg daily for treatment of engraftment syndrome following autologous stem cell transplant

Primary Author: Zach Click, Rush University Medical Center, IL; Email: zach_click@rush.edu

Additional Author(s):
Laura Geswein

Purpose: Engraftment syndrome is a constellation of symptoms such as skin rash, diarrhea, pulmonary infiltrates, and/or weight gain that can occur during the early phase of neutrophil recovery following hematopoietic stem cell transplant. To date, there is limited data to establish a consensus regarding diagnostic criteria and steroid dosing. The purpose of this study is to evaluate for resolution of signs and symptoms of engraftment syndrome in patients prescribed prednisone 40 milligrams daily or its equivalent for treatment of the syndrome following autologous stem cell transplant.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will be used to identify patients who have received an autologous stem cell transplant, were diagnosed with engraftment syndrome, and were treated with oral prednisone 40 milligrams or equivalent. Patients to be included will be greater than 18 years old who received an autologous stem cell transplant during the period of July 1, 2011 to July 1, 2016 and received prednisone 40 milligrams daily or equivalent for treatment of engraftment syndrome. Patients will be excluded if it is not their first transplant, if steroids were used for prevention of engraftment syndrome, or if any other dose of steroid was used for treatment. The following data will be collected: Age, sex, diagnosis, baseline weight, admission length, time to engraftment, conditioning regimen, intensive care unit transfer, time to symptom onset and resolution, steroid use, antibiotic use, antihypertensive and insulin addition or increase, blood glucose, blood pressure, microbiology data, oxygen saturation, supplemental oxygen requirements, absolute neutrophil count, serum transaminases, serum creatinine, total bilirubin, stool output, and chest x-ray. All data will be recorded without patient identifiers and maintained confidentially. The primary outcome of this study will be symptom resolution (yes or no) in patients diagnosed with engraftment syndrome who are treated with prednisone 40 milligrams or equivalent.

Poster Title: Reduction in hospital costs by pharmacy management of hazardous medication waste

Primary Author: Shannon Hindahl, St. Elizabeth’s Hospital, IL; Email: shannon.hindahl@hshs.org

Additional Author(s):
Julia Schimmelpfennig

Purpose: National Institute for Occupational Safety and Health (NIOSH) and the Environmental Protection Agency (EPA) have regulatory guidelines impacting health practices surrounding the use and disposal of hazardous medications. Nursing staff who administer medications are not always aware of changes in the handling and appropriate disposal. Random audits of hazardous waste bins have discovered many non-hazardous medications resulting in increased quantity, weight and cost of hazardous medication waste. The purpose of this study is to reduce the amount of non-hazardous waste by placing pharmacy in charge of hazardous waste and providing education and routine reminders to the nursing staff.

Methods: This is an Institutional Review Board (IRB) exempt project. For the purpose of this study, we chose to focus on the black (hazardous) waste bins available on all nursing units. These black bins are associated with a higher cost per weight than the other bins available on nursing units. Pre-study hazardous medication waste costs will be assessed and compared to post-study costs. Hazardous waste bins will be removed from the nursing units and medications requiring disposal in said bins will be stored with bags for nurses to place the medication in and return the item to the pharmacy via the pneumatic tube system. Education will be provided to the nursing and pharmacy staff regarding these changes.

**Poster Title:** Pharmacist Intervention on Severe Sepsis and Septic Shock Compliance Using Electronic Alerts in a Community Hospital Emergency Department

**Primary Author:** Kourtney Brammeier, St. Elizabeth's Hospital, IL; **Email:** k.brammeier16@gmail.com

**Additional Author (s):**
Jena Foreman
Brian Le
Joshua Schmees

**Purpose:** To determine the impact of a mobile electronic alert and other pharmacy-driven initiatives on Center for Medicare and Medicaid Services (CMS) severe sepsis and septic shock compliance in the emergency department as well as clinical secondary outcomes of decreased hospital length of stay and inpatient mortality.

**Methods:** Following institutional review board (IRB) approval, the pharmacy department implemented a mobile automated alert system to assist with severe sepsis and septic shock identification. The alert has been implemented using a third party electronic monitoring system and notifies the pharmacists when vitals, laboratory data, and medications pertinent to sepsis are ordered for a patient. Pharmacists will then begin the process of ensuring appropriate antibiotic therapy, fluid resuscitation, documentation, and reassessment according to Center for Medicare and Medicaid Services (CMS) requirements. All patients greater than or equal to 18 years of age who present to the emergency department with severe sepsis or septic shock flagged via the new alert between January 1, 2016 and December 31, 2017 will be included in our study. The implementation of this process in the emergency department will serve as a pilot, which if successful, will be applied to the entire hospital.

**Results:** In progress.

**Conclusion:** To be determined.

Poster Title: Prospective comparison of medication reconciliation completed by nurses versus trained pharmacy technicians in the emergency department

Primary Author: Bryant McNeely, St. John’s Hospital - Hospital Sisters Health System, IL; Email: bryant.mcneely@hshs.org

Additional Author(s):
Kristine Valenti
Michael Cusumano

Purpose: The Pharmacy Practice Model Initiative encourages the advancement of pharmacy technicians’ role within patient care allowing pharmacists to practice at the top of their license. Previous studies show that technicians are equally efficacious as pharmacists when completing medication reconciliation, and showing a relative risk reduction of 77% in error rate compared to non-pharmacy personnel. The purpose of this study is to demonstrate the clinical benefit of trained pharmacy technicians gathering medication histories within the Emergency Department (ED).

Methods: A prospective study will be completed at HSHS St. John’s Hospital in the ED. Patients will be included in the study upon presentation to the ED if they are admitted to the hospital, >18 years of age, and who are alert or have a caregiver present who is aware of the patients medication use. Exclusion criteria include: estimated time in ED less than one hour and patients who cannot provide a medication history or outpatient pharmacy. In the first phase, ED nurses will collect patients’ medication history. A pharmacy resident will then complete the medication history again and collect data regarding errors. Following the initial phase, pharmacy technicians will be educated on how to properly and accurately collect medication histories from patients. An education tool has been developed and trained technicians will also use interview guides and templates during each patient interview. Phase two will consist of the trained pharmacy technicians completing the initial medication history instead of an ED nurse. A pharmacy resident will then gather the patient’s medication history again as in phase one. Following both phases, hospitalists will complete a physician satisfaction survey regarding the medication reconciliation process. The primary outcome is the rate of medication reconciliation errors. Secondary outcomes include: Cost avoidance, description of error type, change in
physician satisfaction, and incidence of physicians completing reconciliation prior to medication history collection.

**Results:** Results will be reported at a later date.

**Conclusion:** Conclusions will be reported at a later date.

**Poster Title:** Implementation of strategies to reduce targeted readmissions at a community teaching hospital  
**Primary Author:** Josephine Varda, Swedish Covenant Hospital, IL; **Email:** jkochou@schosp.org  
**Additional Author(s):**  
Alicia Juska  
Ramesh Patel  

**Purpose:** The primary objectives are to evaluate causes and decrease readmissions for diagnoses which are part of the Hospital Readmissions Reduction Program. Readmissions for these diagnoses result in reduced hospital payments and penalties. Institution-specific readmission rates for congestive heart failure, pneumonia, chronic obstructive pulmonary disease, acute myocardial infarction, and hip or knee arthroplasty will be used to implement strategies to prevent readmissions from a pharmacy perspective. By analyzing patients with the highest number of readmission risk factors, a scoring tool will be designed to highlight future patients at risk.  

**Methods:** This retrospective data collection study was approved by the Institutional Review Board. Patients with an unplanned readmission for the same primary diagnosis, as identified by ICD-10 codes and diagnosis-related groups in electronic medical records, within 30 days after discharge will be included. Patients will be excluded if: the patient expired, the patient was discharged after the study time period, the readmission was for an acute medical illness, it was an elective readmission, or the readmission occurred at a different hospital. Historical control data will be collected from October 1, 2015 to June 30, 2016 and compared with post risk factor tool implementation data collected from October 1, 2016 to March 31, 2017; with a maximum of 100 patients in each group. Primary outcomes include: number of patients readmitted for targeted diagnoses to Swedish Covenant Hospital, risk factors for readmissions, and causes of avoidable readmissions. The secondary outcome will evaluate the readmission cost in terms of length of stay. The risk factor scoring tool in addition to pharmacist in-services will be provided so that pharmacists could proactively provide additional medication education and/or make clinical interventions in order to try to prevent future readmissions.

Poster Title: Aztreonam usage in penicillin-allergic patients: assessing the implementation of a penicillin allergy guideline

Primary Author: Michelle Lee, Swedish Covenant Hospital, IL; Email: mlee322@gmail.com

Additional Author(s):
Kwang Yoon

Purpose: Reported penicillin allergies are associated with increased use of alternative antibiotics that may be broader, less effective, and more costly. In an effort to decrease unnecessary alternative antibiotic usage and optimize antibiotic selection, a penicillin allergy guideline was implemented at a community hospital in March 2015 to assist clinicians in properly assessing patient-reported penicillin allergies as well as antibiotic prescribing. The primary objective of this study is to examine the impact of the penicillin allergy guideline by measuring appropriate usage of aztreonam prior to and after guideline implementation.

Methods: This retrospective data collection study was approved by the Institutional Review Board. Electronic medical records will be evaluated for the historical control group from January 2014 to July 2015 and for the post-intervention group from August 2015 to current. Patients who received at least one dose of aztreonam will be included. Patients younger than 18 years old, discharged after one dose in the emergency department, who received one dose for outpatient surgery or in the obstetrics department will be excluded. The following data will be collected and evaluated: hospital stay (date of admission/discharge, readmission), concurrent/alternative antibiotics (indication, duration of therapy, cultures and sensitivities), allergy information (presence/absence, risk stratified by severity), adverse effects, pharmacist clinical interventions, and drug cost. Primary outcome measures include the appropriate usage of aztreonam measured by days of therapy per 1000 patient-days, accuracy of allergy documentation, culture and sensitivity data, and pharmacists’ interventions. Inappropriate usage of aztreonam will be defined as prescribing aztreonam without documentation of a penicillin allergy, prescribing aztreonam when a patient obviously tolerated beta-lactam antibiotics such as penicillins, cephalosporins, and carbapenems, or prescribing aztreonam when drug intolerance or non-IgE mediated reactions occurred with the antibiotics described above. Secondary outcomes include the safety of alternative antibiotic usage assessed by
adverse event documentation, net drug cost savings per year, and estimated length of stay comparing the pre-intervention and post-intervention periods.

Poster Title: Bedside cardiac medication counseling and its impact on post-discharge medication literacy and readmission rates

Primary Author: Melvin George, Swedish Covenant Hospital, IL; Email: mgeorge@schosp.org

Additional Author(s):
Rita Connelly
Teresa Chu

Purpose: The Centers for Medicare and Medicaid Services reduce reimbursements to hospitals with a high readmission ratio. According to a study conducted at Boston University, low health literacy was found to be a significant risk factor for patient readmission. Therefore, counseling points will be incorporated into the electronic medical records at this institution for formulary medications as a way to help staff improve patients’ understanding of their medication regimens. The primary objective of this study is to evaluate the effect of inpatient bedside medication counseling for select cardiac patients on their medication literacy after being discharged back to the community.

Methods: This study has been submitted to the Institutional Review Board for review. Patients admitted with acute myocardial infarction, heart failure, and non-valvular atrial fibrillation or flutter between 10/06/16 and 12/31/16 will be included in this study. During the subjects’ hospitalization period, staff will provide counseling using standardized medication counseling points for each medication being used to treat their specific cardiac disease state. Following the subjects’ hospital discharge, their medication literacy will be assessed by pharmacy staff within four days of discharge and again within 14 days of discharge via telephone with the use of a standardized script. Two medications will be chosen through a randomization process and the subjects will be asked to recall the selected medication’s purpose, strength, dose, frequency, and side effects. The results from the questionnaire will identify which literacy parameter is weakest and would require greater emphasis in the future. The primary outcome will be 30-day readmission rates, while the secondary outcome will be the impact on patient’s perception of medication communication by hospital staff as measured by the Hospital Consumer Assessment of Healthcare Providers and Systems Survey scores. Data collected for the historical control group between 10/06/15 and 12/31/15 will be compared to the results of the study group.

Poster Title: Does pharmacist intervention affect prescription fill rates of antiplatelet medications following percutaneous intervention with stent placement? A comparison of current and historical standards of care

Primary Author: Kenneth Gogol, SwedishAmerican Hospital, IL; Email: kgogol@swedishamerican.org

Additional Author(s):
Brandon Pierce
Kara Clothier
Thomas Carey

Purpose: Antiplatelet therapy for patients undergoing a percutaneous intervention with stent placement is essential for 12 months or more in most patients. The purpose of antiplatelet medications is to curtail adverse outcomes, such as myocardial infarction, restenosis, or death. Patients that do not take antiplatelet medications within 30 days of hospital discharge have a five-fold increase in mortality and a three-fold increase in myocardial infarction. In an attempt to ensure antiplatelet medications are filled within the first 30 days, a pharmacist intervention now occurs at the discharge process as part of the current standard of care.

Methods: This study was approved by the internal review board. The study will compare the fill rate of antiplatelet medications between a historical group without pharmacist involvement in the discharge process and two prospective groups with pharmacist involvement. The historical group will be identified using a computer generated report of patients that received antiplatelet loading doses during a three-month period in the previous year. A daily report of patients loaded with antiplatelet medications will be utilized to identify patients in the prospective groups. Upon discharge, the pharmacist will counsel patients in both prospective groups. A prescription will then be sent to either the hospital outpatient pharmacy (group 1) or an alternative pharmacy (group 2) based on patient preference. Fill rate will be determined utilizing internal data for patients that elect to fill at the hospital outpatient pharmacy. A follow-up call will be made to those patients who fill at an alternative pharmacy to determine fill rates. The primary outcome is the fill rate of antiplatelets, which will act as a surrogate marker of
medication compliance. Secondary outcomes include hospital readmissions, myocardial infarctions, and restenosis rates that occur within 30 days of the stent procedure.

Poster Title: Evaluation of the impact of a workflow system on error rates in sterile compounding

Primary Author: Jacqueline Greatsinger, SwedishAmerican Hospital a Division of UW Health, IL; Email: jgreatsinger@swedishamerican.org

Additional Author(s):
Lisa Thompson
Kara Clothier
E. Thomas Carey

Purpose: Sterile compounding of intravenous medications continues to be a source of error within hospital pharmacies. Errors involving intravenous solutions are especially dangerous and can lead to injury or death of a patient. In April of 2015 BD announced its release of an innovative workflow system that allows for increased safety through more accurate compounding. This system utilizes barcode scanning and a gravimetric workflow to ensure that the correct medication and accurate dose is dispensed. The objective of this study is to determine if the implementation of the workflow system reduces variance when preparing intravenous bags for a stock batch.

Methods: This study is approved by the Institutional Review Board. Both prior to and after the implementation of the workflow system, the following data will be collected for a two-week period: the weight of the intravenous bag prior to adding drug, the weight of the intravenous bag after adding drug, the amount of drug added to the bag. The difference between the beginning and end weight of each bag in a batch will be calculated and the overall variance between the bags in each batch will be determined. The data collected before and after the implementation of the workflow system will be compared to determine the impact the workflow system has on the error rate when compounding sterile intravenous medications for a stock batch.

**Primary Author:** Kripa Patel, University of Illinois at Chicago, IL; **Email:** kpate39@uic.edu

**Additional Author(s):**
Keri Kim
Jeffrey Mucksavage

**Purpose:** Predominant anticoagulation methods including warfarin and Factor Xa (FXa) inhibitors (fondaparinux, apixaban, edoxaban, and rivaroxaban) have a major bleed risk. Management of patients presenting with anticoagulation-related major bleeds includes 3-factor and 4-factor prothrombin complex concentrates (3F-PCC, 4F-PCC), and recombinant factor VIIa. The efficacy and safety of 4F-PCC in a larger patient population is needed. Additionally, its use in FXa inhibitor-related major bleeds is limited. In May 2016, our institution created an antithrombotic reversal guideline. Our goal is to examine the safety and efficacy of its use for patients on anticoagulation requiring urgent reversal for major bleeding or an invasive procedure.

**Methods:** This study is a retrospective chart review of all patients receiving PCC product(s) from May 2016 to April 2017. A patient list generated through Cerner prescribing reports for all PCC administration will be utilized. Patients’ electronic medical record will be reviewed from the day of admission and will end upon hospital discharge in order to obtain all safety and efficacy outcomes. The primary objective is to examine the efficacy of PCC products for warfarin or FXa inhibitor reversal. The primary objective will be determined for warfarin based on a decrease in INR to < 1.3 at 0.5 hours after infusion of PCC product, clinical assessment of bleeding cessation, and ≥ 1 blood product (FFP) within 12 hours after administration for warfarin. The primary objective will be determined for FXa inhibitors based on clinical assessment of bleeding cessation and ≥ 1 blood product (FFP) within 12 hours after administration. Secondary objectives will examine the safety of PCC products through collecting data on adverse events such as the development of thrombosis. An additional secondary objective will be to examine the time to order and administration of PCC after the implementation of the Antithrombotic Reversal Guideline and Order Set at our institution.

**Poster Title:** Characterizing Clostridium difficile Infection Rates, Risk Factors, and Outcomes in Hematopoietic Stem Cell Transplant Recipients

**Primary Author:** Tetyana Melnyk, University of Illinois at Chicago, IL; **Email:** tmelny2@uic.edu

**Additional Author(s):**
Karen Sweiss

**Purpose:** The main purpose of the study is to identify the incidence, risk factors for and outcomes for Clostridium difficile infections in patients undergoing hematopoietic stem cell transplantation at the University of Illinois Hospital. Additionally, we are aiming to evaluate transplant-related morbidity and mortality outcomes in those who develop Clostridium difficile infection.

**Methods:** This study is a retrospective chart review, where we will identify patients who underwent hematopoietic stem cell transplantation (HSCT) at the University of Illinois Hospital (UIC). We anticipate about 900 patients who underwent HSCT and about 150 patients who developed a Clostridium difficile infection. Patient data will be collected through a Cerner generated report identifying patients who have undergone HSCT at UIC. Data collected from the manual Cerner reviews will be stored in the REDcap program, which will only be accessible to the PI and co-investigators with unique passwords and usernames. Any Microsoft Excel documents used for data collection will be created with this numeric coding system and will NOT include any patient identifiers or PHI. These reports will be stored in university’s “H” drive under the principal investigator’s personal desktop and visible only to the principal investigator. Disposal of the Cerner prescribing report will occur prior to start of data analysis. We will be collecting data on patients from January 1, 2005 through July 31, 2015.

Poster Title: Comparative nephrotoxicity of aminoglycosides and polymyxins during treatment of multidrug-resistant Gram-negative infections

Primary Author: Jamie Micheletto, University of Illinois at Chicago (UIC) College of Pharmacy, IL; Email: jmichel@uic.edu

Additional Author(s):
David Martin
Michael Postelnick
Mahesh Patel
Alan

Purpose: The increasing prevalence of multidrug-resistant (MDR) Gram-negative pathogens has introduced numerous challenges for healthcare providers when treating these patients. Due to a lack of therapeutic options, there has been resurgence in the use of older antibiotic classes including polymyxins (colistin and polymixin B) and aminoglycosides. These agents are known to cause nephrotoxicity. There have been studies that have assessed the nephrotoxic effects in patients receiving aminoglycosides or polymyxins but few comparative data in similar patient populations. The purpose of this study is to compare the nephrotoxic effects of these last-line antibiotic agents in a multicenter, retrospective study.

Methods: Patients will be identified through both University of Illinois Hospital & Health Sciences System and Northwestern Memorial Hospital records based upon antibiotic use specifically with aminoglycosides, polymyxin B or colistin for the treatment of a multidrug-resistant (MDR) Gram-negative bacterial infection from 01/01/2006 to 08/01/2016. Patients excluded from the study are those who are less than 18 years of age, with end stage renal disease (ESRD) requiring hemodialysis or anyone requiring renal replacement therapy within 24h of therapy initiation. Patients who have been initiated on both an aminoglycoside and a polymyxin to treat their infection will also be excluded. Patient demographics and past medical history will be collected from hospital admission in which patient was being treated for the MDR Gram negative. Patients will be stratified based on the antibiotic they received (aminoglycoside, polymyxin B, or colistin) and patient groups will be compared. Nephrotoxicity will be assessed via the RIFLE (risk, injury, failure, loss, end-stage renal disease) classification.
Baseline serum creatinine will be the most recent level prior to initiation of antibiotics. Kidney function will be assessed every 24 hours after initiation of the antibiotic agent and will continue to be assessed 7 days after discontinuation. Secondary endpoints include microbiologic cure and clinical cure.

Poster Title: Sodium Bicarbonate Use for In-Hospital Cardiac Arrests

Primary Author: Kevin Chang, University of Illinois at Chicago College of Pharmacy, IL; Email: kchang29@uic.edu

Additional Author(s):
Scott Benken
Renee Petzel Gimbar

Purpose: The use of sodium bicarbonate to correct acidosis in cardiac arrests has become controversial. Trials studying bicarbonate use in cardiac arrests have been conflicting, with multiple studies finding a mixture of benefit, no benefit, or harm. The 2015 Advanced Cardiac Life Support guidelines do not recommend the routine use of sodium bicarbonate during cardiac arrests. The primary objective of this evaluation is to determine if sodium bicarbonate use during in-hospital cardiac arrests increases the amount of epinephrine required. Secondary objectives will evaluate various other patient outcomes.

Methods: This retrospective, cohort evaluation will be submitted to the Institutional Review Board for approval. In-hospital cardiac arrest patients will be initially identified for the evaluation via a REDCap database containing a list of all patients who experienced a cardiac arrest at University of Illinois Hospital and Health Sciences System from 2014 to present. Data will then be extracted from each patient’s cardiac arrest documentation from the hospital electronic medical record. Baseline characteristics including age, sex, race, past medical history, hospital location, number, type, and location of intravenous (IV)/intraosseous (IO) accesses, and baseline laboratory values will be collected. The primary outcome will be the difference in the total number of doses of IV/IO epinephrine pushes administered during the cardiac arrest in patients that receive sodium bicarbonate compared to those that do not. Other data points that will be collected include attainment of return of spontaneous circulation, duration of cardiac arrest, whether the patient was discharged from the hospital, discharge disposition, outcomes dependent on type of cardiac rhythm, medications other than epinephrine and bicarbonate used during the cardiac arrest, total milliequivalents of bicarbonate administered, total milligrams of epinephrine administered, and impact of time-of-administration when sodium bicarbonate was the medication administered directly before or after epinephrine. All
data will be recorded confidentially with no patient identifiers in REDCap and will be evaluated using descriptive and comparative statistics.

Poster Title: Evaluation of VTE Prophylaxis in Patients s/p Total Joint Arthroplasty at UIH

Primary Author: Danielle Tompkins, University of Illinois at Chicago College of Pharmacy, IL; Email: tompkind@uic.edu

Additional Author(s):
Nina Huynh
Julie Jun
Margaret Choye

Purpose: At UIH, orthopedic patients are typically treated with aspirin, warfarin, or fondaparinux post-operatively. The decision on which method of VTE prophylaxis to use is based upon the type of procedure, patient specific factors, and is ultimately up to the discretion of the physician. Despite patients being treated with guideline recommended pharmacologic agents for prophylaxis post-operatively, VTE rates remain high. This project will serve as a baseline foundation for development of a standardized orthopedic protocol. This will benefit UIH’s patient population, through the identification of areas of improvement that may be made in order to potentially prevent VTE events.

Methods: The study protocol will be submitted to an IRB for approval prior to initiation. A list of patients will be compiled using ICD-9 or ICD-10 codes for orthopedic procedures. A patient will be eligible for enrollment if they received a TKA, THA, or a revision of either of these surgeries between 01/01/2012 and 12/31/2015. Estimated sample size is 300 patients. Data points to be collected are: patient baseline characteristics (demographics, weight, laboratory results, comorbidities, presence of a concomitant blood thinning medication ie. anticoagulant, antiplatelet, NSAIDs, SSRI, presence of concomitant hormonal therapy, dates of admission/surgery/discharge), surgical and post-operative care information (type of surgery performed, name of orthopedic service, type of anesthesia, medications used for pain control, tranexamic acid utilization), VTE prophylaxis (medication name, dose, time to initiation, intended duration, mechanical prophylaxis use, time to mobilization, anticoagulation clinic follow-up, time to therapeutic INR in warfarin treated patients), outcome data (VTE events as noted in chart/follow-up clinic appointments, diagnostic test results, bleeding events). These medical record numbers and data collected from each patient will be stored using the REDCap
system, which is a secure web application designed for database storage. This allows patient confidentiality to be maintained, while also allowing securely coded patient information to be exported for the purpose of data analysis. As this is a retrospective chart review, a waiver of informed consent will be sought.

**Results:** N/A

**Conclusion:** N/A
Purpose: In April of 2016, the University of Illinois Hospital (UIH) implemented a deep vein thrombosis (DVT) prophylaxis order set with the goal of reducing incidence of postoperative DVTs and (pulmonary emboli) PEs. The order set included 4 components with 1 assessment and 3 orders: DVT risk assessment, mobility order, pharmacologic prophylaxis order, and mechanical prophylaxis order. This study is needed to evaluate the efficacy of the implemented DVT prophylaxis order set for postoperative patients at UIH and identify other potential areas for improvement to further decrease the rate of postoperative DVT/PE.

Methods: This study will be a retrospective, cohort study evaluating the compliance of 3 forms of thromboprophylaxis regimen before and after the implementation of the DVT prophylaxis order set, which was introduced in April 2016. The current study will collect data beginning April 2016 because data prior to April 2016 has already been collected. Postoperative patients over the age of 18 with venous thromboembolism (VTE) will be included and will be identified based on the Agency for Healthcare Research and Quality Patient Safety Indicator 12: Postoperative Pulmonary Embolism or Deep Vein Thrombosis Rate, which is provided by Vizient (formerly known as University HealthSystem Consortium, UHC) quarterly. Data collection will include demographic data, risk factors for VTE, and thromboprophylaxis regimen.

Poster Title: Palatability of effervescent vs standard oral n-acetylcysteine: Is it worth all the fizz?

Primary Author: Anne Marie Guthrie, University of Illinois at Chicago College of Pharmacy, IL; 
Email: guthrie@uic.edu

Additional Author(s):
Renee Petzel Gimbar
Frank Paloucek

Purpose: Acetaminophen overdose continues to be one of the most common medication exposures reported to the US Poison Control Centers. Standard n-acetylcysteine is known for its strong sulfur taste and smell, which makes oral administration challenging in the setting of acetaminophen overdose. Recently, the Food and Drug Administration approved a flavored, effervescent n-acetylcysteine tablet for the treatment of acetaminophen poisoning. A palatability study will determine how this product compares to standard oral n-acetylcysteine diluted in different beverages.

Methods: This is a prospective, cross-over, palatability study. Up to 55 healthy volunteers will be enrolled to ensure that 45 participants complete the study. Informed consent will be obtained prior to study participation. Subjects will participate in three separate sessions: one session will be dedicated to tasting effervescent n-acetylcysteine in water and effervescent n-acetylcysteine in lemonade; one to tasting standard n-acetylcysteine in Fresca, standard n-acetylcysteine in Coca-Cola, and standard n-acetylcysteine in cranberry juice; and one session for smelling all of the product mixtures. Each session will be conducted on separate days. For tasting sessions, ten milliliters of the solution will be placed in an opaque cup with lid and straw. Participants will be asked to sample enough of each mixture to evaluate the taste and score the palatability using a visual analog scale with zero being least offensive and ten being most offensive. For smelling sessions, the solutions will be placed in glass beakers that have been covered with paper to de-identify each solution. After smelling each mixture, the subject will score the smell using a visual analog scale. Data collection will include visual analog scale scores from all sessions and be managed using the secure data system RedCap. Data analysis will be completed using Friedman ANOVA and Wilcoxon signed rank test.

Poster Title: Making the best choice: norepinephrine vs phenylephrine for intraoperative use

Primary Author: Elina Delgado, University of Illinois at Chicago College of Pharmacy, IL; Email: elina_delgado@yahoo.com

Additional Author(s):
Julie Golembiewski
Randal Dull

Purpose: Intraoperative hypotension has been linked to acute kidney injury, cardiac complications, myocardial infarction, and mortality. Historically, phenylephrine has been the vasopressor of choice by anesthesiologists. The objective of this retrospective study is to examine the intraoperative use of norepinephrine vs. phenylephrine, and to identify patients' hemodynamic response to each vasopressor. Specifically, we will determine if, based on perioperative variables, one vasopressor provides better hemodynamic control.

Methods: Pending the approval of the institutional review board, a retrospective chart review will be done examining patients who underwent total hip arthroplasties, colo-rectal surgery, or gastro-intestinal surgery and received norepinephrine or phenylephrine for intraoperative hypotension. Additional inclusion criteria aside from those aforementioned are age 18 or greater, surgery case within the last 3 years, intraoperative use of EV1000 hemodynamic monitor, and surgery duration of three hours or greater. Exclusion criteria are emergent surgery and lack of Foley catheter placement. Patients will be divided into three groups: those who received norepinephrine, phenylephrine, or both. The electronic medical records of these patients will be utilized to gather background and surgery specific data metrics. These will include general patient demographics, co-morbid conditions, blood pressure (BP) related home medications, baseline BP, type of surgery, length of operation, mode of ventilation, ins and outs (to include all fluids, blood products, medications administered, estimated blood loss, urine output), heart rate, blood pressure, mean arterial pressure, stroke volume, stroke volume index, and cardiac output. All data will be recorded without patient identifiers and maintained confidentially. Statistical analysis will be done to assess patients’ demographics, MAP variations, and clinical outcomes associated with intraoperative PE vs NE use. Excel code will be used to collect area under the curve (AUC) for each patient’s intraoperative hemodynamics.

Poster Title: Long-term outcomes of kidney transplant patients receiving treatment for biopsy proven vs. empiric therapy for rejection

Primary Author: Ashley Loethen, University of Illinois at Chicago College of Pharmacy, IL; Email: aloeth2@uic.edu

Additional Author(s):
James Thielke

Purpose: A primary concern for kidney transplant recipients is rejection of the graft. Renal biopsies are still considered the mainstay of therapy for diagnosing rejection. The biopsy results are used to help guide treatment. Knowing this, there are still patients who receive empiric rejection treatment. The objective of this study is to see if there are long-term effects on graft function with empiric rejection treatment compared to biopsy proven rejection treatment.

Methods: All kidney transplant recipients will have their charts reviewed to see if they qualify for this study. They will qualify if they have had a per cause biopsy or empiric rejection treatment. After the selection of patients is complete a full chart review will be conducted and the following data will be collected: age, induction therapy, type of donor, race, risk factors for rejection, induction therapy, maintenance immunosuppression, level of tacrolimus/cyclosporine, past rejection history, height, weight, BMI, time post transplant, serum creatinine before and after, fluid status, indications for biopsy, indications for empiric therapy, biopsy results, complications, documented reason for no biopsy, treatment post biopsy, empiric treatment, graft survival, graft function at 3 and 6 months, return to baseline serum creatinine, future rejection, if no improvement from empiric treatment was a biopsy taken. Primary endpoints will be return to baseline serum creatinine and graft loss. The secondary endpoint will be the rate of biopsies post empiric treatment.

**Poster Title:** Hydration protocol and early readmission rate in pancreas transplant  

**Primary Author:** Yu-Hsueh Wu, University of Illinois at Chicago College of Pharmacy, IL; Email: ywu97@uic.edu  

**Additional Author(s):**  
Maya Campara  

**Purpose:** High early readmission rate is an issue in pancreas transplant and it is commonly associated with dehydration. The home hydration regimen was implemented at University of Illinois Hospital (UIH) in 2012 in pancreas transplant patients to prevent dehydration-related early readmission. The purpose of this study is to analyze whether the implementation of a home hydration regimen can result in 50% reduction in early readmission rate and to determine whether it can become a standard of care in pancreas transplant at UIH.  

**Methods:** This is a retrospective, chart-review, historic-control study. Adult patients who received whole pancreas transplant (either simultaneous pancreas and kidney, pancreas alone, or pancreas after kidney) at UIH from 01/01/2008 to 09/30/2016 would be included as eligible participants. The primary outcome of this study is to determine whether the implementation of hydration protocol resulted in reduction of early readmission rate. Early readmission rate is defined as any hospitalization in the first 14 days following pancreas transplantation. ER visit will be collected but excluded from the category of “early readmission”. The secondary outcomes are to identify the compliance with protocol implementation; to investigate the reason of readmission; to establish the risk factors of early readmission; to assess the safety of central line placement and associated issues for home hydration infusion; and to justify the cost-effectiveness of hydration regimen.

**Poster Title:** Assessment of the quick sepsis-related organ failure assessment in the initial evaluation of patients with suspected infection  

**Primary Author:** Rachel Murdock, University of Illinois College of Pharmacy, IL; Email: murdockr@uic.edu  

**Additional Author (s):**  
Kristen Bunnell  
Larry Danziger  

**Purpose:** The Third International Consensus Definitions for Sepsis (Sepsis-3) revised the definition of sepsis to include an assessment of organ dysfunction with the sepsis-related organ failure assessment (SOFA) score. The authors also devised an abbreviated quick SOFA (qSOFA) scoring system to identify patients with suspected infection at risk for poor outcomes. Previous sepsis definitions emphasized inflammation, with the systemic inflammatory response syndrome (SIRS) criteria being a key component of the evaluation of patients with suspected infection. The purpose of this research is to compare qSOFA and SIRS in the initial assessment of potentially infected patients.  

**Methods:** This is a retrospective, observational cohort study of adult patients presenting to the emergency department with suspected infection, as identified by the presence of orders for blood cultures, between January 1, 2014 and September 1, 2016. Patients will be identified by a query of microbiology orders and data will be extracted from the electronic medical record following institutional review board approval. Patients who are receiving systemic antibiotics for previously diagnosed infection will be excluded. Included patients will be evaluated for their highest qSOFA and SIRS criteria score within 6 hours of the order for blood cultures, and classified according to qSOFA positivity (2 of 3 criteria) and SIRS positivity (2 of 4 criteria). The primary endpoint is the incidence of microbiologically-confirmed infection. Secondary endpoints include the concordance of SIRS and qSOFA positivity, the incidence of SEPSIS-3 defined sepsis and septic shock, and progression to critical illness.  

**Results:** N/A, this research is in progress
Conclusion: N/A, this research is in progress

Poster Title: Sepsis Evaluation Following Central Line Discontinuation in the Neonatal Intensive Care Unit

Primary Author: Sana Said, University of Illinois College of Pharmacy, IL; Email: ssaid3@uic.edu

Additional Author(s):
Jennifer Pham
Kirsten Ohler
Aarti Raghavan

Purpose: Central line placement is a well-described risk factor for the development of sepsis in neonates. There is an increased risk of sepsis in the 72 hours following removal of central lines. Different strategies to combat the risk of central line infections have been utilized, including the administration of prophylactic antibiotics at the time of removal. The purposes of this study are to describe the incidence of sepsis and the evaluation for sepsis in neonates following central line removal in the neonatal intensive care unit and to determine the risk factors associated with central line infections before implementation of prophylactic antibiotics.

Methods: This is a retrospective chart review of electronic medical records. Neonates with central lines from June 1, 2013 to August 31, 2016 will be assessed. Neonates who die while the central line is still placed, those who are transferred from or to a different hospital, and those receiving antibiotics at the time of central line removal that are continued more than 24 hours after line discontinuation will be excluded. The number of neonates with sepsis and sepsis evaluation performed will be measured. This will be done through examining the start of antibiotics from the time of removal of the central line to 72 hours after discontinuation. Sepsis evaluation labs and cultures will be assessed. Antibiotic use from birth will be recorded to evaluate any protective effects afforded by their use. Complete histories of central lines including type of line, date of insertion, date of removal, reason for removal, and presence of previous lines will be recorded. Comorbidities and other factors known to be risk factors of sepsis (necrotizing enterocolitis, surgical interventions, prior exposure to antibiotics, patient demographics and anthropometrics, and total parenteral nutrition use) will also be assessed. Lastly, length of hospital stay and mortality will be examined.
Results: No results have been collected at this time.

Conclusion: No conclusions have been made at this time.

Poster Title: Assessing Medication Errors and Developing Strategies to Ensure Safe Practices with the use of Oral Chemotherapy in Chronic Myeloid Leukemia Patients

Primary Author: Atika AlHarbi, King Abdulaziz Medical City - Western Region, King Abdulaziz Medical City - Western Region Jeddah, Kingdom of Saudi Arabia (KSA); Email: alharbiat@ngha.med.sa

Additional Author(s):
Queenet Ibekweh
Mohammed Aseeri
Ahmed AlSaeed
Ayoub Ahmed

Purpose: Medication errors are relatively common with intravenous chemotherapy regimens in inpatient and outpatient settings. However, oral chemotherapy is becoming more commonly prescribed and as such, requires additional personnel training in safe medication dispensing and adequate patient education. The goal of this study is to assess the prevalence of oral chemotherapy medication errors at a tertiary care hospital in Saudi Arabia and develop strategies to ensure safe practices in the ordering and dispensing of oral chemotherapy drugs used in the treatment of Chronic Myeloid Leukemia (CML).

Methods: This retrospective chart review study will evaluate all CML patients at or over the age of 14 years receiving FDA-approved oral chemotherapy drug for CML at a tertiary care hospital in Saudi Arabia. Investigation Review Board (IRB) approval was attained at our institution in June 2016. Patients were identified through Information System Development (ISD) department at our institution. Our primary source of patient information is our hospital database and patients’ medical reports. The following data will be collected: patient’s age, sex, presence of comorbidities, date of CML diagnosis, quantification of BCR/ABL fusion gene in the blood, and Adverse Drug Events (ADE), secondary to CML treatment, reported by patients and/or caregivers. In order to assess the medication errors associated with patient adherence and drug-drug interactions, patients/patient caregivers will be interviewed once during the study period. Furthermore, Institute for Safe Medication Practices (ISMP) International Medication Safety Self-Assessment® for Oncology will be used to identify causes and triggers of
medication errors at our institution. Once data collection is complete, data will be collected and analyzed over a period of approximately 6 months.

Poster Title: Impact of BioFire FilmArray multiplex polymerase chain reaction for blood culture identification on antimicrobial use in a community hospital

Primary Author: Alexis Boyce, Baptist Health Lexington, KY; Email: alexis.boyce@bhsi.com

Additional Author(s):
Brian Host

Purpose: The Biofire FilmArray Blood Culture Identification (BCID) Panel was implemented by the Antimicrobial Stewardship Committee at our hospital in December 2015. While previous studies have shown that the BioFire BCID Panel is a reliable test for the identification of common bloodstream pathogens, less is known about the effect of this tool on appropriate antibiotic utilization. The primary objective of this study is to determine the impact of a rapid blood culture identification tool on antimicrobial use before and after its implementation.

Methods: This retrospective chart review was submitted to and approved by the local Institutional Review Board. Patients admitted before the implementation of BioFire from January 1, 2015 through May 31, 2015 will be compared to patients admitted after the implementation of BioFire from January 1, 2016 through May 31, 2016. All inpatients 18 years of age or older who had a positive blood culture during their hospitalization will be included. Patients who expired or were discharged before final culture and sensitivity data was available will be excluded. The following data will be collected utilizing the electronic medical record system: patient age, gender, comorbidities, location prior to admission, principal diagnosis, length of hospital stay, days in the intensive care unit, source of bacteremia, antimicrobials received, infectious disease consult (yes/no), discharge diagnosis, and discharge disposition. The primary endpoint is antimicrobial use, which will be measured by calculating days of antimicrobial therapy.

Poster Title: Characterization of pharmacy-initiated medication reconciliation in reducing medication errors in breast cancer patients receiving treatment in an outpatient cancer center

Primary Author: Jacqueline Norris, Baptist Health Lexington, KY; Email: jacqueline.norris770@gmail.com

Additional Author (s):
Megan May

Purpose: Medication reconciliation is critical for decreasing medication errors and providing safe patient care. Patients are at an increased risk of medication errors any time a new medication is initiated or they undergo a transition of care. Cancer patients are at risk due to the vast array of drug-drug interactions associated with chemotherapy agents. The purpose of this study is to determine the quantity of interventions made from a pharmacy-obtained reconciled medication list.

Methods: The electronic medical system will identify patients with breast cancer receiving treatment at Baptist Health Lexington’s outpatient cancer center from September 1, 2016 to December 31, 2016. The following data will be collected: patients’ age, breast cancer stage, race, chemotherapy treatment cycle, total number of medications each patient takes, number of comorbidities, and the type and number of interventions completed by pharmacy. Pharmacy personnel will interview each breast cancer patient presenting to the infusion center and obtain an accurate medication list and update information in the patients’ chart. After the medication reconciliation is completed data collected will be analyzed to determine how many interventions were made on average and how many of those interventions could have resulted in serious adverse reactions if not discovered. Interventions being analyzed include: prescriptions added to or deleted from the medication list, over the counter or herbal supplements added to the medication list, drug form, dosage, or schedule discrepancies, and drug-drug interactions, including the severity of the interactions.

Poster Title: Implementation and evaluation of a controlled substance auditing program in a community hospital

Primary Author: Hannah Bennett, Baptist Health Lexington, KY; Email: hannah.bennett@bhsi.com

Additional Author(s):
William Stewart

Purpose: The tracking of controlled substance usage and waste in a hospital is a necessary but difficult process. It is important to have a precise and efficient controlled substance auditing program in order to quickly act on possible diversion, to keep an accurate inventory, and to ensure patients are billed correctly. This study seeks to assess multiple controlled substance use-reporting systems in order to develop an effective controlled substance auditing program in a community hospital.

Methods: There will be five pre-specified areas of the hospital which will be included in the study: two intensive care units, two medical-surgical floors, and the emergency department. The primary objective of this study is to characterize, evaluate, and when applicable, compare four primary controlled substance use-reporting systems in order to implement a controlled substance auditing program. The first report will be generated using a third party reporting system to identify discrepancies in controlled substance usage. Reports from both the electronic health record and the automated dispensing cabinet software will be reconciled to show instances where controlled substance medications were pulled without an associated order. Lastly, accuracy of the procurement and storage of controlled substances will be evaluated by comparing invoices to inventory logged into the controlled substance vault. Each report will be run on a monthly basis. Secondary objectives include identifying common controlled substance use discrepancies, identifying common medications and amounts involved in controlled substance use discrepancies, the frequencies of controlled substance use discrepancies, the amounts of controlled substance use discrepancies that occur in specific areas of the hospital, and how much time it will take to analyze each of the controlled substance use reporting systems.

**Poster Title:** Evaluation of the effectiveness of urinary tract infection treatment protocol in the inpatient setting

**Primary Author:** Ahmed Shammisaldeen, Baptist Health Lexington, KY; **Email:** ahmed.shammisaldeen@bhsi.com

**Additional Author (s):**
Whitney Thomas

**Purpose:** In 2012-2013, the local antimicrobial stewardship team developed a urinary tract infection (UTI) protocol to streamline the use of antibiotics toward appropriate empiric therapy. The UTI protocol was implemented into the previous computerized physician order entry system, but it has not yet been integrated into the current electronic medical record system. The goal of this study is to evaluate the effectiveness of the UTI protocol by measuring microbiological failure rates, length of stay, readmission rates within 30 days, and antibiotics used in treatment of UTI.

**Methods:** The study design involves a retrospective review of medical charts and has been approved by the institutional review board. This study will examine a six-month period where the UTI treatment protocol was active and another six-month period where the previous UTI protocol was inactive. Inclusion criteria consist of any patients 18 years and older with a primary or secondary diagnosis of UTI. Any patients who have catheter associated urinary infections, pregnancy, sepsis, or are incarcerated will be excluded. Baseline demographics will be collected for each patient including age, weight, sex, renal function, comorbidities, the length of stay, the sensitivity of the isolates, readmission rates within 30 days, and the antimicrobial therapy. The primary objective of this study is to measure and compare microbiological failure rates (the resistance of isolates to the current antibiotic therapy), average length of stay, sensitivity of the isolates from urine cultures, and readmission rates between the two time periods specified above.

William Stewart
Amy Weir

Purpose: Society of Critical Care Medicine (SCCM) sedation/agitation guidelines currently recommend that sedatives/analgesics be titrated to light sedation, defined as a Richmond Agitation Sedation Scale (RASS) greater than or equal to -2, rather than deep sedation for patients requiring invasive mechanical ventilation. Studies have shown positive outcomes from light sedation on intensive care unit (ICU) length of stay, hospital length of stay, days on mechanical ventilation, and other targeted metrics. The primary objective of the study is to both define current sedation practice within a community medical/surgical ICU and insure compliance with guideline recommendations through a pharmacy driven nursing education.

Methods: A protocol outlining an observational retrospective chart review was submitted to the Institutional Review Board for approval. The electronic medical record was utilized to identify patients that are mechanically ventilated for greater than 48 hours who did not have contraindications for light sedation. Exclusion criteria included acute neurologic injury, neuromuscular blocker administration, alcohol dependence, external cooling, and death within 72 hours. Data pulled from the electronic medication record will be utilized to evaluate compliance with sedation/agitation practice guidelines and develop a targeted education based on possible deficits in recommendations. Along with sedation practice analysis, billed medication quantities will be compared pre and post education to assess any changes in drug utilization and validate the sedation/agitation practice education provided. Current sedation/agitation practices were assessed using the Richmond Agitation Sedation Scale (RASS). The percentage of time spent within light sedation will be the primary outcome assessed. Secondary outcomes include benzodiazepine use, analgesia first-sedation (analgosedation), days on mechanical ventilation, ICU length of stay, hospital length of stay, ICU mortality, hospital mortality, and re-intubation events. Post-evaluation, the nursing staff of a
medical/surgical ICU will be provided sedation/agitation education based on gaps in current practice pertaining to guideline recommendations. Post education, a second retrospective chart review will be completed to compare the effect of the targeted sedation/agitation education.

**Poster Title:** Implementation of a meropenem de-escalation protocol utilizing prospective audit and feedback in a community hospital

**Primary Author:** Mallory Megee, Baptist Health Lexington, KY; **Email:** mallory.megee1@BHSI.com

**Additional Author (s):** Layla Marefat

**Purpose:** Current Infectious Diseases Society of America (IDSA) recommendations include prospective feedback and review as a core component of antimicrobial stewardship teams. This mechanism of review and feedback serves to help tailor antimicrobial agents and decrease excessive use of unwarranted broad-spectrum antibiotics. Decreasing meropenem usage has become a focus area for our local antimicrobial stewardship committee with the goal of preventing the development of multi-drug resistant organisms at our institution.

**Methods:** This study was approved by the institutional review board to take place from September 1, 2016 through March 31, 2017. A prospective review will be performed on eligible adult, non-ICU patients on meropenem therapy with definitive cultures that allow alternate therapy or who are receiving empiric therapy for > 72 hours. The pharmacist will perform daily audits on meropenem usage and attend biweekly antimicrobial stewardship committee meetings to discuss eligible patients. Eligibility is determined by using a physician approved de-escalation protocol which includes culture results and patient specific factors such as normalization of WBC, CRP, and lactic acid as well as clinical improvement as determined by the primary or infectious disease physician. The primary outcome of this study is to evaluate the impact of a meropenem de-escalation protocol using antimicrobial stewardship team intervention on meropenem usage. Secondary outcomes include pharmacist intervention acceptance rate, hospital length of stay, duration of antibiotic therapy and mortality at hospital discharge.

**Poster Title:** Development of a tool for prevention of inpatient falls based on Beers Criteria and STOPP: A pilot study.

**Primary Author:** Vishal Patel, Baptist Health Louisville, KY; **Email:** patelvishal235@gmail.com

**Additional Author(s):**
Anna Hitron
Jessica Covington
James Terry

**Purpose:** Falls are a leading source of accidental death in people greater than age 65. The Beers criteria and Screening Tool of Older Person’s Prescriptions (STOPP) have been developed to help identify potentially inappropriate medications (PIMs) in patients age 65 or older. However, the list of drugs provided by these two tools is exhaustive and primarily focuses on outpatient and long-term care settings. Many are not realistic targets for potential interventions in inpatient environments. This study aims to create a more focused list of drugs to target for discontinuation/medication optimization within an inpatient population at a large community hospital.

**Methods:** This study is a two phase study. The first phase will involve the development and creation of a tool to assist pharmacists in recommending interventions regarding potentially inappropriate medications (PIMs). This phase will consist of a literature review as well as a voluntary survey. Medications published in the Beers/STOPP criteria will be compared with other evidence to identify the highest risk PIMs. Additionally, a survey will be conducted among admitting physicians to gain insight into prescribing practices that could impact PIMs. This survey will run over the course of two weeks and be administered via SurveyMonkey. The results of the survey will be analyzed and combined with the literature review to provide a streamlined list of PIMs. This list will be used to build the tool to assist pharmacists in recognizing PIMs targeted for inpatient populations.

The second phase is a pilot study evaluating tool usage within an inpatient setting. Patients will be selected based on the inpatient floor during their stay. Pharmacists will use the tool previously built in phase one to identify PIMs and provide recommendations to the attending physician. Patients will be randomized; data collected will include the number of falls, the
number of interventions made and the number of accepted interventions. Primary endpoints include acceptance of pharmacist intervention; secondary endpoints include the effect of tool usage on number of inpatient falls.

**Results:** Expected by spring 2017.

**Conclusion:** Expected by spring 2017.
**Poster Title:** Impact of pharmacist counseling on congestive heart failure 30-day readmissions at a community hospital

**Primary Author:** Radhika Patel, Baptist Health Louisville, KY; **Email:** radhikap88@yahoo.com

**Additional Author(s):**
Megan Webb  
Shelly O'Bryan  
Kevin Maginnis

**Purpose:** Congestive heart failure (CHF) is the leading cause of mortality in the United States. CHF affects 5.7 million adults and is responsible for one in nine adult deaths. Additionally, CHF patient hospital readmission rates remain high, where the current national average for CHF 30-day readmission rates is 21.9%. The purpose of this study is to determine the incidence of 30-day readmission in CHF patients before and after implementation of pharmacist provided inpatient counseling.

**Methods:** This is a retrospective, single center, cohort study, involving chart review from April 2016 to November 2016. A new clinical service wherein pharmacists provide inpatient counseling to CHF patients was implemented in August 2016. This study will evaluate the impact of this new service by comparing the rate of 30-day hospital readmission between the group of CHF patients who received pharmacist inpatient counseling versus the CHF patients who did not receive counseling. Secondary outcomes include the amount of time required by the pharmacist to conduct an inpatient counseling session, the number of pharmacist interventions, emergency department visits within 30 days after discharge, and factors associated with prevention of 30-day readmission will also be analyzed in this study. Eligible patients for inclusion are at least 18 years old, admitted to the hospital with a history or admission diagnosis of heart failure. Prisoners, pregnant women, patients with altered mental status, and patients who will be discharged to skilled nursing facilities or long-term care facilities will be excluded from the study. In this study, all continuous data will be analyzed using student’s t test and nominal data will be analyzed using Chi-square test. Factors associated with prevention of 30-day readmission will be analyzed by univariate and multivariate logistic regression.

Poster Title: Evaluating carbapenem use before and after providing carbacarbapenem-resistant Enterobacteriaceae education to physicians

Primary Author: Amy Staples, Baptist Health Madisonville, KY; Email: amyleigh2189@gmail.com

Additional Author(s):
Kenneth Allen
Jeffrey Cavanaugh

Purpose: Carbapenem-resistant Enterobacteriaceae (CRE) have become a global healthcare problem over the last few decades. Resistance to carbapenems was first seen in Klebsiella pneumoniae and has passed its plasmid-born resistance to several species of the Enterobacteriaceae family, including multi-drug resistant organisms (MDRO). Studies have shown that patients previously treated with carbapenems are at a much higher risk of colonization or infection with CRE. The purpose of this study is to determine if providing CRE education to physicians affects the percentage of patients that receive carbapenems during their hospital stay.

Methods: This study will be submitted to the Institutional Review Board for approval. The percentage of patients receiving at least one dose of a carbapenem during their hospital stay before providing education will be determined. Physicians will be provided brief, general education on CRE with an emphasis on prevention. The physicians included in the education component of this study will be limited to hospitalists and family practice medical residents and faculty. The percentage of patients receiving at least one dose of any carbapenem during their hospital visit will be determined after educating all physicians. This rate will be followed for several months to track changes.

**Poster Title:** Impact of patient education on hospital readmission rates in a rural community teaching hospital

**Primary Author:** Carson Schlich, Baptist Health Madisonville, KY; **Email:** carson.schlich@bhsi.com

**Additional Author (s):**
Margo Ashby
Jeffrey Cavanaugh
Kimberly Webb

**Purpose:** Readmission rates are an important area for hospitals to continually make improvements. Many factors can contribute to patient readmissions, such as education, new disease onset, or previously failed treatments. This project seeks to evaluate and determine the impact of patient education on hospital readmission rates.

**Methods:** Patients/caregivers located on a pre-determined med-surg pilot unit in a rural community hospital will be surveyed on day 3 of admission to determine level of education regarding their disease states and/or medications. Surveys will be conducted with a standardized form that was developed by team members composed of a physician champion, nursing, clinical dietitian, physical therapy, pharmacy, case managers, and a social worker. The trial will be conducted from September 2016 through November 2016. A sample size of at least 100 patients will be obtained during the trial period. Upon completion of data collection, historical and post implementation readmission rates will be compared. This data will then be correlated to patient education levels.

Poster Title: Utilization of sedation agents in the critical care unit of a rural community hospital

Primary Author: Patrick Roland, Baptist Health Madisonville, KY; Email: patrick.roland@bhsi.com

Additional Author(s):
Margo Ashby
Matt Cavanaugh

Purpose: According to the 2013 Clinical Practice Guidelines for the Management of Pain, Agitation, and Delirium in Adult Patients in the Intensive Care Unit, the Richmond Agitation Sedation Scale and the Sedation Agitation Scale are the most valid and reliable sedation assessment tools for measuring quality and depth of sedation in adult ICU patients. Our facility’s sedation order set includes the Ramsay Scale. The primary objective of this study is included, but not limited to, assessing the utilization of sedation agents listed in our sedation order sheet for ventilated patients as we implement the Richmond Agitation Sedation Scale.

Methods: This study will be submitted to the institutional review board for approval. A retrospective chart review will be performed on patients admitted from September 1, 2015 to September 1, 2016. This review will focus on the usage and indication of agents in our facility’s current sedation order sheet for ventilated patients. The selected agents include, but are not limited to, midazolam, lorazepam, propofol, dexmedetomidine, morphine, hydromorphone, and fentanyl. Any incidental findings will also be included in the review. These findings will be utilized to reinforce the adherence to sedation guidelines and recommended monitoring parameters for sedatives used in the critical care setting. Results of this review will be presented to applicable staff and any revisions made to the order set will require focused education.

Poster Title: The Impact of a Pharmacist-Reviewed Medication Reconciliation Process within a State Psychiatric Hospital

Primary Author: Courtney Newby, Central State Hospital, KY; Email: cnewby@sullivan.edu

Additional Author(s):
Emma Palmer
Gilbert Smith

Purpose: The purpose of this study will be to determine the most common medication variances seen within our hospital. After identifying the most commonly seen variances, we will determine the reason for the errors and implement educational interventions to the hospital staff in efforts to correct common variances. After implementing education, we will again review medication variances and assess if there are any changes after educational implementation.

Methods: Data collection and analysis will commence upon IRB approval at Central State Hospital (CSH) and the Kentucky Cabinet for Health and Family Services. This study will be retrospective and prospective in nature. Retrospective data collection will include the time frame from April 2015 to April 2016. Initially, past charts will be reviewed for any commonly seen errors during the medication reconciliation process (i.e. missing or incorrect home medications, inappropriate indications). By identifying these common errors, we will formulate educational sessions for our physicians and nursing staff. After implementation of an educational series, we will analytically review patient charts to determine if a pharmacy-reviewed medication reconciliation process decreases the number of medication variances within a state psychiatric hospital.

Results: To be presented at ASHP Midyear Regional Meeting.

Conclusion: To be presented at ASHP Midyear Regional Meeting.

Poster Title: Chronic obstructive pulmonary disease (COPD) discharge prescribing prior to and post implementation of a pharmacist-driven, evidence-based protocol in a rural community hospital setting

Primary Author: Nicholas Wilson, Ephraim McDowell Regional Medical Center, KY; Email: nawilson@emhealth.org

Additional Author (s):
Joan Haltom
Kourtney Shewmaker
Brett Vickey
Allison Williams

Purpose: At 10.4%, Kentucky has the highest COPD prevalence in the nation; nearly 380,000 Kentuckians have been diagnosed. Failure to treat high-risk COPD patients according to GOLD guideline treatment regimens may lead to inadequate therapy and increase risk of hospital readmission. The primary objective of this research is to evaluate and compare discharge prescriptions for COPD patients to Global Initiative for Chronic Obstructive Lung Diseases (GOLD) guidelines pre- and post-implementation of a pharmacist-driven discharge protocol. A secondary objective will be to identify patient-reported barriers to filling prescribed COPD discharge prescriptions.

Methods: This study has been approved by the Institutional Review Board. A retrospective chart review will be completed to establish baseline-prescribing habits of COPD medications upon discharge. Data collected will include patient medical record number, age, sex, race, drug allergies, provider, COPD medications prescribed at discharge, and modified COPD Assessment Test (CAT) score. A pharmacist-driven, evidence-based protocol will be developed based on current GOLD first-line recommendations. After implementation of the protocol, concurrent review of medical charts will be completed to identify COPD patients meeting inclusion criteria. Once identified, the patients will be asked for written informed consent. The principal investigator or designee will survey the participants about current symptoms using a modified version of CAT. Dependent upon the score, this assessment will place COPD patients in one of two possible classes as outlined by GOLD guidelines, and ultimately dictate the medications
prescribed at discharge. Five additional questions will be asked that will help identify patient
perception of their clinical status and any barriers reported in obtaining or complying with
COPD medications. During the study period, the discharging pharmacist will review
prescriptions and implement changes as necessary per protocol to meet GOLD guidelines. An
evaluation and comparison will be made between COPD discharge medications and GOLD
guidelines recommendations to determine appropriateness. Comparisons will be made
between discharge prescriptions for COPD patients pre- and post-implementation of the
protocol.

**Poster Title:** Impacting antimicrobial stewardship in a community hospital through the use of BioFire FilmArray®

**Primary Author:** Chelsea Stamper, Ephraim McDowell Regional Medical Center, KY; **Email:** cegoodman@emrmc.com

**Additional Author (s):**
Joan Haltom
Angie Hatter
Rick Scott

**Purpose:** BioFire FilmArray® technology allows for rapid pathogen identification of blood culture pathogens through the use of polymerase chain reaction (PCR) testing. In theory, more rapid identification of the organism should allow for less empiric treatment days and a faster time to treat with an appropriate targeted antimicrobial regimen. The primary objective of this research is to compare the duration of empiric antibiotic therapy to the duration of targeted antibiotic therapy pre- and post- implementation of the BioFire FilmArray® technology in a community hospital. A secondary objective is to evaluate the accuracy of the BioFire FilmArray® technology compared to plated specimens.

**Methods:** This study is a retrospective medical chart review of adult patients (age ≥ 18) who had positive blood cultures that were tested using the BioFire FilmArray® technology at Ephraim McDowell Regional Medical Center (EMRMC) in Danville, Kentucky. A report from the electronic medical record will be generated for all inpatient adults with positive blood cultures between March 1st, 2015 and September 30th, 2015. This report includes those patients prior to the implementation of the BioFire FilmArray® technology. A second report will be generated for all adult patients who had positive blood cultures between March 1st, 2016 and September 30th, 2016. This report includes those patients post implementation of the BioFire FilmArray® technology. Data collected will include patient age, blood culture results, number of days of empiric antibiotic therapy, number of days of targeted antibiotic therapy, total number of days of antibiotic therapy, accuracy of BioFire FilmArray® results, and length of stay. If population numbers exceed that needed for significant significance and/or power, participants will be randomly selected using a random number generator. All the data collected for this study will
be removed of any subject identifiers and will be maintained confidentially. This study design has been approved by the Ephraim McDowell Regional Medical Center Institutional Review Board.

Poster Title: Evaluation of influenza vaccine screening and administration rates in a single academic pediatric medical center

Primary Author: Savannah Gulley, Kosair Children's Hospital, KY; Email: savannah.gulley719@gmail.com

Additional Author(s):
Joshua Elder
Bethany Wattles
Shannon Mayes

Purpose: Influenza in pediatric patients leads to illness, hospitalization, and possibly death. The best way to prevent influenza is through vaccination. In 2014, the Centers for Disease Control and Prevention reported that roughly 50% of patients aged six months to seventeen years received their annual influenza vaccine (AIV). Children hospitalized during influenza season should receive an AIV prior to discharge, but despite institutional nursing protocols, children are remaining unvaccinated. This study serves to assess the compliance of nursing staff screening and administration of AIV to eligible patients.

Methods: This is a quality improvement project exempt from institutional review board approval, which serves to evaluate the compliance of nursing staff AIV screening and administration. Secondary objectives will include why AIV was not administered, compliance rates between different hospital units, and a nursing survey of barriers to vaccination. Data will be collected from September 15, 2016 to November 15, 2016 at Kosair Children’s Hospital. Patients aged six months to seventeen years of age, who have an AIV order, and are not located in the emergency department or an intensive care unit will be included. Data to be collected on patients includes age, hospital unit, compliance with administration of AIV, and documented reason to not vaccinate. An electronic survey will be sent to nursing staff in order to identify perceived barriers to vaccination. Evaluation of data will include descriptive statistics to assess primary and secondary objectives.

**Poster Title:** Assessment of high-dollar medication waste at a pediatric institution

**Primary Author:** Sarah Mitchell, Kosair Children's Hospital, KY; **Email:** sarah.mitchell@nortonhealthcare.org

**Additional Author(s):**
Joshua Elder
Brian Yarberry

**Purpose:** The increasing use of high cost biologic agents and chemotherapeutic medications in pediatric patients is associated with a growing problem of medication wastage. This study will examine the cost associated with chemotherapy and monoclonal antibody waste in a single pediatric institution. This information will then be used to assess the cost-effectiveness of various waste-reducing methods including the implementation of a closed-system transfer device for use during medication preparation.

**Methods:** This quality improvement project is exempt from IRB approval. Vials of chemotherapeutic agents and monoclonal antibodies that would otherwise be wasted will be collected from September to October of 2016. Medication vials will be measured to determine remaining medication and this waste will be recorded on a weekly basis. Waste associated cost will be determined using purchasing history from the pharmacy wholesaler database. Descriptive statistics will be used to analyze this cost information and extrapolate to a yearly cost of chemotherapy and monoclonal antibody waste for the hospital. Medications with the highest volume of waste as well as the highest cost of waste will be identified. This information will be used to examine the feasibility and cost-effectiveness of implementing a closed system transfer device for medication preparation and other methods for limiting waste such as utilization of smaller vial sizes or extended stability testing on the most expensive agents.

**Poster Title:** Cost-effectiveness of filgrastim biosimilar use in a healthcare system

**Primary Author:** Kendra Sanderson, Kosair Children's Hospital, KY; **Email:** kendra.sanderson@nortonhealthcare.org

**Additional Author(s):**
Joshua Elder  
Brian Yarberry  
Kyle Franco

**Purpose:** Granulocyte colony stimulating factor (G-CSF) analogues such as filgrastim promote production, maturation, and activation of neutrophils. They are commonly used to hasten neutrophil recovery after myelosuppressive chemotherapy and prevent complications associated with neutropenia. The first FDA approved biosimilar was released in 2015 after phase III study results demonstrated equivalence of filgrastim-sndz with regard to its ability to increase absolute neutrophil count and CD34+ cell counts when compared with filgrastim. This study aims to identify cost savings after a system wide transition from filgrastim to filgrastim-sndz in August 2016.

**Methods:** This is a quality improvement project exempt from IRB approval. Monthly purchasing data for filgrastim will be collected from the system's wholesaler for each of its facilities from May through July of 2016. This cost data will be compared to monthly purchasing costs for the months of August through November of 2016 post transition to filgrastim-sndz. Descriptive statistics will be used to project the mean annual cost savings for each facility as well as for the healthcare system. In addition to cost analysis, the study will evaluate usage data at each individual institution over this timeframe. Descriptive statistics will be performed in order to assess the cost-effectiveness of biosimilar use. Specifically in the pediatric population, data will be evaluated regarding actual dose administered in micrograms and subsequent waste of filgrastim-sndz as it is only available in pre-filled syringes.

**Results:** N/A

**Conclusion:** N/A

Session-Board Number: 9-293

Poster Title: Recombinant activated factor VII for refractory bleeding in pediatric patients on ECMO

Primary Author: Hillary Orr, Kosair Children's Hospital, KY; Email: hillary.orr@nortonhealthcare.org

Additional Author(s):
Heather Damhoff
Cynthia Zoeller
Shannon Mayes

Purpose: The purpose of this study was to evaluate the efficacy of recombinant activated factor VII (rFVIIa) for refractory bleeding in pediatric patients on extracorporeal membrane oxygenation (ECMO). The primary objective was to quantify the impact of rFVIIa on bleeding severity by evaluation of blood product administration and blood loss. The secondary objective was to assess the frequency of thrombotic events after the administration of rFVIIa warranting change in the ECMO circuit.

Methods: This was a single center, retrospective, descriptive analysis of patients admitted to the PICU at Kosair Children's Hospital from September 2013 to August 2015. Demographics were obtained from the medical record. Data pertaining to blood loss and transfused blood products administered 24 hours prior to the first dose and 24 hours after the final dose of rFVIIa was attained. Thrombotic events necessitating change in the ECMO circuit were documented.

Results: Five patients were included in the study. One patient received aminocaproic acid and one received phytonadione prior to rFVIIa administration. Discontinuation of heparin therapy occurred in two patients prior to rFVIIa administration. A median dose of rFVIIa 60 mcg/kg (range 26-90 mcg/kg) was observed among the five patients. Four patients received one dose of rFVIIa, while one patient initially administered 26 mcg/kg/dose required one additional dose. Blood loss decreased by an average of 3.52 mL/kg/hr (range 0.11-12.67 mL/kg/hr). Blood transfusions decreased by an average of 119 mL/kg (range 28.4-254.5 mL/kg). One patient developed a decrease in oxygenator efficiency, while another developed a thrombus...
warranting change in the ECMO circuit. Surgical exploration was observed in one patient due to persistent hemorrhage.

**Conclusion:** Administration of rFVIIa during ECMO support was associated with a decrease in bleeding severity observed by a decrease in blood loss and transfusion rates and was not associated with increased thrombotic events. More robust, prospective randomized trials are needed to evaluate the efficacy of rFVIIa administration in ECMO patients.

Shannon Allcron  
Kristan Vollman  

**Purpose:** Management of patients with a major bleed while on a vitamin K antagonist (VKA) is a common clinical challenge. Historical reversal agents available for this indication include vitamin K as well as fresh frozen plasma. Approved in the United States in 2013, four-factor prothrombin complex concentrate (4F-PCC) provides urgent reversal of VKA. This reversal agent may be useful in patients who are taking a VKA and present with major, life-threatening bleeding or who require emergency surgery or urgent procedure. The objective of this study is to evaluate the use of 4F-PCC at the study institution.  

**Methods:** Prior to data collection, this study was approved by the Institutional Review Board. This is a retrospective chart review of adult patients who received 4F-PCC at the study institution between January 1, 2013 and June 30, 2016. Demographic information, including age, sex, and weight, as well as anticoagulant administration prior to 4F-PCC intervention and indication for chronic anticoagulation was collected. Indication and dose of 4F-PCC were evaluated as well as baseline and post-PCC INR. Other data points collected were administration of additional reversal agents, location of 4F-PCC administration, prevalence of thrombotic events, and in-hospital mortality. Prisoners and pregnant patients will not be included in this research. Data will be analyzed using descriptive statistics.

**Poster Title:** Trastuzumab loading, reloading, and monitoring evaluation in a regional community hospital

**Primary Author:** Jennifer Kwok, Owensboro Health Regional Hospital, KY; **Email:** jennifer.kwok@owensborohealth.org

**Additional Author (s):**
- Claire Boomershine
- Tracy Haley

**Purpose:** Trastuzumab is a human epidermal growth factor receptor 2 (HER-2) antagonist indicated for HER-2-overexpressing breast and metastatic gastric cancer. Dosing is once weekly or every three weeks, with a loading dose indicated on the first treatment day. Based on previous clinical studies, a repeat loading dose should be administered if a dose is missed by more than one week. Despite this recommendation, adherence varies in clinical practice. The objective of this study is to evaluate trastuzumab use practices at the study institution with a primary focus on loading and reloading doses.

**Methods:** Prior to data collection, this study was approved by the Institutional Review Board. Patients who received trastuzumab for breast or gastric cancer from May 1, 2012 to July 31, 2016 were included in this retrospective chart review. Study data was obtained using the institution’s electronic medical record. Subjects were excluded if under 18 years of age, pregnant, or on a non-standard dosing regimen. The following key information on each subject was collected: patient demographics, dosing weight, type of cancer, goal of treatment, trastuzumab dosing and frequency, administrations of initial loading or subsequent loading doses, indications for dose delays, concurrent chemotherapy, ejection fraction (EF) and frequency of EF monitoring. Data will be analyzed using descriptive statistics.

Poster Title: Retrospective review of patients presenting to a rural community teaching hospital with intracerebral or gastrointestinal bleeding

Primary Author: Brook Walsh, Saint Claire Regional Medical Center, KY; Email: walshbrook@gmail.com

Additional Author (s): Stephanie Baker Justice

Purpose: When patients present with major bleeds, the bleed may be secondary to anticoagulant therapy. In recent years, several anticoagulants with different mechanisms and their respective reversal agents have become available. The intention of having a reversal agent available for patients presenting with major bleeding and concomitant anticoagulant therapy is to decrease or stop that anticoagulant effect of medications thereby decreasing the amount of time for the cessation of blood loss and amount of blood ultimately lost. However, many of these products are not readily available at all institutions. The purpose of this retrospective review is to investigate the outcomes in patients presenting with a major bleed at a rural community hospital where many of the reversal agents are not readily available. In-hospital pharmacologic interventions for reversal are currently limited to the administration of the following: phytonadione and fresh frozen plasma.

Methods: A retrospective chart review of patients presenting with major bleeding events and who were on concomitant anticoagulant therapy between January 1, 2014 and December 31, 2015 will be performed. The electronic medical record will be evaluated for each presentation, diagnosis and subsequent treatment or management. Treatments utilized, relevant laboratory parameters and outcomes will be recorded.

**Poster Title:** Evaluating Blood Glucose as an Indicator of Outcomes in Patients with Bacteremia  
**Primary Author:** Kacie Migliavacca, Saint Joseph East, KY; **Email:** kaciemigliavacca@sjhlex.org  

**Additional Author(s):**  
Steve Burger  
Chelsea Owen  
Greg Mateyoke  

**Purpose:** Bacteremia is a significant cause of morbidity and mortality throughout the United States. A wide variety of risk factors for the development of bacteremia exist, including but not limited to diabetes mellitus. Studies have been done investigating the relationship between diabetic patients and their risk for developing bacteremia, as well as their outcomes based on their initial blood glucose control upon diagnosis. However, studies examining outcomes based on level of control while hospitalized for bacteremia are lacking. This project aims to determine whether well- versus poorly-controlled blood glucose during hospitalization for bacteremia is a factor in overall patient outcomes.  

**Methods:** This research will be conducted as a single-center, retrospective, observational cohort study. The study will include diabetic patients admitted to the hospital from July 2012 to July 2016 with a diagnosis of bacteremia. The primary endpoint will be 30 day mortality. Secondary endpoints will include length of hospital stay, time from diagnosis to receipt of first antibiotic, appropriate definitive antibiotic use at time of identification of pathogen, and time to resolution of bacteremia from time of diagnosis. Data will be obtained utilizing electronic medical records. Data collected will include age, sex, weight/height, bacteria present in blood culture, mean and median daily blood glucose readings, A1c upon admission, antihyperglycemic medications received during hospital stay, length of hospital stay, time to resolution of bacteremia, time to de-escalation of antimicrobial therapy, length of antibiotic therapy, relevant comorbidities, and source of bacteremia (if known). Categorical data will be evaluated utilizing the chi-squared test (x2) and Fisher’s exact test where appropriate. Continuous data will be evaluated utilizing the Student’s t-test for parametric data and the Wilcoxon rank sum test for non-parametric data, where appropriate. An a priori alpha of 0.05 will be set for significance. Data analysis will be performed using Microsoft Excel and SAS statistical software.
Data will be recorded in such a manner that subjects cannot be identified, directly or through identifiers linked to the subjects.

**Results:** The final results and conclusions of this study are pending and will be presented at the Great Lakes Pharmacy Residency Conference.

**Conclusion:** The final results and conclusions of this study are pending and will be presented at the Great Lakes Pharmacy Residency Conference.

**Poster Title:** Vasopressor requirements in mechanically ventilated patients receiving dexmedetomidine versus propofol  

**Primary Author:** Breanne Martinez, Saint Joseph East, KY; **Email:** breannemartinez@sjhlex.org  

**Additional Author(s):**  
Greg Mateyoke  
Chelsea Owen  
Steven Berger  

**Purpose:** Propofol and dexmedetomidine are commonly used sedative agents in the intensive care unit (ICU), both of which have been known to cause hypotension. Given currently available literature, it is unknown if patients require increased vasopressor support or have variable requirements due to sedating medications. A comparison is needed to determine if there is a difference in vasopressor requirements in patients receiving propofol versus dexmedetomidine while intubated in an ICU.  

**Methods:** This project will be conducted as a multi-center, retrospective, observational cohort study. The study will include patients admitted to the intensive care unit at Saint Joseph East and Saint Joseph Hospital between July 2014 and July 2016. The primary endpoint will be the incidence of vasopressor use in patients receiving propofol versus dexmedetomidine. Secondary endpoints include, length of time at goal mean arterial pressure (MAP), duration of vasopressor use, number of vasopressor agents required, maximum infusion rate of vasopressors overtime, percent change of MAP overtime, and ICU and in-hospital length of stay. Additional data to be collected include age, sex, APACHE II score, admitting diagnosis, and midazolam or fentanyl utilization. Data will be obtained utilizing physical and electronic health records. Categorical data will be evaluated utilizing the chi-squared test (X2) and Fisher’s exact test where appropriate. Parametric continuous data will be evaluated utilizing the Student’s t-test; non-parametric continuous data will be evaluated using the Wilcoxon rank sum test. An a priori alpha of 0.05 will be set for significance. Data analysis will be performed using Microsoft Excel and SAS statistical software.

Poster Title: Rivaroxaban versus enoxaparin for the secondary prophylaxis of venous thromboembolic disorder in patients with active cancer

Primary Author: Carley DeVee, Saint Joseph East, KY; Email: carleydevee@sjhlex.org

Additional Author(s):
Kim Flynn
Chelsea Owen
Greg Mateyoke

Purpose: Due to the hypercoaguable nature of malignancy, venous thromboembolic disease (VTE) is a major source of morbidity and mortality. In fact several national guidelines, including the CHEST guidelines and the National Comprehensive Cancer Network both recommend secondary prophylaxis against VTE. They also recommend enoxaparin as the drug of choice for this indication over warfarin, and claim insufficient data to recommend the direct oral anticoagulant (DOAC) agents. Therefore, it is the aim of this study to compare the efficacy and safety of enoxaparin versus rivaroxaban for the secondary prevention of VTE in patients with active cancer.

Methods: This research is a multi-center, retrospective, observational cohort study. Inclusion criteria are patients with active cancer receiving care at Kentucky One Health ambulatory oncology clinics between July 6, 2013 and July 6, 2016. The first cohort will consist of patients receiving rivaroxaban for secondary VTE prophylaxis with active cancer. The second cohort will consist of patients receiving enoxaparin for secondary VTE prophylaxis with active cancer. The primary endpoint of this study is the incidence of VTE up to six months past initiation of anticoagulation for an acute VTE. Secondary endpoints include: major bleeding, mortality, and incidence of gastrointestinal bleed. Data will be collected utilizing a chart review process of all patients on enoxaparin or rivaroxaban in the Kentucky One ambulatory oncology system during the observation period. Data collected will include: gender, age, weight, serum creatinine, current smoking status, history of smoking, previous VTE type (DVT or PE), type of malignancy, history of GI bleed, other anticoagulation/antiplatelet therapy present, patient comorbidities, etc. Categorical data will be evaluated utilizing the chi-squared test and Fisher’s exact test where appropriate. Parametric continuous data will be evaluated utilizing the Student’s t-test;
non-parametric continuous data will be evaluated using the Wilcoxon rank sum test. An a priori alpha of 0.05 will be set for significance. Data analysis will be performed using Microsoft Excel and SAS statistical software.

**Results:** The final results and conclusions of this study are pending and will be presented at the Great Lakes Pharmacy Residency Conference.

**Conclusion:** The final results and conclusions of this study are pending and will be presented at the Great Lakes Pharmacy Residency Conference.

**Poster Title:** Ceftriaxone versus levofloxacin for the empiric treatment of Escherichia coli urinary tract infections in the setting of high fluoroquinolone resistance

**Primary Author:** Samantha Wang, Saint Joseph Hospital, KY; Email: samanthawang@sjhlex.org

**Additional Author(s):**
Patrick Ratliff
Russ Judd

**Purpose:** Urinary tract infections (UTIs) are among the most common bacterial infections, most commonly caused by Escherichia coli. Per the Infectious Disease Society of America guidelines, options for the initial treatment of pyelonephritis requiring hospitalization include intravenous levofloxacin or extended-spectrum cephalosporins. Globally, uropathogenic E. coli resistance rates to fluoroquinolones have increased over 10-fold in the past twenty years. In 2015, 38% of uropathogenic E. coli at this institution were levofloxacin-resistant and 10% were ceftriaxone-resistant. The purpose of this study is to investigate the impact of high rates of fluoroquinolone resistance on clinical outcomes among patients receiving guideline-directed therapy for UTI treatment.

**Methods:** This is a retrospective, single center, cohort study of adults at a 433 bed community hospital had a urine culture positive for E. coli between January 1, 2012 and December 31, 2015 who received either intravenous (IV) levofloxacin or IV ceftriaxone for the empiric treatment of a UTI. Included patients will be divided into two groups based upon the first dose antibiotic. Exclusion criteria encompass patients with polymicrobial UTIs, patients who received both agents as empiric therapy prior to the availability of susceptibility results, concomitant infection that occurred outside of the urinary tract (unless E. coli was also identified in the blood and the bacteremia was thought to be secondary to the UTI), renal transplant recipients, and patients with suspected or confirmed prostatitis. The primary outcome is hospital length of stay. Baseline demographics, susceptibilities, time to appropriate antibiotic therapy, comorbidities, in-hospital mortality, ICU length of stay, 30-day readmission, total hospital cost, time to switch to PO agent, and susceptibility to empiric therapy will be collected through a review of electronic medical records. Continuous variables will be compared using a two-sample t-test or Mann-Whitney U test for normal and non-normal distributions, respectively. Categorical
variables will be compared using the Chi-squared or Fisher’s exact test. P-values less than 0.05 will be considered statistically significant.

**Poster Title:** Evaluation of proton pump inhibitor effect on tyrosine kinase inhibitor therapy in chronic myeloid leukemia patients

**Primary Author:** Nicole Edmonds, Saint Joseph Hospital, KY; **Email:** nedmonds16@gmail.com

**Additional Author(s):**
Patrick Ratliff  
Kimberly Flynn  
Ryan Shely

**Purpose:** Tyrosine kinase inhibitors (TKIs) including imatinib, nilotinib, and dasatinib are considered first-line treatment options for Chronic Myeloid Leukemia (CML). Patients have been shown to achieve faster and more complete responses if treated with nilotinib or dasatinib. The absorption of these two agents is maximized in an acidic pH, and have been shown to yield lower serum concentrations when co-administered with Proton Pump Inhibitors (PPIs). However, the clinical implications of this interaction have not been studied. The purpose of this study is to determine if concomitant administration of PPI and TKI agents impacts clinical response rates in patients with CML.

**Methods:** This is a retrospective analysis of adult patients greater than 18 years of age who received imatinib, dasatinib, or nilotinib for CML while being seen at an outpatient oncology clinic of a 433-bed community hospital from July 2013 to July 2016. Included patients will be stratified based upon concomitant use of PPI and divided into two groups; those who received a PPI, and those who did not. Exclusion criteria include Philadelphia Chromosome negative CML; use of Ritonavir, Phenytoin, or Phenobarbital; and treatment with bosutinib, omacetaxine, or ponatinib. The primary outcome of the study is rate of major molecular response at 12 months. Baseline demographics, laboratory data, time from diagnosis to initiation of treatment, dose intensity, duration of treatment, rate of progression, and mortality will be collected through a review of electronic medical records. Patient identifiers will be removed from all data to protect confidentiality. Study outcomes will be compared with Independent samples t-test, Mann Whitney U, chi-squared, and Fisher’s exact tests, depending on the type of data contained within each data set. Tests will be found to be significant with a p-value of less than 0.05.

**Poster Title:** Impact of Pharmacist Attendance on Acute Code Stroke with Administration of Alteplase

**Primary Author:** Yuyun Rahmasari, Saint Joseph Hospital, KY; **Email:** yrahm2@gmail.com

**Additional Author(s):**
Lauren Cottingham
Kip Eberwein
Patrick Ratliff
James Ross

**Purpose:** Stroke is a leading cause of mortality and morbidity in the United States. Current stroke guidelines recommend the administration of intravenous alteplase within 4.5 hours of symptom onset in the setting of acute ischemic stroke. Timely treatment is essential to salvage the damaged tissue caused by loss of blood flow. In June 2014, the study facility implemented a code stroke team to assure rapid, consistent assessment and initiation of treatment for patients presenting with acute stroke symptoms. The purpose of this study is to evaluate if the participation of a pharmacist at code strokes expedites the process of alteplase administration.

**Methods:** This is a retrospective analysis of patients age 18 years and older who received intravenous alteplase for acute ischemic stroke between June 2014 to December 2016. Patients included in the study will be divided into two groups: group A includes patients receiving alteplase from 07:00 to 21:00 while a pharmacist attends code stroke, and group B includes patients receiving alteplase from 21:01 to 06:59 while a pharmacist is not available to attend code stroke. Exclusion criteria include patients who are pregnant or incarcerated. The primary endpoint of the study is time to bolus of intravenous alteplase from the time of order. Secondary endpoints include onset of stroke symptoms to alteplase bolus, time of code stroke call to initial alteplase bolus, correct alteplase dosing, deep venous thrombosis prophylaxis, bleed on computerized tomography scan, National Institutes of Health Stroke Scale (at baseline, 12-h and 24-h post stroke), hospital length of stay and in-hospital mortality. All data and patient information, including demographic and clinical characteristics, will be collected through the review of electronic medical records. Continuous data will be analyzed using an independent samples t-test or Mann Whitney U as appropriate. Categorical endpoints will be
analyzed using a chi-square or Fischer’s exact test as appropriate. All tests will show significance with a p-value of less than 0.05.

**Poster Title:** Impact of real-time notification of Clostridium difficile rapid diagnostic test results and early initiation of effective antimicrobial therapy  

**Primary Author:** Christian Polen, Saint Joseph Hospital, KY; **Email:** cpolen7392@my.sullivan.edu  

**Additional Author(s):**  
Patrick Ratliff  
Shawn King  
Russ Judd  

**Purpose:** Clostridium difficile is an increasingly prominent nosocomial pathogen, and is the most common causative organism of healthcare associated diarrhea. While there is ample evidence to suggest that early initiation of effective antimicrobial therapy improves outcomes in patients with bacterial infections, no studies have investigated the impact of real-time notification of positive Clostridium difficile culture results with rapid pharmacologic intervention. The purpose of this study is to assess the impact of real-time notification of toxigenic Clostridium difficile detection of DNA amplification in patients with confirmed Clostridium difficile infection.  

**Methods:** This is a retrospective review of Clostridium difficile infected patients in a community hospital. The study will have two cohorts: patients treated for Clostridium difficile infection (CDI) prior to implementation of the real-time notification system, and patients treated for CDI post implementation of the real-time notification system. The Antimicrobial Stewardship Program (ASP) will be contacted by the microbiology laboratory via a secure email listserv regarding positive toxigenic Clostridium difficile DNA amplification results. An alert was also created in an electronic surveillance system that notifies the ASP in real time when Clostridium difficile is identified in the laboratory. Once a positive CDI is detected, the ASP will proceed to ensure the initiation of antimicrobial therapy and implementation of contact precautions. Oral vancomycin or metronidazole will be considered effective for mild-to-moderate infections. Oral vancomycin, with or without metronidazole, will be considered effective for severe or severe, complicated infections. The primary outcome will be time to initiation of therapy. Secondary outcomes will include time to order entry of therapy, time to initiation of contact precautions, all-cause mortality, length of stay, length of stay in the ICU, length of stay from specimen
collection to discharge, 30-day readmission, and total hospital cost per case. Data will be recorded without patient identifiers and maintained confidentially. Appropriate statistical tests will be used with significance shown by a p-value less than 0.05.

**Poster Title:** Heparin use in patients undergoing therapeutic hypothermia

**Primary Author:** Brandon Fugate, St. Elizabeth Healthcare, KY; **Email:** brandon.fugate@stelizabeth.com

**Additional Author(s):**
Jillian Arrasmith

**Purpose:** Therapeutic Hypothermia has shown to improve outcomes in cardiac arrest patients and is recommended for return of spontaneous circulation after an out of the hospital cardiac arrest. Hypothermia can have effects on metabolism and clearance of medications due to it slowing down temperature dependant enzymatic reactions. Heparin is one medication that may be affected by this decrease in metabolism. Current studies that evaluated the effect of hypothermia on aPTT levels showed that aPTT time was increased and that heparin may require dose adjustment in this patient population. This study aims to evaluate heparin dosing in patients under therapeutic hypothermia.

**Methods:** The institutional review board approved this multicenter retrospective study. During a 36-month period all patients admitted to St Elizabeth Healthcare, who underwent therapeutic hypothermia while also receiving continuous heparin infusions, were analyzed. Patients were excluded from the study if they did not have an Anti-Xa level drawn during hypothermia, patients younger than 18 years of age, hypercoagulable states such as cancer or antiphospholipid syndrome, or if patients did not reach goal temperature during hypothermia (Define goal temp). Data collected included initial heparin rate, initial Anti-Xa levels during hypothermia, and any documented major bleeding events. Gender, age, and weight were assessed as possible covariates. Patients’ initial Anti-Xa values were evaluated as being sub-therapeutic, supra-therapeutic or in therapeutic range (0.3-0.7 IU/mL). The primary outcome in this study was to analyze the initial heparin rate (units/kg) and it’s incidence of causing an elevated Anti-Xa levels among a patient population with acute coronary syndrome receiving both heparin and therapeutic hypothermia. Logistic regression was used to estimate the probability of elevated Anti-Xa level (defined by Anti-Xa > 0.70) during therapeutic hypothermia. A secondary outcome was to evaluate the incidence of bleeding in patients receiving the combination of heparin and therapeutic hypothermia.
Results: 55 patients were included in this study. The initial heparin rate (units/kg) was shown to significantly increase the risk of producing a supra-therapeutic Anti-Xa Value [P value: 0.006, Odds Ratio: 1.3972, Confidence Interval: (1.0584, 1.8445)]. 63.6% of patients had an initial supra-therapeutic Anti-Xa, with 69% having any supra-therapeutic Anti-Xa during hypothermia. The average heparin rate of all patients that had an initial Anti-Xa in therapeutic range was 11.2 units/kg/hr. The average heparin rate of all patients that had an initial Anti-Xa above range was 13.1 units/kg/hr. Pharmacists were able to adjust the heparin rate during therapy. The average heparin rate of all patients at the conclusion of hypothermia was 10.0 units/kg/hr. None of the potential covariates were statistically significant (p-values 0.363, 0.511, and 0.322 respectively). No bleeding events were documented.

Conclusion: Using the current heparin dosing protocol of St. Elizabeth Healthcare, in this patient population, leads to increased incidence of elevated Anti-Xa levels. Despite these supra-therapeutic levels, no major bleeding events were documented. However, dosing adjustments still should be made for these patients in order to minimize risk. This acutely ill patient population presents unique pharmacokinetic circumstances that may warrant future research to determine additional medication dosing adjustments.

Poster Title: Retrospective evaluation of continuous renal replacement premixed solution utilization and associated electrolyte replacement

Primary Author: Megan Heath, St. Elizabeth Healthcare, KY; Email: megan.heath@stelizabeth.com

Additional Author(s):
Elizabeth Giordullo
Katherine Logue

Purpose: Continuous renal replacement therapy (CRRT), a method of extracorporeal blood purification, is often used in hemodynamically unstable patients with acute kidney injury. CRRT removes electrolytes from the blood; subsequently, patients often require electrolyte replacement. Dialysate and replacement fluids are electrolyte solutions used in CRRT that can have a further impact on patients’ electrolyte levels. The purpose of this study is to evaluate the use of standard CRRT solutions at St. Elizabeth Healthcare and measure potential effects on electrolyte replacement requirements. Furthermore, this study aims to determine whether solutions containing a different composition and/or concentration of electrolytes would benefit patients.

Methods: The institutional review board approved this retrospective study. The electronic medical record system will be used to identify all patients receiving CRRT at St. Elizabeth Healthcare Edgewood, Florence and Fort Thomas over the span of one year. Patients at least 18 years old receiving CRRT for at least 24 hours will be included in the study. Exclusion criteria include patients receiving custom dialysate or replacement fluid or patients on CRRT for less than 70 percent of every 24 hour period. Additionally, any CRRT cycle, defined as a period where dialysate and replacement fluid rate and composition did not change, lasting less than 12 hours was excluded. The following data will be collected: demographics (including age, sex, and BMI), duration of CRRT, use of citrate anticoagulation, type of dialysate and replacement fluid, custom electrolyte additives, dialysate and replacement fluid rates, daily potassium, calcium, magnesium, and phosphate replacement required, and 30 day mortality. Data collection is currently ongoing.

**Poster Title:** Evaluation of intravenous (IV) to oral (PO) conversion of medications: a look at opportunity, compliance, cost, and possible expansion of the current procedure.

**Primary Author:** Katelyn Gaines, St. Elizabeth Healthcare, KY; **Email:** katelyn.gaines@stelizabeth.com

**Additional Author (s):**

Julie Spanyer

**Purpose:** With the recent implementation of the Affordable Care Act, health care systems across the United States are searching for ways to reduce costs as well as improve quality of care for patients. Studies have shown that converting from intravenous to oral therapy as soon as patients are clinically stable can reduce the length of hospitalization and lower associated healthcare costs. This study will evaluate the current protocol at St. Elizabeth Healthcare Edgewood, Florence and Fort Thomas and the effectiveness of that policy in cost savings.

**Methods:** The Institutional Review Board approved this retrospective chart review. The electronic medical records will be reviewed for patients admitted to the hospital from June 1st, 2015 to May 31st, 2016 who received one of eight medications on the current intravenous to oral conversion protocol: fluconazole, azithromycin, ciprofloxacin, levofloxacin, linezolid, metronidazole, famotidine, or pantoprazole. The following data will be collected on 600 randomized patients: demographics (age, sex, height, weight), hospital site location, identified intravenous to oral medication, eligibility for intervention, date eligible for intervention, physician intravenous to oral conversion, pharmacist intravenous to oral conversion, date of pharmacist intervention, if applicable the difference between date of eligibility and date of pharmacist intervention, cost savings associated with pharmacist intervention and cost savings associated with missed interventions.

**Results:** In Progress

Poster Title: Clinical outcomes for Clostridium difficile–associated diarrhea: fidaxomicin, metronidazole and vancomycin

Primary Author: Jordan Adkins, St. Elizabeth Healthcare, KY; Email: j-adkins.1@onu.edu

Additional Author(s):
Deanna Ratermann
Joseph Emmons

Purpose: The Infectious Disease Society of America Clostridium difficile guidelines currently only recommend usage of oral vancomycin, along with intravenous and oral metronidazole. Since the advent of these guidelines, fidaxomicin was Food and Drug Administration approved for treatment of Clostridium difficile. Fidaxomicin is non-formulary in many hospitals due to exorbitant costs in comparison to conventional therapy. The objective of this study is to determine the clinical success rates of fidaxomicin in a community hospital system, compared to current standards of therapy for treatment of moderate to severe and recurrent Clostridium difficile-associated diarrhea.

Methods: The Institutional Review Board approved this retrospective chart review evaluating patients from January 2013 to December 2015, by utilizing the EPIC electronic medical record. Patients included in this study are 18 years or older, prescribed fidaxomicin, oral vancomycin, metronidazole, or a combination of these agents. Patients also have a diagnosis of Clostridium difficile confirmed by clinical signs and symptoms, along with positive polymerase chain reaction (PCR) or endoscopically observed pseudomembranous colitis. Data collection points include: gender, age, body mass index, new or recurrent C. difficile episode, PCR results for admission, concomitant systemic antibiotics used, number of concomitant systemic antibiotics, C. difficile treatment group (fidaxomicin, fidaxomicin and intravenous or oral [IV/PO] metronidazole, fidaxomicin and oral vancomycin, Fidaxomicin with oral vancomycin and IV/PO metronidazole, oral vancomycin, oral vancomycin and IV/PO metronidazole), duration of treatment, length of stay, proton pump inhibitor use 90 days prior to admission or during admission, and readmissions within 30, 60, and 90 days. Due to significantly fewer patients receiving fidaxomicin, treatment groups are to be randomized to equal sized groups of patients,
based on fidaxomicin groupings. Data will be analyzed for average rates of readmission for all treatment groups, with a focus on fidaxomicin groups versus non-fidaxomicin groups.

**Poster Title:** Retrospective evaluation of pharmacy-led medication reconciliation and the impact on readmission and length of stay in high risk patients

**Primary Author:** Taylor Hanahan, St. Elizabeth Healthcare, KY; Email: taylor.hanahan@stelizabeth.com

**Additional Author (s):**
Elizabeth Giordullo
Kathleen Miller

**Purpose:** Literature has shown that pharmacists can have an impact on patient care by reducing medication discrepancies and reducing length of stay or readmissions. An interdisciplinary pilot program was initiated to reduce readmissions. Pharmacists performed admission medication reconciliation for patients deemed high-risk of readmission. The primary outcomes of this study are to determine the number of variances found by pharmacists on admission medication reconciliation and to determine the impact on length of stay and readmission rates within 30 days. The secondary outcome evaluated the impact of other services such as home health referral and free meals after discharge.

**Methods:** This retrospective chart review was approved by the Institutional Review Board. Patients were included into the intervention group of the study if they were >18 years or older, had a readmission risk score of greater than or equal to 15 according to the Mayo Readmission Risk Score Algorithm, length of stay of at least 48 hours, and medication reconciliation completed by a pharmacist within 24 hours of admission to a hospital unit. Patients were included into the control group if they were >18 years or older, had medication reconciliation performed according to the standard of care at the institution, and length of stay of at least 48 hours. Each group included equal numbers of patients with readmission risk scores. Data collected included baseline demographic information, readmission risk score, number of medications on admission, number of variances and types of variances found, length of stay, other services from care coordination, and readmission within 30 days. Statistical analysis was performed using ANOVA and logistic regression models for length of stay and readmission, respectively.
Resident Poster Abstracts

**Results:** There were 170 patients included in each group. The mean number of variances found in the pharmacist-led medication reconciliation group was 3.15. The average time spent per patient on medication reconciliation was 33.35 minutes. There were 256 failures to discontinue inactive medications. The length of stay in the intervention group was 5.06 days vs. 5.81 days in the control group. Patients who received admission medication reconciliation did not have a statistically significant reduction in length of stay (p=0.172). However, a 1.5 day reduction in length of stay is possible (CI -1.561, 0.281). Patients who received admission medication reconciliation had a statistically significant association with regard to readmission rates (p=0.004), but only when grouped together with other services. For the secondary outcome, there was a statistically significant association between medication reconciliation, age, and home health with regard to readmission within 30 days. Upon analysis of all 3 parameters combined, using logistic regression, patients with home health trended toward a higher rate of readmission, although not statistically significant.

**Conclusion:** Length of stay was shorter in patients with medication reconciliation performed by a pharmacist, however this was not statistically significant. Many variables have a significant impact on readmissions, such as age, medication reconciliation, and home health at discharge. This can be observed by the fact that medication reconciliation alone did not significantly impact 30-day readmission rates. The study is limited by the retrospective nature, as well as small sample size. In the future, a prospective study with a larger sample size, may be warranted in order to determine the impact that medication reconciliation has on length of stay and readmission in high-risk patients.

**Poster Title:** Retrospective evaluation of hospital acquired pneumonia and healthcare associated pneumonia: An effort to minimize carbapenem use  

**Primary Author:** Jennifer Copenhaver, St. Elizabeth Healthcare, KY; **Email:** jennifer.byerly@stelizabeth.com  

**Additional Author (s):**  
Eric Nordman  
Benjamin Bloemer  

**Purpose:** According to the 2016 Infectious Disease Society of America (IDSA) guidelines for hospital acquired pneumonia (HAP), carbapenems are acceptable first line agents for a duration of 7 to 14 days. Healthcare associated pneumonia (HCAP) was not included in the 2016 IDSA guidelines, however, there has been little change in antimicrobial prescribing practices for patients who would have met the definition of HCAP. The primary outcome of this study is to evaluate the duration and time to de-escalation based on culture and sensitivity results. The secondary outcome of this study is to assess the incidence of Clostridium difficile and Stenotrophomonas infections.  

**Methods:** The Institutional Review Board approved this retrospective chart review. Electronic medical records will be used to identify patients greater than 18 years of age who: were admitted to one of the three St. Elizabeth Healthcare Hospitals between January 1, 2016 to June 30, 2016, met the criteria for HCAP or were diagnosed with HAP, and received meropenem therapy for greater than 48 hours. Patients will be excluded if they have: a history of co-infection with ESBL-producing bacteria, an infectious disease consult, have a chronic tracheostomy or known colonization in the respiratory tract. Data collection will include: baseline demographics, allergies, previous diagnosis of chronic obstructive pulmonary disease or interstitial lung disease, previous antibiotic use in the last 90 days, white blood cell count, temperature at admission, initial procalcitonin and lactic acid levels, level of care, total duration of meropenem therapy, concomitant antibiotic therapy, and culture reports.

Poster Title: Evaluation of perioperative amiodarone dosing protocol on rates of post-surgical atrial fibrillation

Primary Author: Robert Hughes, St. Joseph Hospital, KY; Email: roberthughes@sjhlex.org

Additional Author(s):
Marintha Short
Patrick Ratliff
Shawn King
Raymond Holmes

Purpose: Despite the administration of perioperative beta-blockers and vitamin-C, both shown to decrease atrial fibrillation, postoperative atrial fibrillation persists as a common complication to cardiothoracic surgery which is correlated with an increased hospital length of stay and increased morbidity. The objective of this study is to evaluate the effect of a perioperative amiodarone dosing protocol on the rates of postoperative atrial fibrillation and adverse event profiles attributable to the administration of amiodarone.

Methods: The Lumedx reporting system will be used to identify patients that underwent CABG, aortic valve, or mitral valve surgeries prior to and following the implementation of a perioperative amiodarone dosing protocol. By reviewing the electronic health record, data will be collected including: patient demographics, serum creatinine, liver and thyroid function tests, incidence of atrial fibrillation, hospital morbidity/mortality, mean number of grafted vessels, estimated left atrial size, mean aortic cross-clamp time, use of intra-aortic balloon pump, requirement of postoperative pacing, duration of hospital and critical care unit stay, and total hospital cost. All patient data will be de-identified to maintain confidentiality throughout the study. Effective participation in protocol administration will be defined as greater than 60% compliance of doses given during the hospital stay. Rates for incidence of postoperative atrial fibrillation, pacing requirement, and duration of post surgical hospital stay will be compared between each group. Statistical significance will be evaluated based upon an α= 0.05 using independent samples. Continuous data will be compared with student's t test or Mann-Whitney test. Categorical data will be compared with Chi Square or Fischer’s exact test.

**Poster Title:** Measuring students’ knowledge, skills, and attitudes of the pharmacists’ patient care process in an interprofessional setting

**Primary Author:** Emily Smith, Sullivan University College of Pharmacy and The Center for Health and Wellness, KY; **Email:** easmith@sullivan.edu

**Additional Author(s):**
Kimberly Elder
Sarah Raake

**Purpose:** The purpose of this study is to examine Doctor of Pharmacy (PharmD) and Physician Assistant (PA) students’ views on interprofessional learning with the goal to increase awareness of the roles of the different professions. Doctor of Pharmacy students will also be evaluated for their knowledge, skills, and attitudes of the Pharmacists’ Patient Care Process (PPCP) with the goal of increasing awareness and performance of this process. The primary objective of this study is the change in perceptions of the Pharmacists’ Patient Care Process from the PharmD students and the secondary objective is the change in perception of healthcare professions.

**Methods:** Students in the second year PharmD class at Sullivan University College of Pharmacy will participate in a sequential case based simulation with students in the first year class of the Master’s in Physician Assistant program at Sullivan University. The Institutional Review Board application for this study has been submitted. The students will be placed together in teams and will collect information, assess, and create a plan for a simulated patient with diabetes. All students will be asked to complete a Readiness for Interprofessional Learning Scale (RIPLS), a validated survey tool, before and after each lab simulation session. PharmD students will also be asked to complete an additional survey that will assess their knowledge, skills, and attitudes in regards to the PPCP. It is anticipated 130 total students (90 PharmD and 40 PA) will participate in the surveys. At the end of each case based simulation, there will be a guided debriefing session to discuss thoughts, feedback, and items related to the patient case. After data is collected, it will be analyzed using a Mann-Whitney U Test.

Poster Title: Implementation of a Pharmacist Run Non-Opioid Addiction Treatment Clinic in Collaboration with a Referring Practitioner

Primary Author: Emily Blaiklock, Sullivan University College of Pharmacy Center for Health and Wellness and St. Matthews Community Pharmacy, KY; Email: eblaiklock@sullivan.edu

Additional Author(s):
Stacy Miller
Chris Harlow

Purpose: The opioid epidemic in the United States continues to be a pressing issue at the forefront of the medical community. With the limited number of medication-assisted treatment options and the low success rates with what is currently available, it has become evident that a new approach to opiate addiction treatment is needed. This research program will look at the benefits of implementing a pharmacist run Non-Opioid Addiction Treatment Clinic in collaboration with a referring physician.

Methods: Providers in both an inpatient and outpatient setting can refer patients to the Non-Opioid Addiction Treatment Clinic. Once the collaborative care agreement has been signed, the pharmacist will set up an appointment with the patient at the community pharmacy. Patients will be required to obtain a negative urine toxicology screen on the same day as the injection is administered. Once the appropriate lab work has been obtained the patient will be scheduled for a 1-hour appointment at the clinic. The collaborating pharmacist will provide patient education and an oral naltrexone challenge will be initiated. This confirms the patient does not have any opioids in their system as well as ensures they will not have an allergic reaction to the active ingredient prior to administering the injection. Once 30 minutes has elapsed and the patient has not become ill or had an allergic response, the pharmacist will begin counseling on the risks/benefits of the long-acting naltrexone injection. A communication card provided by the manufacturer will be provided to each patient at every appointment. The injection will be filled and administered by the pharmacist on a 28-day basis and follow-up calls will be made as needed. A goal of six months of treatment will be set for each patient based on clinical trial data and the clinic will track success rates with pharmacist involvement.

**Poster Title:** Discharged on direct oral anticoagulants: assessing affordability and compliance  

**Primary Author:** Cale Averill, Sullivan University College of Pharmacy/Frankfort Regional Medical Center, KY; **Email:** caverill@sullivan.edu  

**Additional Author(s):**  

**Purpose:** Direct oral anticoagulants (DOACs) appear to be a patient and prescriber friendly option when compared to warfarin due to the lack of required routine laboratory monitoring as well having standardized dosing regimens. Each of the DOACs have some form of copay savings program, such as a 30-day free trial and/or a discount off the patient’s copay, which can make these agents even more appealing to patients and prescribers. The objective of this study is to determine whether patients who are prescribed these agents have difficulty paying for them and if affordability affects medication compliance after they are discharged.  

**Methods:** This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will be used to identify patients who are newly prescribed a DOAC. The following data will be collected via survey: patient age, gender, indication for DOAC therapy, type of insurance policy, patient’s concern over medication costs, whether they have difficulty paying for medications, whether the patient has been noncompliant as a way to reduce medication costs, and if they have been given a coupon. An offer for a follow up call 6 weeks after discharge will be made, and if consent is obtained the patient’s contact information will be collected. All data will be maintained confidentially, and all data will be de-identified once the follow up contact is made or refused.

**Poster Title:** Patient-centered education: Traditional warfarin counseling vs. an experimental video series  

**Primary Author:** Mallory Durham, Sullivan University College of Pharmacy/The Center for Health & Wellness, KY; **Email:** mdurham@sullivan.edu  

**Additional Author (s):**  
Amanda Miller  
Amanda Jett  
Abby Johnson  
Madison Vaughn  

**Purpose:** Warfarin has been identified by the Institute of Safe Medication Practices (ISMP) as a high-alert medication. When used incorrectly, it can cause significant harm to the patient. An effective way to minimize the risk of harm and error is through patient education. Patient education on warfarin therapy has shown to improve anticoagulation control and reduce adverse events. The objective of this study is to compare the effectiveness of traditional face-to-face counseling to education via informational videos.  

**Methods:** The Institutional Review Board has approved this non-blinded, randomized study, which will be conducted at an anticoagulation clinic within a community hospital. Men and women aged 18 or older who are new to warfarin therapy will be randomized to one of two groups. One group will receive traditional face-to-face warfarin counseling and the other group will be shown a short educational video series about warfarin. Traditional counseling and the video series will be conducted over four consecutive appointments. Both groups will receive education on warfarin therapy including, but not limited to, dosing, administration, and safety precautions. Two weeks after the 4th educational session, study participants will be given a warfarin assessment to evaluate warfarin knowledge and will be asked to complete a patient satisfaction survey. Other data to be collected includes sex, age, race, primary language, education level, warfarin indication, and expected treatment duration. Upon conclusion of the study, the reviewers will analyze the data to determine which group scored better on the warfarin assessment, thus providing means as to which educational method was more effective.

Poster Title: A comparison of smoking cessation outcomes between The Cooper-Clayton Method to Stop Smoking and Freedom from Smoking in a community clinic setting.

Primary Author: Kayla Kreft, Sullivan University College of Pharmacy/The Center for Health and Wellness, KY; Email: kkreft@sullivan.edu

Additional Author (s):
Amanda Jett
Caitlyn Elmes
Courtney Smith
Virginia Whitt

Purpose: Tobacco use is one of the leading causes of many serious health issues. Individuals who choose to stop smoking drastically reduce their risk for morbidity and mortality associated with tobacco use. Kentucky ranks second in the United States for tobacco use, justifying a great need for smoking cessation programs in the state. This study aims to compare the cessation rates between The Cooper-Clayton Method to Stop Smoking and the Freedom from Smoking programs in a pharmacist-run community clinic in Kentucky. While there is literature available on the programs individually, a study directly comparing the two has not previously been conducted.

Methods: This study will be conducted at The Center for Health and Wellness, a pharmacist-run ambulatory care clinic located at Sullivan University College of Pharmacy in Louisville, KY. This study has received approval from the Sullivan University Institutional Review Board. The Center for Health and Wellness previously offered The Cooper-Clayton Method to Stop Smoking, a 13-week program. This year, the clinic will adopt a new program, Freedom from Smoking, an 8-week program created by the American Lung Association. The programs will be compared based on cessation rates at 12 weeks from the quit date. Cessation rates will be stratified according to the Fagerstrom Nicotine Dependence Test, a validated method for assessing nicotine dependence. Non-pregnant participants 18 years of age or older who enrolled in the clinic’s smoking cessation program and signed informed consent will be included. Data from The Cooper-Clayton Method to Stop Smoking program will be obtained retrospectively and data from the Freedom from Smoking program will be obtained prospectively. The data
collected will include demographic information, the score on the Fagerstrom Nicotine Dependence Test, and self-reporting of smoking cessation. Most of this information will be obtained via paper survey with one exception. For the Freedom from Smoking arm, the self-reporting of smoking cessation will be obtained via a phone survey.

Poster Title: Measuring clinical and economic outcomes in a community pharmacy hypertension management program

Primary Author: Kimberly Cooper, Sullivan University College of Pharmacy/Walgreens, KY; Email: kcooper@sullivan.edu

Additional Author(s):
Cathy Spencer
Katie Blain

Purpose: The objective of the study is to demonstrate the benefit of a community pharmacist-led hypertension management program and to evaluate the sustainability of such a program in a large chain drug store.

Methods: A prospective cohort study will be conducted at a Walgreens pharmacy in Jeffersonville, IN that is piloting a hypertension management program. Patients participating in the program will receive a free blood pressure monitor. Patients will be included in the trial if they are greater than 18 years of age who provide informed consent and self-report a diagnosis of hypertension who are not currently meeting their goal blood pressure. The primary outcome is change in blood pressure, pre- and post-management, with patients serving as their own control group. Secondary outcomes include improvement in medication adherence, proportion of patients achieving blood pressure goal, and proportion of patients receiving miscellaneous services such as immunizations. The study will be powered to detect a 13 mmHg difference in systolic blood pressure, based on prior trials describing the impact of independent community pharmacists on blood pressure. Utilizing 80% power and a 95% confidence interval, a sample size of 35 was calculated. With an estimated 20% drop out rate a minimum of 42 participants need to be enrolled. An expedited IRB has been approved for the study.

Poster Title: Using pharmacist-driven recommendations to optimize management of staphylococcal bacteremia

Primary Author: Sarah Tennant, University of Kentucky Health Care, KY; Email: stennant@ghs.org

Additional Author(s):
Donna Burgess
Thein Myint
David Burgess

Purpose: The annual incidence of Staphylococcus aureus bacteremia (SAB) ranges from 4.7-38.2 per 100,000 person-years with a 30-day mortality rate of 20%. Source control, targeted antibiotic therapy, and appropriate duration of therapy are the tenets of management of SAB. This study aimed to increase appropriateness of treatment for SAB at an academic medical center.

Methods: A quasi-experimental design was used to analyze periods before and after implementation of a SAB treatment protocol. An institution-wide, multidisciplinary SAB treatment protocol was developed approval by the pharmacy & therapeutics committee. During the intervention period, an infectious diseases pharmacist left a structured medical note in the electronic medical record at day 2 and day 5 after positive S. aureus blood cultures. Patients with SAB treated before implementation of the protocol were compared to patients treated after protocol implementation for appropriateness of therapy. Appropriate therapy was defined as appropriate antistaphylococcal therapy and duration of therapy documented as 2 weeks for uncomplicated bacteremia or 4-6 weeks for complicated bacteremia. Appropriate antistaphylococcal therapy consisted of nafcillin or cefazolin for methicillin-susceptible S. aureus (MSSA) and vancomycin, daptomycin, and/or ceftaroline for methicillin-resistant S. aureus (MRSA).

Results: One hundred eighty-two patients were analyzed: 106 in the pre-implementation group and 76 in the post-implementation group. The median age was 50 years (IQR 35.5-63), 58% of the cohort was male, 26% of the cohort had a history of IV drug abuse. The most common
sources of infection were vascular access (23%), osteoarticular (20%), and respiratory tract (19%). The rate of MRSA in each group was 59%. In both groups, 63% of bacteremia cases were complicated. Seventy-two percent of patients in the pre group and 86% of patients in the post group were on appropriate therapy (P=0.03). In patients with MSSA, 73% of patients in the pre group and 81% of patients in the post group were treated with nafcillin or cefazolin. In patients with MRSA, 24% in the pre group and 49% in the post group were definitively treated with vancomycin. Median duration of therapy was 27 days in the pre group and 19 days in the post group (P=0.98). Mortality was significantly lower in patients who received appropriate therapy compared to patients who received inappropriate therapy (16% vs. 37%, P=0.008).

**Conclusion:** A pharmacist-driven, systematic approach to management of SAB significantly increased the number of patients on appropriate therapy. This was driven by increases in the number of patients receiving antibiotics for the appropriate duration of therapy and increases in timely collection of repeat blood cultures. Patients who receive appropriate therapy have significantly reduced mortality compared to patients who receive inappropriate therapy.

**Poster Title:** Hemodynamic changes during procedural sedation with “ketofol” in the emergency department

**Primary Author:** Kristen Sherlin, University of Louisville Hospital, KY; **Email:** krishe@ulh.org

**Additional Author (s):**
Hugh Shoff  
Christine Duff  
Jennifer Wiedmar

**Purpose:** The goal of procedural sedation in the emergency department (ED) is to provide safe and effective analgesia and sedation. Little information is available regarding the hemodynamic effects of ketamine plus propofol (“ketofol”) as compared to alternative agents. Etomidate with or without fentanyl has shown to maintain hemodynamic stability during procedural sedation leading to patient and provider satisfaction. The objective of this study is to determine if “ketofol” has significant effects on hemodynamic stability while being used for procedural sedation in the ED compared to etomidate with or without fentanyl.

**Methods:** A retrospective, case-control study of patients undergoing procedural sedation in the ED will be conducted at University of Louisville Hospital. Patients over the age of 18 who received ketamine, propofol, or etomidate for procedural sedation from August 4, 2013 to August 4, 2016 will be screened for inclusion. The treatment group will include patients who received “ketofol” while the control group will be those who received etomidate with or without fentanyl. Patients undergoing procedural sedation by other means or who are allergic to any of the study medications will be excluded. The primary endpoint will be defined as a change in systolic blood pressure (classified based on a change of greater than 20%, a change between 20% and 50%, or a change greater than 50%). Secondary endpoints will include changes in heart rate, diastolic blood pressure, respiratory rate, oxygen saturation, and cumulative doses of sedative and analgesic agents. Chi-square tests and student’s t tests will be used for data analysis.

Poster Title: Diuretic prescribing, pharmacovigilance and correlation with adverse events in a geriatric primary care clinic

Primary Author: Emily Doss, University of Louisville Hospital, KY; Email: emidos@ulh.org

Additional Author(s):
Vanessa VanArsdale
Kristina Evans
Demetra Antimisiaris

Purpose: Thiazides are currently recommended as an initial therapeutic option for the treatment of hypertension in patients age 60 and older by the Eighth Joint National Committee(JNC 8). Although recommended, this therapeutic class has potential adverse effects including electrolyte abnormalities, hypotension and increased serum glucose and uric acid levels. Appropriate monitoring of thiazides is paramount as the number of elderly patients continues to increase, and guidelines addressing monitoring of geriatric patients prescribed thiazide diuretics are limited. The objective of this study is to evaluate if appropriate monitoring practices for geriatric patients prescribed thiazide diuretic medications reduce rates of adverse drug effects.

Methods: This is an investigator-initiated, single-center retrospective study that will compare the adverse events found in geriatric patients receiving a thiazide who were appropriately monitored versus those who were not appropriately monitored. Patients seen at the Geriatric Clinic at University of Louisville Hospital age 65 years or older who were prescribed a thiazide diuretic from January to December 2015 will be screened for inclusion. Patients will be excluded if they carry a diagnosis of active cancer, end stage renal disease, or heart failure with reduced ejection fraction (defined as a documented echocardiogram showing ejection fraction < 40%).

The primary outcome of this study is to evaluate if appropriate monitoring practices for geriatric patients prescribed thiazide diuretic medications reduce rates of adverse drug effects. Secondary outcomes include the rate of development of individual adverse events including hypotension, new onset type 2 diabetes, new onset gout, electrolyte abnormalities and falls. This study aims to investigate if known adverse effects of thiazide diuretics can be avoided with
appropriate monitoring practices, or if thiazide diuretics have the potential to cause adverse effects in the elderly regardless of adequate monitoring by providers. This study has been submitted to the University of Louisville Institutional Review Board (IRB) for approval.

**Poster Title:** Analysis of desmopressin administration in intracranial hemorrhage (ICH) for reversal of antiplatelet agents

**Primary Author:** Amy Braden, University of Louisville Hospital, KY; **Email:** amyste@ulh.org

**Additional Author(s):**
Christine Duff
Jennifer Wiedmar
Adam Ross
Kimberly Meyer

**Purpose:** ICH accounts for 15 percent of strokes annually and is related to a 6-month mortality of 30-50 percent. Patients taking anticoagulation or antiplatelet therapy at the time of ICH have a high likelihood of secondary hematoma expansion, which correlates with neurological deterioration and poor outcomes. Desmopressin administration has shown to increase Von Willebrand factor in patients with ICH, leading to shortened bleeding time, improved hemostasis and reduced postoperative blood loss. The purpose of this study will be to evaluate outcomes in patients with ICH receiving desmopressin for anti-platelet reversal.

**Methods:** A retrospective, case-control study of patients with ICH will be conducted at a university hospital designated as a level I trauma center. Data for the study population will be generated based upon International Classification of Diseases, tenth revision (ICD-10) diagnostic codes. The treatment group will include patients who present with ICH, have documented home use of aspirin or clopidogrel and received desmopressin for reversal. The control group will include the same presenting inclusion criteria, but will include patients who did not receive desmopressin as part of ICH treatment. Patients will be excluded if they are less than 18 years old, have documented home use of oral anticoagulation, diagnosis of a pre-existing blood disorder or documented end stage renal disease. The primary endpoint of the study will be survival to hospital discharge. Secondary endpoints will include hematoma growth, surgical intervention, and discharge status (defined as death, discharge to home, acute rehabilitation, or long term sub-acute rehabilitation). A subgroup analysis will be conducted assessing patient outcomes based on type of home antiplatelet therapy (aspirin vs. clopidogrel).
A chi-square test will be used to analyze the primary outcome as well as the subgroup analysis. Secondary endpoints will be descriptive in nature and will be analyzed using a student’s t-test.

**Poster Title:** Anticoagulation appropriateness in elderly patients with chronic atrial fibrillation  

**Primary Author:** Benjamin Yu, University of Louisville Hospital, KY; **Email:** bjamy015@gmail.com  

**Additional Author(s):**  
Demetra Antimisiaris  
Daniel Truelove  

**Purpose:** Increased age is a risk factor for stroke in patients with atrial fibrillation. Recent literature provides evidence suggesting patients with atrial fibrillation and one additional risk factor, excluding sex category, benefit from anticoagulation therapy. Literature also recognizes that a large number of elderly patients potentially receive inappropriate medications. Elderly patients on anticoagulation may be on concomitant medications that increase risk of bleed and are not therapeutically appropriate. The objective of this study is to assess the appropriateness of anticoagulation in elderly patients with chronic atrial fibrillation in the University of Louisville Physicians patient population.  

**Methods:** This study has been submitted to the Institutional Review Board for approval. A data query of University of Louisville Physicians patients will be used to identify patients 65 years or older and have a diagnosis of chronic atrial fibrillation. Patients with a history of a myocardial infarction within the past year and/or an acute coronary syndrome within the past 3 months will be excluded. The information collected will include patient age, gender, estimated glomerular filtration rate, anticoagulant therapy, antiplatelet therapy, and nonsteroidal anti-inflammatory drug therapy. Appropriateness of anticoagulation therapy will be assessed using the Screening Tool of Older Persons’ potentially inappropriate Prescriptions (STOPP) criteria and Screening Tool to Alert doctors to the Right Treatment (START) criteria. Appropriateness of renal dosing for direct oral anticoagulants will be based on the most recent laboratory estimated glomerular filtration rate and package insert recommendations. For chronic atrial fibrillation patients without anticoagulation or aspirin therapy, a review of the patient’s chart will be conducted to identify any documented contraindications for anticoagulant use. Data will be collected by study staff and stored on a secured network database with password protection. Information will be coded in order to omit patient identifiers, with a separate file
linking patient identifiers to data. Both files will only be accessible by study staff and password protected.

Poster Title: Pharmacy-led inpatient and discharge medication education and its impact on HCAHPS scores, medication adherence, medication errors, and 30-day hospital readmission rates

Primary Author: Sarah Seger, University of Louisville Hospital, KY; Email: saraseg@ulh.org

Additional Author(s):
Mika Kessans Knable
Jennifer Wiedmar

Purpose: Despite the documented positive impact pharmacists have on medication adherence, medication error rates, patient satisfaction, and 30-day readmission rates, pharmacists provided discharge education in only 24 percent of hospitals surveyed in 2012. Furthermore, existing literature focuses on the benefits of pharmacy-led discharge education of high-risk patients versus all patients. Data on the benefits of pharmacy-led inpatient medication education is lacking. The objective of this study is to determine if routine pharmacy-led inpatient education and discharge education to all patients, regardless of their risk, improves patient outcomes and satisfaction.

Methods: This study will be submitted to the Institutional Review Board for approval. Informed consent will be required for enrollment. Patients will be included if they are 18 years or older, admitted or transferred to University of Louisville Hospital 6-South or 6-East unit, and discharged from University of Louisville Hospital 6-South or 6-East unit. Patients will be consented on the day of admission and randomized according to the date they were admitted. Patients admitted on an odd day of the month will be randomized to the intervention group and receive medication education at least every five days during admission and at discharge. Patients admitted on an even day of the month will be randomized to the control group and receive discharge medication education if the medical team has consulted pharmacy for medication education, if they are prescribed warfarin, or if they are newly diagnosed with congestive heart failure. The control group reflects the current clinical pharmacy services standard of care at University of Louisville Hospital. A phone survey will be conducted five to seven days post discharge. The primary outcome of the study is patient satisfaction, assessed by medication-related questions from the Hospital Consumer Assessment of Healthcare
Providers and Systems (HCAHPS) survey. Secondary outcomes include medication adherence, medication errors, and 30-day readmissions to the hospital.

Poster Title: Current antiretroviral therapy prescribing practices in HIV-infected men versus women with drug resistance mutations

Primary Author: Lauren Kirkpatrick, University of Louisville Hospital, KY; Email: laurkir@ulh.org

Additional Author(s):
Daniel Truelove
Mary Bishop
Cathy Spencer
Jennifer Wiedmar

Purpose: Human immunodeficiency virus (HIV) treatment guidelines are based on evidence from clinical trials enrolling 80 percent men. Existing literature suggests that sex-based differences in antiretroviral efficacy may exist, but trials lack appropriate power to demonstrate a statistically significant difference. A local pilot study suggests that regimens containing two active drugs may be as efficacious as a three drug regimen in women with the M184V mutation. The purpose of this study is to determine if gender differences impact the ability to attain viral suppression in patients with drug resistance mutations.

Methods: A retrospective electronic medical record review will be conducted on patients receiving treatment at the University of Louisville HIV Clinic from January 1, 2003 to July 30, 2016. This study focused on prescribing practices in HIV-infected men compared to women with one or more drug resistance mutation(s). Patients will be excluded for lack of a genotype result prior to initiating or changing antiretroviral therapy and inadequate documentation of viral load or CD4 counts prior to and/or following the initiation of new therapy. The most common drug resistance mutations will be identified and drug regimens will be evaluated for viral suppression success. To reduce the effect of confounding variables, male patients will be matched with female patients based on age, length of HIV diagnosis, baseline viral load and CD4 count at time of genotyping. Viral load will be transformed into a categorical variable for measuring virologic failure. Data will be analyzed using descriptive statistics, Chi-square tests, and logistic regression.

Poster Title: Optimal maintenance immunosuppression in lung transplant recipients

Primary Author: Chelsey McPheeters, University of Louisville Hospital, Kentucky One Health, KY; Email: chelmcp@ulh.org

Additional Author(s):
David Nunley
Christopher Barger
Bikash Bhandari
Daniel Truelove

Purpose: The optimal maintenance immunosuppression regimen for lung transplant recipients has not yet been fully elucidated. Maintenance immunosuppression following lung transplant is largely based off of clinical experience and case reports that do not define a single ideal regimen. Questions remain regarding optimal immunosuppressive therapy, including the appropriate target calcineurin inhibitor serum concentration at various intervals following transplant. The purpose of this study is to evaluate the degree of immunosuppression in post-lung transplant recipients and the associated rates of biopsy proven acute rejection.

Methods: This retrospective, single-center study has been approved by the Institutional Review Board. Patients who received a lung transplant between January 1, 2011 and December 31, 2015 will be included. Patients who have undergone re-transplantation will be excluded. All patients will have received maintenance immunosuppression according to the institution’s lung transplant protocol. Degree of immunosuppression will be determined based on serum tacrolimus trough levels. The protocol identifies a goal serum tacrolimus trough level of 10-12 mcg/L for the first three months post-transplant and 8-10 mcg/L thereafter. Patients will be evaluated for the initial 12 months post-transplant to assess the primary outcome of biopsy proven acute rejection rates via surveillance bronchoscopies. Each patient will serve as their own control when comparing the average trough levels over the first three months post-transplant to the average trough levels over the subsequent three to twelve months post-transplant on rates of biopsy proven acute rejection. A subgroup analysis will compare the implications of triple therapy immunosuppression with a calcineurin inhibitor, nucleotide blocking agent, and a corticosteroid versus dual therapy immunosuppression with only two of
the previously mentioned pharmacologic classes on the primary outcome. Secondary outcomes include rates of bronchiolitis obliterans syndrome, cytomegalovirus (CMV) infection, non-CMV infection, and mortality. Continuous and categorical variables will be analyzed for significance using Student’s t tests and chi-square analyses respectively.

Poster Title: Effect of post-bleed nonsteroidal anti-inflammatory drug use on intracranial hemorrhage progression

Primary Author: Jacob Rigdon, University of Louisville Hospital, Kentucky One Health, KY; Email: jacobri@ulh.org

Additional Author(s):
Kimberly Meyer
Tyler Ball
Shawn Adams
Mark Cox

Purpose: A common complication in the acute phase of intracranial hemorrhage is fever. The presence of fever in these patients is not benign. In subarachnoid hemorrhage patients, fever has been associated with increased mortality, disability, and cognitive impairment. Thus, fever is treated vigorously in intracranial hemorrhage patients, with the typical pharmacologic intervention being acetaminophen. Nonsteroidal anti-inflammatory drugs are not typically used for fever control in the intracranial hemorrhage population due to their antiplatelet effects via cyclooxygenase-1. The purpose of this study is to determine if nonsteroidal anti-inflammatory drug use in intracranial hemorrhage leads to an increase hematoma volume or significant re-bleeding.

Methods: This retrospective study evaluated adult patients with spontaneous intracranial hemorrhage as identified by a stroke database review. The patient population was obtained from a Level I trauma center between January 1st, 2013 to December 31st 2015. The primary outcome of this study was progression of intracranial hemorrhage on computerized tomography imaging 24 to 72 hours after nonsteroidal anti-inflammatory drug administration. Secondary outcomes included in-hospital mortality, intensive care unit length of stay, and hospital length of stay. Patient exposure to nonsteroidal anti-inflammatory drugs was categorized by drug, dose, and number of administrations. In order to determine progression of intracranial hemorrhage, neurosurgery practitioners assessed computerized tomography scans of included patients at baseline and 24 to 72 hours after nonsteroidal anti-inflammatory drug exposure. Amount of midline shift and hematoma volumes were assessed. Progression was
described as stable, clinically insignificant progression, or clinically significant progression. Patients were included if they were diagnosed with a non-traumatic intracranial hemorrhage within 48 hours of onset. Patients were excluded if they had a history of coagulation disorder, benign hematologic disorder, if they were initiated on warfarin or aspirin during their admission, or if they were initiated on a heparin drip with a partial prothrombin time greater than 60 seconds.

**Results:** Results are pending and will be presented at Midyear Clinical Meeting.

**Conclusion:** Conclusions are pending and will be presented at Midyear Clinical Meeting.
**Purpose:** Fingolimod (Gilenya®) is the first approved oral medication for relapsing forms of multiple sclerosis (MS). It reduces the incidence of clinical exacerbations and delay the accumulation of physical disability. Due to the safety concerns, complicated monitoring, and high cost of fingolimod; the formulary and therapeutics committee (FTC) at our tertiary care hospital decided to conduct a medication utilization evaluation (MUE). This MUE aims to evaluate the utilization of fingolimod with regards to the approved FTC indications and restrictions along with the adherence to the risk evaluation and mitigation strategy (REMS) program.

**Methods:** This is a retrospective chart review of patients who received fingolimod from January 2015 to March 2016. Data was collected from both electronic and paper chart. Total of 85 patients received fingolimod during the study period. Sixty patients were included based on the joint commission (TJC) recommendations for sample size calculation. Inclusion criteria was any patient who received one dose, or more, of fingolimod. Patients who received fingolimod outside of the study period were excluded.

**Results:** Majority of patients were females (n=49, 82%). Initial doses of fingolimod were prescribed by neurology consultants for all patients. Almost all patients started fingolimod for the proper indication (n=59, 98%), except one patient who was started for primary progressive MS. In regards to REMS program adherence; patient observation for 6-hours and ECG prior to the first dose were completed in 49 patients (82%). Two patients (5%) required monitoring overnight post initial 6-hours ECG due to new onset of 2nd degree AV block and prolonged QT; respectively. Fifty six patients (93%) gave history of chickenpox prior to initiation or had positive varicella zoster virus titer. All the reviewed patients underwent initial ophthalmologic
evaluation before starting fingolimod and regularly, every 3-4 months, regardless of the presence of uveitis or diabetes mellitus. None of the females in childbearing age became pregnant during the study period. Complete blood count and liver function tests were done in 48 (80%) patients prior to and every 3-6 months of fingolimod initiation. Eight patients (13%) discontinued fingolimod due to various reasons including; ineffectiveness, leukopenia, lymphopenia, elevated liver enzymes 5 times above normal level, or patients deciding to get pregnant.

**Conclusion:** In the past year the neurology department has developed a checklist and dedicated a coordinator for the sole purpose of optimizing adherence to the REMS program. Overall, the adherence to the REMS program and the restrictions at KFSH&RC is acceptable. The hospital continuously encourages diverse approaches to enhance patient care as well as improve the practice.

**Submission Type:** Evaluative Study  

**Session-Board Number:** 9-327  

**Poster Title:** Aspirin for long-term prevention of recurrent venous thromboembolism after unprovoked event: Is it effective in the Saudi population?  

**Primary Author:** Albatoul Al Meshari, King Abdulaziz Medical City - Central Region-, Saudi Arabia; **Email:** almesharial@ngha.med.sa  

**Additional Author (s):**  
Kwame Amoh  
Maha Al Ammar  
Shmeylan Al Harbi  

**Purpose:** Venous thromboembolism (VTE) has high-risk of recurrence rate after anticoagulant therapy is discontinued. This risk is particularly high among patients with unprovoked VTE. Extended treatment with new oral anticoagulants and vitamin K antagonist reduced the risk, but they are associated with an increased risk of bleeding. Furthermore, there are limited studies suggesting that aspirin has a potential benefit in prevention of recurrent VTE after first unprovoked episode without significantly increasing the risk of bleeding. However, results are still controversial. We, therefore, sought to evaluate the benefit of aspirin use for preventing recurrent VTE in our patient population after unprovoked VTE.  

**Methods:** We conducted a retrospective cohort study by using hospital computer systems and medical charts. Men and women aged 16 years and older were enrolled if they had had a first unprovoked VTE event during the period between 2010 and 2015, after completing their course of anticoagulant therapy, and were prescribed a daily dose of aspirin over 2 years. The primary outcome measure was to evaluate the recurrence of VTE in patients who received a daily dose aspirin over 2 years after completing anticoagulant therapy. The secondary outcome was to evaluate the safety outcome measures of long-term use of aspirin. These safety outcome measures comprise major bleeding (intracranial, intra-spinal, intraocular, retroperitoneal, intra-articular, pericardial or intramuscular with compartment syndrome), fall in hemoglobin level of 2 g per deciliter from the baseline, required transfusion of two or more units of whole blood or red cells, minor bleeding (any bleeding requiring a medical intervention and does not meet the definition of major bleeding), and requirement for upper or lower gastrointestinal endoscopy while on aspirin therapy.
Results: A total of 63 patients were included in our study. Fifty-five percent of them were female. Mean age of patients was 64 ± 18 years. Venous thromboembolism recurred in 6 patients (9.5%) who received aspirin over the two years. The types of recurrent VTE were deep vein thrombosis, pulmonary embolism and both in 4,1,1 patients, respectively. Minor bleeding in the form of gastrointestinal bleeding and bruises occurred in two patients. However, none of the patients had a major bleeding episode. Six patients out of 63 had a drop in hemoglobin level of 2 g/dl and more over the period of 2 years. However, only one of them required packed red blood cell transfusion as well as had abnormal upper gastrointestinal endoscopy. The overall upper GI endoscopy requirement was in 6 patients and only 4 of them had abnormal results. Lower GI endoscopy was requested for 2 patients and in both patients the results turned out to be normal.

Conclusion: Daily doses of aspirin in the Saudi patient population prevent the recurrent of VTE in ninety percent of patients with unprovoked venous thromboembolism who had completed anticoagulant treatment, with no apparent increase in the risk of neither minor nor major bleeding. However, a larger multicenter study is needed to confirm the finding of our study.
Purpose: Vaso-occlusive crisis is one of the acute complications of sickle cell disease. The mainstays of treatment are hydration and pain control by analgesics. Adequate pain relief is not easily accomplished during episodes of vaso-occlusive crisis. Treatment varies according to pain severity, severe pain should be aggressively treated with opioids, which can be administered intravenously either by intermittent or continuous via patient controlled analgesia. The objectives of our study is to compare pain intensity between patient controlled analgesia and intermittent intravenous opioid therapy in addition to the prevalence of cardiovascular and respiratory adverse events in sickle cell vaso-occlusive crisis patients.

Methods: We conducted a retrospective study at King Abdul-Aziz Medical City Central Region, a tertiary care hospital which has bed capacity of more than 800 beds in Saudi Arabia. Approval from Institutional Review Board was obtained for this study. Patients admitted to emergency department secondary to vaso-occlusive crisis necessitating treatment with intravenous opioid either by intermittent infusion or continuously via patient controlled analgesia for at least 72 hours during the period of 2010 to 2014 were included in this study. A chart review was conducted to determine patients with vaso-occlusive crisis. Using the hospital electronic system the following data were collected: patient’s age, gender, blood pressure, heart rate, respiratory rate, oxygen saturation and pain score on admission and daily for 3 days as well as the cumulative opioid analgesic dose for 72 hours which is reported as morphine equivalent. Average pain score, blood pressure, heart rate, respiratory rate were calculated. All data were recorded without patient identifiers and maintained confidentially. Pain intensity was evaluated by using numerical scale from 0-10, defined as follow: mild pain: if reported pain intensity between 1-2, moderate pain: if reported pain intensity between 3-6, severe pain: if reported
pain intensity between 7-10. An adverse reaction was defined as hypotension (systolic blood pressure less than 90 mm Hg), respiratory depression (respiratory rate less than 12 breaths per minute).

**Results:** We screened 117 patients during the period from January 2010 to December 2014. Of those, 99 (84.6%) met the study inclusion criteria and 18 patients (15.4%) were excluded. During the first 72 hours of admission, there was a significant reduction in pain score for patients in intermittent intravenous group in compared to those in patient controlled analgesia group (P < 0.05) where the mean pain score were 3 and 5, respectively. The total amount of morphine administered over 72 hours of admission was significantly (P < 0.05) higher in patient controlled analgesia group (777 ± 175 mg) in compared to the intermittent intravenous group (149 ± 74mg). Clinically significant hypotension or respiratory depression was not observed in both groups over the 72 hours of admission.

**Conclusion:** Our data indicate that during the first 72 hours of admission, intermittent intravenous morphine was more effective than patient controlled analgesia infusion in term of pain control. In addition, the total amount of morphine administered over 72 hours of admission was higher in patient controlled analgesia group in compared to the intermittent intravenous group.

**Poster Title:** Digoxin use and outcomes among patients with atrial fibrillation  

**Primary Author:** Waad Alghamdi, King Abdulaziz Medical City Central Region (KAMC-CR), Saudi Arabia; Email: waad.m.alghamdi@gmail.com  

**Additional Author(s):**  
Maha Alammari  
Hind Almodaimegh  
Shmylan Alharbi  

**Purpose:** Digoxin is a cardiac glycoside used for rate-control in patients with atrial fibrillation which is a major cause of morbidity and mortality. Although it has a narrow therapeutic window and can easily reach toxic serum level, it is one of the most frequently prescribed drugs and therefore intoxication could be overlooked. The purpose of this study is to evaluate safety outcomes of digoxin use, monitoring, hospital admissions and emergency visits, and the number of reported toxicities.  

**Methods:** The institutional review board (IRB) approved this retrospective electronic chart review study on February 2016. Patients’ data were collected over a period of one year from November 2014 to October 2015. The study included male and female aged above 18 years old with a confirmed diagnosis of atrial fibrillation and on digoxin treatment for a minimum of 6 months. Oncology patients were excluded. Data collected included demographics, co-morbidities, laboratory values of renal function and serum electrolytes, digoxin regimen, digoxin serum level, the number of digoxin level tested per year, concomitant medications and possible drug interactions. The primary outcome measures were to assess the number of hospital and emergency admissions, and evaluate digoxin monitoring plan. The secondary outcome measures were the average digoxin dose, percentage of patients on beta-blocker and calcium channel blocker treatment, and the signs and symptoms associated with digoxin toxicity. The results were analyzed using SPSS software version 22. The categorical variables were presented as mean and standard deviation, and the continuous variables were presented as n (%).
Results: The study included 184 patients with atrial fibrillation out of 250 patients on digoxin, of whom 58.7% were females. Demographics showed an average age of 67 ±13 years, and comorbidities including heart failure (63%), hypertension (79.3%), diabetes (69%), hyperthyroidism (1.1%), hypothyroidism (19%), chronic obstructive pulmonary disease (19%) and chronic kidney disease (23.4%). Patients were found to have an average number of one hospital admission and two emergency visits per year. The average digoxin dose was 0.125 mg for all patients, and digoxin level was tested at least once in 27.2% of the patients. The average levels of potassium were 4.3 ±0.4 micromol/L, and 0.77 ±0.3 micromol/L for magnesium. The renal function tests were done for 95% of the patients. Potassium and magnesium electrolytes were tested in 95% and 43% of patients, respectively. Thirty-six patients (34.8%) were on calcium channel blocker and beta-blocker with digoxin, and twenty-eight (15.2%) were on digoxin alone. Digoxin toxicity with a level of 2.3 micromol/L was reported in one patient and manifested as repeated vomiting and bradycardia of 50 beats per minute.

Conclusion: Findings showed that seventy-two percent of patients had no digoxin level tested, and one digoxin toxicity-related emergency visit per year. The study results reinforce the need to develop an institutional-based practice guideline about digoxin safe use and monitoring in atrial fibrillation patients.

**Poster Title:** Impact of implementing a pharmacy resident-centered medication reconciliation program on medication errors in cardiac surgery units

**Primary Author:** Lujain Al-Suhaibani, King Faisal Specialist Hospital and Research Center, Saudi Arabia; **Email:** lalsuhaibani60@kfshrc.edu.sa

**Additional Author (s):**
Abdulrazaq Al-Jazairi
Rayd Al-Mehizia
Elias Saad
Glyn Lewis

**Purpose:** When medication reconciliation was performed by pharmacists; frequency and severity of medication errors were significantly reduced. Shortage in the qualified manpower is always challenging. Several studies were conducted to solve this issue utilizing several pharmacy resources, such as pharmacy students and technicians, for medication reconciliation. However, none of those studies tested the utilization of pharmacy residents for this purpose. Utilizing pharmacy residents for medication reconciliation may lead to an optimum utilization of pharmacy resources and positively impact patient care. The purpose of this study is to assess the impact of implementing a pharmacy resident-centered medication reconciliation program on medication errors.

**Methods:** This is a single arm prospective study that was conducted in an academic tertiary care center and approved by the institutional review board. Patients were eligible to be included in the study if they were admitted, transferred and/or discharged under cardiac surgery team care from September, 2015 to March, 2016. Cardiac Surgery Intensive Care Unit (CSICU) in this center is a fast paced unit, with a 23-bed capacity, divided between adult and pediatric units, with an average of 1,000 surgical cases performed per year. Once the patient is stable, he/she will be transferred to the Cardiovascular step-down unit (CVSD) or to the Cardiovascular Telemetry unit (CVT). The primary outcome was to assess the number and rate of unintentional medication discrepancies in this setting. Secondary outcomes included the number of interventions done by the pharmacy resident in order to resolve discrepancies and their clinical significance, percentage of acceptance, rate of interventions per patient,
medication regimen complexity index (MRCI) and its correlation with medication discrepancies. The study was designed to include 1,000 patient encounters (i.e. admissions, transfers and discharges) which were sufficient to estimate the true unintentional discrepancy rate with 4.5 percentage points. Descriptive statistics were used to summarize data. Correlation was calculated using the nonparametric Spearman’s correlation coefficient and all statistical analyses were done using the SAS® software package, version 9.4 (The SAS Institute Inc., Cary, NC, USA).

**Results:** A total of 374 patients were included and 1,000 encounters have been tracked. The one thousand encounters were distributed as follows; 374 (37.4 percent) admissions, 308 (30.8 percent) transfers and 318 (31.8 percent) discharges. Four-hundred and seventy of the included encounters were for adult patients (47 percent). A total of 260 medication discrepancies have been detected; the majority were detected during admission 181 (69.61 percent), followed by transfer 49 (18.84 percent) and discharge 30 (11.53 percent). Discrepancy rates among all of the study patients were of 0.48, 0.15 and 0.09 and 0.913, 0.307 and 0.176 among adult patients upon admission, transfer and discharge, respectively. The majority of these discrepancies resulted from the omission of home medications (207; 79.61 percent). Out of the 260 interventions recommended by pharmacy residents, 200 (76.92 percent) were accepted, as is, by the medical team, and the remaining were accepted with modifications. One-hundred and sixty six of the accepted interventions were of a high clinical significance (83 percent). There was a persistent significant correlation between the number of medication discrepancies and the MRCI upon admission (p-value < 0.0001; r= 0.34), transfer (p-value= 0.0003; r= 0.21) and discharge (p-value= 0.0672; r= 0.1).

**Conclusion:** Implementation of a pharmacy resident-centered medication reconciliation program can be a powerful approach for identifying medication errors in cardiac surgery patients at admission and throughout the transition of care.
Purpose: Cytomegalovirus (CMV) is an infectious complication post-transplant that is associated with high rates of mortality. Valganciclovir (VGVC) is approved for the prevention of CMV in pediatrics in kidney/heart transplant. Two approaches are used to prevent CMV post-transplant; prophylaxis or pre-emptive therapy. A study comparing between them showed no statistically significant difference in CMV disease. Due to the lack of recommendations in pediatrics post-HSCT, clinicians are utilizing doses that are either derived from adults’ post-HSCT or pediatrics post solid organ transplant. This study assesses the efficacy of valganciclovir in preventing CMV re-activation in pediatrics post-HSCT when dosed on this equation(900mg/m2/day)

Methods: All pediatric patients who underwent hematopoietic stem cell transplant (HSCT) at a tertiary hospital in Saudi Arabia between January 2009 and December 2015 and patients who received valganciclovir (VGVC) as pre-emptive therapy were identified. Data were collected through chart review of patients’ medical record and integrated clinical information system. Inclusion Criteria
1. Pediatric patients (Age 0–14 years) who underwent HSCT between 2009–2015
2. Received VGVC as pre-emptive therapy post-HSCT
Exclusion Criteria
1. Pediatrics patients who can’t take oral medication

Study Outcomes
Primary:
To study the efficacy of VGVC dose in the prevention of CMV reactivation in pediatrics who underwent HSCT using the following equation (900 mg/m2/day) Re-activation was defined as
positive DNAemia ≥ 1000 copies/ml for high risk patients and DNAemia ≥ 5000 copies/ml for low risk patients

Secondary:
To evaluate the hematological toxicities (i.e. neutropenia, leukopenia, thrombocytopenia) of VGVC in pediatrics who underwent HSCT using the pre-specified equation

Statistical Analysis
Descriptive statistics for the continuous variables were reported as mean±standard deviation and categorical variables were summarized as frequencies and percentages. All continuous variables were compared by Student’s t-test, while categorical variables were compared by Chi-square test. Univariate and multivariate logistic regression were used to study the effect of different risk factors on the outcomes of this study. A P value of < 0.05 was considered statistically significant. Analysis was performed with Statistical Analysis System (SAS)

Results: A total of 979 HSCT have been performed on pediatrics between 2009 – 2015 at a tertiary hospital in Saudi Arabia. One hundred and forty three patients met our inclusion criteria and were included in the analysis. The majority of patients were high risk (98%). One hundred and twenty five patients were seropositive (87%) and 18 patients were recipients of seropositive grafts (13%). None of those patients experienced CMV re-activation while on therapy. Adverse events in the form of hematological toxicities were reported as follow leukopenia, anemia and thrombocytopenia (22%, 80% and 23%, respectively).

Conclusion: Based on our preliminary findings, we concluded that; the use of valganciclovir when dosed based on this equation (900 mg/m2/day) was effective in the prevention of CMV re-activation in pediatrics post-HSCT. Correlation analysis will be performed to identify the impact of hematological toxicities on the study outcomes.

Poster Title: Tacrolimus induced neurotoxicity in early post liver transplant saudi patients: incidence and risk factors

Primary Author: Dema Alissa, King Faisal Specialist Hospital and Research Centre, Saudi Arabia;
Email: dalissa@kfshrc.edu.sa

Additional Author (s):
Ahmed Aljedai
Delal Alkortas
Mohammed Alsebayel

Purpose: Tacrolimus is a calcineurin inhibitor (CNI) that is commonly used as an immunosuppressant to prevent rejection of organ transplants. It may cause early neurological complication after liver transplantation known as early calcineurin inhibitor-induced neurotoxicity (ECIIN). The incidence and risk factor of ECIIN has not been reported in Saudi population. We investigated the incidence, risk factors, and clinical outcomes of ECIIN after liver transplant. We also looked at the length of stay in intensive care unit, hospital, and 30 day mortality as secondary endpoints.

Methods: This is a retrospective, cohort study of adult patients on tacrolimus with mild, moderate or severe neurological events within the first month after liver transplantation at a single center of patients who meet inclusion criteria between 2004 and 2014. A total of 338 patients were included in the analysis and the sample size was calculated based on a pilot study.

Results: Among 338 patients of liver transplantation, 63 patients (19 percent) developed ECIIN. Forty eight percent of patients had seizures, 15 percent had agitation, 13 percent psychosis, 10 percent severe tremors, 14 percent had confusion, and 6 percent developed coma. The average time of incident to develop ECIIN was $11 \pm 8$ (mean $\pm$ SD) days post-transplant. Thirty eight patients were managed by switching to cyclosporine, 12 required a reduction in the dose, and 3 were managed temporarily by discontinuing therapy. Average length of ICU stay was $4 + 18$ days, hospital length of stay was $19 + 38$ days, and total of 9 patients died within 30 days post-transplant.
Conclusion: The rate and risk factors of ECIIN occurrence at our center is similar to that reported in other population reported in the literature.

**Poster Title:** Midodrine for vasoplegia after critical illness

**Primary Author:** Hadeel Samarkandi, King Faisal Specialist Hospital and Research Centre, Saudi Arabia; **Email:** hsamarkandi61@kfshrc.edu.sa

**Additional Author(s):**
Rashid Amin
Nawal Salahuddin
Khaled Ghorab

**Purpose:** Vasoplegia is the final common pathway of prolonged and severe circulatory shock for which patients require low doses of intravenous vasopressors to maintain their blood pressure. Midodrine, an oral peripheral α1-agonist was approved for the management of symptomatic orthostatic hypotension but has been used off-label in the management of vasoplegic patients in the ICU. Although the data is scarce for midodrine use in this setting, the possibility of a clinically significant vasopressor effect has prompted intensivist to prescribe it. Therefore, this study was designed to establish the efficacy and safety of oral midodrine in weaning off patients from intravenous vasopressors.

**Methods:** This retrospective observational study was conducted at a tertiary hospital to evaluate the vasopressor effect of oral midodrine in patients who were not able to be weaned off IV vasopressors. Data were collected from adult medical and surgical ICU patients during 5 years period from 2011-2015. Patients were included if they required minimum dose of intravenous vasopressor and were attempted to be weaned off with introduction of midodrine. Patients were excluded if they were hemodynamically unstable, had documented adrenal insufficiency, on benzodiazepines, or received vasodilator in the preceding 24 hour.

Patient demographics, severity of illness scores including Acute Physiology and Chronic Health Evaluation II, admitting diagnosis, daily hemodynamic were collected. Types and doses of IV vasopressor, total daily dose of midodrine and variables related to other reasons for hemodynamic instability.

The primary end point was the complete wean off IV vasopressor within 72hr of midodrine start. Secondary end points were percent of IV vasopressor dose reduction in patient where
complete wean off was not observed, adverse effects specified as uncontrolled hypertension or cardiac ischemia, and the time to restart of IV vasopressor.

Data analysis was presented in mean ± SD in case of continues variables or in case of skewed data as medians with interquartile ranges. Fisher’s Exact test was used for categorical covariates and Mann-Whitney for continuous covariates.

**Results:** Out of 200 encounters screened, 68 met the inclusion criteria. The majority of patients were male and the mean age of subjects were 66 ± 14 years. The majority of patients received norepinephrine (87 percent) followed by dopamine (10 percent). During the study period (i.e. within 72hr of midodrine start), 46 patients (68 percent) were completely weaned off IV vasopressors where 22 patients (32 percent) either partially weaned off or no dose reduction was observed. Among patients who were not weaned off IV vasopressor, 10 patients (45 percent) of them had dose reduction without complete wean off IV vasopressor and the median dose reduction was 50 percent ranging from 13 percent to 87 percent. Among those who were completely weaned off IV vasopressor, 24 out of 46 patients (52 percent) had IV vasopressor resumed within 72 hours with mean time to restart IV vasopressor of 20 ± 15 hours. Adverse drug reaction occurred in 2 out of 68 patient (3 percent) presented as uncontrolled hypertension.

**Conclusion:** Our findings showed that oral midodrine appears to have a clinically significant vasopressor effect on some patients when added to persistently vasoplegic patients in the ICU. However this effect appears not to be sustained with a large percentage requiring resumption of IV vasopressors.

Poster Title: Bridging the gap between theory and practice; the active role of inpatient pharmacists in therapeutic drug monitoring

Primary Author: Abrar Al-Hameed, Pharmacy Residency Program at King Abdulaziz Medical City - Western Region, Saudi Arabia; Email: alhameedab@ngha.med.sa

Additional Author(s):
Sara AlKhansa
Hani Hasan
Sherine Ismail
Mohammad Aseeri

Purpose: Therapeutic drug monitoring (TDM) is a fundamental responsibility of all pharmacists to provide optimized therapeutic outcomes for patients. It leads to a reduced incidence of adverse effects, a reduction in mortality, and cost-savings. However many hospitals have faced barriers in implementation including pharmacists spending most of their time on dispensing and dealing with inventory issues, lack of practical knowledge and pharmacokinetic expertise. Therefore, this project aims to evaluate the impact of a pharmacist-led TDM service to improve therapeutic drug monitoring of vancomycin and aminoglycosides with the goal of optimizing patient care at a tertiary care hospital.

Methods: The institutional review board approved this pre-post study. The pre-phase consists of a report of all patients that have been administered vancomycin, gentamicin and amikacin for 3 months. Orders will be evaluated for correct dosing and ordered levels. A team of pharmacists will then be trained by several educational methods including interactive lectures, flowcharts and checklists. These sessions will be followed by assessment questions. The post-phase will consist of pharmacists reviewing a daily report of the 3 antibiotics on a 24-hour 7 days basis and provide recommendations to either the clinical pharmacist or physician regarding the following parameters: Initial dose, dose adjustment, and laboratory drug level requests. The primary outcome is to assess the proportion of correct initial doses of prescribing orders for vancomycin, gentamicin and amikacin as per hospital approved guidelines. Secondary outcomes include proportions of correct dose adjustment orders and correct orders
for drug sampling time. It was determined that 75 patients per treatment group would yield a 90% power to detect a difference of 25% between different phases for the primary outcome.

**Results:** N/A

**Conclusion:** N/A

Poster Title: Analysis of oral therapies used in non-pancreatic neuroendocrine tumor at a tertiary university hospital and their safety

Primary Author: Goizane Ros Bernaola, Cruces University Hospita, Spain; Email: grosbernaola@gmail.com

Additional Author (s):
Begoña San José Ruiz
Leocadio Rafael Lópex Giménez
Mª Angel Gil Lemus

Purpose: Neuroendocrine tumors (NETs) are a heterogeneous group of tumors of various locations that are treated with different chemotherapy protocols and targeted therapies. In the last years, the evidence on the use of oral therapies for its treatment has multiplied, mostly for pancreatic NET and, to a lesser extent, gastrointestinal or lung origin NETs, but they are still not approved for all kinds of NETs. The aim of this review is to analyze how non-pancreatic NETs are treated at our center and the safety of the therapies that are nowadays being used.

Methods: We analyzed all the patients with non-pancreatic advanced progressive NET that have been treated at our hospital with oral therapies. We recorded the age of the patients, their NET localization, what drug they were treated with and for how long they were on that treatment. We analyzed the treatment sequence with those drugs and whether they were being concomitantly treated with somatostatin analogs. In what refers to safety, we reviewed if a dose reduction of the treatment had occurred during each treatment due to toxicity. Finally, the date of death and data on overall survival of the registered patients was collected, when applicable.

Results: 10 patients received 17 different oral treatments. Their average age at the beginning of the first treatment was 60 [19-81]. Three patients had pulmonary, four intestinal, one thymic and one ovarian NET and one MEN (thymic and pancreatic). All of them were on treatment with somatostatin analogs. Five patients were treated with sunitinib on first line, three of whom received a second line with everolimus and two of them a third line with capecitabine and temozolomide. The other five patients received everolimus as first line and one of them was
subsequently treated with sunitinib. The mean duration of treatment with everolimus was 440 days[182-699], 325 days[155-464] with sunitinib and 400 days[338-462] with capecitabine and temozolomide. Dose reductions occurred in four out of eight patients on everolimus due to stomatitis, diarrhea, asthenia, infections and cytopenias. In the case of sunitinib, dose reductions occurred in four patients out of six due to nausea, diarrhea, stomatitis, drug intolerance. In the case of capecitabine and temozolomide, one out of two had it reduced due to hand-foot syndrome. Out of the five patients that are deceased at the moment of analysis, the mean overall survival since the first line of treatment was 26 months [6.4-56.1].

**Conclusion:** Our safety findings were consistent with the known side effects of everolimus, sunitinib and capecitabine. The mean duration of treatment with everolimus was longer than previously reported in the RADIANT-4 study. The overall survival of our series is similar to the one estimated in this study. Nevertheless, the low incidence of these tumors makes it hard to analyze treatments depending on localization and to determine the best treatment sequence.

Poster Title: Pharmaceutical interventions: ¿How do we do?

Primary Author: Yoar Labeaga, Hospital de Cabueñas, Spain; Email: yoarfh@gmail.com

Additional Author(s):
Cristina Duran Roman
Alba León Barbosa
Rubén Pampín Sánchez
Ana Lozano Blázquez

Purpose: The main objective of pharmaceutical care, is to improve the quality of patient care and ensure that the patient recives the most appropriate therapy. In order to demonstrate the impact of pharmaceutical care on the individualized care of patients, pharmacists must record the clinical activities and evaluate results. The aim of this study was to analyze and determine the degree of acceptance of pharmaceutical interventions from the area of unit dose dispensing pharmacy service.

Methods: Descriptive prospective study over a period of 3 months (during the period January to March 2016) for the analysis of pharmaceutical interventions carried out through electronic medical records (SELENE®), on medical prescription with patients admitted to hospital clinical units with unit-dose drug distribution system.

As part of the daily work of pharmaceutical validation, the different interventions were carried out included as "Comments of Pharmacy", in the notes of clinical history of the patient. To facilitate the drafting and subsequent monitoring, predefined AutoText were used. In this way, notifications made by the pharmacist were classified into: clarification of the drug, administration, adjustment for renal impairment, dose or incorrect regimen, duration of treatment, duplication, therapeutic equivalent, interaction, therapy sequential and safety.

During the study period a daily record of the interventions made, which were obtained on the previous day, reviewing the prescription to determine the acceptance or not of the intervention. In those where no change was observed at 24h, the situation was reevaluated at 48h. For notifications made during the weekend, the assessment period was increased to 72 hours.
The variables gather were: patient demographic data, type of pharmaceutical notification made, active treatment group and affected, medical service which was directed and non-acceptance or intervention.

**Results:** During the study period a total of 909 pharmaceutical interventions were performed corresponding to 644 patients, 330 women and 314 men with an average age of 70.5 years (range 5-99).
The degree of acceptance of the recommendations made was 69.1%.
The most common types of pharmaceutical intervention were: duplicity (35.9%), or incorrect dose regimen (17.2%) and adjustment for renal failure (15.5%). Within each type, the degree of acceptance was 72.7%, 72.4% and 62.4%, respectively. In duplicate notifications, most intervention was applied to prescription of analgesia (29.4%), as in the case of incorrect dosage or regimen (14.7%); antibiotics were the largest group intervention in setting renal failure (53.2%).
Regarding medical services, those that most notifications were sent were: Traumatology (21.6%), internal medicine (19.0%) and urology (8.9%). The degree of acceptance of the interventions received was 73.5%, 61.3% and 53.1%, respectively.

**Conclusion:** The number of interventions on prescribing consolidates the contribution of pharmaceutical validation and registration in the medical history of the patient.
The percentage of interventions over duplicate prescriptions shows the problems that would have the alert activation by duplication and the risk of generating "fatigue in the prescriptor". On the other hand, the acceptance of interventions not only reflects a positive assessment of the clinic, in addition the result in the modification of prescriptions, affects the impact on the adequacy of treatment for inpatients and therefore in improving the quality of health-care.

Julia López-Santamaría

Purpose: Methotrexate (MTX) is an important chemotherapeutic agent that contributes to the high cure rate of pediatric acute lymphoblastic leukemia (ALL), however, high-dose methotrexate (HDMTX) has been associated with potentially severe toxicities. The purpose of this study was to evaluate the variability of exposure to MTX in pediatric patients with ALL who received a fixed dose of HDMTX to quantify how many patients could benefit from a dosage adjustment.

Methods: Retrospective observational study, between October 2007 and September 2016. We included children up to 18 years old with ALL who received a fixed dose of 5000mg/m² over 24h in accordance with LAL-SHOP-2005 or LAL-SEHOP-PETHEMA 2013 protocols. The target range of exposure was defined as a steady-state plasma concentration (Cpss) of 65 μM (55-75 μM), this is the suitable Cpss to maintain adequate exposure while minimizing toxicities, considering the extreme values positioned above 75 μM. The plasma samples were obtained at 2, 12, 23, 36, 42 and 60 hours after the start of infusion. Methotrexate pharmacokinetics parameters were estimated by Bayesian analysis. (software abbott PKs). MTX was measured by a fluorescence polarization immunoassay (TDx/FLx, Abbot Laboratories) (until February 2015) and by architect chemiluminescence immunoassay (since March 2015).

Results: We included 44 children from 4 to 18 years old (9 ± 4.1) who received 141 cycles of MTX.
The average Cpss was $85.6 \pm 22.2 \, \mu M$ (range, 29.4 – 169.2 \, \mu M), only 20.6 % of the patients showed values within the target Cpss (55-75 \, \mu M), and 73 % showed extreme values (>75 \, \mu M). The average Area under the curve (AUC) was $2140.7 \pm 616.3 \, \mu M.h$.

Other pharmacokinetic parameters were analysed, the average clearance and volume of distribution were $85.6 \pm 22.2 \, ml/min/m^2$ and $0.47 \pm 0.15 \, l/kg$ respectively.

**Conclusion:** The variability of the clearance explains the variability in MTX Cpss between patients. The variability of exposure to methotrexate (25.9%) would justify the need to optimize therapy. Dosage adjustment could result in fewer extreme Cpss values and less risk of toxicity.

Submission Type: Evaluative Study

Session-Board Number: 9-338

Poster Title: Aztreonam lysine inhaled in chronic bronchopulmonary Pseudomonas aeruginosa infection

Primary Author: Julia López-Santamaría Donoso, Hospital Universitario Reina Sofía (Córdoba, Spain), SPAIN; Email: julia_lopez_2@hotmail.com

Additional Author(s):
Maria Dolores Lopez-Malo de Molina
Maria Concepción Donoso-Rengifo
Pablo Montejano-Hervás
Inmaculada Reyes-Torres

Purpose: Chronic bronchopulmonary colonization by Pseudomonas aeruginosa (PA) and exacerbations arising from it are one of the most important causes of the deterioration of lung function. Aztreonam lysine inhaled (AZLI) could be an alternative to other antibiotics in cases of microbial resistance, poor clinical outcome or intolerance to other antibiotics. To assess the effectiveness and safety of AZLI for the treatment of patients with chronic pulmonary PA infection in a tertiary hospital.

Methods: A descriptive retrospective observational study of patients treated for at least 6 months with AZLI (April/15 to September/16). Demographic, analytical, microbiological and clinical data were collected: sex, age, pathology, Forced Expiratory Volume in the first second (FEV1), colony-forming units (CFU) of PA, AZLI concomitant antibiotic treatment and also antibiotics required for exacerbation of the disease and adverse effects. The effectiveness was assessed measuring the difference between FEV1 pre/post treatment, by the number of exacerbations treated with intravenous or oral antibiotic and by the difference in CFU of PA in sputum pre/post treatment. The safety was measured by adverse reactions related to AZLI and by its tolerability. The information was obtained from outpatient prescription program Farmatools® and electronic medical records of patients.
Results: 2 men with a median age of 38 years old [29-46] were included. The mean treatment duration was 11.5 months [6-17]. Both patients were colonized with PA and suffering from cystic fibrosis. None of them underwent lung transplantation. They were treated with 75 mg AZLI/8h for 28 days on-off cycles, combined with colistin and with tobramycin. The two patients had moderate or severe pulmonary disease (FEV1 < 75%), improving the mean FEV1 compared to the average of the previous year treatment 5.5% and 2.5%. The number of antibiotic treatment due to disease exacerbation were an average of 3.5 [3-4] treatments in the year before the start of AZLI and 0.5 [0-1] antimicrobial treatments in the subsequent year. The number of CFU of PA was reduced in both patients, 24.33% and 66.95%. AZLI treatment was well tolerated by patients, not referring any adverse reactions.

Conclusion: We observed that AZLI in on-off cycles was an effective drug since there was a FEV1 improvement and a decrease in number of exacerbations requiring antibiotic treatment and CFU of PA in the sputum. Moreover AZLI was well tolerated. It seems that AZLI is a safe and effective alternative to other inhaled antibiotics in the treatment of bronchopulmonary PA infection.

**Poster Title:** Educating new residents on computerized physician order entry

**Primary Author:** Silvia Mendiola Garcia, not applicable, Spain; **Email:** silvia.mendiolagarcia@osakidetza.eus

**Additional Author(s):**
Goizane Ros Bernaola  
Leocadio Rafael Lopez Gimenez  
Saioa Sautua Larretegi  
Beatriz Baza Martinez

**Purpose:** To describe and evaluate a resident-focused computerized physician order entry (CPOE) education activity, recently started by our pharmacy service as part of the Sade Medication Use Plan of the hospital. Usually physicians are only trained in CPOE at its implementation at the hospital, without further education to prevent errors, an improvement opportunity our pharmacy answered starting this course we will evaluate on this work.

**Methods:** At the beginning of their formative period, residents are included in a cross specialty training program to learn the basics about our hospital. Our CPOE education activity was included in that program. We used the MOODLE platform to communicate with residents and provide them with reading material about CPOE prior to the formative event. They were divided in three groups and took part in a 45 minute no-site activity. After a short introduction about CPOE, some exercises were proposed to explore all the functionalities of our CPOE system, using virtual patients created for their practical training. After the on-site training, we kept in touch with the residents via MOODLE and additional written information was provided to them. Finally, they completed a 13-item satisfaction survey we analysed with descriptive statistics in order to improve for next year’s activity.

**Results:** 60 out of the 76 new residents attended the activity. 28 of them downloaded the documents available via MOODLE prior to the course. The overall opinion about the workshop was “very good” for 42% of the residents and “good” for 55% of them. They found the training was “very useful” in 67% of the cases and “useful” in 33% of them. Suggestions were focused
were focused on the activity duration, considered too short by most of them (?). For this reason, the training will last two hours next year.

**Conclusion:** The preliminary information provided via MOODLE and the virtual patients for the practical training helped the residents learn. The high number of residents that took part in the activity could be related to its inclusion in our hospital’s introductory training program. This CPOE education is considered useful for new residents.

Poster Title: Compilation of antibiotic susceptibility of uropathogens in an emergency department to create a department specific antibiogram

Primary Author: Andrew Good, Intermountain Healthcare, UT; Email: andrew.good@imail.org

Additional Author (s):
David Hwang

Purpose: Urinary tract infections (UTIs) are one of the most common conditions seen in the emergency department (ED) and are diagnosed over 2.4 million times per year in emergency departments across the nation. Resistance rates of common urinary pathogens have recently seen dramatic increases to multiple antibiotics. The purpose of this study is to provide susceptibility data for pathogens causing UTIs in the ED. The results from this study will assist in creating a department specific antibiogram for the emergency department and in providing ED practitioners appropriate drug therapy options for patients being seen for UTIs.

Methods: Electronic medical records will be reviewed for every patient seen at a 395 bed acute care referral hospital and ED from January 1, 2015 through December 31, 2015 to identify all patients with positive urine cultures. Each patient will be evaluated to determine if they meet the inclusion and exclusion criteria and the data will be divided into ED and inpatient isolates. After identifying the patients with positive urine cultures from the ED, patients with more than one positive culture will only have their first positive culture for a specific pathogen carried through to be evaluated in accordance with Clinical and Laboratory Standards Institute’s standards for analyzing cumulative susceptibility data. Susceptibility data specific for uropathogens in the ED will be used to educate the ED providers on primary and alternative therapies for pathogens causing UTIs.

Poster Title: Evaluating mortality in patients with massive pulmonary embolism receiving standard dose versus low dose tissue plasminogen activator (tPA)

Primary Author: Rebecca Christiansen, Intermountain Healthcare, UT; Email: rebecca.christiansen@imail.org

Additional Author(s):
Anastasia Diamantopoulos
Sophia Maedjaja

Purpose: The purpose of this study is to compare outcomes in patients with massive pulmonary embolism receiving standard dose (100 mg) or low dose (less than 100 mg) tPA to determine if one dosing regimen is preferred in terms of efficacy and safety. Bleeding risks are dose dependent therefore, the potential for improving safety by reducing the dose while maintaining efficacy has led to few, small, randomized controlled trials comparing standard dose versus low dose tPA. With limited amount of data, it remains unclear whether low dose tPA provides the same efficacy as standard dose tPA while minimizing risk of bleeding.

Methods: This is a retrospective, multi-center, cohort study. This study has been submitted to the Institutional Review Board for approval. Electronic medical records will be reviewed from January 1, 2011 through September 15, 2016 to identify patients aged 18 years and older with suspected or confirmed massive pulmonary embolism who received tPA. Furthermore, chart review will be performed on identified patients to confirm diagnosis of massive pulmonary embolism and to exclude patients who received tPA for medical conditions other than massive pulmonary embolism (e.g., ischemic stroke). Identified patients will be separated into two treatment groups, those treated with standard dose tPA and those treated with low dose tPA. The following data will be collected: patient age, gender, ethnicity, weight, height, patient specific vitals, admitting diagnosis, hospital admission date and time, hospital discharge date and time, facility name, discharge location, patient specific hematological monitoring parameters, tPA dose administered, anticoagulants received inpatient, antiplatelet agents received, home medication list, bleeding events, and in-hospital mortality. The primary outcome measured will be in-hospital all-cause mortality. Secondary outcomes include length
of hospital stay, recurrent pulmonary embolism within 14 days, and in-hospital pulmonary embolism specific mortality.

**Poster Title:** Effect of discharge medication delivery service on medication adherence

**Primary Author:** Keeshia Christensen, Intermountain Healthcare, UT; **Email:** keeshia.christensen@imail.org

**Additional Author(s):**
Bradly Winter
Kim Compagni

**Purpose:** Following discharge, medication non-adherence is common, which often leads to more health concerns. Intermountain Healthcare Community Pharmacy Services have created a program, called Med-READI, with the goal to improve patient adherence following discharge. Med-READI stands for Medication Reconciliation Education Adherence and Delivery Initiative. It is a free service including bedside delivery and personalized counseling, provided by a pharmacist. To determine if Med-READI has an impact on medication adherence, patients with a new onset venous thromboembolism (VTE), discharged with a prescription for a direct oral anticoagulant (DOAC) will be studied.

**Methods:** To determine whether the Med-READI program is effective in improving medication adherence, an observational, retrospective, case control study will be performed. This study will include retrospective data from the electronic medical record (EMR), discharge medication record, community pharmacy database, and insurance claim history. The adherence of SelectHealth insured patients, discharged with a DOAC prescription, who received the Med-READI service (the experiment group), will be compared to SelectHealth insured patients, discharged with a DOAC prescription, who did not receive the Med-READI service (the control group) from the same hospital. Patients will be matched based on similar baseline characteristics. The primary endpoint will be calculated daily medication possession ratio (MPR), for 120 days following discharge date. Adherence will be defined as ≥0.80 MPR; this cut-off has been widely used in previous research and is considered a valid point to stratify adherence. The date range for this study will be January 1, 2015 to October 31, 2016. Secondary outcomes will include 90-day hospital readmission rates, effect of pharmacist counseling, additional medication refills captured at Intermountain Healthcare community pharmacies, reoccurring VTE events, and major bleeding events. Additional variables, such as
patien’t overall history of adherence will also be analyzed. This study is pending IRB approval. We hypothesize that the Med-READI service will show a positive impact on patient medication adherence after being discharged from an Intermountain Healthcare facility.

Results: N/A

Conclusion: N/A
Poster Title: Impact of pharmacist-delivered inpatient medication counseling on 30-day readmission rates

Primary Author: Mary Dimaano, Intermountain Healthcare, UT; Email: nicole.dimaano@imail.org

Additional Author(s):
Jenna Negrelli
Scott Yost
Sarah Yost
Patrick Welch

Purpose: Optimizing the transition from the hospital to the outpatient setting may decrease the risk for adverse events, promote patient satisfaction, and most importantly, reduce rates of rehospitalization in certain disease states. Pharmacists have the opportunity to directly impact the health care system by effectively providing medication education, medication reconciliation, and discharge planning for these high-risk transition periods. This quality improvement project outlines an innovative approach to implementing and strengthening pharmacists-led medication counseling services at a tertiary care hospital. The primary objective is to assess the impact of pharmacist medication counseling on all-cause 30-day readmission rates.

Methods: A quality improvement project with pharmacist-led medication counseling prior to discharge was implemented in three cardiovascular units at a tertiary care hospital in October 2015. Standardization of pharmacist counseling notes in the electronic medical record was implemented in August 2016, allowing for consistent tracking of patients who receive counseling. Current pharmacy resources can provide medication education to approximately 40% of patients being discharged from these units. The primary outcome assessing the impact of this initiative will be a comparison of 30-day all-cause readmission rates between pharmacist counseling and standard of care. Patients at least 18 years old and discharged from the coronary intensive care unit or acute care cardiology floors with at least one new medication prescribed at discharge will be included. The pilot group receives medication reconciliation, a patient-specific pharmaceutical care plan, and medication counseling by a pharmacist. Standard
of care includes medication reconciliation by a provider and discharge medication review by a nurse. Secondary outcomes will include 30-day Emergency Department visit rate and 30-day mortality rate. Additionally, a secondary analysis will be completed to determine if counseling on specific medications (eg, antiarrhythmics or P2Y12 inhibitors) or counseling patients with specific disease states (eg, heart failure or myocardial infarction) reduces 30-day readmission rates. Data will be analyzed using descriptive statistics and secondary analyses will utilize binary logistic regression.

Poster Title: Rate of Naloxone use in patients receiving an opioid compared to those using opioids and a sedative/hypnotic medication.

Primary Author: Gavin Gardner, Intermountain Healthcare, UT; Email: gavin.gardner@imail.org

Additional Author(s):
Tim Drake
Craig Gale

Purpose: Opioids were identified in 75.2% of all pharmaceutical-related overdose deaths in 2010. Data also indicates that as the percentage of in-patient opioid use increases, so does the opioid related adverse events per patient exposed. Where the data is lacking is the effect that concomitant use of opioids and other sedative/hypnotics have on drug induced adverse events in the acute care setting. This study is aimed to measure the rate of use of naloxone in patients using opioids alone compared to those using opioids and a sedative/hypnotic in combination.

Methods: A retrospective chart review of in-patients throughout the Intermountain Healthcare system composed of 22 hospitals located in Utah and Idaho was conducted between January 2012 and December 2014. Patients included in this study were 18 years of age or older and received at least one opioid medication throughout their stay. Patients in the emergency department and the labor and delivery unit were excluded from the study population. The primary outcome is the rate of naloxone use in patients that received concomitant administration of an opioid and a sedative/hypnotic agent compared to an opioid alone. Medication lists from included patients included any opioid with or without the addition of naloxone, benzodiazepines, non-benzodiazepine sleep aids, muscle relaxants or other sedative-hypnotics. As a secondary outcome, analysis of the individual drug classes will also be performed to identify any differences in adverse events, with the use of naloxone being the surrogate marker. Descriptive and inferential statistics will be used to analyze and assess the collected data.

Poster Title: Evaluation of sodium glycerophosphate (NaGP) versus inorganic phosphates in the incidence of metabolic bone disease (MBD) in premature neonates

Primary Author: Christian Armstrong, Intermountain Healthcare, UT; Email: christian.armstrong@imail.org

Additional Author(s):
Collin Anderson
Brian Winther

Purpose: Neonate nutritional guidelines recognize that parenteral nutrition (PN) predisposes the patient to MBD. Further, currently approved inorganic phosphates exacerbate MBD by limiting the amount of calcium and phosphate allowed in PN due to higher precipitation risks. In 2013, shortages of inorganic phosphate lead to the temporary importation of organic NaGP. NaGP is reported to lessen precipitation risk and allow for higher concentrations of calcium and phosphate in PN. The objective of this study is to determine if the use of organic phosphates in PN decrease the incidence of MBD when compared to inorganic phosphates in premature neonates.

Methods: This study is submitted to the Institutional Review Board and awaiting approval. Patients included in the study will be premature neonates diagnosed with MBD while receiving PN in the hospital. The use of ICD-9 and ICD-10 codes will be used to identify any premature neonates diagnosed with MBD from the years 2010 to August 2016. Imagining results, if available, will be used to verify the diagnosis of MBD. The following data will be collected: gestational age, weight, gender, PN ingredients, serum calcium, ionized calcium, serum phosphate, alkaline phosphatase, parathyroid hormone, serum vitamin D, renal function test, liver function tests, serum trace elements, medications used during hospital stay, microbiology results, and duration of PN. All data will be kept in a secure database with patient identifiers removed in order to protect the patient’s confidentially. The incidence rate of MBD will be pooled and averaged for patients on organic compared to inorganic phosphates. Secondary markers of MBD such as alkaline phosphatase, parathyroid hormone will also be compared to patients receiving organic phosphates versus inorganic phosphates.

**Poster Title:** Development of a scoring tool to identify patients to target during pharmacist-provided transitions of care medication reconciliation

**Primary Author:** Diana Fischer, Intermountain Healthcare, UT; **Email:** diana.fischer@imail.org

**Additional Author(s):**
Peggy Tilbury
Jeffery Olson

**Purpose:** Transitions of care (TOC) medication reconciliation improves continuity of patient care during transition periods from inpatient to outpatient settings. Several patient screening tools have been developed to help healthcare providers identify patients at risk of readmission. While these tools have been validated in the hospital setting, they have not been validated in the outpatient setting. If pharmacists could better target patients at risk of 30-day readmission, they could focus efforts on these patients and improve productivity. The purpose of this study is to develop an outpatient risk-assessment tool to identify patients for pharmacists to target during TOC medication reconciliation.

**Methods:** A retrospective chart review will be conducted on a historical cohort of transitions of care patients for whom a pharmacist previously performed medication reconciliation. The historical data collected for each patient includes: number of changes to medication list, number of changes to drug therapy, number of drug-drug interactions, number of adverse drug reactions, number of access issues, number of times patient/caregiver was redirected, and pharmacist time spent on the TOC follow up. Additional data collected from the electronic medical record will include: age, sex, reason for hospital admission, medications (including number of medications), laboratory values, length of hospital stay, ICD coded procedures while admitted to the hospital, chronic medical conditions, and admission within the previous year. The patient data collected will be used to develop an outpatient 30-day readmission risk assessment tool to allow pharmacists to better target patients during transitions of care. The level of risk determined by the tool will then be compared to pharmacist time spent, changes to medication list/drug therapy, number of drug interactions, number of adverse drug reactions, and access issues obtained from the historical data to determine if the data correlates to level of risk using the tool.

Poster Title: Economic Implications of Collaborative Pharmacist Support in Primary Care

Primary Author: Hannah Pratt, Intermountain Healthcare, UT; Email: hannah.pratt@imail.org

Additional Author (s):
Bradly Winter
Jeffery Olson

Purpose: The purpose of this study is to investigate the value-based economic impact of outcomes obtained by ambulatory care clinical pharmacist (CP) interventions in the management of patients with Type 2 Diabetes (T2DM) and High Blood Pressure (HBP) as provided under collaborative drug therapy management (CDTM) versus the outcomes of patients not managed by ambulatory care CP who served as the control. Controls were selected from the central Salt Lake region and must have had a primary care provider (PCP) visit within case enrollment time frame and matched using propensity matching in a 1:3 ratio on a number of parameters.

Methods: This is a retrospective, observational cohort using matched controls for each patient who received the intervention: ambulatory care CP management of T2DM and/or HBP under CDTM. The primary outcome is the difference in efficiency of the primary care team with the addition of a CP in order to achieve maximum number of patients at goal. Measurements will include the number of visits and time spent by a CP and PCP to achieve superior results compared to the control group. It will be assumed that in order to achieve similar results the PCP would have to spend the same amount of time with each control patient. The difference in time will be related to the cost for additional PCP time minus any additional revenue generated by their visits. The hypothesis is that the cost to have a PCP theoretically reach the same results would be prohibitive compared to the cost of including a CP. Additional measurements will include improved efficiency of the primary care team and estimated economic impact of superior achievement of goals in CP group versus the control group using local estimated costs and savings associated with meeting hemoglobin A1c and HBP goals. This will involve relating achievement of clinical goals to decrease in complications and adverse events seen in clinical trials. Secondary outcomes include estimated overall cost-avoidance by assessing hospitalizations and/or ED visits.

Poster Title: Utilization of 340B savings to develop a pharmacy-driven diabetes starter kit for pediatric patients newly diagnosed during hospital admission

Primary Author: Aubrey Pimsakul, Intermountain Healthcare - PGY1-Utah Valley Regional Hospital, UT; Email: aubrey.pimsakul@imail.org

Additional Author(s):
Emily Summers
Alan Horrocks
Tammy Potter

Purpose: Newly diagnosed patients with diabetes are faced with many barriers to care including the high cost of diabetic supplies and lack of education regarding the complex nature of diabetes treatment. Children with diabetes represent an especially vulnerable population that would benefit from enhanced quality of care. The purpose of this program is to provide a 340B-funded diabetes starter kit to newly diagnosed pediatric patients. The starter kit would provide improved access to diabetes medications and supplies at low costs prior to discharge, encourage early compliance, and provide a platform for pharmacist-driven education to patients and their caregivers.

Methods: For pediatric patients with new onset diabetes admitted to Utah Valley Hospital (UVH), a new service to provide access to low cost diabetes medications and supplies is in development. Pharmacists and nurse educators will be surveyed to determine what medications, supplies, and educational materials should be included in the starter kit. Diabetes medications will be supplied through Timpview Pharmacy, the affiliated outpatient pharmacy of UVH. The supplies in the starter kit will be paid for through savings from the 340B Drug Pricing Program in which UVH participates. The number of patients who may benefit and the savings available through the 340B program will be estimated and a budget for the kit determined. Once the kit components are finalized, they will be purchased and stored in a separate inventory from other supplies. Providers, diabetes educators, and other pediatric floor staff will be educated on the implementation of the service. Pharmacists covering the pediatric floor will identify patients who qualify for the starter kit. Before discharge, a process will be developed
to provide patients with the starter kit and to be educated by a pharmacist. A follow-up questionnaire will be distributed to patients and caregivers.

Poster Title: Determining optimal initial heparin infusion rates in pediatric patients on extracorporeal membrane oxygenation (ECMO)

Primary Author: Elmer Smith, Intermountain Healthcare - Primary Children’s Hospital, UT; Email: trey.smith@imail.org

Additional Author(s):
Carly Heyrend
Chanelle Stidham
Brent Kay
David Bailly

Purpose: Patients who receive ECMO require anticoagulation, most commonly with heparin, and close monitoring to avoid the bleeding and clotting complications inherent to ECMO therapy. At this time the optimal initial heparin infusion rate is not known. We hypothesize that the initial heparin infusion rate used by clinicians can be improved, resulting in a shorter time to therapeutic anticoagulation. The purpose of this study is to determine the optimal initial infusion rates of heparin for pediatric patients receiving ECMO and thereby minimize the time to therapeutic anticoagulation.

Methods: The institutional review board of Primary Children’s Hospital (PCH) has approved this retrospective, observational study. Patients 18 years of age or younger admitted to PCH from March 2012 to December 2016 who received heparin anticoagulation for ECMO will be included in the study. Data to be collected includes patient demographic information (weight, height, BSA, age, gestational age, and race); laboratory markers related to anticoagulation (unfractionated heparin (UFH) anti-Xa levels, partial thromboplastin time, activated clotting time, prothrombin time, international normalized ratio, complete blood counts, and other pertinent labs); medication data (date and time of the start of heparin therapy, all dose adjustments, and other concomitant anticoagulants). Patient outcomes to observe include time to therapeutic heparin anticoagulation as measured by UFH anti-Xa and associated heparin rate changes, hospital length of stay, intensive care unit length of stay, clinically significant bleeds, and death. ECMO outcomes include circuit clotting, time to circuit change due to circuit failure, bleeding, and thrombotic complications. Using the above variables we hope to build a model
that predicts the optimal initial heparin rate based on patient specific values and the type of ECMO circuit deployed.

Poster Title: Patient characteristics associated with elevated serum lidocaine levels

Primary Author: Melanie Madorsky, Intermountain Healthcare - Utah Valley Hospital, UT;
Email: melanie.madorsky@gmail.com

Additional Author(s):
Jenna Negrelli
Wilson Pace

Purpose: Lidocaine is a Class Ib antiarrhythmic agent used for the treatment of ventricular arrhythmias. Adverse effects associated with intravenous lidocaine include altered mental status, visual disturbances, tremors, and seizures. These effects are typically dose-dependent, with the risk of toxicity increasing when levels exceed the therapeutic range of 1.5 to 5mcg/mL. Patients with congestive heart failure and/or hepatic dysfunction have an increased risk of toxicity and require lower doses of lidocaine. However, interpatient variability in levels does not appear to be based on these factors exclusively. This study seeks to determine other characteristics associated with toxic serum lidocaine levels.

Methods: This is a multicenter, retrospective electronic medical record review. Patients will be evaluated from January 1, 2000 to December 31, 2015. Patients will be eligible for inclusion if they are at least 18 years of age, received intravenous lidocaine, and had at least one lidocaine level drawn during hospitalization. Prisoners and pregnant women will be excluded.

Demographic and clinical data will be evaluated in patients who have supratherapeutic levels of lidocaine greater than 5mcg/mL compared to those with levels within the range of 1.5mcg/mL to 5mcg/mL. Data collected will include age, weight, height, gender, lidocaine levels, average lidocaine dose during infusion, creatinine clearance, serum potassium, ejection fraction, liver function tests, concomitant medications, and past medical history. Lidocaine levels drawn within 12 hours of a previous lidocaine level for the same patient will not be evaluated. Otherwise, all lidocaine levels will be assessed as individual events, considering patient characteristics are likely to change throughout hospital admission. Data will be analyzed using Generalized Estimating Equations. It is anticipated that this study will have multiple encounters per patient. Each encounter will have a unique binary outcome representing whether the patient’s lidocaine levels were toxic or within normal range. Data collected will be compared to
assess which predictors significantly influence toxic lidocaine levels. This study was approved by the healthcare system Institutional Review Board.

Poster Title: Does pharmacist-driven nasal swab methicillin-resistant Staphylococcus aureus (MRSA) PCR screening decrease time to de-escalation of MRSA coverage in patients with pneumonia?

Primary Author: Anthony Putich, Intermountain Healthcare McKay-Dee Hospital, UT; Email: anthony.putich@imail.org

Additional Author(s):
Dustin Waters

Purpose: Vancomycin is frequently used as empiric therapy in patients with pneumonia. MRSA nasal PCR screening, with a high negative predictive value for MRSA in pneumonia, can assist in de-escalation of MRSA coverage in patients with pneumonia. Recently, a protocol was implemented to allow pharmacists to order the PCR in pneumonia patients and de-escalate MRSA coverage following a negative test result. The objective of this study is to evaluate the impact on time to de-escalation of MRSA coverage in pneumonia by a pharmacist-driven nasal MRSA PCR testing protocol as compared to standard of care.

Methods: Intermountain McKay Dee Hospital’s electronic medical record system will be used to identify patients 18 years and older with a diagnosis of pneumonia who had empiric MRSA coverage (vancomycin or linezolid) initiated for pneumonia. Exclusions include cystic fibrosis, nasal mupirocin on medication history, patients receiving MRSA coverage for any other indication, and vulnerable populations including pregnant women, prisoners, and Intermountain employees. The following data will be collected through chart review: age, gender, birth date, pneumonia ICD9 codes and equivalent, allergies, admission and discharge dates, concurrent disease states, home medications, nasal MRSA PCR with results, chest x-rays, vancomycin troughs, initiated and discontinued times of antibiotics, blood/respiratory culture and susceptibilities, BMP, CBC, and vitals. Time to de-escalation will be calculated from the time of order placement to order discontinuation of linezolid or vancomycin. The difference in time to MRSA de-escalation will be compared from pre-pharmacist driven MRSA nasal swab protocol time (10/01/12 to 02/28/2013) to during pharmacist-driven MRSA nasal swab protocol time (10/01/2016 to 02/28/2017) to evaluate the effectiveness of pharmacist-driven MRSA nasal PCR screening in time to de-escalation. Additional outcomes will be the incidence of
nephrotoxicity, as defined as an increase in creatinine of 0.5 mg/dL or a 50% reduction in creatinine clearance, and number of patients restarted on MRSA therapy following pharmacist discontinuation.

**Poster Title:** Diuretic efficacy of the co-administration of albumin and furosemide in cirrhotic patients

**Primary Author:** Lauren Flieller, Intermountain Medical Center, UT; **Email:** lauren.flieller@imail.org

**Additional Author (s):**
Debra Ramirez
Sarah Yost
Lance Lindberg

**Purpose:** There is little data and no current guideline recommendations regarding the use of albumin in combination with loop diuretics as a method of diuresis in cirrhotic patients. Because albumin is a colloid, the theory is that the oncotic gradient will pull the extravascular fluid into the vasculature which will lead to greater diuretic efficacy of furosemide. The objective of this study is to assess the diuretic efficacy of intravenous furosemide-albumin combination therapy compared to intravenous furosemide without albumin specifically in cirrhotic patients.

**Methods:** This IRB-approved study is a retrospective electronic medical record (EMR) chart review of data mined from the Help1™ and Help2™ systems from November 1, 2007 to September 30, 2015. The two comparison groups are furosemide without albumin for diuresis and the combination of furosemide and albumin for diuresis. Only cirrhotic patients will be included and will be defined based on at least two overlapping International Classification of Disease, Ninth revision (ICD-9) coding diagnoses that incorporate sequelae of end stage liver disease. Exclusion criteria are defined as diagnoses that may complicate the evaluation of diuresis such as nephrotic syndrome, chronic kidney disease and heart failure. The primary outcomes will be urine output within 8, 12 and 24 hours after the initial dose of diuretic and weight loss within 24 hours of the initial dose. Secondary outcomes will include hospital length of stay and need for abdominal paracentesis. Baseline differences between groups will be mitigated with the use of a propensity score and/or logistic regression including variables associated with the receipt of albumin, such as age, sex, and MELD score. The following data will be collected: BUN, AST/ALT, albumin level, total bilirubin, INR, urine output, diuretic
administration and doses, albumin administration and doses as well as fluid intake. All data will be recorded without patient identifiers and maintained confidentially.

**Results:** N/A

**Conclusion:** N/A
**Poster Title:** Antithrombotic use for acute ischemic stroke secondary to infective endocarditis and the risk of major hemorrhage: a multi-center retrospective cohort study

**Primary Author:** Joshua Jacobs, Intermountain Medical Center, UT; **Email:** josh.jacobs@imail.org

**Additional Author (s):**  
Jenna Negrelli  
Neil Rosenberg  
Gabriel Fontaine

**Purpose:** Infective endocarditis (IE) can lead to cerebrovascular complications (CVCs), such as mycotic aneurysms and acute ischemic strokes (AIS). The use of antithrombotic therapy for secondary prevention in IE patients with AIS is controversial, however. Some literature suggests hemorrhagic complications increase when antithrombotics are used, while other studies found antithrombtics beneficial in preventing AIS. Ultimately, the risk/benefit ratio of antithrombotic therapy in IE patients with AIS is not well defined. This retrospective cohort study will further elucidate the risk of hemorrhagic complications in patients with IE and AIS receiving antithrombotic versus no antithrombotic therapy.

**Methods:** This will be a retrospective cohort study conducted within Intermountain Healthcare (IHC) inpatient, acute care hospitals between November 1, 2007 and September 30, 2015. Data will be retrieved using electronic medical records and manual chart review. We aim to determine the risk of hemorrhagic complications in IE patients with AIS receiving antithrombotic vs. no antithrombotic therapy for secondary prevention of AIS. Patients admitted with AIS secondary to IE as defined by relevant International Classification of Diseases, Ninth Revision coding and subsequent manual chart review will be included. The primary outcome will be incident in-hospital major bleeding, defined as fatal bleeding, bleeding into a critical organ space, or bleeding requiring ≥2 units packed red blood cells. Secondary outcomes will include the incidence of minor bleeding, major or minor bleeding, all-cause mortality, and subsequent CVCs. Additional variables including microbiology, imaging, left-sided vs. right-sided IE, native vs. prosthetic valve involvement, pertinent lab values, APACHE (Acute Physiology and Chronic Health Evaluation) II score, Charlson comorbidity index score, history of
CVC, previous use of antithrombotic medications, age, timing of antithrombotic use, and intensive care unit medication use will be incorporated into a multiple logistic regression and/or propensity score to analyze their impact on major bleeding. Institutional Review Board approved this study via expedited review.

**Poster Title:** Acute kidney injury in the setting of hyperchloremia in patients with traumatic brain injury

**Primary Author:** Alina Kurita, Intermountain Medical Center, UT; **Email:** akurita7@gmail.com

**Additional Author(s):**
Stephanie Chauv
Quang Hoang
Margaret Baldwin
Sarah Majercik

**Purpose:** There are reports of acute kidney injury (AKI) from hyperchloremia-induced vasoconstriction of the renal tubules. The association has been examined in septic and post-surgical patients, however, the data in trauma patients is limited, specifically in traumatic brain injury (TBI). The purpose of this study is to examine the association of hyperchloremia from hypertonic saline administration and the incidence of AKI in adult patients with TBI.

**Methods:** This will be a single-center, retrospective cohort study and has been submitted to the Institutional Review Board for approval. Patients with TBI admitted to the intensive care unit who received hypertonic saline will be identified through the Trauma Registry and Enterprise Data Warehouse. Patients will be excluded if the following are met: Cockcroft-gault creatinine clearance of < 50 mL/min on admit (within first 24 hours), AKI on admission (within first 24 hours) defined as more than two-fold increase in serum creatinine, glomerular filtration rate decrease by >50%, or urine output < 0.5 mL/kg/hr for >12 hours, and history of chronic kidney disease documented in patient chart. Cohorts are defined by the degree of hyperchloremia: mild (110-119 mEq/L), moderate (120-129 mEq/L), and severe (>130 mEq/L), which will be determined based upon peak chloride levels within a 10-day period after initial onset of injury. The primary outcome is the incidence of AKI as defined by RIFLE criteria within 7 days after peak chloride level. Secondary outcomes include identifying risk factors associated with AKI by collecting demographic information, comorbidities, concurrent nephrotoxic medications and/or contrast given, concurrent infection, vasopressor exposure, and additional therapies such as blood transfusion, drain placement, invasive mechanical ventilation, and operating room
interventions. Secondary outcomes include the need for renal replacement therapy from the AKI-induced hyperchloremia during admission.

Poster Title: Comparison of extended interval and conventional gentamicin dosing protocols on renal function in preterm neonates born less than 30 weeks

Primary Author: Dylan Nelson, Intermountain Medical Center, UT; Email: dylan.nelson@imail.org

Additional Author(s):
Danielle Scott
Elizabeth O'Brien
Shannon Inglet
Whitney Buckel

Purpose: Critically ill patients admitted to the newborn intensive care unit (NICU) are often administered gentamicin because of its effectiveness in neonatal sepsis. In 2014, our institution implemented an extended-interval dosing protocol to standardize dosing regimens, decrease time to target concentrations, and minimize phlebotomy losses. Since implementation, a trend toward decreased renal function has been observed anecdotally in our extremely low-birth weight infants. This study aims to evaluate renal function in NICU patients born < 30 weeks gestation who received gentamicin at conventional doses compared with extended-interval doses within 24 hours of life.

Methods: This retrospective, single-center, cohort study was approved by our Institutional Review Board. Our review will include all subjects born at < 30 weeks gestation who received at least one dose of gentamicin within 24 hours of life during two specific time periods. Infants born January 1, 2013, through December 31, 2013, received conventional gentamicin dosing, and will be compared with infants who received extended-interval dosing born January 1, 2015, through December 31, 2015. Subjects diagnosed with hypoxic-ischemic encephalopathy (HIE) or subjects with congenital or anatomical renal abnormalities will be excluded. The primary endpoint is comparing the impact of extended-interval with conventional gentamicin dosing on renal function. Secondary endpoints include modifications to protein intake and the incidence of changing from gentamicin to alternative therapy. Renal function will be determined by changes in serum creatinine, blood urea nitrogen, and urine output for a period of 96 hours.

Poster Title: Safety and effectiveness of apixaban versus warfarin in patients with severe renal dysfunction

Primary Author: Kyle Malhotra, Intermountain Medical Center, UT; Email: kyle.malhotra@imail.org

Additional Author(s):
Jenna Negrelli
William Dominic

Purpose: There is an overall lack of data assessing apixaban use in patients with severe renal dysfunction. Large randomized controlled trials assessing apixaban versus warfarin excluded patients with a SCr > 2.5 mg/dL and/or CrCl < 25 mL/min. This study will evaluate apixaban’s safety and effectiveness compared to warfarin in patients with severe renal dysfunction.

Methods: This is a multi-center retrospective review. Adult patients were enrolled if they were seen at an Intermountain Healthcare (IHC) facility between December 28, 2012 and August 23, 2015, had severe renal dysfunction defined as SCr > 2.5 mg/dL and/or CrCl < 25 mL/min, and were prescribed either apixaban or warfarin for therapeutic anticoagulation. Patients with a bleeding incident secondary to trauma, who had a bleeding incident during hospitalization after having received a dose of both apixaban and warfarin, or who were diagnosed with liver failure were excluded. The primary outcome was clinically relevant bleeding, defined as any bleeding event requiring an emergency department visit or inpatient admission. Secondary outcomes assessed were thrombotic events (deep vein thrombosis, pulmonary embolism, or stroke), minor bleeding events, and major bleeding events. Patients will be assessed for at least one year after enrollment. Events will be evaluated throughout the study period and reported as annualized event rates. This study was approved by IHC’s Institutional Review Board.

Poster Title: Ketamine for refractory and super-refractory status epilepticus
Primary Author: Michelle Adamczyk, Intermountain Medical Center, UT; Email: michelle.adamczyk@imal.org
Additional Author(s):
Neil Rosenberg
Amie Quinones
Gabriel Fontaine

Purpose: Ketamine is an N-methyl-D-aspartate (NMDA) receptor antagonist, used for a variety of indications including depression, sedation, and seizure cessation. Due to its unique mechanism of action, ketamine has been used in conjunction with GABA-ergic antiepileptic drugs and anesthetics in refractory and super-refractory status epilepticus (R/SRSE). There are a paucity of studies comparing the relative effectiveness of ketamine in patients with R/SRSE, however. The purpose of this study is to evaluate the effectiveness of R/RSRE regimens with and without ketamine within the Intermountain Healthcare System.

Methods: This will be a retrospective cohort study of patients diagnosed with R/SRSE receiving at least one antiepileptic anesthetic infusion within Intermountain Healthcare (IHC) between November 1, 2007 and August 31, 2016. Eligible patients will be identified via electronic medical records using International Classification of Diseases, Ninth and Tenth Revision (ICD-9/10) codes and medication administration records. The following demographic and outcomes data will be collected: patient age, gender, weight, height, primary admit diagnosis, outpatient medications, pertinent past medical history, social history, and laboratory values upon admission and throughout hospitalization such as creatinine phosphokinase, triglycerides, and basic metabolic panels, Charleston Comorbidity Index, APACHE II score, Glasgow Coma Scale (GCS) score, vital signs, vasopressor use, electroencephalogram (EEG) report findings, hospital and intensive care unit (ICU) lengths of stay, duration of mechanical ventilation, duration of status epilepticus prior to and following ketamine administration, duration of antiepileptic infusions, and antiepileptic medications utilized. The primary endpoint will be the time to the first 24-hour period free of all continuous sedative or antiepileptic infusions in subjects receiving ketamine versus no ketamine as part of their R/SRSE treatment regimen. Secondary
endpoints include mortality, total number of antiepileptic drugs used, ICU-free and mechanical ventilation-free days, frequency of subjects requiring vasopressors, presence of hemodynamic derangements and discharge disposition. The study is currently undergoing expedited review by the IHC Institutional Review Board.

Poster Title: Assessing time to coronary artery bypass grafting (CABG) in ST-elevation myocardial infarction (STEMI) patients

Primary Author: Klayton Ryman, Intermountain Medical Center, UT; Email: klay.ryman@imail.org

Additional Author(s):
Jenna Negrelli
Stephanie Chauv
Crosby Oldham

Purpose: Ideally coronary artery bypass grafting (CABG) is delayed 5-7 days after administration of a P2Y12 inhibitor. However, loading doses are required for patients that undergo percutaneous coronary intervention (PCI). A minority of ST-elevation myocardial infarction (STEMI) patients undergo CABG, yet administration of P2Y12 inhibitors is commonly held until coronary anatomy is known. The study aims to assess the average time from hospital arrival to CABG in STEMI patients not receiving a P2Y12 inhibitor loading dose, which will help elucidate if this time is clinically different than the delay in CABG that would be ideal if a P2Y12 inhibitor was given.

Methods: This study is a multi-center, retrospective electronic medical record review. Patients at least 18 years of age admitted from October 29, 2007 to September 30, 2015 with STEMI requiring CABG will be included. Patients that underwent PCI, received thrombolytic therapy, or took P2Y12 inhibitors outpatient will be excluded. The Intermountain Healthcare electronic database warehouse and The Society of Thoracic Surgeons database will be used to identify patients who have been admitted for STEMI and subsequently went to CABG. The primary endpoint is time to CABG from hospital admission. Secondary endpoints include incidence of major bleeding, length of hospital stay, length of intensive care unit stay, and 30–day mortality. Subset analyses will assess secondary end points in regard to how long patients waited to go to CABG as well as time to CABG in patients who received a loading dose of P2Y12 inhibitor compared to those patients who did not. This study has been submitted to the institutional review board for approval.

Poster Title: Influenza infection and the risk of thromboembolic events in critically ill patients

Primary Author: Ruixin Shi, Intermountain Medical Center, Intermountain Healthcare. Murray, UT, UT; Email: ray.shi@imail.org

Additional Author(s):
Gabriel Fontaine
Stephanie Chauv
Nathan Grossman
Peter Crossno

Purpose: The influenza A/H1N1 outbreak in 2009 became the first pandemic of the 21st century. Since the emergence of the pandemic H1N1, reported cases of severe influenza infections and requirement of intensive care unit (ICU) hospitalization have increased. Potentially higher rates of thromboembolism have also been reported in these patients. The purpose of this study is to determine whether critically ill patients with influenza infections have a higher incidence of 30-day thromboembolic events (TE) compared to those with non-influenza respiratory viral infections. The study also aims to identify specific risk factors associated with the development of TE.

Methods: This study is a retrospective, multicenter cohort compiled using electronic medical records and chart review of patients admitted with respiratory viral infections and spending greater than 24 hours in an ICU within Intermountain Healthcare, from November 1, 2007 to August 23, 2016. Patients who are pregnant, receiving therapeutic anticoagulation within 48 hours of admission, presenting with TE or trauma/surgery within 7 days prior to or following admission, and previously diagnosed thrombophilia are excluded. The primary endpoint is 30-day incident TE, compared between those diagnosed with influenza versus non-influenza respiratory viral infections. Presence of influenza infection is identified via positive lab findings of real-time reverse transcriptase polymerase chain reaction (PCR) tests or influenza antigen testing. Non-influenza respiratory infections is identified through respiratory film array PCR. TE includes deep vein thrombosis, pulmonary embolism, acute ischemic stroke, acute myocardial infarction, and arterial thrombosis, identified using a combination of Natural Language Process and ICD-9/10 codes cross referenced with manual chart review for confirmation. Additional
subgroup analysis will compare 30-day incident TE between 2009 H1N1 influenza A and other respiratory viral infections. Multiple logistic regression and/or propensity score will use the following additional variables for TE risk evaluation: age, sex, co-infection, disease severity, estrogen therapy, obesity, previous TE, mechanical ventilation, length of ICU stays, chemoprophylaxis, and presence of central venous catheters. Institutional Review Board expedited review is currently pending.

Poster Title: Effect of amlodipine on calcineurin inhibitor induced renal dysfunction following allogeneic hematopoietic stem cell transplantation

Primary Author: Ryan Jensen, LDS Hospital (Intermountain Healthcare), UT; Email: ryan.jensen@imail.org

Additional Author(s):
Regan Healy
Clyde Ford
Berrie Child
Jacob Majers

Purpose: Calcineurin inhibitors are widely used immunosuppressive medications for the prevention of graft-verse-host disease following allogeneic hematopoietic stem cell transplantation (allo-HSCT). Their use is associated with a high incidence of nephrotoxicity and hypertension. In renal transplantation, calcium channel blockers are hypothesized to prevent calcineurin inhibitor induced nephrotoxicity and have become standard treatment for hypertension. No study has evaluated their effect on renal function in the post allo-HSCT population. This study will evaluate the impact amlodipine, a calcium channel blocker, has on renal function in allo-HSCT patients receiving a calcineurin inhibitor.

Methods: The institutional review board has approved this study. Three hundred and sixty-two subjects who have undergone allo-HSCT between January 1, 2006 and August 31, 2016 have been identified for enrollment. Those under the age of 18 or undergoing repeat allo-HSCT have been excluded. Subjects will be placed into one of two groups based on whether or not they were treated with amlodipine. Amlodipine treatment must have begun prior to hospital discharge and continued for a minimum of two weeks. Subject data will be collected retrospectively and include one year from initiating amlodipine or until they fall out of their study group based on the following criteria: loss to follow up, calcineurin inhibitor discontinuation, death, or the date of August 31, 2016 is reached. Data will be collected from electronic medical records. Subject identifiers will be removed before data is analyzed. The data to be collected will include: patient age, gender, date of birth, weight, height, diagnosis related to transplant, serum creatinine levels, BUN levels, blood pressures, medications prescribed, and
dates of hospital admission, hospital discharge, and death. The primary outcome will be the mean change in serum creatinine over time. Hospitalization due to acute kidney injury will be a secondary end point. The following confounding variables will be accounted for: incidence of GVHD, supratherapeutic calcineurin inhibitor levels, use of nephrotoxic drugs, and blood pressure.

Poster Title: Rates of serious adverse events associated with targeted specialty therapies in the treatment of inflammatory diseases at a managed care plan: a historical claims analysis

Primary Author: Kyle Stirewalt, SelectHealth, UT; Email: kyle.stirewalt@unmc.edu

Additional Author(s):
Natalia Ruiz-Negrón
Cody Ball
Brandon Bellows

Purpose: While effective in treating inflammatory conditions, targeted specialty therapies have been associated with serious adverse events (SAEs) requiring hospitalization. The primary objective is to compare the rates of SAEs among specialty therapies used to treat immune-mediated inflammatory diseases (IMIDs) in a managed care population. Secondary outcomes include discontinuation rates due to SAEs and the difference in rates of SAEs among patients taking specialty therapies with or without conventional systemic therapies.

Methods: This historical claims analysis, approved by the institutional review board, includes patients at least 2 years of age with an ICD-9 or ICD-10 diagnosis code of a select IMID (i.e., ankylosing spondylitis, Crohn’s disease, juvenile idiopathic arthritis, psoriasis, psoriatic arthritis, rheumatoid arthritis, ulcerative colitis) between 7/1/2009 and 6/30/2016. Patients must have a pharmacy or medical claim for a specialty therapy (i.e., tocilizumab, certolizumab, secukinumab, etanercept, vedolizumab, adalimumab, anakinra, abatacept, infliximab, golimumab, ustekinumab, ixekizumab, apremilast, tofacitinib) between 7/1/2010 and 6/30/2015, with the index date defined as the first specialty claim. Patients must also be continuously enrolled in the plan for at least 1 year prior to and after the index date. Baseline characteristics will be reported using descriptive statistics. Unadjusted SAE incidence rates and associated discontinuation rates in the post-index period will be compared using a one-way analysis of variance. Pairwise comparisons between specialty therapies will be calculated using t-tests applying a Bonferroni correction to account for multiple comparisons. Post-index SAE incidence rate ratios will be compared using a zero-inflated negative binomial regression while controlling for potential confounders. Finally, an analysis will be conducted to investigate the
difference in rates of SAEs between patients with and without concurrent conventional systemic therapies in the post-index period using independent t-tests.

Poster Title: Medication utilization evaluation of eptifibatide at a community hospital in Salt Lake City, Utah

Primary Author: Leila Khurshid, St. Mark’s Hospital, UT; Email: leila.khurshid@mountainstarhealth.com

Additional Author (s):
Lisa Arrigo

Purpose: Eptifibatide blocks the platelet glycoprotein IIb/IIIa receptor and reversibly blocks platelet aggregation, preventing thrombosis. It is indicated in the treatment of ACS for patients undergoing PCI or in the setting of elective PCI and often used off-label to support PCI during STEMI when administered at the time of primary PCI. Use of this medication can result in increased bleeding and have a substantial financial impact on the patient and the health system. The purpose of this retrospective medication use evaluation is to characterize eptifibatide use at St. Mark’s Hospital and to evaluate optimal, safe, and cost effective treatment of patients.

Methods: All patients who received eptifibatide therapy at St. Mark’s Hospital from January 1 to September 30, 2016 were evaluated for age, weight, renal function, location of treatment initiation, dose, time of administration, duration of therapy, indication, concurrent therapy and time of its administration, change in hemoglobin, route of administration, and type of closure device. In addition, lengths of hospital stay and discharge disposition were collected. Data was accessed using electronic medical records and information was collected using a standardized data collection form. The data was subsequently analyzed to determine rates of bleeding and cost to the institution. Bleeding rate was defined as ≥ 3 g/dL decrease in hemoglobin from baseline or documented hematoma. Using this information, a recommendation for optimal, safe, and cost effective treatment of patients was formulated.

Poster Title: Creation and implementation of a new chemotherapy training program with policies and procedures specifically designed to ensure staff competence in accordance with USP.

Primary Author: Darren Seegmiller, St. Mark's Hospital, UT; Email: darren.seegmiller@gmail.com

Additional Author(s):
Darrin Cutler
Chelane Phillips

Purpose: A comprehensive chemotherapy training program does not currently exist at St. Mark’s Hospital. It is critical that pharmacy staff who handle these drugs be informed of risks and thoroughly trained to safely prepare these agents using proper aseptic technique. This project is intended to provide a comprehensive chemotherapy training program that will prepare our institution for the implementation of standards set by USP Chapter < 800>. The goal of implementing a new chemotherapy training program is to build employee confidence and knowledge to safely and effectively compound chemotherapy agents.

Methods: The current model for chemotherapy training at St. Mark’s Hospital consists of a one-on-one demonstration only presentation performed by a designated pharmacist. A comprehensive training program will be established for all pharmacy staff which will include both written and audio/video presentations in addition to the standard one-on-one demonstration. It will also include the addition of final testing and an assessment of the new training program. Each trainee will receive the current standard training followed by an assessment comprised of a hands-on proper technique test, competency quiz, and survey to assess confidence. Trainees will then receive the new comprehensive training followed by the same assessment received after the standard training. The results from each training technique will then be compared to measure improvements in competency and confidence in compounding chemotherapy agents.

**Poster Title:** Evaluating the impact of pharmacist led intervention(s) in patients with COPD

**Primary Author:** Caroline Droste, Appalachian College of Pharmacy, VA; Email: cdroste@acp.edu

**Additional Author(s):**
Michael Justice
Crystal Phillips
Benjamin Price

**Purpose:** Chronic Obstructive Pulmonary Disease (COPD) has remained the 4th major cause of death for the past decade. Central Appalachia is abundant with coal miners and moderate to strong increases in mortality from COPD, primarily in the elderly population. Pharmacists can play a pivotal role in managing COPD in the outpatient setting. Implementing spirometry testing in the community setting and evaluating patient education and adherence can lead to better disease management, fewer hospitalizations, and improved overall quality of life. This study will determine if pharmacists’ interventions including patient counseling, medication management, spirometry testing, and adherence encouragement improve outcomes related to COPD.

**Methods:** This study is currently pending Institutional Review Board approval. Patients at two independent pharmacies and a free clinic in Central Appalachia, will conduct a patient assessment survey to determine baseline COPD knowledge and correct inhaler technique. Additionally, a spirometry reading will be conducted at the primary visit to determine the current stage of COPD and correct medication regimen based on the Global Initiative for Chronic Obstructive Lung Disease (GOLD) guidelines. Subjects will be seen every 30 days to assess adherence, inhaler technique, spirometry data, and symptoms/exacerbation changes. If patients are unable to be seen every 30 days, patients will be assessed over the phone to obtain as much information as possible related to adherence, symptoms, exacerbations, and technique. Finally, the subject will complete a final spirometry reading and retake the patient assessment survey.

Data will be collected on patient demographics, number of medications, classification/severity of COPD, FEV1/FVC ratio, Peak flow reading, knowledge of disease state, number of missed
doses, number of errors in inhaler technique, and number of time patient has been hospitalized for acute COPD exacerbation in the past year. Statistical analysis will be performed using chi square and logistic regression analysis.

**Poster Title:** Effect of Community Pharmacy Outreach on Immunization Rates in Rural Central Appalachia

**Primary Author:** Travis Garrett, Appalachian College of Pharmacy, VA; **Email:** tgarrett@acp.edu

**Additional Author(s):**
Michael Justice
Emily Rourk
Crystal Phillips

**Purpose:** The influenza virus is responsible for many hospitalizations and deaths each year. According to the CDC the best method of prevention against influenza is vaccination. Healthy People 2020’s goal for non-institutionalized adults aged 18 to 64 years who are vaccinated annually against seasonal influenza is 80%. The 2010-2011 influenza season reported a baseline immunization rate of 24.9%. Community pharmacists are in an ideal position to increase immunization rates. Determining the optimal mode of outreach will allow pharmacists to increase immunization rates at a higher level of efficiency.

**Methods:** Annual influenza immunizations will be encouraged to patients through various modes of outreach including social media, flyers, pamphlets, posters, pharmacist consultation, word of mouth, and flu clinics. Any patient offered an influenza vaccination will be asked to complete a short questionnaire. Telephone offers will be conducted and document by pharmacy representatives. A declination of either vaccine or questionnaire will be recorded as refused for both groups. Each patient motivated to receive immunization will be screened to ensure immunization is appropriate and all necessary documentation (pre-screening questionnaire, consent to vaccination, and Vaccine Information Sheet or VIS) will be reviewed and collected prior to immunization. Influenza immunizations will be administered by either pharmacists, student pharmacists, or other approved healthcare providers at an independent pharmacy in Wise, VA. After immunization, each patient will complete a set of surveys/questionnaires obtaining information on motivating factors, preferences for future vaccinations, and an open comment section. If a patient is unable to complete a questionnaire, assistance will be provided by a representative in the form of reading or documenting answers.
Effectiveness of flu clinics will be evaluated by completion of questionnaires from participants at locations where this is already standard practice and already provided.

Poster Title: Retrospective evaluation of the use of dulaglutide in an outpatient family practice setting

Primary Author: Melissa Morris, Bernard J. Dunn School of Pharmacy, Shenandoah University/Collaborative Ambulatory Care Clinics, VA; Email: mmorris12@su.edu

Additional Author(s):
Dawn Havrda
Michelle Rager

Purpose: The purpose of this study is to evaluate the efficacy and tolerability of dulaglutide in Type 2 diabetics within an outpatient family practice setting. The objectives of the study are to determine the percentage of hemoglobin A1c reduction prior to starting dulaglutide compared to every 3, 6, 9, and 12 months following initiation; to evaluate tolerability of dulaglutide, including the rate of discontinuation due to adverse effects; to determine the number of patients who reached their individualized hemoglobin A1c goal on dulaglutide therapy; to determine when in therapy dulaglutide was initiated.

Methods: A retrospective chart review will be conducted at a physician group practice in Winchester, Virginia. A list of patients prescribed dulaglutide before July 1, 2016 will be generated from querying the electronic health record at the practice. The study will include established patients at the practice who are at least 18 years of age, have a diagnosis of Type 2 diabetes, and are currently taking one or more oral diabetes medications. Exclusion criteria include patients who have not been on dulaglutide for greater than 3 months or have not had a 3-month hemoglobin A1c lab value since initiation of dulaglutide therapy. Eligible patients’ electronic medical record will be reviewed to collect information regarding demographics, details of diabetes diagnosis and medication therapy, lab values, and documented intolerances or adverse effects from related therapy. This study has been submitted to the institutional review board.

**Poster Title:** Evaluation of echinocandin use in a community hospital

**Primary Author:** Briana Ferebee, Bon Secours Memorial Regional Medical Center, VA; **Email:** briana_ferebee@bshe.org

**Additional Author(s):**
Emily Roth

**Purpose:** Echinocandins are frequently used for the treatment of patients with suspected invasive candidiasis. Per Infectious Diseases Society of America guidelines, echinocandins are recommended as first line agents; however, fluconazole is a suitable alternative in patients who are not likely to have Candida resistant to azoles or in patients who are not critically ill. The purpose of this study is to evaluate the appropriateness of echinocandin use at a community hospital and whether prescriber pre-emptive treatment for Candida is warranted.

**Methods:** This is a retrospective, single center, chart review of patients who were initiated on an echinocandin in a community hospital from January 1, 2016 to June 30, 2016. The primary outcome is the percent of patients initiated on an echinocandin who grew azole-resistant species of Candida. Secondary outcomes include the percent of patients initiated on an echinocandin who grew systemic Candida and the percent of patients initiated on an echinocandin who had risk factors for candidiasis. Data to be collected include: age, gender, risk factors for candidiasis (receiving parental nutrition, recent abdominal surgery, anastomotic leaks, necrotizing pancreatitis, central venous catheter use, high risk comorbidities including renal disease or dialysis, immunosuppression, human immunodeficiency virus, or malignancy), prior exposure to azole antifungals, exposure to broad spectrum antibiotics, or history of resistant fungal infection. Additional data to be collected include culture type, Candida species and susceptibilities, patient location in hospital (ICU versus non-ICU), ordering provider, and whether an infectious disease consult was placed. This study is exempt from the Institutional Review Board as it is a retrospective study evaluating medication use and will only serve for quality improvement measures.

Poster Title: Total body weight dosing versus ideal body weight dosing of intravenous immunoglobulin

Primary Author: Maria Leusink, Bon Secours Memorial Regional Medical Center, VA; Email: maria_leusink@bhsi.org

Additional Author(s):
Marshall Pierce

Purpose: The American Academy of Allergy Asthma and Immunology does not have a clear guideline on whether to use ideal body weight (IBW) or total body weight (TBW) with regards to dosing intravenous immunoglobulin. Our institution has recently changed from total body weight based dosing to ideal body weight based dosing. The objective of this medication use evaluation is to identify the impact of the implemented weight based dosing change on patients and pharmacy budget by focusing on clinical responses.

Methods: IRB approval is not necessary for this medication use evaluation. Electronic medical record system will be used to retrieve patients who received intravenous immunoglobulin 9 months before and after the implementation of weight-based dosing change. Microsoft Office Excel will be used for data collection and analysis. All patients will be de-identified and kept confidential as required by HIPAA. Patient demographic information will be collected, such as age, sex, race, height, and weight. For patients who are 60 inches or taller, IBW will be calculated as 50 kg plus (2.3 times height in inches over 60) for males and 45.5 kg plus (2.3 times height in inches over 60) for females. Demographic information will be analyzed using descriptive statistics. Clinical responses will be determined by collecting reported administration frequency, adverse reactions, pre-dose IgG levels, infection rate, and admission rate. These data will be analyzed using t-test and chi-square. Lastly, cost analysis will be conducted to estimate the cost-savings from using IBW dosing.

**Poster Title:** Arformoterol use as part of an inhaler to nebulizer interchange protocol at a community hospital

**Primary Author:** Justin Hair, Bon Secours Memorial Regional Medical Center, VA; **Email:** hair.justin@gmail.com

**Additional Author (s):**
Emily Roth

**Purpose:** In 2015, arformoterol was added to the Bon Secours St. Mary’s Hospital formulary for use in an inhaler to nebulized medication interchange. This interchange specifies that arformoterol is to be used in place of the long acting beta-agonist (LABA) component of inhalers and will be automatically substituted by a pharmacist during order verification. The purpose of this medication use evaluation is to determine if prescribing of arformoterol coincides with the pharmacy and therapeutics (P&T) committee approved use as part of the inhaler to nebulizer interchange.

**Methods:** Patients who were prescribed arformoterol will be identified for chart review using the electronic health record. The primary endpoint is the percent of arformoterol orders that adhere to the P&T-approved criteria for use. The secondary endpoints are the total number of arformoterol administrations that did not meet P&T approved criteria and the estimated cost savings if nebulized albuterol would have been used in place of arformoterol. The following data will be collected during chart review: patient age, gender, ethnicity, ordering provider, whether a LABA was prescribed prior to admission, indication for LABA, the number of arformoterol doses received, and whether a LABA was continued at discharge. Patients age 18 years and older with orders for arformoterol between May 1, 2016 to August 30, 2016 will be considered for inclusion. Patients will be excluded if arformoterol is discontinued before any doses are given. Data will be de-identified and collected in a password protected Microsoft Excel file. Descriptive statistics will be used to analyze the results of this medication use evaluation. IRB approval is not necessary for this study as it does not constitute human subjects research.

**Poster Title:** Evaluation of the utilization of opioids, benzodiazepines, and muscle relaxant combination therapy for the geriatric population in the primary care setting

**Primary Author:** Thu Thuy Tran, Bon Secours Memorial Regional Medical Center, VA; **Email:** thuthuy_tran@bshsi.org

**Additional Author (s):**
Kerri Musselman

**Purpose:** In mid-March, the Centers for Disease Control and Prevention’s (CDC) chronic pain management guideline highlighted the need to avoid co-prescribing of opioids, benzodiazepines, and muscle relaxants whenever possible. Patients on this combination therapy are at an increased risk for adverse drug events such as central nervous system depression, over-sedation, falls, opioid-induced constipation, and fatal respiratory depression. This study aims to evaluate how the concurrent utilization of these classes affects the geriatric patients, the incidence of subsequent adverse events, and whether primary care providers are implementing the CDC’s guideline into practice.

**Methods:** This retrospective chart review will examine all patients greater or equal to 65 years of age, within the Bon Secours Medical Group (BSMG) practices, who are prescribed an opioid, benzodiazepine, and/or muscle relaxant, from April 1st to August 31, 2016, for the presence of adverse event documentation. The targeted adverse events will be reports of falls, orthostatic hypotension, complaints of gastrointestinal discomfort requiring medication management, and emergency department visit or hospitalization. Three BSMG practice sites will be included in this study, Laburnum Medical Center, Patterson Avenue Family Practice, and Memorial Medical Center. The following data queries will be collected: patient’s age, gender, practice site, blood pressure readings, related medication name(s), recent addition of gastrointestinal agents for medication-induced constipation, and number of hospitalization or emergency room visits. The data will be de-identified and stored in a password-protected, network shared drive. The investigators will evaluate if an adverse event occurred after the initiation of the targeted pharmacological class combination therapy.

Poster Title: Retrospective analysis of unfractionated heparin use in patients with percutaneous ventricular assist devices

Primary Author: Jenna Dietrich, Carilion Roanoke Memorial Hospital, VA; Email: jenna.n.dietrich@gmail.com

Additional Author(s):
Hasan Kazmi

Purpose: Impella pumps are percutaneous left ventricular assist devices used for cardiogenic shock and ST-elevation myocardial infarction. These devices require heparinized purge solution to prevent pump thrombosis. The Impella manufacturer now recommends using a less viscous, 5% dextrose solution as the diluent instead of 20% dextrose, which may result in higher purge flow rates, infusion volumes, and heparin exposure. This may place patients, especially those with low body weight, at increased risk of bleeding events. Additionally, increased heparin exposure may necessitate decreasing the heparin concentration in the purge solution. Using multiple concentrations of a high-risk medication may introduce potential medication errors.

Methods: This study will be submitted to the Institutional Review Board for approval. This is a single center retrospective cohort analysis of patients on Impella pumps who received heparinized purge solution from January 2014 through September 2016. Exclusion criteria include patients who had the Impella discontinued prior to obtaining an activated partial thromboplastin time (aPTT) and patients receiving a direct thrombin inhibitor. The primary outcome will evaluate the number of patients with at least one supratherapeutic aPTT while receiving purge solution without systemic heparin. Secondary outcomes include the number of heparin concentration changes needed, as well as bleeding events and thrombotic events. Bleeding will be assessed based on the Bleeding Academic Research Consortium (BARC) definitions. Data collection points will include demographic information (age, weight, height and gender), past medical history, duration of Impella support, total number of heparin concentration changes in the purge solution, concentration of dextrose in the purge solution, rate of heparinized purge solution, rate of intravenous heparin, laboratory data (aPTT and hemoglobin), and adverse events (bleeding and thrombotic events).

**Poster Title:** Evaluation of appropriate total parenteral nutrition (TPN) use in the pediatric population

**Primary Author:** Caitlin Meanor, Carilion Roanoke Memorial Hospital, VA; **Email:** cpmeanor@carilionclinic.org

**Additional Author (s):**
Allison Graham
Lark Dunton
Susan Gladfelter
Robert Howitt

**Purpose:** Total parenteral nutrition (TPN) is initiated in pediatric patients who are unable to tolerate enteral feeds for a period of time or in anticipation of a lack of enteral feeding in the future due to bowel dysfunction. Many factors determine the appropriate use and continuation of TPN in pediatric patients, including indication, patient characteristics, and feeding status. TPN use may result in complications including cholestasis, electrolyte imbalances, and infection. The main goal of this investigation is to evaluate the appropriate use of pediatric TPN before and after implementation of a new pediatric TPN guideline in January 2015.

**Methods:** This medication use evaluation is a retrospective analysis of TPN data collected from the electronic medical record at Carilion Roanoke Memorial Hospital (CRMH). Information will be reviewed for pediatric patients from birth to 18 years old who received TPN from July 2013 to July 2016. Indication for use, patient characteristics, prescribing methods of TPN, and any complications will be collected. Specifically, the TPN order will be evaluated for appropriateness. Determination of the appropriate use will be based on ASPEN guidelines for pediatric TPN. The impact of the CRMH pediatric TPN guideline will also be evaluated. Descriptive statistics will be used to evaluate this data. All data will be recorded without patient identifiers.

Poster Title: Evaluation of antihypertensive medication use for patients requiring hemodialysis

Primary Author: Alexandra Greco, Carilion Roanoke Memorial Hospital, VA; Email: argreco@carilionclinic.org

Additional Author(s):
Morgan Oxley
Randi Earls
Ann Lucktong
Megan Goodwin

Purpose: The most common cause of adverse events related to hemodialysis is medication errors, with medication dose omissions being the most frequently reported. Missed doses may occur at various times throughout a patient’s hemodialysis therapy. Since hypertension affects approximately 86% of patients requiring hemodialysis, it’s imperative that optimal hypertensive treatment is provided for this population. Since most antihypertensive medications are dosed once daily, inappropriately holding medications in preparation for hemodialysis can prevent the patients from receiving their daily treatments. The main goal of this investigation is to evaluate antihypertensive medication use for patients requiring hemodialysis in a large community teaching hospital.

Methods: This is a retrospective medication use evaluation of information documented in the electronic medical record of a large community teaching hospital. Medical information will be evaluated for patients 18 years of age and older who have received hemodialysis. After the list of hemodialysis patients is generated, patient data from twenty-five random patients per month spanning January 1, 2016 to July 31, 2016 with a diagnosis of hypertension will be analyzed. Data to be collected includes: patient baseline demographics, antihypertensive medications prescribed, information related to the dialysis session, if the medications were held and reasons why, blood pressure measurements, and if the patient needed a rescue antihypertensive medication. The information that will be evaluated will reveal antihypertensive medication use in hemodialysis patients, and the outcomes will then be assessed to determine whether the antihypertensive medication was held with or without a physician’s order.

**Poster Title:** Evaluation of held scheduled insulin orders for appropriateness at a community teaching hospital

**Primary Author:** Clare McMahon, Carilion Roanoke Memorial Hospital, VA; **Email:** cpmcmahon@carilionclinic.org

**Additional Author(s):**
Emily Bailey
Meghan Kamrada
Bridgette Smigiel
Jennifer Wright

**Purpose:** Currently, patients with diabetes consist of 25-30% of adult hospitalized patients. When patients with diabetes are admitted to the hospital, glycemic control is crucial to their care. Various consequences of uncontrolled blood glucose include: hyperosmolar hyperglycemic state (HHS), diabetic ketoacidosis (DKA), impaired wound healing, end organ damage, and prolonged length of stay. By evaluating appropriateness of held scheduled insulin orders, this medication use evaluation can identify patterns and health consequences of inappropriately held insulin. In addition, this data will provide information for development of nursing education and optimization of medication administration record (MAR) documentation by nursing.

**Methods:** This medication use evaluation is a retrospective analysis of information documented in the electronic medical record at a large community teaching hospital. Medical information will be reviewed for patients who are 18 years of age and older with an order for scheduled subcutaneous insulin detemir, insulin aspart, insulin aspart protamine 70%/insulin aspart 30%, and neutral protamine Hagedorn (NPH) insulin between January 1, 2016 and February 1, 2016. Evaluated data will include baseline characteristics, held insulin order information, and clinical outcomes. Specific clinical assessment will include rebound hyperglycemia, anion gap reopening, and initiation of continuous insulin infusion. Held insulin is considered appropriate if there is documentation of communication between nurse and provider. Descriptive statistics will be used to describe the cohort of patients. Patient variables will be compared using Student’s t-test or Mann-Whitney U test for continuous variables. Fisher’s
exact test or Chi-Square will be used for categorical variables. Continuous data will be described using mean plus standard deviation or median (interquartile range, IQR) depending on the distribution of the data. All data will be recorded without patient identifiers. The institutional review board (IRB) categorized this review as a quality assurance/quality improvement activity exempt from IRB oversight.

Poster Title: Fidaxomicin as a first-line agent in the treatment of Clostridium difficile infection: a cost/benefit analysis

Primary Author: Angela Perhac, Carilion Roanoke Memorial Hospital, VA; Email: perhac@goldmail.etsu.edu

Additional Author(s):
Nathan Everson
Gus Stefanadis

Purpose: Clostridium difficile (C. diff) is the leading cause of infectious diarrhea in hospitals. Even with proper treatment, 20-30% of people have recurrent episodes. Fidaxomicin has been shown to reduce recurrence rates of infection, while providing similar efficacy to the current standard of care: oral vancomycin. Many institutions have not utilized fidaxomicin in treatment protocols due to increased cost of this medication compared to other options. The objective of this MUE is to determine whether the cost of using fidaxomicin first-line for treatment of initial or first recurrence of C. diff can be justified by reducing recurrence and admission rates.

Methods: This study will be a single-center, retrospective, descriptive analysis. Patients 18 years and older with a positive C. diff test admitted from September 2015 to September 2016 will be included. A positive C. diff test will be determined using our 2-step antigen and toxin test, with reflex PCR. The cost-effectiveness will be assessed using the cost of a 10 day course of fidaxomicin versus oral vancomycin or metronidazole and readmission costs for recurrent C. diff infection. We will estimate the reduction in readmissions based on reductions seen in previous literature and estimate cost savings based on the readmission costs for Carilion Roanoke Memorial Hospital. The data collected from patient’s charts will be as follows: age, sex, unit, prior antibiotics (dates used), length of stay, C. diff test results and dates (GDH antigen and toxin – PCR, if applicable), C. diff treatment (drug and dates), number of C. diff recurrences, degree of infection (mild, moderate, severe), concomitant systemic antibiotics, mortality (if applicable).

Poster Title: Vancomycin dosing in obese patients: effect of a BMI specific volume of distribution on serum levels

Primary Author: Shehrin Chowdhury, Centra Lynchburg General Hospital, VA; Email: shehrin.chowdhury@centrahealth.com

Additional Author(s):

Purpose: Vancomycin is one of the mainstay antibiotics used for a variety of systemic gram positive infections, particularly Methicillin-Resistant Staph. aureus. Available literature has analyzed use of adjusted body weight, decreased volume of distribution, and other pharmacokinetic parameter changes in obese patients, to achieve goal trough levels in the 10 to 20mg/L range. However, there is still no consensus on the most effective dosing strategy in obese patients. The purpose of this study is to observe the effect on initial trough levels using a BMI specific volume of distribution as compared to traditional methods for vancomycin dosing in obese patients.

Methods: The study was submitted and approved by the Institutional Review Board. Data collected during implementation of the new protocol will be between October 2016 to January 2017 and compared to retrospective data within the institution. Subject characteristics include intravenous vancomycin therapy for at least 4 to 5 half lives, age greater than or equal to 18 years, body mass index (BMI) greater than or equal to 30 kilogram/meters squared, and creatinine clearance greater than 30ml/min (using Cockroft-Gault). For the new protocol, a volume of distribution of 0.7L/kg will be used for BMI 30 to 39 kilogram/meters squared, and 0.5L/kg will be used for BMI greater than or equal to 40 kilogram/meters squared, calculated using patients total body weight. Attainment of initial trough levels within target range of 10 to 20 mg/L at steady state will then be assessed. Subsequently, the frequency of trough levels that are within range (10 to 20 mg/L), below range (less than 10 mg/L) and above range (greater than 20 mg/L) will be collected and analyzed. Incidence of nephrotoxicity, defined as a serum creatinine increase of 50 percent or greater from baseline, will also be assessed.

Poster Title: Evaluation of tolvaptan use in a four-hospital health-system

Primary Author: Jordan Cooler, Centra- Lynchburg General Hospital, VA; Email: jordan.cooler@centrahealth.com

Additional Author(s):

Purpose: Hyponatremia, defined as plasma sodium concentrations of less than 135 mEq/L, is considered the most common electrolyte disturbance in hospitalized patients. It can be further categorized as hypovolemic, hypervolemic, or euvolemic hyponatremia. Tolvaptan is a vasopressin antagonist approved to treat hypervolemic or euvolemic hyponatremia defined as plasma sodium less than 125 mEq/L or as plasma sodium 125-135 mEq/L with symptoms that is unresponsive to fluid restriction. Concern for safe and appropriate management of hyponatremia prompted review of tolvaptan use within Centra Health. Therefore the purpose of this retrospective review was to assess appropriate utilization of tolvaptan in treating hyponatremia.

Methods: All patients who received at least one dose of tolvaptan at any of the four Centra Health inpatient hospitals between September 2014 and September 2016 were included and assessed. Initial review began with collection of patient specific demographics. In order to evaluate that tolvaptan was used in the correct patient population, information regarding patient demographics, laboratory values such as serum sodium concentration, relevant past medical histories, and diagnoses documented by physicians were evaluated. To assess management of hyponatremia at different severity levels, data related to therapies utilized prior to tolvaptan was documented. Tolerability of tolvaptan was measured through physician documentation and pertinent lab values. Based on patient specific data points collected during chart review, determination of appropriate use of tolvaptan was documented in a binary fashion (appropriate or inappropriate).

Results: N/A

Conclusion: N/A
Purpose: Although drug-induced thrombocytopenia due to a histamine-2 receptor antagonist (H2RA) is reported as a rare occurrence, H2RA’s are often discontinued or substituted for a proton-pump inhibitor (PPI) if a patient develops moderate to severe thrombocytopenia. This study looked to evaluate if there is a difference in outcomes for patients who remain on an H2RA, are switched to a PPI, or who have their H2RA discontinued without a replacement acid suppressant after they experience a clinically significant drop in their platelet count.

Methods: In this retrospective cohort study, the primary endpoint was to determine whether the different interventions resulted in a recovery of platelets. The secondary endpoints were to evaluate if patients had an accepted indication, received testing for heparin-induced thrombocytopenia, and the incidence of pneumonia and Clostridium difficile infections (CDI’s). Adults who received an H2RA for at least 24 hours while admitted for at least 72 hours, and experienced a 25% or greater drop in their platelet count resulting in a count of less than 100,000/mm3 were included in this study. Patients were excluded if thrombocytopenia occurred while receiving CRRT or within 48 hours of having surgery, received both an H2RA and PPI concomitantly, had certain conditions known to cause thrombocytopenia, had chemotherapy within 21 days, or were pregnant.

Results: All but one of the eight patients meeting study criteria saw an increase in their platelet count once an intervention was made. One patient continued on an H2RA and had their platelet count recover, five patients were continued on an H2RA and did not have their platelet count recover, one patient was changed to a PPI and had their platelet count recover, and one patient was changed to a PPI and did not have their platelet count recover. Patients who were...
continued on an H2RA had lower average baseline, nadir, and final platelet counts compared to patients who were switched to a PPI. Three patients received heparin products; however none received testing for heparin-induced thrombocytopenia. One patient was on therapy for GERD, while the others were on stress ulcer prophylaxis. None of the eight patients developed pneumonia or CDI’s.

**Conclusion:** It may be beneficial to discontinue or replace an H2RA in patients that experience an unexplainable, significant platelet drop. If the patient’s platelet count does not recover in response to discontinuing or replacing the H2RA with a PPI, it may similarly be beneficial to rechallenge the patient with an H2RA in order to maintain them on stress ulcer prophylaxis and to limit their potential for developing pneumonia or CDI’s.

**Poster Title:** Evaluation of benzodiazepine and/or non-benzodiazepine receptor agonist administration on fall rates in a community medical center

**Primary Author:** Elizabeth Taber, CJW Medical Center, VA; **Email:** elizabeth.taber2@hcahealthcare.com

**Additional Author (s):**
Torill Yamarik
Megan Sarashinsky

**Purpose:** Medications with central nervous system (CNS) effects are ten times more likely to cause an inpatient fall. Data suggest anxiolytics and sedative-hypnotic medications are inappropriately prescribed for geriatric patients. The purpose of the study investigate whether the administration of benzodiazepines or non-benzodiazepine receptor agonists, such as zolpidem, attributed to a fall in the hospital setting and if appropriate geriatric dosing was utilized in this population. Secondly, the occurrence of polypharmacy will be evaluated.

**Methods:** This retrospective cohort study has approval from the Institutional Review Board. The study population will include patients 65 years of age and older who have a recorded fall at CJW Medical Center between June 1, 2015, and May 31st, 2016. Patients will be excluded if they were admitted due to an outpatient fall, experienced the fall on an intensive care unit, received Clinical Institute Withdrawal Assessment medications, received palliative care protocol medications, admitted for less than 48 hours, and/or had documented orthostatic hypotension. The quality assurance team will generate a list of patients with documented falls and it will be randomly assorted and evaluated until 200 patients are enrolled or the list of eligible patients has been exhausted. The following data will be collected from patient profiles and administration reports: time of the fall, time of administration of a benzodiazepine or non-benzodiazepine receptor agonist, specific medication, dosing, and polypharmacy, defined as receiving at least one dose of both investigated medication classes within a 48 hour time frame.

Poster Title: Evaluation of initial dofetilide dosing for patients with risk for QT interval prolongation

Primary Author: Johanna Behrens, CJW Medical Center, VA; Email: behrensje@vcu.edu

Additional Author(s):
Timothy McLlarky

Purpose: Dofetilide is known to prolong the corrected QT interval (QTc) which is associated with ventricular arrhythmias. Current dofetilide labeling recommends utilizing renal dose adjustments to reduce the risk of QTc prolongation, but does not consider other risk factors such as gender or age. The objective of this study is to investigate whether an initial empiric dose reduction of dofetilide in patients with risk factors for dofetilide induced QTc prolongation is associated with a reduced need for further dose reductions without reducing efficacy.

Methods: This retrospective cohort study has been submitted and approved by the Institutional Review Board. The data mining function of a clinical support software program will be used to generate a report of eligible patients who are >18 years old and who were newly initiated on dofetilide during an in-patient admission between August 1, 2014 and July 31, 2016. All data will be collected retrospectively by reviewing the electronic medical record. Protected health information and patient identifiers will be maintained throughout the study using a password protected database.

Patients will be categorized into two groups: (i) the reduced dose group if the initial dose of dofetilide was lower than the recommended starting dose based on creatinine clearance and (ii) the standard dose group if the initial dose was the same as the recommended dose for the creatinine clearance. The primary endpoint is a composite of dofetilide dose reduction, discontinuation of therapy due to prolongation of the QTc, or discontinuation due to lack of efficacy during the first three days of dofetilide therapy. The secondary endpoints include the individual components of the composite primary endpoint, the peak QTc during the first 3 days of therapy, absolute change in QTc from baseline to peak, and time from dofetilide initiation to discharge.

**Poster Title:** Efficacy of liposomal bupivacaine to improve outcomes in breast reconstruction

**Primary Author:** Zachary McConnell, Henrico Doctors' Hospital, VA; **Email:** zachary.mcconnell@hcahealthcare.com

**Additional Author(s):**
Celene Amabile

**Purpose:** Breast reconstruction surgery leads to severe post-operative pain in a substantial number of patients. It can be relatively challenging to adequately manage this type of post-operative pain due to its complex nature. The oncoplastic breast reconstruction best practice guidelines recommend a multimodal approach to successfully managing patients, which may include patient-controlled analgesia, opioids, non-opioid analgesics, local nerve blockade, and local anesthetic infiltration. This study was designed to determine the efficacy of liposomal bupivacaine in reducing post-surgical pain scores and opioid use in patients undergoing breast reconstruction surgery, with other notable endpoints including length of stay and post-operative anti-emetic use.

**Methods:** A retrospective chart review of patients undergoing breast reconstruction surgery will be performed. The following will be collected from each patient chart: age, weight, baseline serum creatinine, creatinine clearance, allergies, type of surgical procedure, date and time of surgery, date and time of discharge, pain scores, analgesic usage, anti-emetics usage, antispasmodic usage, and any complications that may occur. Inclusion criteria require patients to have undergone breast reconstruction with tissue expanders between the dates of January 1, 2015 and August 15, 2016. Patients will be excluded for chronic pain conditions defined by a pertinent diagnosis in the patient chart or chronic analgesic use, uncontrolled pain at the time of the surgery defined as the need for analgesics unrelated to the procedure prior to surgery, or if a flap-based reconstruction is performed. All opioid doses will be converted to morphine equivalents. Total length of hospital stay will be calculated. All patient information will be de-identified and analyzed in aggregate to protect the patients’ right to privacy. This study has been exempted from requirement of Investigational Review Board approval by the Research Review Committee.

**Poster Title:** Medication use evaluation of tolvaptan in a community hospital setting

**Primary Author:** Ashley-Nicole Carmichael, Inova Alexandria Hospital, VA; **Email:** ashley-nicole.carmichael@inova.org

**Additional Author (s):**
Jalpa Patel
Phyllis Hashemi

**Purpose:** Tolvaptan (Samsca)® is a selective V2-receptor antagonist currently FDA approved for the treatment of clinically significant hypervolemic and euvolemic hyponatremia, including patients with heart failure and Syndrome of Inappropriate Antidiuretic Hormone (SIADH). At this hospital, tolvaptan has specific criteria and limitations for use. Recently, our hospital has seen a substantial increase in the cost of tolvaptan usage in the pharmacy over the past year. The purpose of this evaluation is to determine the impact of these criteria on the utilization of tolvaptan, evaluate potential changes to the criteria and project associated cost impacts.

**Methods:** All patients from September 2015 to present who received tolvaptan will be included in this medication use evaluation by utilizing a retrospective chart review design. The electronic medical record will be accessed and reviewed to collect the following information: age, date of admission, principal diagnosis, basic metabolic panel results, volume status, diuretic medication administration, fluid restriction status, interacting medications and neurologic conditions. Information including tolvaptan dose, indication for use, prescribing doctor, number of doses, adherence to hospital-approved criteria for use, as well as serum sodium values and trends will also be collected. Lastly, length of stay and overall mortality will be assessed.

**Poster Title:** Medication use evaluation of nicardipine in the setting of acute ischemic stroke treated with alteplase.

**Primary Author:** Cindy Esterline, Inova Alexandria Hospital, VA; **Email:** cynthia.esterline@inova.org

**Additional Author(s):**
Gina Patel
Phyllis Hashemi

**Purpose:** Nicardipine is an intravenous dihydropyridine calcium channel blocker with FDA approval for the treatment of acute hypertension. Nicardipine produces relaxation of coronary vascular smooth muscle and coronary vasodilation. In the setting of acute ischemic stroke (AIS), AHA/ASA recommends nicardipine or labetalol to be used for the management of hypertension. The purpose of this evaluation is to determine the current use of nicardipine at Inova Alexandria Hospital (IAH) and in turn provide guidance for the future use of nicardipine in the management of blood pressure following AIS treated with alteplase.

**Methods:** All patients from January 23, 2016 to August 10, 2016 who received alteplase for the treatment of AIS will be included in this medication use evaluation through retrospective chart reviews. The electronic medical record will be accessed and reviewed to collect the following information: age, gender, allergies, home medications, blood pressure readings prior to and 24 hours after receiving alteplase as well as door to needle time. Information regarding medications utilized for blood pressure management will include antihypertensive agent name, dose, timing and titration as applicable.

Poster Title: Antihypertensives via intermittent bolus versus continuous infusion for the management of hypertensive emergency in the emergency department

Primary Author: Lindsay Waddington, Inova Fairfax Hospital, VA; Email: lindsay.waddington@inova.org

Additional Author (s):
Mona Shah

Purpose: Hypertensive emergency requires an immediate reduction in blood pressure (BP) with intravenous antihypertensives to prevent further end organ damage. Available guidelines (JNC7 and ESH/ESC) establish blood pressure goals, but do not have specific recommendations for a preferred agent in the absence of additional emergent complications. In the emergency department at Inova Fairfax Hospital there is no standard approach to treatment of hypertensive emergency when evaluating agent used or type of administration (e.g. bolus dosing versus continuous infusion). The study objective is to compare intermittent bolus dosing of antihypertensives versus continuous infusion to achieve the treatment goals established by JNC7.

Methods: A single center, retrospective chart review from January 2015 to June 2016 will be conducted in patients who are prescribed intravenous (IV) antihypertensives (labetalol, nicardipine, hydralazine, or enalaprilat) in the emergency department at Inova Fairfax Hospital. Patients 18 years or older with hypertensive emergency will be included if they received at least one dose of an IV antihypertensive. Patients with stroke, myocardial infarction, unstable angina, heart failure, dissecting aortic aneurysm or pregnancy will be excluded. Patients who transferred with treatment already in progress or did not remain in the ED for at least 1 hour after medication administration will also be excluded. The primary outcome is difference in achieving a 20-25 percent reduction in mean arterial pressure 1 hour after the initial antihypertensive medication was administered. Secondary outcomes include achieving a blood pressure of less than 160/110mmHg at 2 to 6 hours, frequency of hypotension (less than 90/60mmHg) or bradycardia (less than 60bpm), and return of elevated blood pressure after meeting the 1 hour or 2 to 6 hour goal. For patients who meet criteria we will collect demographic information (age, gender, home antihypertensives), serial blood pressures, serial
heart rates, medications administered, time of administration, and concomitant medications that may influence blood pressure. If available we will also collect serum creatinine, urinary analysis, and physical exam findings associated with end organ damage as needed.

**Poster Title:** Evaluating the outcomes of obese patients undergoing induction chemotherapy for acute leukemia.

**Primary Author:** Lauren Dombrowski, Inova Fairfax Hospital, VA; **Email:** lauren.dombrowski@inova.org

**Additional Author(s):**
Leila Mohassel

**Purpose:** Obesity continues to be a growing epidemic in the United States. Guidelines published by ASCO in 2012 recommend dosing chemotherapy using actual body weight, including in obese patients. However, the guidelines do not specially mention this dosing strategy for hematologic malignancies and no studies referenced for the guidelines were hematologic-based. The objective of this study is to evaluate outcomes in obese patients undergoing induction chemotherapy for acute leukemia versus non-obese patients using actual body weight.

**Methods:** The study is currently under Institutional Review Board for approval. This will be a single-center, retrospective analysis from November 9, 2012 to August 31, 2016. Patients will be identified from an electronic medical record with a diagnosis of acute leukemia. Patients included will be 18 years of age or older with newly diagnosed acute leukemia who received and completed induction chemotherapy at Inova Fairfax Medical Center (IFMC). All data will be de-identified to maintain confidentiality. The primary outcome is complete remission (CR) rates after induction therapy. Secondary outcomes include: time to ANC and platelet recovery, incidence of febrile neutropenia, clinical or microbiological infections, overall survival at 6 months, early (0-15 days) and in-hospital mortality. Data points collected will include sex, age, weight, height, BMI/BSA, co-morbidities, baseline laboratory values, type of leukemia, cytogenetics/molecular abnormalities, % blasts at baseline, day 14, and at time of recovery, type of infection if documented, length of hospitalization, and cause of death. Comparison of groups will be looking at statistical and clinical differences in primary and secondary outcomes between obese patients and non-obese patients using descriptive statistics, chi squared or Fisher’s Exact Test, and Student’s t-test.

Poster Title: Direct oral anticoagulants for the treatment of venous thromboembolism in cancer patients

Primary Author: Kimberly Sorensen, Inova Fairfax Hospital, VA; Email: kimberly.sorensen4@gmail.com

Additional Author (s):
Leila Mohassel
Jenny Kim

Purpose: Cancer patients are more likely to develop venous thromboembolism (VTE) compared to non-cancer patients. The recommended treatment for cancer-associated thrombosis is low molecular weight heparin (LMWH) therapy. However, the high cost associated with this treatment and the need for daily injections are major barriers to its use in clinical practice. A Meta-Analysis suggests that direct oral anticoagulants (DOACs) are as effective as vitamin K antagonists in cancer patients. Although these findings are encouraging, further data in patients with active cancer is warranted. The objective of this study is to assess the safety and effectiveness of DOACs in cancer-associated thrombosis.

Methods: This study has been submitted to the Institutional Review Board for approval. It is a single-center, retrospective analysis from November 9, 2012 to July 31, 2016. Adult cancer patients with active disease receiving DOAC therapy will be identified using an electronic medical record system and included in the study. Patients initiated on DOAC therapy for VTE treatment more than six months prior to cancer diagnosis or once in remission will be excluded. The primary outcome measure is incidence of recurrent VTE by diagnostic imaging. Secondary outcomes include rate and severity of bleeding, time to bleed, and time to recurrent VTE. Data collected will include: age, race, sex, weight, height, past medical history, type of VTE (deep vein thrombosis, pulmonary embolism, or both), type of recurrent VTE, cancer diagnosis and stage, cancer treatment, relevant drug-drug interactions, type and dose of DOAC (rivaroxaban, dabigatran, or apixaban), and type of bleed (major or clinically relevant nonmajor) and location. Descriptive statistics will be used to analyze the final results.

**Poster Title:** Management of new onset atrial fibrillation during sepsis in critically ill patients

**Primary Author:** Christine Brun, Inova Fairfax Hospital, VA; **Email:** christine.brun@inova.org

**Additional Author(s):**
Jenna Smith
David Allen

**Purpose:** Studies have shown that 6 to 20 percent of severe sepsis patients develop new-onset atrial fibrillation (AF). New-onset AF is associated with increased ICU and hospital length of stay, increased stroke risk, heart failure, and increased mortality. The 2014 AHA/ACC/HRS guidelines recommend the use of intravenous beta-blockers or non-dihydropyridine calcium channel blockers to slow the ventricular rate in the acute setting. There is limited literature to guide the treatment of new-onset atrial fibrillation in sepsis patients. The goal of this study is to determine what medications are most effective for the management of new onset AF in septic patients.

**Methods:** This single center, retrospective chart review received IRB approval. Subjects will be identified by medication and diagnosis codes, and separated into three groups: calcium channel blockers and beta blockers, digoxin, amiodarone. Electronic health records will be reviewed for inclusion criteria: at least 18 years old, admitted to non-cardiovascular ICU from November 2012 to July 2016, diagnosis of sepsis or septic shock and development of new-onset AF during hospital admission. Patients will be excluded if they are pregnant, have known history of atrial fibrillation (AF), or underwent electrical cardioversion before receiving study medications. Data to be collected includes: age, sex, date of ICU admission, date of transfer from ICU, medical and medication history, diagnosis, BP and HR, and use of vasopressors. Time of AF onset will be recorded, along with medication, dose, and administration time. Investigators will record the occurrence of rate (HR less than 100 but greater than or equal to 60) and/or rhythm control (documented sinus rhythm) for each medication. Investigators will evaluate subjects for 24 hours after first drug administered. Presence of hypotension (BP less than 90/60 mmHg) and bradycardia (HR less than 60 bpm) in these 24 hours will be recorded, along with HR at time of rate and/or rhythm control. Comparisons will be made between the 3 medication groups to determine effective management of new onset AF in septic patients.

**Poster Title:** Evaluating the use of antibiotics and infectious complications in neonates with gastroschisis

**Primary Author:** Amy Olander, Inova Fairfax Medical Campus, VA; **Email:** olander.12@osu.edu

**Additional Author(s):**
Van Tran

**Purpose:** Gastroschisis is a congenital defect in which the intestines protrude through an opening in the abdominal wall. Studies have shown high rates of infectious complications and the importance of prophylactic antibiotics in patients in the NICU born with gastroschisis. Currently, there are no evidence based guidelines for the management of antibiotics in gastroschisis patients. The purpose of this study is to characterize current antibiotic management of patients with simple and complex gastroschisis by assessing infectious complications.

**Methods:** This study has been submitted to the Institutional Review Board and is currently under review. This is a single-center, retrospective chart review of a 108 bed, level IV Neonatal Intensive Care Unit (NICU). Patients were included if they were born with gastroschisis and admitted to the NICU. Subjects will be identified using ICD-9 and ICD-10 codes. Pertinent information to assess primary and secondary outcomes will be obtained by reviewing the eligible patients’ electronic medical record. The following data will be collected: patient gestational age, gender, birth weight, comorbidities, surgical intervention, gastroschisis type, infectious complications, antibiotics, duration of antibiotics, neonatal death, length of hospital stay, and nothing by mouth (NPO) status, and maternal age, race, antibiotics received during delivery, and delivery method. Collected patient data will be de-identified and data collection spread sheets will be password protected. The incidence of infectious complications will be reported as a percentage of patients who were positive for infection. Initial choice of antibiotics, subsequent de-escalation or escalation of antibiotics, and organisms that were isolated in positive cultures will also be recorded. Descriptive statistics will be used to report the total duration of antibiotics, duration of antibiotics post-surgical closure, time to surgical closure from birth, length of hospital stay, NPO status and neonatal death.

**Poster Title:** Assessing the use of hydromorphone in an emergency department at a community hospital

**Primary Author:** Kathryn Muha, Inova Mount Vernon Hospital, VA; **Email:** kathryn.muha@inova.org

**Additional Author (s):**
Kristin Marge

**Purpose:** Pharmacists are identified by The Comprehensive Addiction and Recovery Act of 2016 as critical team members in tackling the rising problem of opioid abuse. According to the Institution for Medication Safety’s Health’s National Prescription Audit Plus Retail database, the number of prescriptions legally dispensed for hydromorphone has increased from 2.6 million in 2009 to 3.8 million in 2014, which is a 44.9 percent increase. The objective of this medication use evaluation is to analyze the use of opioid analgesics, specifically morphine and hydromorphone, in the emergency department of a community hospital and determine opportunities to improve practice.

**Methods:** A retrospective chart review was performed analyzing data from the emergency department at a community hospital for the time period January 1, 2016 through July 31, 2016. The primary endpoint evaluated was monthly morphine and hydromorphone usage in mg per 1,000 patient visits. Data collected included: drug administered, date and time of ordering, date and time of administration, dose of drug, route of drug (intravenous, intramuscular and oral), frequency of administration, patient name, patient sex, patient weight, patient allergies, and diagnosis code(s). A subset of the patients who received hydromorphone 2 mg intravenous or intramuscular were analyzed to determine if patients were opioid tolerant prior to arrival in the emergency department. A subset of the patients who received hydromorphone due to an allergy to morphine were analyzed to determine the patient-specific reaction to morphine. This medication use evaluation will be conducted as a part of the pharmacy department quality assurance program and as such does not require Institutional Review Board approval.

Poster Title: Evaluation of darbepoetin alfa usage in a community hospital setting

Primary Author: Marilyn Hill, Inova Mount Vernon Hospital, VA; Email: marilyn.hill@inova.org

Additional Author(s):
Kristin Marge

Purpose: Darbepoetin alfa is an erythropoiesis-stimulating protein indicated for anemia due to chronic kidney disease (CKD) and anemia secondary to chemotherapy. To promote safe and cost-effective usage, our hospital system has restriction criteria based on indication and an electronic order set to guide appropriate dosing and monitoring. The purpose of this evaluation is to determine the effectiveness of the current order set in guiding safe, appropriate, and cost-effective therapy for both new starts and continuation of therapy; and to identify opportunities for improvement.

Methods: A retrospective electronic chart review will be performed for a sample of inpatient adults who received darbepoetin alfa from January 1, 2016 to June 30, 2016. The primary outcome to be assessed is appropriateness of the darbepoetin alfa regimen for orders placed using the electronic order set compared to orders not placed utilizing the order set. Patients will be identified as either new starts or continuation of therapy. New starts will be evaluated for appropriateness based on indication and initial weight-based dosing. Darbepoetin alfa maintenance regimens will be assessed for appropriateness of ongoing dose adjustments. Deviations from order set recommended dosing will be evaluated to determine potential for cost savings. This site-approved medication use evaluation is to be used as part of the pharmacy department’s quality assurance program and presented to local pharmacy and therapeutics committee. IRB approval is not required for this study.

Poster Title: Comparison between the old and new CIWA-Ar Protocols on the effect of ICU length of stay in alcoholic withdrawal patients in the ICU

Primary Author: Esther Lee, Reston Hospital Center, VA; Email: leeec@vcu.edu

Additional Author(s):
Kevin Roshak
Arthur Harralson

Purpose: CIWA-Ar score helps stratify severity of alcohol withdrawal syndromes, guides treatment, and the decision to transfer to the ICU. The hospital will implement a new CIWA-Ar-based alcohol-withdrawal protocol for the ICU in October 2016. This retrospective observational study aims to determine the efficacy and safety of the new protocol compared to the old protocol in patients presenting with alcohol withdrawal syndrome. The primary objective is to compare the average length of stay in the ICU. The secondary endpoint is to evaluate whether there is a decrease in the average number of ventilator days for patients that have been ventilated.

Methods: The ICU admission for patients diagnosed with alcohol withdrawal syndrome or related diagnosis or those with a CIWA-Ar >20 will be reviewed through their electronic health records identifying these patients using the appropriate ICD-10 codes during the study periods of November 2015 to February 2016 (old protocol) and November 2016 to February 2017 (post new protocol). Alcoholic withdrawal patients in the ICU will be included if they are ≥18 years of age, had the alcohol withdrawal protocol followed during the ICU admission, and assessed for a CIWA score documented in the electronic medical record. Patients will be excluded if they are on the general medical floor, patients that have been in the ICU < 12 hours, have a primary diagnosis other than alcohol withdrawal, and pregnant. The primary and secondary outcome will compare the old and new protocol and be measured by the average number of days for the following data that will be collected: ICU length of stay and the number of ventilator days. Additional information that will be gathered will be the number of specific medications used between the old and new protocol. Length of stay and ventilators days will be compared with the t-test if normally distributed or Mann-Whitney if not normally distributed. This
retrospective case-control study will be submitted to the Institutional Review Board for approval.

**Poster Title:** Standardized counseling of medications’ side effects and improvement of hospital consumer assessment of healthcare providers and systems (HCAHPS) scores in a community hospital.

**Primary Author:** Elmira Darvish, Reston Hospital Center, VA; **Email:** edarvish12@su.edu

**Additional Author (s):**
Kevin Roshak
Arthur Harralson

**Purpose:** HCAHPS scores provide a standardized measurement of consumer satisfaction and allow for an objective comparison between hospitals’ quality of care. This randomized telephone questionnaire evaluates various aspects of patient care including medication communication. This includes how often hospital staff describe possible side effects in a manner that is understood by the patients and their respective families. This study aims to evaluate the effect of a standardized patient counseling approach on the HCAHPS scores at Reston Hospital Center.

**Methods:** This prospective quality improvement study will require collaboration between the pharmacy and nursing departments. Patients who are starting a new medication on the surgical floor will be identified on a daily basis using the hospital’s electronic health record system. A standardized medication-counseling sheet will be prepared for each patient and a pharmacy or nursing staff member will directly counsel the patient. Furthermore, a teach-back method will be applied to validate a patient’s understanding of a medication’s side effects. After being discharged, patients will randomly receive a telephone questionnaire from a third-party for the assessment of HCAHPS scores in multiple categories including medication communication. The primary outcome of this study is improvement in the HCAHPS scores regarding the communication of medications’ side effects. The secondary outcome is any other improvement in the HCAHPS scores pertaining to patients’ understanding of why they are given certain medications. Chi-square test will be used to analyze the categorical data.

Poster Title: Fluid resuscitation in end stage renal disease and congestive heart failure patients presenting with sepsis

Primary Author: Khalida Amini, Riverside Regional Medical Center, VA; Email: khalida.ami@rivhs.com

Additional Author (s):
Sean Nix
Heather Nix

Purpose: Under the current Surviving Sepsis Campaign (SSC) guidelines the recommended initial fluid resuscitation is 30 mL/Kg of crystalloid over the first 3 hours. There are no adjustments or recommendations for patients with conditions that are associated with chronic fluid overload at baseline. The primary aim of this study is to evaluate the volume of fluid resuscitation given to patients with end stage renal disease (ESRD) and congestive heart failure (CHF) admitted to Riverside Health System (RHS) with a diagnosis of sepsis. Through this analysis we hope to identify an optimal range of fluid volume for resuscitation of these patients.

Methods: This study is in the process of being reviewed by the Institutional Review Board. This is a multi-institutional retrospective data analysis, analyzing the charts of ESRD and CHF patients that have been identified as having sepsis in the RHS over the prior 2 years. The researchers will collect data on the daily volume of resuscitation, primary and secondary diagnosis, microbiology, ICU length of stay (LOS), mortality and overall hospital LOS. To help define the patients more accurately we will calculate the Sequential Organ Failure Assessment (SOFA) score for each patient. Each patient will have a randomly assigned identification number and no patient identifiers will be recorded. The primary outcome of mortality will be compared to historical outcomes at Riverside. This study will utilize a SAS version 9.3 (Cary, NC) to perform a multivariate and univariate regression analysis. Means, medians and standard deviations will be reported for continuous variables. This data set will be utilized to determine the optimal volume resuscitation model with the best outcomes for ESRD and CHF patients.

Poster Title: Enhancing an antimicrobial streamlining program: Implementing process improvement strategies

Primary Author: Brooke Smithson, Riverside Regional Medical Center, VA; Email: brooke.smithson@rivhs.com

Additional Author (s):
Larry Davis
Brad Heidenthal

Purpose: Antibiotic stewardship programs have become a large area of interest since the Centers for Medicare and Medicaid Services (CMS) released a proposed rule that would require hospitals to implement such programs. Antibiotic streamlining, a part of the stewardship initiative, is a major focus to minimize antibiotic resistance, secondary infections, drug toxicity and healthcare costs. A previous study was completed to assess the extent to which clinicians participated in antibiotic streamlining at a large, community, non-profit hospital. The objective of this study is to identify causes/barriers that led to low program involvement and to develop program enhancement strategies.

Methods: This study will be conducted in three phases. During Phase I, two surveys will be conducted, one for pharmacists, the other for physicians. The survey for pharmacists will include questions regarding an antibiotic software alert system, barriers to de-escalating antibiotics, suggestions for program improvement, and documentation of interventions. The physicians’ survey will include questions concerning streamlining barriers and suggestions to improve the role of themselves and pharmacists in the program. Phase II will be building and implementing strategies based on Phase I findings to increase clinician participation and improve the antibiotic streamlining program. Phase III will be reassessing the program after implementation of Phase II.

Poster Title: Enhancing appropriate antibiotic use in bacteremia with PCR rapid testing.

Primary Author: Amel Abdulaziz, Riverside Regional Medical Center, VA; Email: amel.abdulaziz@rivhs.com

Additional Author(s):
Larry Davis
Brad Heidenthal

Purpose: Beginning appropriate antibiotic therapy directly following the culture sensitivity results is imperative. PCR rapid testing identifies bacteria within 1 to 2 hours following the gram stain. Early identification of bacteria will aid in prescribing the appropriate antibiotic treatment sooner. The primary objective of this study is to enhance appropriate antibiotic use with the results obtained through PCR rapid testing. Following the culture sensitivity test; patients that are not prescribed the appropriate antibiotics are identified. Secondary objective observes the time the physician requires to prescribe the appropriate antibiotic therapy and compare the PCR rapid test results with the culture sensitivity results.

Methods: This study will be submitted to the Institutional Review Board for approval. Forty gram positive and forty gram negative rapid tests will be provided to the laboratory. The laboratory will perform gram staining and the blood samples will undergo forty consecutive gram positive and forty consecutive gram negative PCR rapid tests. The results from the rapid tests will be provided to the pharmacist and the pharmacist will compare the results with the patients existing therapy. If an adjustment is necessary, the pharmacist will record the appropriate antibiotic therapy using a treatment algorithm approved by an infectious disease physician. Once the culture sensitivity results are available they are compared to the determined algorithm treatment. The time the physician requires to prescribe the appropriate antibiotic therapy will be recorded. Final data from all testing and results will be evaluated to compare the efficacy of rapid testing to standard culture and sensitivity reporting in improving appropriate antibiotic use.

**Session-Board Number:** 9-397

**Poster Title:** Comparison of bleeding and thrombosis rates in rivaroxaban dosed patients using adjusted body weight versus true body weight, a retrospective analysis

**Primary Author:** Judd Compton, Riverside Regional Medical Center, VA; **Email:** judd.compton@rivhs.com

**Additional Author(s):**
Brad Heidenthal
Jason Ferrell

**Purpose:** Renal dosing of rivaroxaban in the ROCKET-AF trial used actual body weight; however, the trial also did not include a large number of patients with extreme body weights. The current dosing practice at Riverside Regional Medical Center (RRMC) is to use adjusted body weight to calculate creatinine clearance. The goal of this study is to compare incidence of bleeding and thrombosis between current dosing practices for rivaroxaban and dosing practices as presented in ROCKET-AF using unadjusted body weight.

**Methods:** Paper records will be used to identify patients who were taking rivaroxaban prior to admission. The electronic medical record will be analyzed to determine the patient’s weight (kg), height (m), BMI (kg/m2), unadjusted creatinine clearance [UCrCl] (mL/min), adjusted creatinine clearance [ACrCl] (mL/min), rivaroxaban dose (mg) prior to admission, gender, and age. All data will be recorded using medical record numbers for confidentiality. For obese patients (BMI > 30 kg/m2), there is a higher likelihood that UCrCl and ACrCl will lead to different doses. Patients will be divided into four groups: correct dosing where UCrCl and ACrCl agree (control group), incorrect dosing where UCrCl and ACrCl agree (excluded group), correct dosing per UCrCl, and correct dosing per ACrCl. The group with incorrectly dosed rivaroxaban where both UCrCl and ACrCl agree will be excluded. The control group will be the patients taking rivaroxaban where dosing with UCrCl and ACrCl agree. Co-primary endpoints are the difference in incidence of thrombosis between test groups and the control group and the difference in incidence of bleeding events between test groups and the control group. Bleeding events are defined as the composite of major and non-major clinically relevant bleeding as defined by ROCKET-AF. Thrombosis events are defined as ischemic stroke, transient ischemic stroke, deep vein thrombosis, pulmonary embolism, and any systemic emboli as charted by the physician.

Poster Title: Implementation and evaluation of a pharmacist-driven transition of care (TOC) service at hospital discharge for elderly patients at high risk for readmission

Primary Author: Christopher Robbs, Sentara Healthcare System, VA; Email: cmrobbssentara.com

Additional Author(s):
Allison Roman
Ashley Darden

Purpose: Adverse drug reactions and hospitalizations pose significant safety concerns for older adults, as both can decrease functionality and increase morbidity and mortality. In addition, an estimated 20% of older adults who are hospitalized are then readmitted within 30 days of discharge. Adverse drug reactions are a common contributor to emergency department visits as well as hospital admissions and have been reported to contribute to anywhere from 10% to 40% of hospital readmissions in the elderly. Studies have demonstrated that pharmacist intervention during hospitalization and at hospital discharge can reduce inappropriate prescribing, discharge medication errors, all-cause hospital visits, and drug-related readmissions.

Methods: Institutional Review Board approval is pending. We will utilize an electronic medical record to identify patients 65 years of age or older admitted to Sentara CarePlex Hospital who have a primary care provider within Sentara Medical Group. These identified patients will then be screened to determine whether they meet designated criteria for high risk of readmission. Patients who meet these criteria will then be randomized to receive either standard care (control group) or pharmacy intervention. The intervention group will undergo chart review by a resident or a clinical pharmacy specialist. The interventionist will then make recommendations regarding medication regimen optimization and potentially inappropriate medications as outlined by the Beers criteria. Recommended interventions will be sent to primary care providers via electronic message before the follow-up appointment. A retrospective chart review will be performed to determine the number of recommendations accepted by the primary care provider and presence of all-cause 30-day readmission. The success of this service will be measured against the control group by reduction in number of
potentially inappropriate medications, number of interventions made and accepted by the primary care provider, and all-cause 30-day readmission rates.

Session-Board Number: 9-399

Poster Title: Medication utilization evaluation of liposomal bupivacaine (Exparel) within a medical and surgical community hospital

Primary Author: Ann Bernacchi, Sentara Martha Jefferson Hospital, VA; Email: acbernc@sentara.com

Additional Author(s):
Margaret Taylor

Purpose: Liposomal bupivacaine (Exparel) is approved for postoperative analgesia in patients undergoing bunionectomy or hemorrhoidectomy. The extended half-life and duration of action of Exparel has been shown to diminish opioid usage and shorten the hospital length of stay. Exparel is currently being utilized in many types of off-label surgical procedures at this institution. The purpose of this medication utilization evaluation (MUE) was to evaluate the post-operative use of opioids and analgesics in patients receiving Exparel as a local analgesic agent during surgery. The evaluation was conducted to characterize usage patterns and clinical outcomes in surgical patients.

Methods: An observational MUE was conducted over a 3-month period (May 1, 2016 through July 31, 2016) at Sentara Martha Jefferson Hospital, a 176-bed medical and surgical community hospital. A retrospective chart review was performed using the system’s electronic medical record, via a data inquiry generated from AcuDose-Rx automatic dispensing cabinet records. All patients dispensed at least one dose of Exparel were eligible for inclusion in the MUE. Data collected included the type of surgery, type of anesthesia used, surgeon, length of stay, additional local analgesics given with liposomal bupivacaine, and strength and number of doses of opioids and other pain relievers, such as non-steroidal anti-inflammatory drugs (NSAIDs) and acetaminophen (APAP). Additional clinical data was compiled by orthopedic surgery team members, which included post-operative distance walked and range of joint motion in degrees. This 2016 data was compared to previously collected data in two earlier MUE projects at the institution conducted in 2014, characterizing Exparel use between May 19, 2014 through June 30th 2014 and July 1, 2014 through September 15, 2014.
Results: During the 2016 three-month data collection period, 193 surgeries were performed utilizing Exparel, with the most commonly performed surgery being total knee replacement. The average length of stay for the collection period was 2.1 days, which has decreased from 2.8 days in 2014. The total amount of additional opioid analgesics in morphine equivalents during post-operative hospitalizations has decreased from an average of 205.8mg immediately pre-Exparel implementation in 2014, to 174.7 and 141.5mg later in the year in 2014, to 123.9mg in 2016, demonstrating an overall reduction of 81.9mg in oral morphine equivalents or an average 39.8% reduction in opioid usage. The use of NSAIDs has decreased along with opioid use. After Exparel implementation, total APAP used for post-operative pain increased by 3-fold (2,456mg to 6,935mg average throughout hospitalization). Seventy-one percent of patients received one or more additional local analgesics along with Exparel. The mean pain score, recorded on a scale of 1 to 10, for the patients receiving Exparel in 2016 was 3.5. The average distance walked during hospitalization was 981.9 feet in hip and 953.1 feet in knee surgeries. At discharge, for patients who underwent knee surgeries, the average joint flexion and extension were 90.7 and -2.07 degrees, respectively.

Conclusion: Overall opioid use for post-operative pain at this institution decreased after the addition of Exparel to formulary, which could be attributed to the use of Exparel, conscientious prescribing of opioids, or an increasing comfort of physicians with non-opioid pain control regimens. The increasing use of APAP in place of opioids is seen as a positive change, given a patient has adequate hepatic function and maximum daily doses are monitored. Limitations include the retrospective nature of this study and inconsistencies between the separate MUE comparison groups. Future clinical and cost-benefit analyses are needed to further document the use of Exparel.

**Poster Title:** Retrospective evaluation to determine safety and efficacy of ultra long acting insulin analogs (Tresiba® and Toujeo®) versus long acting insulin analogs (Lantus® and Levemir®)  

**Primary Author:** Meredith McCauley, Shenandoah University, VA; **Email:** mmccaule2@su.edu  

**Additional Author(s):**  
Kacey Carroll  
Michelle Rager  
Dawn Havrda  

**Purpose:** The purpose of this study is to evaluate the safety and efficacy of ultra long acting basal insulin compared to long acting basal insulin in diabetics seen in a pharmacist-led diabetes service within an internal medicine, family practice and cardiology outpatient clinic. Safety will be assessed based on hypoglycemic events and efficacy will be assessed based on glycemic control through hemoglobin A1c analysis.  

**Methods:** A retrospective chart review will be conducted at a physician group practice in Winchester, Virginia. Patients will be identified from excel spreadsheet that track patients who are followed by the pharmacy team. Patients included in analysis will be on Tresiba®/Toujeo® or Lantus®/Levemir® from the time period of January 1, 2015 through June 30, 2016. Patient selection for analysis will be determined by assessing eligibility of every 3rd patient from spreadsheet and repeating process until approximately an N = 50 meet inclusion criteria. Inclusion criteria: on long acting or ultra long acting basal insulin, over 25 years of age, and an established patient at Selma Medical Associates, Inc. (at least 2 office visits with pharmacy team within last 18 months). Exclusion criteria: not on long acting or ultra long acting basal insulin, less than 25 years of age, less than 2 office visits over the last 18 months and incomplete chart information. Eligible patients’ electronic medical record will be reviewed to collect information regarding demographics, details of basal and bolus insulin drug therapies, diagnoses, lab results: A1c and fasting blood glucose, home blood glucose monitoring, hypoglycemic events, starting insulin dose (if identifiable) and dose when A1c at goal.

Poster Title: Venous thromboembolism (VTE) prophylaxis in obese patients: A medication use evaluation of low molecular weight heparin and unfractionated heparin

Primary Author: Joseph D’Astoli, Valley Health, VA; Email: jda-stoli@valleyhealthlink.com

Additional Author(s):
Linda Fang
Jeffery Spray
Lisa Hammond

Purpose: Venous thromboembolism (VTE) prophylaxis is recommended for most patients admitted to the hospital. Obese patients in particular (patients with a body mass index greater than 30) are more likely to experience VTE and twelve times more likely to die of a pulmonary embolism. Recent studies show that standard prophylaxis dosing of enoxaparin and heparin may be insufficient in obese patients. The purpose of this study is to assess how often VTE prophylaxis with heparin and enoxaparin is dose adjusted for obesity. This study is designed to evaluate if there is any benefit or harm associated with dose adjusting for obesity.

Methods: This medication use evaluation will be submitted to the Institutional Review Board. The electronic medical record will identify a list of four hundred patients weighing greater than 150 kilograms. A retrospective chart review will be performed on each patient to determine the agent and dose used for VTE prophylaxis. Other data collected will include age, sex, platelet count, body mass index (BMI), the distribution of surgical and medical patients, and length of stay. The primary objective of this medication use evaluation is to determine the current practice in terms of dosing obese patients. Secondary objectives will be correlating current practice with the rate of VTE and the rate of major and minor bleeding in the obese population receiving prophylaxis. Patients will be excluded from this analysis if they have a history of atrial fibrillation, are already on systemic anticoagulation, or are admitted for bleeding.

Results: To be reported.

Conclusion: To be reported.

**Poster Title:** Evaluation of prothrombin complex concentrate (PCC) use in a 445-bed community hospital

**Primary Author:** Elizabeth Walters, Valley Health, VA; **Email:** ewalters@valleyhealthlink.com

**Additional Author(s):**
Linda Fang
Lisa Hammond
Jeffery Spray

**Purpose:** Prothrombin complex concentrate (PCC; Kcentra) was approved by the FDA in April 2013 for urgent reversal of warfarin induced coagulopathy in adults with major bleeding. The medical center approved PCC for (1) International Normalized Ratio (INR) greater than two and life-threatening bleed due to warfarin (2) urgent or emergent surgery in patients taking warfarin or Xa inhibitor (3) bleeding due to warfarin or Xa inhibitor. PCC is a medication of interest due to expense, potential thromboembolic events, and specific indications. The purpose of this retrospective study is to evaluate appropriateness of PCC prescribing and the safety implication of this agent.

**Methods:** This medication use evaluation will be submitted to the Institutional Review Board for approval. A retrospective chart review using the electronic medical record will be conducted on patients administered PCC from February 2015 to September 2016. Patients will be excluded if they are younger than 18 years of age. The primary end point is to determine if PCC was used appropriately for (1) a Xa Inhibitor or a vitamin-K antagonist induced bleed or (2) urgent or emergent surgery in patients taking warfarin or Xa inhibitor. Secondary end points are incidence of thromboembolic events (TEE), risk for thrombosis, PCC dose, off-label use, length of stay, and INR at baseline, after PCC and at 24 hours. TEE is defined as deep venous thrombosis (DVT), pulmonary embolism (PE), myocardial infarction (MI), stroke or transient ischemic attack, or any other arterial or venous thrombosis by imaging. TEE that occurred within 3 days of PCC administration will be consider to be caused by PCC, due to K-dependent clotting factors long half-lives.

Data collected will include demographic information, prescriber, location of administration, indication, type of surgery, dose (units/kg), administration time, pre and post PCC
Results: Results to be reported.

Conclusion: Conclusion to be reported.

**Poster Title:** Impact of chronic obstructive pulmonary disease (COPD) pocket card and provider education on the number of patients discharged on optimized therapy regimens.

**Primary Author:** Natalie Winters, Valley Pharmacy, VA; **Email:** nwinters@valleyhealthlink.com

**Additional Author(s):**
Lori DeHaven
Jeffery Spray
Susan Cooper
Helene Matassa

**Purpose:** The Affordable Care Act (ACA) called for the Center for Medicare and Medicaid (CMS) to implement changes to payment models for hospitals, including the Bundled Payments for Care Improvement (BPCI) initiative and the Hospital Readmissions Reduction Program (HRRP). Due to the high prevalence and readmissions associated with COPD admissions in the region, the health system investigated ways to prevent readmissions and elected to participate in the COPD BPCI initiative. The health system initiated a multi-modal approach to optimize medication therapy on discharge, which was achieved through use of provider education and development of a COPD pocket card.

**Methods:** A problem solving A3 was performed to identify barriers that contribute to COPD readmissions. Through a fish bone analysis, provider education and optimizing medication regimens were selected as key areas of improvement. Based on the Global Initiative for Chronic Obstructive Lung Disease (GOLD) guidelines, a recommended regimen for patients admitted with a COPD exacerbation includes a short-acting rescue inhaler, an inhaled corticosteroid (ICS), a long-acting beta agonist (LABA), and a long-acting muscarinic agonist (LAMA). To aid providers in selecting the appropriate combination therapy, a COPD pocket card was created to include medication classes and dosing regimens. Medication classes were distinguished by color to ensure providers were selecting the appropriate combination. Two educational sessions were held to review the recommended COPD therapy regimen, one for internal medicine staff and one for providers. The COPD pocket card was distributed to providers in April 2016 and the educational sessions were in April and May 2016. To assist providers, a team of nurse educators and pharmacy residents consulted on COPD-related admissions for patient education and
medication recommendations to optimize quadruple therapy. All patients with COPD-related diagnosis related-group (DRG) codes were included to determine the number of patients discharged on quadruple therapy.

**Results:** From January 2015 to March 2016, 33.83 percent (standard deviation 9.41) of patients discharged with a COPD-related DRG code were on quadruple therapy. From April 2016 to August 2016, 51.19 percent (standard deviation 9.99) of the same population were discharged on quadruple therapy. Utilizing a two-sample T-test, a statistical difference was found after implementing the COPD pocket card and education classes with continued nurse educator and pharmacy resident involvement. (P equals 0.014, 95 percent CI -29.80, -4.92).

**Conclusion:** Significantly more patients were discharged on quadruple therapy after initiating provider education and the use of a COPD pocket card along with the continued support of nurse educators and pharmacy residents.

**Poster Title:** Implementation of an electronic alerting tool in a community teaching hospital to prevent inpatient hypoglycemic adverse drug events

**Primary Author:** Amir Haddad, Virginia Hospital Center, VA; **Email:** ahaddad@virginiahospitalcenter.com

**Additional Author(s):**
Karima Waziri
Brian Caruth

**Purpose:** Glycemic control efforts in hospitals are often limited by the concern for hypoglycemic adverse drug events. Hypoglycemia, defined by the American Diabetes Association (ADA) as a blood glucose (BG) < 70 mg/dl and severe hypoglycemia defined as a BG < 40 mg/dl, constitutes a medical emergency. Inpatient team members must be vigilant in detecting, treating, and most of all preventing hypoglycemia in diabetic patients. The specific aim of this study is to show that implementing a hypoglycemic alerting tool supported by trained pharmacist responders is valuable for reducing the incidence of hypoglycemic adverse drug events in our hospital.

**Methods:** This study will involve monitoring patients admitted to a 350-bed community teaching hospital located in Arlington, VA, from October 2016 through January 2017. A computer-generated alert will identify patients with a potential risk for drug-associated hypoglycemic events. The alert will be directed to the pharmacist for any adult patient with a BG < 90 mg/dl and an active hypoglycemic medication order. The pharmacist is responsible for reviewing the patient’s profile and then contacting the prescriber for modification to therapy. The primary outcome of this study is the rate of hypoglycemic occurrence before and after implementation of the alert system. The secondary outcomes are rates of severe hypoglycemia episodes of BG < 40 mg/dl, length of stay, transfer to a higher level of care, and percentage of prescriber’s acceptance of pharmacist recommendations. All data will be de-identified and maintained in a secure and confidential manner. This study will be submitted to the institutional review board for approval.

**Results:** N/A

**Poster Title:** Implementation of pharmacy resident directed antimicrobial stewardship activities in a community teaching hospital

**Primary Author:** Yousef Lafi, Virginia Hospital Center, VA; **Email:** ylafi@virginiahospitalcenter.com

**Additional Author (s):**
Bernadette Wolford
Brian Caruth
Karima Waziri

**Purpose:** Pharmacists have a responsibility to take prominent roles in antimicrobial stewardship programs in the hospital setting. The Joint Commission recently announced a new Medication Management standard for hospitals which addresses antimicrobial stewardship and becomes effective January 1, 2017. Additionally, the Centers for Medicare and Medicaid Services is developing a Condition(s) of Participation on antimicrobial stewardship in the hospital setting. The Virginia Hospital Center antimicrobial stewardship program emphasizes generally accepted interventions recommended by Infectious Disease Society of America Guidelines. The purpose of this research is to determine the impact of pharmacy resident directed antimicrobial stewardship activities in a community teaching hospital.

**Methods:** Pharmacists at Virginia Hospital Center are responsible for daily monitoring and documentation of antimicrobial stewardship activities for all adult patients with antibiotic orders. Patients receiving antibiotics are identified by an electronic report. The pharmacy resident will receive antimicrobial stewardship training during the Infectious Disease rotation. After successful completion of the Infectious Disease rotation, the resident will perform antimicrobial stewardship activities for the medical oncology unit beginning October 2016. Protocol compliance will be reviewed as the primary outcome measure. Secondary outcome measures include intervention documentation, estimated cost savings, de-escalation activities and rate of prescriber accepted recommendations.

**Poster Title:** Analysis of drug shortages’ effect and cost at a tertiary university hospital

**Primary Author:** Alba Fernandez, not applicable, not applicable; **Email:** alba.fernandezpena@osakidetza.eus

**Additional Author(s):**
Goizane Ros
Silvia Mendiola
Leocadio Rafael López
Miren Karmele Larrinaga

**Purpose:** Drug shortages are becoming more frequent in our country as well as in the rest of the world and working to find a solution, at least for some of them, is mandatory. With this work, we decided to analyse the drugs that had shown a shortage at some point in the last three months as reported by the Spanish Drug and Health Product Agency (AEMPS) and how they have affected our hospital, as well as the measures we have had to take to overcome those shortages and the cost associated with those measures.

**Methods:** We analysed the notifications of drug shortages of the AEMPS that remained active at any time point from the 1st of June to the 31th of August 2016, shortages solved or not at the moment of analysis. We studied how long the shortage had lasted only in the ones that had already resolved, since the notified end of shortage date usually changes several times before the real resolution of the situation. We then divided drugs into two categories, those that we have at our hospital and those we don’t. Among the drugs included at our hospital, we registered what measures we had to take to overcome that shortage. We analysed the direct cost associated to buying alternative drug products due to the shortage and the price increase percentage of each one of those. In the case of drugs with a change of dosage comparing to the drug product used at our hospital, the cost was calculated per active unit of drug (milligrams or grams) instead of per presentation unit (tablet, bottle). We finally looked into the laboratories that produced the drugs affected by shortages.
Results: We analysed 238 shortages of 231 different drug products. Eight companies produce 59.2% of these drugs on shortage and two 24.4%, from a total of 57 companies. 91 shortages had already resolved. The average time of resolution was 69 days. 56 shortages, of 52 different drug products, involved drugs used at our hospital. To overcome this shortages, we borrowed the drug from another hospital (2), we obtained it from a pharmaceutical wholesaler instead of doing it directly from the pharmaceutical company (5), we ordered another drug with the same active principle, national (11) or foreign (4), we restricted the drug’s use (6), we changed the active principle (1), we had enough stock until the resolution of the shortage (27) or nothing could be done (1). 16 cases involved buying a different product. The median of the original cost of these 16 drugs was 1.1$ per unit [0.04-70.6$]. The price of the alternative was a median of 121.5% (97%-4422%) higher, with a mean direct incremental cost of 592.4$ [-44.4$] (+4034.9$)]. The total cost of buying these alternative drugs was 9487.3$.

Conclusion: Our analysis shows that drug shortages are a prevalent problem. There is a monetary cost associated to them and a big relative cost increase but the global economic burden is low, probably due to the low price of most of the drugs on shortage. The fact that shortages can cause delays of treatment and medication errors because of the need to use drug products with different active ingredients, doses or presentations, seems more worrisome. A reflection needs to be done in order to understand the causes of these shortages and to try to find global solutions to this growing problem.

Poster Title: Antimicrobial Stewardship in a Rural Community Hospital  

Primary Author: Caitlin Sinclair, St. Claire Regional Medical Center, KY; Email: Caitlin.Sinclair@st-claire.org  

Additional Author(s):  
Stephanie Justice  

Purpose: Antibiotic use in the treatment of numerous bacterial related infections has improved the health and wellbeing of countless patients. However, 20-50% of the antibiotics prescribed in our hospitals are excessive and unwarranted and can lead to the growing problem of antibiotic resistance. In response to this growing problem, antimicrobial stewardship programs (ASPs) are being implemented in hospitals across the country to better manage antibiotic use. The purpose of this study is to compare the use of now ‘restricted’ antimicrobial agents prior to the implementation of an ASP to the use after the program has been implemented.  

Methods: This study is a single center, combined retrospective/prospective, observational study on the impact of an ASP with regards to the use of restricted antibiotics within the institution. It will include all patients who are prescribed meropenem, ertapenem, daptomycin, linezolid or who are on piperacillin/tazobactam for greater than three days. The data being collected will consist of baseline demographics (including but not limited to sex, race, history of a multidrug-resistant organisms), the restricted antibiotic ordered, antibiotic allergies, description of allergy (if available/known), prescribing physician, date/time provider contacted, positive culture, source of positive culture, kidney function measures (baseline and on day of order), antibiotic indication, rationale for selection, and did provider change antibiotic selection after being contacted. Results will be grouped into whether the initial restricted antibiotic was indicated initially and whether or not a non-indicated medication was changed based on pharmacist recommendation.  

Results: Data collection is currently in progress so results and conclusions are pending completion of this process.

Poster Title: Identification and management of patients at risk of secondary osteoporosis in a community pharmacy setting: evaluation of clinical and humanistic outcomes of community-based MTM service

Primary Author: Kevin Astle, Auburn University Harrison School of Pharmacy, AL; Email: kna0018@auburn.edu

Additional Author(s):
Courtney Gamston
Kimberly Braxton Lloyd
Salisa Westrick

Purpose: Osteoporosis is a condition which affects over ten million Americans, contributes to over two million bone fractures annually, and is responsible for billions of dollars in healthcare costs alone. Secondary osteoporosis is low bone mineral density which occurs subsequent to specific medical conditions and medication use. Few studies have been conducted to evaluate pharmacist-led screening and management of secondary osteoporosis. With the known association between medication use and secondary osteoporosis, community pharmacists can provide enhanced screening and counseling services to improve identification and management of secondary osteoporosis. This study seeks to provide a framework for pharmacist-led ambulatory osteoporosis screening services.

Methods: This prospective cohort study will take place at the Auburn University Employee Pharmacy (AUEP) and Auburn University Pharmaceutical Care Clinic (AUPCC). Within the AUEP, medication fill histories will be reviewed at the time of prescription data entry and verification for: long-term use (use > 12 months) of proton pump inhibitors, selective serotonin reuptake inhibitors, and injectable medroxyprogesterone use > 3 months. Once identified, patients will be provided information regarding secondary osteoporosis and offered an appointment to meet with a pharmacist for bone mineral density assessment and counseling. At the appointment at the AUPCC, participants will have their bone mineral density assessed via quantitative ultrasound. A pharmacist or student pharmacist will discuss the results with participants as well as provide additional information regarding secondary osteoporosis and
contributing risk factors. Participants will be counseled on the prevention of osteoporosis and provided with supplementation for calcium and vitamin D. Patients identified with clinical osteoporosis will be referred for further evaluation. The primary outcome to be evaluated is the number of patients identified with osteopenia (defined as T-score < -1 but > -2.5) and osteoporosis (defined as T-score < -2.5). The secondary outcome of the study is an evaluation of baseline characteristics and association with risk of osteopenia or osteoporosis. Ultimately, this study will provide data and insight into the impact of a community-based pharmacist targeted osteoporosis screening program.

**Poster Title:** Evaluating fourth year student pharmacist empathy towards patient weight loss through active learning.  
**Primary Author:** Rachael Talaski, Auburn University Pharmacy Health Services, AL; **Email:** rlt0018@auburn.edu  
**Additional Author (s):**  
Margaret Williamson  
Jingjing Qian  

**Purpose:** With the growing obesity epidemic, an interdisciplinary approach that includes pharmacists is being proposed to assist obese patients in losing weight. Empathy from providers has been shown to help patients with weight loss. While accreditation standards place greater emphasis on developing skills such as empathy, the rates of empathy decrease throughout a professional program. Having students participate in active learning activities has increased empathy towards patients with other disease states. The study objective is to determine if fourth year pharmacy students participating activities focused on the tools for weight loss will impact their empathy towards patients attempting to lose weight.  

**Methods:** This study will take place at various ambulatory care practice sites affiliated with Auburn University. Fourth year pharmacy students who are completing their advanced pharmacy practice experience (APPE) rotations will be asked to participate. Students will have their empathy measured towards patients attempting lifestyle changes with the Jefferson Scale of Empathy on the first day of their rotation. Additionally students will be asked about their own diet and exercise before starting the activity, this will be done in an attempt to see if students’ habits prior to the study will have an effect on their empathy level. The students will then start tracking their calories and steps on applications available on smart phones. There will not be a requirement to set any calorie or exercise goals, however students will not be penalized if they choose to do so. Students will be excluded if they participated at another practice site or have a history of anorexia nervosa or bulimia. At the end of the five weeks, students will then take the same empathy scale to document if there are any changes in their empathy toward patients. Additionally their confidence level will be assessed along with the student’s compliance with the activity.

Poster Title: Evaluation of RASS Documentation in an Intensive Care Unit
Primary Author: Amanda McKinney, Baptist Medical Center South, AL; Email: almckinney@baptistfirst.org
Additional Author(s):
Rachel Settle
Matthew Nolin

Purpose: The Richmond Agitation Sedation Scale (RASS) is a validated instrument used to measure the level of sedation of patients in the ICU. The current sedation policy at Baptist Medical Center South requires intensive care nurses to perform RASS assessments and document RASS scores every four hours, titrating sedatives as needed to maintain a goal score of 0 to -2. It is unclear whether these assessments are being conducted appropriately and if the corresponding titrations are being made. The purpose of this study is to evaluate the accuracy of RASS assessments and determine if they are associated with appropriate sedative titrations.

Methods: This study will be submitted to the Institutional Review Board for approval. All patients in the cardiac intensive care unit receiving mechanical ventilation and continuous sedative infusions during the months of October and November will be included in the study. Patients receiving neuromuscular blockers, brief mechanical ventilation (< 12 hours), solely intermittent sedation, or tracheostomy will be excluded from the study. A clinical reference rater (BMCS pharmacy resident) will conduct twice daily RASS assessments on each patient meeting criteria and compare their RASS scores to the documented RASS scores obtained from the electronic medical record. Results will be evaluated using overall weighted-kappa to determine the level of agreement between parties. Demographics, RASS scores (nursing and reference rater), amount of sedation used, length of ICU stay, length of hospital stay, and incidence of ventilator-associated pneumonia (VAP) will be collected. Nursing education will be conducted after the first month of the study and additional data collection will take place during the second month. Results will be evaluated for improvement in RASS accuracy (i.e. improved level of agreement between reference rater and nurse) over the course of the study period. All data will be recorded without patient identifiers to maintain confidentiality.

Poster Title: Implementing a benzodiazepine-sparing sedation protocol for ventilated patients in the intensive care unit

Primary Author: Fran Grappe, Baptist Medical Center South, AL; Email: fgrappe@samford.edu

Additional Author(s):
Matthew Nolin
Kaitlin Moulton

Purpose: The 2013 Pain, Agitation, and Delirium guidelines suggest using nonbenzodiazepines as the sedative of choice. This choice is associated with improved clinical outcomes in mechanically ventilated ICU patients. Benzodiazepines may be a risk factor for the development of delirium; therefore avoiding their use may reduce mortality, ICU and hospital length of stay, and the development of post-ICU cognitive impairment. The purpose of this study is to analyze patient outcomes associated with decreasing the use of benzodiazepines and utilizing fentanyl’s analgesedative properties in combination with propofol to acquire proper sedation in the Medical ICU.

Methods: This study will be submitted to the Institutional Review Board for approval. A benzodiazepine-sparing sedation protocol will be initiated in the Medical ICU for ventilated patients that targets analgesedation with fentanyl in combination with propofol. Each patient will receive treatment from the study protocol within 48 hours of intubation. Alternative sedation regimens used prior to study enrollment will be discontinued upon initiation of study protocol and patients will be sedated with a RASS goal of 0 to -2. Collected data will include patient’s age, gender, weight, renal function, reason for admission, neuromuscular blockage usage, and medications used prior to initiation of study drug protocol. Patient outcomes prior to and after implementation of the study protocol in the Medical ICU will be compared. The following outcomes will be analyzed: number of days in the ICU and hospital, number of attempts to wean a patient off the ventilator until successful, occurrence of RASS documentation between 0 to -2, administration of antipsychotic medications, and occurrence of delirium. The reviewers will compare each study group to determine benefit from eliminating benzodiazepine usage for sedation.

Poster Title: Use of a procalcitonin-based antimicrobial stewardship recommendation to reduce duration of antibiotics in patients with sepsis and/or pneumonia

Primary Author: Elizabeth Covington, DCH Regional Medical Center, AL; Email: ecovington514@gmail.com

Additional Author (s):
Stephen Eure
Christen Freeman
Douglas Carroll

Purpose: The purpose of this research project is to analyze the effect of procalcitonin-based antimicrobial stewardship recommendations on antibiotic duration for pneumonia and sepsis. Procalcitonin (PCT) is a biomarker that is specific for bacterial infections versus viral or non-infectious causes, making it a useful tool in identifying the need for antibiotics. Studies utilizing PCT to guide antibiotic decision-making for patients with lower respiratory tract infections (LRTI) and sepsis have found reductions in antibiotic durations ranging from 1.5 – 4 days and a potential cost savings of ~10%, with no increased risk of mortality, adverse events, or infection relapses.

Methods: This study will utilize a pre/post study design, with a retrospective control group and a prospective intervention group. A non-binding PCT algorithm for suspected pneumonia and sepsis has been developed by the pharmacy resident, approved by the hospital’s infectious disease physician, and will be used to base antibiotic stewardship recommendations after the availability of in-house PCT testing in November 2016. Patients will be included in the prospective study if they have at least 1 PCT level ordered and a newly suspected infectious process of pneumonia and/or sepsis (based on physician diagnosis). The pharmacy resident will actively follow patients and make recommendations for prescribers to discontinue or de-escalate antibiotic therapy based on PCT results. The retrospective control group will consist of chart reviews to determine average antibiotic duration prior to the availability of PCT testing and prior to the implementation of PCT-based stewardship recommendations. The primary outcome will be duration of antimicrobial therapy, defined as the number of hours between the start and end of antibiotic treatment. Secondary outcomes
will include length of stay (LOS) in the hospital, LOS in the ICU, antimicrobial costs, mortality, rate of antibiotic de-escalation based on PCT interventions (defined as discontinuation of an antimicrobial agent or change of antibiotic to one with a narrower spectrum), number of PCT stewardship recommendations accepted vs. rejected, and time taken for stewardship interventions.

Poster Title: Evaluation of Pharmacy Resident Discharge Counseling on 30-Day Readmission Rates for High-Risk for Readmission Patients with a Heart Failure Exacerbation or Acute Myocardial Infarction

Primary Author: Megan Borchers, DCH Regional Medical Center, AL; Email: megan.borchers@dchsystem.com

Additional Author (s):
Doug Carroll
Kim Hooker

Purpose: The purpose of this research project is to evaluate the effect of pharmacy resident driven discharge counseling for patients at a high risk for readmission admitted with a heart failure (HF) exacerbation or acute myocardial infarction (AMI). Studies have shown pharmacist involvement at discharge can improve patient satisfaction, readmission rates, and ease transitions of care. This study will be conducted in a community hospital where the current standard of care is having nurses complete all aspects of discharge counseling.

Methods: This is a prospective study with an intervention made by the pharmacy resident completing this study. There will be two patient groups, the intervention group and the control group. Patients will be included into either group if they are identified as high-risk for readmission and admitted due to a HF exacerbation or AMI. Once a discharge order is placed, the resident will receive an email for patients included in the study. If the resident is able to reach the patient before he/she leaves, he/she will be included in the intervention group. In the intervention group, the resident will complete a medication review of the physician’s reconciliation and make interventions as needed. These patients will also receive a medication schedule and education from the resident. The control group will obtain the current standard of care. Both groups will be followed 30 days after discharge to determine primary and secondary outcomes. The primary objective for this study is 30-day hospital readmissions. The secondary objectives include, categorization of pharmacist interventions, reasons for hospital readmission, the time interval between discharge and readmission, the number, reasons, and time interval for emergency department (ED) visits within 30 days of discharge, the percentage of patients
who fill their new prescriptions through insurance within two weeks of discharge, and the time to complete interventions, create medication schedules, and counsel the patients.

Poster Title: Evaluation of infection risk associated with biologic treatment in rheumatic diseases

Primary Author: Veena Gadepalli, East Alabama Medical Center, AL; Email: veenagadepalli91@gmail.com

Additional Author(s):
Beth Butz
Christine Cicci
Kristen Helms

Purpose: While rheumatic diseases left untreated can result in severe disabilities and reduced quality of life, previous studies have confirmed the direct relationship between use of biologic agents and high incidence of infections as a result of secondary immunodeficiency. The purpose of this study is to objectively quantify the infection risks associated with biologic disease-modifying anti-rheumatic drugs (DMARDs) so that opportunities to improve outcomes and decrease hospital admissions/readmissions related to infectious complications may be identified.

Methods: This single-center retrospective study has been approved by the Institutional Review Board. The primary outcome will be incidence of serious infections defined as those that lead to Intensive Care Unit (ICU) admission, hospital floor admission, or intra-venous (IV) antibiotic use. The secondary outcome will be prescriptions written for antibiotics in the outpatient setting. The electronic medical record system will identify patients ≥19 years old, currently treated for any rheumatic disease, and with a disease duration of ≥ 6 months. All data will be recorded without patient identifiers and maintained confidentially. The following data will be collected: 1) Age 2) Comorbidities 3) Smoking status 4) Previous and current DMARD therapy 5) Previous and current steroid use (dose equivalent to ≥ 10 mg prednisone ≥ 2 weeks) 6) Number of observations resulting from infections and corresponding level of care received. Patients will be stratified into the following risk categories: 1) Traditional DMARD monotherapy 2) Traditional DMARD combination therapy 3) Biologic DMARD monotherapy 4) Biologic + traditional DMARD combination therapy; all groups +/- steroid use. Collected number of observations and their
corresponding level of care will be analyzed in each stratification group to evaluate infection risk.

**Poster Title:** Comparison of vancomycin treatment failures for methicillin-resistant Staphylococcus aureus bacteremias (MRSABs) stratified by minimum inhibitory concentrations (MICs)

**Primary Author:** Mary Joyce Wingler, East Alabama Medical Center, AL; **Email:** mgb0008@auburn.edu

**Additional Author(s):**
Darrell Childress
Amber Hutchison
Ricardo Maldonado

**Purpose:** Optimal treatment of methicillin-resistant Staphylococcus aureus bacteremias (MRSABs), when vancomycin minimum inhibitory concentrations (MICs) are high within the susceptible range, is of concern due to the high rate of mortality and increased prevalence of this infection. The reported incidence of vancomycin treatment failures when MICs are greater than 1 microgram per milliliter varies in recent literature, and current guidelines do not provide definitive recommendations for this situation. The purpose of this study is to evaluate vancomycin treatment failures in patients with MRSAB stratified by vancomycin MIC.

**Methods:** This study has been approved by the Institutional Review Board. This will be a retrospective chart review to evaluate vancomycin MICs and patient outcomes at one center between July 2010 and December 2016. Patients with positive blood culture data for MRSA will be reviewed via electronic health records for inclusion and for the collection of all data points. Data to be collected will include: demographic information, antibiotic selection for MRSAB, antibiotic dosing information, laboratory information relating to monitoring of antibiotics and renal function, source of MRSAB, comorbid conditions, source control, and concomitant medications. The primary outcome is to determine a difference in rates of vancomycin treatment failure between patients with vancomycin MICs less than or equal to 1 microgram per milliliter or vancomycin MIC of 2 micrograms per milliliter. Vancomycin treatment failure will be defined as microbiological failure or persistent signs and symptoms of infection at seven days. Inpatient mortality, 30-day readmission, vancomycin-associated nephrotoxicity, early
bacteremia clearance at 48 to 96 hours, and vancomycin treatment failures at 96 hours will be assessed as secondary endpoints.

Poster Title: Piperacillin-tazobactam loading doses prior to extended infusion in critically ill patients

Primary Author: Kavita Patel, East Alabama Medical Center, AL; Email: khp0004@auburn.edu

Additional Author(s):
Sarah Cogle
Darrell Childress
Ricardo Maldonado

Purpose: Piperacillin-tazobactam is a time dependent antibiotic. Prolonged infusion piperacillin-tazobactam has been shown to improve outcomes, however different loading doses prior to prolonged infusions have not been evaluated. Loading doses administered over 30 minutes prior to initiation of prolonged infusions prevent delays in concentrations reaching the minimum inhibitory concentration (MIC) and allows other intravenous medications to be administered sooner. The objective of this study is to determine if a difference in hospital length of stay exists between patients receiving a 3.375 gram or a 4.5 gram loading dose prior to initiation of extended infusions of piperacillin-tazobactam in critically ill patients.

Methods: This institutional review board approved retrospective chart review will utilize electronic medical records to identify patients who meet the following inclusion criteria: adult patients admitted to the intensive care unit (ICU) treated with piperacillin-tazobactam for at least 48 hours and have a creatinine clearance of 20 milliliters per minute or greater. Patients to be excluded are those who have hospital acquired pneumonia, ventilator associated pneumonia, those who received a concurrent anti-pseudomonal beta lactam within 5 days of piperacillin-tazobactam therapy, if goals are changed to comfort care, and those transferred from another facility. The primary outcome will be hospital length of stay (LOS). The secondary outcomes include ICU LOS, all cause hospital mortality, 30 day mortality, 30 day readmission, duration of therapy, time to defervescence, and time to white blood cell count resolution. A 3.375 gram loading dose given over 30 minutes followed by prolonged infusion 3.375 grams every 8 hours from September 2015 to May 2016 will be compared to a loading dose of 4.5 grams given over 30 minutes followed by prolonged infusion 3.375 grams every 8 hours from September 2016 to May 2017. Data to be collected includes demographic information,
comorbidities, recent healthcare institution exposure, microbiological data, concomitant antibiotics, the acute physiologic assessment and chronic health evaluation II (APACHE II) score, and the sequential organ failure assessment (SOFA) score.

**Poster Title:** Transitions of care in a large community based hospital

**Primary Author:** Adrienne Davis, Huntsville Hospital, AL; **Email:** adrienne.davis@hhsys.org

**Additional Author (s):**
April Williams
Mary Dang
Katie Farris

**Purpose:** Transitions of care is defined as changes in the level, location, or providers of care as patients move within the health care system. Such transitions can be critical points in a patient’s care. If transitions of care are poorly coordinated, especially when a patient is discharged from a healthcare facility, the chance of readmission is greatly increased. Improving care transitions continues to be a major focus in the national healthcare system. The purpose of this study was to study the impact made by starting a transitions of care pharmacy pilot in a large community based hospital.

**Methods:** The transitions of care pilot was initiated on three of the family practice units of the hospital. A major aspect of the pilot was daily multidisciplinary rounds between social workers, nurses, pharmacists, and physical therapists. The transitions of care pharmacist would then determine from the information received during rounds which patients should be seen for the day for medication reconciliation or discharge education. High priority was given to patients with multiple disease states, multiple medications, and to patients being discharged either to home self-care or home health. The transitions of care pharmacist was responsible for discharge medication reconciliation and for providing the patient with a written discharge sheet overviewing the medications the patient would take upon discharge. For the pilot, there was one transitions of care pharmacist, two licensed practical nurses, and several fourth-year pharmacy students who took an active role.

Data was collected on each medication reconciliation, whether admission or discharge, with emphasis on the duration of time spent, any errors corrected, and whether or not the transitions of care team was simply reviewing, correcting, or completing the medication reconciliation. The data was then compared to data collected before the pilot was started, and
evaluated to determine whether or not there was a difference in the duration of time it took to complete a medication reconciliation and the amount of errors corrected.

**Poster Title:** Implementation of guidelines for the management of duplicate medication orders

**Primary Author:** Shea Davis, Huntsville Hospital, AL; **Email:** shea.davis@hhsys.org

**Additional Author (s):**
Michele Durda

**Purpose:** Duplicate medication orders can lead to patients receiving inappropriate therapy as well as unintentional outcomes. These duplicate orders are often a result of multiple overlapping orders sets in combination with previous individual orders. Moreover, duplicate orders may lead to regulatory compliance issues with Joint Commission. For these reasons, institutional guidelines were established to provide pharmacists strategies for responding to duplicate medication orders without clear criteria for their use. The purpose of this study is to determine if the implementation of these guidelines effectively reduced the amount of duplicate medication orders with the ultimate goal of improving patient safety.

**Methods:** Duplicate medication orders guidelines were developed and approved by the Huntsville Hospital Pharmacy and Therapeutics committee. These guidelines allow pharmacists to automatically discontinue duplicate medication orders or adjust the "as needed" (PRN) indication on orders with duplicate indications. For this study, new guidelines for addressing duplicate medication orders were established, and pharmacist education was provided for their use. Data will be collected from chart reviews and compared to data collected prior to establishing new guidelines. In general, the pharmacist will review the following characteristics of the orders to determine the appropriate action to follow per the guidelines: PRN versus scheduled, sequence of orders, origin of each order, dose, frequency, route, and indications. Pharmacists will use their clinical judgment and contact the prescriber with concerns regarding duplicate orders or duplicate indications. Any duplicate medication order without clear criteria will be assessed by the reviewing pharmacist and automatically discontinued if deemed appropriate.

**Results:** Data is currently being collected for this study. The status is research-in-progress.

**Conclusion:** Data is currently being collected for this study. The status is research-in-progress.

**Poster Title:** Evaluation and implementation of an automatic nurse-driven protocol for discontinuation of alvimopan in post-operative colorectal surgical patients  

**Primary Author:** Fernando Diggs, Huntsville Hospital, AL; **Email:** fernando.diggs@hhsys.org  

**Additional Author(s):**  
Jonathan Spry  

**Purpose:** Alvimopan is indicated to accelerate the time to upper and lower gastrointestinal recovery following surgeries that include partial bowel resection with primary anastomosis. Alvimopan is administered for up to seven days or until the patient is discharged, usually following the first post-operative bowel movement. The objective of this study is to analyze the utilization of alvimopan in post-operative colorectal surgical patients at Huntsville Hospital and to determine if an automatic nurse-driven protocol after the first post-operative bowel movement results in decreased unnecessary use and cost savings.  

**Methods:** This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will be used to identify patients who have had a colorectal procedure and received alvimopan. The following data will be collected: patient age, gender, surgery type, pertinent medications, and reported adverse medication events. If available, results of renal and hepatic function tests will be collected. All data will be recorded without patient identifiers and maintained confidentially. This information will be analyzed to determine the total number and cost of alvimopan doses administered following the first post-operative bowel movement. A nurse-driven discontinuation protocol will be implemented for the patients of one colorectal surgeon and similar data will be recorded. The protocol will give nurses the autonomy to discontinue alvimopan after the first post-operative bowel movement. Pharmacy will provide nursing education and will utilize a clinical rule based system to simultaneously follow patients to ensure proper alvimopan discontinuation. This data will be reviewed to compare the total number of doses of alvimopan administered following the first post-operative bowel movement in patient sets utilizing the nurse-driven protocol and those not utilizing the protocol. Clinicians will also evaluate potential cost savings between the control and test groups. Upon completion of the analysis, the data will be interpreted to determine if the protocol can be extrapolated to other colorectal surgeons.

Poster Title: Impact of a standardized protocol on the incidence of phlebitis in patients receiving peripherally infused amiodarone

Primary Author: Kate Adcock, Huntsville Hospital, AL; Email: kathryn.adcock@hhsys.org

Additional Author(s):
Sharon Baty
Sara Jones
Gregg Knowles

Purpose: Intravenous amiodarone is a class III antiarrhythmic agent used in the treatment and prevention of life-threatening arrhythmias. Though not always feasible, it is recommended to administer amiodarone through a central venous catheter. It has been noted that infusing amiodarone through a peripheral vein commonly results in the complication of phlebitis. Phlebitis can result in patient discomfort, delay in treatment, or the need for additional medical intervention. The purpose of this study is to evaluate the impact of a standardized protocol, which limits the duration of the peripheral infusion, on the incidence of phlebitis in patients receiving peripherally infused amiodarone.

Methods: This retrospective chart review will be submitted to the Institutional Review Board to request exemption from review. The Allscripts EPSi™ Cost Manager will identify patients who received intravenous amiodarone and had a discharge diagnosis of phlebitis or thrombophlebitis. Patients will be reviewed pre- and post- adjustments to a standardized amiodarone infusion protocol which limits the duration of the peripheral infusion to less than twenty-four hours. Data collected for these groups will include: patient age, gender, ethnicity, protocol used, drug dose, type of intravenous access, duration of peripheral infusion, appropriateness of transition, interventions needed, and other possible causes of phlebitis. Following completion of data collection, the current protocol will be reviewed to determine if adjustments are needed. Also, the process for verification in the electronic medical record as well as nursing procedures will be reviewed. Finally, education will be provided to various members of the healthcare team who are involved in this process.

Poster Title: A Clinical and Economic Evaluation of Fecal Microbiota Transplant in a Community Hospital

Primary Author: Brian Boyett, Huntsville Hospital, AL; Email: brian.boyett@hhsys.org

Additional Author(s):
Jonathan Edwards

Purpose: Fecal Microbiota Transplant (FMT) has been demonstrated as a highly effective last-line treatment option for patients experiencing recurrent Clostridium difficile infections. Previously, FMT required the physician to find a suitable donor, usually a close relative of the patient, and prepare the stool for transplantation via colonoscopy. A non-profit organization aims to make this treatment more accessible to patients by providing standardized, ready-to-use formulations for providers to more easily perform FMT. The objective of this study is to evaluate the effectiveness and economic impact of commercially available FMT in patients with recurrent C. difficile infections in a large community hospital.

Methods: This study has been submitted for approval by the Institutional Review Board (IRB). The study population will include all adult patients with recurrent C. difficile that have been treated with FMT from 4/1/16 until 12/1/2016 in the hospital or at the hospital-owned outpatient center. Patients will be identified and enrolled by IRB approved infectious disease and gastroenterology physicians after experiencing at least two treatment failures with antimicrobial therapy. FMT will be administered rectally via colonoscopy or orally via capsules. Each patient will be evaluated at eight weeks post-transplant to identify if the patient suffered an adverse event and to determine if the patient experienced a sustained clinical cure. Clinical cure will be defined as the absence of C. difficile associated diarrhea. The economic impact of FMT will be evaluated using historical data collected from the electronic medical record including: C. difficile infection (CDI) rates, CDI readmission rates, CDI associated colectomy rates, cost of admissions and re-admissions, and antibiotic treatment cure rates. This data will be analyzed to determine the potential cost-avoidance FMT will provide for the hospital.

**Poster Title:** Improving the electrolyte replacement order set process at a large community hospital

**Primary Author:** Wassamon Viriyakitja, Huntsville Hospital, AL; **Email:** wassamon.viriyakitja@hhsys.org

**Additional Author (s):**
Jerry Robinson
Michele Durda

**Purpose:** Electrolyte management plays a vital role in providing safe and effective patient care. Since the adult electrolyte order set is frequently utilized in the hospital, it is important to evaluate its efficacy and safety for possible process improvements and order set changes. The primary objective of this study is to evaluate phosphorus and potassium repletions, review safety reports concerning electrolyte process, and to recommend order set and process changes based on analysis of collected data.

**Methods:** This project will be submitted to the Institutional Review Board for approval. The electronic medical record will identify patients who have received phosphorus and/or potassium repletion per the hospital adult electrolyte protocol. The following data will be collected: patient demographics, phosphorus and potassium levels pre- and post-treatment, and type of electrolytes administered. All data collected will be retrospective and de-identified. Data collected will be analyzed for efficacy and safety. Data from the medication error reporting system will also be analyzed to identify problems and areas of improvement. Then, the current protocol will be evaluated based on the data collected and improvements to the process and order set will be recommended for future implementation.

**Poster Title:** Retrospective evaluation of anti-psychotic medications for the treatment of Intensive Care Unit (ICU) delirium post-ICU discharge  
**Primary Author:** Steven Lee, Huntsville Hospital, AL; Email: lee.steven@utexas.edu  
**Additional Author(s):**  
Adam Sawyer  
Katie Sims  

**Purpose:** ICU delirium is associated with increased mortality, post-ICU cognitive impairment, and prolonged ICU and hospital length of stay. An ICU delirium protocol is utilized that addresses preventative non-pharmacologic interventions as well as medication treatment regimens for Confusion Assessment Method for the ICU (CAM-ICU) positive patients. However, no current process ensures pharmacologic treatment is discontinued when patient is CAM-ICU negative for 24 hours, discharged from the ICU, or after 10 treatment days. The objective of this study is to evaluate anti-psychotic medication discontinuation practices to improve patient safety and decrease medication costs associated with unnecessarily continued anti-psychotic agents.  

**Methods:** This study will be evaluated by the Institutional Review Board prior to data collection. A retrospective chart review of the past two years will be conducted on patients who had the “Adult Critical Care Sedation, Analgesia, and Delirium” protocol implemented. Patients will be included in the study if anti-psychotic medications (haloperidol, quetiapine, or ziprasidone) were administered during the ICU stay. Data collected will include CAM-ICU results, medication order continuation and administration of ICU delirium anti-psychotic medications post-ICU discharge, whether anti-psychotic medications were prescribed as a continuation of a home medication or as a new anti-psychotic medication initiation, patient death during hospitalization, and prescriber specialties utilizing pharmacologic treatment of ICU delirium. Data collection will not include any patient specific identifiers to maintain confidentiality.

Poster Title: Evaluation of intravenous immunoglobulin G (IVIG) product use in a large community hospital

Primary Author: Justin Meyer, Huntsville Hospital, AL; Email: justin.meyer@hhsys.org

Additional Author(s): Richard Cramer
Chris Pamperin
Adam Sawyer

Purpose: Four possible intravenous immunoglobulin (IVIG) formulations are currently available for use by clinicians in inpatient and outpatient settings in our institution. The objective of this study will be to evaluate the current IVIG product formulary for appropriate usage in regards to cost-effectiveness and patient tolerability and to recommend alterations to current practice if indicated.

Methods: An initial cost and formulary evaluation will be performed to determine if the current workhorse IVIG agent, Gamunex®, is the most cost-effective formulation available. After approval through the Institutional Review Board, a retrospective chart review will be performed on patients receiving IVIG therapy to determine which IVIG products were administered. Patients who received products other than Gamunex® will be evaluated for appropriateness of product selection and eligibility for product interchange. Reimbursement data for both inpatient and outpatient facilities will be evaluated. Adverse event information will be assessed and used to further qualify product appropriateness.

Poster Title: Impact of Structured Query Language (SQL)-driven pharmacist medication review on heart failure-related quality measures

Primary Author: Taylor Tran, Mobile Infirmary, AL; Email: taylor.tran@ttuhsc.edu

Additional Author(s):
Hong Duong
Michael Scalese
Olivia Nguyen

Purpose: Heart failure has been one of the fundamental disease states since inception of the Core Measures and has prevailed through all subsequent revisions. Unfortunately, the increasing scarcity of resources such as staffing makes it virtually impossible to provide due diligence and evaluate every single patient’s medication regimen. Structured Query Language (SQL) queries may serve as useful tool to hone in on patients who are missing pertinent medications. The objective of this study is to implement and evaluate the effect of Structured Query Language (SQL)-driven, pharmacist medication review on heart failure-related quality measures.

Methods: This study will be submitted to the Institutional Review Board for approval. An in-service on heart failure guidelines and core measures will be provided for clinical operations pharmacists (COPs). A designated pharmacist will write a series of Structured Query Language (SQL) statements that will identify the following specific subsets of patients:
• Patients with a principle diagnosis of heart failure and a documented EF of ≤ 35% without an aldosterone antagonist
• Black patients with a principle diagnosis of heart failure and a documented EF of < 40% without hydralazine/nitrate
• Patients with a principle diagnosis of heart failure history and atrial fibrillation without an anticoagulant

Upon 48 to 72 hours of admission, a trained pharmacist will perform a targeted medication review to assess the patient’s heart failure regimen and address any potential concerns and/or recommendations. Retrospective chart reviews will determine the effect of this process on the following heart failure-related measures: hydralazine/nitrate at discharge, aldosterone
antagonist at discharge, and anticoagulant prescribed at discharge. The primary outcome will be the American Heart Association’s Get With The Guidelines – Heart Failure Quality Measures scores following implementation and the differences in scores pre- and post-intervention rates will be used to examine effectiveness. The secondary outcome will be the number of pharmacist interventions.

Poster Title: Evaluation of precipitating delirium medication and the pharmacist impact through medication management in the ICU; A pilot study

Primary Author: Jessica Smith, Mobile Infirmary, AL; Email: jessica.smith@infirmaryhealth.org

Additional Author(s):
Olivia Nguyen
Charles Durant

Purpose: Studies have proven that the incidence of delirium can be reduced by more than half when precipitating medication for delirium is avoided. Medication management by the pharmacist can assist in early detection and prevention of delirium. The purpose of this study is to evaluate the utilization of precipitating delirium medication that occur in the medical and surgical intensive care units and implement a pharmacy service to minimize the usage.

Methods: This is a prospective study of patients admitted to medical and surgical intensive care units. A chart review will be performed from March 01, 2016 to September 31, 2016. This collection of data will identify common utilized precipitating delirium medication in the medical intensive care unit and surgical intensive care units. From October 01, 2016- March 31, 2017 the medication review with delirium medication guide will begin. Identified patients that meet the inclusion criteria will be undergo further evaluation by pharmacist. Designated pharmacists working in the medical and surgical intensive care units will be educated on identifying precipitating medications and risk factors for delirium using the medication guide. This guide will provide precipitating delirium medication and alternative medications that can be suggested to physician. Delirium inducing medications will include the following drug categories: opioids, benzodiazepines, and anticholinergics. Selected patients will be monitored upon admission to the ICU and throughout ICU stay. Once the monitoring period is completed, a retrospective look at the number of pharmacist intervention in medication management in delirium precipitating medications.

Poster Title: Evaluation of hospital acquired methicillin resistant staphylococcus aureus (HA-MRSA) infection rates in a surgical ICU setting

Primary Author: Rachel Simons, Mobile Infirmary Medical Center, AL; Email: rachelasimons@gmail.com

Additional Author(s):
Sara Utley
Charles DuRant

Purpose: Decolonization strategies have the potential to decrease rates of infection from methicillin resistant staphylococcus aureus (MRSA) in hospitalized patients. The purpose of this study is to evaluate the current hospital acquired MRSA infection rate in a surgical intensive care unit and determine if this patient population would benefit from implementation of a decolonization strategy.

Methods: This study received approval from the hospital Institutional Review Board. A retrospective chart review will be performed on fifty randomly selected patients admitted to the surgical intensive care unit over a three month time period. All patients admitted to the surgical intensive care unit from May 1, 2015 to July 31, 2015 are eligible for inclusion. There are no criteria that would exclude a patient from this review. Charts will be reviewed for methicillin resistant staphylococcus aureus (MRSA) positive cultures and use of antibiotics with activity against MRSA. Hospital acquired infection will be defined as an infection with onset greater than forty-eight hours from admission to the intensive care unit. Anti-MRSA antibiotics will include: vancomycin, tigecycline, linezolid, daptomycin, or clindamycin. All data will be recorded without patient identifiers and will be maintained confidentially.

Poster Title: Assessment of the effectiveness of a novel vancomycin nomogram at achieving steady-state trough concentrations of 15-20 mg/L

Primary Author: Cara Bujanowski, Princeton Baptist Medical Center, AL; Email: cara.bujanowski@bhsala.com

Additional Author(s):
Jessica Starr
Sarah Blackwell
Hillary Holder

Purpose: The majority of vancomycin nomograms currently available target trough concentrations of 10-15 mg/L. Guidelines now recommend higher target trough concentrations of 15-20 mg/L to improve penetration, increase the probability of optimal target serum concentrations, and improve clinical outcomes of complicated infections, such as bacteremia, endocarditis, osteomyelitis, meningitis, and hospital-acquired pneumonia caused by S. aureus. This study aims to investigate the effectiveness of a novel vancomycin nomogram at achieving trough concentrations of 15-20 mg/L.

Methods: This is a retrospective chart review of patients aged 18 to 89 who received vancomycin therapy dosed to target trough concentrations of 15-20 mg/L before and after implementation of a vancomycin nomogram dosing protocol. The post-protocol group will include patients dosed per the nomogram with steady-state trough concentrations reported between October 2016-January 2017, and the pre-protocol group will include patients dosed prior to implementation of the nomogram with steady-state trough concentrations reported between October 2015-January 2016. Patients will be excluded if they meet any of the following criteria: receipt of renal replacement therapy, acute kidney injury defined as an increase in baseline SCr by 0.5 mg/dL or 50% in the past 12 months, SCr less than 0.5 or greater than 2 mg/dL, BUN/Cr ratio greater than 40:1, cystic fibrosis, cirrhosis, paraplegia, or quadriplegia. The primary endpoint is the number of patients with steady-state vancomycin trough concentrations between 15-20 mg/L. Secondary endpoints include the number of patients with steady-state trough concentrations between 14-21 mg/L, greater than 20 mg/L, and less than 15 mg/L. Additional secondary endpoints include number of patients within the
following subgroups with steady-state trough concentrations between 15-20 mg/L and 14-21 mg/L: 70 years of age and older, 30 percent or more over ideal body weight, and critical care patients.

Poster Title: The management of Staphylococcus aureus bacteremia at Princeton Baptist Medical Center

Primary Author: Mary Stuart, Princeton Baptist Medical Center, AL; Email: mkg0006@gmail.com

Additional Author(s):
Kenda Germain
Nathan Pinner
Matthew Brown

Purpose: To assess the management of Staphylococcus aureus bacteremia at Princeton Baptist Medical Center in Birmingham, Alabama as compared to evidence-based standards of care. Following the conclusion of the study, the investigators plan to use the findings to enhance the management of Staphylococcus Aureus Bacteremia at Princeton Baptist Medical Center.

Methods: This study is an observational, retrospective chart review. Charts of non-pregnant adults with at least one Staphylococcus aureus positive blood culture at Princeton Baptist Medical Center from September 1, 2014 to August 31, 2016 will be reviewed. Only initial episodes of bacteremia will be included. Patients will be excluded if they are less than or equal to 18 years of age, have bacteremia secondary to an organism other than Staphylococcus aureus, or if any of the following occur within two days of initial positive blood cultures: death, discharge to another institution, left against medical advice, or deemed palliative. The primary outcome of the study is to determine the percentage of Staphylococcus aureus bacteremia cases managed in full concordance with evidence-based standards of care. Full concordance will be defined as appropriate definitive therapy, repeat blood cultures obtained within two to four days of positive cultures, documentation of sterile blood cultures, appropriate duration of therapy and completion of echocardiography. Secondary endpoints will include the individual components of the primary endpoint and the following: appropriate empiric therapy following positive blood cultures, time to initiation of empiric therapy from positive blood cultures, time to de-escalation (if appropriate) following Staphylococcus aureus sensitivity results, source control, in-hospital mortality, metastatic infection occurrence, infectious disease consultation, and pharmacy consultation.

**Poster Title:** Development of a delayed erythropoietin stimulating agent initiation protocol in the inpatient setting

**Primary Author:** Aaron Garrett, Princeton Baptist Medical Center, AL; **Email:** alg0026@auburn.edu

**Additional Author(s):**
Ashley Core
Rebecca Maxson
Jessica Starr

**Purpose:** Erythropoietin stimulating agents (ESAs) are used for anemia of chronic kidney disease (CKD) and anemia of chemotherapy. Our formulary ESA is epoetin alpha which is administered thrice weekly. However, there has been an increased use of methoxy polyethylene glycol-epoetin beta which is administered monthly. Varied dosing regimens with different ESAs present a challenge during hospitalization, as outpatient ESA dosing regimens are difficult to determine. This can result in potentially unnecessary doses and more frequent adverse events. The objective of this study is to develop a new ESA prescribing protocol at our hospital to improve safety and reduce costs.

**Methods:** To determine the current prescribing patterns of ESA therapy at our institution, we will complete a retrospective chart review from October 1st to December 31st 2016. Patients will be identified from an automatically generated daily list of ESA patients. All patients who receive a dose of ESA while in the hospital will be included. The following data will be collected for each ESA dose: indication, dose administered, administration time, hemoglobin level, and blood pressure. Additional data will include ferritin, transferrin saturation, administration of oral or intravenous iron supplementation, and length of hospital stay. Based on the formulary change at nearby Fresenius dialysis units to methoxy polyethylene glycol-epoetin beta, we will compare our data on when ESA doses were given to estimates of when the Fresenius dialysis patients received methoxy polyethylene glycol-epoetin beta to determine if we need to delay ESA initiation for hospitalized patients. From the collected data, an updated ESA protocol will be developed.

**Poster Title:** Appropriate antibiotic use for acute bacterial sinusitis in the primary care setting.

**Primary Author:** Jordan Wulz, Samford University, AL; Email: jwulz@samford.edu

**Additional Author (s):**
Katie Boyd

**Purpose:** The purpose of this project is to evaluate the use of antibiotics in patients with a diagnosis of acute bacterial sinusitis in a primary care setting. The Centers for Medicare and Medicaid (CMS) have developed a Physician Quality Reporting System (PQRS) that allows physicians and physician groups to report quality of care to Medicare. This project will assess if PQRS measure #332 is being met within a primary care physician office. This measure assesses the percentage of adult patients who were prescribed amoxicillin as a first line antibiotic at the time of diagnosis of acute bacterial sinusitis.

**Methods:** This will be a retrospective chart review assessing the percentage of adults 18 years of age or older who were diagnosed with acute bacterial sinusitis who were prescribed amoxicillin, with or without clavulanate, as a first line antibiotic at the time of diagnosis. Data to be collected includes age, sex, diagnosis, antibiotic prescribed, culture, and subsequent antibiotics prescribed if applicable. This data will be used to analyze the primary outcome (PQRS measure #332) and the secondary outcome of percentage of adults who received amoxicillin as a second-line antibiotic. There is estimated to be 100 patients in this cohort.

**Poster Title:** Retrospective drug utilization evaluation of intramuscular corticosteroid injections in the outpatient setting

**Primary Author:** Hanna Sung, Samford University, Jefferson County Department of Health, AL; Email: hsung@samford.edu

**Additional Author(s):** Rachel Slaton

**Purpose:** Corticosteroids are a widely used class of medications, due to its anti-inflammatory and immunosuppressive properties. There are studies that indicate that corticosteroid injections and tablets produce similar efficacy for certain disease states. In the outpatient setting, it is difficult to distinguish whether or not providers are utilizing corticosteroid injections based on evidence-based clinical indications. The purpose of this study is to evaluate the appropriate use of intramuscular corticosteroid injections administered in an ambulatory care setting.

**Methods:** This study is a retrospective chart review assessing appropriate use of intramuscular corticosteroid injections: methylprednisolone, dexamethasone, or betamethasone, given to patients who are 18 years of age or older at a primary care clinic from July 1, 2015 to June 30, 2016. The following data will be collected: age, sex, insurance status, corticosteroid injected, number of corticosteroid injections per patient throughout the study duration, dose, and indication for corticosteroid. The medication utilization evaluation will identify the indications for use of corticosteroids in the ambulatory care setting based on electronic medical records denoted in providers’ chart notes. Based on the indications gathered, a literature review will be conducted to assess whether the indication was evidence-based or not. The primary outcome will be the percentage of patients who had an evidence-based indication for corticosteroids. There will be an estimated 100 patients in the cohort.

**Poster Title:** Assessment of dexmedetomidine use before and after pharmacy led education.

**Primary Author:** James Carroll, St. Vincent’s Health System – Birmingham Hospital, AL; **Email:** james.david.carroll@gmail.com

**Additional Author (s):**
Dan Gillis
Camellia Speegle

**Purpose:** In February of 2016, a subcommittee of Ascension Health’s Therapeutic Affinity Group issued recommendations for the use of dexmedetomidine in the Intensive Care Unit setting. These recommendations were made as a direct result of a 2013 update to evidence-based practice guidelines published by the Society of Critical Care Medicine. The objective of this study is to investigate the proportion of dexmedetomidine use at St. Vincent’s Health System-Birmingham before and after education by clinical pharmacists.

**Methods:** This study will be sent to the Institutional Review Board for approval. The electronic medical record system at St. Vincent’s Health System-Birmingham will be used to retrospectively identify patients admitted in the 3 months before and 3 months after the implementation of a targeted education program. This program will consist of educational sessions given to pertinent health care members held by clinical pharmacists. Pharmacists will also disseminate electronic and print guides consisting of Therapeutic Affinity Group recommendations for dexmedetomidine use.

Patients admitted during the pre-specified time frame will be included based on the use of dexmedetomidine, unit location at time of administration, and date of administration. Once selected, de-identified demographic and clinical information will be collected. These data will be reviewed to determine if dexmedetomidine use is in agreement with guideline-based Therapeutic Affinity Group recommendations. An analysis will then be conducted to determine the proportion of patients meeting appropriate use criteria before and after the implementation of the pharmacist led educational program.

**Poster Title:** Evaluation of pharmacist interventions to improve prescribing of parenteral nutrition in a community hospital.

**Primary Author:** Bethany Brock, St. Vincent's Health System - Birmingham Hospital, AL; **Email:** bethany.brock@stvhhs.com

**Additional Author (s):**
Sam Faircloth
Crystal Deas
Dan Gillis

**Purpose:** One in every three patients admitted to the hospital are suffering from malnutrition. Hospitalized patients are at risk for developing malnutrition due to the body’s increased energy demands or inability to meet nutritional needs. Malnutrition adversely impacts all disease states. Strategies for implementation of nutritional support should be in place to ensure appropriateness and avoid delay of initiation. The American Society for Parenteral and Enteral Nutrition provide guidelines for proper implementation of nutritional support. The objective of this study is to determine the effect of a pharmacy-based intervention strategy on prescribers’ adherence to criteria for appropriate indications for parenteral nutrition.

**Methods:** The study was submitted to the Institutional Review Board for approval. Identification of patients who have been prescribed parenteral nutrition over a course of four months was collected by an electronic pharmacy data-tracking system. The following patient data was collected retrospectively for 100 patient charts using electronic medical record software: demographic information, primary diagnosis, length of hospital stay, number of days on parenteral nutrition, and indicating factors for initiation of parenteral nutrition. All data was maintained confidentially. De-identification tools were used to avoid having any patient identifiers in data analysis. Each patient’s data was reviewed and analyzed using Qualtrics software to determine if parenteral nutrition was indicated according to the ASPEN guidelines. An estimated percentage of non-indicated parenteral nutrition orders was determined. As an intervention strategy, implementation of pharmacist-led, prescriber education programs were conducted at in-service meetings, P&T committee meetings, and face-to-face interactions. Furthermore, upon reviewing orders for parenteral nutrition, pharmacists were to evaluate
patient data and determine if the therapy was appropriate or not, based on the indications set forth by the guidelines. In the circumstance of inappropriate or non-indicated parenteral nutrition orders, dialogue between the pharmacist and prescriber occurred to advise on guideline-driven parenteral nutrition initiation. Prospective data collection is occurring and will be analyzed following the pharmacist intervention strategy to determine the percentage of change in appropriately prescribing parenteral nutrition.

Poster Title: Low-dose versus high-dose aminoglycoside use for antimicrobial prophylaxis of type III open fractures
Primary Author: Christine Tafoya, Banner - University Medical Center Phoenix, AZ; Email: christinetafoya@outlook.com
Additional Author(s):
Mark Culver

Purpose: In open fractures, cefazolin is frequently the antibiotic of choice for infection prophylaxis. For patients sustaining Gustilo Classification type III open fractures, the Eastern Association for the Surgery of Trauma guidelines recommend the antibiotic coverage be expanded to include gram-negative organisms. While aminoglycosides have historically been selected, optimal dosing strategies have not been determined. The aim of this study is to compare infection rates in patients receiving either (1) less than 5 mg/kg/day (“low-dose”) or (2) at least 5 mg/kg/day (“high-dose”). Additionally, factors associated with infection risk will be identified.

Methods: In this Institutional Review Board-approved retrospective cohort study, data will be collected for patients with type III open fractures (Gustilo Classification) receiving either high-dose or low-dose aminoglycosides within the first 24 hours of injury. The primary outcome will be infection rates within 30 days of injury. Demographic data will be collected, and all data obtained will be recorded without patient identifiers. Variables collected with regards to the fracture will include: type, location, mechanism of injury, and surgical management approach. Timing (hours) to first dose of aminoglycoside, surgery, and closure of wound will be recorded. Aminoglycoside choice, duration, initial dose, daily dose (mg/day), and interval will also be recorded. If antibiotics are stopped prior to 72 hours, only the days on antibiotics will be used for categorization. Infection data will include: location, positive culture, organism, day diagnosed from admission, inpatient/outpatient treatment, antibiotic choice, and need for surgical intervention. Follow-up data will be collected utilizing both inpatient and outpatient medical records. Statistical analysis will be performed to determine if a significant difference exists in 30 day infection rate between the two dosing groups. Based on literature review, an infection rate of 7 percent can be considered reasonable with usual dosing. Assuming an
infection rate of 20 percent in the low-dose group, enrollment of 108 patients in each group will be necessary to detect a difference.

**Poster Title:** Weight-based versus standard vancomycin loading: the effect on 24-hour area under the curve over minimum inhibitory concentration ratio

**Primary Author:** Jennah DeVoll, Banner - University Medical Center Phoenix, AZ; **Email:** jennah.devoll@bannerhealth.com

**Additional Author (s):**
Mark Culver  
Dale Bikin  
Emily Richards

**Purpose:** Guidelines recommend targeting a 24-hour area under the curve over minimum inhibitory concentration ratio of 400 or greater to predict vancomycin efficacy. Initiating loading doses of 25–30 mg/kg for complicated infections or 20–25 mg/kg for mild–moderate infections is also recommended. The primary purpose of this study is to determine whether there is a difference in the proportion of patients achieving a 24-hour area under the curve over minimum inhibitory concentration ratio of at least 400 between patients receiving weight-based versus standard 1,000 mg loading doses of vancomycin, when vancomycin is maintained by a pharmacist after initiation.

**Methods:** This is a single-center, retrospective chart review study currently under review by the Institutional Review Board. Investigators will identify patients who have received vancomycin for confirmed methicillin-resistant S. aureus infection using the electronic medical record and vancomycin monitoring forms. The following data for each patient will be collected into a standard, de-identified monitoring form: age, gender, actual and ideal body weight, information pertaining to vancomycin trough results and medication administration, methicillin-resistant S. aureus minimum inhibitory concentration values for vancomycin, 30-day inpatient mortality, comorbidities, infection source, location of admission, alternative methicillin-resistant S. aureus antibiotics used, and Sequential Organ Failure Assessment and Glasgow Coma Scale scores. Investigators will perform statistical analyses to determine if there is a significant difference in the proportion of patients achieving a 24-hour area under the curve over minimum inhibitory concentration ratio of 400 between patients receiving weight-based versus standard 1,000 mg loading doses of vancomycin.
concentration ratio of at least 400 between patients receiving different vancomycin loading dose strategies.

Poster Title: Improving transitions of care for hematopoietic stem cell transplant (HSCT) recipients after discharge

Primary Author: Alyssa Hinchman, Banner - University Medical Center Tucson / University of Arizona College of Pharmacy, AZ; Email: hinchman@pharmacy.arizona.edu

Additional Author(s):
Ali McBride
Jerrelee Hollings
Ivo Abraham

Purpose: Hematopoietic stem cell transplantation (HSCT) is often used to treat a variety of disease states, including lymphoma, multiple myeloma, acute myeloid leukemia, and acute lymphocytic leukemia. These patients are discharged with numerous supportive care medications, such as immunosuppressive agents, anti-infective prophylaxis, anti-nausea medications, and other agents for home administration. This patient population is at a higher risk of complications and adverse outcomes in the transition setting between inpatient transplantation and outpatient follow-up care after discharge. The purpose of this study is to evaluate the impact of a pharmacist-led, transitions of care intervention for HSCT recipients between inpatient and outpatient care.

Methods: This study is currently undergoing review by the Institutional Review Board for approval. Patients will be enrolled during their pre-transplant, outpatient work-up for either allogeneic or autologous HSCT. During this pre-evaluation, patients undergo assessment of their adherence risk regarding supportive care therapies, and are educated by the ambulatory oncology clinical pharmacist on their transplant conditioning regimen, anticipated side effects, and supportive care medications. Enrolled participants will receive a monitoring telephone call within 24 hours of discharge from the inpatient bone marrow transplant service. Using a structured call script, researchers will evaluate participant adherence and understanding of discharge therapies, with particular emphasis on anti-rejection and infection prophylaxis medications. Potential medication-related problems, such as improper dosing, side effects, or pharmacy dispensing issues will be documented and assistance provided to attempt resolution of the problems. After completion of the telephone call, a post-intervention survey will be
administered to participants at their first post-transplant care appointment. Additional surveys will also be administered to members of the healthcare team at the cancer center. Descriptive analysis will be used to (1) summarize medication-related problems that occur in HSCT recipients after discharge, (2) summarize patient perceptions of the intervention and its impact on their healthcare and personal satisfaction, and (3) summarize the perceptions of the multidisciplinary hematology/oncology team regarding the impact and utility of the intervention.

**Conclusion:** N/A
Poster Title: Safety of rapid infusion of rituximab in the elderly patient

Primary Author: Eric Vertin, Banner Boswell Medical Center, AZ; Email: eric.vertis@.bannerhealth.com

Additional Author(s):
Tai Huynh
Randee Cottam

Purpose: Rituximab is a form of immunotherapy used to treat disease states both cancerous and non-cancerous. Infusion-related reactions are common, and rituximab is conventionally administered as a slowly titrated infusion resulting in prolonged infusion times and increased healthcare costs. Rapid infusion protocols with infusion times of 60 or 90 minutes have been shown to be safe and effective in various populations, but evidence supporting the use of rapid infusion rituximab in the elderly is limited. This study will assess the safety of rapid administration of post-first-dose infusions of rituximab in patients aged 65 and older as compared with standard infusion protocol.

Methods: This will be a retrospective cohort study. Institutional Review Board approval for this study is still pending. Data from the medical records of three outpatient infusion centers between January 1, 2014 and September 15, 2016 will be reviewed. Subjects must be 65 years or older to be included and must have received intravenous rituximab for any indication. The following parameters will be excluded: a subject’s first lifetime infusion of rituximab, infusions without administration of pre-medications, and infusions during hospital admission. Subjects will be de-identified by the assignment of a study identification number. The primary outcome will be the rate of infusion-related reactions among all rapid infusions and all standard infusions. Infusion-related reaction will be defined as any infusion that was stopped early with the administration of one or more rescue medications, or any abnormal change in vital signs from a baseline measured prior to infusion. Rapid infusion will be defined as any rituximab infusion completed as intended in 120 minutes or less. Standard infusion will be defined as any rituximab infusion completed in more than 120 minutes. The statistical analysis will include the use of generalized estimating equations to compare the rates of infusion-related reactions among all rapid infusions and all standard infusions.

Poster Title: Retrospective, qualitative review of the enhanced care process of the HEART pathway tool in a geriatric population

Primary Author: Kristye Russell, Banner Boswell Medical Center, AZ; Email: kristye.russell@bannerhealth.com

Additional Author(s):
Nicole Murdock
Randee Cottam

Purpose: The HEART Pathway is a risk stratification tool combining the HEART (history, echocardiogram, age, risk factors, and initial troponin level) score with serial troponin tests. The American Heart Association HEART Pathway Randomized Trial substantiated the real-time applicability and sensitivity of the HEART Pathway in detecting the risk for major adverse cardiac events in patients presenting to the emergency department with symptoms of acute coronary syndrome. The purpose of this retrospective, observational study is to describe the use of the Heart Pathway in patients aged 65 years or older.

Methods: This is a retrospective, observational chart review of patients 65 years or older presenting to the emergency department with chest pain. In addition to demographic data the following risk factors for acute coronary syndrome will be collected from the electronic medical records of selected patients: current smoker, hypertension, hyperlipidemia, diabetes mellitus, family history of coronary artery disease, body mass index greater than 30 kilograms per square meter, previous coronary artery disease, previous cerebral vascular accident, and previous peripheral vascular disease. HEART scores will also be manually extracted from the electronic medical record. For those patients without a recorded HEART score, a score will be retrospectively applied based on the HEART Pathway parameters (history, echocardiogram, age, risk factors, and initial troponin level). The risk category assessed to the patient as determined by the HEART Pathway tool will be compared to the disposition of the patient following the emergency department visit; early discharge, admission to observation unit, inpatient admission for cardiac intervention. Additionally, the occurrence of a major adverse cardiovascular and bleeding events leading to hospitalization within 30 days’ post index emergency department visit will be collected and analyzed via hospital system records. Patients
selected for inclusion in the study will be de-identified using a randomly assigned code statement consisting of alpha and numerical values.

Poster Title: Characterization of methylnaltrexone utilization and laxation in the acute care setting

Primary Author: Kathryn Qualls, Banner Desert Medical Center, AZ; Email: kathrynequalls@gmail.com

Additional Author(s):
Genesis Sezate

Purpose: The primary objective is to evaluate appropriate methylnaltrexone (MNTX) usage by assessing utilization indicators such as documented lack of laxation, nothing by mouth (NPO) status, opioid use and laxative use with dosage escalation prior to MNTX administration. Appropriate dosing regimen based upon renal function and indication (opioid-induced constipation with chronic non-cancer pain, opioid-induced constipation with advanced illness, postoperative ileus) will also be evaluated. The secondary objective is to assess time to laxation after initial MNTX administration.

Methods: An electronic medical record system will identify patients 18 through 89 years of age with orders for MNTX between January 1, 2016 and June 30, 2016. Patients taking MNTX, linaclotide, or lubiprostone prior to admission will be excluded. Retrospective review of the patients’ medical records will be utilized to collect the following data: age, gender, initial weight, and creatinine clearance, NPO status, time (hours) of last laxation prior to MNTX initiation and opioid usage prior to MNTX (defined as greater than or equal to two doses of scheduled or as needed narcotics in the preceding 24 hours prior to MNTX administration). Additional data will include: stimulant and/or osmotic laxative use and dosage escalation in the 48 hours preceding MNTX administration, MNTX dosage, and time (minutes) to laxation following first MNTX administration. After data collection and analysis, descriptive statistics will be used to characterize patients and utilization indicators. Additional statistical tests will be performed to determine if any correlation exists between utilization indicators and time to laxation.

Poster Title: Validation of anti-factor Xa response in patients with a body mass index greater than or equal to 60 kg/m2 receiving enoxaparin 60 mg twice daily

Primary Author: Charlott Fielding, Banner Desert Medical Center, AZ; Email: charlotte.fielding@bannerhealth.com

Additional Author(s): Kellie Fortier

Purpose: Banner Desert Medical Center implemented an enoxaparin dosing protocol for morbidly obese patients in 2015. Enoxaparin doses are automatically adjusted to 60 mg subcutaneously every 12 hours in patients with a body mass index (BMI) of greater than or equal to 60 kg/m2. Anti-factor Xa levels are drawn and prospectively evaluated on these patients with a goal target range defined as 0.2-0.5 units/mL. The primary purpose of this project is to validate this dosing protocol in adults with a BMI greater than or equal to 60 kg/m2.

Methods: This study was submitted to the Institutional Review Board for approval. Patients who received enoxaparin 60 mg every 12 hours with a BMI greater than or equal to 60 kg/m2 will be included. Patients will be identified retrospectively who are 18 years of age, admitted from August 1, 2015 to August 30, 2016, were on enoxaparin 60 mg every 12 hours, had a weight greater than or equal to 140 kg, and a creatinine clearance greater than 30 mL/min. Demographic data for age (less 90 years of age), gender, actual body weight at admission, ideal body weight, and BMI will be collected. Collection of outcomes data will include serum creatinine and creatinine clearance at baseline and at time of anti-factor Xa levels draw, deep vein thrombosis risk score, prophylaxis vs treatment indication, level drawn, administration of enoxaparin, anti-factor Xa level within 3-6 hours after 3 or more doses of enoxaparin, lab processing time greater than or equal to 60 minutes, major and minor bleeding, and thrombotic events. Descriptive statistics will be used to report continuous variables as means and standard deviations and categorical variables as percentages. For all tests, p values less than or equal to 0.05 will be considered significant.

**Session-Board Number:** 10-035

**Poster Title:** Validation of a pediatric vancomycin dosing protocol for patients 12 to 18 years old

**Primary Author:** Sue Lee-Chuu, Banner Desert Medical Center, AZ; **Email:** sue.lee-chuu@bannerhealth.com

**Additional Author(s):**
Hannah Dyk

**Purpose:** In this community hospital, a pharmacist driven vancomycin dosing protocol was implemented in order to improve the effectiveness of initial vancomycin dosing in attaining therapeutic troughs based on patient's diagnoses. The purpose of this evaluation is to assess the number of adolescent patients between ages 12 to 18 years in whom therapeutic trough levels were achieved using this weight based pediatric vancomycin dosing protocol. This evaluation will also evaluate the number of doses required to reach target trough levels of 10-15 mg/L and 15-20 mg/L in patient population.

**Methods:** In this Institutional Review Board approved, retrospective study, patients between ages 12 to 18 years who had vancomycin empirically dosed utilizing a pediatric protocol will be evaluated for the number of therapeutic trough levels achieved. This protocol included empiric dosing strategies based on patient’s weight, treatment indication, and target trough level. Subjects will be retrospectively identified through electronic medical records. Patients will be included aged 12 to 18 years, were prescribed vancomycin therapy for greater than or equal to 48 hours, empirically utilized the protocol, and had a documented steady-state trough concentration obtained. Patients will be excluded if they received less than 3 doses of vancomycin, vancomycin was initiated at another facility, initial trough concentrations were drawn inappropriately, or if they received hemodialysis or extracorporeal membrane oxygenation (ECMO). Data collection will include: age, gender, weight, height, if a patient was on hemodialysis or ECMO during vancomycin treatment, if trough was drawn appropriately, renal function, empiric dose and interval given, indication for therapy, and target trough. The following outcomes will be analyzed in order to validate this dosing protocol: vancomycin trough levels, whether trough level obtained was therapeutic according to goal, and development of acute kidney injury based on pRIFLE criteria.

**Poster Title:** Evaluation of the impact of a computerized physician order entry antimicrobial stewardship program targeting linezolid, with and without a lead infectious disease physician

**Primary Author:** Andrew Sam, Banner Estrella Medical Center, AZ; **Email:** asam34@midwestern.edu

**Additional Author (s):**
Sara Eichner
Katherine Rable
Bo Liu

**Purpose:** To compare the appropriate use of linezolid in a community hospital setting using a proactive, computerized physician order entry antibiotic stewardship program (CPOE-ASP) with and without the presence of an infectious disease physician lead.

**Methods:** A CPOE-ASP addressing the utilization of linezolid was designed for a 305-bed community hospital with a computerized physician order entry system already in place. Physicians ordering linezolid are presented with a dialog window summarizing the current approved usages for linezolid, as well as alternative antibiotics and hyperlinks to evidence-based articles. Utilization of this antibiotic was based on Food and Drug Administration and Pharmacy and Therapeutics Committee approved indications and limited to patients with: 1) treatment failure after at least five days of vancomycin therapy, 2) vancomycin-resistant enterococcus, or 3) history of allergic reaction to vancomycin. Linezolid use for bacteremia, endocarditis, and osteomyelitis is considered inappropriate unless all other treatment options have been unsuccessful. A medication utilization evaluation (MUE) for linezolid over a four month period in 2016 will be performed to assess the appropriateness of linezolid ordering, during which time there was no lead infectious disease physician present. This data will be compared to MUE data over a four month period in 2012 when a lead infectious disease physician was present. Chi squared analyses will be performed to assess statistical significance.

Poster Title: Assessing appropriate albumin use at an academic medical center

Primary Author: Angelina Castillo, Banner University Medical Center - South, AZ; Email: amcastillo@utexas.edu

Additional Author(s):
Jamie Natkowski
Georgina Rubal-Peace

Purpose: Albumin is routinely used throughout the intensive care unit (ICU) and medical floors. Albumin is recommended in certain settings, such as large volume paracentesis and spontaneous bacterial peritonitis (SBP) treatment. However, there is little data proving mortality benefit of albumin as the initial resuscitation fluid over less expensive crystalloids. Depending on the dose and concentration, albumin can be up to one hundred times more expensive than crystalloids. Inappropriate fluid selection can have a large economic impact on institutions. The purpose of this study is to determine the rate of inappropriate albumin prescribing and the direct albumin costs associated with them.

Methods: A retrospective observational study will be performed to assess appropriate albumin use at an academic medical center by reviewing no more than 100 charts. Patients prescribed and administered at least one dose of albumin will have their charts reviewed for inclusion into the study. In addition to determining which units of the hospital utilize the most albumin, the study will also evaluate the appropriateness of albumin use based on Federal Drug Administration approved labeling and national guidelines. The dose and appropriate concentration of albumin based on indication, as well as direct albumin costs will be evaluated. Results from this study will be used to create a pharmacy driven protocol outlining appropriate albumin use to align clinical practice with evidence-based literature and lower the economic impact of albumin, while maintaining the integrity of patient-centered care. Strategies to decrease inappropriate albumin usage may include prescriber education, formulary restrictions, and criteria based ordering.

Poster Title: Effect of pharmacist-led interventions on the inappropriate use of nitrofurantoin in an academic medical center

Primary Author: Jennifer Navar, Banner University Medical Center- South, AZ; Email: jennifernavar@utexas.edu

Additional Author (s):
Kristen Ellis
Georgina Rubal- Peace

Purpose: The purpose of this study is to determine the prevalence of inappropriate use of nitrofurantoin in an academic medical center. In addition, this study aims to evaluate the impact of a pharmacist-led intervention on hospital readmissions within 30 days as a result of inappropriate treatment with nitrofurantoin.

Methods: This study will include patients who either had an order for nitrofurantoin during their hospital stay or received a prescription for nitrofurantoin upon hospital discharge between October 1, 2015 and February 28, 2017. Patients will be identified through reports created on the electronic health record system. In order to determine prevalence of inappropriate nitrofurantoin therapy upon discharge, a retrospective chart review for each patient identified is conducted by a pharmacist and alternative recommendations are made as appropriate. Nitrofurantoin therapy is documented in the chart as appropriate only when used to treat uncomplicated urinary tract infections, as defined by the Infectious Disease Society of America (IDSA), in female patients with a creatinine clearance of 30 mL/min or greater. To evaluate the impact of pharmacist interventions, pre-intervention data will be collected for nitrofurantoin discharge prescriptions from October 1, 2015 through September 30, 2016. Post-intervention data will be collected from October 1, 2016 through February 28, 2017. A chi square test will be used to compare appropriateness of pre and post-intervention data. Additionally, number of patients readmitted within 30 days for infection that did not improve due to use of nitrofurantoin outside of IDSA guidelines before pharmacist interventions will be compared to rates after implementation of this initiative. Nitrofurantoin use during hospital stay will also be evaluated to determine effectiveness of pharmacist monitoring through documented interventions.

**Poster Title:** Comparison of safety and efficacy between two different computerized insulin management algorithms in a multi-hospital system

**Primary Author:** Chelsea Spencer, HonorHealth - Scottsdale Medical Centers, AZ; **Email:** chelsea.spencer@honorhealth.com

**Additional Author(s):**
Dyan Cherry

**Purpose:** Longstanding hyperglycemia is correlated with increased morbidity and mortality. Numerous studies have shown that tight glycemic control reduces these complications, but obtaining this control is associated with increased adverse events. Hypoglycemia, an adverse event related to tight glycemic control, is associated with increased mortality. Studies have shown that computerized insulin protocols are superior to manual or paper calculations. The objective of this study is to compare the safety and efficacy of two computerized insulin management algorithms across a wide variety of populations in a multi-hospital system.

**Methods:** This study will be submitted to the Institutional Review Board for approval. The primary outcome is rate of hypoglycemia, number of cases with severe hypoglycemia, and any sentinel events associated with hypoglycemia. Hypoglycemia will be defined as a capillary blood sugar < 70mg/dL, with severe hypoglycemia being < 50mg/dL. This will be assessed by D50W, glucose tablet, glucose gel, and glucagon usage from automated dispensing technology reports. All patients receiving one of these agents over 24 hours after admission will be included in the study. Patients receiving these agents within 24 hours of admission are excluded from the study as cause of hypoglycemia is more likely related to admission than because of an insulin protocol. The following data will be collected: patient age, gender, indication for insulin, blood glucose values and time drawn, admission date and time. All data will be recorded without patient identifiers and maintained confidentially. Patients receiving insulin where 3-component, LIIP, or Glucommander® was not utilized will be excluded from the study. The secondary outcome will be time to euglycemia while on an insulin infusion protocol. Time to euglycemia will be determined by hours until attainment of a fasting blood sugar between 140 - 180mg/dL.

Poster Title: Evaluation of procalcitonin utilization and subsequent antimicrobial de-escalation in critically ill patients.

Primary Author: Laura Macaveiu, HonorHealth - Scottsdale Medical Centers, AZ; Email: laura.macaveiu@honorhealth.com

Additional Author (s):
Amanda Johnson
Emanuel Nites

Purpose: Procalcitonin (PCT) levels are being used more commonly to drive clinician confidence of the presence of a bacterial infection in patients with sepsis and/or lower respiratory tract infections. It remains unclear if the results of PCT testing are being used to initiate or guide antimicrobial therapy. The objective of this study is to evaluate whether PCT levels are being utilized correctly based on the health system protocol (namely, the presumed disease state and number of levels ordered) and, when used appropriately, whether the results are used to initiate or de-escalate antimicrobial therapy if possible in critically ill patients.

Methods: This is a retrospective study that will be submitted to the Institutional Review Board for approval. The electronic medical record of two medical centers will be screened for adult patients who were admitted to the intensive care unit (ICU) and had at least one PCT level drawn in the unit. Patients will be excluded if they have chronic kidney disease stages four, five, or are on dialysis. The reviewers will compare the presumed disease state for obtaining a PCT and number of PCT levels on each patient to the health system protocol for appropriateness. The patient will fall into either the appropriate group or the inappropriate group. Screening will continue until 125 patients are identified for the appropriate group. The number of patients in the inappropriate group at that time will indicate how well PCT is being utilized. Data to be collected for the appropriate group includes: age, gender, infectious disease diagnoses, creatinine clearance, number of PCT levels, antimicrobials and positive culture results before and after PCT results, length of antibiotic treatment, and length of stay in the ICU. Data for the inappropriate group includes: number of PCT levels and presumed disease state for PCT level. Of the appropriate group, the reviewers will determine whether PCT results affected the decision to initiate or de-escalate antimicrobials (if appropriate), or did not affect treatment.

Poster Title: Comparison of standard and reduced-dose pegfilgrastim dosing regimens on clinical outcomes in an outpatient clinic

Primary Author: Adam Odeh, HonorHealth Scottsdale Medical Centers, AZ; Email: aodeh@email.arizona.edu

Additional Author(s):
Krystal Hicks

Purpose: Pegfilgrastim is a key component in the recovery of oncology patients after chemotherapy cycles in helping to prevent febrile neutropenia. However, a common side effect of bone pain can be debilitating for some patients, leading some providers to use reduced-dose pegfilgrastim, although limited data exists to support this practice. This project was designed to determine if there are negative clinical outcomes associated with reduced-dose pegfilgrastim regimens versus standard dosing regimens.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic health records will be retrospectively analyzed for all patients who received pegfilgrastim as part of their chemotherapy regimen. Patients will be separated into groups based on whether they received standard dose (6 mg) or a reduced dose ( < 6 mg). The following data will be collected: age, ethnicity, type of cancer, dose received, absolute neutrophil counts (ANC), reported bone pain events, current antimicrobial prophylaxis status, infection rates, febrile neutropenia rates, and whether chemotherapy had to be held or delayed. Particular attention will be devoted to whether or not the patients experienced negative clinical outcomes, such as neutropenic fever and/or infection. All data will be recorded without patient identifiers and maintained confidentially.

**Poster Title:** Time to target vancomycin trough concentrations in obese patients based on renal function

**Primary Author:** Linh Duong, HonorHealth Scottsdale Medical Centers, AZ; **Email:** linhyduong@gmail.com

**Additional Author (s):**
Kevin Malina

**Purpose:** About a third of the US population is obese, but there is a lack of data regarding appropriate antimicrobial dosing for these patients. Vancomycin is one of the most widely used antibiotics in the healthcare setting. Due to its high volume of distribution, safe and effective dosing of vancomycin in obese patients remains a challenge. The objective of this retrospective study is to evaluate how effective the current pharmacist directed vancomycin-dosing protocol is in attaining timely therapeutic trough concentrations without compromising safety in obese patients with varying renal function.

**Methods:** This study will be submitted to the Institutional Review Board for approval. This retrospective, multicenter chart review is composed of obese adult patients started on intravenous vancomycin therapy dosed by pharmacy from March 1, 2016 to August 31, 2016 admitted at one of three acute care community hospitals within the network. Patients to be included had a target trough of 15-20 mcg/ml and at least one trough drawn appropriately at steady state. Excluded patients will include pregnant, immunocompromised, dialysis patients, or an estimated creatinine clearance less than 30 ml/min, or a change in vancomycin dose prior to obtaining the initial trough. Data to be collected from eligible records include demographics, labs (serum creatinine, creatinine clearance, white blood cell count, max temperature), indication, loading dose if given, initial maintenance dose, frequency, initial trough level and whether it was therapeutic, subtherapeutic, or supratherapeutic, if levels were drawn appropriately, if vancomycin doses were given appropriately, final cultures, the number of days to reach therapeutic range, and duration of therapy. The primary endpoint is the number of days to achieve therapeutic troughs in obese patients based on renal function. Secondary endpoints include: nephrotoxicity rate, frequencies of therapeutic, subtherapeutic, and
supratherapeutic troughs, degree of obesity, and weight based dosing. The above data will be analyzed using descriptive and inferential statistics.

Poster Title: Antimicrobial stewardship intervention: Impact of audit and feedback on inappropriate urine cultures from the emergency department

Primary Author: Larissa Chin, Kingman Regional Medical Center, AZ; Email: larissakchin@gmail.com

Additional Author(s):
Dana Bowers
Claire Parker

Purpose: A major focus of antimicrobial stewardship programs is to improve patient outcomes through appropriate antibiotic use. It is estimated that the majority of antibiotic prescriptions are unnecessary or inappropriate. Antibiotics are often prescribed based on laboratory data without correlating clinical information. An example of this is asymptomatic bacteriuria, where there is a positive urine study without any accompanying signs and symptoms of urinary tract infection. The purpose of this study is to evaluate the appropriateness of urine cultures and antibiotic prescribing through targeted education and audit and feedback in the emergency department (ED).

Methods: This study is a retrospective audit and feedback intervention and will be submitted to the Institutional Review Board. All patients with positive urine cultures ordered through the ED from 10/1/2016 – 4/30/2017 will be identified through the laboratory system. The following data will be collected: age, gender, microbiologic data, signs and symptoms of urinary tract infection (UTI) at time of urine culture, diagnosis, antibiotic prescribed, length of antimicrobial therapy, hospital length of stay (LOS), and Clostridum difficile infection (CDI) within 28 days of antibiotics. Urine culture appropriateness will be based on signs and symptoms of UTI. Patients will be defined as having classic signs and symptoms (dysuria, frequency, urgency, flank pain, hematuria, suprapubic pain or costovertebral angle tenderness on percussion) or vague signs and symptoms (unexplained altered mental status, fever or rigors). On a monthly basis, urine cultures will be reviewed retrospectively for the preceding month and then targeted education and feedback will be given to providers regarding the appropriateness of urine cultures and antibiotic prescribing. The primary endpoint will be number of appropriate urine cultures. Secondary endpoints will be CDI rates, LOS, and antibiotic utilization. The Student’s t test will be
used to compare continuous variables. Categorical variables will be compared by Fischer’s exact or Chi-squared test. P values of less than 0.05 will be considered statistically significant and all tests will be two-tailed.

Poster Title: Retrospective review of discharge oral anticoagulation therapy for new onset atrial fibrillation at emergency department discharge

Primary Author: Douglas Lee-Chan, Northwest Medical Center, AZ; Email: douglas.leephan@northwestmedicalcenter.com

Additional Author(s):
Stephen Perona
Edina Hall
Michelle Garwacki
Jon Glover

Purpose: Anticoagulation plays a key role in stroke prevention for patients with atrial fibrillation (AF). Unfortunately, published literature suggests that emergency department (ED) patients who are not given an anticoagulant prescription upon discharge take longer to be adequately anticoagulated in the outpatient setting. The purpose of this review is to evaluate the frequency of prescribed oral anticoagulation therapy in new onset AF patients at discharge and its effects on outpatient anticoagulation compliance at 3, 6, and 12 months.

Methods: This study has been submitted to the Institutional Review Board for approval. Retrospective chart review will be completed for patients with an ED visit between October 1, 2015 and June 30, 2016 and an ICD10 code for AF. Patients will be excluded if they have a primary diagnosis of atrial flutter or chronic AF, death in the ED, admission to the hospital, discharge to hospice, pregnancy, oral anticoagulant prior to presentation to the ED, or INR ≥ 1.2 upon presentation. The following patient information will be collected through an electronic medical records system and electronic outpatient prescription claims database via Surescripts: demographic data, various comorbidities, CHA2DS2-VASc score, HAS-BLED score, and if a prescription for oral anticoagulation was processed at discharge and 3, 6, and 12 months post discharge. All data will be collected without patient identifiers and be securely stored to maintain confidentiality. The primary outcome of this study will determine the incidence of oral anticoagulation in patients discharged from the ED at 3, 6, and 12 months post discharge. Secondary outcomes will include days lapsed before anticoagulation initiation and if there are
any predictors that effect the prescribing of oral anticoagulants by ED physicians upon discharge from the ED.

Post Title: Comparison of post-intubation interventions early versus late after rapid sequence intubation (RSI) with rocuronium

Primary Author: Emily Kilber, The University of Arizona, AZ; Email: ekilber@email.arizona.edu

Additional Author(s):
Daniel Jarrell
Asad Patanwala
Christopher Edwards

Purpose: When rocuronium is used in combination with etomidate for rapid sequence intubation (RSI), patients are sedated for only a fraction of the time they are paralyzed because of etomidate's short duration of action and rocuronium's long duration. The purpose of this study is to compare the number of sedation interventions between 0 and 30 minutes to those occurring between 60 and 90 minutes after RSI induction with rocuronium. Compare propofol infusion rate at initiation of sedation versus 90 minutes after initiation for patients who had RSI induction with rocuronium.

Methods: This will be a retrospective cohort study that will include patient records from Banner University Medical Center Tucson. Patients will be included if they were intubated in the emergency department between 1/1/2014 and 9/1/2016, received etomidate and rocuronium prior to intubation, and were initiated on propofol and fentanyl infusions within 15 minutes of rocuronium dose. Patients will be excluded if they are less than 18 years old, initiated on midazolam infusion between time 0 and 90 minutes after rocuronium dose, Glasgow coma scale of 3 prior to intubation, or if they received any vecuronium or additional rocuronium for up to 90 minutes post-intubation. The main outcome measure is a sedative intervention in addition to initial propofol and fentanyl infusion rates. A sedative intervention will be defined as any one of the following: sedative bolus, sedative infusion rate increase, opioid bolus, opioid infusion rate increase, and haloperidol use. We will not include interventions that occur during initiation of sedation and analgesia. The number of interventions will be categorized based on time intervals with time 0 being the time of rocuronium dose: 0 to 30 minutes (early), 30 to 60 minutes (middle), and 60 to 90 minutes (late). The primary comparison will be the number of
interventions that occurred between the early and late phases. We will target a sample of 100 patients for this study.

Poster Title: Joint pharmacist-physician patient visits billing model and its impact on reimbursement

Primary Author: Amani Alshehri, University of Arizona College of Pharmacy/Banner-University Medical Center South Campus Family Medicine and Diabetes, AZ; Email: amanitinn@gmail.com

Additional Author(s):
Maryam Fazel
Marion Slack
Julio Valencia

Purpose: Despite the recognition of pharmacists’ cognitive/clinical services such as Medication Therapy Management (MTM) for reimbursement in the past decade, barriers to pharmacist billing continues to exist. Unlike physicians, pharmacists are not reimbursed based on the complexity level of the services they provided but are reimbursed mostly based on the time spent providing services. Consequently, pharmacist reimbursement is mostly limited to level 1 or low complexity equivalence if at all possible. This approach undervalues the reimbursement for pharmacists’ clinical services. The purpose of this study is to evaluate the impact of joint pharmacist-physician visits billing model on improving reimbursement.

Methods: At our ambulatory care endocrinology clinic, joint pharmacist-physician visits are implemented and billed by the physicians as per complexity of the services, using Evaluation and Management (E/M) CPT codes. During each typical visit, the pharmacist gathers information, interviews patient, and assesses patients’ diabetes regimen, treatment efficacy, adherence, disease/therapy complications, provides diabetes self-management education as indicated, and formulates therapy and monitoring plans. Based on the pharmacist-physician-joint decision-making, a final treatment plan is communicated to the patient. The primary objective of this study is to investigate the impact of pharmacists’ contribution to the visits’ revenue compared to both the revenue from the time spent by physicians alone, level 1 E/M CPT code, and MTM codes by comparing such reimbursement rates. This retrospective, single center study will be submitted to the University of Arizona institutional review board for approval. It will include all adult patients with diabetes who were seen in joint pharmacist-physician visits from November 2014 to August 2016. Patient baseline characteristics (age, sex,
body mass index), most recent glycosylated hemoglobin (HbA1c) lab test, diabetes type and duration, insulin/insulin pump use, and pertinent comorbidities will be collected. The level of service billed, reimbursement amount in dollars, insurance plan, time spent by pharmacist and physician will be collected. Descriptive analyses will be used to analyze the data.

Poster Title: Implementation of Med-to-Bed Program for Post-PCI Patients Receiving Ticagrelor

Primary Author: Ashley Swan, Yavapai Community Hospital Association, AZ; Email: aswan@yrmc.org

Additional Author(s):
Teresa Garcia
William Brown
Jeffrey Anderson
Jonathon Nuckles

Purpose: In the US, nearly 8 million Americans have a history of myocardial infarction; they are at higher risk for recurrent ischemic events. While treatment is started in the hospital, patients may experience fragmentation during transitions of care. The Med-to-Bed program was designed to improve compliance with an antiplatelet agent after discharge from the hospital. Eligible patients are provided with a complimentary 30 day supply of ticagrelor and bedside education. The aim of this retrospective analysis is to evaluate the impact of the program on readmission rates and mortality in post percutaneous coronary intervention (PCI) patients in a community hospital system.

Methods: This retrospective analysis was performed via electronic chart review. Inclusion criteria included patients who were greater than 18 years of age admitted with an acute coronary event requiring PCI and discharged with ticagrelor at Yavapai Regional Medical Center-West Campus in Prescott, AZ. The cohort was divided into two groups, patients who participated in the Med-to-Bed program and those who were not enrolled in the program. The chart review consisted of patient demographics, admitting diagnoses, and the date ticagrelor was initiated. The primary outcome measure was the rate of readmission within 30 days from initiation of treatment. Secondary outcomes include, 90 day readmission rates, mortality rates and diagnoses and any change in antithrombotic therapy within 30 days.

Results: Patients initiated on the Med-to-Bed program experienced less readmission to the hospital. Within a thirty day period, 10% (n=4) of patients participating in the Med-to-Bed program were readmitted compared to the 27% (n=12) of patients in the control group. No
patients in the Med-to-Bed program expired compared with two patients in the control group. A higher number of patients in the Med-to-Bed program (n=15) compared to the control group (n=7) switched to a different antithrombotic agent thirty days after initiation. The primary reason for changing antithrombotic agents in both groups was attributed to increased shortness of breath.

**Conclusion:** Patients participating in the Med-to-Bed program had a lower hospital readmission rate than the control group within thirty days of initiation of therapy, as well as lower mortality rate post PCI. The Med-to-Bed program group did have an increased rate of changing antithrombotic therapy after thirty days of initial treatment. The Med-to-Bed program appears to be most beneficial in reducing the rate of readmission to the hospital. Further investigation is clearly warranted.

Poster Title: Evaluation of the use of aztreonam for the use of empiric treatment of infections in a rural community hospital

Primary Author: John Riddle, Yuma Regional Medical Center, AZ; Email: jriddle@yumaregional.org

Additional Author (s):
Jacob Schwarz

Purpose: Aztreonam is a beta-lactam antibiotic that is often used in patients who have a reported penicillin allergy. It has been previously shown that the majority of patients with a reported penicillin allergy in fact do not have a true allergy, and those that are allergic to penicillins have a small risk for any cross-sensitivity reaction to cephalosporins. This means we may be empirically giving patients a less effective and more costly antibiotic when it isn’t necessary. The purpose of this Medication Use Evaluation (MUE) is to identify inappropriate use of aztreonam at a rural community hospital.

Methods: This MUE is exempt from Institutional Review Board (IRB) approval because it is a quality assurance project that will review patient charts from a 1-year period of July 1, 2015 to June 30, 2016. The researcher will collect data on patient’s age, gender, weight, allergies (and reactions), serum creatinine, diagnosis (with culture and sensitivities), history of antibiotic use, days of antibiotic therapy and number of recent hospitalizations. By retrospectively reviewing patient charts, the investigator will determine whether the use of aztreonam was appropriate. Aztreonam use will be deemed appropriate if; the patient has a documented allergy to penicillin or a penicillin derivative and the patient has not received a penicillin or a penicillin derivative since the date of documentation, or if the patient has ever received any cephalosporin without an adverse reaction. Descriptive statistics will be used to describe the number of patients who meet the criteria for appropriate use. Patient information will be omitted from the data collection tool and all data collection sheets will be kept confidential and in a locked cabinet in a locked office. The investigator’s findings will be delivered to the Pharmacy and Therapeutics committee at Yuma Regional Medical Center (YRMC) and suggestions will be provided on how to improve the use of aztreonam at YRMC.

Poster Title: Evaluation of the appropriate use of daptomycin in a rural community hospital

Primary Author: Imaan Gill, Yuma Regional Medical Center, AZ; Email: imaan.gill20@gmail.com

Additional Author(s):
Jacob Schwarz

Purpose: Daptomycin is a lipopeptide antibiotic indicated for serious infections with gram-positive organisms such as vancomycin-resistant enterococci and methicillin-resistant staphylococci. Daptomycin is also employed in patients who are intolerant to or experience therapy failure with vancomycin. Given the relatively high cost of daptomycin compared to other antibiotics with gram-positive coverage, its unique mechanism of action and side effect profile, it is important to reserve this medication for proper use. Hence, the purpose of this retrospective medication use evaluation is to determine the appropriateness of current prescribing practices of daptomycin in a rural community hospital.

Methods: Patients who received daptomycin during an inpatient admission at Yuma Regional Medical Center over a twelve-month time period were identified via reports generated by EPIC, the institution’s electronic medical record. Patients were evaluated for age, gender, weight, hospital location, pertinent allergies, baseline serum creatinine and creatinine clearance, type of infection, culture and sensitivity findings, daily dose of daptomycin ordered, total number of daptomycin doses and duration of therapy, adverse effects, ordering physician and the presence or absence of an infectious diseases consult. Appropriateness of daptomycin use was determined by documented patient indication, encompassing both type of infection and cultures/sensitivities, dose and antibiotic allergy history. Other data collected during the study will be used to enhance knowledge of current prescribing practices, including the physician services that typically prescribe daptomycin, areas of the hospital that utilize it most often, average duration of treatment and frequency of monitoring for adverse effects, namely creatine phosphokinase (CPK) elevations.

**Poster Title:** Ketamine versus opioid analgesics for pain control in the emergency department

**Primary Author:** David Sharkey, Bayhealth, DE; **Email:** david_sharkey@bayhealth.org

**Additional Author(s):**
Karen Freid
Erika Rust

**Purpose:** Ketamine has been utilized as an alternative to traditional opioid analgesics for treatment of acute pain in the emergency department setting. Ketamine may potentially offer a longer duration of pain relief with fewer side effects, including addiction potential, compared to opioids. We conducted a study to determine the effectiveness and safety of ketamine compared to opioids for the relief of pain in the emergency department.

**Methods:** This non-inferiority cohort study will compare the effect of two pain treatment interventions on pain scores one-hour post initial analgesic doses. The treatment groups will be patients receiving ketamine 25 mg intravenous (IV) bolus doses (followed by 25 mg ketamine infusion doses if needed) and patients receiving traditional opioid analgesic doses (converted to IV morphine equivalents). The primary study endpoint is the number of patients in each group that achieve at least a 50 percent reduction in the pain score on a 0-10 numeric scale at one hour post initiation of treatment. Secondary outcomes are: average difference in pain scores 60 minutes post treatment initiation, adverse event rates, significance of adverse events (serious or non-serious), time to hospital/emergency department discharge, need for additional analgesia and analgesia doses, and difference in pain score at 120 minutes post initiation of analgesia doses. Inclusion criteria for the trial are; age greater than 17 years, presenting pain score of 5 or greater out of 10 on a 0-10 numeric pain rating scale, at least one dose of IV opioid medication or IV ketamine for pain relief, and documentation of at least one follow-up pain assessment by a numeric pain rating scale. Exclusion criteria for the trial are: intracranial hemorrhage, allergy to ketamine, current pregnancy, or inability to vocalize pain score.

**Poster Title:** Financial impact of pharmacy charge on administration versus charge on dispense in a community hospital setting

**Primary Author:** Kaci Coveleski, Bayhealth, DE; **Email:** kaci_coveleski@bayhealth.org

**Additional Author(s):**
Karen Freid  
Ryan Majchrzak  
Tara Kompare

**Purpose:** In order to maintain hospital revenue and financial viability, it is important to accurately charge patients for administered medications. Most hospital pharmacy departments accrue revenue by either charging when a medication is dispensed or when a medication is administered. Depending on the method of charge capture, revenue may potentially be undervalued or even overvalued. Implementation of a computerized electronic health record system may allow for more precise charging on administration. This study will examine the financial impact of pharmacy charging on administration compared to charging on dispense in a community hospital setting.

**Methods:** This study is a non-blinded economic trial. The primary endpoint is average pharmacy department revenue before and after implementation of a new electronic health record system. The secondary endpoints are: change in pharmacy revenue for inpatient and outpatient areas, percent change in total medication scanning compliance, and percentage change in revenue for inpatient and outpatient areas before and after implementation of a new computer system. Revenue information will be obtained from seven monthly computer-generated revenue reports immediately preceding the intervention of the complete electronic health record system and for seven months following the implementation. These reports will be compared to the monthly work load indicators (patient census) and adjusted as needed for each study phase. The correlation between medication scanning compliance and revenue for each study phase will be examined. All revenue in the pre-implementation phase will be adjusted upward by the same whole sale percentage mark-up applied in the post-implementation period. The primary and secondary endpoints will be analyzed using the
Student’s t-test while Pearson’s correlation coefficient will be utilized to determine the correlation of revenue with medication scanning compliance.

**Poster Title:** Continuous ketamine infusion for sedation and analgesia in the surgical intensive care unit

**Primary Author:** Vivek Kataria, Christiana Care Health System, DE; **Email:** vivek.k.kataria@christianacare.org

**Additional Author(s):**
Tep Kang

**Purpose:** The Society of Critical Care Medicine (SCCM) guidelines for the management of pain, agitation, and delirium consider opioid analgesics as one of the mainstay therapies for intensive care unit associated pain. When opioids have been titrated to their maximum tolerated effect, non-opioid analgesics can be considered. The role of glutamate neurotransmission in promoting and maintaining pain states has been studied as a new pathway for analgesia. In the setting of persistent peripheral injury or inflammation, glutamate neurotransmission has been shown to increase, resulting in activation of N-methyl-d-aspartate (NMDA) receptors. Spinal neurons therefore become hyper-responsive to repetitive painful stimulation, which may be clinically observed as hyperalgesia. Ketamine, an NMDA receptor antagonist possesses both analgesic and sedative properties. Although it has not been extensively studied, it has demonstrated a unique opioid-sparing effect that helps to reduce both the overall quantity of opioids administered and the incidence of opioid-related side effects. This report discusses the utility of a continuous ketamine infusion in a 51-year-old woman presenting to our emergency department with a chief complaint of a new onset pain in her right lower extremity. Upon evaluation, the patient’s past medical history was significant for methicillin resistant Staphylococcus aureus (MRSA) and Pseudomonas aeruginosa infections to her right lower extremity for which she had surgical debridement and a skin graft placement. Additionally, her social history was significant for polysubstance abuse with cocaine and heroin. Due to the severity of her necrotizing acute soft tissue infection, the patient was taken to the operating room for further excisional debridement. Post-operatively, dressing changes were performed using conscious sedation methods with ketamine 30 milligrams (mg), midazolam 4 mg, as well as a hydromorphone patient-controlled analgesia (PCA) pump. The hydromorphone PCA was set to deliver a loading dose of 0.5 mg, a PCA dose of 0.3 mg (12 minute lock-out) and a continuous infusion of 1 mg/hour. Despite this, the patient’s pain was inadequately controlled,
with consistent pain scores of 10 out of 10. A continuous ketamine drip was therefore started at 9 mg/hour. After three days of overlapping therapy, the hydromorphone PCA was adjusted to deliver a PCA dose of 0.5 mg (15 minute lock-out) and a continuous infusion of 0.5 mg/hour. Additionally, her pain scores markedly improved after the initiation of ketamine, ranging between 4 and 6. The ketamine drip was subsequently discontinued and the patient continued to improve clinically throughout her hospital course. The hydromorphone PCA was gradually weaned off and the patient was transitioned to oral opioids prior to discharge. Ketamine is known to cause psychomimetic reactions, such as vivid dreams and hallucinations, however no such effects were reported in this patient. As this case suggests, a continuous ketamine infusion has the possibility to assist in both analgesia and sedation. Although further studies are needed, clinicians should be aware of the non-opioid alternatives available to assist with ICU associated pain.

**Poster Title:** Prosthetic valve endocarditis due to Mycobacterium chimaera in a patient following open-heart surgery

**Primary Author:** Mathew Mason, Christiana Care Health System, DE; **Email:** matthew.j.mason@christianacare.org

**Additional Author (s):**
Nicole Harrington
Julianne Gardner
Jillian Dougherty
David Cohen

**Purpose:** This patient case summarizes the importance of increased clinical suspicion for Mycobacterium chimaera (M. chimaera) in patients following open-heart surgery that present with culture-negative endocarditis. There has been a recent increase of case reports of infective endocarditis due to non-tuberculosis mycobacterium. Within the past year, both the United States Food and Drug Administration (U.S. FDA) and Centers for Disease Control and Prevention (CDC) released statements regarding safety concerns for non-tuberculosis mycobacterium infections following open-heart surgery. Studies have shown that contamination of heater-cooler units, which are used to control a patient’s blood temperature during cardio-pulmonary bypass, is the likely source of infection. Specifically, a sequevar of the Mycobacterium avium (M. avium) complex, M. chimaera, has been identified in these heater-cooler units worldwide. Our patient was a 68 year-old white male with a significant cardiovascular medical history including atrial fibrillation, third degree heart block status post permanent pacemaker placement, coronary artery disease status-post a coronary artery bypass graft in November 2015, and aortic valve stenosis status-post an aortic valve replacement also performed in November 2015. The patient presented with a 7-week course of low-grade fevers, generalized weakness, and intermittent nausea and vomiting. Routine blood cultures were collected but no causative organisms were identified. Diagnostic imaging via a transesophageal echocardiogram revealed a vegetation surrounding the newly-placed, prosthetic aortic valve. He was initially treated with vancomycin, cefepime and gentamicin for culture-negative endocarditis. After three days of this regimen, his renal function started to decline. By the tenth day, his renal function continued to deteriorate and he required intermittent hemodialysis. Because of the
acute renal failure and persistently negative blood cultures, the antibiotic regimen was consolidated to just ceftriaxone. Additional blood cultures were collected to allow for an extended incubation time to rule out the growth of fastidious organisms. In addition, acid-fast bacilli blood cultures were obtained. The patient also had a further work-up of culture-negative endocarditis that included testing for Bartonella, Coxiella, Mycoplasma, and Legionella, and all testing remained negative. Approximately one month into the patient’s hospital stay, the acid-fast bacilli blood cultures demonstrated positive growth. Due to the recent reports of non-tuberculosis mycobacterium and this patient’s recent surgical history, there was strong clinical suspicion of prosthetic valve endocarditis due to M. chimaera. The patient was started on an anti-mycobacterial regimen consisting of ethambutol, rifabutin, and azithromycin. The patient was discharged from the hospital two days after the initiation of this regimen and was to follow up as an outpatient. Six days after the detection of a positive blood culture, further speciation of the culture revealed growth of M. avium complex. Additional work-up of the blood cultures at an outside laboratory confirmed the detection of M. chimaera. Because of the increase in case reports and safety concerns with contamination of heater-cooler units, patients who have a history of open-heart surgery and present with symptoms of infective endocarditis should have M. chimaera included in the differential diagnosis of possible causative organisms.

Poster Title: Infliximab medication use evaluation in a pediatric hospital.

Primary Author: Sara Gattis, Children's Healthcare of Atlanta, GA; Email: sara.gattis@choa.org

Additional Author(s):
Jeremy Adaza

Purpose: Infliximab is an anti-TNF monoclonal antibody that has been utilized in various autoimmune disease states such as Crohn’s (CD), ulcerative colitis (UC) and rheumatoid arthritis. Rates of incidence for CD and UC are highest in the age group of 15-35, with 20-30% of Crohn’s patients diagnosed before the age of 20. From January to July of 2016, Children's Healthcare of Atlanta has infused infliximab to 530 patients, and due to increased incidence rates in adolescent patients this number is expected to rise. A retrospective chart review will be conducted to trend infliximab prescribing to evaluate its use and cost.

Methods: A retrospective chart review will be conducted by generating a report identifying patients who received infliximab between January 2016 and July 2016. Patients administered infliximab will be categorized by outpatient or inpatient use. Information will be collected regarding prescribing patterns, monitoring parameters, reimbursement, and admission rates, as well as time of inpatient infusion in relation to admission and discharge. Data elements collected will also assess other biologics, such as adalimumab, and gastrointestinal medications used prior to infliximab administration and during infliximab therapy to determine appropriate use in relation to these additional agents.

Poster Title: The effects on mortality of etomidate and midazolam used for induction during rapid sequence intubation in septic patients

Primary Author: Katie Fulks, Columbus Regional Health Midtown Medical Center, GA; Email: katie.fulks@columbusregional.com

Additional Author(s):
Lea Bonner
Corinne Murphy
Matthew McAllister

Purpose: Rapid Sequence Intubation (RSI) is a process that secures the airway for those who are at risk of aspiration, or have an impending loss of airway. RSI involves successive administration of a rapid-acting induction agent and neuromuscular blocking agent. Common agents used for induction include etomidate and midazolam. It remains controversial if a single dose of etomidate has a significant effect on adrenal suppression and in turn mortality in patients with sepsis. This study will provide insight into the benefits and side effects of etomidate and midazolam for induction in RSI in patients with sepsis.

Methods: This study will focus on examining the safety of etomidate and midazolam for RSI in septic patients through a retrospective chart review of septic patients intubated at Midtown Medical Center.

Inclusion criteria will consist of: age greater than 18 years old, an ICD-10 code pertaining to sepsis with sepsis being confirmed by the presence of at least 2 out of 4 SIRS criteria (temperature greater than 38C or less than 36C, pulse rate greater than 90 beats/minute, respiratory rate greater than 20 breaths/minute or PaCO2 less than 32 mmHg, WBC greater than 12,000mcl or less than 4,000mcl or greater than 10% bands) and the presence of a confirmed infection or strong suspicion of infection resulting in administration of antimicrobial agents; need for RSI, and induction of RSI utilizing etomidate or midazolam. Exclusion criteria will include: patients transferred to other hospitals.

Data to be collected during the chart review: (1) medications for rapid sequence intubation, (2) survival at 28 days, (3) length of ICU stay, (4) duration of mechanical ventilation, (5) length of hospital stay, (6) hydrocortisone use >100mg per day, or equivalent, and (7) baseline
demographics including gender, age, weight, source of infection, maximal SOFA score within 3 days of intubation, septic shock requiring vasopressor therapy.

Poster Title: Retrospective evaluation of pharmacist-initiated albuterol order optimization in an adult asthma population

Primary Author: Kathryn McDaniel, Kaiser Foundation Health Plan of Georgia, Inc., GA; Email: kathryn.b.mcdaniel@kp.org

Additional Author(s):
Beth Barham
Babafunlola Davis

Purpose: Asthma is one of the most prevalent chronic diseases, and the annual cost of care in the United States is estimated to be over 50 billion dollars. Many patients require both controller and reliever medications to prevent asthma exacerbations. For various reasons, some patients may manage their asthma inadequately using only a reliever medication, such as an albuterol inhaler, or by seeking emergency medical attention instead of purchasing controller medications. This study aims to evaluate the impact of a pharmacist-initiated intervention to optimize albuterol inhaler orders and reduce overutilization of these reliever medications.

Methods: This retrospective cohort study will be submitted to the institutional review board. The electronic medical record will be used to identify patients that were included in the historical intervention in which pharmacists initiated conversion of albuterol prescription orders for multiple canisters of albuterol inhalers to orders for a single canister without refills for adult patients with persistent asthma. As part of the historical intervention, patients received notification of prescription changes and explicit instructions to seek follow-up with the physician should they need additional refills of albuterol. Patients will be included in the study if there is continuous membership with the sponsoring organization throughout the six month period of review with no more than a ninety-day gap in coverage. Claims data will be used to assess the primary outcome: albuterol utilization before and after the intervention and the secondary outcome: adherence to controller medications in patients before and after the intervention. A sub-group analysis will be performed in the group of patients that request additional refills after the intervention to determine if there is a difference in utilization and adherence. All data will be recorded without patient identifiers and maintained confidentially.

Poster Title: Evaluation of proactive panel management (PPM) meeting attendance and A1c control

Primary Author: Michelle Aslami, Kaiser Permanente Georgia, GA; Email: michelle.aslami@kp.org

Additional Author(s):
Nadia Hassan
Teri Laurenti

Purpose: The clinical and economic impact of diabetes have inspired efforts to improve A1c control and close care gaps through proactive panel management (PPM). PPM meetings are a novel multidisciplinary approach consisting of a primary care physician (PCP) and clinical pharmacy specialist or registered nurse. During PPM meetings, PCPs guide clinical decision making for their patient population (panel) with diabetes and an A1c greater than 8% to improve A1c control. This study aims to evaluate the relationship between PCP PPM meeting attendance and the proportion of patients in their panels with an A1c less than 8% after implementation of this initiative.

Methods: A retrospective cohort study to evaluate PCP panels will be performed. Each PCP will be categorized based on the number of PPM meetings he or she attended between May and November 2016 (ie, category 1= attended 1 out of 7 meetings). For each PCP attendance category, the percentage of patients with an A1c less than 8% in each PCP panel at baseline and at the end of the study period will be determined. The median percentage change between these proportions will be determined for each PCP attendance category. Linear regression will be performed to assess the relationship between the median change in proportion of patients with an A1c less than 8% and the number of meetings the PCPs attended. The primary outcome will be the median percentage change in proportion of patients with an A1c less than 8% for each PCP attendance category. Data for this study will originate from the electronic medical record. This study will be submitted to the institutional review board.

**Poster Title:** Clinical and patient-related outcomes following optimization of interferon beta and glatiramer acetate for multiple sclerosis

**Primary Author:** Sara Ly, Kaiser Permanente of Georgia, GA; **Email:** sara.l.ly@kp.org

**Additional Author(s):**
Folayemi Fashola

**Purpose:** Interferon (IFN) beta and glatiramer acetate (GA) are among the first-line disease-modifying therapies (DMT) for relapsing forms of multiple sclerosis. While DMTs have demonstrated improved clinical outcomes, they represent a significant and growing cost for patients and health plan payers. In July 2015, Kaiser Permanente of Georgia (KPGA) implemented an initiative to optimize utilization of DMTs using criteria based on safety, efficacy and cost. Patients receiving IFN beta-1a and GA were reviewed for eligibility. This study aims to compare relapse rates in patients who transitioned to IFN beta-1b compared to patients who remained on IFN beta-1a or GA.

**Methods:** A retrospective cohort study will be conducted to evaluate outcomes following therapy transition to IFN beta-1b based on established criteria compared to patients who remained on IFN beta-1a or GA. The study will review data between July 21, 2015 and November 30, 2016 for KPGA members 18 years and older receiving IFN beta-1a, GA, or IFN beta-1b for at least nine months. The primary outcome will assess the difference in relapse rate for the two study groups and will be evaluated for significance with the Student’s t-test. Secondary outcomes will include differences in adherence to DMT, voluntary membership termination rate, and patient out-of-pocket cost for the two groups. This study will be submitted to the KPGA Institutional Review Board for approval.

**Poster Title:** Implementation of a web-based warfarin education tool in an integrated healthcare system

**Primary Author:** Danyae Lee, Kaiser Permanente of Georgia, GA; **Email:** danyae.e.lee@kp.org

**Additional Author(s):**
Suzanne Booth
Naomi Yates

**Purpose:** Warfarin is a commonly used anticoagulant for the prevention and treatment of thromboembolisms in order to avert thromboembolic events which increase the morbidity and mortality of cardiovascular disease. However, its use is associated with a high risk of bleeding. Employing a multidisciplinary approach, pharmacists in anticoagulation clinics provide patient education and assist physicians with warfarin management. Technological advancements now enable education to be obtained utilizing web-based technology. The objective of this study is to evaluate the change in time pharmacists spend providing initial education to patients started on warfarin pre and post implementation of a web-based educational tool.

**Methods:** The study is a quasi-experimental, longitudinal prospective cohort. To be enrolled, patients must be referred to the anticoagulation clinic for warfarin management, be over 18 years old, have no cognitive deficiencies, and be initiated on warfarin within the last week. The control arm will receive warfarin education through traditional telephonic means. The interventional arm will receive education through a pharmacist proctored, instructional web-based multimedia educational program. The web-based warfarin tool will include all points of discussion currently provided telephonically for standardization. The primary outcome is to evaluate the change in time pharmacists spend providing initial warfarin education. To assess this change, the following demographic data, patient age and gender, will be collected as well as the following encounter data: number of calls, day of the week of calls, time call initiated, time call ended, and total time of calls. The total time of calls will be divided by the number of calls to determine the average time per call. In addition, the total time spent on initial education calls per day and per week will be tabulated pre and post implementation of the warfarin web-based educational tool. This study will be submitted to the Institutional Review Board for approval.

Poster Title: Impact of sedative choice on clinical outcomes in acute respiratory distress patients requiring neuromuscular blocker infusions

Primary Author: Chelsea Dodd, Memorial Health University Medical Center, GA; Email: dodch1@memorialhealth.com

Additional Author(s):
Stephanie Hyche
Michael Melroy

Purpose: The Society of Critical Care Medicine’s 2013 Pain, Agitation, and Delirium guidelines make no specific recommendation on sedative choice in patients requiring deep sedation. The aim of this study is to determine which sedative agent, propofol or benzodiazepines, is associated with better clinical outcomes in mechanically ventilated acute respiratory distress patients requiring neuromuscular blocker infusions.

Methods: This single center, retrospective cohort study will be conducted at a 600-bed tertiary care hospital. Patients will be screened if they had an active neuromuscular blocker infusion order in the electronic medical record between May 2015 and March 2017. Patients will be included if they had acute respiratory distress syndrome defined as a ratio of arterial oxygen tension to the fraction of inspired oxygen less than 300 mmHg and bilateral opacities on a chest radiograph or computed tomographic scan. Patients will be excluded if they were minors, pregnant, had documented allergies to propofol or benzodiazepines or neurological disorders, expired less than 24 hours into ICU stay, and if they received the neuromuscular blocker infusion for less than 12 hours or a concomitant ketamine infusion. The primary outcome is percentage of time the bispectral index score was in goal range (between 40 and 60) during neuromuscular blocker infusion. Secondary outcomes include duration of mechanical ventilation, ICU and hospital length of stay, and incidence of in-hospital mortality. Data to be collected includes patient demographics and comorbidities, bispectral index scores, neuromuscular blocker agent used, cumulative dose and duration of use, primary sedative agent used, cumulative dose, equivalent dose to achieve deep sedation range and duration of use, additional therapies required including sedatives, analgesia, steroids and vasopressors, clinical outcomes, and discharge disposition.

**Session-Board Number:** 10-062  

**Poster Title:** Albumin and furosemide versus furosemide for volume overload after initial sepsis resuscitation in intensive care patients  

**Primary Author:** Steven Robinette, Memorial Health University Medical Center, GA; Email: srobinettepharmd@gmail.com  

**Additional Author (s):**  
Stephanie Hyche  

**Purpose:** Intensive care unit (ICU) patients commonly require fluid resuscitation to maintain hemodynamic stability and improve perfusion to vital organs. Aggressive fluid resuscitation can lead to fluid overload and peripheral or pulmonary edema. Achievement of a negative fluid balance is associated with survival. Hyperoncotic (25 percent) albumin plus furosemide is a strategy commonly utilized in our intensive care units to attempt to reduce net fluid balance and resulting edema, but the effectiveness of this strategy is unknown. The objective of this study is to determine if albumin plus furosemide results in a lower net fluid balance than furosemide alone.  

**Methods:** This study will be submitted to the institutional review board for review. A retrospective chart review will be completed on intensive care patients who were diagnosed with sepsis or septic shock and received either albumin and furosemide or furosemide between May 2015 and October 2016. Patients will be included if they received at least two consecutive doses of albumin and furosemide or furosemide after sepsis resuscitation. The following data will be collected: demographic data, admitting diagnosis, comorbidities, suspected source of infection, sepsis or septic shock, ICU location, ICU length of stay (LOS), hospital LOS, in-hospital mortality, duration of mechanical ventilation, fluid intake and output, type of fluids received, serum albumin, creatinine and blood urea nitrogen, albumin and furosemide dosing, other diuretics received, and need for dialysis. The primary outcome will be the difference in net fluid balance between groups five days after diuretic initiation. Secondary outcomes will be: ICU LOS, duration of mechanical ventilation, in-hospital mortality, and cumulative doses received of albumin, furosemide, and other diuretics.

**Session-Board Number:** 10-063

**Poster Title:** Appropriate use of four-factor prothrombin complex concentrate before and after implementation of point-of-care international normalized ratio testing in the emergency department

**Primary Author:** Angelique Pereira, Memorial Health University Medical Center, GA; **Email:** ang.pereira4@gmail.com

**Additional Author (s):**
Michael Melroy
Katherine Jones
Kevin Sullivan

**Purpose:** Point-of-care (POC) international normalized ratio (INR) testing eliminates the delay of waiting for the INR to be processed by the laboratory, which can help guide appropriate dosing of four-factor prothrombin complex concentrate (4PCC) and avoid unnecessary administration of 4PCC in patients who have normal INRs. The aim of this study is to assess the appropriate use of 4PCC before and after implementation of POC INR testing in the emergency department as well as the potential cost savings associated with appropriate use of 4PCC.

**Methods:** A single-center retrospective review will be conducted through the electronic medical record system to analyze the use of 4PCC before the implementation of the POC INR test. After implementation of POC INR testing, a subsequent retrospective review will be conducted to analyze the use of 4PCC in patients who received the POC INR test. Patients will be included if they are 18 years of age or older, received a dose of 4PCC, and were taking warfarin. The primary outcome is the appropriate use of 4PCC in warfarin patients before and after implementation of POC INR testing. Reviewers will determine the appropriate use of 4PCC based on pre-determined criteria, which are that the INR resulted before 4PCC was ordered and that the dose of 4PCC is based on the hospital’s protocol for emergent reversal of anticoagulation. Secondary outcomes include whether or not the INR resulted prior to the 4PCC order, appropriate dose of 4PCC, and cost savings/avoidance from implementation of POC INR testing. The following data will be collected: patient age, gender, ethnicity, weight, date/time of admission to the emergency department, indication of 4PCC, INR prior to and after administration of 4PCC, time of INR collection and result, dose of 4PCC, time 4PCC was ordered...
and administered, complications, additional therapies, cost of 4PCC dose administered, and cost of appropriate dose of 4PCC.

Poster Title: Evaluating inpatient treatment of extended-spectrum beta-lactamase isolates in urinary tract infections

Primary Author: Phillip Cole, Memorial Health University Medical Center, GA; Email: coleph1@memorialhealth.com

Additional Author(s):
Jason Lin
Mike Melroy

Purpose: Extended-spectrum beta-lactamase (ESBL) producing microorganisms have become a worldwide concern and have increasingly been associated with poor outcomes. There are several agents commonly used to treat ESBL microorganisms. Carbapenem therapy has been noted as the best treatment against these microorganisms. However, there is limited local, national, and worldwide data to support any clinical decisions on which therapy to use for ESBL urinary tract infections.

Methods: This single center, retrospective cohort study will be conducted at a 600-bed tertiary care hospital using the electronic medical record system. Patients will be screened if they have had a confirmed extended-spectrum beta-lactamase (ESBL) producing microorganism isolate on a final urine culture result. Patients will be included if they are of 18 years of age or older with a confirmed ESBL urinary culture isolate. Patients will be excluded if they were outpatient, pregnant, inmates, or less than 18 years of age. Data to be collected includes patient demographics, comorbidities, antibiotic selection, persistence of fever, length of stay, 30-day readmissions, cost comparison between antibiotic therapy, and mortality. Patient health information will be de-identified.

Poster Title: Impact of pharmacist-led assessment of penicillin allergy histories in adult medical-surgical patients

Primary Author: Joseph Morris, Memorial Health University Medical Center, GA; Email: morrijo2@memorialhealth.com

Additional Author(s):
Jason Lin

Purpose: Penicillin allergies limit antibiotic selection considerably as there is fear of cross-sensitivity between penicillins and other beta-lactam antibiotics such as cephalosporins. Prior studies demonstrate that many of these reported allergies are intolerances rather than true hypersensitivity reactions and should not preclude patients from receiving preferred therapy. Further research shows increased hospital days and severe infection rates in this population. These findings exhibit the importance of accurate allergy history in hospitalized patients. The purpose of this study is to determine if pharmacist-led assessment of penicillin allergies can increase the proportion of patients that can safely receive beta-lactams.

Methods: This project includes the pilot of a pharmacist-led penicillin allergy evaluation service and subsequent evaluation of the service. Subjects included in the study are non-pregnant, non-incarcerated adults with a documented penicillin allergy admitted to a medical-surgical unit of a 600 bed academic medical center. Each subject’s allergy will be evaluated by a pharmacist to determine the risk for reaction upon receipt of a beta-lactam antibiotic. Assessment will begin in the electronic medical record to determine what details are available on the allergy, if the patient has previously received and tolerated penicillins or cephalosporins, and if the patient is prescribed antibiotic therapy at the time of assessment. The next phase of assessment will include a thorough subjective history collected by the pharmacist from the patient or designated caregiver. The pharmacist will gather details concerning the offending agent, reaction, and tolerability of related agents. Patients determined to be suitable candidates for penicillin skin testing will be initiated on the institution’s penicillin allergy testing protocol with patient and physician consent. After assessment, physicians will be informed if patients are deemed to be low risk to begin beta-lactam therapy. The primary outcome will be the proportion of patients determined to be low risk to receive beta-lactams. Additional
outcomes include the days of non-beta-lactam therapy spared and cost difference following pharmacist intervention.

Poster Title: Characterization of pharmacist interaction regarding natural supplement use in the community setting.

Primary Author: Tyler Kiles, Mercer University College of Pharmacy, GA; Email: tyler.kiles@gmail.com

Additional Author (s):
Joshua Kinsey
Maria Yi
Andi Clark

Purpose: Herbal supplements are widely available, but the community pharmacy setting provides a unique opportunity for patients to interact with a pharmacist with specialized knowledge of both prescription and non-prescription medications. The primary endpoint of this study is to identify gaps in initiation of pharmacist counseling regarding natural supplements. Secondary endpoints include: determining the rates at which patients seek pharmacist advice about herbal supplement use, identifying sources of information regarding herbal supplements other than pharmacists, characterizing retail pharmacist perceptions and awareness of resources available regarding herbal supplements, and determining pharmacist barriers to providing counseling on herbal supplements.

Methods: This study will survey a convenience sample of subjects in the greater Atlanta area in retail chain pharmacy stores, 2 AADE Certified Diabetic Education sites, a multidisciplinary clinic, and community flu shot clinics serviced by the chain pharmacy. The 10-item paper questionnaire will be voluntary, self-administered and validated by expert opinion and pilot testing. The questionnaire will collect the following data: demographic information, disease states, use of common natural supplements, consultation with a pharmacist, and other sources of information regarding natural supplements. No identifiable data will be collected. This investigation will also extend to a survey of retail pharmacists at the participating stores. Pharmacists will be interviewed regarding their herbal supplement education background, confidence in making recommendations related to herbal supplements, knowledge of applicable resources, as well as barriers to initiating herbal supplement counseling. Quantitative and qualitative data collected will be analyzed using descriptive statistics.
Results: I anticipate that the majority of patients are not discussing their herbal supplement use with a pharmacist and are getting their information from other sources. Based on surveyed disease state and medication information, I hope to determine if there are any interactions that may have been prevented by pharmacist intervention. I expect that many pharmacists will discuss ‘time’ as a barrier to herbal supplement counseling, but I hope to probe more into their personal education and experiences to discern what gaps can be filled.

Conclusion: At the end of this study, it is my aim to provide education and/or propose suggestions to fill the knowledge gaps identified.
Purpose: The purpose of this study is to determine the effect of comprehensive medication reviews (CMRs), corresponding risk factor(s) and comorbidities on pneumococcal vaccination rate.

Methods: The research design is a retrospective case-control study. The study population will include 400 adult patients indicated for pneumococcal vaccination who have filled at least one prescription at a particular grocery store pharmacy in three states since January 2013. Data will be collected via Medication Therapy Management (MTM) platforms, chart review on the pharmacy’s electronic prescription medication record system and immunization registries by the principal investigator or co-investigator(s). Data collected includes, but is not limited to: age, gender, medical conditions, prescription medications, vaccinations, CMR status, pharmacist providing CMR, medication adherence and pharmacy. Vaccination rates will be calculated and compared among patients receiving a CMR and not receiving a CMR, a patient’s usual staff pharmacist versus a district pharmacist, medical conditions and other factors. Data will be analyzed using an unpaired student’s t-test.

Results: To be determined. Patients receiving a CMR are expected to have higher vaccination rates than patients who do not receive this service.

Conclusion: To be determined. This study should determine the effect of CMRs on vaccination rate and likelihood of a patient to receive an indicated vaccination. The study may also determine an association of vaccination rates in patients with certain risk factor(s) or
comorbidities. The conclusions found in this study may identify potential gaps in care based on certain risk factors and potentially identify targets for future strategies to improve pneumococcal vaccination rates.

**Poster Title:** Adherence to hydroxyurea suspension and rates of hospitalization in pediatric patients with sickle cell disease  
**Primary Author:** Renzo Gonzalez, Mercer-Walgreens, GA; **Email:** gonzalez_rp@mercer.edu  
**Additional Author(s):**  
Adam Schneppe  
Joshua Kinsey  

**Purpose:** The purpose of this study is to evaluate the relationship between varying levels of adherence to hydroxyurea suspension and rates of hospitalization in pediatric patients with sickle cell disease. The role of hydroxyurea in decreasing vaso-occlusive pain, acute chest syndrome and subsequent hospitalization has been well established in clinical trials. However, there are very few studies that assess the role of adherence with improved outcomes. The primary objective of this study is to assess the relationship between adherence to hydroxyurea and rates of hospitalization. The secondary objective of this study is to assess causes of non-adherence.  

**Methods:** This study will be submitted to the Institutional Review Board for approval. This study is designed as a retrospective, cross-sectional study. The inclusion criteria for this study are patients under the age of eighteen who are receiving hydroxyurea suspension for the treatment of sickle cell disease and have a fill history of at least six months. Eligible patients will be identified using the pharmacy prescription dispensing system. Once identified, the parents or legal guardian will be contacted via phone to ascertain willingness to complete a survey. The survey will consist of sixteen questions that will assess general adherence behaviors and any hospitalizations in the last six months. Upon confirmed disposition, a consent form and survey will be mailed to the address on file. All other data used in this study will be collected retrospectively from pharmacy data. The following data will collected: Patient’s age, gender, length of hydroxyurea therapy, and refill dates. To assess the primary endpoint, patients will be divided into two groups (adherent and non-adherent) based on proportion of days covered (PDC), and results from the survey will be used to calculate the number of hospitalizations in the past six months. Results from the survey will also be used to evaluate the secondary endpoint.

Poster Title: Evaluation of oritavancin use at a community hospital

Primary Author: Daniel Co, Northeast Georgia Medical Center, GA; Email: daniel.co@nghs.com

Additional Author (s):
Leslie Roebuck
Jason VanLandingham

Purpose: Oritavancin is a lipoglycopeptide antibiotic indicated for the treatment of acute bacterial skin and soft tissue infections caused by gram-positive organisms. The prolonged half-life of this agent allows for a course of therapy to be completed with a single dose. In June 2015, oritavancin was added to our formulary as an option for treatment of acute bacterial skin and soft tissue infection to reduce admission and length of stay for this indication. The purpose of this study is to determine if oritavancin is used appropriately at our hospital and to evaluate the impact of that use to the institution.

Methods: In this Institutional Review Board approved study, a retrospective and concurrent chart review will be performed on all patients who have received oritavancin within our health system between June 2015 and December 2016. Information that will be collected for each patient includes age, gender, prior antibiotic use, renal function, indication for oritavancin, prescriber, and admission dates. The primary endpoint will be to determine the indication of oritavancin as defined by criteria for use at our institution. The secondary endpoints will include readmission rates for patients prescribed oritavancin, and financial impact. Any admission within 14 days of oritavancin administration from our health system will be included in the analysis of readmission rates. Financial impact will be assessed using the cost of drug to the institution compared with an average value for the total cost of hospitalization for treatment of a skin and soft tissue infection.

**Poster Title:** Transitioning from oral direct acting factor Xa inhibitors to intravenous unfractionated heparin in a community hospital  

**Primary Author:** Jae Yook, Northeast Georgia Medical Center, GA; Email: jae.yook@nghs.com  

**Additional Author(s):**  
Sherri Merritt  
Amy Knauss  

**Purpose:** In 2009, our hospital began monitoring intravenous unfractionated heparin (IV UFH) with the anti-Xa assay. With increasing numbers of patients on an oral direct acting factor Xa inhibitor being admitted, a concern has emerged when these patients need to be transitioned to IV UFH. Pharmacokinetic studies have demonstrated that the anticoagulants have a linear relationship with the anti-Xa level but can be very sensitive. This study is designed to assess how patients are managed upon transitioning from oral direct acting factor Xa inhibitors to IV UFH within the hospital.  

**Methods:** The study will consist of two parts. The first part will be a retrospective evaluation of patients 18 years and older transitioning to IV UFH from an oral direct acting factor Xa inhibitor with a baseline anti-Xa level greater than 1. The study period for part 1 will be between January 2016 and June 2016. At least 60 patients will be selected randomly to represent the target population. Exclusion criterion includes patients that are taking the oral direct thrombin inhibitor, dabigatran. The primary endpoint is the time delay in hours when transitioning from oral direct acting factor Xa inhibitors to IV UFH. The secondary endpoint is the number of treatment failures as a result of the time delay when transitioning. Treatment failures are defined as a new development of stroke or venous thromboembolism (VTE) within the hospitalization. The second part will be a concurrent study utilizing an activated partial thromboplastin time (aPTT) based heparin monitoring pilot protocol. Patients with a baseline anti-Xa level greater than 1 and with orders for IV UFH during the period of January 2017 and February 2017 will be evaluated. The resident will recommend the pilot protocol. The same information will be collected as in the retrospective chart review to directly compare the results. The pilot protocol will be updated according to the results and will be finalized for official use.
Results: N/A

Conclusion: N/A
Purpose: Tissue plasminogen activator (tPA) remains the only medication proven to positively affect outcomes in the treatment of acute ischemic stroke. The primary objective of this review is to assess the door-to-needle time in patients receiving tPA for the treatment of acute ischemic stroke when a pharmacist is present to mix tPA versus when a pharmacist is not present. The goal door-to-needle time is always less than 60 minutes, which studies have shown improves patient outcomes greatly. The results of this review may bring awareness to the importance of pharmacist participation on the stroke team.

Methods: This study has been submitted to the Institutional Review Board. We will conduct a retrospective chart review utilizing computerized physician order entry and the patient’s electronic medical records to gather data on the administration of tPA at Gwinnett Medical Center- Lawrenceville. A report will be run gathering all patients who have received tissue plasminogen activator (tPA) from August 2015 through August 2016. At Gwinnett Medical Center- Lawrenceville an emergency department (ED) pharmacist is present during the hours of 1:30 pm to midnight every day. We will evaluate 25 patients who received tPA with an ED pharmacist present compared to 25 randomly selected patients who received tPA without an ED pharmacist present. Data collection will include emergency department arrival time, tPA administration time, patient’s emergency department weight, patient’s weight used for tPA dosing, and patient’s weight post-admission. Our primary endpoint will be door-to-needle time, defined as the time from when the patient enters the ED to the time tPA is administered. The secondary endpoint that will also be evaluated is the accuracy of the patient’s weight that is used to calculate the tPA dose. Following data collection, we will evaluate our results using the Chi-Squared statistical test for nominal data and Student T-test for continuous data.

Poster Title: Evaluating the use of phenobarbital for the treatment and prevention of alcohol withdrawal syndrome in acute psychiatric inpatients

Primary Author: Erin Waldee, Phoebe Putney Memorial Hospital, GA; Email: ewaldee@ppmh.org

Additional Author (s):
Stephanie Phan

Purpose: The goal of treating and preventing alcohol withdrawal syndrome is to reduce morbidity and mortality by targeting symptoms associated with central nervous system hyperactivity, including anxiety, irritability, and autonomic disturbances. Benzodiazepines are considered first-line agents for this purpose. Phenobarbital is also utilized in practice, but some clinicians have concerns related to the safety of phenobarbital, including potential drug interactions, long half-life, and oversedation. Such adverse outcomes have not been documented in the literature. The purpose of this study is to identify the prevalence and evaluate the safety and efficacy of phenobarbital use for alcohol withdrawal syndrome in acute psychiatric inpatients.

Methods: This study is a retrospective, pre- and post-intervention observational chart review. The electronic medical record will be used to identify patients at least 18 years old admitted to the psychiatric unit and administered phenobarbital for the treatment or prevention of alcohol withdrawal syndrome. Patients will be excluded if they are pregnant or have recent prior use of barbiturates. The desired sample size is 100 patients. The following demographic data will be collected: gender, age, ethnicity, medical and psychiatric diagnoses, urine drug screen, alcohol level upon admission, alcohol use patterns (number of drinks per day, drinking days per week, length of time of alcohol use, history of alcohol withdrawal symptoms), length of stay, dosage form(s) of phenobarbital used, frequency and size of phenobarbital doses, total cumulative dose. The primary outcome will be change in respiratory rate. Secondary outcome measures will be blood pressure, heart rate, temperature, presence of sedation or altered mental status, changes in signs and symptoms of alcohol withdrawal, administration of additional medications for alcohol withdrawal, need for admission to critical care unit. Patients will also be sub-divided into groups characterized by results of their urine drug screen to identify trends related to the
safety of phenobarbital in the presence of other substances. Descriptive statistics will be used to characterize demographic data, the t-test for continuous data, and the chi-square test for categorical data.

Purpose: Routine administration of sliding scale insulin is no longer recommended as a primary strategy to treat hyperglycemia in hospitalized patients. Studies have demonstrated the significant improvement in glycemic control in patients treated with basal-bolus insulin versus sliding scale insulin alone and improvement in the adverse effects of hypoglycemia. However, the effect of sliding scale alone or basal-bolus insulin on hypoglycemic events is less well known. Our study investigates the effect of the use of basal-bolus insulin versus the use of sliding scale insulin alone on hypoglycemic events in hospitalized elderly patients. This can ultimately guide inpatient management of hyperglycemia.

Methods: This Institutional Review Board approved retrospective study identified patients 65 years and older, admitted to Phoebe Putney Memorial Hospital who received any type of insulin between April 1, 2016 and June 30, 2016. All data are de-identified, kept confidential, and include demographic information, admitting diagnosis, parenteral nutrition administration, diabetes diagnosis, other diabetic maintenance medications, treatment for hypoglycemia, blood glucose levels, length of stay, mortality and higher level of care required within 24 hours post hypoglycemic events. The primary outcomes of the study are the differences in hypoglycemic events among groups including the average hypoglycemia reading, and the percentage of patients on sliding scale insulin alone. Secondary outcomes include length of stay, mortality, intensive care units transfer, and the glucose reading for the hypoglycemia. Exclusion criteria include pregnancy, patients in the intensive care units (medical, surgical and cardiac), patients who are hypersensitive to insulin and patients who received insulin only for the management of hyperkalemia.

Poster Title: Implementation and evaluation of strategies to reduce catheter-associated urinary tract infections (CAUTI) in patients with critical illness

Primary Author: Andy Duong, WellStar Atlanta Medical Center, GA; Email: an.duong@wellstar.org

Additional Author(s):
T.Vivian Liao
Kristen O'Brien
Teresa Pounds
Zandraetta Tims-Cook

Purpose: CAUTIs, one of the most common hospital-acquired infections, have been associated with increased patient morbidity and mortality and increased hospital costs. Development of a CAUTI team, including an infection control specialist and a pharmacist, was implemented at Atlanta Medical Center (AMC). The objective of this study is to evaluate the impact of this team and a new system of education modules and reminder alerts on CAUTI rates in the surgical and neurological intensive care units.

Methods: The institutional review board approved this prospective cohort study with a historical control. A retrospective chart review of the electronic medical record will be performed to determine baseline CAUTI rates for the surgical and neurological intensive care units (ICUs). The baseline period, serving as the historical control, will include data from September 2015 to February 2016. The prospective phase of the study will be from September 2016 to February 2017. During this time, the CAUTI team will perform the following interventions: healthcare provider education with pre- and post-assessments and daily indwelling urinary catheter (IUC) reassessment reminders. Education will be provided on appropriate indications for IUC use, alternatives to IUCs, and aseptic technique for IUC insertion, maintenance, and removal. The IUC reminder system will involve the CAUTI team contacting the physician or nurse of those patients with an IUC in place for five days or longer. Patients 18 years or older who are admitted to the surgical or neurological ICU in the time frame specified and who have an IUC in place for two or more days will be eligible for inclusion
in the study. The primary outcome of CAUTI rates will be calculated by number of CAUTIs per 1000 urinary catheter days.

Poster Title: Impact of a transdisciplinary opioid-reduction team in the reduction of opioid use in orthopedic surgery patients at a community teaching hospital

Primary Author: Tina Simpson, WellStar Atlanta Medical Center, GA; Email: tina.simpson@wellstar.org

Additional Author (s):
Azelia Brown
Ashish Advani
Quwanna Clemons
Pamela Moye

Purpose: Opioid analgesics are the mainstay of postoperative pain management. While opioids have shown to be effective, they can be accompanied by preventable opioid-related adverse events (ORADEs). Multimodal analgesia and other opioid-sparing pain management protocols have been developed with aims to reduce or eliminate opioid use, lower incidence and cost of ORADEs thus leading to faster functional recovery, higher patient satisfaction, and shorter length of stay. The primary objective of this study is to reduce opioid analgesic utilization by assessing the impact of a Transdisciplinary Opioid Reduction Team and academic detailing of orthopedic surgeons on incorporating individualized multimodal pain management practices.

Methods: The Institutional Review Board approved this single-center observational study. Patients 18 years or older admitted to the orthopedic surgery department who had an International Classification of Diseases, Tenth revision (ICD 10) procedure code to undergo total hip arthroplasty or total knee arthroplasty between July 2016 and March 2017 will be studied. The historical control group will consist of patients who had their pain managed according to current standard of care. The prospective intervention group will consist of patients who will receive care after the development and implementation of the Transdisciplinary Opioid Reduction Team, opioid reduction initiatives, and from orthopedic surgeons who have completed academic detailing. All patients will be screened based on defined inclusion and exclusion criteria. Using the electronic medical record, pain management regimen administered perioperatively and up to 48 hours postoperatively will be determined via the medical administration record which includes administration dates, times, doses, and route of
administration. The occurrence of specified adverse drug events will be determined by documentation of a clinician from the progress note as well as ICD 10 diagnosis code. Upon identification of an adverse event, the date, time, and length of stay will also be captured. All activities and outcomes obtained will be recorded as outlined on the approved data collection form. Data will be verified for accuracy by at least two members of the team.

Poster Title: Impact of pharmacist led nursing education on antimicrobial stewardship

Primary Author: Mehul Patel, WellStar Kennestone Hospital, GA; Email: mehul.patel@wellstar.org

Additional Author(s):
Joy Peterson
Karen Barlow
Terri Moore
Shana Pursner

Purpose: The newly released Infectious Diseases Society of America (IDSA) guidelines (2016) for the development of an antimicrobial stewardship program (ASP) support the use of passive educational activities to compliment other stewardship activities. The objective of this study is to evaluate the impact of pharmacist led nursing education on antimicrobial stewardship (AMS) at WellStar Kennestone Hospital between the months of October 2016 and January 2017.

Methods: This study will begin with the development of an education program covering important AMS topics such as: appropriate empiric treatment for common infections, narrowing antibiotic treatment based on microbiology, appropriate durations of therapy, importance of antibiotic timeouts, de-escalation of antibiotics, and criteria for intravenous (IV) to oral (PO) conversion. A pre-test will be developed and administered to gauge the base knowledge of the nursing staff. A post-test will also be given after completion of the education program. The results of the two tests will be compared to determine the level of change in knowledge. The effects of the nursing education program will be evaluated through monitoring of the following data points: changes in antimicrobial consumption and IV to PO conversions. IV to PO conversions will be prompted by nurses via use of nursing communication messages to pharmacy staff who will document the suggested conversion in the electronic medical record as accepted or rejected and provide reasoning for their decisions. If the suggestions are accepted pharmacists will convert the medications from IV to PO per hospital policy. Appropriateness of other nursing activity will be assessed through weekly discussions with the medical staff. Antimicrobial consumption will be directly compared to data collected from the same time
period in the previous year. Changes between the two time frames will be documented as a percent change over time.

**Poster Title:** Impact of a standardized screening tool to assess potentially inappropriate penicillin allergies for removal from the electronic medical record

**Primary Author:** Arielle Orridge, WellStar Kennestone Hospital, GA; **Email:** arielle.orridge@wellstar.org

**Additional Author(s):**
Nicholas Phillips
Joy Peterson

**Purpose:** Penicillin allergies are among the most commonly reported drug allergies in hospitalized patients. Less than one percent of patients are truly allergic to the penicillin class. Inappropriate reporting of penicillin allergies could result in unnecessary use of second- or third-line antibiotics and increased healthcare costs. The purpose of this study is to identify patients with potentially inappropriate documentation of a penicillin allergy for possible removal from the electronic medical record (EMR), or clarification regarding ability to tolerate cephalosporins or carbapenems. Additionally, to identify candidates for Pre-Pen® testing and evaluate cost savings data resulting from decreased alternative antibiotic use.

**Methods:** This study has been approved by the Institutional Review Board. This study will be a prospective evaluation of patients admitted to our institution, Monday through Friday only, from October 1, 2016 until a minimum of 200 patients have been evaluated. Patients will be identified and randomly selected via a report designed to detect penicillin allergies. Identified patients who are admitted to non-intensive care units and are at least 18 years of age or older will be interviewed using a standardized screening tool to detect inappropriate penicillin allergy documentation or ability to tolerate cephalosporins or carbapenems. If the penicillin allergy is found to be inappropriate, the patient and attending physician will be notified for removal of the penicillin allergy from the EMR. If the ability to tolerate cephalosporins or carbapenems is identified, but the penicillin allergy cannot be ruled out, the penicillin allergy will be updated with comments regarding potential cephalosporin/carbapenem use. Written informed consent will be obtained from each patient to confirm willingness to participate. The following data will be collected: patient age, gender, prescriber service, allergy type, reaction type, time frame of allergic reaction, current antibiotics at time of screening and indication, if applicable, and
exposure to cephalosporins, carbapenems, or penicillins since allergy was documented. All data will be recorded will be de-identified to maintain confidentially.

**Poster Title:** Aptitude of nasal methicillin-resistant Staphylococcus aureus (MRSA) screening to rule out MRSA pneumonia

**Primary Author:** James Lufkin, Eastern Idaho Regional Medical Center, ID; **Email:** lufkjame@pharmacy.isu.edu

**Additional Author (s):**
Eliza Borzadek
Michelle Ivie
Eric Sievers
Matthew Anderson

**Purpose:** Current guidelines recommend that patients at risk of MRSA pneumonia be treated empirically pending culture results. However, de-escalation can prove challenging given the low yield of sputum cultures. Studies have shown that nasal colonization with MRSA has strong (>95%) negative predictive value with MRSA pneumonia making this test a valuable tool in the decision to de-escalate empiric MRSA coverage. The objective of this study will be to evaluate the ability of MRSA screening to rule out MRSA pneumonia and report the potential reduction in antibiotic treatment days, acute kidney injury (AKI), and cost of implementing a MRSA screening protocol.

**Methods:** This is a retrospective multi-center cohort study at the Healthcare Corporation of America, MountainStar Division between September 1, 2014 and August 31, 2016. All medical records will be queried to identify patients ≥18 years old, who had MRSA screening performed by polymerase chain reaction (PCR), bacterial cultures (blood, sputum, or bronchoalveolar lavage (BAL)), and had an ICD-9 or ICD-10 pneumonia diagnosis code billed within the study period. Medical records of patients meeting this criteria will then be reviewed for clinical confirmation of pneumonia and the following information: age, sex, pneumonia type, anti-MRSA antibiotic(s) prescribed, days of treatment, and culture data. This information will be maintained confidential and reported without patient identifiers. Patients will be excluded if they did not have clinically confirmed pneumonia or the if nasal screening sample was attained more than one month prior to bacterial cultures for patients presenting from outpatient settings, seven days prior to bacterial cultures inpatient, or more than three days after bacterial
cultures. Primary outcomes will be the sensitivity, specificity, positive predictive value, and negative predictive value of nasal MRSA screening and MRSA pneumonia. Secondary outcomes will include the total number of anti-MRSA treatment days, and the potential reduction in treatment days, vancomycin-induced AKI, and costs that would result from a policy of discontinuing anti-MRSA antibiotics within 24 hours of receipt of negative screenings.

Poster Title: Utilization of a pneumonia-specific antibiotic de-escalation algorithm to guide student pharmacists in providing clinical recommendations

Primary Author: Nam Nguyen, Idaho State University, Departments of Pharmacy Practice and Family Medicine, ID; Email: nguynam@isu.edu

Additional Author (s):
Brooke Bautista
John Holmes
Kasidy McKay
Scott Killian

Purpose: Inappropriate and unnecessary antibiotic prescribing is common in the intensive care unit (ICU). Antibiotic de-escalation, an Antimicrobial Stewardship Program (ASP) strategy, consists of reducing the duration of broad-spectrum antibiotics by narrowing antibiotic therapy based on microbiological data and clinical improvement. Institutions without established decentralized-pharmacy services and ASPs, such as ours, may find difficulty in ensuring appropriate antibiotic de-escalation and benefit from utilizing student pharmacists as clinical pharmacist extenders. This quality improvement intervention sought to utilize student pharmacists’ recommendations to improve antibiotic de-escalation for pneumonia in the ICU.

Methods: A daily electronic health record query of patients admitted to the ICU with a diagnosis-related group code for pneumonia was used to identify potential patients to be included for algorithm development and implementation analysis. Patients included were those over 18 years of age, admitted to the ICU for at least 72 hours, and treated with antibiotics. Patients excluded were those with concurrent complicated urinary tract infections, osteomyelitis, intra-abdominal infections, endocarditis, or skin and soft tissue infections. An antibiotic de-escalation algorithm was developed through literature review of antibiotic use in ICU pneumonia and institution-specific baseline data collected from December 28, 2015 to April 29, 2016. Decision points for the algorithm were determined to be results from methicillin-resistant Staphylococcus aureus nasal swabs and sputum and blood cultures. From May 16, 2016 to September 16, 2016, using the pneumonia-specific antibiotic de-escalation algorithm, students provided antibiotic de-escalation recommendations to the intensivist after review and
approval by a staff pharmacist. Opportunities for antibiotic de-escalation were compared to actual rates of antibiotic de-escalation. Antibiotic de-escalation was considered to be performed if at least one antibiotic was discontinued from empiric therapy or a change of antibiotic from broad to narrower spectrum of coverage occurred within 24 hours of test results.

**Results:** Eighteen patients were identified and analyzed to determine algorithm decision points and provided pre-interventional data during institution-specific baseline data collection. Ten patients were included in post-intervention analysis. Empiric antibiotic durations were 5.0 days pre-intervention and 3.1 days post-intervention (P equals 0.06) and total antibiotic durations were 6.7 days pre-intervention and 5.4 days post-intervention (P equals 0.29). Multiple other changes occurred at the institution during protocol implementation that may have directly or indirectly impacted the findings. This includes change in director of pharmacy, introduction of a decentralized pharmacist during ICU rounds, ongoing family medicine resident education, and rotation of locum tenens intensivists.

**Conclusion:** Although not statistically significant, empiric and total antibiotic therapy durations were lower in the post-intervention period indicating improvement in antibiotic de-escalation for pneumonia in the ICU; however significant confounding occurred. Development and implementation of an institution-specific, student pharmacist-driven de-escalation algorithm is a potential method to improve antibiotic de-escalation in ICU pneumonia for institutions that lack decentralized pharmacy services and ASPs and have the ability to utilize student pharmacists as clinical pharmacist extenders.

Poster Title: Development of a pharmacist-provider co-visit-driven opioid pain management protocol in a family medicine residency clinic

Primary Author: Pilar Davila, Idaho State University, Departments of Pharmacy Practice and Family Medicine, ID; Email: davipila@isu.edu

Additional Author(s):
Brooke Bautista
Kasidy McKay
David Glenn
John Holmes

Purpose: Primary care providers are increasingly called upon to provide chronic pain management, improve their opioid prescribing practices, and identify and treat patients with substance abuse. This project was designed to implement an evidence-based chronic pain management protocol in a family medicine residency clinic utilizing a pharmacist-provider co-visit model to 1) improve the performance and documentation of 6 Centers for Disease Control and Prevention recommended process measures, 2) increase provider knowledge of chronic nonmalignant pain management and 3) improve provider attitudes toward treating patients with chronic pain.

Methods: Patients taking chronic opioids will be identified by an electronic medical record query. Chart abstraction will be used to collect demographic information and measure the proportion of patients for which each of the following 6 processes were performed and documented: pain management agreement, state prescription monitoring program review, Patient Health Questionnaire-9 assessment, risk abuse and divergence assessments, urine toxicology screening, and formal pain control assessment. In addition, a survey assessing knowledge and attitudes of chronic pain management will be developed and distributed to all clinic providers. Utilizing these data and current guideline recommendations, a pharmacist-provider co-visit-driven protocol will be developed. Patients will be scheduled for a pharmacist-provider co-visit strictly for pain management initially and every 6 months. These visits will consist of performing and documenting the 6 process measures, discussing management goals and need for referrals, monitoring for adverse drug reactions, drug-drug interactions, and
adherence, and making decisions for ongoing opioid therapy. Changes in the 6 process measures and provider knowledge and attitudes will be assessed following protocol implementation.

Poster Title: Implementing a pharmacy-driven discharge education service utilizing pharmacy students and residents: a pilot study of the effects on patient satisfaction, understanding, and readmission

Primary Author: Preston Taylor, Kootenai Health, ID; Email: pttaylor@kh.org

Additional Author(s):
Duane Siercke
Barbara Steele

Purpose: With healthcare evolving to focus on improving patient outcomes and decreasing costs, there is a need for modern-day health systems to ensure medication continuity across various facets of care. This includes the assessment of patient medication regimen understanding to ensure adherence and, ideally, to prevent readmissions. Research has demonstrated the value and capability of pharmacy students within clinical pharmacy practice. Our objective is to develop a discharge medication education service, administered by pharmacy students and residents, and to assess its impact on patient satisfaction and understanding.

Methods: This study will pilot the implementation of a pharmacy student and resident driven discharge education service at a 254 bed rural community hospital. This service will provide medication education to patients prior to home discharge from the hospital. The cardiology unit will be selected as the primary site of investigation due to the high rate of patient turnover and the number of patients admitted for diagnoses that require significant medication management including myocardial infarction, heart failure, and atrial fibrillation. Education will be overseen by the clinical pharmacist or clinical pharmacy manager until the students’ skills are determined to be sufficient. All utilized materials for administering patient education will come exclusively from a predetermined, published source. Additionally, medication lists will be reviewed by students prior to education and any subsequent interventions will be documented. Following the patient encounter, students will document the interaction within the electronic medical record. Outcomes will be primarily assessed as the change in HCAHP question number 16, 17, 24, and 25 pertaining to patient education. Secondary outcomes include patient comprehension, assessed with a modified Self-Administration of Medication Tool; 30 day
readmission rate; and an analysis of perceived student educational benefit, described with a novel likert-scale-based questionnaire. The study will be submitted to IRB-Spokane for review and approval.

**Poster Title:** Implementing a patient-centered approach for preventing and addressing delirium in dementia patients admitted to a community hospital

**Primary Author:** Rachel Christiansen, Kootenai Health, ID; **Email:** rchristiansen@kh.org

**Additional Author(s):**

**Purpose:** The hospital setting presents many challenges for patients with behavioral and psychological symptoms of dementia (BPSD), and currently, there are no psychotropic medications approved for the management of BPSD. Multicomponent interventions combining comprehensive risk factor assessments and non-pharmacological therapies appear to be the most effective strategy in preventing delirium in older patients.

The primary goal of this study is to improve quality of care for dementia patients admitted to the hospital by utilizing a standardized, multicomponent protocol for the management of BPSD.

**Methods:** This study will be conducted at a 254-bed community hospital and piloted on 2 units, the general medical and cardiology units. Risk factor assessments will be completed on every dementia patient regularly as part of standard care and documentation will be provided by the nursing staff in the electronic medical record. When a dementia patient begins to exhibit changes in behavior, the interdisciplinary care team will utilize a step-wise protocol that will help identify or exclude delirium. Next, it will guide the team through non-pharmacological interventions and therapies. The last step of the protocol will guide the decision making process for choosing a pharmacotherapy option as a last-line intervention for patients who are experience severe, inconsolable distress or become a violent threat to themselves or others.

The primary outcome will be the percentage or average use of psychotropic medications for agitation. The secondary outcomes will include the incidence of delirium, assessment of non-pharmacological interventions, length of hospital stay, education provided to family and caregivers, and continuity of care.

**Results:** N/A - research in progress

**Conclusion:** N/A - research in progress

Session-Board Number: 10-084

Poster Title: Implementation of a pharmacy discharge medication education program and its effect on post-discharge health-care utilization in patients at high risk for hospital readmissions

Primary Author: Zachary Durtschi, St. Luke’s Magic Valley Regional Medical Center, ID; Email: durtschz@slhs.org

Additional Author(s):
Jeremy Plumb
Bradley Barnes
Dallin Poulsen

Purpose: The aim of this project is to improve patient care through pharmacy-led discharge medication education for a cohort of patients at high risk for hospital readmission. These high-risk patients are likely to have other comorbidities and be on a number of medications. As the pharmacy department is not currently involved in comprehensive discharge medication education, a pharmacy led initiative will likely enhance patient understanding of discharge medication plans. The effect this pharmacy discharge medication education has on 30-day readmission rates and return to ED rates before and after implementation will be evaluated.

Methods: Discharge medication education will be provided by the pharmacy department to the following patients at high-risk for hospital readmissions:
Patients greater than or equal to 65 years old with Medicare insurance, who are admitted to St. Luke’s Magic Valley Medical Center and have a primary diagnosis of pneumonia with a secondary diagnosis of COPD, or a primary diagnosis of sepsis with a secondary diagnosis of pneumonia.
Pharmacy personnel will review and provide education on discharge medications, with an emphasis on changes to the medication regimen as compared to what patients were taking prior to admission. Approved medication written information will be given to patients for at least the newly prescribed medications (i.e. those that were prescribed as a part of the hospital stay). Other helpful aids, such as medication calendars, picture representations of medications, and pillboxes, may be given to patients to augment the discharge medication education provided.
As a process improvement project, the discharge medication education program will be evaluated on an ongoing basis in order to ensure optimal implementation.

**Results:** Results of this project will include: A comparison of 30-day readmission rates and frequency of return to the emergency department before and after implementation; comparison of readmission diagnoses before and after implementation; operational outcomes including percentage of patients who actually received the pharmacy intervention, time spent with each patient, and barriers to successful discharge education; other results may include classes of medications counseled on and cost-savings data.

**Conclusion:** Implementation of this pharmacy-led discharge medication education program is likely to enhance individual patient understanding of their discharge-medication plan. In turn, this hopefully will lead to better adherence and outcomes for these patients at high-risk for hospital readmission.
Poster Title: Improving the clinical practice of anticoagulation therapy management with warfarin in the inpatient setting at St. Luke’s Magic Valley Regional Medical Center.

Primary Author: Quyen Bui, St. Luke's Magic Valley Regional Medical Center, ID; Email: buiq@slhs.org

Additional Author(s):
Lisa Maxwell
Rebecca Arborgast-Green
Dallin Poulsen

Purpose: Despite a long existence and prevalent use of warfarin, safe management of this drug remains a challenge for clinicians due to a narrow therapeutic index and long duration of action. Initial warfarin dosing is based on multiple risk factors and research demonstrates that the same dose should be given for at least two consecutive days before making dose adjustments. There is variability in warfarin initial dosing, as well as how and when dose adjustments should be made by pharmacists. This project will assess the consistency of dose initiation, while also proposing a more systematic guideline for pharmacists to manage warfarin.

Methods: A record of all adult inpatients whose warfarin is managed by the pharmacy will be used to gather data for this project. Patients’ specific information such as warfarin dosing, INR labs and its frequency, patients’ risk factors, additional anticoagulant medications, other medications, diets, etc., will be collected and taken into consideration to assess the appropriateness of warfarin management. Data gathered from this project will be compared with the American College of Chest Physicians Antithrombotic Therapy and Prevention of Thrombosis guidelines and the University of Washington Medicine Anticoagulation Services. The result from this study will be used to contrive a more consistent standardized guideline for warfarin management at St. Luke’s Magic Valley.

Results: This study is still in process, however, its result is expected to identify deficiency in warfarin management and devise a more systematic guideline for use in the hospital.
Conclusion: A more consistent standardized guideline will be helpful in providing a better and easier guidance for pharmacist-managed warfarin in the hospital. Furthermore, it will improve patient outcome, minimize adverse events, and more smoothly facilitate patient transition of care to the outpatient setting once they are discharged from the hospital.

**Poster Title:** Characterization of hyperglycemic episodes among non-critically ill hospitalized patients within a community hospital

**Primary Author:** Sapna Shah, Baptist Health Floyd, IN; **Email:** shah.sap519@gmail.com

**Additional Author(s):**
Shanna Hays
Abigail Breit
Joshua Senn
LeAnn Doddrige

**Purpose:** Numerous studies have demonstrated hyperglycemia among hospitalized patients can result in an increase in infections rates, mortality, hospital length of stay, and higher healthcare related expenses. The purpose of this study is to characterize hyperglycemic episodes based on current hospital practices. Results will be utilized to improve existing practices and develop new strategies to improve glycemic control in hospitalized non-critically ill patients.

**Methods:** This study will be submitted for Institutional Review Board approval. This is an observational, retrospective chart review of non-critically ill patients admitted to medical inpatient units from April 1, 2016 to June 30, 2016 receiving oral anti-hyperglycemics or insulin therapy for at least 48 hours. Medical records will be obtained for all adult patients with hyperglycemic events as defined by blood glucose levels greater than 180 mg/dL. Subjects who are not receiving anti-hyperglycemic therapy prior to admission or during inpatient stay, admitted to medical inpatient floors for less than 48 hours, admitted with diabetic ketoacidosis or hyperosmolar hyperglycemic state, receiving insulin drips or on an insulin pump, and receiving total parental nutrition containing insulin will be excluded. Data to be collected includes: demographic information, inpatient hyperglycemia treatment including medication name, dose, route, frequency, date and time administered or omitted dose, home hyperglycemia medications, point- of-care blood glucose levels, hemoglobin A1c, nutrition status, admitting diagnosis, comorbidities, and use of corticosteroid during hospitalization. All subject data reported will be de-identified and will be maintained confidentially.

Poster Title: Effect of pharmacist intervention on glycated hemoglobin in poorly controlled diabetic patients at an internal medicine office

Primary Author: Kathryn Loeser, Columbus Regional Health, IN; Email: kloeser@crh.org

Additional Author(s):

Purpose: Pharmacists collaborate with physicians to optimize therapy for diabetic patients. The objective of this study is to determine the impact of pharmacist intervention on glycated hemoglobin in poorly controlled diabetic patients during internal medicine office visits.

Methods: Patients with poorly controlled diabetes such as glycated hemoglobin greater or equal to nine will be identified. All data will be recorded without patient identifiers and maintained confidentially. At minimum, the following data will be collected at baseline before pharmacist intervention: age, gender, glycated hemoglobin, number of diabetes medications, type of diabetes medications, body mass index, diagnosis of hypertension, angiotensin-converting-enzyme inhibitor or angiotensin receptor blocker use, statin use, blood glucose, and number of office visits within the previous three months. At each appointment, the following data will be collected if available: body mass index, number of diabetes medications, diagnosis of hypertension, angiotensin converting enzyme inhibitor or angiotensin receptor blocker use, statin use, blood glucose. At minimum, any of the following interventions may be performed during each pharmacist appointment: dose adjustment, medication addition, medication removal, medication counseling, lifestyle counseling, plan for follow up. Glycated hemoglobin will be collected every three months. After each appointment, the pharmacist will document intervention data using a standardized form. Other outcome data that will be collected if available include hospitalization for diabetes related issue, number of appointments with a pharmacist during study time frame, and number of referrals to a specialist regarding diabetes related diagnoses. The impact of pharmacist involvement in diabetes management will be evaluated based on intervention data and effect on glycated hemoglobin.

Poster Title: Exploring the correlation of insulin use and inpatient hypoglycemic events

Primary Author: Jessica Durham, Columbus Regional Hospital, IN; Email: jdurham1@crh.org

Additional Author(s):

Purpose: Currently, inpatient hypoglycemia rates at the hospital are higher than other hospitals in the state of Indiana. From reviewing previous data collected by the hospital, the morning is the time that most hypoglycemic events occur at the hospital. The objective of this study is to determine if hypoglycemic events between the hours of 00:00 and 09:00 are being caused by a particular insulin regimen, and if so to identify the regimen.

Methods: Patients that had morning hypoglycemic events, while on either formulary insulin glargine or formulary insulin lispro during their stay at the hospital will be reviewed, utilizing the electronic database. Hypoglycemic events will defined as a blood glucose value of less than or equal to 70 mg/dL. The following data will be collected age, gender, the time of last administration of both insulin lispro and insulin glargine, the dose of insulin administered, blood glucose values associated with date and time from the morning prior and morning after hypoglycemic event, diagnosis of type 1 or type 2 diabetes mellitus, glycosylated hemoglobin values (hemoglobin A1C), and diet status. All data collected will be confidential and contain no patient identifiers. This data will be trended to see if morning hypoglycemic events can be attributed to a specific insulin regimen, based on time of insulin administration and time of hypoglycemic event.

**Poster Title:** Incidence of post-operative atrial fibrillation after implementation of prophylactic amiodarone

**Primary Author:** Hanna Corey, Community Health Network, IN; **Email:** hcorey@ecommunity.com

**Additional Author(s):**
Brenda Clark
Brian Lindvahl

**Purpose:** Atrial fibrillation is the most common arrhythmia following cardiac surgery occurring in 25 to 50 percent of patients. Various regimens have been studied with amiodarone for the prevention of atrial fibrillation. Historically within Community Health Network, there was no consistent approach to prevent post-operative atrial fibrillation besides beta blockers. However in 2015, a prophylactic strategy utilizing amiodarone was implemented. The objective of this study is to compare the incidence of post-operative atrial fibrillation after implementation of prophylactic use of amiodarone for patients undergoing coronary artery bypass graft surgery and/or valve replacement compared to the incidence before implementation.

**Methods:** This will be a single center retrospective cohort study. Post-operative atrial fibrillation will be defined as atrial fibrillation lasting 5 minutes or longer that prompted therapy by the sixth postoperative day or discharge, whichever was sooner. Prophylactic amiodarone is defined as 600 mg orally twice daily for two doses prior to surgery; then 400 mg orally twice daily post-operatively until discharge. The inclusion criteria for the study are patients 18 years of age or greater that underwent cardiac surgery and received prophylactic amiodarone from January to June of 2016 compared to control patients from January to June of 2015. The exclusion criteria for the study are patients with active atrial fibrillation at the time of surgery, past medical history of atrial fibrillation, emergency surgery, uncontrolled hyperthyroidism, or receiving any antiarrhythmic drugs with the exception of beta blockers. Secondary outcomes include length of stay and documented adverse effects associated with amiodarone. Additional data to be collected includes: demographics; past medical history; concomitant pre-operative cardiac medications; number and duration of atrial fibrillation episodes; time to post-operative atrial fibrillation; number of days of hospitalization, days in the intensive care unit (ICU), and
days of mechanical ventilation; number of vessels bypassed/valves replaced or repaired; Society of Thoracic Surgeons risk scores; medications used to treat atrial fibrillation if it occurred; and drug interactions with amiodarone.

Poster Title: Comparison of Burst Versus Taper Steroid Dosing in COPD Exacerbations

Primary Author: Paul Szostak, Community Health Network, IN; Email: pszostak@ecommunity.com

Additional Author(s):
Tracy Costello
Kellianne Webb

Purpose: For chronic obstructive pulmonary disease (COPD) exacerbations, the Global Initiative for Chronic Obstructive Lung Disease (GOLD) guidelines recommend treatment with 5 days of prednisone 40 mg to improve outcomes. The objective of this study is to assess 30 day readmission rates based on prescriber practices of either steroid taper dosing versus sustained, burst steroid dosing.

Methods: This study is pending Institutional Review Board approval. A retrospective, observational chart review will be performed at Community Health Network in Indianapolis, Indiana. Patients eligible for inclusion will have been admitted to Community Health Network with a primary diagnosis of acute exacerbation of COPD. Additionally, patients must be between the ages of 18 and 89 years of age and discharged on a systemic corticosteroids (SCS). Patients will be excluded if they are pregnant, a prisoner, discharged to hospice, expire on initial admission, or have a history of asthma.

Data collected will include: age, gender, smoking history, initial hospital length of stay, hospital of admission, patient location, comorbidities, home COPD medications, medication changes at discharge, doses of SCS used, antibiotics given, supplemental oxygen, readmission in 30 days from discharge, number of days until readmission, primary diagnosis at readmission, and death within 30 days.

Burst therapy will be defined as not more than one decrease in steroid dose throughout admission and discharge prescription. A SCS regimen will be considered a taper if the dose of SCS is changed more than once throughout the course of the admission and upon discharge. Statistical analysis will be used to compare if a significant difference exists between readmission rates based on type of steroid regimen prescribed.

**Poster Title:** Incidence and clinical outcomes of unintended discrepancies in warfarin discharge orders

**Primary Author:** Lindsay DeWend, Community Health Network, IN; **Email:** ldewind@ecommunity.com

**Additional Author(s):**
Tracy Costello
Jake Lemon

**Purpose:** Warfarin is a commonly prescribed anticoagulant with many dosing complexities due to variable patient response, a narrow therapeutic index, and drug interactions. Due to this, Community Health Network implemented a protocol allowing pharmacists to automatically manage adult inpatient orders for warfarin. However, upon patient discharge, it is the physicians’ responsibility to reconcile the dosing. The objective of this study is to determine the percentage of patients discharged on warfarin with an unintended discrepancy in warfarin dosing. If necessary, the information collected will be used to propose a collaborative drug practice agreement allowing pharmacists to prescribe a warfarin regimen at discharge.

**Methods:** A retrospective chart review will be conducted within the Community Health Network hospitals. Eligible patients for the study will be identified through a report of patients using a Community Health Network-affiliated anticoagulation clinic with an admission into one of the four hospitals between July 1, 2015 and June 30, 2016. Patients may be newly initiated on warfarin or continued on warfarin from home during the hospitalization. Patients will be excluded if they are in a protected patient population, have an INR goal of anything other than 2-2.5, 2-3 or 2.5-3.5, were prescribed short term warfarin therapy (less than 2 weeks), were hospitalized for less than 2 days, or did not have a follow-up anticoagulation clinic appointment within 2 weeks of discharge. The following data will be collected: patient age, sex, primary admission diagnosis, Charlson Comorbidity Index, admitting hospital, discharging unit, indication for warfarin, chronic home medication or new start for warfarin, INR at discharge, discharge warfarin dose recommended by the pharmacist, discharge warfarin dose written by prescriber in discharge summary, type of discrepancy, location of pharmacist dosing recommendation in the chart, day of the week discharged, INR at first follow-up
anticoagulation clinic appointment post-discharge, number of days until anticoagulation clinic appointment after discharge, readmission event, and outcome of readmission.

Poster Title: Development of screening criteria to assess appropriateness of outpatient DVT treatment in ED patients.

Primary Author: Shaina Musco, Community Health Network, IN; Email: smusco@ecommunity.com

Additional Author(s):
Shannon Smallwood
Jill Gossard
Yi Zhou

Purpose: Evidence-based clinical practice guidelines recommend that patients with acute deep vein thrombosis (DVT) for whom “circumstances are adequate” be treated at home rather than in the hospital. There is no protocol at Community Health Network (CHNw) to identify candidates for outpatient treatment of DVT. The development and implementation of such a protocol represents an opportunity to avoid unnecessary hospitalization, sparing patients from nosocomial exposures and improving satisfaction. Additionally, projected cost savings based on retrospective application of the screening criteria may justify addition of a new emergency department (ED) pharmacist position to advocate for outpatient treatment of appropriate patients with DVT.

Methods: This study will be submitted to the Institutional Review Board for approval. It will be conducted in three sequential phases: compilation and vetting of screening criteria, evaluation of criteria through retrospective chart review and quantification of potential cost savings, and implementation and operationalization of criteria within an ED-based screening protocol. In the first phase, criteria to identify individuals qualifying for outpatient treatment of DVT were developed through collaboration with content experts and stakeholders across CHNw. This was accomplished by examining and adapting high-quality primary literature and similar procedures in place at other institutions. A preliminary search was performed using the indexing and abstracting services PubMed and Ovid MEDLINE with terms “venous thrombosis”, “ambulatory care”, and “anticoagulants.” Pertinent results were individually examined to assess criteria used either for exclusion from study eligibility for safety purposes or exclusion from outpatient treatment study arm. Consensus criteria across resources were automatically included, while
discrepancies were resolved using a simple majority rule. The criteria were then compiled and end user feedback was solicited for improvement and refinement.

**Results:** A total of 17 resources were reviewed for criteria to determine appropriateness of outpatient DVT treatment. Primary literature included review articles, randomized controlled trials, and cohort studies. Internal and public documentation of similar screening protocols in place at a large health maintenance organization and academic medical center, respectively, were also analyzed. Prescribing information for individual anticoagulant agents was referenced for safety information. Exclusion criteria derived from these resources were distributed into five categories: significant organ dysfunction, high risk of bleeding or clotting, high risk venous thromboembolism characteristics, hemodynamic instability, and abnormal pharmacokinetic parameters. A detailed description of measureable parameters associated with each criterion as well as a sample screening tool was distributed to ED personnel, including pharmacists and physicians, for comment. Following the vetting process, appropriate revisions were made and the criteria assembled into a data collection form.

**Conclusion:** Screening criteria to assess eligibility for outpatient treatment in ED patients diagnosed with DVT were compiled from evidence-based exclusions utilized in primary literature and current practice, then vetted through a multi-disciplinary review process. These criteria can now be assessed in phases two and three of this study. By developing, evaluating, and implementing a protocol to assess appropriateness of outpatient DVT treatment in ED patients, CHNw can at once improve patient care and reduce costs.

**Poster Title:** Implementation of a pharmacist-driven, emergency department culture review in a community hospital

**Primary Author:** Eileen Rohrbach, Community Health Network / Butler University College of Pharmacy and Health Sciences, IN; **Email:** ecarroll2@ecommunity.com

**Additional Author (s):**
Sarah Lackey
Alishia Vanus
Tracy Costello

**Purpose:** Knowledge of evidence-based regimens, drug interactions, and formulary options as well as the ability to collaborate with patients and healthcare providers equip pharmacists for involvement in emergency department (ED) clinical functions, such as antimicrobial stewardship programs. Previously published studies have shown these programs decrease ED visits and 30-day readmission rates while reducing the time to positive culture review. Larger-scale impact on the hospital system can be observed secondary to minimized resistance development and improved resource utilization. The primary objective of this study is to compare and contrast readmission rates, process time, and antibiotic appropriateness between a nursing-driven and pharmacist-driven process.

**Methods:** A retrospective case-control study with Institutional Review Board approval is planned comparing pre- and post-implementation of a pharmacist-led emergency department microbial culture review process. Eligible patient will be identified through an a computerized decision-support program which will include patients from June 1, 2016 through August 31, 2016 and October 1, 2016 through December 31, 2016 for the pre- and post-implementation groups, respectively. Included patients will have been treated in the study hospital’s ED and had a urine culture drawn that resulted positive in the study timeframe. Excluded patients were those who were admitted inpatient or observation; those less than 18 years of age or greater than 89 years of age; and those with protected status. The following data will be collected: patient demographics; ED diagnosis; antibiotic allergies; cultured species and sensitives; antibiotic prescribed at discharge; time from positive culture to intervention by staff member; intervention required, if necessary; and ED visits or hospital admissions within 8 weeks. Data
from the two study groups will be compared to identify any differences in readmission rates, process time, and antibiotic appropriateness.

**Poster Title:** Analysis of four-factor prothrombin complex concentrate use in a community hospital setting

**Primary Author:** Kristine Manlimos, Community Healthcare System - Community Hospital, IN; Email: kristine.manlimos@gmail.com

**Additional Author(s):**
Bhavik Nana

**Purpose:** Four-factor human prothrombin complex concentrate (PCC) was approved in 2013 for urgent reversal of acquired coagulation factor deficiency induced by warfarin, a Vitamin K antagonist, in adults with acute major bleeding. Four-factor PCC is currently available at Community Healthcare System (CHS), however restrictions have been placed on its usage. This review is the first evaluation of current prescribing practices since its addition to the formulary in September 2013. The purpose of this review is to evaluate the utilization of four-factor PCC at the three hospitals within CHS by analyzing the appropriateness of prescribing practices in relation to current institution-specific restrictions.

**Methods:** In this retrospective review, any patient within CHS who received at least one dose of four-factor PCC within July 1, 2013 to June 30, 2016 will be included and evaluated in this study. The primary endpoint is the appropriate usage of four-factor PCC in the hospital based on current restrictions: Symptomatic warfarin-related intracranial hemorrhage with INR greater than 1.5 or severe to life-threatening bleeding with a reasonable attempt at a Hematology consult. Secondary endpoints include the use of multiple doses of four factor PCC, appropriateness of dosing, use of four-factor PCC to reverse warfarin versus non-warfarin-related bleeding, time between order verification and medication administration, and cost effectiveness in terms of whole vial utilization. Primary safety endpoints include the incidence of complications from four factor PCC, including thrombotic events, or use in patients with or the development of contraindications to use (hypersensitivity to PCC or any of the formulation components, including factors II, VII, IX, X, protein C and S, antithrombin III, human albumin, disseminated intravascular coagulation (DIC), or heparin-induced thrombocytopenia (HIT)).

**Session-Board Number:** 10-095  

**Poster Title:** Compliance with a tbo-filgrastim protocol via a drug use evaluation in a community hospital setting.  

**Primary Author:** Garrett Rompelman, Community Healthcare System - Community Hospital, IN;  
**Email:** garrett.h.rompelman@comhs.org  

**Additional Author (s):**  
Sean Chantarapanont  
Junyu Zhang  

**Purpose:** Current recommendations restrict the timing of tbo-filgrastim administration in order to promote optimal patient response to therapy. A formulary restriction protocol was initiated within the Community Healthcare System to ensure proper utilization of tbo-filgrastim. Therefore, a retrospective review of tbo-filgrastim utilization was conducted in order to evaluate compliance with the protocol and facilitate optimal patient outcomes in a community hospital setting.  

**Methods:** Electronic health records will be analyzed for appropriate use of filgrastim/tbo-filgrastim. Any patient receiving tbo-filgrastim will be included in the study. Patient records will be analyzed to determine if tbo-filgrastim is being properly restricted to primary and secondary prophylaxis in malignancy and appropriately administered and discontinued. Primary prophylaxis in malignancy was defined as 1) use with all high risk chemotherapy regimens with greater than 20 percent risk for febrile neutropenia and 2) potential use with intermediate risk chemotherapy regimens with 10 to 20 percent risk for febrile neutropenia per National Comprehensive Cancer Network guidelines. Patients with an intermediate risk should be administered tbo-filgrastim based on an evaluation for patient specific risk factors: age greater than or equal to 65 years, poor performance status, preexisting neutropenia, previous chemotherapy, previous radiation therapy, bone marrow involvement with tumor, infection/open wounds, recent surgery, poor renal function, and/or liver dysfunction (increased bilirubin). Secondary prophylaxis in malignancy was defined as use in patients with prior neutropenic complications: febrile neutropenia or treatment delay and/or chemotherapy dose reduction due to neutropenia. Appropriate administration of tbo-filgrastim was considered defined between 24 to 72 hours of receiving chemotherapy. Appropriate discontinuation of
tbo-filgrastim was defined as once a patient’s ANC was either less than 2000 cell/mm3, less than 5000 cell/mm3, or per physician discretion.

Poster Title: Strengthening of pharmacy clinical services in the neonatal intensive care unit

Primary Author: Kate Allen, Deaconess Health System, IN; Email: kate.henderson@deaconess.com

Additional Author(s):

Purpose: To serve as a successful level III neonatal intensive care unit (NICU), it takes a strong multidisciplinary team that encourages learning and growth. In the NICU, our pharmacists currently have a role in standard pharmacy practice and consults for pharmacokinetic services in complex patients. The need for clinically-focused pharmacists is evident in order to maximize the role of pharmacists in this area. When serving as a clinical pharmacist in the NICU, it opens opportunities to have a larger role during rounds, prevent medication errors, optimize medication management, and serve as the medication expert for drug-related questions.

Methods: To further educate the pharmacists currently working in NICU operations, strategies and tools will be developed to enhance their ability to make interventions confidently. Complete and concise medication lists with dosing information will be provided to all pharmacists, as well as pertinent pharmacokinetic information. An improved rounding tool will be prepared in order to assist the clinical pharmacist during rounds, providing guidance on common interventions that can be made. To provide a standard of practice, a clinical competency program will be developed. This program will target common disease states found in the NICU, as well as patient cases with pharmacokinetics and dosing questions. After all pharmacists who practice in the NICU complete the program, a survey will analyze their confidence in making NICU interventions and recommendations.

Results: Results and conclusions will be presented at the Great Lakes Pharmacy Resident Conference.

Conclusion: Results and conclusions will be presented at the Great Lakes Pharmacy Resident Conference.

Session-Board Number: 10-097

Poster Title: Development of an oncology symptom management clinic

Primary Author: Jennifer Dueker, Deaconess Health System, IN; Email: jennifer.dueker@deaconess.com

Additional Author(s):

Purpose: Oncolytic therapy is associated with a myriad of adverse drug events that often result in patients seeking emergency medical attention and hospital admissions. The purpose of this project is to determine the most common reasons oncology patients go to the emergency room after receiving chemotherapy and, in collaboration with the oncology physicians, manage these symptoms per developed protocols and ultimately prevent similar occurrences in the future.

Methods: Data collection includes patients with both outpatient chemotherapy infusions and emergency room encounters over the past six months. Chart reviews will be performed to determine the most common causes of emergency room visits or hospital admissions in this patient population after receiving treatment with chemotherapy. Expected diagnoses include dehydration, febrile neutropenia, mucositis, hand-and-foot syndrome, nausea and vomiting, and pain management. With this data, protocols will be developed and a collaborative agreement will be established with the oncology physicians allowing for the management of these adverse drug events by pharmacists per best practice guidelines. Patient education is also a large portion of this project and will play a vital role in symptom management and in preventing future emergency room visits. Both new and established patients will be addressed. Utilizing associated MD Anderson oncology resources, pharmacists will educate these patients on pertinent information related to their cancer treatment and alert them to potential side effects. Additionally, discussion regarding specific plans with the patient and the patient’s oncologist regarding treatment may help to prevent unnecessary trips to the hospital. Outcomes will be measured by patient feedback and evaluation of data at six months after implementation compared to baseline data.

**Poster Title:** Effect of a bedside medication delivery service on 30 day readmission rates in a disproportionate share hospital

**Primary Author:** Howard Wang, Franciscan Health – Hammond and Dyer, IN; **Email:** howard.wang@franciscanalliance.org

**Additional Author(s):**
Bindy Cooc
Kimberly Beranek
Susan Jula

**Purpose:** With the full implementation of the Hospital Readmissions Reductions Program by Center for Medicare and Medicaid Services, healthcare institutions across the country have begun implementing programs aimed at reducing 30 day readmissions. Disproportionate share hospitals (DSH) face unique challenges in obtaining access to resources for their uninsured and underinsured patient populations. The goal of this study is to determine the impact of a bedside medication delivery service on 30 day readmission rates and patient satisfaction at a DSH.

**Methods:** This study has been approved by the Institutional Review Board. The bedside medication delivery service will be provided through an in-house outpatient pharmacy. Data will be collected on all participating patients admitted from September 1, 2016 to April 30, 2017 and will include: age, gender, comorbidities, reason for admission, admission date, discharge date, discharge unit, number of new prescriptions upon discharge, if there is 30 day readmission, and the reason for readmission. Patient satisfaction will be measured with an anonymous survey included with the filled prescriptions. At the end of data collection period, monthly 30 day readmissions, total 30 day readmissions, and readmission rates by unit will be compared to historical data to determine the impact of the bedside medication delivery program on 30 day readmissions. The primary endpoints are 30 day readmission rates versus the comparator group and patient satisfaction and feedback. The secondary endpoints are percentage of eligible patients participating in the program, reasons for non-participation, reasons for readmission versus the comparator group, and the number of prescriptions filled by...
participating patients. For the purposes of this study, the comparator group will be patients whom were admitted from September 1, 2015 to April 30, 2016.

Poster Title: Identification of risk factors associated with multi-drug resistant infections at a community hospital

Primary Author: Mark Biagi, Franciscan Health – Hammond and Dyer, IN; Email: markbiagi4@gmail.com

Additional Author(s): Sergio Villicana
Eric Pelletier

Purpose: As the prevalence of multi-drug resistant (MDR) infections continues to grow, it has become increasingly important that clinicians be able to properly identify and treat high risk patients in a timely manner. In addition to increased healthcare costs, MDR infections are also associated with longer lengths of stay and poorer clinical outcomes. The purpose of this study is to retrospectively analyze cases of MDR infections at a community hospital to identify risk factors associated with their development and, based on the results, implement measures to effectively screen, identify, and treat patients at risk for MDR infections.

Methods: This study will include patients at least 18 years old, admitted to our institution from January 1, 2013, through December 31, 2015, who had at least one positive culture for either an extended-spectrum beta-lactamase (ESBL) producing organism or carbapenem-resistant Enterobacteriaceae (CRE). Initial isolates from each hospital admission will be included for analysis, and all subsequent isolates from the same hospital admission will be excluded. Retrospective data collection will be performed via chart review and will include patient demographics, comorbid conditions, surgical procedures in the 90 days preceding admission, length of stay, site and date of culture, MDR organism(s) isolated, and antimicrobial exposure in both the 90 days preceding admission and during the hospital admission prior to CRE or ESBL culture isolation. The study has received Institutional Review Board approval.

Poster Title: Impact of targeted transition of care services by clinical pharmacists on hospital readmissions

Primary Author: Rachel Alm, Franciscan Health Hammond, IN; Email: rachel.alm@franciscanalliance.org

Additional Author(s):
Elizabeth Sullivan
Alexandra Goncharenko
Sun Lee-Such

Purpose: Transition of care (TOC) is defined as the movement of a patient from one setting of care to another. Pharmacists have the ability to provide patient education as well as clarify medication discrepancies during this TOC period. While previous studies have shown conflicting data on the impact of pharmacist intervention on hospital readmission rates, a targeted approach to pharmacist TOC services based on institution-specific trends may be beneficial. The purpose of this study is to identify factors associated with readmission at a community hospital, implement targeted pharmacist TOC services, and evaluate the impact on patient satisfaction and hospital readmission rates.

Methods: This study is approved by the Institutional Review Board. Adults admitted with an inpatient status and then readmitted within 30 days to a single community hospital whose initial admission occurred from May 2016 through July 2016 are eligible for inclusion. Pre-built electronic health record (EHR) reports will be used to identify patients and determine 30-day readmission rates. Data will be collected on the following: patient demographics, insurance provider, past medical history, discharge details, medications, initial discharge diagnosis, readmission diagnosis, cause(s) of readmission, medication history, and if discharge counseling was completed by a pharmacist. ICD-10 codes will be used to determine initial discharge diagnosis as well as subsequent readmission diagnosis. Causes of readmission will be categorized and analyzed for trends to develop a targeted approach to TOC services. After the interventions are made, a comparator group of patients will be identified and impact of services will be assessed. Patient satisfaction will be tracked using HCAHPS scores.

Poster Title: Pharmacist-initiated de-escalation of empiric intravenous vancomycin therapy in critically ill patients utilizing methicillin-resistant Staphylococcus aureus polymerase chain reaction (MRSA PCR) nasal screens

Primary Author: Maryam Noureldin, Franciscan Health Lafayette, IN; Email: maryamnoureldin93@gmail.com

Additional Author(s):
Katherine Pickerill

Purpose: Intravenous (IV) vancomycin is first-line therapy for suspected MRSA infections. It is frequently initiated for patients with risk factors for MRSA colonization and signs of an infection in an acute care setting. Culture and susceptibility results typically guide the de-escalation of vancomycin. However, practitioners hesitate to discontinue vancomycin for patients clinically improving, even if cultures suggest discontinuation. Nasal MRSA screens are shown to have a negative predictive value for MRSA infections of up to 99 percent. The objective of this study is to utilize MRSA PCR nasal screens to facilitate timely de-escalation of IV vancomycin therapy in critically ill patients.

Methods: A novel protocol, pending Institutional Review Board approval, is formed and awaiting approval by the hospital medication use committee to de-escalate IV vancomycin based on MRSA PCR nasal screen results. Adult patients receiving IV vancomycin that meet inclusion criteria are eligible for de-escalation of vancomycin within 48-72 hours of admission by clinical pharmacists. Inclusion criteria consists of a negative MRSA nasal screen within 24 hours of admission and cultures negative for organisms warranting IV vancomycin therapy (i.e. MRSA, methicillin-resistant Staphylococcus epidermidis, and/or other resistant gram positive bacteria). Existing hospital protocol states patients admitted to critical care units are to be screened for MRSA colonization upon admission using the nasal screen. Exclusion criteria covers patients not clinically improving in the absence of cultures, patients with cultures obtained more than 48 hours after admission, or patients not receiving other antibiotics to cover isolated pathogen(s). Intravenous vancomycin use will be evaluated in critical care units before and after implementation of the de-escalation protocol. Vancomycin days of therapy will
be the primary outcome measure. Descriptive statistics and a student t-test will be utilized in analyzing outcome results.

Poster Title: Pharmacist conducted education on the appropriate prescribing of stress ulcer prophylaxis to reduce inappropriate usage in an acute care setting

Primary Author: Sylvia Lefebvre, Franciscan Health Lafayette, IN; Email: sylvia.lefebvre@franciscanalliance.org

Additional Author(s):
Allyson Howard

Purpose: Stress ulcer prophylaxis (SUP) therapy is recommended in certain critically ill patients to prevent gastrointestinal bleeding and ultimately affect the length of stay and mortality. Currently, medications for SUP are prescribed to the majority of admitted patients, often unnecessarily. Data shows that the overuse of these medications is not without risks. Both proton pump inhibitors (PPI) and histamine H2-receptor antagonists (H2 blocker) have an increased rate of Clostridium difficile infection (CDI) in hospitalized patients. The objective of this study was conducted to evaluate the use of these medications and take actions to reduce unnecessary use.

Methods: Retrospective chart review the use of famotidine and pantoprazole used in all inpatient units for the week of July 24th through July 31st. Criteria for stress ulcer prophylaxis were obtained from American Society of Health-System Pharmacists (ASHP) stress ulcer prophylaxis guidelines from 1999. Appropriate use was defined by meeting one or more of the following criteria: coagulopathy (defined as platelet count less than 50,000, international normalized ratio (INR) greater than 1.5, partial thromboplastin time (PTT) greater than 2 times control value), mechanical ventilation for greater than 48 hours, history of gastrointestinal (GI) ulceration or bleeding within the past year, traumatic brain injury/traumatic spinal cord injury/burn injury, or two or more of the following minor criteria (sepsis, intensive care unit (ICU) stay greater than 1 week, occult GI bleeding for 6 or more days, and glucocorticoid therapy defined as greater than 250mg hydrocortisone or equivalent). Patients that were on proton pump inhibitors (PPI) or histamine H2-receptor antagonists (H2 blocker) prior to admission were excluded. Addition or continuation of a PPI or H2 blocker to the discharge medication list was also recorded.

**Poster Title:** The opioid- and sedative-sparing effects of chlorpromazine in children less than 3 years of age after cardiovascular surgery

**Primary Author:** Kelsey Browder, Indiana University Health, IN; **Email:** kbrowder1@iuhealth.org

**Additional Author (s):**
Christopher Thomas
John Brown
Elizabeth Moser

**Purpose:** Pediatric patients with congenital heart disease often require cardiac surgery which results in the need for pain and sedative medications after the operation to maintain comfort and decrease anxiety. Although chlorpromazine is commonly used at our institution as an adjunct medication for pain and sedation after pediatric cardiovascular surgery, literature demonstrating the safety and/or efficacy of this practice is scant. The objectives of this study are to determine the safety and efficacy of chlorpromazine and determine its opioid- and sedative-sparing effects.

**Methods:** In this retrospective cohort study, 72 patients aged 1 month to 3 years who received chlorpromazine within 72 hours of cardiovascular surgery between January 1, 2010 and August 1, 2016 will be included. Patients who received chlorpromazine will be matched via a cohort control model with patients who did not receive chlorpromazine in a 1:1 ratio based on age, primary congenital heart lesion, cardiac surgery, surgery year, and post-operative day. Patients with Trisomy 21 will be included in the study and analyzed separately. Baseline characteristics to be collected include age, weight, gender, severity of illness score, primary congenital heart lesion, cardiac surgery, and prior surgeries. The cumulative daily dose of sedatives and opioids in the 72 hours following chlorpromazine initiation will be collected, as well as efficacy endpoints such as sedation and pain scores, duration of mechanical ventilation, duration of hospital length of stay, ICU length of stay, and mortality. Safety endpoints that will be collected include naloxone or flumazenil administration, incidence of QTc prolongation, Torsades de pointes, extrapyramidal symptoms, and neuroleptic malignant syndrome.

**Poster Title:** Impact of emergency department discharge order folder on prescribing errors and optimization

**Primary Author:** Christine Kane, Indiana University Health, IN; **Email:** ckane@iuhealth.org

**Additional Author(s):**
Lauren Buenger
Cory Showalter

**Purpose:** In a pediatric emergency department, a pre-populated order folder was integrated into the electronic medical record with the goal to minimize prescription errors upon discharge. The objective of this study is to compare the rate of errors pre and post-implementation of the folder to evaluate the discharge order folder.

**Methods:** A retrospective chart review will be conducted of prescriptions written in the pediatric emergency department (PED). The two groups for comparison will include a sample of 200 prescriptions prior to folder implementation (February 1, 2014 – July 31, 2014) and a sample of 200 prescriptions post-implementation (December 1, 2014 – May 31, 2015). Prescriptions included in the discharge prescription order folder will be included in data collection focusing specifically on albuterol, acetaminophen, amoxicillin, ibuprofen, prednisolone/prednisone, and erythromycin prescriptions. Primary end point analysis will evaluate the rate of error occurrence between groups. Secondary analysis will provide further breakdown by classifying the type of error that occurred, the training level of the physician, error rates within specific commonly prescribed pediatric medications, and the impact of pharmacist presence in the PED on error rates. Errors will be categorized into one of the following groups: dose too low, dose too high, inappropriate dose for indication, incorrect direction, incorrect quantity prescribed, inappropriate product, and omission. A reduction in overall error rate would demonstrate a positive impact directly related to the implementation of the prescription discharge order folder.

Poster Title: Assessing clinical utility of thromboelastography versus conventional coagulation tests in patients with cirrhosis

Primary Author: Sandra Thorarensen, Indiana University Health, IN; Email: sthorarensen@iuhealth.org

Additional Author(s):
Sandra Kuehl
Haley Peters

Purpose: Patients with advanced liver disease are known for having hemostatic abnormalities and are at an increased risk for procoagulant and anticoagulant effects. Thromboelastography is a point of care assay that assesses the clotting cascade in its’ entirety from clot initiation to lysis in a whole blood sample. Thromboelastography provides an overall assessment of hemostasis in an individual compared to conventional coagulation tests. The objective of this study is to evaluate if the use of thromboelastography changes medical management in patients with cirrhosis compared to conventional coagulation tests.

Methods: This study will be submitted to the Institutional Review Board for approval. An electronic medical record system will be used to include patients who are 18 years or older, diagnosed with cirrhosis, and received thromboelastography (TEG) and an international normalized ratio (INR) value within a 24-hour period. Patients who received an INR only will be compared to patients who received an INR and TEG. The two groups will be compared by using a matched case control based on factors such as disease severity, INR values, and reason for admission. Baseline demographics such as patient age, gender, etiology of liver disease, and Child-Pugh scoring on admission will be collected. This study will assess the amount of blood products such as fresh frozen plasma, and platelets, blood factors, and other pharmacologic agents a patient received after receiving a TEG or INR value. Secondary outcomes to be evaluated are incidence of bleeding, thrombus formation, and mortality at 28 days.

Poster Title: Evaluation of implementation of pharmacist ambulatory care services in heart failure management

Primary Author: Brittany Oliver, Indiana University Health Bloomington, IN; Email: boliver1@iuhealth.org

Additional Author (s):
Jennifer Reiter
Miranda Arthur
Alaina Rotelli

Purpose: Numerous studies show that pharmacist involvement in heart failure (HF) management improves clinical care, yet statistics demonstrate that HF outcomes are not optimized in most settings. The objective of this study is to initiate pharmacist HF services in a mid-size clinic system and demonstrate subsequent improvement in patient outcomes and adherence to treatment guidelines. Baseline data (n=84) will be evaluated to assess current adherence to guideline recommendations and evaluate need for pharmacist services.

Methods: The study will be submitted to the International Review Board for approval. Pharmacist HF services will be implemented according to institution-approved protocol. The pre-intervention cohort will consist of patients with a diagnosis of heart failure with reduced ejection fraction (HFrEF) and under the care of an Indiana University Health Southern Indiana Physicians (IUHSIP) cardiologist. The post-intervention investigational cohort will consist of patients with HFrEF diagnosis under care of IUHSIP cardiologist and referred to pharmacist services to be compared with the control post-intervention cohort of patients with HFrEF diagnosis under care of IUHSIP cardiologist but not referred to pharmacist services. Retrospective chart reviews will be conducted for pre-implementation and post-implementation groups to determine which HF patients meet the primary composite endpoint of: percentage of patients taking an angiotensin converting enzyme inhibitor (ACEi), angiotensin receptor blocker (ARB), or angiotensin receptor-neprilysin inhibitor (ARNI) at target dose; taking a beta blocker at target dose; not using tobacco products or have documentation of tobacco cessation education; and who have received appropriate pneumococcal and influenza immunizations. Secondary endpoints include improvement in 30-day HF hospital readmission
rates and percentage of patients on spironolactone. Frequency of pharmacist initial and follow-up visits, medication review interventions, drug therapy adjustments, and educational sessions will also be quantified. Data analysis will include comparison of pre- and post-implementation rates for the primary and secondary endpoints.

**Poster Title:** Evaluation of a Vancomycin Dosing Protocol in Obese and Non-Obese Patients

**Primary Author:** Daniel Wilson, Indiana University Health Bloomington, IN; **Email:** dwilson10@iuhealth.org

**Additional Author (s):**
Khyati Desai

**Purpose:** After many decades, vancomycin remains a mainstay of treatment due to its vast supporting literature, low cost, and the desire to minimize exposure to newer agents to avoid resistance. Obesity has been a factor that has challenged each of these qualities, making the use of vancomycin problematic in this population. Despite being widely studied in this population there is little consensus on dosing strategies, and clinicians struggle to obtain safe and therapeutic troughs. This retrospective review will demonstrate whether the dosing protocol of the institution being studied is equally safe and effective in obese and non-obese patients.

**Methods:** This retrospective study will be submitted to the Institutional Review Board for approval. Data will be collected from the electronic medical records of patients who received intravenous vancomycin from June 1, 2016 through August 31, 2016. Patients ages 18 and older who had at least one vancomycin trough drawn during treatment will be included. Patients with end stage renal disease, baseline creatinine clearance (GFR=130% of ideal body weight) or non-obese. The primary endpoint is the proportion of patients who achieved the target vancomycin trough at the first level in these two groups. Secondary endpoints include the proportion of patient experiencing a subtherapeutic trough at the first and all levels, a supratherapeutic trough at the first and all levels, a therapeutic trough at all levels, and nephrotoxicity. Statistical analysis will be performed to detect statistical difference in these endpoints.

Poster Title: Evaluation of preoperative and post-operative venous thromboembolism (VTE) prophylaxis

Primary Author: Nsik Ekanem, Lutheran Hospital, IN; Email: nekanem@lhn.net

Additional Author(s):
Nora Klemke
Jacqueline Clouse

Purpose: The purpose of this quality initiative (phase I and phase II) study is to retrospectively and prospectively look at Lutheran Hospital’s multidisciplinary teams’ adherence to national guidelines regarding venous thromboembolism (VTE) prophylaxis assessment and prevention. Our primary objective is to evaluate the efficacy of Caprini VTE risk assessment tool in preventing post-operative VTE.

Methods: This study will be completed at Lutheran Hospital, Indiana. Authorization to complete this study was presented to the Lutheran Hospital institutional review board and was approved. The First phase of the study is a retrospective chart review of venous thromboembolism (VTE) events that occurred in hospitalized surgical and medical patients from January 1, 2015 until implementation of the protocol. The protocol will assess whether appropriate prophylaxis was utilized prior to implementation of the VTE risk assessment tool. Our patient population included surgical and medical patients who were found to have a post-operative VTE event. The incidence of post-operative VTE at Lutheran hospital for the year 2015 was 43 and the goal is to reduce that rate by 50%. To determine appropriateness of VTE therapy in our patient population, we plan to utilize the Caprini thrombosis risk scoring method. The number of events that could have been prevented if a protocol and risk assessment was put into place will be analyzed. Phase II will prospectively look at the rate of decrease for VTE events post-operatively. The recommended treatment algorithm for VTE prophylaxis was created and presented to the committee. Once this algorithm is approved, the committee will then set a timeline to implement the use of the risk assessment tool to determine the appropriateness of VTE prophylaxis.

Poster Title: Impact of pharmacist-run annual wellness visits in a private physician’s office

Primary Author: Aleksandra Voght, Lutheran Hospital, IN; Email: apopovski2016@gmail.com

Additional Author(s):
Andrea Wilhite

Purpose: The purpose of this study is to implement a process for pharmacist-run Medicare annual wellness visits (AWV) in a private physician’s office. The primary objective is to assess cost revenue through this service. In addition, time saved for the physician and types and number of pharmacist medication interventions will be evaluated.

Methods: This study will be submitted to the Institutional Review Board for approval. A pharmacist-run Medicare annual wellness visit (AWV) will be implemented within a private physician’s office. There are approximately 500 Medicare patients qualifying for these visits. A referral by the primary physician will be utilized for recruitment. The pharmacist will perform several low risk assessments during an AWV posing no risk to the patient. These assessments include a health risk assessment, physical assessment, and a patient history including: family history, past medical history, allergies, medications, vaccination history assessment, and a provider list. Three patient health questionnaires (PHQ) will be conducted to review risk factors for dementia and depression (PHQ-2, PHQ-9, and Mini Cognitive test). Based on these assessments, a pharmacist will provide personalized health advice to the patient. Data will be collected including number of patients seen by the pharmacy service, time saved for physician, and cost revenue for the clinic. In addition, type and number of interventions made will be evaluated.

**Poster Title:** Impact of a free heart failure medication program on thirty-day hospital readmission rates

**Primary Author:** Kathryn Mischler, Memorial Hospital of South Bend, IN; **Email:** katie.mischler@gmail.com

**Additional Author(s):**
Jeanne Anderson
Mark Herriman
Kaitlyn Priniski

**Purpose:** Decreased hospital readmissions of heart failure patients would lead to improved clinical outcomes. Additionally, increased readmissions can cause hospitals to receive reduced payments from the Center for Medicare and Medicaid Services. One strategy to avoid these penalties would be providing certain medications to patients for free since the inability to afford medications upon discharge can lead to decreased compliance with medications proven to decrease morbidity and mortality. The objective of this study is to determine whether a free heart failure medications initiative decreases thirty-day readmission rates of patients discharged from Memorial Hospital of South Bend.

**Methods:** Electronic medical records will be examined to complete a retrospective review of patients who were discharged with a thirty-day supply of heart failure medications before and after this program began on April 11, 2016. Medications provided to patients from this initiative include lisinopril, carvedilol, furosemide, and potassium chloride extended-release tablet. These medications are filled at the hospital’s pharmacy prior to the patient’s discharge. Medications dispensed will be at the discretion of the prescribing physician. Patients admitted with the primary diagnosis of heart failure will be included in this study. The primary endpoint of this study is all-cause hospital readmission rates thirty days following the patient’s discharge from Memorial Hospital of South Bend. The secondary endpoints will be hospital readmission rates due to heart failure exacerbations thirty days following the patient’s discharge and percent reduction in all-cause hospital readmissions. This study has been approved by Memorial Hospital of South Bend’s Institutional Review Board.

Poster Title: Impact of pneumatic tube system on time to medication administration

Primary Author: Anu Thinda, Memorial Hospital of South Bend, IN; Email: athinda@beaconhealthsystem.org

Additional Author(s):
Jeanne Anderson
James Galasso
Kirsten Galasso

Purpose: Pneumatic tube systems are used in many institutions for rapid and reliable transport of medical material. Memorial Hospital of South Bend Pharmacy Department recently installed a pneumatic tube system. The objective of this study is to see how effective the use of the new tube system will be by comparing the time from order entry to drug administration before and after the implementation of the pneumatic tube system at Memorial Hospital of South Bend.

Methods: This study was submitted to the Institutional Review Board and has been approved. The study will be a retrospective analysis and data points will be gathered for patients with medications delivered to floors which have the tube system. Memorial Hospital of South Bend uses an electronic medical record that supports computerized prescriber order entry and this study will involve collecting data from the electronic medical record regarding time to administration of a medication following order entry. This data will be looked at prior to the implementation of the new system for a time frame of 90 days and then again for the same time frame after education for and implementation of the system has taken place. A set sample size of 100 will be used for each time period. Prior to utilization of the pneumatic tube system, education will be provided to staff utilizing it. Once that education is delivered, tube system use will be initiated and data after its implementation will be collected. The primary end point of this study is time from order entry to medication administration prior to and following implementation of the pneumatic tube system. The secondary endpoint is percentage of STAT medications administered within 60 minutes.

**Poster Title:** Impact of rapid identification technology on the management of coagulase-negative Staphylococcus blood cultures in a multi-center community hospital system

**Primary Author:** Jaxson Burkins, Parkview Health, IN; **Email:** jaxson.burkins@parkview.com

**Additional Author(s):**
Michele Swihart
Jesse Christman

**Purpose:** Coagulase-negative Staphylococcus (CoNS) bacterial species are typically colonizers of the skin and often considered contaminants of blood cultures. Generally, these gram-positive cocci are empirically treated by providers while awaiting final speciation. Rapid polymerase chain reaction (PCR) technology can distinguish CoNS from other gram-positive species more rapidly than conventional cultures. This technology, combined with antimicrobial stewardship, may reduce the time to clinical decision of contamination and shorten the duration of unnecessary empiric antibiotics. The objective of this study is to evaluate the clinical impact of rapid PCR identification on the management of CoNS-contaminated blood cultures in a community hospital system.

**Methods:** This retrospective chart review will evaluate subjects with CoNS-contaminated blood cultures before and after implementation of rapid PCR identification technology at seven community hospitals. Blood culture PCR and stewardship review were fully implemented by January 2016. Therefore, the post-implementation group timeframe is January to June 2016 and the pre-implementation comparator group timeframe is January to June 2015. Subjects eligible for inclusion will meet the following criteria: 18 years or older, inpatient at a Parkview Health facility in the listed timeframes, positive CoNS blood culture documented as a contaminant by a clinician in the medical record, and receipt of at least one dose of antibiotic therapy with activity against CoNS. Subjects will be excluded for the following: concurrent infection and receipt of antibiotic therapy not specific to CoNS, presence of polymicrobial bacteremia, physician-documented CoNS infection, history of CoNS bacteremia, documentation of immunocompromised status, or transition to hospice during admission. The primary outcome will be the difference in time to discontinuation of CoNS-related treatment, while secondary outcomes will include length of hospital stay, percent of pharmacist-initiated
discontinuation, and difference in estimated pharmacy drug cost. Subgroup analyses will be performed on the post-implementation group to evaluate therapy duration in ICU versus non-ICU subjects and in cases with an Infectious Diseases consult versus no consult. An additional analysis will assess the time to antibiotic discontinuation following a pharmacist recommendation.

**Poster Title:** Effect of body mass index on stroke outcomes after alteplase administration

**Primary Author:** Kelsi Wurm, Parkview Health, IN; **Email:** k-wurm@onu.edu

**Additional Author(s):**
Timothy Johnston
Megan Straub

**Purpose:** Stroke is a leading cause of disability in the United States. Alteplase is the only approved treatment for acute ischemic stroke. Obesity’s increasing rate, its elevation of stroke risk, and possible cause of variation in alteplase response suggest a need for further study. The purpose of this study is to evaluate the response to alteplase categorized by body mass index (BMI).

**Methods:** This retrospective review will utilize an institutional stroke database and electronic medical record to identify patients who received alteplase within 4.5 hours of symptom onset. Patients will be selected from March 1, 2013 until September 1, 2016. The following data will be collected: patient age, gender, ethnicity, height, weight, admission systolic and diastolic blood pressures, time from symptom onset to alteplase administration, alteplase dose, National Institutes of Health Stroke Scale (NIHSS) scores, hemorrhagic complications, clot size, hospital duration, discharge location, and in-hospital mortality. Differences in NIHSS will be calculated and a change in NIHSS greater than or equal to 4 will be considered significant. The proportion of patients with a significant change in NIHSS will be compared between each BMI category: underweight, normal weight, overweight, obese class I, obese class II, and obese class III.

**Poster Title:** Effects of body mass index on the safety and efficacy of direct oral anticoagulants

**Primary Author:** Jared Netley, Parkview Health, IN; Email: jared.netley@outlook.com

**Additional Author(s):**
Kris Howard
Kassandra Koopman

**Purpose:** Direct oral anticoagulants prevent stroke and systemic embolism in patients with atrial fibrillation and are used as prophylaxis and treatment in patients at risk for venous thromboembolism. In the 2016 guidelines, the International Society on Thrombosis and Haemostasis suggested avoiding direct oral anticoagulants in patients of extreme body weight or body mass index due to limited safety and efficacy data for this population. The purpose of this study is to determine the influence body mass index may have on the occurrence rate of thrombotic and significant bleeding events for patients treated with direct oral anticoagulants.

**Methods:** This study is a retrospective chart review that captures hospital admissions and emergency department visits for subjects at a community hospital system. The study is being performed as a quality improvement strategy and will not be taken for institutional review board approval. Subjects are collected if they present with a thrombotic or significant bleeding event and have a direct oral anticoagulant documented on their prior to admission medication list. Subjects are stratified into groups correlating to their body mass index. Comparisons will be made to determine if there is a higher frequency of thrombotic or significant bleeding events relative to body mass index grouping. Efficacy will be assessed by comparing frequency rates to determine if there is a relative variation in thrombotic events among stratified groups. Safety will be assessed by comparing frequency rates to determine if there is a relative variation in significant bleeding events among stratified groups. Patient charts will also be assessed for concomitant medications that have serious drug-drug interactions, as reported in the package inserts. The primary endpoint will be the comparison of thrombotic and significant bleeding events among body mass index, regardless of direct oral anticoagulation therapy. The secondary endpoint will be the comparison of thrombotic and significant bleeding events between each direct oral anticoagulant, regardless of body mass index.

**Session-Board Number:** 10-115  
**Poster Title:** Validation of the NOVA predictive measure and comparison of Enterococcal infective endocarditis patient outcomes  
**Primary Author:** Jennifer Sposito, Parkview Hospital, IN; **Email:** jennifer.sposito@parkview.com  
**Additional Author (s):**  
Trent Towne  
Kelli Salmon  

**Purpose:** Recent changes to the American Heart Association guidelines for the treatment of Enterococcal Infective Endocarditis (EIE) as well as new literature on scoring measures predicting the development of EIE following bacteremia merit further evaluation. Two primary objectives will be considered, 1) to further validate the predictive value of the NOVA score by determining if the score would have successfully predicted the likelihood of patients with Enterococcal bacteremia developing EIE, and 2) to determine if the shift in recommended antimicrobial therapy for patients treated for EIE has affected patient outcomes and the incidence of adverse effects.

**Methods:** This is a dual-aim, single-center, retrospective review of community hospital patient medical records from April 1, 2013 to June 30, 2016. To be included in the first objective of this study, subjects must be at least 18 years old and have at least 1 positive blood culture for Enterococcus during the study period. Patients will be evaluated on their proportion of positive blood cultures, origin of bacteremia, history of prior heart valve disease, and documented auscultation of a heart murmur to determine if a Transesophageal Echocardiograms (TEE) was warranted for further evaluation per NOVA criteria. Inclusion in the second objective of the study required subjects in objective one to also be diagnosed with possible or definite EIE per modified DUKE criteria and have been treated with either 1) beta-lactam plus gentamicin or 2) ceftriaxone plus ampicillin. Patients will be evaluated for clinical outcomes, frequency of adverse effects and monitoring, and length of stay.

**Results:** Pending study completion.

**Conclusion:** Pending study completion.

Poster Title: Reducing fluoroquinolone use through implementation of a urinary tract infection (UTI) treatment pathway and healthcare provider education

Primary Author: Erica Little, Riverview Health, IN; Email: elittle@riverview.org

Additional Author(s):
Brian Peters
Nikki Land
Tracey Ikerd

Purpose: Fluoroquinolones are associated with significant adverse effects, including tendonitis, tendon rupture, and Clostridium difficile infection, especially when used in older adults. Additionally, there is a trend of increasing resistance of Escherichia coli and other gram negative organisms to fluoroquinolones. The objective of this study is to decrease the inappropriate use of fluoroquinolones for treatment of urinary tract infections in patients admitted to or seen in the outpatient setting of this institution through implementation of a UTI treatment pathway and targeted provider education.

Methods: Provider education sessions focusing on UTI treatment and practicing fluoroquinolone avoidance will be completed. A new UTI treatment pathway will be created and added to the electronic medical record system. A query of the electronic medical record will be used to identify patients who have had a diagnosis associated with UTI who have also been prescribed ciprofloxacin, levofloxacin, or moxifloxacin, both before and after implementation of the intervention. Data collected will include age, gender, ethnicity, comorbidities, allergies to antibiotics, culture data, antibiotic prescribed, diagnosis, days of therapy, reported adverse events, and pharmacy interventions. The primary endpoint measured will be prescriptions or orders for fluoroquinolones per patient diagnosed with UTI before and after the intervention. Secondary endpoints include duration of antibiotic therapy compared to guideline recommendations, documentation of adverse events or Clostridium difficile infections in the electronic medical record, number of UTI treatment pathway overrides, and pharmacy interventions. This data will be analyzed to determine effectiveness of the UTI treatment pathway along with provider education in reducing fluoroquinolone use in this health system.
Results: Results are pending.

Conclusion: Conclusion is pending.

Poster Title: Improving adherence to a standardized sepsis treatment protocol in a community hospital

Primary Author: Amanda Hunnicutt, Riverview Health, IN; Email: ahunnicutt@riverview.org

Additional Author(s):
Jeffrey Perdiew
Nicole Land
Brian Peters
Madeline Larsen

Purpose: A diagnosis of sepsis is associated with increased healthcare costs, morbidity and mortality, and length of hospital stay. Ensuring compliance with established order sets following guidelines set forth by the Surviving Sepsis Campaign are critical to improved outcomes associated with sepsis. A standardized treatment protocol was established by our institution in order to improve adherence to directives from Centers of Medicare and Medicaid Services (CMS) National Core Measure for Sepsis. The objective of this study is to assess and identify opportunities to improve compliance with our institution’s standardized sepsis treatment protocol to reduce patient morbidity and mortality.

Methods: A pre-post study will be used to measure the impact of targeted interventions to improve adherence to the standardized sepsis treatment protocol and subsequent patient outcomes will be measured. Data collection will start 60 days pre-intervention and then continue for 60 days post-intervention. Data collected will include patient demographics, type and amount of resuscitative fluids used, sequence of antibiotic administration, vasopressor selection, Systemic Inflammatory Response Syndrome (SIRS) score, and origin of infection. Targeted interventions will take place in areas where sepsis is commonly identified and treatment protocol is initiated. Interventions will include education of relevant healthcare staff, implementation of a checklist to be utilized when a diagnosis of sepsis is made, provision of compounded norepinephrine solution, and numerical labeling of antibiotics prior to dispensing in the pharmacy. The primary endpoint is the measured difference in patients who receive appropriate therapy per standardized sepsis protocol pre vs post interventions. Secondary endpoints will include rates of morbidity, mortality, length of hospital stay, and fallout from
CMS Core Measures for sepsis. The chi-squared test will be employed to evaluate the primary endpoint. Descriptive statistics will be used to compare other data.

**Results:** Results are pending.

**Conclusion:** Conclusion is pending.

Poster Title: Assessment of pharmacist-managed ambulatory care asthma clinic

Primary Author: Diana Mechelay, Saint Joseph Regional Medical Center/Family Medicine Center, IN; Email: diana.mechelay@sjrmc.com

Additional Author(s):

Purpose: Asthma is a common chronic disease in the United States, affecting approximately seventeen million adults and six million children in 2014. Although the number of asthma-related deaths has decreased recently, significant morbidity due to asthma exacerbations still remains. Pharmacist involvement in the management of asthma has been shown to improve asthma outcomes and quality of life. This has been demonstrated in a variety of settings, however to a lesser extent in pharmacist-managed clinics. The purpose of this study is to assess the effectiveness of a pharmacist-managed asthma clinic in improving asthma outcomes in the ambulatory care setting.

Methods: This observational cohort study has received Institutional Review Board approval. The study seeks to assess the effectiveness of the asthma clinic by measuring the number of asthma-related hospitalizations and emergency department visits in the twelve months prior to and after the initial visit with the clinic in pediatric patients with asthma. Secondary outcomes include asthma control test (ACT) scores, asthma quality of life questionnaire (AQLQ) scores, missed days at work or school, recommendations made to the patient, asthma medications prescribed at each visit, and follow-up with visits with Saint Joseph Family Medicine Center (SJFMC) physicians. Patients eligible for enrollment include those less than or equal to eighteen years of age with asthma, who are referred to the clinic by a physician at the SJFMC. Pharmacist interventions include providing patients with self-management education, an action plan, and making pharmacotherapy recommendations to physicians as necessary. Data collection will include the previously mentioned outcomes and pertinent patient medical history via patient interview and chart search. All recorded data will be stored under lock and key and on a password protected secure computer for paper and electronic files, respectively. The primary and secondary endpoints will be evaluated using the paired t-test.

Poster Title: Analysis of several psychological factors among PGY2 pharmacy residency programs tracked throughout the year

Primary Author: Jason Isch, Saint Joseph's Regional Medical Center, Family Medicine Center, IN; Email: jason.isch@sjrmc.com

Additional Author(s):
Brock Davis
Rachel Feit

Purpose: The number of residents and residency programs have increased every year and the American Society of Hospital Pharmacists currently accredits over 2,000 unique residency programs. Post-graduate training can be a stressful and trying time for pharmacists within this new role. There are several studies available assessing stress and burn-out in medical residents, however few studies exist for pharmacy residents. The purpose is to identify potential factors contributing to stress tracked throughout the resident year and to discover how these pharmacists pursuing residency training handle these new challenges.

Methods: In order to evaluate the purpose, this IRB approved, prospective study encompasses surveys via Survey Monkey Pro that will be sent to all ASHP accredited second year post-graduate pharmacy programs to determine levels of stress, anxiety, and depression throughout the residency year. Pharmacy residents will be asked baseline questions about themselves along with a series of psychological questions asked within the Depression-Anxiety-Stress Survey (DASS-21). Initial survey results will be compiled throughout the first few weeks of October, and repeat surveys will be distributed at the end of every quarter until the end of the 2017 residency year. A final survey will be sent to reflect on levels of stress throughout the year and will be compared to quarterly data.

Poster Title: Venous thromboembolism prophylaxis in trauma patients

Primary Author: Sushma Shiravanthe, St. Vincent Anderson Regional Hospital, IN; Email: sushma.shiravanthe@stvincent.org

Additional Author (s):
Kristine Swank
Kristen McDaniel
Michelle Moore
Kathi Wasilewski

Purpose: Venous thromboembolic (VTE) events are common, preventable causes of mortality and morbidity in trauma patients. The American College of Chest Physicians recommends use of mechanical and/or chemical prophylaxis in trauma patients, dependent on VTE risk stratification. However, concerns over hemorrhagic complications often dissuade providers. A survey of St. Vincent Anderson Regional Hospital by the American College of Surgeons reported patients were not consistently receiving chemical VTE prophylaxis. In response, physician education regarding VTE prophylaxis recommendations in trauma patients was provided. This study aims to measure the impact of physician education on the use of chemical VTE prophylaxis in trauma patients.

Methods: This study is approved by the Institutional Review Board. All patients admitted with a trauma diagnosis between March 1, 2016 and January 31, 2017 will be reviewed for inclusion. The following data will be collected from the electronic medical record: baseline patient demographics, injury severity score (ISS), Glasgow coma scale (GCS) score, VTE risk factors, length of stay, trauma type, chemical and/or mechanical VTE prophylaxis agent and length of therapy, time to initiation of chemical and/or mechanical prophylaxis, and incidence of VTE, myocardial infarction (MI), stroke, major bleed or death from stroke or MI at 14 days or the incidence of readmission for VTE, MI, stroke or major bleed within 14 days of the initial trauma. All data will be recorded and maintained confidentially. The primary objective is to report and compare rates of chemical VTE prophylaxis utilization prior to and after the physician education intervention. The secondary objective is to report and compare rates of VTE, stroke, MI, and death from stroke or MI. For the safety endpoint, rates of major bleed will be compared.
Unpaired t-test, Mann-Whitney U test, chi-square test, and logistic regression analysis will be utilized depending on the level of analysis and variables. P-values ≤0.050 will be considered significant.

**Poster Title:** Evaluating naloxone administrations retrospectively to improve opioid prescribing patterns and patient safety in a community hospital setting.

**Primary Author:** Kashyap Padmaraju, Union Hospital, IN; **Email:** kpadmaraju@uhg.org

**Additional Author(s):**
Marcia Hunt-Curran

**Purpose:** Overdose by opioids is a preventable and potentially lethal condition which can arise from prescribing practices, inadequate patient understanding, medication misuse, and errors in drug administration. Our purpose is to evaluate naloxone as a trigger tool to identify areas for improvement in our institutions opioid prescribing. After reviewing our naloxone use we plan to implement changes to our opioid prescribing patterns.

**Methods:** We conducted a retrospective medication use evaluation of all naloxone administrations within a three month period, May – July 2016. A query was conducted and resulted in 86 administrations of naloxone. Thorough manual chart review was done to evaluate each administration for appropriateness and documented key clinical factors that led to each administration. All administrations were categorized based on specific factors to help identify prescribing practices including but not limited to the unit which naloxone was most used, opioids given in the past 24 hours, and disease states of patients at highest risk. Patients that were excluded include emergency room patients and naloxone used for itching. We also evaluated the severity (example; death, ICU transfer, intubation) of any adverse event that occurred to gather data to aid in implementation of policies and procedures that benefit patient safety.

Poster Title: Implementation of transitional care pharmacist model and the effects on readmission rates of high risk patients

Primary Author: Stephanie Matta, Union Hospital, Inc., IN; Email: smatta@uhh.org

Additional Author(s):
Megan Lotz
Haley Britton
Jenny Wulf

Purpose: Hospital readmission rates are a major indicator of inpatient quality of care. Centers for Medicare and Medicaid Services (CMS) have developed financial incentives for healthcare systems in an effort to decrease readmissions. This stemmed from the Medicare Payment Advisory Commission estimation that readmissions resulted in a $15 billion increase in annual expenditures. The LACE score is used to identify patients’ risk for readmission; a score of 10 or greater indicates high risk. The purpose of this study is to evaluate the effectiveness of interventions made by transition of care pharmacists upon discharge of patients identified as high risk for readmission.

Methods: Two transition of care pharmacist positions were occupied effective September 2016 in this three hundred forty-five bed community teaching hospital. Transition of care pharmacists will work closely with case managers and discharge planners to determine the patients that will most benefit from pharmacist interventions. Also, a daily report of patients with a LACE score of 10 or greater will be generated to help prioritize workflow. Pharmacists will attempt to perform medication reconciliation and profile review, provide patient education, and assist with medication accessibility to the identified patients. The primary outcome will be the 30 day all cause readmission rate. This data will be compared to the previous year in all cause 30 day readmission rate based on the pharmacists’ interventions for each patient. Transition of care pharmacists will communicate their follow up and interventions to inpatient clinical pharmacists through the hospital-based clinical pharmacy support system. The pharmacy team will work together to optimize each patient’s discharge therapy, improve the patient’s and caregiver’s understanding of medications and corresponding disease states, and ensure adequate continuity of care. They will also communicate to the patient's outpatient
providers through a note in the discharge plan. Medication accessibility will be facilitated through the hospital’s outpatient pharmacy and 340B pricing system. This project has been approved by the Hospital Readmissions Team.

**Poster Title:** Comparison of medication histories completed by a pharmacist versus emergency department personnel

**Primary Author:** Shannon Sullivan, Lawrence Memorial Hospital, KS; **Email:** ssullivan88@gmail.com

**Additional Author (s):**
Christina Graham
Pat Parker

**Purpose:** Obtaining an accurate medication history for patients admitted to the hospital is a very important component of patient safety. In many hospital settings, these medications histories are obtained by emergency department providers not by a pharmacist. A multitude of studies confirm medication histories completed by non-pharmacy personnel are incomplete and contain errors potentially compromising medication safety. Conversely, literature suggests pharmacists provide a more complete medication history with less errors. The purpose of this study is to compare medication histories obtained by ED providers versus pharmacists and to identify the type of interventions made on medication histories by pharmacists.

**Methods:** This will be a two month, retrospective study comparing medication histories for all admitted patients obtained by ED providers versus those obtained by a pharmacist. Currently, an ED physician or nurse obtains a medication history from the patient or patient representative. Once the patient is admitted to the floor, a pharmacist or pharmacy intern also obtains a medication history. Following each medication history, the pharmacist completes an electronic form in the patient’s medical record to detail the interventions made. These interventions are classified as follows: add/delete a medication, wrong frequency, wrong dose, allergy added, and allergy clarified. Patient charts will be reviewed to identify the type of interventions made by pharmacists with an emphasis on high risk and narrow therapeutic index medications. Patients who were not admitted to the hospital through the emergency department, pediatric patients and patients admitted to the mother baby unit will be excluded from this study. This study will be submitted to the Institutional Review Board for Approval. Patient identifiers will be removed and all information will be maintained in a confidential manner.

Poster Title: Assessment of fluoroquinolone use for uncomplicated urinary tract infections in a 173 bed community hospital emergency department

Primary Author: Lauren Aversman, Lawrence Memorial Hospital, KS; Email: lauren.aversman@lmh.org

Additional Author(s):
Jeff Pierce
Mackenzie Magid

Purpose: The U.S. Food and Drug Administration recently completed a safety review on fluoroquinolone antibiotics, resulting in an updated Black Boxed Warning and safety labeling changes. These safety changes advise health care providers to limit the use of fluoroquinolones for patients with serious bacterial infections; therefore, their use should be avoided in patients with acute bacterial sinusitis, acute exacerbation of chronic bronchitis and uncomplicated urinary tract infections (UTI), unless no alternative treatment options remain. The primary objective is to assess fluoroquinolone use for the treatment of uncomplicated UTIs. The secondary objective is to assess the overall antibiotic selection for uncomplicated UTIs.

Methods: This quality improvement project will be a retrospective chart review of patient visits in the Emergency Department for an uncomplicated UTI from May through July 2016. Patient charts will be identified from the electronic medical record based on the ICD-10 diagnosis code of N39*. The following data points will be abstracted from the electronic medical record database: patient age, gender, pertinent drug allergies, antibiotic received, duration of therapy, prescribing physician, and assessment of risk factors for uncomplicated versus complicated UTI. The Infectious Disease Society of America (IDSA) defines an uncomplicated UTI as cystitis occurring in healthy, non-pregnant, non-menopausal women who are absent of fever, flank pain, or other suspicion for pyelonephritis. Patients less than or equal to 18 years of age or those identified to have a complicated UTI (i.e. pregnancy, men, indwelling catheters, etc.) will be excluded. Data will be collected and recorded using a standardized chart review process. All patient identifiers will be removed and data will be maintained in a confidential manner. This study will be submitted to the Institutional Review Board for approval.

**Poster Title:** Evaluation of pharmacists' clinical interventions at a community hospital

**Primary Author:** Patricia Hoover, Olathe Medical Center, KS; Email: patricia.hoover@olathehealth.org

**Additional Author(s):**
Amber Lucas

**Purpose:** Health care payments are increasingly tied to quality and value-based care. The pay-for-performance model requires measurable health quality and outcomes. Pharmacists provide clinical services and medication interventions on a daily basis through approved protocols, medical staff consults, and pharmacist-identified medication-related issues. Some examples of interventions include: pharmacovigilance in medication safety, therapy optimization, pharmacokinetic consultations, formulary management, treatment monitoring, and patient counseling. The objective of this study is to quantify clinical interventions performed by pharmacists and assess their potential impact on patient care in a community hospital.

**Methods:** Pharmacists at a community hospital will document their clinical interventions in the electronic medical record system through their normal course of daily activity. The following data will be documented: types of intervention, initiator of the clinical intervention, associated medication order(s), the prescriber, prescriber's response, clinical significance of the intervention, patient outcome, pharmacist intervention time, and any additional information provided by the pharmacists. For the purpose of this study, the Cerner Discern Analytics® reporting system will identify all pharmacist clinical interventions documented between October 2016 and February 2017. In addition, the study investigators will collect the patient census each month. The study investigators can further calculate provider acceptance rate of recommendations, pharmacist time per intervention, and number of pharmacist-led intervention(s) per patient. Based on results of other similar studies, the investigators can then quantify cost-savings and cost-avoidance of pharmacist interventions. All data will be recorded without patient identifiers and maintained confidentially.

Poster Title: Evaluating compliance to a hypoglycemic protocol in a community hospital

Primary Author: Carleigh Cozad, Salina Regional Health Center, KS; Email: ccozad@srhc.com

Additional Author(s):
Linda Radke

Purpose: Hypoglycemia is an avoidable complication that occurs in approximately 7 to 10 percent of hospitalized patients and is associated with increased mortality. The American Diabetes Association recommends a hypoglycemia management protocol be implemented by each hospital system. The protocol should provide information on treatment for patients showing signs and symptoms of hypoglycemia. This project was designed to find areas where compliance to our protocol can be improved in order to ensure patient safety.

Methods: Prior to commencement, this study will be submitted to the Institutional Review Committee for approval. The electronic medical record system was used to identify patients with blood glucose readings less than 50 mg/dL between January 2016 and June 2016. Treatment for hypoglycemic episodes will be evaluated for appropriateness according to the guidelines that are provided in the current hypoglycemic protocol. The following data will be collected: time and date of protocol initiation, time and date of hypoglycemic event, 15 minute blood glucose recheck reading, and type of treatment given. All data will be maintained confidentially and no patient identifiers will be retained.

**Poster Title:** Assessment of clinical benefit of empiric double coverage for Pseudomonas infections

**Primary Author:** Zahra Nasrazadani, Salina Regional Health Center, KS; **Email:** znasrazada@srhc.com

**Additional Author(s):**
Steven Blanner

**Purpose:** As antibiotic resistance increases and antimicrobial stewardship efforts intensify, clinicians must reevaluate routine practices to ensure optimal therapeutic approaches, particularly with regard to empiric antimicrobial treatment strategies. The objective of this study is to assess the probability of clinical benefit when greater than one antimicrobial agent is utilized for empiric treatment of presumed Pseudomonas aeruginosa infections, a technique colloquially known as “double coverage.” Due to the disproportionately high rate of patient mortality and antibiotic resistance associated with this organism, developing effective Pseudomonas treatment strategies is critical to stewardship efforts.

**Methods:** This study has been submitted to the Institutional Review Board for approval. The electronic medical record will be utilized to isolate the records of inpatient stays for which Pseudomonas aeruginosa was identified as a causative organism upon microbiological culture. The following data will be collected: length of stay, indication for antimicrobial use (and intubation or catheterization status, when the associated indication is a respiratory or urinary tract infection, respectively), empiric antimicrobial regimen and treatment regimen, treatment day on which susceptibility data was finalized, antimicrobial resistance, adverse drug reactions related to the antimicrobial therapy, selected comorbidities, steroid use, whether the patient was admitted to the critical care unit, and the patient outcome (discharge versus expiration). The patient record will be utilized to assess the sequence of events during the course of treatment and to determine the utility of the double coverage strategy. Based on antimicrobial resistance and other patient-specific risk factors, data will be evaluated to ascertain the probability of clinical benefit versus risk of unnecessary treatment and adverse events. Data will also be analyzed to identify any critical patient population whose high risk stratification warrants the more aggressive double coverage approach. Finally, overall frequency of empiric
double coverage will be compared to total confirmed Pseudomonas for the same time period to determine likelihood of P. aeruginosa as the causative organism when it is suspected.

Poster Title: Reducing utilization of fluoroquinolones through the implementation of a targeted antimicrobial stewardship protocol in a community hospital

Primary Author: Ryan Fleer, Shawnee Mission Medical Center, KS; Email: ryan.fleer@ucdenver.edu

Additional Author (s):
Heidi Calvin
Rudd Hetrick
Glenn Mackay

Purpose: Fluoroquinolones are among the most popular antibiotics used by prescribers in the United States. Their broad spectrum of bactericidal activity makes them highly effective against a variety of gram positive and negative organisms. While highly effective, fluoroquinolones are not without consequences; a recent FDA safety communication broadened the boxed warning, advising providers to reserve fluoroquinolones for more serious infections due to potentially permanent adverse effects associated with the antibiotic class. Similarly, concerns have arisen due to increased resistance of Escherichia coli and Pseudomonas aeruginosa. Prior studies have observed increased susceptibility to fluoroquinolones following implementation of antimicrobial restriction programs.

Methods: This is an ongoing retrospective cohort study conducted at a community hospital in Shawnee Mission, KS. The study will be submitted to the hospital Institutional Review Board for approval. An antimicrobial stewardship protocol designed to limit empiric fluoroquinolone therapy will be implemented in October 2016. This protocol will be developed based upon both IDSA guidelines and input from the clinical infectious diseases pharmacist and physicians; it will function as a guideline for appropriate fluoroquinolone alternatives. Following development, this protocol will be distributed hospital-wide, and utilization will be encouraged via provider education sessions performed by the PGY-1 resident. Treatment groups will include 100 patients randomly selected before and after protocol implementation (November 2015 to March 2016 and November 2016 to March 2017, respectively) using an AB number generator. Patients will be included if they received any antibiotic as empiric therapy, defined as initial treatment for any infection prior to availability of antimicrobial sensitivities. Primary outcomes
will include the number of inpatient days of fluoroquinolone therapy/1000 patient days, in addition to the number of Emergency Room (ER) prescriptions/1000 ER visits. Secondary outcomes include appropriateness of antibiotic selection, as determined by IDSA guidelines, and hospital seven-day readmission rates. Chi-square tests will be used for nominal data, and a t-test or Mann Whitney-U test will be used for continuous data as appropriate.

Poster Title: Antenatal opiate exposure and effects on neonatal outcomes: Observations at a community birth center
Primary Author: Brianne Sutherland, Shawnee Mission Medical Center, KS; Email: brianne.sutherland@shawneemission.org
Additional Author (s):
Alexandra Oschman
Betsy Knappen
Jodi Jackson
Nicole Winistoerfer

Purpose: Neonatal abstinence syndrome (NAS) is a withdrawal syndrome that occurs at birth following prenatal exposure to opioids. Maternal antepartum use of opioids has increased dramatically in the United States over the last decade, with the incidence of NAS demonstrating corresponding growth. While the factors contributing to the severity of NAS remain largely undefined, potential variables may include specific type of opiate exposure, extent of exposure, and concomitant use of other substances. This study was designed to evaluate whether associations exist between severity of neonatal abstinence syndrome and specific characteristics of antenatal opiate exposure.

Methods: This study is a retrospective cohort analysis of infants born at Shawnee Mission Medical Center between September 1, 2014 and August 31, 2016, who were identified as at risk for NAS due to prenatal opioid exposure. The study will undergo submission to the Internal Review Board for approval. The inclusion criteria are as follows: documentation of chronic opioid use during pregnancy from maternal disclosure or positive maternal/infant drug screen, and infant scored for NAS utilizing the modified Finnegan score. Exclusion criteria will include earlier than 32 weeks gestation or NAS secondary to prenatal exposure to substance(s) other than opiates. Characteristics of antenatal opiate exposure will be defined by opioid type (short-acting, long-acting, maintenance/opioid replacement therapy, polysubstance) and extent of exposure. The primary endpoint will be severity of NAS, defined by neonate requiring pharmacologic treatment with morphine. Secondary endpoints will include infant length of stay and admission to the neonatal intensive care unit (NICU). We will attempt to control for...
confounding by analyzing variables that may influence outcomes, such as concomitant exposure to nonopiates, provision of comfort cares, breastfeeding, and maternal demographics. The results of this study will serve to enhance existing knowledge related to the management of neonatal abstinence syndrome.

Poster Title: Evaluation of pharmacy services and multimodal pain management in patients undergoing colorectal surgery in an enhanced recovery program

Primary Author: Matthew Gutzmer, Stormont Vail Health, KS; Email: mgutzmer@stormontvail.org

Additional Author(s):
Nicholas Gallinger
Katie Burenheide

Purpose: Enhanced recovery programs (ERP) implement various strategies with the primary goal of reducing time to recovery after major surgical procedures. Pharmacists are involved with multiple interventions throughout the ERP process, including: conducting medication reviews, assessing bowel regimens, recommending antibiotics, and optimizing pain management. The objective of the current study is to assess the pharmacy services utilized and the impact of multimodal analgesia on patients undergoing colorectal surgery in an ERP versus standard protocol.

Methods: This project will be submitted to the Stormont Vail Institutional Review Board for approval. Information will be collected from the electronic medical record in a retrospective chart review for the time period of January 1 to September 30, 2016. The study will utilize a comparison design between two cohorts: patients that underwent a colorectal surgery under ERP protocols and patients that were eligible for ERP but underwent surgery though a traditional protocol. Pharmacy services will be assessed in both groups by evaluation of intervention notes and other medical record documentation. Data will be collected from the date of surgery through admission for each patient and include: length of stay (LOS), age, gender, type of surgery (laparoscopic vs. open), and opioid medications used after surgery. All opioid medications used will be converted using standard calculations to oral morphine equivalents (OME) for comparison. Patients that did not undergo all aspects of the ERP protocol will be excluded in the final analysis.

Poster Title: Antimicrobial stewardship in critically ill patients diagnosed with pneumonia: A retrospective evaluation of an integrated health care system’s current practice.

Primary Author: Jennifer Doughty, Stormont Vail Health, KS; Email: jedought@stormontvail.org

Additional Author (s):
Christy Rooks
Laura Carson
Katie Burenheide

Purpose: A joint statement issued in 2012 from the Society for Healthcare Epidemiology of America, the Infectious Diseases Society of America, and the Pediatric Infectious Diseases Society recommended mandatory antimicrobial stewardship programs through a regulatory mechanism. As a result, the Centers for Medicare and Medicaid Services proposed a new rule in June 2016 requiring all hospitals to have an antimicrobial stewardship program to receive federal and state funding. Some of the primary goals of an antimicrobial stewardship program is to ensure appropriate empiric drug therapy, de-escalation of therapy with culture-directed results, and appropriate duration of therapy based on current guidelines.

Methods: To evaluate the adherence to current guidelines, a retrospective data review looked at patients who were admitted to the intensive care units at an integrated health care system with a diagnosis of pneumonia. The study period was from January 1, 2016 through February 29, 2016. Inclusion criteria included age greater than or equal to 18 years of age, admission to the intensive care unit, and an international classification of diseases, tenth revision, (ICD-10) diagnosis code for bacterial pneumonia. Exclusion criteria included pneumonia due to viral, fungal, or undetermined causes. Once the subjects were identified, a review of their electronic medical record was conducted to identify: date, time, and agent of empiric therapy, when cultures resulted and which organism was identified, when de-escalation of therapy happened, and when discontinuation of therapy occurred. Each case was then further categorized into community-acquired pneumonia (CAP), healthcare-associated pneumonia (HCAP), hospital-acquired pneumonia (HAP) or ventilator-associated pneumonia (VAP). The data for each category was pooled to determine mean length of empiric therapy, length of culture-directed therapy, and duration of therapy. This data was compared to the current guidelines available at

**Poster Title:** Impact of prolonged intravenous fluids administration on critically ill patients’ outcome

**Primary Author:** Talal Nassar, Stormont Vail HealthCare, KS; **Email:** tnassar@stormontvail.org

**Additional Author(s):**
Katherine Burenheide
Kevin Waite

**Purpose:** Fluid resuscitation therapy (FRT) is designed to optimize stroke volume to maximize perfusion and reduce organ failure. There are no guidelines that define optimal length of therapy or parameters to guide discontinuation of fluid resuscitation therapy. Studies have shown prolonged fluid administration results in increased mortality and morbidity in critically ill patients. This study includes examining the prescribing pattern of maintenance intravenous fluid therapy in our hospital in different adult ICUs and post ICU discharge, evaluating intravenous fluid volumes administered and effects of intravenous fluid maintenance therapy on total fluid balance, and inpatient morbidity and mortality throughout hospital stay.

**Methods:** This is a retrospective study that reviews patients admitted to any adult critical care unit (ICU) that fit the inclusion/exclusion criteria from Sep 1st 2015 through Dec 31st 2015. Patients will be followed during their ICU admission and after transfer from the ICU to any floor up to 7 days or discharge from the hospital whichever comes first. Investigational Review Board has approved this study.
Data collection includes age, gender, actual body weight, ideal body weight, reason of admission, SOFA score, lactate, bicarbonate and chloride levels, serum creatinine, mean arterial pressure, past medical history and chronic use of diuretics.
The primary end points will include prescribing patterns of intravenous fluid therapy and the relationship between both bolus therapy and the maintenance fluid therapy with fluid weight ratio. The secondary end points will include correlation between daily and cumulative fluid balance and mortality and morbidity. All data will be recorded without any patient identification and maintained confidentially. We will assume after applying the inclusion/exclusion criteria that the number of subjects will provide us with a power of 80%
with an alpha error of 0.05. We will assume that positive balance > 8% will increase mortality by 20%.

**Poster Title:** Effect of pharmacist directed education for health care workers on pneumococcal vaccination rates in outpatient clinics

**Primary Author:** Stacy Reid, Via Christi Hospitals Wichita, Inc, KS; **Email:** stacy.reid@viachristi.org

**Additional Author(s):**
Meghan Haftman
Lyndsey Hogg

**Purpose:** Patient and provider barriers to vaccination, including lack of education, have been reflected in pneumococcal vaccination rates in elderly patients which remain low and unchanged. The aim of this study is to determine if education provided by pharmacists to health care workers in primary care clinics will increase pneumococcal vaccination rates.

**Methods:** This study has received Institutional Review Board approval. The retrospective chart review will be conducted utilizing electronic medical records of patients who visited a primary care provider. The primary objective is to determine the difference in pneumococcal vaccination rates between 2015 and 2016 among primary care clinics. Between September and October 2016, pneumococcal vaccination education occurred for six clinics which have an embedded pharmacist. Seven clinics without an embedded pharmacist did not receive education and therefore serve as the comparator group. The 2015 and 2016 vaccination rates are determined from data from October through December of 2015 and 2016, respectively. Data will be collected to identify patients 65 years and older and who had a visit to their primary care provider between October 1, 2015 – December 31, 2015 and October 1, 2016 – December 31, 2016. Data collected will include date of birth, type of pneumococcal vaccines received (PCV13, PPSV23), date pneumococcal vaccines received and date of most recent visit to primary care clinic in 2015 and 2016. The secondary objectives include the change in rate of patients with both recommended vaccines documented, percentage of patients with vaccines documented in a CDC recommended order and percentage of unnecessary vaccination.

**Results:** N/A
Conclusion: N/A
Purpose: Increased time in therapeutic range (TTR) is associated with better outcomes for patients receiving warfarin therapy. A previous study published in Circulation in 2008 concluded that 58% is the minimum TTR threshold for benefit with warfarin therapy compared to antiplatelet therapy. The purpose of this study is to determine the effectiveness of warfarin therapy management performed by a new outpatient anticoagulation service, staffed by pharmacists and registered nurses.

Methods: This study has received Institutional Review Board approval. The retrospective chart review will be conducted utilizing an electronic medical record system to identify patients who were managed by the anticoagulation service during a period of five months. Patient data that will be collected includes dates of patient encounters, age, race, gender, primary indication for anticoagulation, international normalized ratio (INR) goal ranges, INR values, INR dates, hemoglobin levels, and reported adverse events. This data will be used to include patients over the age of 18 with an INR goal range of 2-3 or 2.5-3.5. The primary objective is to determine if mean TTR for each INR goal range is greater than the 58% TTR threshold for warfarin efficacy. The TTR for each patient will be calculated using the Rosendaal method, using linear interpolation for INRs between patient encounters. The secondary objective is to assess the effectiveness of the warfarin maintenance adjustment protocol used by the anticoagulation service. This includes analyzing the percentage of protocol-adherent warfarin dose adjustments that result in the next INR being within goal range, the mean number of consecutive protocol-based warfarin dose adjustments made to achieve INR within goal range, and the incidence of reported adverse events.

**Poster Title:** Use of rapid diagnostics to improve time to appropriate antibiotic therapy for Staphylococcus aureus bacteremia

**Primary Author:** Kathryn Smith, Via Christi Hospitals, Inc, KS; **Email:** kathryn.smith@viachristi.org

**Additional Author (s):**
Patrick Evans  
Rebecca Nolen  
Todd Schroeder

**Purpose:** Staphylococcus aureus bacteremia (SAB) is associated with longer hospital stays, increased costs, and mortality. Vancomycin is the antibiotic of choice for methicillin-resistant Staphylococcus aureus (MRSA) bacteremia. However, compared to beta-lactams, vancomycin is associated with an increase risk of mortality in methicillin-susceptible Staphylococcus aureus (MSSA) bacteremia. A real-time polymerase chain reaction assay detects and differentiates between MRSA and MSSA in the blood stream in approximately two hours, allowing the opportunity for appropriate therapy to be initiated more quickly. The purpose of this study is to evaluate the impact of rapid diagnostics on time to appropriate therapy for SAB.

**Methods:** This retrospective, comparative study has received Institutional Review Board approval. Electronic medical record reports will be utilized to identify patients over the age of 18 years who were diagnosed with SAB both before and after the polymerase chain reaction assay (PCR) testing was implemented. GeneXpert, the PCR assay utilized in this study, was incorporated by our institution in January of 2014. The pre-intervention group will consist of patients diagnosed with SAB prior to availability of the PCR assay. The post-intervention group will consist of patients with SAB following implementation of the PCR assay. The following patient specific data will be collected: age, gender, allergies, date of admission, date of discharge, antibiotic days, hours to appropriate therapy, and condition at discharge. For the primary outcome, this data will be utilized to determine if the use of a real-time PCR assay decreases time to appropriate therapy by at least 24 hours. Secondary outcomes will be compared between the groups and will include hospital length of stay (LOS), intensive care unit (ICU) LOS, time to appropriate antibiotic therapy in patients with MSSA bacteremia,
vancomycin utilization, duration of therapy targeted at gram-positive organisms, and in-house mortality.

Poster Title: Failure rates of parenteral versus direct-oral anticoagulants in patients with malignancies

Primary Author: Samantha Maples, Via Christi Hospitals, Inc., KS; Email: samantha.maples@viachristi.org

Additional Author (s):
Jatandra Owens Birney

Purpose: It has been established that the presence of a malignancy equates with a significantly higher risk of developing venous thromboembolism (VTE). Although there is a large amount of evidence on warfarin and parenteral therapies for anticoagulation in the cancer population, there is little evidence on the use of direct-oral anticoagulants (DOACs) for preventing VTE, specifically compared to parenteral agents. The objective of this study is to evaluate whether DOACs had a similar efficacy and safety profile when compared to parenteral anticoagulants at preventing VTE in patients with malignancies.

Methods: An electronic medical record system will be queried to identify patients who were admitted to Via Christi Hospitals Wichita, Inc. from October 1st, 2014 to September 30th, 2016 with a home medication of either a parenteral (low-molecular-weight heparin or fondaparinux) or direct-oral anticoagulant (dabigatran, rivaroxaban, apixaban, or edoxaban) and also had an active cancer diagnosis. Patients will be identified who failed their initial anticoagulant as defined by one of the following: acute VTE diagnosis or those discharged on a different anticoagulant than they were admitted on. Patient-specific data that will be collected includes, but is not limited to: demographic information, hemodialysis or peritoneal dialysis orders, home and discharge medications, serum creatinine, platelets, hemoglobin, comorbid conditions, VTE and cancer diagnoses, and inpatient-mortality rate. The primary endpoint for this retrospective review is failure rate of anticoagulation treatment for the prevention of VTE for both the DOAC and parenteral anticoagulant groups. The secondary efficacy endpoint includes failure rates for hematologic versus solid tumor malignancies. Additionally, secondary safety endpoints include the occurrence of major bleeds and all-cause inpatient deaths in each treatment group. This retrospective study is approved by the Institutional Review Board.

Poster Title: Analysis of tranexamic acid use in massive blood loss for gastrointestinal bleeding and postpartum hemorrhage with a focus on 24 hour mortality

Primary Author: Michael Reichert, Wesley Medical Center, KS; Email: mreichert42@gmail.com

Additional Author (s):
Katherine Hall

Purpose: The purpose of this study is to assess if there is a difference in 24 hour mortality in patients receiving tranexamic acid (TXA) during a massive blood transfusion (MBT) due to postpartum hemorrhage (PPH) or gastrointestinal bleeding (GIB) as compared to those that did not receive tranexamic acid.

Methods: The study protocol for this non-interventional, single center, retrospective, chart review is under review by the Wichita Medical Research and Education Foundation Institutional Review Board. Patients who are greater than 18 years of age diagnosed with GIB or PPH who received MBT and were included in the massive blood transfusion data set up to August 2016 will be included. Patients will be excluded if trauma was the cause of massive blood loss or if the patient received aminocaproic acid. Data collection will include age, gender, cause of massive blood loss, anticoagulant usage, TXA administration, total amount of blood products received, mortality at 24 hours, survival to discharge, prothrombin complex concentrate (PCC) administration, surgical intervention to control bleeding and TXA administration prior to activation of MBT. The primary outcome of this study is to compare the mortality at 24 hours in patients that received TXA as part of the MBT pathway versus those that did not receive TXA. Secondary outcomes include comparison of the use of PCC, patient survival to discharge, amount of blood products administered and surgical intervention in patients that received TXA as part of the MBT pathway versus those that did not receive TXA. Patient demographics will be assessed using descriptive statistics. Nominal data will be compared using Fisher’s exact or Chi squared. Continuous data will be compared using student’s T test.

**Additional Author(s):**  
Fogg Sarah  
Frasier Lauren  

**Purpose:** Wesley Medical Center (WMC) is a 760 bed tertiary care facility with a clinical pharmacy staff of 15 satellite pharmacists daily. Pharmacists currently write electronic medication management notes, which are available for providers to view and implement recommendations for improved patient care as necessary. The aim of this project is to assess if providers are reading the medication management notes written by pharmacists at WMC. Other outcomes include assessing the providers’ viewpoints on the utility of pharmacist progress notes, determining if providers are implementing recommendations from these notes and evaluating the best forms of provider-pharmacist communication.  

**Methods:** This quality improvement project will include all physicians and mid-level practitioners that practice at WMC. Pediatric, neonatology, and obstetrics-gynecology (OB-GYN) providers will be excluded. This project will be survey based and will occur between October and December 2016. The survey will be distributed at executive meetings as well as electronically via the WMC physician relations department. Survey results will be analyzed and descriptive statistics will be utilized to present survey results.

Poster Title: Potential risk factors associated with repeated systemic corticosteroids after a single dose of dexamethasone during acute asthma exacerbations

Primary Author: Coty Tunwar, Wesley Medical Center, KS; Email: coty.tunwar@wesleymc.com

Additional Author (s):
Lela Hernandez

Purpose: Asthma is a major cause of morbidity and mortality in pediatric patients. Corticosteroids, along with bronchodilators, are the mainstay of therapy in acute asthma exacerbations. Studies have shown that a single dose of dexamethasone is non-inferior to prednisone and offers several advantages like a shorter course of therapy and fewer side effects. However, patients occasionally need additional doses of systemic corticosteroids after a single dose of dexamethasone. The purpose of this study is to evaluate risk factors that may increase the need for additional systemic corticosteroids after a single dose of dexamethasone during acute asthma exacerbations.

Methods: The study is a single center, retrospective chart review of approximately 60 patients that received a onetime dose of dexamethasone for acute asthma exacerbation between January 2015 and September 2016. Patients will be included if they were less than 18 years of age, admitted for an acute asthma exacerbation, and received a single dose of dexamethasone. Patients will be excluded if they had any chronic pulmonary disease (i.e. cystic fibrosis, bronchopulmonary dysplasia), or systemic corticosteroid use within two weeks prior to admission. The primary outcome is to identify risk factors that may lead to additional doses of systemic corticosteroids. Secondary outcomes include length of stay and adverse effects observed from the additional doses. Data collection will include age, gender, asthma severity score on admission, asthma severity classification, tobacco smoke exposure, history of seasonal allergies, history of premature birth (less than 34 weeks gestations), and hospitalizations within the last year. In addition, corticosteroid therapy (total doses, strength), length of stay and adverse effects will also be examined. Data collection will commence once Institutional Review Board approval is obtained.

Poster Title: Estimated aluminum exposure through parenteral nutrition in neonatal morbidities.

Primary Author: Megan Fortenberry, Wesley Medical Center, KS; Email: meganwfortenberry@gmail.com

Additional Author (s):
Lela Hernandez
Jacob Morton

Purpose: The purpose of this study is to determine if estimated aluminum exposure as part of parenteral nutrition is increased in neonates with poor outcomes, including necrotizing enterocolitis, rickets/osteopenia, and/or seizures.

Methods: This is a single center, retrospective case-control study of approximately 180-225 neonatal intensive care unit patients, including both cases and controls. Patient selection will occur between January 1, 2015 and June 30, 2016. Patients will be included as cases if they have a diagnosis of necrotizing enterocolitis, rickets/osteopenia, or seizures and have received at least 14 days of parenteral nutrition. Patients will be excluded if they are diagnosed prior to parenteral nutrition exposure, received less than 14 days of parenteral nutrition, or were small for gestational age. Patients who meet the inclusion criteria will be matched 1:2 by gestational age and birth weight to control patients without listed diagnoses for comparison. Controls will be selected using a random sequence generator. Mean total aluminum exposure for the first 14 days of parenteral nutrition will be calculated using manufacturer label information. Differences in mean aluminum exposure between cases and controls will be analyzed using a Student’s t-test. Subgroup analysis in those with renal impairment or cholestasis will also be conducted using Student’s t-test. If a significant difference is found between cases and controls, a classification and regression tree (CART) analysis will be conducted to determine the doses (mcg/kg/day) to which more cases were exposed.

Poster Title: Levetiracetam versus lorazepam as abortive therapy in breakthrough seizures in pediatric patients

Primary Author: Jordan Snyder, Wesley Medical Center, KS; Email: jordan.snyder@wesleymc.com

Additional Author (s):
Lela Hernandez

Purpose: Two-thirds of patients will become seizure-free following the first or second antiepileptic drug regimen. The remaining patients may experience continuous seizures despite adequate treatment with antiepileptic medications, termed breakthrough seizures. Benzodiazepines are first line therapy for the acute management of seizures, although no comparison studies have been conducted evaluating breakthrough seizure management, only status epilepticus. The objective of this study is to determine if a difference in ability to terminate breakthrough seizures exists between levetiracetam and lorazepam in pediatric patients.

Methods: A retrospective, single site, chart review comparing efficacy of levetiracetam to lorazepam therapy for breakthrough seizures will be conducted. Breakthrough seizures will be defined as a patient experiencing seizures following a seizure-free period in which the patient did not need maintenance therapy or was adequately controlled on therapy. All patients aged 18 years and younger identified with breakthrough seizures, as listed in the electronic medical record, receiving either lorazepam or levetiracetam intravenously as needed will be included; only those who did not receive a dose of the study drug(s) will be excluded. The following will be collected from the electronic medical record: age, name of home antiepileptic medication(s), name, strength, number of doses of study drug(s) received, response to study drug(s), additional antiepileptic medication given, adverse effects following administration of study drug(s), and medication(s) that the patients received which may lower seizure threshold. Data collection will begin pending IRB approval. Chi-squared tests will be utilized to compare response rates to study drugs, rate of adverse events, and need for additional antiepileptic medications.

**Poster Title:** Comparison of Sepsis-3 criteria versus SIRS criteria in screening patients with sepsis in the emergency department

**Primary Author:** Brian Gilbert, Wesley Medical Center, KS; Email: brian.gilbert.pharmd@gmail.com

**Additional Author (s):**
Amber Meister
Lanae Faires
Suzanne Fletcher

**Purpose:** Systemic Inflammatory Response Syndrome (SIRS) symptoms and suspected infection is how we have identified sepsis since 1991. Previous literature has shown that with this criteria patients are misidentified as septic while omitting patients who are septic. A new consensus of sepsis and septic shock (Sepsis-3) was recently developed by collaborative groups. Sepsis-3 utilizes the Quick Sepsis Related Organ Failure Assessment (qSOFA) as a way to identify patients at risk for development of sepsis. The purpose of this study is to compare Sepsis-3 versus SIRS criteria in screening patients who are diagnosed or treated for sepsis from the emergency department (ED).

**Methods:** This is a single center, retrospective, cohort study of approximately 100 patients admitted to Wesley Medical Center (WMC) through the ED with suspected sepsis. Patients greater than 18 years old admitted through the ED who received antibiotics within 48 hours of admission will be included. Retrospective data will be generated beginning from 8/01/16 backwards until the study participation number is met. Patients will be stratified into four different groups: only qSOFA positive, only SIRS positive, qSOFA and SIRS positive, qSOFA negative and SIRS negative. Data to be collected by the research team will include: age, gender, arrival time to ED, SIRS criteria data, qSOFA criteria data, time in which the patient received antibiotics, serum lactate values, mortality data, and ICD code for sepsis.

Poster Title: Assessing adherence to new pediatric traumatic brain injury (TBI) pathway

Primary Author: Greg Scott, Wesley Medical Center, KS; Email: darkragemma@live.com

Additional Author(s):
Chris Durham

Purpose: Pediatric traumatic brain injury (TBI) is a significant contributor to morbidity and mortality in the United States. Improved outcomes have been shown when an evidence based protocol is implemented. At Wesley Children’s Hospital, a pediatric traumatic brain injury pathway was developed using current literature and an intervention log was created. The purpose of this quality improvement project is to review the pediatric TBI management pathway and intervention log for adherence and ease of use.

Methods: This is a single site, observational study assessing adherence to the pediatric TBI clinical pathway following implementation in July 2016. Pediatric patients admitted to the PICU for TBI between the dates of July 1, 2016 to April 1, 2017 will be included in the study. The primary outcome is to assess deviations from the pediatric TBI clinical management pathway and the secondary outcome is to determine if aspects of the pediatric TBI clinical management pathway are difficult to follow and need adjustment. The following data will be collected: age, history of seizures, Glasgow coma score, cause of traumatic brain injury, home medications, medications given, core temperature, end tidal carbon dioxide, oxygen saturation, hemoglobin, glucose, serum sodium, partial pressure of carbon dioxide in arterial blood, intracranial pressure, cerebral perfusion pressure, central venous pressure, mean arterial pressure, continuous electroencephalogram, head of bed position, temperature management system, art line, and intervention log. All data will be recorded without patient identifiers and maintained confidentially. The data will be reviewed to assess adherence and ease of use.

Poster Title: Implementing a hydromorphone ‘free’ Emergency Department

Primary Author: Lindsey Steffee, Carroll Hospital Center, MD; Email: lsteffee@carrollhospitalcenter.org

Additional Author(s):
Tamara Kozlowski

Purpose: Emergency Department providers are inundated with patients. It is frequently an area where people present for secondary gain. Opioid abuse has become a worldwide problem and it is estimated that 1.9 million people in the United States meet criteria for abuse of prescription painkillers. A 2014 statistic estimated that 4.3 million Americans used prescription painkillers for non-medical uses in the last month. Among individuals that abuse illicit and prescription substances, the thought is intravenous hydromorphone gives a better high. Carroll Hospital Emergency Department decided to try and reduce the misuse of hydromorphone in the Emergency Department.

Methods: The institutional review board at our institution does not review medication use evaluations. A policy was developed to discourage the use of intravenous hydromorphone in the Emergency Department. A multidisciplinary committee made up of pharmacists, nurses, care navigators and providers created and implemented the policy. Pharmacy created order sets for intravenous morphine and hydromorphone to encourage appropriate dosing and to attempt to limit the use of intravenous hydromorphone. Beginning in December 2015, intravenous hydromorphone could only be prescribed in 6 specific patient situations: sickle cell disease, cancer or terminal illness, biliary disease, kidney stones, multiple trauma and those with a true morphine allergy. In addition, when used, intravenous hydromorphone was now administered by intravenous infusion over 15 minutes instead of by intravenous push. This was done to decrease the chance of the patient getting a “rush” from the medication. Data was collected on the number of doses of morphine, fentanyl, hydromorphone and ketorolac for the quarter before the policy implementation and the first 2 quarters after implementation. Pain satisfaction scores were also analyzed before and after the policy was implemented. All medications discussed in this abstract are the intravenous forms of the drug, no oral forms of these medications were analyzed.

**Results:** Table 1 shows a 91 percent decrease in hydromorphone doses in quarter two compared to quarter one and a 50.9 percent increase in morphine. There was a 87.4 percent decrease in hydromorphone use and a 43.7 percent increase in morphine use when comparing quarter three to quarter one. Table 2 demonstrates a 3.64 percent decrease in ketorolac use during quarter two compared to quarter one. There was also a 7.1 percent increase of ketorolac use from quarter two to quarter three. Data was compiled from 25 patients who frequently visited the Emergency Department with pain related complaints before the policy implementation. The selected patients presented frequently with chief complaints of back or abdominal pain. The number of visits by this group was followed for two quarters after policy implementation. Shown in Table 3, a 74.5 percent decrease in visits occurred when comparing quarter two to quarter one. There was a 20 percent increase from quarter two to quarter three. The percentage of Emergency Department patients that rated their pain satisfaction scores as “very good” did not significantly change after the policy implementation. The number of total patient visits to the Emergency Department across all three quarters did not vary significantly.

**Conclusion:** When analyzing the number of visits from the sample patient group there was a 69.4 percent decrease in visits. The implementation of the hydromorphone free Emergency Department policy was successful in significantly decreasing the number of suspicious behavior visits. As represented by the data, the physicians were compliant with maintaining the policy implementation throughout the quarters. It should also be noted that the percentage of patients rating their pain satisfaction scores as “very good” did not change after the policy implementation. This leads us to conclude that pain medications, other than hydromorphone, can be used successfully for pain management in the Emergency Department.

Poster Title: Medication use evaluation of phytonadione in a community hospital

Primary Author: Hyunah Kim, Frederick Memorial Hospital, MD; Email: hkim892@gmail.com

Additional Author (s):
Amanda Bertele
Lorrie LeClair

Purpose: Phytonadione is a synthetic form of vitamin K that is indicated for the prevention and treatment of warfarin-induced hypoprothrombinemia. Inappropriate use of phytonadione can lead to excessive reversal causing sustained subtherapeutic INR putting patients at risk for thromboembolic complications. Conversely, inadequate dosing of phytonadione can lead to ineffective reversal, putting patients at risk for bleeding. The purpose of this study is to investigate the appropriateness of phytonadione use at Frederick Memorial Hospital and to assess its impact on patient outcomes by looking at time to reach therapeutic INR, and thromboembolic or bleeding complications post phytonadione administration.

Methods: The study is a retrospective chart review of patients who were admitted to Frederick Memorial Hospital (FMH) between July 2015 and July 2016. Patients were identified by searching the pharmacy records for phytonadione medication orders. Inclusion criteria are as follows: at least 18 years old who received at least one dose of phytonadione via oral, intravenous or subcutaneous route during either the Emergency Department or inpatient admission at FMH. Exclusion criteria are as follows: any bleeding (minor and major) at the time of supratherapeutic INR, end of life care patients, an indication for immediate INR normalization (bleeding, surgery or other invasive procedures), severe liver disease, known bleeding diathesis or thrombolytic treatment within 48 hours of screening, platelet count less than 50000 per mcL, administration of phytonadione or plasma in 48 hour period prior to screening, known allergy/sensitivity to plasma or other contraindications to phytonadione. Appropriate use of phytonadione is defined as use of 2.5 to 5 mg oral phytonadione in patients with INR greater than 10.0. The primary outcome of this study is to investigate overall appropriate/inappropriate use of phytonadione. The secondary outcome of this study is to assess the impact of phytonadione use on patient outcomes by looking at time to reach
therapeutic INR post administration, and thromboembolic or bleeding events within 4 weeks of phytonadione administration.

Poster Title: Appropriate use of clonidine patch with respect to dosing and safety

Primary Author: Spencer Banks, Frederick Memorial Hospital, MD; Email: spencer.banks@trivergenthealth.com

Additional Author(s):

Purpose: Clonidine patches can be beneficial for patients when used appropriately; however, improper use can increase costs to the hospital and has the potential to cause harm to patients. The purpose of this medication use evaluation is to evaluate appropriate use of clonidine patch within the hospital. Two major areas of concern for using clonidine patch is hypertensive urgency and opioid withdrawal. In both of these critical illnesses the crisis needs to be addressed urgently and cannot wait for clonidine patch to take effect in two to three days.

Methods: This study will be submitted to the Institutional Review Board for approval. The study is a retrospective chart review of patients admitted to the hospital and or emergency room between January 2016 and June 2016. Using the electronic medical record system a search for clonidine patch orders will be conducted to identify patients for inclusion in the study. Patients that will be included in the study need to be 18 years or older, seen in the emergency department or admitted to the hospital and receive a clonidine patch. The following data will be collected: age, gender, ethnicity, blood pressure, indication for clonidine patch, clonidine dose, emergency room visit and hospital admission data (post-initiation), current medications, changes in mediations (specifically antihypertensive medications). Data will be collected confidentially without patient identifiers. The reviewer will record data and analyze if clonidine patch is appropriate based on dosing, indication, and safety parameters. Safety parameters will include blood pressure and readmissions to the emergency department or hospital due to hypotension or syncope.

**Poster Title:** Impact of a pharmacist-led medication reconciliation and discharge counseling in the inpatient setting on readmission rates and patient hospital experience

**Primary Author:** Gilda Yeboah, Holy Cross Health, MD; **Email:** gilda.yeboah@holycrosshealth.org

**Additional Author (s):**
Kikelola Gbadamosi
Chinyelu Onwumbiko
Beatrix Lam
Meriam Senay

**Purpose:** Currently, Holy Cross Hospital's medication reconciliation and discharge counseling process is managed by nursing and medical staff. Often times allergies, organ function, dosing, and other patient-specific parameters are overlooked in this fast-paced and complex setting. Additionally, medication history collection is often inadequate. Pharmacists can play an integral role in care transitions by facilitating the medication reconciliation process and conducting discharge counseling, drug therapy reviews, identifying potentially inappropriate medication therapy and serving as drug information experts to the patient. The purpose of this study is to determine the impact of a pharmacist-led medication reconciliation and discharge counseling service in patients.

**Methods:** This research project was submitted to the institutional review board for approval. Medication reconciliation and discharge counseling will be identified using the inclusion criteria for this study. A pharmacist will complete medication history after a nurse has completed medication history to allow identification of discrepancies. The discrepancies and drug therapy related issues will be compared and statistically analyzed. Discrepancies will be documented after review of the missing or incorrect: medication, dose, route of administration, frequency of administration, indication, allergies, and duplication. Adherence will be documented after reviewing the medications with the patients. The pharmacist will review the medications the patient is being discharged with, which include home medications and new medications they will begin or continue taking upon discharge. Any discrepancy in the medication regimen will be reconciled with the patient’s physician and clarified. After the patient’s medication list has been
reconciled, the patient will be counseled prior to discharge on the medication name, indication, strength, dose, frequency of administration, timing of administration, any special administration instructions, and the most common side effects they may experience. Patients who enroll in this study will receive a survey after receiving discharge counseling to assess the overall patient care experience. The survey will be collected before the patient is discharged. A follow-up call will occur within 3-7 days post-discharge to review medications and actions steps.

Poster Title: Impact of a pharmacist-physician collaborative drug therapy management on hospital admission rates for high-risk patients managed in a health center for under-insured patients

Primary Author: Kristina Luong, Holy Cross Health, MD; Email: kristina.luong@holycrosshealth.org

Additional Author(s):
Kikelola Gbadamosi
Imran Chuhtai
Meriam Senay
Claude Manjo

Purpose: Collaborative practice between a pharmacist and physician has been shown to improve care access, clinical outcomes, and overall healthcare costs. Currently, the readmission rate for under-insured patients is higher than insured patients at the health center. Additionally, population health measures could be optimized with the addition of pharmacists due to practice standardization, access to care, reducing preventable adverse drug events, and improving medication adherence. The purpose of this study is to examine whether the implementation of a team-based collaborative drug therapy service can decrease hospital and emergency room encounters and improve therapeutic outcomes for high-risk, under-insured patients.

Methods: The study was submitted to the Institutional Review Board for approval. The collaborative drug therapy management service between pharmacists and physicians at Holy Cross Health Aspen Hill Clinic has four protocols based on current evidence-based practice guidelines: hypertension, dyslipidemia, diabetes, and anticoagulation. This agreement allows the pharmacists to provide direct patient care including modifying therapy, ordering and reviewing labs, and medication teaching. Patients will be scheduled to be seen by a pharmacist for any medication issues related to the protocols. Patient at high risk for readmission with diabetes, hypertension, dyslipidemia, or anticoagulation needs would be identified by the case manager and referred to the pharmacist by the physician. The following data will be collected: patient age, medications, laboratory values, vital signs, and adverse reactions. The number of
visits with a physician, hospital admissions, and emergency room visits will also be collected. The patient’s hospital and emergency room encounters, therapeutic outcomes, and access to care will be compared to data prior to the implementation of team-based collaborative drug therapy services. All data will be recorded without patient identifiers and maintained confidentially.

Poster Title: Innovative pharmacy advancement initiative: measuring the value of pharmaceutical care through competency based performance metrics

Primary Author: Amanda Richards, Holy Cross Health, MD; Email: amanda.richards@holycrosshealth.com

Additional Author (s):
Kikelola Gbadamosi
Karen Michaels
Chinyelu Onwumbiko
Haijing Tran

Purpose: ASHP's pharmacy advancement initiative (PAI) aims to optimize pharmacists' role in the care of patients. Holy Cross Health's Strategic Plan strives to provide innovative, high quality, and safe healthcare access to all populations. Pharmacy initiatives have been modified to ensure patient care is aligned to strategic initiatives and practice standards, along with performance metrics used to evaluate the value of services pharmacists provide. The purpose of this study is to evaluate pharmacist performance using key clinical interventions such as anticoagulation monitoring, antibiotic streamlining, emergency response, IV to PO conversion, and medication teaching, and pharmacokinetic consults.

Methods: Each month for the upcoming year 2016-2017, the clinical interventions made by pharmacists will be analyzed for each performance metric quarterly. Once the data is collected for each metric, it will be combined for an annual report to be compared to the results collected in 2015-16. In the previous year the significant performance improvements included antibiotic streamlining, emergency and rapid response team, and pharmacokinetic consults. The key performance metrics will be used to measure individual performance in alignment with organizational targets. Performance metric results will provide a balance scorecard on areas to be improved by individuals and overall for the pharmacy department. The competency performance will measure alignment with pharmacy activities with organizational targets by standardizing practice standards and define the vision for success in daily performance including measurable targets. The study will provide measurable outcomes that can determine barriers to achieving the measurement target and prioritization of services.

**Poster Title:** Impact of an antimicrobial stewardship program on clinical outcomes and antibiotic consumption at a community teaching hospital

**Primary Author:** Lynne Ngouajio-Teguiafa, Holy Cross Hospital, MD; **Email:** lynne.ngouajio-teguiafa@holycrosshealth.org

**Additional Author(s):**
Kikelola Gbadamosi
Haijing Tran
Beatrix Lam
Claude Manjo

**Purpose:** The CDC, IDSA and TJC all recognize that implementation of antimicrobial stewardship programs (ASPs) is a promising strategy to reduce clinical variation and collateral damage. Effective ASPs may be able to improve the bottom line by reducing length of hospital stay, readmission rates and promote cost savings. In a hospital setting where delivery of exceptional quality care is epicenter of practice, continuous improvement through innovation in clinical and operational excellence is crucial. The objective of this study is to assess the impact of an established ASP on clinical outcomes and antibiotic consumption at a community teaching hospital.

**Methods:** The research project has been submitted to the Institutional Review Board for approval. The electronic medical health records and the antibiotic surveillance software will be used to identify patients who were treated for one or more of the following conditions: urinary tract infection, pneumonia, staphylococcus aureus bacteremia, skin and soft tissue infection. The following data will be collected: age, gender, type(s) of antibiotics used for treatment, renal function tests, microbiology data, reported adverse events and resistance patterns at the hospital. All health records will be de-identified and maintained under password-protected encryption. Records meeting the inclusion criteria will be reviewed and analyzed by the principle investigator for the following: days of antibiotic therapy, consumption of antibiotics, number of adverse events associated with antibiotic use, compliance to evidence-based national guidelines, length of hospital stay, resistance rates and overall cost expenditures.

**Poster Title:** Implementation of a pharmacist-driven medication counseling program  

**Primary Author:** Soumil Sheth, Howard County General Hospital, MD; **Email:** ssheth11@jhu.edu  

**Additional Author(s):**  
Susan Shermock  
Margaret Curtin  
Adrienne Shepardson  

**Purpose:** Hospitalizations often involve discontinuity in care and multiple changes in medication regimens which can lead to adverse drug events (ADEs) and avoidable health care utilization without adequate patient education upon discharge. Patients on high risk medications are at higher risk for ADEs which can lead to non-adherence and may result in hospital readmission. Nurses currently perform discharge education at this hospital and coordination with pharmacists is anticipated to improve patient outcomes. The impact of pharmacist involvement at hospital discharge will be measured by Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) scores and reduction in 30-day all-cause readmissions.  

**Methods:** A nursing discharge education pilot using the teach-back method was initiated on a 30-bed medicine unit (2 Pavilion) at Howard County General Hospital in February 2016. All nurses working on this unit are expected to be trained on the teach-back approach for medication counseling through a video and will be observed in practice. Initial results demonstrated increased HCAHPS scores in the medication domain. In order to provide counseling for high risk patients, a pharmacist will provide discharge education for all eligible patients that meet one of the following criteria: (1) age of 65 and older or on greater than 10 medications or (2) on a high-risk medication. Nurses will identify these patients for pharmacist intervention, or discharge counseling. This study was submitted to the Institutional Review Board for exempt review. Results of this study will be compared to the data from prior to pharmacist involvement to assess outcomes including readmission rates and HCAHPS scores. The goals of the study are to demonstrate that discharge counseling for high risk patients by
pharmacists improves quality and safety of care in order to validate expansion of this service to the entire institution.

**Poster Title:** Influence of a 90 day, $0 mail-order Medicare Part D (MPD) benefit design on medication adherence

**Primary Author:** Brittany Vogel, Kaiser Permanente Mid-Atlantic States, MD; **Email:** brittany.n.vogel@kp.org

**Additional Author (s):**
Megan Famodu

**Purpose:** Poor medication adherence can result in unnecessary suffering, negative disease state outcome and possible increased health care services, leading to overall increased health care costs. Interventions to lower barriers to medication adherence can include prescribing 90 day medication supplies. This study evaluates Medicare Part D members’ medication adherence as measured by proportion of days covered (PDC) 8 months prior and 8 months post the implementation of a $0 90 day mail-order copay benefit. The study will also assess the impact on members’ utilization of the mail-order pharmacy.

**Methods:** The Institutional Review Board has approved this retrospective claims analysis. On January 1, 2016, Kaiser Mid-Atlantic States (KPMAS) implemented a new pharmacy benefit design for Medicare Part D direct pay members. This design implemented a $0 copay for 90 day supply of preferred generic medications filled at mail-order. The 2015 pharmacy benefit design for Medicare Part D direct pay members included copays ranging from $10-$14 per 90 day supply. A retrospective claims analysis will be performed using claims data extracted from the Kaiser Mid-Atlantic Pharmacy Data Warehouse. This data warehouse contains claims-based records of all outpatient and mail order pharmacy prescriptions filled at Kaiser and participating network pharmacies for Kaiser Mid-Atlantic members. Prescriptions filled for Medicare Part D direct pay members for drugs identified as preferred generics on the Medicare Part D formulary from April 1, 2015 to August 31, 2016 will be extracted. Adherence rates will be calculated using proportion of days covered (PDC) prior to and after the implementation of the $0, 90 day copay to determine differences in adherence rates. Additionally, the pharmacy location type used by the member to fill their medications (i.e. mail order, network, and Kaiser outpatient pharmacies) will be compared prior to and after the implementation of the new pharmacy benefit design.

**Poster Title:** Retrospective review on effectiveness of seizure control in patients switched from brand to generic antiepileptic drugs in an integrated healthcare delivery system

**Primary Author:** Sarah Neeler, Kaiser Permanente of the Mid-Atlantic States, MD; **Email:** sarah.e.neeler@kp.org

**Additional Author (s):**
Angela Olenik
Kaysha Lancaster

**Purpose:** Concerns have been raised about variances in bioavailability between brand and generic antiepileptic formulations which may result in loss of seizure control or drug toxicity after conversion. The American Academy of Neurology and the Epilepsy Foundation support therapeutically equivalent generic substitution of antiepileptic drugs. In 2012, Kaiser Permanente of Mid-Atlantic States (KPMAS) decided to reduce the use of non-formulary brand antiepileptic drugs when therapeutically equivalent generics are available in order to maintain the affordable, high quality care it provides to its members. This study will determine the effects of switching from brand to generic antiepileptic medications in this healthcare setting.

**Methods:** This study has been approved by the KPMAS Institutional Review Board (IRB). A retrospective review of 252 patients who were converted from brand name to generic formulation of the following antiepileptic drugs will be completed: Carbital to carbamazepine ER, Depakene to valproic acid, Depakote to divalproex sodium DR, Depakote ER to divalproex sodium ER, Felbatol to felbamate, Keppra to levetiracetam, Keppra CR to levetiracetam XR, Lamictal to lamotrigine, Neurontin to gabapentin, Tegretol to carbamazepine, Tegretol XR to carbamazepine XR, Topamax to topiramate, Trileptal to oxcarbazepine, and Zonegran to zonisamide. All patients who were converted to generic formulations will be included in the study. Patients will be excluded from review if they are less than 18 years of age or if follow up data is not available. Demographic information such as patient medical record number, age, gender, ethnicity, height and weight will be collected from KPMAS electronic records. Clinical information to be collected are as follows: drug strength, drug dose, generic manufacturer, date when current regimen was initiated, date when therapy with generic formulation was initiated, most recent pre-conversion blood level of brand name antiepileptic, post-conversion
blood level and the date which it was obtained, date of last seizure episode pre-conversion, most recent pre/post conversion liver function tests, most recent pre/post conversion renal panel, and most recent pre/post conversion CHEM7.

**Poster Title:** Evaluating the clinical pharmacists’ impact on medication adherence and clinical outcomes in type 2 diabetic patients

**Primary Author:** Jasmine Ebron, Kaiser Permanente of the Mid-Atlantic States, MD; **Email:** jasmine.m.ebron@kp.org

**Additional Author (s):**
Cheryl Simmons-Gray
Katherine Harrigan
Angela Patanawong,

**Purpose:** Intense glycemic management is associated with fewer incidences of retinopathy, nephropathy, and neuropathy in type 2 diabetic patients. An interdisciplinary approach to diabetes management has proven to be beneficial on suboptimal glycemic control and adherence rates. In June of 2016, all primary care clinical pharmacist at Kaiser Permanente Mid-Atlantic States started type 2 diabetes management panels. This study aims to evaluate the impact of clinical pharmacist management on medication adherence rates, glycated hemoglobin (HgbA1C) and hospitalizations rates associated with diabetic complications as a result of being enrolled into a pharmacist-managed diabetic program.

**Methods:** A retrospective chart review of 100 type 2 diabetic patients assigned to one clinical pharmacist will be conducted. The study population will serve as their own control. Data will be collected from January 1, 2016 – May 30, 2016, before the panel was enrolled into a pharmacist-managed diabetes program, compared to data from June 1, 2016 – November 30, 2016, after enrollment. Prescription drug claims for the following diabetic agents, statins, angiotensinogen converting enzyme (ACE) inhibitors, and angiotensin II receptor blockers (ARBs) will be reviewed: acarbose, glipizide, Humalog vial, Humulin N 70/30, Humulin N, Humulin R Vial, Lantus Vial, metformin HCL, metformin ER, pioglitazone HCL, atorvastatin calcium, lovastatin, pravastatin Sodium, simvastatin, captopril, enalapril maleate, lisinopril, lisinopril and hydrochlorothiazide, losartan potassium, losartan potassium and hydrochlorothiazide. Glycated hemoglobin (HgbA1C) data and hospitalization admissions associated with diabetic complications, between January 1, 2016 to May 30, 2010 and from June 1, 2016 to November 30, 2016 will be reviewed for each study participant. All uncontrolled
type 2 diabetic patients who were not previously enrolled into the clinical pharmacist managed program with a glycated hemoglobin (HgbA1C) of ≥8% will be included in this study. Patients will be excluded from this study if they are less than 18 year of age, pregnant, or have been hospitalized for more than 1 week.

Poster Title: Evaluating outcomes from a pilot pharmacy initiative to limit duration of empiric ciprofloxacin and vancomycin use in a small community hospital

Primary Author: Sheena Mathew, MedStar Union Memorial Hospital, MD; Email: smathew183@gmail.com

Additional Author(s):
Daryn Norwood
Allison Chilipko

Purpose: Ciprofloxacin and vancomycin are commonly used as empiric therapy for various infections. However, their widespread use is associated with an increased risk of antimicrobial resistance. Inappropriate use of these agents may lead to development of extended-spectrum beta lactamase (ESBL) producing pathogens, methicillin-resistant Staphylococcus aureus (MRSA), and vancomycin-resistant Enterococcus (VRE). To limit empiric, broad-spectrum ciprofloxacin and vancomycin use, a pilot pharmacy initiative was implemented to contact providers after 72 hours of negative cultures and recommend de-escalating or discontinuing therapy. This study evaluates antibiotic duration after implementation of this initiative and the impact of pharmacy intervention for antibiotic streamlining.

Methods: This study will be submitted to the Institutional Review Board for approval prior to initiation. A retrospective chart review will be performed for randomly selected eligible patients. Inclusion criteria include patients age ≥18 years who received oral or intravenous ciprofloxacin and/or vancomycin as initial antibiotic therapy between June 1, 2016 and March 31, 2017. Patients with a length of stay less than 72 hours or who received another antibiotic prior to initiation of ciprofloxacin and/or vancomycin will be excluded. Outcomes from before implementation of the pharmacy pilot will be compared to those after implementation to evaluate the impact of pharmacy intervention. Data collection will include patient demographics, antibiotic indication, regimen, duration, microbiology culture results (if positive cultures are available), vancomycin levels, occurrence of adverse drug reactions, incidence of antibiotic de-escalation, and the outcomes of pharmacist intervention. Study outcomes will evaluate mean duration of antibiotic use between the pre-pilot and post-pilot group, the result of pharmacist intervention (de-escalation or discontinuation after a targeted intervention at 72
hours compared to conventional interventions in the pre-pilot group), and the incidence rate for adverse events and/or supratherapeutic vancomycin trough levels in patients who continued empiric antibiotics for more than 72 hours with negative cultures.

Poster Title: Evaluating the effect of a sepsis order set on time to first dose of antibiotics after sepsis diagnosis in a community teaching hospital

Primary Author: Chih-Wei Hsu, MedStar Union Memorial Hospital, MD; Email: hchihwei1@gmail.com

Additional Author (s):
Daryn Norwood
Allison Chilipko

Purpose: According to the Surviving Sepsis Campaign guidelines, once a diagnosis of sepsis has been established, the patient should receive appropriate broad-spectrum antibiotic therapy within sixty minutes. Each hour delay in administration is associated with a measureable increase in mortality. The hospital implemented a sepsis order set to help decrease the time from antibiotic prescribing to administration. This order set includes recommended empiric antibiotic regimens based on suspected source of infection. Thus, the objective of this study is to evaluate outcomes from implementation of the order set on time to antibiotic administration in septic patients.

Methods: The study will be submitted to be approved by Institutional Review Board. This study will be conducted as a retrospective chart review comparing time from sepsis diagnosis to first dose of antibiotics before and after order set implementation. Adult patients (age 18 and older) who were diagnosed with sepsis from July 2014 to July 2016 will be eligible for inclusion. Patients will be excluded if there is insufficient time documentation for evaluation. The investigation will minimize the use of protected health information to maintain patient confidentiality. Data collection will include: patient demographics and survival data and total time to antibiotic administration including the following stepwise time points: time from sepsis diagnosis to antibiotic order, time from order to verification by pharmacy, time from verification to nurse administration. Antibiotic class, duration of use, and the appropriateness of antibiotic de-escalation based on microbiology data will also be collected for the study. The primary outcome will be to determine if the sepsis order set helps improve the total time from diagnosis of sepsis to antibiotic administration. Secondary outcomes will be to identify the rate-
limiting step and evaluate the appropriateness of antibiotic class used, duration, and de-escalation of the antibiotics.

Poster Title: Evaluating outcomes after implementation of a new vancomycin dosing protocol at a small community hospital

Primary Author: Priyana Kumar, MedStar Union Memorial Hospital, MD; Email: priyana.kumar@medstar.net

Additional Author(s):
Allison Chilipko
Daryn Norwood

Purpose: Vancomycin is commonly used to treat serious infections, including those caused by methicillin-resistant Staphylococcus aureus (MRSA). Despite the development of dosing protocols and close therapeutic monitoring, the incidence of supratherapeutic trough levels and increased risk for nephrotoxicity remains a concern. Given prior study results from hospital drug use evaluations of vancomycin, the pharmacy dosing protocol was revised to exclude loading doses, limit empiric use of every eight hour dosing regimens, and require closer monitoring for patients with hypoalbuminemia. This study aims to evaluate the patient outcomes from the new vancomycin dosing protocol compared to the previous vancomycin protocol.

Methods: This study will be submitted to the Institutional Review Board for approval prior to initiation. A retrospective chart review will be performed for randomly selected eligible patients. Inclusion criteria include patients of an age greater than or equal to 18 years who have received vancomycin for at least 48 hours and had at least one vancomycin level available during hospitalization. Patients with renal impairment, defined as a creatinine clearance of less than 20 mL/minute or those receiving concomitant nephrotoxic medications will be excluded from the study. Data collection will include patient demographics, concomitant antibiotics, vancomycin regimen and levels, renal function at baseline and during hospitalization, and adverse effects. Study outcomes will evaluate the incidence of subtherapeutic, therapeutic, or supratherapeutic vancomycin levels at lab draws and the percentage of patients experiencing acute kidney injury or the occurrence of other adverse effects. Outcomes after implementation of the new dosing protocol will be compared against a historical control group with the prior protocol.

Poster Title: Medication use evaluation of cangrelor at a 292-bed acute care community hospital

Primary Author: Wai Chan, Peninsula Regional Medical Center, MD; Email: wai.chan@peninsula.org

Additional Author(s):
Hillary Schlerf

Purpose: Cangrelor is an intravenous potent and predictable inhibitor of ADP-induced platelet aggregation with an immediate onset of action used in percutaneous coronary interventions (PCI). Prior to the Food and Drug Administration (FDA) approval of cangrelor in June 2015, the previously existing P2Y12 platelet inhibitors have several limitations such as delayed onset and offset of action, inter-individual variability, and only oral availability. Since the addition of cangrelor to the formulary, its utilization has not been monitored for appropriate indication, dosing, and transition to an oral P2Y12 platelet inhibitor. The purpose of this study is to assess the appropriateness of cangrelor use.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will be used to identify patients who were administered cangrelor since its addition to the formulary in August 2015. The following information will be collected: indication for use, weight, dosing, and timing of oral P2Y12 platelet inhibitor initiation. In addition, provider documentation and catheterization laboratory reports will be reviewed if there is reason to clarify any of the aforementioned information. Only the minimum necessary information will be collected, and all information will be collected without patient identifiers and maintained confidentially. The information will be evaluated for appropriate use based on three criteria: [1] for bridging those with high thrombotic risk who need to interrupt oral agents, [2] for those with acute coronary syndromes, particularly ST-elevation myocardial infarction (STEMI), intended for PCI where the oral route is suboptimal, and [3] for those undergoing urgent PCI who were not adequately loaded with an oral P2Y12 inhibitor and are not receiving a glycoprotein IIb/IIIa inhibitor. In addition, the reviewers will evaluate whether the weight-based dosing for the bolus and infusion and transition to an oral P2Y12 platelet inhibitor were performed properly.

Poster Title: Evaluation of 4-factor prothrombin complex concentrate vs 3-factor prothrombin complex concentrate in warfarin and factor Xa inhibitor reversal

Primary Author: Jerry Van, Sinai Hospital, MD; Email: jvan@lifebridgehealth.org

Additional Author(s):
Ricky Amoateng
Diana Guon

Purpose: The 2012 American College of Chest Physicians antithrombotic guidelines suggests a preference for the use of 4-factor prothrombin complex concentrate (PCC) for reversal of warfarin therapy-associated major bleeding with no recommendation for or against the use of 3-factor PCC. In addition, current guidance for the practical management of direct oral anticoagulants suggests that 4-factor PCC should be considered for factor Xa inhibitor reversal. There is a lack of high-quality evidence to support 4-factor PCC as a reversal agent over others, such as 3-factor PCC. The objective of this study is to evaluate the effectiveness of 4-factor PCC versus 3-factor PCC.

Methods: The study has been approved by the Institutional Review Board. A retrospective review of the electronic medical record will screen patients who have received a dose of 3-factor PCC for warfarin or factor Xa inhibitor reversal. Then a prospective chart review will be conducted and identify patients who have received a dose of 4-factor PCC for warfarin or factor Xa inhibitor reversal. The following data will be collected: patient age, gender, weight, height, hemoglobin, hematocrit, platelets, INR, aPTT, PT, anti-factor Xa level, anticoagulation indication, type of bleeding, bleeding reversal adjuncts (i.e. transfusions, blood factors, fresh frozen plasma, platelets, vitamin K, tranexamic acid, desmopressin, aminocaproic acid), type of PCC used, number of PCC doses used, duration of hospitalization, and adverse events. Hemostatic efficacy will be determined with a rating scale used in previously published studies. All data will be recorded without patient identifiers and confidentiality will be maintained. Reviewers will determine successful reversal in warfarin-associated major bleeding by an INR reduction to less than 1.5 and successful reversal in factor Xa inhibitor associated major bleeding by achieving an effective hemostatic efficacy rating. Standardized difference will be calculated for baseline characteristics and any imbalances between groups will be adjusted.
through logistic regression. Statistical analysis of the primary outcome will be determined with Fisher’s exact test. Secondary outcome analysis will be determined with a 2-sample t-test.

Poster Title: Effect of probiotic use in prevention of hospital-acquired Clostridium difficile infection in a community hospital

Primary Author: Negin Deyhim, Sinai Hospital of Baltimore, MD; Email: neginleyhim@yahoo.com

Additional Author(s):
Jean Lee

Purpose: Hospital-acquired Clostridium difficile infection (CDI) has been associated with increased costs in health care systems and increased rate of morbidity and mortality. CDI is increased in hospitalized patients receiving broad-spectrum antibiotics such as cephalosporins, fluoroquinolones, penicillins, and clindamycin. Probiotics are live organisms that have been proposed to prevent CDI. Probiotics can maintain or restore gut flora during or after antibiotic treatment. However, studies have shown conflicting results regarding the use of probiotics in prevention of CDI. The purpose of this study is to investigate if pharmacy-driven probiotic protocol will reduce the rate of hospital-acquired CDI.

Methods: This study will be done at Northwest hospital, a not-for-profit community acute care hospital located in Randallstown, Maryland with 254 beds. Pharmacy-driven probiotic protocol was implemented in March 2016 to reduce rate of HA-CDI. Patients were included in the study if they are ≥18 years of age, who receive oral or intravenous antibiotics Zosyn, Clindamycin, Ciprofloxacin, Levofloxacin, Ceftriaxone and Cefepime. Patients on chemotherapy, radiotherapy treatment and Leukopenia (WBC count less than 4000 mcg/L) will be excluded from the study. All patients are given 4 tablets of Floranex four times a day or Lactobacillus granules in the equivalent dose from the moment they begin antibiotic therapy per pharmacy protocol. Floranex contains a blend of lactobacillus acidophilus and lactobacillus helveticus (bulgaris). Each capsule contains 100 million live cells of lactobacillus species. Pre-intervention rate of HA-CDI from July 2015 to December 2015 will be compared to post-intervention rate of HA-CDI from July 2016 to December 2016. Primary objective will be rate reduction of HA-CDI with probiotic implementation at Northwest hospital.

**Poster Title:** Analysis of predicted benefits through incorporating rapid identification testing for gram positive blood cultures in an acute care, community hospital

**Primary Author:** Sherin Pathickal, Suburban Hospital, MD; **Email:** spathic1@jhmi.edu

**Additional Author(s):**
Brittany Copeland
Julie Trivedi

**Purpose:** Traditional organism culture and identification can take 72 to 96 hours before susceptibilities are known, during which patients receive broad spectrum antibiotics that are potentially unnecessary. With new diagnostic technology, final species identification can occur within hours, allowing fewer doses of broad spectrum antibiotics, and earlier initiation of deescalated therapy. The primary objective is to determine the mean time to targeted antibiotic therapy for gram positive bacteremia following final cultures. Secondary objectives include evaluating the timing of antibiotic initiation relative to culture collection and speciation and performing a cost benefit analysis to evaluate the potential utility of rapid diagnostic testing.

**Methods:** Data regarding gram positive cultures collected from August 1, 2015 through July 31, 2016 will be reviewed in a retrospective analysis. Patients greater than 18 years of age with gram positive blood cultures will be included. Patients will be excluded if they were pregnant or incarcerated, had a polymicrobial bacteremia, did not receive antibiotic therapy during hospital stay, received treatment for another culture positive infection, had antibiotics administered prior to culture collection, or had a culture result that was known at the time of admission. Additionally, only the first positive culture from admission will be analyzed. Further, the number of patients unable to receive optimal deescalated treatment due to a documented penicillin allergy will be assessed. Data collection will include, but is not limited to, baseline demographics, identified pathogen, duration of broad spectrum therapy, time (hours) from culture collection to final speciation and susceptibility, resulting speciation as contaminant or infection, antibiotic(s) administered, and length of stay.

**Poster Title:** Comparison of day and night shift sedative and analgesic use in a community hospital intensive care unit

**Primary Author:** Adriana Soto-Aviles, Suburban Hospital, MD; **Email:** adrianaesoto@gmail.com

**Additional Author(s):**

Nicholas Peters

**Purpose:** Intensive Care Unit (ICU) patients commonly receive sedatives and analgesics for the management of pain, agitation, and delirium. Under-treating or over-treating pain or agitation can cause many complications. The 2013 pain, agitation, and delirium (PAD) guidelines recommend light levels of sedation to decrease duration of mechanical ventilation, ICU length of stay (LOS), and hospital LOS. Studies have shown more sedatives and analgesics are administered during night shifts compared to day shifts. We hypothesize that patients receive more sedatives and analgesics during night shifts at this community hospital, and that nursing education will reduce the amounts administered during both shifts.

**Methods:** This is a retrospective pre-post study in mechanically ventilated adult ICU patients who are in the ICU for greater than 24 hours, mechanically ventilated for greater than 12 hours, and received a sedative or analgesic. Quantitative data will be collected in two separate time periods. A retrospective chart review will occur evaluating sedative and analgesic use from October 1, 2016 to October 31, 2016. In December 2016, day and night shift ICU registered nurses (RN) will receive a survey and education regarding appropriate PAD management. A repeat retrospective chart review will occur evaluating sedative and analgesic use from January 1, 2017 to January 31, 2017. Using opioid and sedative dose equivalents, we will compare the amount of sedative and analgesics received and percentage of appropriate Richmond Agitation-Sedation Scale (RASS) and Confusion Assessment Method for the ICU (CAM-ICU) RN monitoring and documentation. The primary outcome of this study is a quantitative comparison of sedatives and analgesic doses administered during day and night shifts. Secondary outcomes include the percentage of patients at goal RASS, presence of delirium using the CAM-ICU, presence of coma, percentage of appropriate RASS and CAM-ICU documentation, in-hospital mortality, ICU and hospital LOS, and duration of mechanical ventilation. Statistical analysis will
include the two-sided Student’s t-test and the Chi-square test, with a level of significance of 0.05.

Poster Title: Extending a pharmacist directed diabetes self-management education (DSME) program in transitions of care in a medically underserved rural patient population

Primary Author: Tosin David, University of Maryland Eastern Shore/ Apple Discount Drugs, MD; Email: tdamid@umes.edu

Additional Author(s):
Geoff Twigg
John Motsko

Purpose: The community surrounding Apple Discount Drugs has a need for patients with diabetes upon hospital discharge to receive disease state education. The program is located on the rural Eastern Shore of Maryland, where there is a current lack of endocrinologists. In the near future the program will expand their role in providing care for all individuals covered under a large commercial payer. The objective of this study is to explore the role of the pharmacist as a physician extender by providing diabetes education in a community pharmacy setting in a medically underserved, rural patient population.

Methods: The pharmacy has an established accredited diabetes education program. Currently, the pharmacy has the ability to bill Medicare part B through a patient’s durable medical equipment benefit and has received a limited provider status to bill for such services through its largest commercial payer.
The service community currently has a need for patients to gain diabetes education and follow up after a hospital discharge. Due to the documented success with clinical outcomes, the pharmacy has developed a program with the local third party payer to reach out to patients with diabetes complications post hospital discharge. As the program continues to expand their services, the role of the current community pharmacy resident will expand to providing individual care and follow-up for these patients.
Once a patient is referred for diabetes education, the pharmacist will obtain baseline laboratory results and the most recent history and physical from the referring provider. The pharmacist, with the help of the patient and the prescriber, will set patient specific goals. Primary outcomes for the authors will be looking at is the change in A1C from pharmacist directed diabetes self-
management education and number of referrals. Secondary outcomes are adherence to patient identified self-change behaviors and education completion rate.

Poster Title: Cost-benefit analysis of bedside delivery service from a health-system perspective

Primary Author: Timothy Wu, University of Maryland Medical Center, MD; Email: timothywu@umm.edu

Additional Author (s):
Joey Mattingly
Kathryn Vranek
Carla Williams

Purpose: Patients who are being discharged from the hospital are typically given a new prescription to have it filled by their local pharmacy when returning home. However, a large majority of patients do not fill these prescriptions, leading to consequential clinical and financial impacts. The expansion of a bedside delivery service helps to not only provide patients with their new prescription medications, but also benefits the hospital both financial and clinical viewpoints. This study will conduct a cost-benefit analysis of expanding a bedside delivery service in a hospital system.

Methods: Retrospective data from current bedside delivery units will be used to develop a cost-benefit analysis to help determine the net benefit of implementation throughout the remaining units of the medical center. The primary benefit input in the model will be revenue generation from discharge prescriptions. Cost inputs include the pharmacy cost-to-dispense, cost of goods sold, and labor costs associated with delivery. Point estimates and distributions will be used for probabilistic sensitivity analysis using a Monte Carlo simulation to determine uncertainty around the net benefit calculation. Data will be then utilized to extrapolate feasibility of a bedside delivery service to other areas of the hospital and possibly other hospitals within the health system. Descriptive statistics will be used for prescriptions, patients, and financial variables.

Poster Title: Empiric antimicrobial utilization for pneumonia among patients admitted to a neurocritical care unit

Primary Author: Ciera Patzke, University of Maryland Medical Center, MD; Email: cierapatzke@umm.edu

Additional Author (s):
Michael Armahizer
Melissa Motta

Purpose: IDSA guidelines for pneumonia suggest to reassess the need for broad-spectrum empiric antibiotics at 72 hours after initiation. However, current literature reports that 50 percent or more of critically ill patients are continued on broad-spectrum antibiotics beyond 72 hours, despite no confirmed infection. Patients in the neurocritical care unit (NCCU) have a high incidence of central fevers, making it difficult to differentiate infectious fevers. We hypothesize that there is an even higher incidence of prolonged empiric antibiotic use without a guideline-based indication in this population. This study will evaluate empiric antibiotic use for the treatment of pneumonia in NCCU patients.

Methods: This study was submitted to the the Institutional Review Board and is pending approval. This is a retrospective chart review of adult patients who were previously treated with antibiotics for pneumonia in the NCCU. This study will utilize a convenience sample of patients meeting this criteria between November 2016 and August 2016. Transplant patients, patients with neutropenia, and patients who were treated with additional separate courses of antibiotics will be excluded. The primary objective is to determine adherence to guideline-based recommendations regarding indication to treat, selection of empiric antibiotic, 72-hour de-escalation, length of treatment with empiric antibiotics, and length of overall antibiotic treatment. Secondary objectives are to determine the number of patients treated for an infectious fever that meet the criteria for central fever, and to determine the incidence of adverse effects including nephrotoxicity, encephalopathy, and infection due to clostridium difficile. Data to be collected include demographic data, principal problem, admitting service, concomitant diseases, acute physiology and chronic health evaluation score (APACHE II), clinical pulmonary infection score (CPIS), infection probability score (IPS), center for disease control
criteria for pneumonia, previous exposure to antibiotics within 90 days, mechanical ventilation duration, antibiotic used and indication, dose and frequency of antibiotic, culture type and results, daily white blood counts and temperatures, incidence of adverse effects previously noted, and hospital disposition. Final data will be presented using descriptive statistics.

**Poster Title:** Comparison of warfarin dosing requirements before and after intravenous inotrope initiation in acutely ill patients with advanced heart failure

**Primary Author:** Ana Vega, University of Maryland Medical Center, MD; **Email:** anavega@umm.edu

**Additional Author(s):**
- Sandeep Devabhakthuni
- Brent Reed

**Purpose:** Many patients that require anticoagulation with warfarin have several comorbid conditions, such as heart failure, which complicates warfarin dosing. As a result of decreased cardiac output and tissue perfusion, patients with advanced heart failure often have decreased warfarin dose requirements (due to the liver's impaired ability to metabolize the drug). However, heart failure patients requiring therapy with intravenous inotropes experience increased cardiac output. The purpose of this study is to determine the mean difference, if such a difference exists, between warfarin dose requirements pre- and post-inotrope initiation in patients with advanced heart failure.

**Methods:** This study will be a retrospective pilot analysis conducted at University of Maryland Medical Center (UMMC) of patients at least 18 years of age on chronic anticoagulation with warfarin and with a diagnosis of advanced heart failure with reduced left ventricular ejection fraction (HFrEF less than 40 percent) requiring long-term inotrope therapy who were admitted to the Advanced Heart Failure Service at UMMC between May 1, 2010 to May 1, 2015. Our goal sample size is approximately 50 patients. As this is a pilot study and similar data has not been published in the literature, we are unable to perform a power calculation to determine a precise sample size. We will exclude patients who were actively bleeding during admission, received intravenous inotrope therapy for an indication other than the management of symptoms in decompensated heart failure, were on intravenous inotrope therapy for short-term use only, had no indication for warfarin therapy, were newly started on warfarin and intravenous inotropes during the same admission, have a hereditary hypercoagulable state, or had a history of mechanical heart valve replacement. The data analysis plan includes the use of a Wilcoxon Signed-Rank Test will be used to measure a significant difference in the primary
outcome. Logistic regression will be used to control for confounding variables. A p-value of 0.05 will be used to define statistically significant difference between groups.

Poster Title: Evaluation of discrepancies between noninvasive fibrosis testing methodologies and their impact on hepatitis C virus (HCV) treatment regimen

Primary Author: Jackoline Costantino, University of Maryland Medical Center, MD; Email: jackolinecostantino@ummc.edu

Additional Author(s):
Lauren Hynicka
Emily Heil
Darryn Potosky
Kimberly Claeyys

Purpose: Selection of hepatitis C virus medication regimen is based on patients’ genotype and degree of liver fibrosis. The liver biopsy is the gold standard for scoring liver fibrosis. Per the AASLD/IDSA guidelines, two noninvasive tests may replace the liver biopsy, but the scores must match. In practice, if two tests are performed, one test has been used to make treatment decisions even if the two tests are discordant. The objective of this study is to identify the rate of intrapatient discrepancy between the noninvasive tests and determine if that discrepancy affected regimen selection, treatment duration and potentially cure rates.

Methods: This retrospective analysis conducted at University of Maryland Medical Center (UMMC) includes all patients at least 18 years of age with a diagnosis of HCV regardless of genotype or treatment history, that had at least one of the noninvasive tests performed (FibroSure or FibroScan) and was seen in the UMMC Outpatient Infectious Disease Clinic between May 1, 2015 to July 31, 2016. The patient population will be a convenience sample of 250 patients selected by the noninvasive test completed during this time frame. The primary end-point is to determine the frequency of intrapatient discrepancy between two noninvasive scoring modalities. The secondary end-points determine if the discrepancy impacts treatment plan and cure rates as well as determine if the patient demographics skewed treatment decisions based on which test was utilized and instructions followed according to manufactures suggestions. A variety of statistical analyses will be utilized setting a p-value of 0.05 to define statistical significance. Wilcoxon Signed-Rank Test will determine the intrapatient fibrosis score discrepancy. Categorical parameter differences will be compared using Chi Square Test. Patient
baseline demographics will be compared using descriptive statistics, and lastly logistical regression will be performed to account for any confounding variables that may have led to any statistically significant results.

Poster Title: Lacosamide pharmacokinetics in critically ill patients receiving continuous renal replacement therapy

Primary Author: Miguel Franquiz, University of Maryland Medical Center - PGY1 Pharmacy Practice (ASHP Accredited, Code: 35300), MD; Email: mfranquiz@umm.edu

Additional Author (s):
Michael Armahizer
Shamir Kalaria
Neeraj Badjatia
Mathangi Gopalakrishnan

Purpose: Lacosamide is a third generation anti-epileptic drug used frequently for the prevention and treatment of seizures in critically ill patients with epileptiform disorders in neurocritical care settings. Lacosamide pharmacokinetics in this patient population have not been described by any previous study. The purpose of this study is to describe the pharmacokinetic parameters and sieving coefficient of the anti-epileptic drug lacosamide in critically ill patients receiving continuous renal replacement therapy. Knowledge of lacosamide pharmacokinetics in the setting of continuous renal replacement therapy may be useful to clinicians considering alternative dosing strategies.

Methods: This is a prospective, open-label, pharmacokinetic analysis. This study will be approved by the institutional review board at the study center prior to initiation. Subjects will be eligible for approach for consent if they meet the following inclusion criteria: subject prescribed lacosamide while admitted to the neurocritical care unit at the study center, subject prescribed continuous renal replacement therapy, subject expected to survive for greater than 24 hours. Subjects will not be eligible for consent if any of the following criteria are met: pregnancy, prisoner, less than 18 years of age, receiving agents that may alter lacosamide plasma concentrations, subject unable to be consented. Patients will be identified by survey of the neurocritical care service census at the study center. Power analysis was not performed. Following consent lacosamide plasma, ultrafiltrate, and urine concentrations will be obtained at the following intervals: pre-dose, post-dose, 1, 2, 4, and 8 hours. The following pharmacokinetic parameters will be mathematically derived using Phoenix WinNonlin 6.0 (Registered
Trademark, Certara 2009): maximum and minimum plasma concentrations, half life, elimination rate constant, area under the plasma concentration time curve (0-24h), clearance, volume, sieving coefficient. Secondary outcomes include description of admitting diagnosis, lacosamide indication, survival, recurrent seizure activity, continuous renal replacement therapy prescription, demographics.

**Results:** This study is currently being reviewed by the Institutional Review Board at the study center.

**Conclusion:** This study is currently being reviewed by the Institutional Review Board at the study center.

**Poster Title:** Educational Needs of Hospice Providers Regarding the Use of Medical Cannabis

**Primary Author:** Kelly Mendoza, University of Maryland School of Pharmacy, MD; **Email:** ksmendoza11@gmail.com

**Additional Author(s):**
Mary Lynn McPherson

**Purpose:** Currently, 25 states and the District of Columbia have legalized or decriminalized cannabis (marijuana) for medical use despite remaining as Schedule I at the federal level. The benefits of medical cannabis have been shown in nausea and vomiting associated with cancer chemotherapy, cachexia associated with HIV/AIDS, and certain kinds of neuropathic pain or treatment-resistant cancer pain. However, it is unclear how comfortable hospice providers are with the concept of medical cannabis. The aim of this study is to determine changes in knowledge, skills, attitudes, and perceived knowledge gaps from hospice providers (physicians, pharmacists, nurse practitioners, etc.) regarding medical cannabis.

**Methods:** Working with a large national hospice and palliative care program that has operations in 19 states, an educational needs assessment survey has been developed to assess providers' knowledge, beliefs, concerns, and training needs regarding medical cannabis. The survey instrument has been field tested, assuring user friendliness and completeness. Participants will be asked to rate their self-perceived skills in the use of medical cannabis, and their opinion about educational content likely to be of interest to hospice providers. Survey results will guide the development of a training module for the providers regarding best clinical practices of medical cannabis. An online learning activity will be developed for asynchronous delivery. Participants will take a pre-course and post-course survey to assess changes in knowledge, skills, and attitudes in predetermined learning domains.

**Poster Title:** Improving knowledge, skills and attitudes (KSA) of community pharmacists in implementing fall prevention initiatives for older adults

**Primary Author:** Jazmin Turner, University of Maryland School of Pharmacy, MD; **Email:** jturner@rx.umaryland.edu

**Additional Author(s):**
Nicole Brandt
Chanel Whittaker
Lisa Huang
Linda Simoni-Wastila

**Purpose:** Falls in older adults is a growing public health concern, and they affect a large subset of older adults. Oftentimes, they result in injury, decreased quality of life, and death. Pharmacists can play an important role in preventing falls by screening for Fall Risk Increasing Drugs (FRIDs). The intent of this pilot program is to evaluate the effectiveness of a one-time educational seminar for community pharmacists on FRIDs and fall prevention strategies in two components: 1) improving pharmacists’ knowledge, skills, and attitudes (KSA) regarding FRIDs; and 2) increasing long term utilization of falls prevention initiatives in the community pharmacy setting.

**Methods:** This prospective pilot program focuses on practicing full time and part time community pharmacists in the greater Baltimore area in Maryland. Pharmacist participants will attend one live educational seminar regarding FRIDs and fall prevention tools and strategies that can be implemented in a community pharmacy setting. Continuing education credit will be offered as an incentive for participation in the study. At the beginning of the seminar, pharmacists will be asked to complete a survey that will assess demographics and KSA pertaining to FRIDs and implementing fall prevention initiatives. Pharmacists will then complete a post survey that will measure changes in their KSA. In order to measure sustainability and feasibility, the second phase of the study will ask pharmacists to track the number of falls initiatives they complete, as well as time spent (separated by pharmacist and non-pharmacist time) via a reporting system on a weekly basis over a three-month period. The categories for these initiatives include: 1) Educational Brochures; 2) Falls Risk Screens; 3) Patient/Caregiver
Counseling; 4) Medication Therapy Management: Targeted Medication Review focused on FRIDs; and 5) Medication Therapy Management: Comprehensive Medication Review. This study will be submitted to the University of Maryland Institutional Review Board for approval.

Poster Title: Evaluation of albumin use in medicine patients

Primary Author: Anne Masich, University of Maryland School of Pharmacy, MD; Email: amasich@rx.umaryland.edu

Additional Author (s):
Brian Grover
Asha Tata

Purpose: Albumin is a limited resource that can add significant expense to a hospital stay. It has been used for numerous indications, some with more robust evidence than others. While there are many potential uses for albumin, indications for use in adult medicine patients include the following: spontaneous bacterial peritonitis, large volume paracentesis, hepato-renal syndrome, and refractory diuresis. The primary outcome of this study is to characterize the use of albumin for patients admitted to medicine. Based on the results of the review, institutional guidelines may be modified to assist prescribers in ensuring appropriate use in this population.

Methods: This will be a retrospective electronic medical chart review that will be submitted to the institutional review board for approval. All adult patients admitted to general medicine teams who received albumin between January 1, 2016 to June 30, 2016 will be included. Patient demographics will be collected, including patient age, gender, weight, ethnicity, baseline albumin, renal function, and etiology of liver disease. If applicable, total volume removed during paracentesis will be collected. The dose, frequency and duration of albumin use, as well as the total cost and the indication documented on the albumin order will also be collected. Descriptive statistics will be used to analyze the data.

Poster Title: Facilitating home hospice transitions of care in oncology: Evaluation of pharmacist’s interventions and patient representation rates

Primary Author: Jueli Li, University of Maryland, MD; Email: jli@rx.umaryland.edu

Additional Author(s):
Alison Duffy
Nina Bembem
James Trovato

Purpose: Transitioning patients with terminal illnesses from inpatient settings to home hospice is often challenging due to the complex coordination of care required. Failure to anticipate symptom management needs can contribute to poor care transitions and increase representation rates. Pharmacist intervention may improve transitions of care in this population, yet the importance of medication reconciliation to home hospice transition is understudied. A transitions of care initiative was developed to streamline the transition from inpatient to home hospice, consisting of using a hospice discharge checklist, pharmacist discharge medication reconciliation, review of discharge prescriptions, and facilitation of bedside delivery of discharge medications.

Methods: This study evaluates the impact of the transitions of care initiative by characterizing pharmacist interventions, rate of patient representation, and effect on local hospice organizations’ perception of discharge readiness. This is a single center, prospective, pilot study comparing the pre-implementation period from July 1, 2015 through December 31, 2015 to post-implementation period from January 4, 2016 to April 1, 2017. Inclusion criteria include patients aged 18 years and older, an oncologic diagnosis, admission to the medicine service or Cancer Center, who are being transitioned to home hospice. Data identifying drug-related problems and the number and types of pharmacist interventions will be captured by the clinical pharmacist. Documentation in the electronic medical records will be used to retrospectively evaluate representation rates pre- and post-implementation for up to three months after discharge to home hospice. A pre- and post-implementation survey will be used to evaluate hospice organizations’ perception of discharge readiness. Descriptive statistics will be used to analyze the number and type of pharmacist interventions, as well as the hospice survey
responses. The Mann-Whitney U test will be used to compare hospital representation rates. Data collection and analysis are currently in progress.

Poster Title: Comparison of bivalirudin versus heparin in patients with acute coronary syndrome where percutaneous coronary intervention is performed at a private community hospital

Primary Author: Jenna Ramage, Baptist Memorial Hospital - Desoto, MS; Email: jenna.ramage@bmhcc.org

Additional Author(s):
Krista Bachert
Benjamin Eddlemon

Purpose: In the United States, heart disease is the leading cause of death, killing over 370,000 Americans per year. Anticoagulant therapy prevents thrombus formation at the site of arterial injury, on the coronary guidewire, and in catheters used for percutaneous coronary intervention. Conflicting evidence exists between the efficacy and safety of bivalirudin versus heparin in the setting of percutaneous coronary intervention in patients with acute coronary syndrome. The purpose of this retrospective study is to compare the incidence of thrombotic complications and bleeding events in patients who received bivalirudin versus unfractionated heparin during percutaneous coronary intervention for acute coronary syndrome.

Methods: A single center retrospective chart review of patients who underwent percutaneous coronary intervention (PCI) for acute coronary syndrome who received either bivalirudin or unfractionated heparin will be conducted. Adult patients greater than or equal to 18 years of age will be included in this study. Patients excluded from this study are those who experienced cardiac arrest during the procedure, required a mechanical assist device, received target temperature management for pulseless ventricular tachycardia, required coronary bypass graft during the same hospitalization in which PCI was performed, and those who were identified as pregnant at the time of admission. The primary objective is to measure the incidence of thrombotic complications within 30 days of intervention. The secondary objective is to compare the incidence of bleeding events that occurred within 72 hours after PCI in the bivalirudin versus unfractionated heparin groups. The incidence of thrombotic complications will be measured by a chart review of each patient thirty days after PCI. If an admission is available, the
chart will be reviewed to determine if the admission was indicative of thrombotic complications. This study is pending Institutional Review Board approval.

**Poster Title:** Aripiprazole-induced Neuroleptic Malignant Syndrome (NMS): A case report

**Primary Author:** Rachel Swearingen, Baptist Memorial Hospital - North Mississippi, MS; **Email:** rachel.swearingen@bmhcc.org

**Additional Author(s):**

**Purpose:** Neuroleptic Malignant Syndrome (NMS) is a life-threatening neurologic emergency that is characterized by mental status and behavioral changes, muscle rigidity, laboratory abnormalities, fever and dysautonomia. This distinctive clinical syndrome is associated with the use of neuroleptic agents, in particular first generation antipsychotics. This case report illustrates the development of NMS after reinitiating a patient’s home antipsychotic agent. The patient was a 37 year old African American female who was transferred to our facility from an outside hospital for further evaluation of elevated troponin, elevated lactic acid and hypokalemia after prolonged heat exposure on August 24, 2016. She presented with complaints of dizziness, diaphoresis, leg cramping, hand stiffening, and fall. She had a past medical history that included hypertension and bipolar disorder. The patient was admitted to ICU stepdown with a troponin of 3.69 ng/mL and creatinine kinase (CK) of 23750 U/L. She was given Potassium 40mEq, NS (0.9%) 1000mL bolus, Humalog and Pepcid. On the morning of admission day 2, she was found to have a troponin of 4.82 ng/mL and CK of 49508 U/L, and her home medications were restarted, including aripiprazole 10mg po daily. Later this same morning she was diagnosed with rhabdomyolysis and her aripiprazole was discontinued after patient received one dose due to elevated CK. The patient was started on continuous heparin infusion and D5W with Na Bicarb 150mEq infusion. On admission day 3, the patient began complaining of further leg cramping, reported she was hot and dizzy and was found to be hyperthermic, tachycardic with a heart rate in the 150-180’s and had a CK>50000 U/L. At this time, she was thought to have NMS and one dose of IV dantrolene 1mg/kg (92.9mg) was ordered. She was also noted to have contractures in her feet and upper extremities. She was given 5 of IV Valium and transferred to the ICU where her NMS resolved. A few hours later, the morning of day 4, the patient had a recurrent episode of fever and rigidity, and her CK remained >50000 U/L. This recurrent episode was again resolved with one IV dantrolene 1mg/kg (92.6mg). The patient was then ordered oral dantrolene 100mg q6h for maintenance. The afternoon of day 4, the patient had a 3rd episode of NMS, was given a 3rd dose of IV dantrolene 1mg/kg (92.6mg), the
dantrolone 100mg q6h po was changed to IV and she was started on bromocriptine 10mg po TID. By day 5, the patient has improved significantly, lab values began improving and the dantrolene maintenance was discontinued and changed to PRN, while the bromocriptine was increased to 20mg TID until patient was discharged on September 6. Upon discharge, the patient was found to need home oxygen as a result of respiratory distress experienced during her episodes of NMS. Patients typically develop NMS hours or days after first exposure to the causative drug, most within the first 30 days. In this case, the patient had chronically used aripiprazole, a second generation antipsychotic, and the development of NMS after one dose in the hospital was thought to be precipitated by her dehydration and prolong heat exposure. This case of NMS was resolved after aggressive fluid and medication management. Given the amount of neuroleptics prescribed by physicians and the complications of NMS, the recognition and appropriate management of this syndrome should be addressed.

**Poster Title:** Comparison of the risk of bleeding in patients receiving triple antithrombotic therapy in a private community hospital

**Primary Author:** Erik Scott, Baptist Memorial Hospital Desoto, MS; **Email:** erik.scott@bmhcc.org

**Additional Author(s):**
- Ben Eddlemon
- Clara Bailey
- Claudia Smith
- Krista Bachert

**Purpose:** According to the 2016 ACC/AHA Guideline Focused Update on Duration of Dual Antiplatelet Therapy in Patients with Coronary Artery Disease, clopidogrel is the antiplatelet of choice when triple therapy is warranted. The guidelines note the addition of dual antiplatelet therapy to anticoagulant therapy increases bleeding complications by two to three fold. There is limited data comparing the incidence of bleeding among the multiple combinations of antiplatelets and anticoagulants currently available. The purpose of this study is to retrospectively compare the incidence of bleeding events associated with triple antithrombotic therapy over a three, six and/or twelve month interval.

**Methods:** This study is a single center, retrospective chart review of patients receiving triple antithrombotic therapy. Computerized medical records will be used to identify patients at the investigation site who are concurrently receiving aspirin plus either clopidogrel, prasugrel, or ticagrelor plus either warfarin, apixaban, rivaroxaban, or dabigatran from January 2015 through September 2016. Patients will then be divided into twelve groups based on the antithrombotic therapy combination. Patients will be included if they were started on triple antithrombotic therapy during the investigation period. Information gathered for each patient will include comorbidities, duration of triple therapy, INR (if on warfarin) and demographic data to determine population variances. Patients will be excluded if they are pregnant or less than 18 years of age. This study is pending Institutional Review Board approval.

Poster Title: Improving utilization of prescription assistance programs for eligible uninsured and under-insured patients in a community hospital system

Primary Author: Alice Morgan, Baptist Memorial Hospital North Mississippi, MS; Email: akcave1@hotmail.com

Additional Author (s):

Purpose: Pharmaceutical prescription programs are available for eligible patients but are often underutilized in the hospital system. Improved utilization of these programs could improve quality care for the patients and in turn improve quality outcomes within the hospital system. A program to revise the current process for obtaining patient’s medications as they transition out from inpatient care will be implemented through a partnership with case management and pharmacy. Department training and education will be provided and utilization will be evaluated for success prior to implementing revised process compared to after implementation of revised process for utilizing patient assistance programs.

Methods: Patients will be identified through the EPIC system and a partnership between pharmacy and case management to identify eligible patients who are on medications that are available through patient assistance programs. Pharmacy will contact patients who were offered patient assistance options 30 days prior to implementation of revised approach to determine if after discharge medications were accessed and program benefits utilized. Barriers to access post discharge will also be assessed. These results will be compared to patient’s access and barriers after revised program was implemented. The month of October will be used to in-service and educate case management and pharmacy departments on available programs and how to access these programs most effectively. Beginning November 1, 2016, case management will record eligible patients and patient assistance programs offered and pharmacy will follow up with patient post discharge to determine success in obtaining desired medications and any barriers that occurred in the process.

Poster Title: Evaluation of fluoroquinolone use in the behavioral health center population at St. Dominic's Hospital

Primary Author: Cassie Crew, St. Dominic Hospital, MS; Email: ccrew@stdom.com

Additional Author(s):
Jessica Dana
Mary McClung

Purpose: The new fluoroquinolone boxed warning highlights the risk of severe side effects that involve the tendons, muscles, joints, nerves, and central nervous system, thus this class of drugs has now been reserved for more severe infections. Based on the warning, fluoroquinolones are no longer recommended for sinusitis, bronchitis, and uncomplicated urinary tract infection, unless no other antimicrobial options are available. Because of the frequent use of fluoroquinolones in low acuity settings, a medication utilization evaluation is warranted. The purpose of this study is to determine indication, side effects, and drug interactions of fluoroquinolone use in a low acuity setting.

Methods: This will be a retrospective chart review of the first 30 consecutive patients who meet inclusion criteria over a 6 month span. Data will be collected from the patient’s chart and electronic medical record from St. Dominic Hospital. Patients will be analyzed if they meet inclusion criteria: over 18 years old, admitted into the St. Dominic Hospital in-patient behavioral health center, and fluoroquinolone use for over 48 hours. The data collected includes: age, gender, race, number of days on fluoroquinolones, indication for fluoroquinolone use, medication list, drug allergies, home medication list, co-existing conditions, and any adverse reactions. Upon completion of data collection, patient account numbers and patient identifiers will be removed and will not be retained. The data collected will be stored within a password-protected document on a password protected desktop computer. Data will be analyzed using descriptive statistics to explain fluoroquinolone use in behavioral health center population. Inappropriate use of fluoroquinolones in this patient population would include: use for off label indication, use when other antimicrobial agents are preferred, or use for new black box warning criteria of sinusitis, bronchitis, and uncomplicated urinary tract infection.

Poster Title: Evaluation of discharge diuretic dose in decompensated heart failure

Primary Author: Soomin Kim, St. Dominic Hospital, MS; Email: ksoomin@umich.edu

Additional Author (s):
Krista Riche

Purpose: Acute exacerbations of heart failure usually require admission to the hospital, and diuretics are recommended as first-line therapy to manage fluid overload symptoms. It is not clear, however, on how the dose should be transitioned from an inpatient dose to a home dose to be taken after discharge. As of current, we are uncertain of the relationship between admission, inpatient, and discharge doses of diuretics at St. Dominic Hospital. This study will define these relationships and enable us to determine potential targets for improved pharmacotherapy. We will also identify any trends with our diuretic dosing practices and 30-day readmission rates.

Methods: This will be a prospective cohort study that will include patients admitted for heart failure exacerbation to determine their diuretic dose before admission, during admission, and at discharge. Then we will collect data on 30-day readmission rates on the same patients to determine if an association exists between changes in diuretic doses throughout the patient’s hospital stay and 30-day readmission rates. The study population will include patients who were admitted for heart failure exacerbation and met the inclusion criteria. Data will be collected from the patients’ chart and electronic medical record from St. Dominic Hospital. Data to be collected include patients’ home diuretic dose, total daily scheduled dose of diuretic on the last day of admission, and the discharge dose. Other data to be gathered include the prescribing physician, gender, age, and patient’s compliance to the diuretic at home. Protected patient identifiers such as names and account numbers will not be retained. The primary outcome will be differences in diuretic doses prescribed at discharge vs. admission and inpatient. The secondary outcome will be 30-day readmission rates in relation to diuretic doses. For statistical analysis, we will use student t-test for continuous data and X2 test for nominal data. We also plan to perform a subgroup analysis only including those patients who were compliant with their diuretics prior to admission.

Poster Title: Impact of sacubitril/valsartan at lower than target doses on hospitalizations in heart failure with reduced ejection fraction

Primary Author: Kristin Rieser, University of Mississippi School of Pharmacy, MS; Email: krieser@umc.edu

Additional Author (s):
James Pitcock
Scott Malinowski
Anne Marie Liles
Joshua Fleming

Purpose: Many patients are unable to tolerate the target dose of sacubitril/valsartan achieved in the PARADIGM Trial. More information is needed to determine if heart failure patients benefit from lower doses. The primary objective of this study is to determine if sacubitril/valsartan at doses less than 97/103 milligrams twice daily reduces hospitalizations in heart failure patients with reduced ejection fraction compared to other medications that target the renin–angiotensin–aldosterone system, such as, angiotensin converting enzyme inhibitors or angiotensin II receptor blockers. Secondary objective includes determining the percentage of patients started on the dose recommended by the sacubitril/valsartan Food and Drug Administration labeling.

Methods: This study will be submitted to the University of Mississippi Medical Center Institutional Review Board for approval. A report generated through the electronic health record will identify patients that have been prescribed sacubitril/valsartan between July 1st, 2015 and October 31st, 2016. Patients that have been seen in a UMMC Outpatient Heart Failure Clinic at least once in the 6-months prior or 6-months after sacubitril/valsartan initiation will be included. The following data will be collected: patient age, gender, ethnicity, ACC/AHA Heart Failure Stage, NYHA Functional Class, dose of ACEi or ARB prior to sacubitril/valsartan initiation, blood pressure, serum creatinine/eGFR, maximum tolerated dose of sacubitril/valsartan, number of hospitalizations for the 6 months pre- and post-sacubitril/valsartan initiation, and concomitant medications for the treatment of heart failure.
Hospitalizations rates for the 6 months prior to sacubitril/valsartan initiation will be compared to hospitalization rates for the 6 months post sacubitril/valsartan initiation using a McNemar's test. Initial sacubitril/valsartan dose will be categorized as appropriate or not appropriate based on current FDA-approved labeling. Descriptive data will be used to elucidate the existence of trends.

*Poster Title:* Comparison of patient outcomes for patients with diabetes enrolled in different medication adherence programs

*Primary Author:* Lena McDowell, University of Mississippi School of Pharmacy, MS; *Email:* ldmcldowe@olemiss.edu

*Additional Author(s):*
- Jordan Ballou
- Lauren Bloodworth

**Purpose:** In Mississippi, one in eight adults report a diagnosis of diabetes. Medication nonadherence contributes to diabetes progression and complications. The objective of this study is to determine if Parata Patient Adherence Strip System (PASS) packaging improves clinical outcomes in patients with diabetes when compared to a traditional medication vial adherence program.

**Methods:** This study will be submitted to the University of Mississippi Institutional Review Board for approval. Patients of Tyson Drug Company (TDC) who are currently taking at least one medication for diabetes will be invited to participate. Baseline assessments will include hemoglobin A1c (HbA1c), lipid panel, systolic/diastolic blood pressure, waist circumference, and body mass index. Subjects with a HbA1c value above seven percent will continue with the intervention. Subjects will be randomized into one of two intervention groups: TDC model or Right Way Meds (RWM) model. In the TDC model, subjects will receive their medications in medication vials on the same date each month; whereas, subjects in the RWM model will receive their medications in customized Parata PASS packaging every twenty-eight days. In both models, pharmacy technicians will make monthly reminder telephone calls, verifying medications, arranging pickup/delivery, and inquiring about provider visits. The primary outcome will be the change in HbA1c from baseline. The secondary outcomes will include percentage of patients achieving HbA1c goal of less than seven percent, change in blood pressure, medication adherence, patient satisfaction in pharmacy care, and quality of life assessment.

**Poster Title:** Comparison of depression screening methods for patients with diabetes in a community pharmacy setting  

**Primary Author:** Elisha Smith, University of Mississippi School of Pharmacy, MS; **Email:** esmith11@umc.edu  

**Additional Author(s):**  
Leigh Ann Ross  
Olivia Strain  
Anne Marie Liles  
Jordan Ballou  

**Purpose:** Major depressive disorder affects approximately 31% of patients with diabetes. It has been suggested that for a large proportion of people, the diagnosis of depression is unrecognized. The community pharmacist is in a unique position to assist in screening for depression due to their accessibility to the community. The primary objective is to implement and evaluate pharmacist-administered depression screenings for patients with diabetes through 3 different methods within the community pharmacy to determine most effective approach. The secondary objectives are to determine if referral results in initiation of treatment and assess the barriers associated with declined depression screenings.  

**Methods:** This study will be submitted to the Institutional Review Board for approval. Patients filling at least one diabetic medication the last 3 months at 2 Walgreens locations will be invited to participate. Patients will be offered a depression screening (PHQ-9) to be provided in one of the following settings: medication therapy management (MTM) encounter, informational session, or pharmacist consultation. Patients meeting inclusion criteria who are scheduled for MTM visits will be offered the screening after the MTM encounter. The second method includes informational sessions advertised with flyers placed on prescription bags of patients meeting inclusion criteria. During each of four sessions depression and diabetes will be discussed. All attendees will be offered a depression screening. The final method is a pharmacist consultation at prescription pick-up. During prescription verification, a consult requirement will be placed on the prescriptions of patients meeting inclusion criteria. During the pharmacist consultation the screening will be offered. Informed consent will be signed.
Study activities will be conducted in a private consultation room. For the screening, the PHQ-9 will be administered and demographic and primary care provider information will be collected. Patients will be called 3 months following the screening to determine referral results. The primary outcome is percentage of patients screened by each method. Those declining the screening will be invited to complete a brief survey regarding reasons for declining.

Poster Title: Renal and blood pressure outcomes with sodium glucose co-transporter 2 inhibitor initiation and concurrent diuretic dose reduction: a retrospective cohort analysis

Primary Author: Dylan Lindsay, University of Mississippi School of Pharmacy, MS; Email: dlindsay@umc.edu

Additional Author (s):
Courtney Davis
Anne Marie Liles
Scott Malinowski
Marshall Boudin

Purpose: The CDC predicts that 1 in 3 adults in the U.S. will have diabetes by the year 2050. Many patients with diabetes have other cardiometabolic comorbidities, including hypertension. As such, many are already treated with a diuretic prior to initiating an SGLT2 inhibitor. As both of these classes exert their effects renally, many empirically reduce the dose of pre-existing diuretics when initiating an SGLT2 to circumvent potential adverse events. Little data exists confirming the actual benefits of this practice. This project was designed to compare outcomes between cohorts initiating SGLT2s with and without concurrent dose reduction for pre-existing diuretic regimens.

Methods: Electronic patient charts from the Diabetes Care Group clinic in Flowood, MS, as well as family medicine and internal medicine clinics at the University of Mississippi Medical Center will be reviewed in a retrospective fashion for all patients identified as having initiated SGLT2 therapy between March 2013 and September 2016. Information collected will include all of the following for eligible patients at baseline and follow-up: hemoglobin A1C (HgbA1C); serum sodium, potassium, creatinine, blood urea nitrogen, glucose; eGFR; and blood pressure. For the purposes of this study, “baseline” is defined as most recent values within 6 months of SGLT2 initiation; “follow-up” is defined as all values collected within 6 months following SGLT2 initiation. Outcome measures for this study will include mean reductions in HgbA1C and blood pressure in the intervention and control groups, as well as a hazard ratio comparing incidence of AKI between intervention and control groups. A t-test will also be performed to analyze baseline and follow-up laboratory values between intervention and control groups.

**Poster Title:** Patient vs pharmacist perceptions on key educational points in diabetes counseling in the community pharmacy setting.

**Primary Author:** Dhruilikumar Patel, Walgreens, MS; **Email:** dhruil.patel@walgreens.com

**Additional Author(s):**
Catherine Bates
Karla Foster
Olivia Strain

**Purpose:** This study aims to compare the pharmacists’ and patients’ perceptions on key educational points in diabetes counseling in the community pharmacy setting; and to determine pharmacists’ confidence in key areas of diabetic counseling versus patients’ confidence in key areas of diabetes self-care. The American Diabetes Association discusses strategies for improving diabetes care and lists key objectives to help healthcare professionals support diabetic patients. Determining whether pharmacists and patients are synchronized on important areas of diabetes counseling and areas of confidence in diabetes care may help the pharmacist focus on what the patient perceives is most valuable when counseling diabetic patients.

**Methods:** This research is a prospective observational study. It will be implemented at 10 sites of a large chain community pharmacy in the Mississippi. All community pharmacists and patients at participating locations will be asked to complete a 5-point Likert scale survey which will consist of 27 questions each. Participation in the research will be voluntary and anonymous. Participating patients will receive 1000 balance rewards points for completing the survey. Potential participants will be identified during the dispensing process by pharmacists and technicians. A list of diabetic medications will be reviewed with staff members and posted at the filling station to assist in identifying patients. The pharmacists and technicians will flag prescriptions for diabetic medications with a bull’s eye to alert staff members at the prescription pick-up window. At the pick-up window, staff members will be trained to distribute the survey to eligible patients and ask them to participate in the study. Patients 18 years and older with type 2 diabetes will be included. Completed surveys will be returned to a secure area of the pharmacy until collection by the principal investigator. Patients with type 1 diabetes,
pregnant women, those who are unable to speak English, cognitively impaired or unable to make decisions, and who are blind or deaf will be excluded. The data will be analyzed using descriptive statistics.

Poster Title: Implementation of pharmacist-led Medicare annual wellness visits in two hospital-based clinics

Primary Author: Caleb Little, Carolinas Healthcare System, NC; Email: caleb.little@carolinashealthcare.org

Additional Author (s):
Kamaria Brown
Shay Phillips

Purpose: The Affordable Care Act implemented preventive services for Medicare beneficiaries in the form of annual wellness visits (AWV) in 2010. Although there is no patient copay, utilization of AWVs remains low nationwide partially due to the lack of time physicians have to discuss preventive health with patients as opposed to acute issues. However, such visits may be conducted by licensed healthcare professionals, including pharmacists, under the direct supervision of a physician. The objectives of this study are to determine the feasibility of implementing AWVs conducted by pharmacists in two hospital-based clinics as well as explore the outcomes of the visits.

Methods: Screening for participation in the pharmacist-led AWVs will be prospectively conducted via the electronic medical record (EMR). Patients that meet the inclusion criteria (≥ 66 years of age with Medicare coverage, a current patient of either clinic, and have not received an Initial Preventative Physical Examination or AWV within the past 12 months) will be contacted by the pharmacist to determine interest in completing an AWV. A letter will be sent to interested patients providing an overview of the visit and forms the patient should complete prior to their appointment. During the AWV, the following will be determined per Medicare requirements: weight, height, blood pressure, functional status, presence of cognitive impairment, signs of depression, complete medication list, past medical history, social history, list of medical providers, and any other medical information or test deemed necessary based on past medical history or family history. Upon completion of the AWV, the pharmacist will complete medication therapy management (MTM), develop and discuss a personal health maintenance and prevention plan and provide referrals for completion of preventive measures or for follow-up with a provider given uncontrolled/untreated disease states. A patient
satisfaction survey will be provided as well. Completion of preventive screenings and referrals will be assessed 3 months after the visit.

Poster Title: Filgrastim in the inpatient care setting: a medication use evaluation

Primary Author: Morgan Humphrey, Carolinas HealthCare System - NorthEast, NC; Email: morgan.humphrey@carolinashealthcare.org

Additional Author(s):
Jeryl Villalolid
Dragos Plesca

Purpose: Myeloid growth factors such as filgrastim, pegfilgrastim, and sargramostim stimulate proliferation, differentiation, and activity of cells in the myeloid lineage. By shortening the neutropenic interval, patients are less likely to become febrile and acquire infection. Another use includes mobilizing stem cells prior to hematopoietic stem cell transplantation. This medication use evaluation will assess the current prescribing patterns, dispensing, administration, and monitoring of filgrastim in the inpatient care setting at Carolinas Medical Center (CMC) and Carolinas HealthCare System – NorthEast (CHS-NE). Potential cost savings will be evaluated if tbo-filgrastim or filgrastim-sndz were used in place of the reference product, filgrastim.

Methods: This Institutional Review Board-approved, retrospective chart review will include patients who received at least one dose of filgrastim at CMC or CHS-NE during the evaluation period of January 1, 2016 to March 31, 2016. Pediatric patients will be excluded. Documented bone pain will be recorded for adverse event monitoring. Prescribing will be evaluated according to FDA indication, weight-based dose rounding, filgrastim administration timed at least 24 hours post-chemotherapy, and discontinuation in hematopoietic stem cell transplant patients according to standard operating procedures. Data will be collected from the electronic medical record according to proposed criteria and protected within the Research Electronic Data Capture (REDCap) management system. The collected data will be analyzed using descriptive statistics.

Poster Title: Evaluation of a pharmacist-led asthma and chronic obstructive pulmonary disease (COPD) management service in a collaborative primary care setting: a prospective cohort study

Primary Author: Lydia Wang, Carolinas HealthCare System NorthEast, NC; Email: lydia.wang@carolinashcare.org

Additional Author (s):
Casey Burleson
David Frate
Danny Fu

Purpose: Asthma and COPD are two of the most common lung diseases in the United States. Asthma attacks and COPD exacerbations are frequent among these patients and lead to increased healthcare utilization, costs, and mortality. Pharmacists are in a unique position to fill the need for targeted care for these patients with their education, training, and presence in outpatient clinics. The objective of this study is to evaluate the impact of pharmacist intervention on asthma and COPD outcomes in the primary care setting through disease education, guideline-directed optimization of medication regimens, and counseling on inhaler use technique and tobacco cessation.

Methods: Patients who are at least 18 years of age, receive primary care at Ardsley Internal Medicine – Concord, and have uncontrolled, symptomatic asthma and/or COPD will be eligible for selection. Eligible patients will be identified through a population health management database for the practice or will be directly referred by practice healthcare providers. The selected patients will be contacted by phone for enrollment into the study. An initial 60-minute clinic visit with the pharmacist will be scheduled for the patient. During initial visits, patients will fill out questionnaires standard to patients with respiratory conditions. The following data will be collected: age, gender, race, tobacco use, health-related quality of life, medication adherence, unplanned healthcare utilization, vaccination status, and disease/symptomatic control. Patients will then receive spirometry testing performed by the pharmacist and interpreted by the overseeing physician. The pharmacist will provide disease state education, optimize medication therapy through recommendations to providers, counsel on medication and inhaler use technique, and schedule follow-up visits. There will be an interim, optional, 60-
minute group smoking cessation class, as well as a 60-minute follow-up visit to perform repeat spirometry, complete the same questionnaires and a patient satisfaction survey, and assess medication and inhaler use technique. All data will be recorded without patient identifiers and maintained confidentially. Post-pharmacist intervention data will be compared to initial, baseline data to determine changes in pre-specified outcomes.

Poster Title: Pharmacist involvement in an interdisciplinary care team providing personalized healthcare within the Proactive Health model

Primary Author: Stephanie Barquero, Carolinas Healthcare System NorthEast, NC; Email: stephanie.barquero@carolinashc.org

Additional Author (s):
Gregory Weidner
Paige Carson
Monique Lucas

Purpose: Concierge medicine is a growing area of healthcare in which pharmacy services have not yet been implemented. The purpose of this project is to evaluate the impact of a pharmacist as part of a concierge healthcare model by defining potential existing pharmacy related problems and identifying the most needed pharmacist services that will enhance personalized patient care.

Methods: This study has been approved by the Institutional Review Board. The project will enroll and see patients in person and using virtual technology during a six-month period from October 2016 to April 2017. Either the patient or another health care team member can request pharmacy services, at which point the patient would be enrolled. After enrollment and before the patient’s clinic visit is performed, the requested pharmacist services will be recorded and the patient’s electronic medical record will be reviewed for areas needing pharmacist intervention. These areas to be identified on the patient’s medical record would include: number of medications and existing duplications, drug-drug/drug-supplement/drug-food interactions, and needed medication titrations based on most recent labs. The patient will then have a clinic visit to address these issues and be asked to give feedback on pharmacist participation in their care via survey. After the initial visit, the patient can have subsequent visits for follow up on interventions made. They can also interact with the pharmacist (and other team members) via cell phone app for more personalized/on demand care. Patient non-specific requests from other members of the care team (for example drug information questions and drug cost evaluation) will be recorded with the corresponding pharmacist action performed.

**Poster Title:** Medication use evaluation of sodium polystyrene sulfonate in the hospital setting

**Primary Author:** Kyle Osborne, Carolinas Healthcare System Northeast, NC; **Email:** kyle.osborne@carolinashealthcare.org

**Additional Author(s):**
Rebecca Szymanski

**Purpose:** Sodium polystyrene sulfonate (SPS) has been associated with multiple reports of bowel necrosis, and its efficacy has come into question with the emergence of two novel potassium-binding resins for the treatment of hyperkalemia. This study seeks to assess the prescribing patterns, monitoring, efficacy, and incidence of adverse events related to the administration of SPS in the acute care setting.

**Methods:** This is a retrospective chart review of patients admitted to Carolinas HealthCare System NorthEast and administered SPS during their stay. This study was deemed quality improvement by the health system’s Institutional Review Board. The electronic medical record was used to identify patients that received at least one dose of SPS between January 1, 2016 and July 31, 2016. A random sample of 100 patients was chosen for the study. The following data will be collected: patient age, gender, actual body weight, length of stay, comorbidities, prescribing physician, dose and route of SPS, and baseline serum creatinine and potassium level. The medication administration record will be reviewed to identify concomitant medications used for the treatment of hyperkalemia and medications that have the potential to interact with SPS. Lab values and physician progress notes will be used to note any adverse events or electrolyte abnormalities resulting from the administration of SPS. The primary endpoint is to determine the mean change in serum potassium. Secondary endpoints include the percentage of patients remaining hyperkalemic or experiencing hypokalemia following the administration of SPS, the incidence of adverse events related to SPS administration, and the percentage of patients receiving repeat doses of SPS.

Poster Title: Effectiveness of a Pharmacist-Managed Hypertension Clinic with Incorporation of 24-Hour Blood Pressure Monitoring in Patients with Uncontrolled Hypertension: A 6 Month Prospective, Randomized, Controlled Trial

Primary Author: Laura Lacey, Carolinas HealthCare System NorthEast, NC; Email: laura.lacey@carolinash Heathcare.org

Additional Author(s):
Kristie Clark
Andrew Clark
Lindsay Sheehan
Nick Wilkins

Purpose: Although patients with hypertension are at increased risk for multiple comorbidities such as heart disease, stroke, heart failure, and chronic kidney disease, roughly half of patients with hypertension remain uncontrolled. Additionally, ambulatory blood pressure monitors are currently underutilized in practice to identify patients with nocturnal or resistant hypertension. The objective of this study is to evaluate the effectiveness of a pharmacist-led hypertension clinic with incorporation of continuous blood pressure monitors on blood pressure control rates at 3 months in patients with uncontrolled or resistant hypertension.

Methods: This study has been submitted and approved by the Institutional Review Board. The study will be conducted at two internal medicine clinics within Carolinas HealthCare System NorthEast. Study participants will be randomly selected from the Tableau patient population report, as well as through physician referrals. Additionally, a control group will be randomly selected from the Tableau patient population report. Patients in the intervention group will be contacted to schedule an initial pharmacist-led hypertension clinic appointment for a comprehensive medication review, evaluation of adherence and lifestyle, and application of a continuous blood pressure monitor. Using results from the continuous blood pressure monitor, as well as data collected from clinic visits, the pharmacist will make appropriate adjustments to the medication regimen under a collaborative physician-pharmacist practice agreement and protocol. The pharmacist will schedule additional follow-up appointments with each patient to reassess hypertension control, adherence, and lifestyle modifications. All data will be recorded
without patient identifiers and maintained confidentially. In-clinic blood pressure measurements, medication interventions, BMI, and number of antihypertensive medications will be assessed at 3 months and at study end.

**Poster Title:** Medication use evaluation of midazolam infusions in the intensive care unit at Carolinas Healthcare System NorthEast (CHS NE)

**Primary Author:** Erin Cichonski, Carolinas HealthCare System NorthEast, NC; **Email:** erin.cichonski@carolinashealthcare.org

**Additional Author(s):**
Desiree Kosmisky
Sonia Everhart

**Purpose:** The American College of Critical Care Medicine has established guidelines recognizing that the use of benzodiazepines for sedation in the intensive care unit (ICU) may contribute to an increased length of stay, increased time on the ventilator, and delirium. The objective of this study is to determine if the management of sedation at CHS NE complies with current best practice recommendations.

**Methods:** This IRB approved retrospective chart review will identify patients who received a midazolam continuous infusion between 01/01/16 and 06/30/16 through a medication administration report. Patients will be included if they are admitted to the CHS NE ICU and received a midazolam infusion while in the ICU. Patients will be excluded if the patient is less than 18 years old, the midazolam infusion was used for the treatment of status epilepticus, if the patient was pregnant, or if the patient was receiving comfort care. Baseline demographics will be collected including age, sex, weight, renal function, and documented liver impairment. Other characteristics related to medication administration will be assessed: ICU length of stay, target/actual RASS scores, use of alternative agents, midazolam dosing, prescribing physician, adverse effects, the strategy used for discontinuation of midazolam. Appropriateness of prescribing will be evaluated to determine the need for revision of current practice to reduce the risk of adverse events associated with benzodiazepine sedation.

**Poster Title:** Assessing the impact of medication therapy management and pharmacist collaboration with home health allied health professionals on hospital readmission rate, falls, and emergency room visits

**Primary Author:** Jaymin Shah, Carolinas HealthCare System Northeast
North Carolina, NC; **Email:** shahjr@goldmail.etsu.edu

**Additional Author (s):**
Becky Szymanski
Tina Hipp
Dawn Brooks
Jennifer Boggs

**Purpose:** The purpose of this pilot program at Carolinas HealthCare System Northeast (CHS-NE) is to determine the value of medication therapy management (MTM) offered by a pharmacist during discharge for patients who are being newly enrolled in Carolinas HealthCare System Healthy@Home (CHS HH), a home health agency.

**Methods:** This Institutional Review Board exempt quality improvement study will measure readmission rates, emergency room visits, and falls for 30 days following discharge from CHS-NE and admission to CHS HH. Patients experiencing the current standard of care during October and November 2016 will serve as the baseline group. The intervention group will include patients enrolled in CHS HH during the months of December 2016 through February 2017. This group will receive modified MTM services from a pharmacist at discharge and as needed phone collaboration with a CHS HH allied health professional. The modified MTM service will include a comprehensive medication regimen evaluation. Recommendations will be discussed with the provider. At discharge, the medication list will be reviewed by the pharmacist to ensure accuracy and counseling will be provided on this new plan. Inclusion criteria includes age greater than 17 and new enrollment with CHS HH services. Patients with less than five medications and those whose primary language is not English will be excluded. Additionally, patients discharged without the full pharmacist intervention will be excluded from intervention group. Data collected will include demographic variables, number and type of medication
related problems identified, and time to resolve mediation related problems. Pre-defined categories will be used to classify medication problems.

Poster Title: Medication use evaluation: Adjunct aripiprazole use in major depressive disorder

Primary Author: Jayme-Jo TenBieg, Carolinas Medical Center, NC; Email: jayme-jo.tenbieg@carolinashealthcare.org

Additional Author(s):
Kristen Nagy

Purpose: Aripiprazole is an appropriate adjunct medication for the treatment of major depressive disorder (MDD), but there are other medications that cost less, require less monitoring, and have equivalent outcomes. The purpose of this medication use evaluation (MUE) is to assess how many antidepressants were used and maximized prior to the addition of aripiprazole when treating MDD. The results of this evaluation may provide opportunities for medication optimization and determine where a pharmacist can provide education to physicians who are treating patients with major depressive disorder.

Methods: This study is a retrospective review of aripiprazole that was institutional review board exempt. The prescription filling system and the electronic medical record (EMR) will be utilized. Patients who have filled aripiprazole in conjunction with other antidepressants between January 1, 2016 and July 31, 2016 will be evaluated for the following inclusion criteria: at least 18 years of age, being treated for MDD, the prescribing provider is within the Carolinas HealthCare System, and started aripiprazole therapy within the past year of the fill history. Patients with a concurrent mental health diagnosis that would meet a label indication for aripiprazole use outside of MDD will be excluded. After meeting this criteria, a maximum of 100 patients will be reviewed one year prior to filling the medication. The following information will be collected from physician notes and maintained using REDCap: diagnosis of MDD, prescribing provider groups, past MDD treatment (including medications, dosing, and duration of each medication trial), monitoring for adverse drug reactions, and the cost of aripiprazole to both the health plan and the patient. The information will be analyzed through descriptive statistics using percentages, means, medians, modes, and ranges.

**Poster Title:** Medication use evaluation: Digoxin in pediatrics

**Primary Author:** Hali Schwind, Carolinas Medical Center, NC; **Email:** hali.schwind@carolinashealthcare.org

**Additional Author(s):**
Steve Martin

**Purpose:** Routine therapeutic drug monitoring in pediatric patients who are treated with digoxin is not recommended due to a lack of correlation between digoxin levels and clinical efficacy or toxicity in this patient population. Furthermore, the dosing strategy of digoxin is complex and dependent upon indication, age, and route of administration. Without an available prescribing order set, the potential for medication errors exists. The purpose of this medication use evaluation is to assess the current prescribing, monitoring, and outcomes associated with digoxin use in pediatric patients at a children’s hospital.

**Methods:** This study was submitted to the Institutional Review Board for approval and was deemed exempt. It will include pediatric patients at Levine Children’s Hospital from January 1, 2016 to June 30, 2016 who were treated with digoxin. The anticipated sample size will be approximately 30 patient encounters. Patients will be identified via a report of digoxin use provided by pharmacy services. Data will be collected retrospectively via electronic medical record and protected using REDCap data management. Prescribing data, dosing information, product information, laboratory and monitoring data, adverse effects, and outcomes will be collected. Descriptive statistics including means, medians, ranges, and percentages will be used to analyze data.

**Results:** NA

Poster Title: Use of high-dose thromboprophylaxis in obese patients

Primary Author: Enoch Claude, Carolinas Medical Center, NC; Email: enoch.claude@carolinashc.org

Additional Author(s):
Jamie Lynn Sebaaly
Katherine Rector

Purpose: The purpose of this medication use evaluation is to evaluate prescribing, monitoring and outcomes of enoxaparin and unfractionated heparin (UFH) when used for venous thromboembolism (VTE) prophylaxis in obese patients hospitalized at a single academic medical center.

Methods: This medication use evaluation will be a retrospective evaluation of all adult patients on VTE prophylaxis with a body mass index (BMI) greater than or equal to 40 kg/m2. Pregnant patients will be excluded. Additionally, patients with an estimated creatinine clearance less than 30 ml/min in the enoxaparin group will be excluded. An estimated 100 patients will be included.

Variables that will be evaluated include the VTE prophylaxis dosing strategy used, as well as the proportion of obese patients on the recommended VTE prophylaxis dosing for enoxaparin per the institution’s recommended order set. Additionally, VTE during admission, bleeding events and anti-Xa levels (if monitored) will be evaluated. REDCap will be used for data collection and protection of all patient information. Data collected during this evaluation will be analyzed using descriptive statistics (mean, median, mode) and will be represented as percentages.

The primary objective is to determine which dosing strategies for enoxaparin and UFH are being used for VTE prophylaxis in obese patients at an academic medical center. Secondary objectives include incidence of new VTE during admission and bleeding while on therapy. Other secondary objectives include anti-Xa levels, if collected, and dose adjustments performed in response to anti-Xa levels.

Poster Title: Evaluation of the extended spectrum triazoles (voriconazole, posaconazole, and isavuconazole) at a large, tertiary care center

Primary Author: Amy Ellenburg, Carolinas Medical Center, NC; Email: amy.ellenburg@carolinashealthcare.org

Additional Author(s):
Kelly Pillinger
Margaret Croom
Zainab Shahid

Purpose: Invasive fungal infections (IFI) cause significant morbidity and mortality in immunocompromised patients. The extended spectrum triazoles, voriconazole, posaconazole, and isavuconazole, have different roles in the prevention and treatment of IFI. All three agents are on formulary at Carolinas Medical Center; however, prescribing restrictions have been placed on posaconazole and isavuconazole. The purpose of this project is to assess the prescribing patterns and compliance with restriction policies of the extended spectrum triazoles.

Methods: This is a single center retrospective chart review of all adult patients admitted to Carolinas Medical Center between July 1, 2015 to June 30, 2016, who received at least one dose of an extended spectrum triazole. In the event of multiple admissions during the study period, only the first admission will be included provided that the same extended spectrum triazole was used during each admission; if a change of extended spectrum triazole occurred during the study period, the patient may be included more than once. The electronic medical record will be used to gather data including age, gender, comorbidities, indication for use, dispensing formulation, provider and corresponding provider group, inpatient restriction criteria compliance, duration of extended spectrum triazole therapy, change in antifungal agent and reasons for change, use of combination antifungal therapy, therapeutic drug monitoring, and continuation of triazole in the outpatient setting.

Poster Title: Medication use evaluation of erythropoiesis stimulating agents at a tertiary care institution

Primary Author: Maxine Mueller, Carolinas Medical Center, NC; Email: maxine.mueller@carolinashealthcare.org

Additional Author (s):
Mei Ka Fong
Dragos Plesca
Lesli Lavery

Purpose: Epoetin alfa and darbepoetin alfa are erythropoiesis stimulating agents (ESAs) that stimulate the division and differentiation of committed erythroid progenitor cells, ultimately inducing the release of reticulocytes from the bone marrow into the bloodstream. Among the Federal Drug Administration (FDA) approved indications, treatment of anemia due to chronic kidney disease (CKD) and chemotherapy are the most common. The objective of this study is to evaluate the utilization of ESAs at select Carolinas HealthCare System (CHS) facilities, which will include the evaluation of prescribing, dispensing, monitoring, and outcomes of ESA use in CHS, and assess compliance with FDA requirements.

Methods: This study will be submitted to the Institutional Review Board for approval. This will be a retrospective chart review of adult patients who received at least one dose of epoetin alfa or darbepoetin alfa either in the inpatient or outpatient setting during the month of January 2016 at selects CHS facilities. Patients will be identified using the individual charge codes for each ESA on the hospital’s formulary. Data will be deidentified, collected in a password protected database, and analyzed using descriptive statistics.

Results: N/A

**Submission Category:** Drug-Use Evaluation/ Drug Information  

**Submission Type:** Research-in-Progress  

**Session-Board Number:** 10-198  

**Poster Title:** Medication use evaluation: Cefepime and neurotoxicity  

**Primary Author:** Seema Patel, Carolinas Medical Center, NC; **Email:** seema.patel@carolinashealthcare.org  

**Additional Author(s):**  
Carrie Griffiths  
John Story  

**Purpose:** Cefepime can induce neurotoxicity, which can manifest as encephalopathy, aphasia, myoclonus, seizures, and nonconvulsive status epilepticus. The Food and Drug Administration reviewed case reports and case series which showed that patients who most commonly developed neurotoxicity with cefepime were 50 years of age or older, had underlying renal dysfunction, often did not receive appropriate dosage adjustments based on renal function, or had prior neurological disease. The primary objective is to determine the incidence of neurotoxicity with the use of cefepime and describe patient characteristics in patients with neurotoxicity.  

**Methods:** This is a retrospective study conducted at Carolinas Medical Center (CMC) that was deemed exempt by the Investigational Review Board. A preliminary search of the pharmacy database for patients who had cefepime profiled on their medication list during hospitalization at CMC between December 1, 2015 and May 31, 2016 will be performed. A random sample of 200 patients will be included. Patients who are greater than 18 years of age and have received extended-infusion cefepime for at least 72 hours will be assessed. Patients with a documented uncontrolled neurologic disorder at baseline will be excluded. Electronic medical records will be used to collect data, including baseline characteristics, cefepime initial dose and duration, renal function, symptoms of neurotoxicity, and concomitant medications that can also cause neurologic symptoms. Symptoms of neurotoxicity will be identified through physician documentation in daily progress notes, documented Glasgow Coma Scale (GCS), and electroencephalogram (EEG) findings. The Naranjo score will be calculated in patients noted to have evidence of neurotoxicity from cefepime to identify likelihood of causality. All data collected will be protected using the REDCap data management system. Data will be analyzed using descriptive statistics with means, medians, ranges, and percentages.

Poster Title: Pharmacist intervention on antibiotic de-escalation in pneumonia at CaroMont Regional Medical Center

Primary Author: Olivia Morton, CaroMont Regional Medical Center, NC; Email: ohmorton0902@email.campbell.edu

Additional Author(s):
Sarah Murphy
Tamoor Asif

Purpose: The cost of pneumonia care at CaroMont Regional Medical Center is higher than the national average. This has prompted closer prospective antibiotic review to improve patient outcomes by decreasing total days of antibiotic therapy, reduce length of stay and reduce total cost of care. The purpose of this study is to evaluate the impact of pharmacist recommendations for antibiotic de-escalation in pneumonia patients.

Methods: Pending Institutional Review Board approval, this study will be conducted as a prospective cohort study, using a retrospective control group. The following pertinent data will be collected: diagnosis (type of pneumonia), age, gender, renal function, comorbidities, day of therapy that pharmacist intervention occurred, total number of days of antibiotic therapy and length of stay. The information for the retrospective control group will be obtained from patient visits during the months of November 1, 2015-January 31, 2016. For the prospective portion of the study, antibiotic regimens will be evaluated in real-time, using Electronic Health Record software, during the months of November 1, 2016-January 31, 2017. The principal investigator will evaluate the patient based on culture data at 48 hours and clinical signs of infection (white blood cell count, measures of oxygenation, core temperature, initial and follow up chest X-ray), and determine if de-escalation is appropriate. If the patient is clinically stable to no longer require broad spectrum IV antibiotics, the provider will be contacted by telephone to propose de-escalation. If recommendations are accepted, this information will be documented as such. Data will be obtained without any patient identifiers and patient confidentiality will be maintained.

**Poster Title:** Dyspeptic pain relief in an acute care setting when comparing liquid antacid therapy with or without the use of local anesthetic agent

**Primary Author:** Pinky Mahbubani, CaroMont Regional Medical Center, NC; **Email:** pmahbuba@gmail.com

**Additional Author (s):**
Kevin Lynch
Patrick Passaretti

**Purpose:** While the use of liquid antacid combined with viscous lidocaine (GI Cocktail) is widespread, there has been limited research showing that the use of additional agents provides significant pain relief in patients with dyspepsia. The purpose of this study is to determine if liquid antacid (aluminum hydroxide, magnesium hydroxide, and simethicone) alone is as effective as using GI Cocktail when treating dyspepsia related pain symptoms the emergency department.

**Methods:** This study will be conducted as a retrospective chart review study comparing the effects of liquid antacid versus the use of liquid antacid with viscous lidocaine for acute treatment of dyspepsia related pain. Eligible patients will be identified when providers order either liquid antacid or GI Cocktail while in the emergency department. Patients enrolled in this study include those greater than or equal to 18 years old with complaints of dyspeptic symptoms. Patients must have documented baseline pain score prior to receiving the medication and up to three hours after, per standard of care. The following data will be collected: age, gender, date and location of admission, chief complaint, time the medication was administered, pain score at time zero (0) then up to three hours after receiving the medication, rescue agents used, concurrent medications administered during the time frame of assessing pain relief, and documented adverse reactions. Data will also be collected assessing the expenses of compounding GI Cocktail. Data for both groups will be collected in patients who presented to the emergency department prior to July 31, 2016. Patient data will be collected up until the time power is met. Based off of previous studies, adequate pain relief will be defined as a change in pain score greater than or equal to three points from patient’s baseline.

**Session-Board Number:** 10-201

**Poster Title:** Impact of pharmacist-driven intensive care unit (ICU) delirium screening and management on adult patient outcomes

**Primary Author:** Emily Weisz, CaroMont Regional Medical Center, NC; Email: emily.weisz@caromonthealth.org

**Additional Author(s):**
Sarah Murphy
Holly McLean

**Purpose:** ICU-acquired delirium has been associated with poor clinical outcomes, including increased mortality, prolonged hospital and ICU length of stay and extended duration of mechanical ventilation. The Pain, Agitation and Delirium Guidelines advocate the use of validated screening tools to identify patients who develop delirium. The purpose of this study is to implement prospective, pharmacist-driven interventions using a validated screening tool to reduce the incidence, severity and complications of ICU-acquired delirium.

**Methods:** This study will be completed with Institutional Review Board approval and will be conducted as a pre- and post-interventional study with a retrospective control. Pharmacist interventions will include education of ICU nurses, assimilation of the Confusion Assessment Method for the ICU (CAM-ICU) into routine patient assessments, and prospective therapy recommendations to ICU nurses and physicians. Education will ensure baseline understanding of delirium, and provide an introduction to delirium screening using the CAM-ICU. Once education is initiated, delirium screenings with the CAM-ICU will be conducted daily by ICU nurses with the assistance of the primary investigator. The results of the screening will then be used to guide pharmacological and non-pharmacological recommendations as appropriate. Pharmacological interventions will concern the appropriate selection and administration of sedatives, analgesics and antipsychotics in addition to the timely re-initiation of home medications. Non-pharmacological recommendations will include strategies to improve patient orientation. The primary outcome of this study will be to assess the impact of pharmacist interventions on delirium management and patient outcomes, and will be determined by comparing average ICU length of stay prior to and after intervention. The secondary outcomes will be: average number of ventilator days, number of interventions attempted and
implemented, and type of interventions made. Pertinent patient data will include such parameters as demographics, home medications, CAM-ICU findings and ICU length of stay.

Poster Title: Implementation of a pharmacist driven discharge medication reconciliation on the medical unit of a small community hospital

Primary Author: Lindsey Arthur, Carteret General Hospital, NC; Email: lcarthur@ccgh.org

Additional Author(s):
Sara Shearin
Leslie Barefoot
Michael Soucie
Miles Kline

Purpose: The Joint Commission recommends a process for reconciling medications at all interfaces of care, including admission, transfer, and discharge with involvement from patients, responsible physicians, nurses, and pharmacists. Medication reconciliation has been recognized as a National Patient Safety Goal, due to the increase in readmission rates and adverse events medication discrepancies can cause. The purpose of this study is to identify whether a multidisciplinary approach with a pharmacist performing discharge medication reconciliations will reduce discharge-related medication errors in a small community hospital using an electronic health record.

Methods: This study is a retrospective chart review evaluating pre-specified endpoints before and after the implementation of pharmacists driven discharge medication reconciliation on the medical unit of a small community hospital. A list of patients to be potentially discharged will be provided by the case managers and responsible physicians during daily rounds. The patient population will include those that are discharged from the medical unit during clinical pharmacist hours of seven-thirty in the morning to four o’clock in the afternoon. The designated clinical pharmacist will screen each patient’s discharge medication list to ensure proper drug indications, proper dose adjustments if needed, avoidance of duplicate therapy, and drug interactions. The primary endpoint is medication error rates prior to pharmacist review of discharge medication reconciliations compared with pharmacist review of discharge medication reconciliations. The chart review will be conducted utilizing Sentri7 software to analyze patients admitted from December 2015 through January 2016 compared to data from December 2016 through January 2017. Secondary endpoints include percent of medication
errors corrected before discharge, time to perform discharge medication reconciliation, 30 day readmission rates, hospitalist satisfaction with service via electronic survey, and pharmacist satisfaction with service via electronic survey.

**Poster Title:** Implementation and impact of a pharmacist-driven electrolyte replacement policy in a small, community hospital

**Primary Author:** Heather Powell, Carteret Health Care, NC; Email: hrpowell@ccgh.org

**Additional Author(s):**
Leslie Barefoot
Debra Pittman
Miles Kline
Sara Shearin

**Purpose:** Electrolyte disturbances are common in hospitalized patients, and replacement can consume significant nursing, pharmacy and physician time. The practice of electrolyte replacement can be variable and low electrolyte levels can increase patients’ risk of numerous severe outcomes. Currently at Carteret Health Care (CHC), the replacement of potassium, magnesium, calcium and phosphorus are not standardized and rely heavily on provider intervention. The purpose of this study is to evaluate the impact of a pharmacy-driven electrolyte replacement policy developed to more effectively address electrolyte depletion throughout the hospital.

**Methods:** This study is a retrospective chart review comparing the effectiveness of electrolyte replacement at Carteret Health Care before and after implementation of a pharmacist-driven electrolyte replacement policy. The study population will be identified by chart review using the electronic medical records in addition to our web-based pharmacist clinical support tool, Sentri7 software, to analyze patients admitted from December 2015 through February 2016, comparing data from December 2016 through February 2017. Major outcomes include the time between availability of results and the ordering of replacement, post-replacement levels, number of critical low levels per day, replacement doses, replacement route, arrhythmias, overall satisfaction of policy implementation, and length of stay. Inpatients greater than the age of 18, with a serum creatinine less than 2 mg/dL, a BUN less than 30 mg/dL and a urinary output greater than 30 mL/hr will be included in this study. Patients will be excluded from this study if they are receiving total parenteral nutrition, chronically malnourished, experience a rise in serum creatinine >0.5 mg/dL over a 48-hour period, or qualify for inclusion in the diabetic
ketoacidosis/ hyperosmolar hyperglycemic state protocol. At the end of this study, a policy will be developed allowing for the automatic replacement of electrolytes by pharmacists at Carteret Health Care.

Poster Title: Impact of naltrexone for extended-release injectable suspension on alcohol and opioid dependence-related hospital readmissions

Primary Author: Brittany Williams, Catawba Valley Medical Center, NC; Email: brwilliams@cvmc.us

Additional Author (s):
Charles Davis
Isabelle Eustice
Rigardy Munoz
Kevin Ussery

Purpose: Opiate and alcohol abuse-related hospital admissions are a major concern for hospitals nationwide. With limited access to treatment facilities, patients have few options to pursue treatment for addiction when they are ready to stop abusing. Vivitrol is a long-acting opioid antagonist that prevents the user from experiencing effects of abusing alcohol and opiates and reduces cravings. The purpose of this study is to determine if providing Vivitrol to patients admitted to the psychiatric floor for alcohol or opiate abuse will impact alcohol and opiate dependence-related hospital readmissions.

Methods: This study has been approved by the Institutional Review Board. Adult patients admitted to the psychiatric floor for alcohol or opioid dependence who are clinically appropriate for therapy and provide informed consent will be enrolled in the study. Patients who require treatment for any condition with opiates, are unable to complete the entire detoxification period, have psychiatric conditions that require immediate attention as determined by a psychiatrist, female patients who are pregnant or breastfeeding, and patients who fail a naltrexone challenge will be excluded from this study. Participants will receive one 380mg injection of Vivitrol (naltrexone for extended release-injectable suspension) prior to discharge from psychiatric unit. Participants will be required to return to the hospital’s Infusion Center for follow-up Vivitrol injections every 28 days for up to 6 months. At the follow-up injections, patients will complete a survey collecting data on age, gender, ethnicity, substance of abuse, substance use in the last 28 days, cravings experienced, hospital re-admissions, employment status, and satisfaction with Vivitrol treatment. Previous hospital admissions,
length of hospital stay, insurance information, and county of residence will be collected as well. All information will be de-identified, recorded electronically and secured on a private server with two levels of password protection. The primary outcome will be the number of hospital readmissions compared to the number of hospital admissions prior to beginning Vivitrol therapy.

Poster Title: Standardized versus non-standardized management of alcohol withdrawal syndrome.

Primary Author: Tiffany Tweed, Catawba Valley Medical Center, NC; Email: ttweed@cvmc.us

Additional Author(s):

Purpose: Early intervention with symptom-triggered dosing of benzodiazepines (BZDs) is recommended to prevent progression of alcohol withdrawal syndrome (AWS). Symptom-triggered dosing regimens typically utilize one of the validated Clinical Institute Withdrawal Assessments for Alcohol, revised scales (CIWA-AD or CIWA-Ar) designed to identify symptoms of AWS before they escalate into severe complications. The purpose of this study is to compare length of stay and critical care admission rates in patients diagnosed with alcohol withdrawal syndrome managed with or without the standardized CIWA-AD order set.

Methods: This IRB approved research utilizes a descriptive comparative study design. The study setting is a not-for-profit hospital in the Southeastern United States, whose service area ranks fifth among the state’s eight regions in excessive alcohol consumption among its residents. Subject recruitment is based on the 10th revision of the International Statistical Classification of Diseases and Related Health Problems (ICD-10-CM) diagnosis of alcohol withdrawal. Subject selection is dependent on available complete electronic medical record information. Exclusion criteria include: age less than 18 years; admission to psychiatric, emergency and surgical departments; pregnant women; and Department of Corrections patients. Length of stay, critical care unit admission, CIWA-AD score, additional drug therapy required, adverse drug reactions associated with AWS treatment, time from admission to first dose of BZD, treatment duration, comorbidities, inpatient location, age, and gender are the data being collected. Electronically entered data are stored on a private facility server requiring two levels of password protection. Once collection is complete, the data will be de-identified via alphanumerical coding prior to analysis and subsequent reporting of the findings to protect subject confidentiality. Data will be organized with descriptive statistics to include: mean, standard deviation, range, mode, median, frequency, percentage, and correlation coefficient. Inferential statistics will be utilized to determine significance using an alpha of 0.05 to include: two-tailed Student’s t-test, Chi-squared analysis, and stepwise regression.

Poster Title: Retrospective evaluation of an empiric vancomycin dosing nomogram in achieving goal steady-state trough concentrations in obese adults weighing at least 100 kilograms

Primary Author: Riley Bowers, Duke Regional Hospital, NC; Email: riley.bowers@duke.edu

Additional Author(s):
April Cooper
Catherine Wente
Dustin Wilson
Steven Johnson

Purpose: More than one-third of adults in the United States are obese, putting them at increased risk for heart disease, stroke, and diabetes. Additionally, the physiologic changes from obesity impact antimicrobial pharmacokinetic properties. These changes affect antimicrobial efficacy and toxicity, especially in weight-based dosing for antimicrobials such as vancomycin. Published studies have offered differing approaches to vancomycin dosing in obesity with variable results. As of yet, there is no consensus. The purpose of our study is to validate a newly implemented vancomycin dosing nomogram in achieving goal steady-state trough concentrations for obese adults weighing at least 100 kilograms.

Methods: This single-center, retrospective cohort study has been submitted to the Institutional Review Board. The primary objective is to describe the percentage of obese adult patients weighing at least 100 kilograms achieving initial steady state goal trough concentrations when dosing was initiated at a dose and frequency consistent with our institutional nomogram. Patients will be identified using reports generated from the Duke Enterprise Data Unified Content Explorer. Inclusion criteria for the study include adult inpatients who weigh at least 100 kilograms with a body mass index of at least 30 kilograms per meter squared. They must receive at least 3 stable vancomycin doses and have at least one steady-state trough concentration obtained. Exclusion criteria are pregnancy, renal replacement therapy, unstable renal function, severe liver dysfunction, and patients 30 days or less post-transplant. For patients receiving multiple courses of vancomycin during a single admission, only the first course will be included in the study. Separate admissions for the same patient will be counted as individual cases. Data collected will include patient demographics such as gender, age, and
weight. Other data collected will include vancomycin indication, dosing regimen, trough concentrations, and timing of doses and troughs. Serum creatinine and estimated creatinine clearance will also be collected. Upon data analyses, the nomogram will be adjusted in subgroups based on weight and renal function.

**Poster Title:** Risk versus benefit of interrupting oral anticoagulation therapy following gastrointestinal bleed

**Primary Author:** Jordan Carrera, Duke Regional Hospital, NC; Email: jordan.carrera@duke.edu

**Additional Author(s):**
April Cooper
Catherine Wente

**Purpose:** The purpose of this study is to assess risk versus benefit of interruption of oral anticoagulation (OAC) therapy following gastrointestinal (GI) bleed in patients treated at a community hospital. The primary objective is to compare number of thromboembolic events in patients with duration of OAC interruption less than 30 days from GI bleed onset to patients with duration of OAC interruption greater than or equal to 30 days from GI bleed onset. Secondary objectives include: to compare number of re-bleed events, to compare 30-day all-cause hospital readmission rates, and to compare clinical management of patients.

**Methods:** This single-center, retrospective cohort study will be submitted to the Institutional Review Board for approval. We will review the electronic medical records of patients admitted for GI bleed or patients who developed GI bleed during hospitalization between January 1, 2010 and December 31, 2016. Patients will be included if they were at least 18 years old and taking at least one OAC at the time of GI bleed. Patients will be excluded if they had a diagnosis of chronic liver disease, end stage renal disease, or if they did not survive the first 72 hours of GI bleed. Patients will be stratified into two cohorts. The first cohort will consist of patients who were restarted on OAC therapy between zero and 30 days after GI bleed onset. The second cohort will consist of patients who were not restarted on OAC therapy within 30 days of GI bleed onset. The primary outcome will be thromboembolic events. Secondary outcomes will include re-bleed events, all-cause hospital readmissions within 30 days after discharge, continuation of original OAC agent, switching from original OAC agent to an alternative OAC agent, OAC agent ordered on discharge, time until OAC agent restarted, OAC not re-started, blood and/or fresh frozen plasma transfusion, treatment with four-factor prothrombin complex concentrate, hospital length of stay, and mortality.

**Session-Board Number:** 10-208  
**Poster Title:** Impact of a procalcitonin guided algorithm on length of stay in inpatients with acute chronic obstructive pulmonary disease exacerbations  
**Primary Author:** Lori Mor, Duke Regional Hospital, NC; **Email:** lori.mor@duke.edu  
**Additional Author(s):**  
John Boreyko

**Purpose:** Currently, the most common predictor of an acute exacerbation of chronic obstructive pulmonary disease (AECOPD) is the presence of purulent sputum. Although antibiotics are often prescribed for these patients, it has been shown that up to 50 percent of AECOPD cases are of viral origin. The excessive usage of antibiotics can result in increased collateral damage and adverse events. Serum procalcitonin has been found to increase in bacterial infections such as respiratory tract infections but remains low in viral infections. Use of a procalcitonin level may therefore encourage a clinician’s decision to forego antibiotics in a patient experiencing an AECOPD.

**Methods:** This single site, retrospective, cohort study is designed to implement the use of a single procalcitonin level as a surrogate measure for antibiotic usage in AECOPD. Upon admission, based on clinician discretion, the patient will undergo this rapid diagnostic test, which will help guide antibiotic therapy throughout their hospital stay. This procalcitonin guided therapy cohort will be compared to a historical cohort utilizing data collected before the implementation of procalcitonin guided therapy. The primary objectives are to compare the duration of antibiotic usage in regards to AECOPD and assess the effect on length of stay between groups. Thirty day readmission rates will be compared between the procalcitonin guided therapy group and historical control as a secondary endpoint. Additionally, a cost-avoidance analysis will be conducted utilizing length of stay, medication usage, and readmission rates with the use of procalcitonin as a marker for bacterial infection in AECOPD compared to the historical control. This analysis will be assessed in cost per day avoided.

Poster Title: Urine Culture Specific Antibiogram Development for Outpatient Facilities Arranged Within a Multi-Hospital Health System

Primary Author: John Norris, FirstHealth Moore Regional Hospital, NC; Email: jnorris@firsthealth.org

Additional Author(s):
Drew Kessell
Kara Herlihy

Purpose: Urinary tract infections (UTIs) are the most commonly seen community acquired infections in the US, accounting for more than 8.6 million outpatient visits each year. Appropriate use of antibiotics leads to microbial resistance, but misuse of antibiotics greatly accelerates the occurrence. The over-prescribing of antibiotics in the community has become a national epidemic, leading to more severe, resistant infections in the emergency and acute care settings. The Food and Drug Administration recently released a safety alert for fluoroquinolone use in uncomplicated acute cystitis further limiting oral antibiotic options for urinary tract infections.

Methods: To minimize resistance and optimize appropriate antimicrobial therapy, we will assess urine cultures collected from outpatient facilities affiliated within our healthcare system to identify the in-vitro antimicrobial resistance patterns specific to our community. Data will be collected through a retrospective review of outpatient urine culture data from January 1, 2016 to September 9, 2016. Organism identification and antimicrobial susceptibilities were extracted via an automated infection control surveillance system. This surveillance system consolidated organism-specific urine cultures and their respective antimicrobial susceptibilities. Each common pathogen was identified, and specific resistances and susceptibilities data were reviewed. Given the prominent use of antibiotics in the ambulatory setting, specific attention was paid to oral treatment options. Organisms with less than 30 samples of growth on cultures were excluded from this review. Once community antimicrobial resistance patterns are identified, information will then be disseminated to ambulatory care providers affiliated within our healthcare system. Education will be provided regarding resistance issues, most prevalent uropathogens, and appropriate
empiric options. Knowledge of community urine culture resistance patterns will also allow comparison to our current inpatient antibiogram. Comparison of urine cultures to overall antimicrobial resistance patterns may lead to subsequent research opportunities, if antimicrobial susceptibility differences are found between culture sources.

Poster Title: Prescribing characteristics of proton pump inhibitor orders at a small, rural academic medical center

Primary Author: Lundy Gunn, Harnett Health, NC; Email: lrgunn1231@email.campbell.edu

Additional Author(s):
Ruthanne Baird
Kim Kelly

Purpose: The true cost of inappropriate proton pump inhibitor prescribing behavior is largely unknown and has not been clearly defined in the small, rural inpatient hospital setting. Recent studies show associations between proton pump inhibitor therapy and adverse effects such as Clostridium difficile infection, community-acquired pneumonia, acute kidney injury, chronic kidney disease, and increased risk of fractures. The objective of this study is to characterize the rate of inappropriate proton pump inhibitor orders for adult inpatients at a small, rural academic medical center.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify adult inpatients admitted who receive a medication order for a proton pump inhibitor. The following data will be collected: current proton pump inhibitor medication, dose, route, frequency, indication, age, length of stay, C. difficile tests if collected, and whether the patient was discharged on proton pump inhibitor therapy. ICD-10 diagnosis codes and provider documentation will be reviewed to determine indication for proton pump inhibitor treatment. All data will be recorded without patient identifiers and maintained confidentially. Aggregate rate of adult inpatients receiving proton pump inhibitor for all inappropriate indications will be determined as the primary endpoint. Secondary endpoints include rates of adult inpatients receiving proton pump inhibitor orders for individual clinical indications, the number of adult inpatients receiving proton pump inhibitor orders for inappropriate or unclear indications, the number of patients discharged on inappropriate proton pump inhibitor therapy which was not a prior home medication, rate of adult inpatients receiving proton pump inhibitor orders with doses higher than those recommended by guidelines, and incidence of C. difficile infection in patients receiving proton pump inhibitors.

Poster Title: Levofloxac, ciprofloxacin, and ceftriaxone in the hospital for the treatment of uncomplicated urinary tract infection: A retrospective medication-use evaluation

Primary Author: Manali Patel, Harnett Health System, NC; Email: mapatel0123@email.campbell.edu

Additional Author(s):
Ruthanne Baird
Veena Patel
Kim Kelly

Purpose: Antimicrobial resistance is a global public health challenge accelerated by the over-prescribing of antimicrobial medications for conditions that are normally self-limiting; this not only increases the risks of adverse effects, but can also result in longer hospital stays, and increased mortality. Acute uncomplicated urinary tract infection is one of the most common indications for prescribing antimicrobials for otherwise healthy women. The purpose of this study is to evaluate the inappropriate utilization of levofloxac, ciprofloxacin, and ceftriaxone therapy in hospitalized patients for uncomplicated urinary tract infection at a rural, community hospital in North Carolina.

Methods: A retrospective review of electronic medical records (EMR) will be conducted to evaluate the use of levofloxac, ciprofloxacin, and ceftriaxone for the treatment of uncomplicated urinary tract infection. A report will be generated through the EMR to identify patients who received levofloxac, ciprofloxacin, and ceftriaxone between June 1, 2016 and August 31, 2016. A second report will be generated to identify patients between June 1, 2016 and August 31, 2016 who had “Urinary tract infection, site not specified” ICD 10 code assigned upon discharge. The two reports will be used to review medical records retrospectively to screen patients for eligibility to meet the inclusion/exclusion criteria for inclusion in the study. Only adult patients admitted to the inpatient medical or observational unit will be included. Patients treated with levofloxac, ciprofloxacin or ceftriaxone for an indication other than urinary tract infection or asymptomatic bacteriuria will be excluded. The cohort will be evaluated for percent of levofloxac, ciprofloxacin, and ceftriaxone used for the inappropriate
treatment of uncomplicated urinary tract infection. Additionally, it will be evaluated for percent of patients with uncomplicated urinary tract infection treated with a regimen that is in compliance with Infectious Disease Society of America (IDSA) treatment guidelines and percent of patients with uncomplicated urinary tract infection treated for the appropriate duration of therapy as recommended in the IDSA treatment guidelines.

**Poster Title:** Outcomes from the implementation of a pharmacy technician discharge medication review program

**Primary Author:** Douglas Fisher, Mission Hospital, NC; **Email:** douglas.fisher@msj.org

**Additional Author (s):**
Cristy Singleton
Aubrie Rafferty
Brenda Asplund
Sheri Denslow

**Purpose:** Providing patients with an up-to-date, accurate medication list is one of The Joint Commission’s National Patient Safety Goals and provides a safe transition of care out of the hospital. While pharmacists are considered medication experts, budget constraints often prevent institutions from having pharmacists review discharge medication lists for every patient prior to discharge. Therefore, a program was designed using pharmacy technicians to increase the reach of a pharmacy discharge medication review program while minimizing budgetary impact. The study objective is to evaluate the impact of a pharmacy technician-led discharge medication review on 30-day hospital re-presentation rates.

**Methods:** This study has been submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients being discharged who do not already qualify for our existing transitions of care medication review program. The pharmacy technician will review the discharge medication list for accuracy and report any discrepancies identified to a pharmacist. The pharmacist will then contact the prescriber for clarification regarding the discrepancies determined to be clinically relevant. Both the pharmacy technician and pharmacist will complete a data collection form to be reviewed by the principal investigator. The following data will be collected: patient age, gender, race, ethnicity, admission diagnosis, discharge medications, discharge medication discrepancies, discharge disposition, and 30-day hospital re-presentations. The principal investigator will review the type of medication discrepancies identified, the percentage of high risk medications involved, and unplanned hospital re-presentations 30 days after discharge. High-risk medications are defined as any anticoagulant, opioid, or insulin.

**Session-Board Number:** 10-213

**Poster Title:** Impact of incorporating student pharmacists in a transitions of care (TOC) program in a community hospital.

**Primary Author:** Jenna Solomon, Mission Hospital, NC; **Email:** jenna.solomon@msj.org

**Additional Author(s):**
Aubrie Rafferty

**Purpose:** Transitions of care (TOC) is now recognized as a strategic component of hospitalization, and has expanded the role of pharmacists. Some institutions may not have the pharmacist resources for TOC. Student pharmacists can serve as pharmacist extenders in TOC to expand the reach of the inpatient pharmacist, and to provide additional cost-benefit to the hospital. The purpose of this project is to evaluate the impact of student pharmacists performing TOC services while teamed with an inpatient pharmacist.

**Methods:** This study will be a before and after comparison of TOC activities between a dedicated TOC pharmacist (before) and a student pharmacist paired with a TOC pharmacist (after). From September 2013 to May 2014, a study was completed during which a dedicated TOC pharmacist provided inpatient TOC services to a select group of inpatients. The pharmacist reviewed medication history and admission reconciliation, assessed barriers with the patient and caregiver, reviewed discharge reconciliation, performed discharge education, and communicated with the next level of care. Any patient with a planned discharge home from the medical-surgical progressive care unit or the pulmonary care unit was included in the study. Prospective analysis demonstrated a 50% reduction in 30-day re-presentation rates *(p < 0.01).* From June 2014 to October 2014, student pharmacists plus a pharmacist provided all inpatient and transitional medication management for patients discharging home. The pharmacist provided traditional inpatient care, and a student provided transitions of care for the same patients. Comparisons will be made in 30-day re-presentation rates with respect to volume of patients seen and volume of interventions per week. Institutional Review Board approval was obtained.

**Poster Title:** Anticoagulation Stewardship Program Development: Impact of Pharmacist Intervention on Anticoagulant Therapy in Patients with Cardioembolic Stroke Requiring Anticoagulation, a Pilot

**Primary Author:** Anna Bieniek, Mission Hospital, NC; **Email:** annabieniek623@gmail.com

**Additional Author(s):**
Krista Luck
Katie Sheldon
Carey Estes
Charles Allen

**Purpose:** Health-related stewardship programs ensure accountability in the management of resources, like medications. Tenets of stewardship programs include accountability, expertise, action, tracking, reporting, and education. Anticoagulation stewardship programs target safety, quality, and financial factors in all aspects of the medication use process with the goal to optimize the use of anticoagulants and clotting factor concentrates. A multidisciplinary committee currently monitors anticoagulation safety events and leads initiatives involving anticoagulants. The purpose of this study is to simulate stewardship interventions in a pharmacist-led pilot to illustrate the benefits in optimization of anticoagulation therapy and the need for an anticoagulation stewardship program.

**Methods:** This pilot is a prospective, single-center study simulation of an anticoagulation stewardship program on a neurology inpatient unit with a retrospective comparator. Pharmacists and providers will be educated by the investigator prior to the start of the pilot on guideline recommendations. Pharmacist intervention will include assessing anticoagulant therapy for appropriateness, evaluating medication access needs at discharge, commencing anticoagulation clinic referral process, and completing discharge patient education. Patients included in this study are age greater than 18 years of age, have a diagnosis of cardioembolic stroke, and admission to the pilot unit. Exclusion criteria include non-cardioembolic stroke and therapy with antiplatelet agents. The primary outcome is the significance pharmacist interventions targeted toward optimization of anticoagulation therapy upon discharge. Optimal therapy is defined as guideline-based, comorbidity-appropriate, and financially accessible.
Secondary outcomes include adherence to anticoagulation clinic follow-up, adherence to therapy, 30-day re-admission rate, bleeding events, medication access, and survey of provider education.

**Poster Title:** Impact of an expanded pharmacist-run video telehealth anticoagulation service in a rural health system

**Primary Author:** Marissa Rogoff, Mission Hospital and UNC Eshelman School of Pharmacy, NC; Email: marissa.rogoff@msj.org

**Additional Author(s):**
Kristin Duffey
Krista Luck
Elizabeth Michalets
Katie Sheldon

**Purpose:** Video telehealth is an emerging technology that can be utilized for disease state management, particularly for patients in rural communities with limited access to healthcare. Video telehealth may be useful for patients in western North Carolina prescribed warfarin who have to drive more than an hour each way for dosing and monitoring. Our objective is to determine the effectiveness of a recently implemented and expanded video telehealth anticoagulation service as measured by percentage of individual time in therapeutic range (iTTR) compared to baseline iTTR.

**Methods:** This study is a before-and-after comparison of patients managed by an outpatient anticoagulation clinic from August 2016 through February 2017. Patients will serve as their own controls. A subgroup of newly referred clinic patients will be analyzed separately. Data will be electronically abstracted, including calculations of the iTTR. Data collected includes age, gender, race, ethnicity, patient address, indication and duration of warfarin therapy, dates and results of INRs, number of visits, pharmacist visit time, number of cancellations/ no-shows, and number of warfarin dose changes. Rates of adverse effects such as thromboembolism, major bleeding, and clinically relevant non-major bleeding will also be evaluated. Patients will complete a survey before and after participating in the video telehealth service to assess perception of and satisfaction with anticoagulation video telehealth monitoring. Institutional Review Board approval was granted prior to study initiation.

**Poster Title:** Evaluation of antibiotic administration using a multi-disciplinary bundle in septic shock patients who present to the emergency department

**Primary Author:** Rylee Rankin, Mission Hospitals, NC; **Email:** ryleerankin@yahoo.com

**Additional Author(s):**
Ryan Tilton
Tiffany Gardella

**Purpose:** The Surviving Sepsis Campaign stresses the importance of timely antibiotic administration in septic patients. More specifically, it is recommended that antibiotics are administered to patients within three hours of arrival and within one hour of recognition of septic shock. As a result, Mission Hospital has implemented an emergency department (ED) Sepsis Plan. This multi-disciplinary order set assists providers in the rapid recognition of sepsis and provides treatment options including antibiotic recommendations. The objective of this study is to evaluate the use of the ED Sepsis Plan at Mission Hospital with a specific focus on its effect on antibiotic administration times.

**Methods:** In this single-center, retrospective, observational study, we evaluated 585 patients greater than or equal to 18 years of age who presented to the Mission Hospital ED with septic shock from December 4, 2013 to April 30, 2016. Patients transferred from another hospital, hospice, or court/law enforcement were excluded. Study subjects were categorized into three groups based on the utilization of the ED Sepsis Plan: patients with no ED Sepsis Plan ordered, patients with ED Sepsis Plan ordered, and patients with ED Sepsis Plan ordered but not utilized for antibiotic orders. Demographics, ED Sepsis Plan order time, first antibiotic order time, first antibiotic administration time, antibiotics administered during hospital stay, hospital length of stay, ICU admission, and discharge disposition were obtained. Time from patient arrival to antibiotic administration, time from antibiotic order to antibiotic administration, and time from recognition of septic shock to antibiotic administration were also determined. This study has received Institutional Review Board approval.

Poster Title: Assessment of the initial management of meningitis in a six hospital health system

Primary Author: Jared Chiusano, Mission Hospitals, NC; Email: jared.chiusano2@msj.org

Additional Author(s):
Lindsay Harris
John Phillips

Purpose: According to the Center for Disease Control, bacterial meningitis leads to death in approximately one in four cases. The disease progression is complex and can change rapidly. Appropriate medication prescribing and initial testing is paramount to the successful treatment of these patients, and omission in either of these areas may dramatically impact outcomes. The aim of this project is to assess the initial management in patients admitted to our six hospital health-system with suspected meningitis, compared to treatment guidelines. If current management is deemed sub-optimal, this may prompt the development of a meningitis specific order set within the health system.

Methods: This is an Institutional Review Board approved, retrospective, cohort study using an electronic medical record system. Patients will be included if they are 2 years to 100 years old and admitted with a diagnosis of meningitis to any Mission Health system hospital between November 2015 and November 2016, with at least one antibiotic administration. Data to be collected on each patient includes: age, gender, race, antibiotics given, doses, timing of administration, lab tests, screening exams, hospital campus, and culture results. Data points will be categorized as “screening” (example: computerized tomography scan), “testing” (example: viral polymerase chain reaction tests), and “treatment” (example: drug dosing and timing). If the management differs from current guidelines in any category, then it will be considered a failure to follow guidelines. Individual components within each category (testing, screening, and treatment) will be reviewed and evaluated as well. The primary objective is to determine the frequency at which providers in the Mission Health system order in accordance with expert guidelines. Secondary objectives are to assess individual parts (screening tests, lab tests, drugs, doses, and timing) of the expert guidelines compared to physician ordering and compare treatment differences by facility.

**Poster Title:** Evaluation of the characteristics and financial implications of inpatient cancer and immunologic treatments  

**Primary Author:** Austin Ginn, Mission Hospitals, NC; **Email:** austin.ginn2@msj.org  

**Additional Author(s):**  
Jolynn Sessions  

**Purpose:** In today’s healthcare environment, it is paramount that patients receive the correct level of care for the healthcare setting. Many new therapies for cancer and immune disorders are far more costly than most medications in an acute care setting, and are occasionally administered to patients while they are admitted at our institution. This raises the question of how often we are using these medications when they could be given in an outpatient setting instead. Our goal is to better understand the characteristics of these inpatient therapies, and uncover costs associated with the administration of these medications.  

**Methods:** This study is an IRB-approved, retrospective cohort study using electronic chart review of patients who were administered medications from a pre-selected list of high-dollar treatments while bedded in an inpatient ward at Mission Hospital. Inclusion criteria: Age > 18, Receiving 1 or more of a list of 30+ medications during admission between 1/1/2014 - 5/31/2016. Exclusion criteria: Pediatric oncology patients, patients with incomplete medical records. No control group on this study, as it is descriptive in nature. Primary outcome: Quantify administration rates of a group of high dollar medications. Secondary outcomes: Characterize the admission details surrounding patients receiving such medications such as admission reason, length of stay, readmission rates, 30d mortality. Determine direct costs associated with the dispensing and administration of these medications. Data collection variables: Age, gender, location, drug given, time drug given, admit date/time, depart date/time, LOS, admit reason, diagnosis for high-cost medicine, 30d mortality, 90d mortality, prescribing MD, admitting MD, total cost of hospital stay, cost of medication, payment data.

William Hitch

**Purpose:** Global health opportunities provide many educational benefits for clinical pharmacists. In 1990, Mountain Area Health Education Center (MAHEC) partnered with the Shoulder-to-Shoulder organization and began an annual inter-professional short-term medical brigade to Honduras. The pharmacy residency has participated in the experience since 2007. The objectives of this study were to describe the global health experiences of members of the inter-professional team specifically from clinical pharmacists’ perspectives and to understand the educational impact of the experiences.

**Methods:** A semi-structured interview study using a nine question interview guide was conducted.
1. Have you ever been to a country in the developing world?
2. Have you participated in medical brigades in the past?
3. What led you to participate in this trip?
4. Tell me about your typical day in Honduras.
5. Tell me about one of your most memorable experiences.
6. Tell me about a learning experience.
7. Tell me about a challenging experience.
8. Describe an experience that captures the essence of this trip.
9. Do you have any other stories or pieces of information you would like for me to know to help us better understand your experience?

Fourteen MAHEC pharmacy and family medicine faculty and residents who participated in the brigade during Fall 2014 and/or 2015 were interviewed. A phenomenological, thematic content
analysis (MAXQDA: Qualitative Data Analysis Software) of all participant interviews was conducted. Five interviews were transcribed verbatim and used to create the initial coding system. The remaining nine interviews were coded auditorily; representative quotes were transcribed verbatim. The results in this poster focus on the pharmacy perspective. Significant quotes from pharmacists were identified to represent and describe each theme. Mission Institutional Review Board approved this qualitative interview research.

**Results:** Five (35.7%) clinical pharmacists and nine (64.3%) physicians were interviewed. Over half of the pharmacists had previous global health experience, but only one spoke Spanish. Five themes that describe pharmacists’ experiences were identified: 1) Individual Experiential Learning; 2) Meaningful Impact; 3) Experiences in Context; 4) Personal Growth; and 5) Sense of Community. Pharmacists expanded clinical and professional skills such as resourcefulness, inter-professional collaboration, communication, and cultural awareness. They questioned the impact they made on the lives of patients in and surrounding Camasca, and they questioned the sustainability and the meaning of their work. Pharmacy participants used previous global health experiences and professional experiences in the United States to help them orient and understand their experiences in Honduras. The medical brigade to Honduras provided pharmacy participants the opportunity to disconnect from their daily schedules and reflect on their experience and its impact on their personal and professional lives. Both pharmacy and family medicine participants recognized the sense of community among the people of Camasca, among the participants in the brigade, and between the people of Camasca and the brigade group.

**Conclusion:** Global health experiences can help residents achieve residency competencies: 1) Humanism and cultural proficiency; 2) Therapeutic knowledge; 3) Patient care; 4) Inter-disciplinary collaboration; and 5) Communication. Global health experiences are an innovative and effective use of pharmacy services.

Poster Title: Implementation of a pharmacist-run naloxone clinic in a family medicine center

Primary Author: Ryan Tewell, New Hanover Regional Medical Center, NC; Email: ryan.tewell@nhrc.org

Additional Author(s):
Elizabeth Kyle
Lisa Edgerton

Purpose: The current opioid epidemic affecting the United States has resulted in a growing number of opioid overdoses. Respiratory depression is the ultimate cause of death in these patients. In 2016 the CDC published guidelines about the prescription of opioids for chronic pain recommending the prescription of naloxone to patients at risk of an opioid overdose. The purpose of this study is to implement a pharmacist-run clinic to identify patients at risk for an opioid overdose, provide a naloxone prescription as well as education to patients and caregivers on the utilization of naloxone to reverse an opioid overdose.

Methods: This study will seek approval from the Institutional Review Board at New Hanover Regional Medical Center (NHRMC). A report will be generated through NHRMC's electronic medical record to identify established patients of the family medicine clinic meeting study criteria. Patients with a current opioid prescription who meet at least one of the following criteria will be included in the study: opioid at a dose of greater than or equal to 50 morphine milligram equivalents (MME) per day, and/or a history of overdose, and/or a history of substance abuse, and/or concomitant chronic use of an opioid and benzodiazepine. Identified patients will be contacted and scheduled for a pharmacy visit to receive education about the use of naloxone as well as a prescription for naloxone. Patients will be encouraged to bring a family member or friend to the visit for participation in naloxone education. Naloxone access will be provided by the NHRMC outpatient pharmacy or another community pharmacy. The following demographics will be studied: patient age and sex, overdose risk factors, number of patients and caregivers educated, and number of patients who obtain naloxone. Patients who seek medical care for overdose treatment as well as request a naloxone refill will also be recorded. The primary outcome is a composite of the number of patients who are educated on and acquire naloxone.

Poster Title: Does thrombin dose matter for intra-operative hemostasis? A retrospective case-controlled study

Primary Author: Barry Stevenson, New Hanover Regional Medical Center, NC; Email: barry.stevenson@nhrmc.org

Additional Author (s):
Joshua Steelman
Lisa Zimmerman
Zachery Bullard
Lesly Jurado

Purpose: Bleeding is a serious complication associated with surgical procedures and prompt hemostasis intraoperatively is imperative. Thrombin, a hemostatic agent, is often employed due to its ability to convert endogenous fibrinogen into fibrin leading to hemostasis. Limited data exists regarding thrombin doses and concentrations to optimize hemostasis. Our institution switched from using thrombin 20,000 unit to 5000 unit vials. Hence, the objective of this study is to compare thrombin dosing strategies to determine effectiveness and safety in providing hemostasis intra-operatively.

Methods: This retrospective study will evaluate adult patients, age greater than or equal to 18 years, who underwent a neurosurgical spine or orthopedic spine procedure and received thrombin intraoperatively. Patients will be case matched in a one to one ratio based on surgical procedure and duration of surgery. Patients will be stratified by dose defined as low versus high dose thrombin: less than 20,000 units versus greater than or equal to 20,000 units. Data collected will include baseline demographics, laboratories, surgical procedure performed, intra-operative data, blood products administered, and adverse drug reactions. In addition, concentration of thrombin used intraoperatively will be compared. Effectiveness of thrombin for hemostasis will be measured by identifying total blood loss during surgery, blood products administered, and hemoglobin trends for 72 hours after end of surgery time. Safety will be measured by identifying adverse drug reactions including thromboembolism, cerebrovascular accidents, acute coronary syndrome, and anaphylactoid type reactions. A cost analysis will be performed comparing low dose thrombin versus high dose thrombin to determine if a cost
savings exists with the change to a smaller vial size of thrombin. Statistics will be performed using Statistical Analysis Software Package and a p-value less than 0.05 will be considered significant.

**Poster Title:** Transitions of care from start to finish: Impact on 30 day health care utilization rates in a community teaching hospital

**Primary Author:** Corianne Wood, New Hanover Regional Medical Center, NC; **Email:** corianne.wood@nhmc.org

**Additional Author (s):**
Amanda Dubil

**Purpose:** In the past decade, care coordination services have become a focal point in health care. Hospital systems have implemented services from emergency department admission to discharge and outpatient follow-up. Our facility has implemented medication reconciliation technicians in 2009 and multiple additional services since 2012. The objective of this quality improvement study is to determine how all of these services at a community teaching hospital work together to influence 30 day health care utilization rates defined as emergency department visits and hospital readmission.

**Methods:** This retrospective review will analyze patients discharged to home or home health. Patients will be excluded if under 18, pregnant, or discharged to skilled nursing or other facility. Data from January 2016 through January 2017 will be collected and assessed. Transitions of care services analyzed include: admission medication reconciliation, prospective medication access barrier assessment, medication assistance evaluation, discharge medication reconciliation, discharge counseling, our facility’s outpatient pharmacy, outpatient transitions of care team, and outpatient pharmacy refill synchronization and mail order delivery to patients. A report from the electronic medical record (EPIC) will be created to collect admission and discharge dates, demographic information, and assess which services were provided to each patient. Reports on fill dates, medication assistance, and synchronized mail-order pharmacy participants will be generated from the outpatient pharmacy system (QS1). Patient lists, EPIC reports, and QS1 reports will be utilized to perform statistical analyses to determine how each pharmacy role impacts 30 day health care utilization rates.

Poster Title: Impact of the Outpatient Pharmacy’s Pharmacy Advantage program on decreasing hospital encounters of clinic patients

Primary Author: Joshua Jones, New Hanover Regional Medical Center, NC; Email: joshua.jones@nhrmc.org

Additional Author(s):
Michael Edgerton

Purpose: The lack of adherence to medication is a factor in the occurrence of re-admissions and emergency department visits in patients. Medication synchronization and shipping can decrease potential barriers to medication compliance. The objective of this study is to determine the effectiveness of New Hanover Regional Medical Center Outpatient Pharmacy’s Pharmacy Advantage program in decreasing potentially preventable hospital encounters through medication synchronization and shipping.

Methods: This study will be submitted to the Institutional Review Board for approval. Costal Family Medicine and Internal Medicine clinic patients will be identified via the Pharmacy Advantage program’s syncing and shipping enrollment list. The prevalence of hospitalization and non-injury emergency department visits in these patients prior to Pharmacy Advantage program enrollment will be compared to the prevalence of hospitalization and non-injury emergency department visits after enrollment. A retrospective review of the intervention group will analyze the time period from twelve months before enrollment into the Pharmacy Advantage program until the date of data collection initiation. This designated amount of time prior to enrollment will coincide with the time immediately preceding enrollment into the Pharmacy Advantage program. A baseline will be established by identifying the prevalence of the primary outcome in each clinic’s respective patient population for the twelve month time period prior to the establishment of the Pharmacy Advantage program. The prevalence of hospitalizations and non-injury emergency department visits for patients in this baseline group will be recorded and compared to the results of clinic patients that are enrolled in the Pharmacy Advantage program. The type of hospital encounter will also be recorded for patients in both the baseline and intervention groups that meet the primary outcome during the designated time period.

Poster Title: Hemodynamic effects of ketamine versus etomidate in pre-hospital emergency transport services

Primary Author: Lucy Stanke, New Hanover Regional Medical Center, NC; Email: lucy.stanke@nhrmc.org

Additional Author(s):
Steven Nakajima
Lisa Zimmerman
Carrie Fales
William Powers

Purpose: Rapid sequence intubation and sedation are often required in managing critically ill patients in the pre-hospital setting. The standard rapid sequence intubation induction agent in this population is etomidate which has neutral hemodynamic effects. With hemodynamic stability being imperative, ketamine has gained new interest in pre-hospital management as it has been reported to have positive hemodynamic effects. Limited data exists to support ketamine as an alternative to etomidate, particularly in the pre-hospital setting. The objective of this study is to determine if a difference exists in hemodynamics after administration of ketamine versus etomidate in pre-hospital patients.

Methods: With Institutional Review Board approval pending, this retrospective comparative study will evaluate consecutive adult (18 years of age or greater) patients treated with ketamine versus etomidate by a regional emergency transport service. This service consists of a county-wide emergency medical service, a critical care transport system with mobile intensive care units and an air ambulance service. Ketamine and etomidate are available to these services for induction of rapid sequence intubation and sedation. All data will be collected from the pre-hospital electronic medical record from December 2015 to December 2016. Data extracted will include ketamine and etomidate doses, blood pressure, heart rate, number of intubation attempts and lost airways, dose and time of adjunct medications, indication for advanced airway placement, admitting service and patient demographics. The primary outcome will be measured by assessing patient hemodynamics for two measurements prior to administration of ketamine or etomidate and for two measurements up to fifteen minutes post-administration or
until additional sedative medications are administered. Data will be used to evaluate if initial hemodynamic readings should influence the decisions to use ketamine or etomidate in critically ill patients. Data will be analyzed using statistical software with a p-value of less than 0.05 being considered significant.

Poster Title: Evaluating diabetes control and metabolic risk factors in patients with human immunodeficiency virus after the addition of a pharmacist to a multidisciplinary primary care clinic

Primary Author: Jenna Picton, New Hanover Regional Medical Center, NC; Email: jenna.picton@nhrmc.org

Additional Author(s):
Mackie King

Purpose: With the development of more potent, convenient, and tolerable anti-retroviral therapies, management of human immunodeficiency virus (HIV) has transitioned from HIV-related illnesses to chronic disease state management as this population lives longer, healthier lives. Literature suggests patients with HIV have 50-100% increased risk of cardiovascular (CV) disease. Management of modifiable risk-factors has become a priority as leading causes of death in this population transitions from HIV-related towards CV-related causes. While literature supports pharmacist impact on viral markers in HIV clinics, little is known about potential benefits of pharmacist-collaboration managing chronic co-morbidities for patients with HIV in the primary care setting.

Methods: This study is a retrospective study involving patients with diagnoses of diabetes and HIV seen in a primary care clinic. An EPIC report will identify patients seen within the clinic with the above diagnoses. The intent is to follow patients from their establishment with the clinic (T minus x) through the time when a pharmacist was introduced to the multi-disciplinary team (T equals 0) and up until as recent as possible (T plus x). Based on data availability, this timeline approach will be utilized using repeated measures within the same patient to draw comparisons in diabetes control before and after the introduction of pharmacists to the multidisciplinary team. If this is not feasible due to a large discrepancy between patients who established with the clinic prior to the initiation of a pharmacist and those still active within the clinic afterwards, aggregate data will be collected on each group as a whole. Data collection points include hemoglobin A1c, blood pressure (BP), low-density lipoprotein (LDL), CD4 count, HIV-RNA viral load, weight, statin therapy, and anti-retroviral therapy. The primary objective will assess percentage of patients achieving individual goals set by Centers for Medicare and
Medicaid Services/National Committee for Quality Assurance for hemoglobin A1c, BP, and LDL. Secondary objectives are percentages of patients achieving composite primary endpoint and patients achieving hemoglobin A1c less than 7 percent.

**Session-Board Number:** 10-226  

**Poster Title:** Impact of a spontaneous awakening trial and spontaneous breathing trial protocol implementation on the amount and duration of sedation and analgesia in the critically ill  

**Primary Author:** Stephanie Price, New Hanover Regional Medical Center, NC; **Email:** stephanie.price@nhrcmc.org  

**Additional Author (s):**  
Lesly Jurado  
Lisa Zimmerman  

**Purpose:** Daily spontaneous awakening trials (SAT) have the potential to decrease the occurrence of oversedation in patients. When paired together with spontaneous breathing trials (SBT), SATs lead to extubation more quickly after passing an SBT as patients are more alert and neurologically prepared for the removal of mechanical ventilation. Literature has shown that paired SAT/SBT protocols lead to less ventilator days and decreased ICU length of stay (LOS). The purpose of this study is to determine if a SAT/SBT protocol decreases the amount and duration of sedation and analgesia in mechanically ventilated patients.  

**Methods:** This will be a retrospective study (IRB pending) of two cohorts of patients before and after protocol implementation. Our facility’s ventilator associated pneumonia protocol addresses spontaneous awakening trials. The respiratory extubation weaning protocol addresses criteria for extubation and is performed by the respiratory therapist (RT). However, both protocols are unclear regarding concomitant SAT/SBT and the criteria for qualifying patients. The SAT/SBT protocol will define SBT criteria based on hemodynamic stability and timing of SAT/SBT. Nurses and RTs will be educated on the protocol. Data will be collected pre- and post-protocol implementation in medical and surgical mechanically ventilated patients. Data collection will include patient demographics, ventilator days, amount of sedation/analgesia, wake up assessments, Richmond Agitation-Sedation Scale (RASS), Critical Care Pain Observation Tool (CPOT), ICU and hospital length of stay. The data will be analyzed to determine the amount and duration of sedation and analgesia before and after the implementation of a concomitant SAT/SBT protocol.

**Poster Title:** Does the prophylactic use of epicardial application of amiodarone-releasing hydrogel prevent postoperative atrial fibrillation in coronary artery bypass grafting patients?

**Primary Author:** Elizabeth Price, New Hanover Regional Medical Center, NC; **Email:** elizabeth.price@nhrmc.org

**Additional Author (s):**
Mary Beth Bobek

**Purpose:** Postoperative atrial fibrillation (POAF) is the most frequently occurring complication following cardiothoracic procedures. Current clinical practice utilizes amiodarone for the prevention of POAF, however, the associated systemic side effects are extensive. The administration of amiodarone directly to the epicardial tissue via a hydrogel delivery system has been shown to localize amiodarone to the cardiac tissues while minimizing amiodarone plasma concentrations. The aim of this study is to assess the effectiveness of amiodarone-releasing hydrogel for the prevention of postoperative atrial fibrillation in patients undergoing coronary artery bypass grafting.

**Methods:** Upon institutional review board approval, patients undergoing coronary artery bypass grafting (CABG) will be identified by accessing electronic medical records and by referring to a composite list of patients that received amiodarone-releasing hydrogel during CABG procedures. Patients will be case matched in a one to one ratio to patients that did not receive epicardial amiodarone. Data to be collected will include: age; sex; race; smoking status; history of stroke, myocardial infarction, heart failure, atrial fibrillation, hypertension and chronic obstructive pulmonary disease; previous CABG; previous percutaneous coronary intervention (PCI), preoperative heart rate, blood pressure, QT interval, serum potassium, and serum magnesium; use of milrinone, dobutamine, dopamine, norepinephrine, vasopressin, beta blockers, and albuterol; total time of CABG; amiodarone dose; documentation of POAF or other postoperative arrhythmias; total length of hospital stay, and mortality. All data collected will be de-identified and securely maintained in an electronic database. Data will be analyzed to determine the prevalence of POAF in patients that received epicardial amiodarone versus patients that received standard treatment with intravenous amiodarone.

**Poster Title:** Evaluation of the safety and financial impact of administering EPOCH-containing regimens in the outpatient setting

**Primary Author:** David Garbarz, Novant Health, NC; **Email:** dgarbarz@gmail.com

**Additional Author(s):**
Jay Brown

**Purpose:** A number of chemotherapy regimens are administered in the inpatient setting to allow for a high level of monitoring and rapid intervention in the result of adverse reactions. However, as healthcare shifts to a patient-centered and financially responsible focus, utilization of the lowest-cost venue for administration of chemotherapy is important in order to maximize the value of care. One such consideration for outpatient administration is etoposide, prednisone, vincristine, cyclophosphamide, doxorubicin (EPOCH). The purpose of this study is to evaluate the safety and financial impact of transitioning EPOCH-containing regimens to the outpatient setting.

**Methods:** This retrospective study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients that have been administered an EPOCH-containing regimen within the health system. Data to be collected will include patient demographics, EPOCH regimen administered, site of care administration (inpatient or outpatient), hospital admissions following each cycle, cause for admission, occurrence of extravasation, length of hospital stay, length of time for outpatient administration, savings from hospital day avoidance, and inpatient/outpatient drug costs. All data will be recorded without patient identifiers and maintained confidentially. Safety, defined by need for hospital admission, will be evaluated based on site of care administration. Descriptive statistics will be used to evaluate data sets.

Poster Title: Evaluation of a Risk Assessment Model to Predict Infection with Extended-Spectrum Beta-Lactamase-Producing Enterobacteriaceae and Methicillin-Resistant Staphylococcus Aureus

Primary Author: Amanda Teachey, Novant Health Forsyth Medical Center, NC; Email: alteachey@novanthealth.org

Additional Author(s):
Steven Johnson
Charles Hartis
Lisa Blanchette
David Priest

Purpose: Previous reports have evaluated risk stratification tools to identify patients at risk for multidrug resistant (MDR) infections. There are currently no studies identified that have evaluated a risk prediction model for multiple organisms, specifically extended-spectrum beta-lactamase-producing Enterobacteriaceae (ESBL-EKP) and methicillin-resistant Staphylococcus Aureus (MRSA), in order to develop a comprehensive risk prediction tool for hospitalized patients. The objective of this study is to describe the ability of a previously developed risk prediction model to predict infection with ESBL-EKP and MRSA upon hospital admission at our facilities and secondarily, to describe the ability of MRSA surveillance PCR testing to predict MRSA infection.

Methods: This multicenter, retrospective, case control study has been approved by the Institutional Review Board. Patients will be included if 18 years of age or more and admitted to Novant Health Forsyth Medical Center or Novant Health Presbyterian Medical Center between April 1st, 2016 to September 30th, 2016 with culture-confirmed infection due to ESBL-EKP and MRSA (cases), or non-ESBL-EKP and methicillin-sensitive Staphylococcus Aureus (controls). Control subjects will be matched to a corresponding case subject with MDR infection using a 1:1 ratio based on pathogen, source of isolate, and hospital ward type. Included patients will receive a weighted score assigned to each of the five risk factors determined in the previously-developed model through logistic-regression based prediction scores calculated on variables independently associated with ESBL-EKP isolation (hospitalization 12 months prior to
index admission, beta-lactam or fluoroquinolone 3 months prior to index culture, transfer from another healthcare facility, urinary catheterization 30 days prior to index culture, immunosuppressive drug therapy during the 3 months prior to index culture). Positive predictive value, negative predictive value, sensitivity, specificity, and accuracy will be calculated at various point cut offs for each of the resistant organisms. The receiver operating characteristic area-under-the-curve (ROC-AUC) will be determined for each group. A logistic regression model will be used in order to create a new risk assessment scoring model if the ROC-AUC is < 0.8.

Poster Title: Effects of parenteral nutrition approaches on growth velocity in the neonate during transition to enteral feeds

Primary Author: Laurie Rollins, Novant Health Forsyth Medical Center, NC; Email: lrollins@novanthealth.org

Additional Author (s):
Amy Holmes
John Harris

Purpose: There is very little data regarding the comparison of custom parenteral nutrition (PN) and standard PN on growth velocity during the transition to enteral feeding in neonates. We are interested in whether standard PN and/or clear fluids maintain the same or similar growth velocity in neonates while transitioning to enteral feeds as does custom PN. Because there is a decreased cost associated with compounding standard PN compared to making custom PN, this interchange has the potential to generate huge health-system savings, especially because minimal volume may be used towards the end of the transition period.

Methods: This is a multicenter retrospective chart-review cohort study that will include approximately 100-150 neonates admitted to the Novant Health Forsyth Medical Center and the Novant Health Presbyterian Medical Center Neonatal Intensive Care Units between August 2015 and July 2016 meeting inclusion criteria.

Inclusion Criteria:
• neonates born and admitted to the Novant Health Forsyth and Presbyterian Medical Center NICUs between August 2015 and July 2016
• received parenteral nutrition between August 2015 and July 2016

Exclusion Criteria:
• short-gut syndrome
• necrotizing enterocolitis
• had surgical procedures or received diuretics or transfusions within the 14 day transition period to enteral nutrition
• have ≤ 1 documented weight during the 7 days before or the 7 days after transition
The following information will be collected on an Excel spreadsheet: gestational age, birthweight, length and head circumference at birth, day of life, gender, hour or life of PN start, daily PN approach used, the day of life PN was discontinued and full enteral feedings began. Recorded weights, along with weekly head circumference and length when available, will be collected starting 7 days before discontinuation of PN and continuing 7 days after discontinuation to calculate the corresponding growth velocity. Z scores will be calculated utilizing the previous data collected. Data will only be collected during the initial PN administration period if the same neonate(s) received multiple PN courses.

Poster Title: Assessing implementation of a new pain, agitation, and delirium protocol in an intensive care unit

Primary Author: Holly Schmidlin, Novant Health Forsyth Medical Center, NC; Email: holly.schmidlin@gmail.com

Additional Author(s):
Jeremy Hodges

Purpose: This study will pilot the updated protocol and determine the protocol’s effectiveness in reaching provider set goals (i.e. RASS goals, CPOT goals) while maintaining manageability for our nursing staff compared to the previous protocol. The pilot will also identify any gaps in the updated protocol such as, transcription errors, issues with flow, and wording of the protocol.

Methods: This will be a 5 month, single-center, prospective, observational, cross-sectional study with data collection between September 2016-February 2017 on patients who present to the intensive care unit at Forsyth Medical Center with placement on the new PAD protocol. The primary objective of this study is to assess the effectiveness of the new PAD protocol for nursing staff versus the previous protocol. There are several secondary objectives in this study (1) to pilot a new PAD protocol in the intensive care unit and compare manageability versus the previous protocol (2) to assess the adherence to protocol by nursing staff (3) to discover and any gaps in the new protocol to improve before implementation system-wide and (4) fix any gaps in the updated protocol. The primary endpoint of this study will be the effectiveness of the new protocol. Results will be obtained by the attached survey given to nurses. The secondary endpoints will be manageability and adherence of the updated protocol. Descriptive statistics and survey results will be used to assess the objectives of this study.

**Poster Title:** Impact of pharmacist interventions on increasing the number of patients on appropriate therapy for osteoporosis.

**Primary Author:** Jennifer McGuirt, Novant Health Forsyth Medical Center, NC; **Email:** jennifer.jones2@novanthealth.org

**Additional Author(s):**
Mary Ellen Pisano
Justine Maher

**Purpose:** In 2013, Centers for Medicare and Medicaid Services reported the lowest star rating for osteoporosis measures across all health plans. Novant Health primary care clinics’ quality assurance metrics are tracking patients who have been diagnosed with osteoporosis and are not currently receiving pharmacological therapy. The goal for this metric is currently not being met at many of the Novant Health primary care practices. The objective of this study is to determine the number of patients receiving pharmacological therapy for osteoporosis management following pharmacist intervention of chart review and recommendations to providers.

**Methods:** This is a retrospective study of at least 100 patients who were identified by a Novant Health quality metric report of patients diagnosed with osteoporosis not currently on pharmacological therapy. Patients included in the study will have received a medication review with recommendations for osteoporosis monitoring and therapy routed to their primary care physicians. Data to be collected includes: patient demographics, dates of chart review and recommendations, number of recommendations made for pharmacological therapy, laboratory and bone mineral density testing, and referrals to Novant Health Osteoporosis Clinic. In addition, the study will look at the number of patients on osteoporosis therapy after recommendations were made by the pharmacist along with the drug class and route of those therapies. The primary outcome is the number of patients for whom osteoporosis therapy was initiated following pharmacist recommendation to the primary care provider. Secondary outcome measures are acceptance rate of recommendations to physicians for osteoporosis pharmacological therapy, subdivided into drug class and route of administration,
Recommendations for laboratory and bone mineral density testing, and recommendations for referral to Novant Health’s Osteoporosis Clinic.

Poster Title: Retrospective evaluation of the management of immune mediated toxicities post immunotherapy in cancer patients across Novant Health

Primary Author: Constance Terrell, Novant Health Forsyth Medical Center, NC; Email: constancemterrell@gmail.com

Additional Author(s):
Amanda Edwards
Morgan Smith
Heather Cox
Marley Linder

Purpose: To evaluate the appropriate management of immune mediated adverse events (imAEs) in patients who have received at least one dose of immunotherapy at Novant Health. This project will assess how immune mediated toxicities are being managed at this time and the appropriateness based on treatment recommendations. With more knowledge on which drug, regimen, and dose is most effective as treatment, better outcomes and management of toxicities can be provided to patients.

Methods: Pending approval from the Institutional Review Board (IRB) a retrospective chart review will be completed for patients across all Novant Health facilities who have received at least one dose of immunotherapy from January 1, 2015- July 31, 2016. Data will be collected from the electronic health record based on the time frame noted and patients will be further narrowed based on the inclusion/exclusion criteria. Medical records for eligible subjects will be reviewed retrospectively to collect relevant clinical data related to the imAE and endpoints including: Common Terminology Criteria for Adverse Events (CTCAE) grade/severity of toxicity, time from immunotherapy treatment to toxicity, agent(s) used to manage toxicity, medication dose used to manage toxicity, length of management, side effects of management, time to clinical resolution of toxicity (defined as grade 0-1), single agent immunotherapy vs. combination agent, and reason for discontinuation of immunotherapy. The study will be analyzed using descriptive statistics (percentages and means) to summarize the primary endpoint, secondary endpoints, and baseline characteristics. Once collected, all data will be assessed for missing and nonsensical data. All missing data will be confirmed with the original
data collection forms and corrected in the database if possible. Subjects missing data for primary or secondary outcomes will not be included in the descriptive analysis for that outcome.

Poster Title: Retrospective review of early onset pneumonia following cardiac arrest: opportunities for antibiotic stewardship

Primary Author: John Kindy, Novant Health Forsyth Medical Center, NC; Email: johnkindy@outlook.com

Additional Author(s):
Charles Hartis

Purpose: Early onset pneumonia (EOP) is a common complication following cardiac arrest. EOP is often treated as VAP, a complication with high attributable mortality. Studies examining early initiation of antibiotics have shown a decrease in the incidence and duration of pneumonia but not survival or good functional outcome improvement. In contrast, there is a preponderance of data supporting that inappropriate antibiotic use is associated with increased medication costs, antimicrobial resistance, and superinfections. The purpose of this study is to determine the incidence of EOP, treatment strategies currently employed, and microbiological characteristics to allow for development of antimicrobial stewardship guidance.

Methods: This study is currently under IRB review. It is a 24 month retrospective descriptive study of all patients admitted to a tertiary community medical center who meet inclusion criteria for early onset pneumonia (EOP) following out of hospital cardiac arrest (OHCA). Subjects to be screened for inclusion will be identified through a data request for patients admitted with a documented ICD-10 code I46.9/ICD-9 code 427.5 (arrest, cardiac) and/or ICD-10 code I46.2 (arrest due to cardiac condition) and, a length of stay greater than or equal to 7 days. Follow inclusion and exclusion screening, data will be collected through review of electronic medical records. The primary endpoint of this study is the percentage of OHCA patients who develop EOP. Secondary endpoints include characteristics of microbiological samples and antimicrobial therapy, including culture positivity, organisms, empiric therapy, definitive therapy, and timing of interventions. The tertiary endpoint of this study is the patterns of resistance in culture positive subjects. Subject data collected will be tabulated on a standardized spreadsheet. All subjects will be given a unique study identification number for de-identification. Descriptive statistics including percentage prevalence and means with standard deviations will be utilized to analyze nonparametric and parametric data respectively.
This study will comply with all federal, state, and organizational regulations for biomedical research.

Caitlin Moorman Spangler
Jennifer Anderson

**Purpose:** A Medicare annual wellness visit (AWV) is a benefit provided to patients insured under Medicare Part B. The visit evaluates the patient’s family and medical history, medication use, and risk factors for certain diseases in order to provide a screening and prevention plan. Currently, AWVs are not completed for all Medicare Part B beneficiaries. This service is one that many patients find beneficial, specifically regarding medication management. Because AWVs may be completed by any healthcare professional under the direct supervision of a physician, pharmacists are able to provide this service along with additional medication guidance and counseling.

**Methods:** This prospective study will analyze provider interest in pharmacist-delivered Medicare AWVs, number and type of pharmacist interventions made, as well as patient and provider satisfaction with the visits. This study will take place over the course of two years with the first year focused on the development of pharmacist-delivered Medicare AWVs and analysis of outcomes from the initial visits. During the second year, additional visits will be completed by pharmacists and outcomes will be analyzed. Development of the AWVs will initially consist of assessing provider interest through a survey. Upon evaluation of the interest surveys, a practice site will be chosen for implementation of the service. An in-service will be provided at the selected site to educate providers on pharmacist-delivered Medicare AWVs. Patients will then be recruited through letters mailed to the patient’s home address and phone calls. Once appointments are scheduled, visits will be completed by pharmacists and the results analyzed. Following completion of the visits, patients will be asked to complete a questionnaire assessing their level of satisfaction with the services provided. Additional surveys will be administered to providers to assess their satisfaction with pharmacist-delivered AWVs. The following outcomes
will be measured upon completion of the visits: number of interventions and type of interventions made by pharmacists, patient satisfaction scores, and provider satisfaction scores.

Poster Title: Implementation of a pharmacist-driven chemotherapy counseling and consent program in an outpatient community cancer center

Primary Author: Carly Sabat, Novant Health Forsyth Medical Center, NC; Email: cmsabat@novanthealth.org

Additional Author(s):
Heather Cox
Marley Linder
M. Jay Brown

Purpose: Patients demonstrate benefit when oncology pharmacists are active participants in their clinical care. The value is less defined in a pharmacist-driven chemotherapy counseling program. The purpose of this study is to evaluate the impact on patient outcomes and satisfaction scores in a pharmacist driven chemotherapy counseling and consent program for intravenous and oral chemotherapy in a community-based oncology clinic.

Methods: This IRB-exempted, retrospective study will evaluate the impact of providing intravenous and oral chemotherapy education to patients treated at Novant Health Oncology Specialist - Forsyth Medical Center. Site-based oncology pharmacists will provide the chemotherapy counseling and consenting of patients. Primary and secondary endpoints include Press Ganey patient satisfaction scores, adherence to regimen (e.g., relative dose intensity), time involved by pharmacist, number and type of interventions made by the pharmacy team, and number of unscheduled admissions due to side effects. Descriptive statistics will be used to assess the impact of this program versus the previous standard program.

**Poster Title:** Comparison of fentanyl and remifentanil on peri-operative medication administration and costs

**Primary Author:** Heather Taylor, Novant Health Forsyth Medical Center, NC; **Email:** hitaylor@novanthealth.org

**Additional Author (s):**
Sara Meyer

**Purpose:** Remifentanil is a synthetic mu-opioid receptor agonist with a unique pharmacokinetic profile. It’s rapid onset of action, short context-sensitive half-life, and organ independent metabolism and elimination may prove advantageous for certain surgical procedures. Currently no direct comparison of overall medication usage between fentanyl and remifentanil when used for craniotomy exists. Remifentanil may offer a potential cost savings by reducing amounts of peri-operative medications to be administered. This study will assess differences in medication usage between fentanyl and remifentanil when used for craniotomy sedation and analgesia to determine if a cost savings may be appreciated.

**Methods:** Following IRB approval a Trendstar report of adult patients who were admitted to Novant Health Forsyth Medical Center or Presbyterian Medical Center between September 1, 2015 and November 30, 2016, who received a continuous infusion of either remifentanil or fentanyl for craniotomy sedation and analgesia will be generated. Subjects who were pregnant, transferred to or from another facility prior to discharge, or experienced an acute life threatening event while in surgery will be excluded. The electronic medical record (EMR) of up to 200 subjects who meet the inclusion and exclusion criteria will be reviewed, and relevant, pre-specified data points will be collected using a standardized data collection form (DCF). DCFs will be assessed for clarity and completeness periodically, and validation queries will be run to ensure accurate data capture and entry. All data will be collected without patient identifiers and maintained confidentially. Outcome measures include amounts of peri-operative medications administered, drug cost per case, intraoperative blood pressure range, post-anesthesia care unit length of stay, and time to extubation. Analysis of the primary and secondary endpoints will be done using descriptive statistics, ratio t-test, and regression analysis. Three subset analyses will also be performed on subjects who have renal impairment,
are obese, or have a greater risk of post operative nausea and vomiting. Subjects missing data will not be included in the primary analysis.

Poster Title: Implementation of a pharmacist-led transitional care protocol for patients post-percutaneous coronary intervention

Primary Author: Lauren Hickman, Novant Health Population Health Pharmacy, NC; Email: ldhickman@novanthealth.org

Additional Author(s):
Maryann Choy-Ames
Jeannie Poon

Purpose: The American College of Cardiology's CathPCI Registry assesses the characteristics, treatments, and outcomes of patients who receive percutaneous coronary intervention (PCI) procedures. Prescription of aspirin, P2Y12 inhibitors, and statins at discharge has demonstrated reduction in morbidity and mortality in several studies of patients post-PCI. The CathPCI Registry’s medication metric measures proportion of patients with aspirin, P2Y12 inhibitor and statins prescribed at discharge. This study will characterize and evaluate the effect of pharmacy interventions on medication discharge practices for patients post-PCI at Novant Health Presbyterian Medical Center (NHPMC) in an effort to improve compliance with the CathPCI Registry’s medication metrics.

Methods: This quasi-experimental, historically-controlled, comparative study has been submitted to the Institutional Review Board for approval. All patients receiving a PCI over the course of a three-month period at NHPMC will be identified using a report generated from Novant Health’s electronic health record. Patient demographics and clinical variables will be assessed by pharmacists and pharmacy technicians, with an emphasis on assuring patients are discharged on the three medications included in the CathPCI Registry medication metric. If a discrepancy is noted by a pharmacy technician, the patient’s chart will be forwarded to the pharmacist for review. If a true discrepancy is present the pharmacist will contact the patient and/or the provider for medication review and reconciliation. The primary endpoint will be number of pharmacy interventions. Secondary endpoints include types of pharmacy interventions, acceptance of pharmacy interventions, proportion of patients prescribed aspirin, P2Y12 inhibitor, and statin at discharge, proportion of patients prescribed beta blockers, ACEi/ARBs, and aldosterone antagonists at discharge, after visit summary and discharge
summary medication discrepancies, and readmission rates. The proportion of patients discharged on the medications included in CathPCI registry metric, will be compared to a historical control. To examine for differences between the control and intervention groups, Student’s t-test will be used to compare continuous variables and a chi-square test will be used to compare categorical variables.

**Poster Title:** Routine vitamin K-1 for erratic international normalized ratio stabilization

**Primary Author:** Valerie Barnett, Novant Health Population Health Pharmacy, NC; **Email:** vrbonnett@novanthealth.org

**Additional Author(s):**
Caitlin Moorman Spangler
Justine Maher
Valerie Southerland

**Purpose:** Patients are at increased risk for major bleeding and thromboembolic events when the international normalized ratio (INR) is outside the therapeutic range. The objective of this study is to determine whether daily low-dose vitamin K-1 (phytonadione) intake will stabilize erratic INRs.

**Methods:** Qualifying patients will be started on daily vitamin K-1 supplementation and followed over a period of three months. The primary endpoint is change in time in therapeutic range (TTR), which will be evaluated by a comparison between TTR from the three months prior to vitamin K-1 initiation and TTR from the three months of vitamin K-1 supplementation. Patients will be included if they have erratic INRs defined as a three month TTR of less than or equal to 50 percent after at least four INR results. An informed consent form will be discussed in full with each patient before they agree to participate. This study has been submitted to the Institutional Review Board for approval. Patients will be provided with OTC Vitamin K-1 100mcg and instructed to start supplementation following the initial appointment. A one week follow-up visit will be scheduled to make any necessary adjustments to the warfarin dose. The three month study period will begin at the appointment succeeding the one week follow-up visit. The following data will be collected: age, sex, race/ethnicity, dates of anticoagulation appointments and associated INR results, patient reported signs and symptoms of bleeding or thromboembolic events, diagnostic test results utilized to detect thromboembolism, and three month time in therapeutic range as calculated by the Rosendaal method.

Poster Title: Evaluation of amiodarone use for the prevention of postoperative atrial fibrillation in cardiac surgery

Primary Author: Jessica Humenik, Novant Health Presbyterian Medical Center, NC; Email: jahumenik@novanthealth.org

Additional Author (s):
Allison Gaddy
Laura Frantz
Nancy Honeycutt
Susan Tharp

Purpose: The most common arrhythmia that occurs after cardiac surgery is atrial fibrillation. In patients undergoing coronary artery bypass grafting (CABG) the incidence of postoperative atrial fibrillation varies, but has been reported as high as forty percent. The purpose of this study is to assess whether the use of amiodarone prophylactically decreases the incidence of postoperative atrial fibrillation in CABG patients at Novant Health Presbyterian Medical Center in Charlotte, North Carolina.

Methods: The electronic medical record system will be used to identify CABG surgeries for this retrospective chart review. The following patients will be excluded: patients with atrial fibrillation or any abnormal heart rhythm other than sinus rhythm prior to surgery, those with concomitant valve surgery, and those who had received treatment with amiodarone within 3 months of surgery. Recommended dosing for the optional amiodarone regimen for prevention of postoperative atrial fibrillation is as follows, amiodarone is started postoperative day one at 400 mg twice daily with decrease to 200 mg daily on postoperative day six. If no postoperative atrial fibrillation occurs the amiodarone is to be stopped at discharge; however, if the patient has atrial fibrillation postoperatively then the amiodarone should be continued for one month. The primary endpoint is to assess the incidence of atrial fibrillation, defined as any episode of atrial fibrillation lasting longer than one hour and/or requiring treatment, post CABG surgery. The following data will be collected: gender, age, arrhythmia history, incidence of postoperative atrial fibrillation, use of amiodarone, any moderate or severe drug interactions, any adverse events that occurred, need for a permanent pacemaker, readmission to the hospital within 30
days of discharge, all-cause mortality within 30 days of discharge, and common labs such as heart rate, liver function tests, QTc, and thyroid function tests.

**Poster Title:** Nimodipine compliance in aneurysmal subarachnoid hemorrhage – pharmacists’ role in comprehensive stroke survey preparation  
**Primary Author:** Chelsea Wampole, Novant Health Presbyterian Medical Center, NC; Email: cwampole11@gmail.com  
**Additional Author(s):**  
Meghan Bryan  
Catherine Salvador

**Purpose:** Novant Health Presbyterian Medical Center (NHPMC) is preparing for The Joint Commission survey to become a comprehensive stroke center. One of The Joint Commission’s quality measures is nimodipine initiation within 24 hours of hospital admission for aneurysmal subarachnoid hemorrhage. The objective of this study is to determine if pharmacist education and involvement can have an impact on the compliance rate with this measure.

**Methods:** This study has been submitted to the Institutional Review Board for approval. The electronic medical record will identify patients admitted for aneurysmal subarachnoid hemorrhage based on ICD-10 code. The following data points will be collected: age, gender, time of arrival, time to computerized tomography (CT) scan from time of arrival to hospital, bleed type identified by CT scan, type of aneurysm, time to nimodipine initiation, nimodipine treatment duration, hospital length of stay, neuroscience intensive care unit (ICU) length of stay, presence of clinical cerebral vasospasm by assessment, transcranial Doppler (TCD) velocities, severity of TCD velocities, interventions by neurosurgery, destination/disposition upon discharge and adverse events related to nimodipine. All data will be de-identified and stored on a password-protected computer. Pharmacists will be educated on the quality measure involving nimodipine and will be asked to look for initiation when verifying orders as part of the subarachnoid hemorrhage order set. Clinical pharmacy specialists will follow-up to make sure nimodipine is started appropriately or document rationale if it was not started. Compliance rates will be compared between pre- and post-pharmacist education groups to determine its effectiveness on the quality measure.

Poster Title: Evaluation of antithrombotic reversal in trauma patients admitted with acute major bleeding

Primary Author: Jessica Glas, Novant Health Presbyterian Medical Center, NC; Email: jessica.m.glas@gmail.com

Additional Author(s):
Christopher Miller
Catherine Salvador

Purpose: Uncontrolled post-traumatic bleeding is the leading cause of death among trauma patients. Because many patients may be on an antithrombotic agent, it is imperative to understand how to properly reverse an antithrombotic in the setting of major bleeding following trauma. The primary purpose of this retrospective analysis is to assess the appropriateness of treatment with the correct reversal agent for antithrombotic medications by evaluating the time to reversal administration and physician adherence to anticoagulant reversal protocols as a composite endpoint.

Methods: Pending IRB approval, the system trauma report will identify patients admitted with a traumatic mechanism experiencing major bleeding based on Advanced Trauma Life Support (ATLS) criteria. The electronic patient chart will then be used to identify patients on oral anticoagulants and antiplatelet agents who received one of the following reversal agents: 4-factor prothrombin complex concentrate, Vitamin K, fresh frozen plasma, recombinant factor VIIa, idarucizumab, tranexamic acid, or platelet transfusion. Patients who receive andexanet in coming months will also be included if data is available. The following data will be collected: age, gender, weight, facility, home anticoagulant or antiplatelet regimen, reversal agent administered with route and dose, INR, anti Xa, thrombin, hemoglobin, hematocrit, platelets, major bleeding class as defined by the ATLS criteria, use of order set, recorded pharmacist interventions involving reversal agent choice, length of stay, and adverse events. Data will be recorded without patient identifiers and be maintained in a password protected file on hospital computers secured within the pharmacy department. Data will be analyzed by descriptive statistics to determine the composite endpoint of appropriateness of treatment based on reversal agent choice, time to reversal agent administration, and physician compliance with
protocols. Length of stay, adverse effects, and effect of pharmacist interventions will also be evaluated as secondary endpoints utilizing descriptive statistics.

Poster Title: Assessment of safety and efficacy of apixaban and rivaroxaban in patients with end stage renal disease

Primary Author: Luc Trinh, Novant Health Presbyterian Medical Center, NC; Email: ltrinh@novanthealth.org

Additional Author (s):
Christopher Miller
Jeannie Poon

Purpose: Evaluate the incidence of thromboembolic events for hemodialysis patients taking either rivaroxaban or abixaban as compared to warfarin.

Methods: Pending IRB approval, this study will be a multi-centered, retrospective chart review comparing the clinical outcomes of hemodialysis patients on either rivaroxaban or apixaban to the same patient population on warfarin. Patients will be matched one to one based on age, weight, and indication for anticoagulation. Patient charts from Novant Health Presbyterian Medical Center, Mathews Medical Center, and Huntersville Medical Center will be reviewed for indications of anticoagulation, thromboembolic events, bleeding events including lab values of CBC, PT, and INR, as well as transfusion requirements. Results will be analyzed using descriptive statistics.

Poster Title: Determining the weight-based efficacy of giving single flat rasburicase doses to prevent tumor lysis syndrome

Primary Author: Brian Fisette, Novant Health Presbyterian Medical Center, NC; Email: brfisette@novanthealth.org

Additional Author (s):
Morgan Smith
Amanda Edwards

Purpose: Tumor lysis syndrome (TLS) is an oncologic emergency occurring in certain types of cancer, including leukemia, lymphoma, and solid tumors. Rasburicase is a urate-lowering agent indicated for hyperuricemia due to malignancy expected to result in TLS. Although a weight-based dosing scheme has been FDA-approved, evidence exists to support flat single doses to reduce uric acid (UA) levels. However, little evidence exists supporting this dosing scheme in the obese population. The primary purpose of this study is to determine if flat single doses of rasburicase are effective in preventing TLS in all patients, regardless of their body mass index (BMI).

Methods: This retrospective chart review will evaluate patients who have received rasburicase for the prevention of TLS. Patients included in this study are 18 years or older with a malignancy diagnosis, having received at least one dose of rasburicase for the prevention of TLS. Patients will be excluded if a baseline UA level is unavailable, if they have a history of hemolytic, hypersensitivity, or methemoglobinemia reactions to rasburicase, or if they were on renal replacement therapy at baseline. The primary outcome of this study is the rate of rasburicase failure, characterized by the development of TLS, stratified by BMI. Secondary outcomes will examine the rate of rasburicase failure with regards to TLS risk level, UA level, and also the rate of hemodialysis initiation and additional doses of rasburicase administered for treatment of TLS.

Poster Title: Clinical efficacy of metronidazole twelve-hour dosing regimens in patients with anaerobic or mixed anaerobic infections

Primary Author: Ashley Soule, Novant Health Presbyterian Medical Center, NC; Email: afsoule@novanthealth.org

Additional Author(s):
Lisa Blanchette
Sarah Green

Purpose: Metronidazole is often used to empirically treat anaerobic and mixed anaerobic infections of the oral and intestinal spaces. Traditional metronidazole dosing recommendations utilize an every 8-hour dosing strategy; however, based on pharmacokinetic studies, Novant Health adopted a 12-hour metronidazole dosing regimen for all anaerobic infections except for C. difficile, central nervous system, or parasitic/amoebic infections. Although there is pharmacokinetic evidence to support this regimen, literature evaluating clinical outcomes is limited. The purpose of this study is to evaluate the frequency of clinical cure among patients receiving metronidazole every 12 hours compared with those who received an every 8 hour frequency.

Methods: This is a retrospective, single-center, pre-post intervention study. Subjects will be identified using a report from the electronic medical record of all adult patients who received at least 72 hours of metronidazole for a presumed anaerobic or mixed anaerobic infection from June 2014 through July 2016. Exclusion criteria include metronidazole use for surgical prophylaxis, receipt of an antibiotic with anaerobic coverage for >24 hours prior to metronidazole, receipt of a concurrent antibiotic with anaerobic coverage, causative organism non-susceptible to empiric antibiotics, and pregnancy. Patients will be matched 1:1 based on metronidazole dosing frequency (every 12 hours versus every 8 hours) and the following criteria: age, gender, BMI, infection type, and which floor the patient was admitted to (general medicine vs. intensive care unit). Clinical cure will be defined as improvement or resolution of the principle sign/symptom of infection with normalization of white blood cells (WBC > 4,000 or < 12,000) and temperature (>96.8 F or < 100.4 F). Secondary endpoints include duration of antibiotics, hospital length of stay, escalation of antibiotic therapy, microbiologic cure, mortality.
rates, and cost savings. The data will be presented using both descriptive and inferential statistics. All data will be recorded without patient identifiers and maintained confidentially.

Poster Title: Impact of dose-capping on time to therapeutic anticoagulation by anti-Xa levels for weight-based unfractionated heparin

Primary Author: Rachel LaBianca, Rex Hospital, NC; Email: rachel.labianca@unchealth.unc.edu

Additional Author(s):
David Collins
Oksana Barakat
Jane Green
Debbie Liang

Purpose: The American College of Cardiology/American Heart Association guidelines recommend weight-adjusted unfractionated heparin (UFH) bolus of 60 Units per kg (maximum 4,000 Units) and initial infusion of 12 Units per kg per hour (maximum 1,000 Units per hour) for treatment of acute coronary syndromes. The impact of these dose maximums on rapid and effective anticoagulation remains unclear. The purpose of this study is to evaluate whether a standardized weight-based dose cap for patients weighing greater than 83.3 kg receiving low-intensity UFH infusions, as defined by the protocol at UNC REX Healthcare, results in a longer time to obtain therapeutic anti-Xa levels.

Methods: This retrospective, observational, single-center study at UNC REX Healthcare will compare anticoagulation parameters and outcomes in study patients greater than 83.3 kg versus a comparison group less than or equal to 83.3 kg. Data will be collected from the electronic medical record for patients at least 18 years of age receiving low-intensity UFH between June 20, 2014 and September 6, 2016 for at least 24 hours. Patients that will be excluded are those that receive heparin infusion without bolus, lack documented baseline complete blood count, receive concomitant treatment with a fibrinolytic or glycoprotein IIb/IIIa inhibitor, receive factor Xa inhibitors without appropriate wash-out period, and documented allergy, contraindication, or intolerance to UFH, including history of heparin-induced thrombocytopenia. The primary endpoint will be percentage of first anti-Xa levels within the goal range (0.31-0.6 U/mL). Secondary endpoints will include mean time required to obtain a first therapeutic anti-Xa level (0.31-0.6 U/mL), mean infusion rate per kilogram of total body weight required to obtain a first therapeutic anti-Xa level, and percentage of cumulative anti-Xa
levels within subtherapeutic (≤0.30), therapeutic (0.31-0.6), and supratherapeutic (>0.6) ranges. Safety and efficacy will be assessed by recording bleeding episodes and recurrent thrombotic events.

**Poster Title:** Evaluation of oral chemotherapy monitoring at an outpatient oncology clinic

**Primary Author:** Shelby Ammirati, Southeastern Health, NC; **Email:** srammirati@gmail.com

**Additional Author (s):**
Jennifer Byrd
April Dyer

**Purpose:** The National Comprehensive Cancer Network (NCCN) guidelines recommend periodic monitoring with oral chemotherapy; however, they do not have specific recommendations for monitoring appropriate laboratory tests. Gibson Cancer Center, an affiliate of Southeastern Health, recommends that laboratory monitoring be completed within seven days of ordering or refilling oral chemotherapy. Currently, there is no process in place to ensure this laboratory monitoring is occurring. Adherence to laboratory parameter monitoring at Gibson Cancer Center should be assessed to evaluate the need for implementation of oral chemotherapy care-plans.

**Methods:** A retrospective chart review will be conducted to determine the compliance rate of laboratory monitoring with oral chemotherapy at Gibson Cancer Center. The electronic medical record system will be used to identify patients who received at least one dose of oral chemotherapy between June 1, 2015 and June 30, 2016. Administration orders, laboratory results, and provider notes within the electronic medical record system will be used to collect data on patients receiving oral chemotherapy within the targeted time frame. Data collected will include patient demographic information, type of oral chemotherapy ordered, provider, other concurrent chemotherapy, and complete blood count and chemistry panel resulting up to 7 days prior to oral chemotherapy prescriptions.

Poster Title: Vancomycin and fidaxomicin use for initial Clostridium difficile infection in a community hospital

Primary Author: Brandy Pauff, Southeastern Regional Medical Center, NC; Email: pauff01@srmc.org

Additional Author (s):
April Dyer

Purpose: Oral vancomycin and fidaxomicin are antibiotics used for the treatment of Clostridium difficile infection (CDI). Per the literature, both agents are more effective than metronidazole at preventing CDI recurrence. Southeastern Regional Medical Center (SRMC) is a member of the Duke Antimicrobial Stewardship Outreach Network (DASON) which noted that SRMC’s fidaxomicin use is higher than other member hospitals, while its oral vancomycin consumption is lower than other hospitals in the network. Since fidaxomicin therapy is more costly, a review was conducted to evaluate appropriate use of these antibiotics at SRMC, and to compare patient outcomes associated with receiving these agents.

Methods: A retrospective chart review was conducted for patients that received oral vancomycin and fidaxomicin therapy between January 1, 2015 and June 30, 2016. Data collected includes CDI episode number, 30 day recurrence, duration of therapy, positive CDI culture, other CDI therapy, risk factors and death. Patients will be excluded if they test negative for CDI or do not receive a dose of the prescribed agent. Patients who fail oral vancomycin therapy prior to receiving fidaxomicin will be evaluated as a subgroup of the fidaxomicin arm. Descriptive statistics will be used to evaluate outcomes in each group, which will include all-cause and CDI-related mortality, 30 day CDI recurrence, and colectomy or GI surgery as a result of CDI.

Poster Title: Use of the North Carolina Controlled Substance Reporting System and its impact on opioid prescribing in a community hospital emergency department

Primary Author: Hunter Ingoe, Southeastern Regional Medical Center, NC; Email: ingoe01@srmc.org

Additional Author (s):

Purpose: Opioid abuse in the United States is a national epidemic with strong ties to prescription medications. The objective of this study is to introduce methods for use of the North Carolina Controlled Substance Reporting System to aid providers in appropriate opioid prescribing in the emergency department at Southeastern Regional Medical Center.

Methods: This study will be submitted to the Institutional Review Board for approval. With use of the emergency department narcotic prescribing report, retrospective data will be collected on prescribing of opioids upon discharge for non-specific pain diagnoses in the emergency department at Southeastern Regional Medical Center. Patient data will be compiled from this list and will be checked within the North Carolina Controlled Substance Reporting System to determine if patients possess a history of chronic opioid use. Data will also be collected on prescribing patterns of each provider and compared to the group of emergency services providers at the institution. Correlation between history of chronic opioid use and opioid prescriptions received from the emergency department will be made with the goal of identifying opportunities for intervention using the North Carolina Controlled Substance Reporting System.

**Poster Title:** Retrospective analysis of the effectiveness of accelerated dose versus standard dose sotalol initiation in patients with atrial fibrillation or atrial flutter

**Primary Author:** John Toler, UNC REX Healthcare, NC; **Email:** john.toler@unchealth.unc.edu

**Additional Author(s):**
- Oksana Barakat
- Nastaran Gharkholonarehe
- Caroline Girardeau
- Stephanie Baumhover

**Purpose:** Sotalol initiation may be performed using two different dosing regimens: an accelerated dose initiation regimen utilizing higher than the maximum initial dose or standard dose initiation according to manufacturer recommendations. Comparative literature between the two initiation regimens has focused on safety and hospital length of stay but there is a lack of evidence regarding antiarrhythmic effectiveness. The purpose of this study is to determine if an accelerated dose sotalol initiation of 120mg or 160mg twice daily is associated with differences in antiarrhythmic effectiveness, safety, or length of stay when compared with a standard sotalol initiation of 80mg twice daily.

**Methods:** This project will be a single-center, retrospective evaluation of the effectiveness of an accelerated dosing initiation of sotalol 120mg or 160mg twice daily or a standard initiation of 80mg twice daily. Data will be collected via electronic medical record and sotalol monitoring record review. All patients receiving sotalol initiation for atrial fibrillation or atrial flutter at UNC REX Healthcare between 8/1/2014 and 8/1/2016 will be included. Excluded patients will be those treated for ventricular arrhythmias, contraindications to sotalol, creatinine clearance less than 40 mL/min, less than 18 years of age, cardiogenic shock, pregnancy, converting from class I or class III antiarrhythmic agents without adequate washout, and missing follow-up documentation within one month after discharge. A random sample of approximately 100 subjects will be used for each arm of the analysis. All clinic, emergency department, telephone, and inpatient encounters in the 30 days post-hospital discharge from the inpatient sotalol initiation will be reviewed. The primary endpoint will be the number of patients with a documented recurrence of atrial fibrillation or atrial flutter in each group within 30 days post-
hospital discharge. Secondary endpoints will include a comparison between groups of the discontinuation rates due to adverse events, the length of hospitalization for the sotalol load, and the proportion of patients requiring direct current cardioversion during sotalol initiation.

**Poster Title:** Evaluation of guideline-concordant empiric vancomycin use in the treatment of febrile neutropenia due to chemotherapeutic agents

**Primary Author:** Zachary Kritzer, UNC Rex Healthcare, NC; **Email:** zachary.kritzer@unchealth.unc.edu

**Additional Author(s):**
Jonathan Gerber
Rebecca Jones
Scott Christofferson

**Purpose:** Vancomycin use has increased dramatically in recent years and studies suggest that inappropriate prescribing has contributed to the rise of multi-drug resistant organisms such as vancomycin-resistant enterococcus. The current National Comprehensive Cancer Network and Infectious Diseases Society of America clinical guidelines for the treatment of febrile neutropenia stress the importance of limiting vancomycin use to certain clinical scenarios. We will evaluate the current prescribing practices at a community hospital to determine the rate of inappropriate vancomycin prescribing in patients with febrile neutropenia, compare clinical endpoints, and explore potential future stewardship opportunities to limit inappropriate vancomycin use in febrile neutropenia.

**Methods:** This study is a retrospective electronic medical record review of patients with febrile neutropenia due to chemotherapeutic agents who have received vancomycin as a part of empiric antimicrobial therapy. For the primary outcome of rate of guideline-concordant empiric vancomycin use, all patients meeting inclusion criteria will be screened by electronic medical record review for documentation of the National Comprehensive Cancer Network and Infectious Diseases Society of America guidelines criteria. These criteria include: suspected intravenous catheter infection, skin or soft-tissue infection, pneumonia, hemodynamic instability, severe penicillin allergy, colonization with penicillin or cephalosporin-resistant pneumococci or methicillin-resistant Staphylococcus aureus, or blood cultures positive for gram-positive organism. Patients who have documentation of at least one of the criteria will be considered guideline-concordant with respect to vancomycin use, and those patients who did not have any of the specified criteria will be considered guideline-discordant. The guideline-
concordant group will then be compared to the guideline-discordant group for the secondary outcomes of rate of adverse events related to vancomycin use, hospital length of stay, rate of discontinuation of vancomycin at 48 hours after initiation for those patients whose cultures have remained negative for gram positive organisms. The results of the study will be used to determine the need for antimicrobial stewardship efforts to reduce inappropriate vancomycin use in febrile neutropenia patients.

**Results:** N/A

**Conclusion:** N/A
Purpose: The 2014 American Society of Clinical Oncology (ASCO) practice guidelines update recommend low molecular weight heparin (LMWH) for treatment and secondary prophylaxis of venous thromboembolism (VTE) in oncology patients. When LMWH is not ideal, vitamin K antagonists are an acceptable alternative. Use of target specific oral anticoagulants (TSOACs) is not currently recommended in oncology patients because of limited data; however, prescribing of TSOACs (apixaban, dabigatran, edoxaban, and rivaroxaban) in this patient population is increasing in clinical practice. The purpose of this study is to evaluate the recurrence of VTE in oncology patients receiving TSOACs compared to those receiving LMWH.

Methods: This study is a retrospective cohort study conducted at multiple sites (hospital and physician clinics) within a single healthcare system. It has been submitted to the Institutional Review Board for approval. Patients included in the study are greater than or equal to 18 years old, have a diagnosis of cancer that confers high risk of VTE, have a diagnosis of deep vein thrombosis (DVT) or pulmonary embolism (PE), and are taking a TSOAC or LMWH. Patients are excluded if they are less than 18 years old, taking warfarin, are pregnant, or currently incarcerated. Patients will be identified using reports generated by the electronic medical record. Data on demographics, occurrence of DVT and PE, and bleeding will be collected using the same reports. Additional data regarding the clinical course will be collected, if necessary, via retrospective chart review. The primary endpoint will be rate of DVT and PE recurrence in the included patients while taking a TSOAC or LMWH. The secondary endpoint will be rate of major bleed defined as: a bleeding event causing a decrease in hemoglobin of 2 g per deciliter or
more; any bleeding event requiring transfusion of 2 or more units of blood; any bleeding event occurring in a critical site (intracranial, intraspinal, intraocular, retroperitoneal, or pericardial area); or any bleeding event contributing to patient death.

**Poster Title:** Use of proton pump inhibitors and association with Clostridium difficile infection at an academic medical center

**Primary Author:** Lauren Bode, University of North Carolina Hospitals and Clinics, NC; **Email:** lauren.bode@unchealth.unc.edu

**Additional Author (s):**
Stacy Campbell-Bright

**Purpose:** This academic medical center currently reports higher Clostridium difficile (C. diff) rates than its UHC counterparts and has begun to implement measures to decrease the incidence of documented C. diff infections by 10% by June 2017. The use of proton pump inhibitors (PPI) is a known risk factor for the development of C. diff, which is particularly problematic due to wide spread use of PPIs in both the inpatient and outpatient settings. This project seeks to describe current PPI use in an attempt to evaluate the efficacy of future interventions in decreasing inappropriate PPI prescribing.

**Methods:** This analysis is a retrospective chart review of 120 patients who were prescribed a PPI while admitted between March 2015 and February 2016. Ten patients will be selected for inclusion by identifying patients prescribed a PPI via the institutional electronic health record. Stratified sampling techniques according to admission date will be used to include 5 patients whose PPI use is a continuation of a home medication and 5 for whom the PPI is started initially as an inpatient each calendar month of the study period. Indications for PPI use will be evaluated based on age, sex, past medical history, current hospital problems, and inpatient medications. Other data collected will include the PPI dosing regimen and duration of use, the ordering provider, and the provider’s service. Outcomes measures to be assessed are proportion of appropriate indications for PPI use, appropriate discontinuation of PPI on discharge, and positive tests for C. diff at any point during admission.

**Poster Title:** Evaluation of clindamycin at a large community health system

**Primary Author:** Nichoals Patricia, WakeMed Health & Hospitals, NC; **Email:** npatricia@wakemed.org

**Additional Author(s):**
Shannon Holt

**Purpose:** Clindamycin is recommended in several guidelines including: surgical prophylaxis, skin and soft tissue infections (SSTI), and MRSA treatment guidelines. Meta-analysis completed in inpatient populations reported that clindamycin carries one of the highest risks for Clostridium difficile infections (CDI) compared to other antibiotic agents. The purpose of the study is to evaluate clindamycin prescribing practices and utilization at a large community hospital. Based on the results, the goal is to identify potential initiatives to optimize clindamycin usage and reduce the risk for hospital acquired-CDI.

**Methods:** This institutional review board has approved this retrospective, single-center study. Any adult inpatients who received at least one dose of clindamycin during February and March 2016 in the health system will be included. Patients who are less than 18 years of age, pregnant, or admitted for less than 24hrs will be excluded. Trends in clindamycin prescribing and potential areas for optimization will be determined. Data to be collected: patient demographics (age, sex, weight, penicillin or cephalosporin allergy), indication for clindamycin use (if utilized for surgical prophylaxis: surgical procedure, surgeon; if utilized for skin and soft tissue: type of SSTI, if culture collected, culture results, clindamycin sensitivity), clindamycin prescriber, location at time of clindamycin initiation, days of clindamycin therapy, presence of ID consult at initial order or during treatment course, and CDI (history of CDI, CDI documented within 90 days after exposure). All data will be recorded using a secure, HIPAA compliant, electronic data collection tool and confidentiality will be maintained.

Poster Title: Evaluation of albumin usage at a large community health system

Primary Author: Caitlin Akerman, WakeMed Health & Hospitals, NC; Email: cakerman@wakemed.org

Additional Author (s):
Ryan Tabis

Purpose: Albumin is a colloid solution used to treat a myriad of conditions, including hypovolemia and shock, as well as displaced fluid caused by large volume paracentesis. Because albumin is an endogenous blood product and is difficult to manufacture, the drug is prone to both high-cost and shortage. The purpose of this study is to quantify how albumin is being prescribed at a large community health system by reviewing the indications, doses, and providers who utilize this medicine.

Methods: This IRB-approved, retrospective, medication-use evaluation includes all inpatients 18 years and older who are not pregnant. A report run in the electronic medical record system identified all patients who received at least one dose of albumin between January 1, 2016 and March 31, 2016. The following data is being collected from the patient’s medical chart: demographic data (patient age, gender, admission date, discharge date, and length of stay), dose, route, and frequency of albumin, as well as indication for use of albumin, number of liters of fluid removed (if paracentesis is the indication), total dosage of albumin received, and provider name/specialty. All data is being recorded without patient identifiers and maintained confidentially. The most common indications and providers, as well as the amount of albumin administered, will be evaluated to determine if albumin is being utilized appropriately within the health system. Based on the results, the goal is to identify potential initiatives to optimize the usage of albumin at a large community hospital.

**Session-Board Number:** 10-256

**Poster Title:** Assessment of high dose gentamicin 7 mg/kg for open fracture prophylaxis in trauma patients

**Primary Author:** Cristina Kaifer, WakeMed Health & Hospitals, NC; **Email:** ckaifer@wakemed.org

**Additional Author (s):**
Mollie Grant
Renee Ackley

**Purpose:** Gentamicin is the most studied antibiotic for gram negative coverage following open fracture in trauma patients. Dosing schemes include conventional and high dose extended interval (HDEI). Advantages of HDEI include improved concentration-dependent killing, increased post-antibiotic effect, decreased risk of toxicity and adaptive resistance. Studies have evaluated 5-6 mg/kg once-daily compared to conventional dosing for prophylaxis and demonstrated once-daily regimens are safe and effective. Our institution administers 7 mg/kg once-daily, which has not been previously studied. The objective of this study is to evaluate the safety and efficacy of 7 mg/kg once-daily for open fracture prophylaxis in trauma patients.

**Methods:** This is a single-center, retrospective cohort study approved by the Institutional Review Board. Patients will be included if they are greater than 18 years of age with lower extremity open fractures, as identified through our institution’s trauma registry, who were admitted from May 2012 to May 2013, prior to implementation of high dose gentamicin for open fracture prophylaxis (conventional group), and from January 2015 to December 2015, after implementation of high dose gentamicin for open fracture prophylaxis (high dose group). The primary endpoint is acute kidney injury, defined as an increase in serum creatinine of ≥0.5 mg/dL or 50% from baseline, whichever is greater for two consecutive days after initiation of gentamicin until 48 hours after completion of therapy. Secondary endpoints will include surgical site infections, defined by the presence of positive microbiologic cultures during the index hospitalization, or during any subsequent admission to our health system within 90 days of the index hospitalization. Additional data to be collected includes: age, weight, body mass index (BMI), comorbidities, concomitant antibiotics, type of fracture, intensive care unit (ICU)
length of stay (LOS), hospital LOS, surgical procedures, and gentamicin levels (if collected for therapy >4 days).

**Poster Title:** Characterization and evaluation of bivalirudin and unfractionated heparin use in primary percutaneous coronary intervention at a large community hospital

**Primary Author:** Eric Sparks, WakeMed Health & Hospitals, NC; **Email:** rsparks@wakemed.org

**Additional Author (s):**
Janna Beavers

**Purpose:** Unfractionated heparin and bivalirudin are recommended as options for anticoagulation in ST-elevation and non-ST-elevation myocardial infarction patients undergoing percutaneous coronary intervention. Older trials suggested that bivalirudin had similar efficacy with reduced bleeding risk when compared to heparin. However, recently published studies demonstrated similar bleeding risks with the two agents. The optimal agent has not yet been identified however it is possible that heparin would be a cost-effective alternative in certain patients. We aim to characterize patients undergoing primary PCI at a large community hospital who received unfractionated heparin and bivalirudin to evaluate bleeding risk and to assess clinical outcomes.

**Methods:** This study will be a single center chart, retrospective cohort with approval by institutional review board. Patients will be included if they are 18 years or older, underwent cardiac catheterization, and received bivalirudin or unfractionated heparin during primary PCI between January 1, 2016 and March 31, 2016. The primary endpoint is the bleeding risk, based on NCDR scoring, for patients who received bivalirudin or unfractionated heparin during PCI. The secondary endpoints are the percentage of patients in bivalirudin and unfractionated heparin groups with a major or minor bleeding event during hospitalization and at 30 days; the percentage of patients in bivalirudin and unfractionated heparin groups with cerebrovascular accident, myocardial infarction, reinfarction, or stent thrombosis during hospitalization and at 30 days. Additional data to be collected will include: age, gender, weight, serum creatinine, hemodialysis status, past medical history, presence of ST-elevation on electrocardiogram, presence of shock, elective vs emergent nature of procedure, cardiac arrest event within 24 hours of PCI, anticoagulant dose, anticoagulant bolus use, post-procedure anticoagulant administration, anticoagulant duration, concomitant medications, procedure access site, and
type of intervention performed. All data will be recorded using a secure, HIPAA compliant, data collection tool.

Poster Title: Utilizing Indian Health Service counseling techniques in an independent community pharmacy to improve adherence rates among patients with diabetes, hypertension or hyperlipidemia

Primary Author: Natasha Colvin, Wingate University School of Pharmacy, NC; Email: n.colvin@wingate.edu

Additional Author(s):
Jennifer Buxton
Robert Ashworth
John Waggett
Billy King

Purpose: The purpose of this study is to utilize Indian Health Service (IHS) interactive counseling techniques and the Morisky Medication Adherence Scale (MMAS-8) to measure nonadherence and identify barriers. Taking medications correctly and not missing doses may lower the risk of having a heart attack, stroke, blindness, loss an arm/leg or kidney failure. It can also decrease emergency room visits and hospitalizations.

Methods: Subjects are current patients at an independent community pharmacy located in southeastern North Carolina and taking medication(s) for high blood pressure, diabetes, and/or high cholesterol. A master list will be obtained from PrescribeWellness, a password protected site only available to the store’s pharmacists. The master list will assign a random research ID number to each patient. To help protect patient’s confidentiality, only the first three letters of their last name, first two letters of their first name and research ID number (ie John Doe would be “DOEJO#”) will be combined to create a code, which will be documented in research records. The code will be used as a reference back to the master list. Each month, research subjects will be telephoned and asked to answer questions about their medications such as what medication(s) they are taking, how they are taking them, what they are taking them for and any missed doses. On the first encounter, subjects may be asked questions about your age, sex, race, type of insurance, years of education and medical conditions (diabetes, high blood pressure and high cholesterol) as they are not listed in their pharmacy profile and will help
describe the study's patient population. The subject’s doctor will be contacted if the pharmacist feels the patient is at risk for any harm based on the information provided.

**Results:** In-progress

**Conclusion:** In-progress
At the end of the study, data will be analyzed to show the impact of counseling techniques on adherence rates.
**Purpose:** The American Psychiatric Association recognizes that delirium can occur in 10-30% of all medically ill persons and is associated with a significant increase in morbidity, mortality, and length of hospitalization. Haloperidol is often prescribed prophylactically to prevent delirium; however it is not without risks, including QT interval prolongation, and extrapyramidal side effects. The objective of this study is to evaluate the appropriate use of haloperidol in a delirium prevention protocol and identify areas for provider education if necessary.

**Methods:** This study was submitted to the Institutional Review Board for approval. The electronic medical record system will be used to identify patients admitted to the hospital who had haloperidol ordered via the delirium prevention protocol from June 1, 2016 through August 31, 2016. The following patient-specific data will be identified: hospital identification number, age, and gender. Additionally, the dose, frequency, and quantity of haloperidol received, along with length of hospital stay will be collected. Provider and nurse documentation will be reviewed to determine if a corrected QT (QTc) interval was obtained, the timing of administration of haloperidol relative to the QTc interval, presence of contraindications for haloperidol use, and administration of haloperidol with disease state interactions. All data will be documented without patient identifiers and maintained confidentially. Data will be reviewed and analyzed to determine if haloperidol was ordered and monitored appropriately. Education to the healthcare team will be provided if areas requiring improvement are identified.

Poster Title: Evaluation of sugammadex usage in a community hospital operating room

Primary Author: Daniel Sullivan, Concord Hospital, NH; Email: daniel2sullivan@gmail.com

Additional Author(s):
Elizabeth Boucher
John Jezak

Purpose: Sugammadex and neostigmine are indicated for the reversal of the effects of the non-depolarizing neuromuscular blocking agents (NMBA) rocuronium and vecuronium in patients undergoing surgery. Sugammadex reverses the effects of these agents more rapidly than neostigmine but is also considerably more expensive. Our hospital has been using significantly more sugammadex than originally expected when it was added to formulary. The objective of this drug use evaluation is to determine the rate of usage of sugammadex since being added to formulary and to evaluate if further restrictions are needed.

Methods: This drug use evaluation will be submitted to the Institutional Review Board (IRB) for approval. The medical record will be used to identify patients who have received sugammadex or neostigmine from June 15, 2016 through August 31, 2016. All patients will be de-identified and information will be maintained confidentially. Patient age, gender, weight, admit time to post-anesthesia care unit (PACU), allergy to neostigmine, creatinine clearance, NMBA given, time NMBA given, dose of NMBA given, NMBA reversal agent given, time NMBA reversal agent given, dose of NMBA reversal agent, and cost of reversal agent will be collected. Factors that would influence the decision to give an NMBA reversal agent and comorbidities that would affect the choice of NMBA reversal agent will be collected if obtainable. The time from NMBA reversal agent administration to PACU admission and time from NMBA administration to NMBA reversal agent administration will be calculated. Data will be reviewed and analyzed to determine the rate of usage of sugammadex since being added to formulary and to evaluate if further restrictions are needed.

**Session-Board Number:** 10-261

**Poster Title:** Evaluation of the current prescribing practices of fluoroquinolone antibiotics for urinary tract infections at a tertiary academic medical center

**Primary Author:** Michelle Blesso, Dartmouth Hitchcock Medical Center, NH; **Email:** michelle.a.blesso@hitchcock.org

**Additional Author (s):**

Monica Andrawes  
Oleksandra Katrych  
Barry Barns Jr.  
Michael Calderwood

**Purpose:** Fluoroquinolone antibiotics are associated with disabling and potentially permanent side effects of the tendons, muscles, joints, nerves, and central nervous system in otherwise healthy patients. Due to this risk, the Centers for Disease Control and Prevention (CDC) and the Food and Drug Administration (FDA) recently recommended limiting the use of fluoroquinolones in acute, non-complicated infections by reserving them for patients with no other treatment options since the benefits do not outweigh the risks. The primary objective of this review is to evaluate prescribing patterns of fluoroquinolones for urinary tract infections at a tertiary academic medical center following new CDC recommendations.

**Methods:** This is a retrospective chart review of patients diagnosed with a urinary tract infection and treated with a fluoroquinolone antibiotic after the CDC released its new recommendations in March of 2016. Patients meeting this criteria between the dates of April 1, 2016 and September 15, 2016 were reviewed. They were identified using the medical center’s surveillance software program and were excluded from analysis if they were less than 18 years of age or were treated with a fluoroquinolone for less than 48 hours. Outcomes evaluated include the appropriateness of drug selection determined by allergy information, renal function, severity of infection, and documented urinary resistance within the past 6 months. Use of a fluoroquinolone in a patient with an uncomplicated urinary tract infection is defined as appropriate when a contraindication or allergy exists towards all other first-line options including nitrofurantoin, sulfamethoxazole/trimethoprim, fosfomycin, and cephalexin. Results
and conclusions are pending the completion of data collection. This study was approved for exemption by the medical center’s Institutional Review Board.

Poster Title: Evaluation of pharmacist-driven vancomycin dosing and monitoring protocol

Primary Author: Anna Espeland, Elliot Health System, NH; Email: aespeland@elliot-hs.org

Additional Author (s):
Jamie Godin

Purpose: Vancomycin, a widely used intravenous antibiotic, has a narrow therapeutic range that puts patients at risk for toxicities (specifically nephrotoxicity and ototoxicity) and/or development of antibiotic resistance and subsequent treatment failure. The objective of this study is to determine the utilization of our institution’s pharmacist-driven vancomycin dosing protocol, areas for improvement within the protocol and risk factors specifically obesity and renal function of patients resulting in non-therapeutic vancomycin levels.

Methods: This study is submitted to the Institutional Review Board for approval. The electronic medical record system will identify adult patients, admitted January 2016 through March 2016, who have had at least one vancomycin trough level for their admission. The following data will be collected: vancomycin dose, frequency, and duration; vancomycin trough concentrations and timing; indication for use and goal trough desired; renal function markers (serum creatinine, creatinine clearance and urine output); use of other nephrotoxic medications; culture identification and susceptibilities; when and if antibiotic coverage was narrowed; patient demographics (age and weight); and total length of stay. All data will be recorded without patient identifiers and maintained confidentially. Using specific institutional trends such as how often desired troughs were achieved and which patients had evidence of renal toxicity, data will be analyzed for quality improvement measures. These measures could include but are not limited to: identifying patients that should receive loading doses, dosing for obese patients, dose adjustment for patients with unstable renal function, dose adjustments for patients not within desired goal range, and trough monitoring optimization of current vancomycin dosing.

**Poster Title:** Evaluation of medication reconciliations at hospital discharge

**Primary Author:** Candace Chin, Elliot Health System, NH; Email: cchin@elliot-hs.org

**Additional Author (s):**
Donna Farrar

**Purpose:** Patients are often discharged with medications that have undergone multiple changes during their lengths of stay in hospitals. Changes may include unintentional addition or deletion of medications, adjustment of doses, or duplication of therapies. These discrepancies may lead to adverse effects after discharge and therefore hospital readmissions. Medication reconciliation is the process of reviewing medication profiles and addressing inconsistencies during transitions of care. The purpose of this study is to evaluate the accuracy of discharge medication reconciliations for inpatients transferring to Northeast Rehabilitation within the hospital.

**Methods:** This retrospective study has been submitted for approval by the Institutional Review Board. A report generated from the electronic medical record will identify all adult patients discharged on at least one prescription or over-the-counter medication to Northeast Rehabilitation from the hospital between July 1st, 2015 and June 30th, 2016. The following data will be collected: number of patients participating in the process, type and number of medication discrepancies encountered (incorrect medications, medication omissions, medication duplications, dosing errors, drug interactions), number of discrepancies involving high-risk medications (anticoagulants, antibiotics, cardiovascular, neurological), number of incomplete prior to admission medication reconciliation lists, and thirty-day hospital readmission rates. All data will be recorded without patient identifiers and maintained confidentially. The data will be analyzed to identify any opportunities for improvement in the medication reconciliation discharge process. Such opportunities may include increasing patient education on their medications upon discharge and creating a process to clarify the status of medications patients take prior to admission. Additionally, results may support the need for multidisciplinary involvement with pharmacists included in the process by having them conduct medication reconciliations upon discharge and create medication lists for patients.

**Poster Title:** A review of a phenobarbital protocol used for acute alcohol withdrawal syndrome in a hospital setting  

**Primary Author:** Ryan Fabrycki, Elliot Health System, NH; **Email:** rfabrycki@elliot-hs.org  

**Additional Author(s):**  
Peter Hughes  

**Purpose:** Acute alcohol withdrawal syndrome is typically managed with benzodiazepines. However, some patients may present with symptoms that are refractory, even to large doses of benzodiazepines. Phenobarbital has been used as an alternative in the treatment of acute alcohol withdrawal syndrome. The objective of this study is to review the utilization of our institution’s phenobarbital protocol and identify areas for improvement.  

**Methods:** This retrospective study has been submitted to the institutional review board for approval. Patients will be identified through the electronic medical record system that were admitted to the hospital and placed on the phenobarbital protocol during the time period of 7/1/2015 to 6/30/2016. The data collected will include number of patients treated, loading doses given, maintenance doses given, CIWA scores (initially, at 24 hours, at 48 hours and at 72 hours), patients discharged on the protocol, patients that completed the protocol, and hospital length of stay. All data will be recorded without patient identifiers and maintained confidentiality. Data obtained from this study will be reviewed to implement any necessary changes to the protocol including but not limited to: increased loading dosing, reduction in duration of therapy and cost savings due to shorter length of stay.  

**Results:** N/A  

**Conclusion:** N/A
**Submission Category:** Clinical Services Management

**Submission Type:** Research-in-Progress

**Session-Board Number:** 10-265

**Poster Title:** Impact of pharmacy students on patient utilization of a hospital provided discharge medication service

**Primary Author:** Sarah Simpson, Wentworth Douglass Hospital, NH; **Email:** sarah.simpson@wdhospital.com

**Additional Author(s):**
Chantale Malone
Tonya Carlton
Ashley Child
Melanie McGuire

**Purpose:** Studies indicate that a significant number of medication-related hospital admissions are due to poor medication management. Pharmacists can improve patient adherence and ensure proper medication use by providing counseling services and access to medications at the time of discharge. The purpose of this project is to incorporate pharmacy students to streamline and promote the utilization of the discharge medication service at Wentworth-Douglass Hospital.

**Methods:** This study will be reviewed by the Institutional Review Board (IRB) for approval prior to initiation. The design will be a retrospective review that will evaluate the number of eligible patients utilizing the discharge medication service. A formalized assessment tool will be used to compare the number of patients using the medication discharge service prior to and after the incorporation of pharmacy students. Baseline utilization data will be measured in a 3 month period prior to the pharmacy student intervention and will be compared to a 3 month period post pharmacy student implementation. Two pharmacy students will be used to identify eligible patients and offer the medication discharge service. Inclusion criteria: patients on medical floors, patients being discharged to home, patients being discharged during outpatient pharmacy hours, and patients with prescriptions. Exclusion criteria: patients being discharged to another facility, patients who have out of network insurance coverage, or patients being discharged outside of outpatient pharmacy hours. The primary endpoint will compare the number of patients utilizing the discharge medication service prior to and after incorporating...
pharmacy students. The secondary endpoints will compare hospital readmission rates and examine the direct and indirect financial impact of this service.

**Results:** In progress

**Conclusion:** In progress

**Poster Title:** Evaluation of Use of Rapid Sequence Intubation Agents and Place in Therapy for Sugammadex in the Emergency Department

**Primary Author:** Christina Aldrich, Avera McKennan, SD; **Email:** christina.aldrich@avera.org

**Additional Author (s):**
William Coolidge
Thomas Johnson

**Purpose:** Recent literature has found shorter recovery time with the use of rocuronium-sugammadex compared to succinylcholine for rapid sequence intubation (RSI) in surgical patients. With recent approval of sugammadex, there is potential for increased use of rocuronium for RSI in the emergency department. The primary objective of this study is to evaluate the appropriate selection of neuromuscular blockade for RSI in the emergency department before and after implementation of an algorithm for selection of neuromuscular blockers (N MBA). The secondary objectives are to evaluate the number of failed intubation attempts and determine a place in therapy for sugammadex in the emergency department.

**Methods:** A retrospective drug utilization review will be performed to analyze the use of NMBAs for RSI in the emergency department from April 1st – July 31st 2016. A report will be generated through the Avera McKennan quality review department to identify patients who received RSI according to preset inclusion criteria. In September 2016, an algorithm will be implemented to guide providers to appropriate NMBA selection. Retrospective chart review will be completed post-implementation from October 1st – December 31st, 2016 to determine if there is a difference in appropriate agent selection before and after implementation. Appropriate use of NMBA agents will be defined according to clinical contraindications. Succinylcholine is contraindicated in patients with a history of myasthenia gravis or malignant hyperthermia, family history of malignant hyperthermia, end stage renal disease, hyperkalemia, denervation injuries, 24—48 hours post crush or burn injuries, and penetrating eye injuries. For these patients, rocuronium should be selected as the agent of choice. However, if there is a lack of clinical contraindications, succinylcholine should be selected. Chart review will be performed.
to collect the following data: age, sex, general medical or trauma patient, Level 1 or Level 2 trauma, agent/dose used, physician, contraindication to succinylcholine, number of intubation attempts, failed intubation. A subgroup analysis will be performed for trauma patients who received RSI in the emergency department.

**Results:** Pending IRB approval and data collection

**Poster Title:** Warfarin reversal for intracranial hemorrhage at an academic medical center

**Primary Author:** Alicia Christensen, Avera McKennan Hospital & University Health Center, SD; Email: alicia.christensen@avera.org

**Additional Author (s):**
Kyle Dvoracek  
Wissam Asfahani  
Kari Taggart  
Thomas Johnson

**Purpose:** Patients with anticoagulant-associated intracranial hemorrhages have increased morbidity and mortality due to larger hemorrhage volumes, hematoma expansion, and increased comorbidities. Reversal of anticoagulation is paramount in the initial management of these patients to attempt to limit hematoma expansion and improve morbidity and mortality. The purpose of this study is to describe how warfarin-associated intracranial hemorrhages are currently being managed at Avera McKennan Hospital & University Health Center, specifically comparing the institution’s adherence to guideline recommendations newly published by the Neurocritical Care Society/Society of Critical Care Medicine and the American Heart Association/American Stroke Association.

**Methods:** This retrospective, observational study will be approved by the institutional review board prior to data collection. The study period will occur from April 30, 2013 to May 31, 2016, and will evaluate patients admitted to Avera McKennan Hospital with a warfarin-associated intracranial hemorrhage. Patients will be selected for review based on discharge ICD9 and ICD10 diagnosis codes. Protected populations and patients initiated on comfort care measures within 48 hours of hospital admission will be excluded from the analysis. Primary endpoints points that will be evaluated include administration of guideline-recommended doses of vitamin K and 4-factor PCC and that the recommended INR monitoring is obtained. Secondary endpoints will examine rates of hematoma expansion, size of hematoma expansion, thrombotic events, mortality, blood pressure and blood glucose excursions, and use of mechanical and pharmacologic VTE prophylaxis. Results will be used to improve care of these patients at the institution and generate hypotheses for further study.
Results: Data collection in process.

Conclusion: To be determined.

Poster Title: Probability of target attainment with broad-spectrum beta-lactam antibiotics against key gram-negative bacteria among inpatients at an academic medical center

Primary Author: Ashley Eckert, Avera McKennan Hospital & University Health Center, SD; Email: ashley.eckert@avera.org

Additional Author(s):
Brad Laible

Purpose: Increasing resistance among gram-negative bacteria and the varying dosing regimens for beta-lactam antibiotics with activity against these bacteria can create uncertainty in choosing an appropriate antibiotic and dosing regimen. The purpose of this study is to determine the minimum inhibitory concentration (MIC) distribution among key gram-negative bacteria at an academic health center and evaluate the adequacy of beta-lactam antibiotic dosing regimens against these bacteria.

Methods: The institutional review board has approved this retrospective, observational study. Infection surveillance software will be used to identify isolates of Escherichia coli, Pseudomonas, Enterobacter and Klebsiella collected in the institution from January 1, 2016 to December 31, 2016. Minimum inhibitory concentration data for cefepime, piperacillin-tazobactam and meropenem will be collected by manual chart review using the electronic medical record. The date of collection and source of the culture will also be recorded for each bacterial isolate identified. All isolates collected from inpatients at the institution during the study period will be included with the exception that exact duplicates will be excluded. Isolates from the same patient and source collected on separate days of the same admission will be included but will be numbered in the order of collection to allow analysis of data for all isolates as well as for first isolates separately. All collected data will be de-identified and maintained in a confidential manner. The collected data will be pooled to determine the overall MIC distribution at the institution for each bacteria. Existing Monte Carlo simulation data will be used to determine the probability of achieving drug concentrations above the MIC for an adequate percentage of time during treatment using each dosing strategy against each studied bacteria.

Poster Title: Evaluation of appropriate monitoring and toxicity management of programmed cell death-1 receptor and program cell death-1 ligand inhibitor therapy in an oncology clinic

Primary Author: Christine McNamara, Avera McKennan Hospital & University Health Center, SD; Email: christy.mcnamara@gmail.com

Additional Author (s):
Robin Lockhorst
Jacob Hobbs

Purpose: Nivolumab, pembrolizumab, and atezolizumab are oncology agents that affect T-cell regulation. The activation of T-cells can potentially cause life threatening immune-related adverse effects (irAE). The package inserts of these medications specifically outline treatment recommendations based on the severity of the reaction, commonly suggesting the use of corticosteroids and withholding treatment. Monitoring for irAEs and clinician awareness of their unique treatment is important due to the unpredictability and seriousness of irAE. This study will assess the appropriate monitoring, incidence and subsequent treatment of irAEs in an ambulatory oncology clinic.

Methods: This study is a single-center, retrospective chart review of patients receiving programmed cell death-1 receptor (PD-1) or programmed cell death-1 ligand (PD-L1) inhibitor therapy, including nivolumab, pembrolizumab or atezolizumab in an ambulatory oncology clinic. Patients will be identified by chart review and data will be collected through the electronic medical record systems of the hospital and oncology clinic between September 1, 2014 and January 31, 2017. The primary objective will quantify the incidence of appropriate monitoring for immune related adverse effects (irAE) based on the recommendations according to the medication package insert and order sets of the cancer institute which are the standard of care based on physician board approval. Data collection for this objective will include labs, physical exams, and provider notes. Secondary objectives will quantify the incidence of irAEs and evaluate the subsequent treatment. Treatment of irAE will be evaluated according to package insert recommendations. Assessment of therapeutic response to drugs will also be collected and analyzed through
medical chart review and will include provider notes and imaging. This study has been approved by an IRB.

**Poster Title:** Evaluating and comparing the risk and implications of serotonin norepinephrine re-uptake inhibitors versus selective serotonin re-uptake inhibitors in patients with congestive heart failure

**Primary Author:** Jessica McManus, Avera McKennan Hospital and University Health Center, SD; Email: jessica.mcmanus@avera.org

**Additional Author(s):**
Kazuhiro Kido
Surachat Ngorsuraches
Luke Klugherz
Andrea Burr

**Purpose:** One antidepressant drug class, serotonin norepinephrine reuptake inhibitors (SNRIs), has been noted by the American Psychiatric Association as appearing to be safe in those with heart diseases, like congestive heart failure (CHF); however, based on the pathophysiological processes associated with the development of CHF and considering SNRIs sympathetic nervous stimulation, SNRIs may be associated with CHF exacerbation. The purpose of this study is to compare the safety and risks associated with using SNRIs versus selective serotonin re-uptake inhibitors (SSRIs) in CHF.

**Methods:** This study has been approved by the Institutional Review Board. It is a retrospective cohort study utilizing electronic medical records to identify patients who were admitted from January 1, 2010 to September 1, 2016. Inclusion criteria includes those 18 years or older, diagnosed with systolic or diastolic CHF (identified by ICD-9 and ICD-10 codes), and are prescribed to either a SSRI or SNRI. Exclusion criteria includes those who are prescribed to a tricyclic antidepressant, prior or current chemotherapy with an anthracycline agent, no available echocardiogram or left ventricle ejection fraction (LVEF), and pregnant or breastfeeding. The following pertinent information will be obtained: Age, gender, race, body weight, type of heart failure (HF), date of diagnosis, LVEF, systolic and diastolic blood pressure, heart rate, major medical history, SSRI or SNRI medication, dose and start date, echocardiogram, New York Heart Association (NYHA) Functional Classification, medications indicated in the management of CHF and acute decompensated heart failure (ADHF) including
medications used for symptomatic relief, BNP (brain natriuretic peptide) and NT-proBNP (N-terminal pro-brain natriuretic peptide), and doses of diuretics. Reviewers will compare SSRI and SNRI all-cause hospitalizations, hospitalizations due to heart failure, and incidence rates of newly diagnosed CHF. Reviewers will also analyze the aforementioned based on a predefined subgroup analysis comparing HF with reduced ejection fraction (EF) versus HF with preserved EF.

Poster Title: Retrospective review of data to compare the effects of various continuous sedation methods on hemodynamics, sedation level, recovery period, and complications in pediatric patients

Primary Author: Hubert Lahr, Avera McKennan Hospital and University Health Center, SD; Email: hubert.lahr@jacks.sdstate.edu

Additional Author(s):
Emily Sass

Purpose: Pediatric sedation necessitates a systematic approach that requires a clear understanding of appropriate medication usage. Also, physicians and other medical staff should know how to consistently treat patients. Two primary pediatric physicians within Avera McKennan have differing preferred continuous sedation methods. As pharmacists, we wanted to compare the effects of the various continuous sedation methods on hemodynamics, sedation level, recovery period, and complications in the pediatric patients. The overall outcome of the study will hopefully improve clinical outcomes for pediatric patients requiring continuous sedation. Also, this study will potentially standardize a pediatric sedation method and improve nursing satisfaction.

Methods: This study will be submitted to the Institutional Review Board for approval. This retrospective study will have data collection take place from August 1, 2015 to December 31, 2016, with plans to perform analysis during January 2017. All data will be recorded without patient identifiers and will maintain confidentially. The following parameters for sedated pediatric patients less than or equal to 18 years of age, receiving either dexmedetomidine or midazolam continuous infusions will be compared: heart rate, blood pressure, respiratory rate, and peripheral oxygen saturation. Sedation level, ventilator days, ICU days, recovery time, and ease of management for nursing will also be collected through number of nursing interventions, boluses given, bags exchanged, and syringes exchanged. Research is needed to optimize best practice within the Avera McKennan health institution and to have a consistent protocol for all professional staff to follow.

Poster Title: Comparison of mTOR inhibitor associated stomatitis rates in oncology patients initiated on everolimus with and without use of prophylactic steroid-based mouthwash: A case-control study

Primary Author: Ashley Losing, Avera McKennan Hospital and University Health Center, SD; Email: ashley.losing@avera.org

Additional Author (s):
Grant Middendorff
Rachel Elsey

Purpose: Stomatitis is one of the hallmark adverse events occurring in patients initiated on mTOR inhibitors, with an incidence rate estimated at sixty-seven percent. Patients experience discomfort or pain, which may escalate to inadequate nutrition or hydration, leading to dose reduction or treatment discontinuation. Recent literature has shown that it may be possible to prevent mTOR inhibitor associated stomatitis with the use of prophylactic steroid-based mouthwash. The objective of this study is to assess the risk of stomatitis in patients that receive a prophylactic mouthwash during the first 12 weeks of treatment versus those who do not.

Methods: This study has been approved by the Institutional Review Board. This study will be a retrospective, case-control analysis of patients over 18 years of age initiated on everolimus therapy between June 2014 and June 2016 at a regional cancer center. Through utilization of the electronic medical record system, cases will be identified as those patients who developed mTOR inhibitor associated stomatitis within 12 weeks of everolimus initiation. These cases will be matched on the basis of age, sex, body mass index, and cancer indication to controls that did not develop stomatitis. Patients will be excluded if stomatitis was present at time of everolimus initiation, chronic treatment with systemic steroids, indication for everolimus other than cancer, or indication of subependymal giant cell astrocytoma. Primary exposure of interest will be receipt of compounded prophylactic mouthwash. Other data to be collected include cancer stage, receipt of previous chemotherapy, treatment regimen, comorbidities, adverse event descriptions, and prescription fill data. Assuming an odds ratio of 4 as clinically significant, and power of 80 percent, we estimate a sample size of 59 cases per group or a total of 118 patients. Multiple logistic regression and descriptive analysis will be conducted.

Poster Title: Evaluation of the accuracy of low molecular weight heparin-calibrated anti Xa levels as a surrogate marker to measure rivaroxaban and apixaban activity

Primary Author: Mindy Hanten, Avera McKennan Hospital and University Health Center, SD; Email: melinda.hanten@avera.org

Additional Author(s):
Jodi Wendte
Brandon Johnson
Alicia Thole

Purpose: Rivaroxaban and apixaban concentrations can be accurately and rapidly obtained using a chromogenic antifactor Xa assay with specific drug calibrator material. However, the only rivaroxaban and apixaban calibrators that are available are approved for research use only. The objective of this study is to explore the relationship and determine the accuracy of using low molecular weight heparin-calibrated anti Xa levels as a surrogate measure of direct oral factor Xa inhibitor activity in samples from subjects taking rivaroxaban or apixaban for the treatment of venous thromboembolism (VTE) or non-valvular atrial fibrillation.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients receiving apixaban or rivaroxaban upon admission for the treatment of venous thromboembolism or non-valvular atrial fibrillation. The following data will be collected: patient age, gender, current direct oral factor Xa inhibitor and dose, low molecular weight heparin-calibrated anti Xa level, and direct oral anticoagulant-calibrated anti Xa level. The electronic medical record system will also identify any recorded history of renal or hepatic insufficiency. An interview to assess the degree of medication adherence will be conducted between the investigator and the patient. All data will be recorded without patient identifiers and maintained confidentially. The results of the direct oral anticoagulant-calibrated anti Xa level and low molecular weight heparin-calibrated anti Xa level will be statistically analyzed to determine if a correlation exists between the two levels. The reviewers will evaluate the utility of the low molecular weight heparin-calibrated anti Xa level as a surrogate marker for measuring apixaban and rivaroxaban activity.

**Poster Title:** Evaluation of the optimal time zero regarding antibiotic administration in severe sepsis/septic shock patients presenting to the emergency department

**Primary Author:** Alyson Schwebach, Avera McKennan Hospital and University Health Center, SD; **Email:** alyson.schwebach@avera.org

**Additional Author (s):**
Kylee Bitner
Ryan Waybright

**Purpose:** The optimal time zero (T0) regarding antibiotic administration in severe sepsis/septic shock patients in the emergency department (ED) remains uncertain. The Surviving Sepsis Campaign guidelines use T0 as the time of triage in the ED, differing from the Centers for Medicare and Medicaid Services Sepsis Core Measure which uses earliest chart documentation of severe sepsis/septic shock. This study aims to evaluate patient outcomes when antibiotics are administered within three hours of a positive severe sepsis/septic shock screen, within three hours of ED presentation, or outside both three hour windows to assist in determining the most beneficial T0 for antibiotic administration.

**Methods:** This study will be submitted to the Institutional Review Board for approval. Patients presenting to the emergency department from October 1st, 2015 through September 30th, 2016 will be retrospectively reviewed for positive severe sepsis/septic shock screens and grouped based on time of antibiotic administration. Data collected will include the following: time of ED presentation, time of positive severe sepsis/septic shock screen (vitals and systemic inflammatory response syndrome (SIRS) criteria), time of antibiotic administration, likely source of infection, duration of hospital stay, inpatient mortality, intensive care unit (ICU) admission, vasopressor and steroid use, comorbidities, and general demographic data. All data collected will be maintained confidentially and will not be associated with patient identifiers. Patients overlapping into both three hour windows of antibiotic administration following presentation to the ED and a positive severe sepsis/septic shock screen will be evaluated as part of the ED presentation group. This subset of patients will also be analyzed separately. The primary endpoint of this study will be inpatient mortality differences among the three comparator
groups. Secondary endpoints will include duration of hospital stay, ICU admissions within 48 hours, and vasopressor and steroid use.

Poster Title: Evaluating the use of appropriate anticoagulation with lenalidomide and pomalidomide in patients with multiple myeloma

Primary Author: Sarah Anderson, Avera McKennan Hospital and University Health Center, SD; Email: sarah.m.anderson.17@gmail.com

Additional Author(s):
Bradley Beck
Susan Sterud
Robin Lockhorst
Surachat Ngorsurach

Purpose: As the number of patients receiving novel therapies for multiple myeloma increases and these patients survive their disease longer, the opportunity for complications arises. Lenalidomide and pomalidomide are two immunomodulatory medications with the potential to improve overall survival for these patients; however, a black box warning for venous thromboembolism (VTE) exists. Therefore, the need for quality assurance with prophylactic anticoagulation guidelines is essential. The purpose of this study is to assess overall adherence to guideline recommendations for anticoagulation therapy with lenalidomide and pomalidomide in multiple myeloma patients.

Methods: This retrospective study has received institutional review board approval. The study will analyze patients diagnosed with multiple myeloma and treated with lenalidomide or pomalidomide. It will focus on those who received care at an ambulatory oncology clinic between the calendar years 2013 through 2015. Patients will be identified from lists generated through the associated specialty pharmacy and REMS. Chart reviews will be utilized to collect pertinent patient data. The primary endpoint of the study is prescription of appropriate anticoagulation upon initiation of therapy based on a list of pre-determined risk factors. These risk factors include: obesity, prior VTE, central venous access device or pacemaker, associated disease (cardiac disease, chronic renal disease, diabetes, acute infection, immobilization), surgery (general surgery, anesthesia, trauma), erythropoietin use, blood clotting disorders, hyperviscosity, multi-agent chemotherapy and/or doxorubicin, and high-dose dexamethasone. Secondary endpoints include incidence of deep venous thrombosis, pulmonary embolism,
myocardial infarction, stroke, and major bleeding; initial anticoagulant prescribed; and whether or not anticoagulation was currently prescribed for another disease state.

**Poster Title:** Evaluating the impact on seizure duration of holding, dose reducing, or continuing anticonvulsant medications prior to electroconvulsive therapy

**Primary Author:** Haylee Brodersen, Avera McKennan Hospital and University Health Center, SD; Email: haylee.brodersen@avera.org

**Additional Author (s):**
Lisa Rausch
Margaret Haberman
Jeremy Daniel

**Purpose:** ECT and scheduled anticonvulsants have individually been shown as safe, effective treatment options for a wide range of psychiatric conditions. A correlation exists between ECT seizure duration and clinical outcomes. However, little research has been conducted regarding the effects of scheduled anticonvulsants on ECT seizure duration. Anticonvulsants potentially interfere with therapeutic seizure precipitation, which could decrease ECT effectiveness. The current ECT order set at the study institution does not address scheduled anticonvulsants prior to ECT. This study aims to detect a difference in seizure duration between patients who had anticonvulsants held, dose reduced, or continued at original dose.

**Methods:** This study has been approved by the Institutional Review Board. A drug search will be performed in the electronic medical record to identify patients prescribed glycopyrrolate, a standard pre-medication for ECT at the study institution. Subjects will be included if they were inpatients 18 years and older, admitted 1 January 2012 to 31 August 2016, received ECT, and received scheduled anticonvulsants. Patients will be excluded if they have a reported pregnancy or positive pregnancy test, or were administered benzodiazepines in the 12 hours prior to ECT. Information collected for each patient will include admission and discharge date; age; sex; length of inpatient stay; ECT indication; anticonvulsant dose, schedule, and indication; anticonvulsant drug levels; and whether scheduled anticonvulsant medications were held, dose decreased, or continued prior to each ECT session. For each ECT session, the following will be collected: ECT number and date; electrode placement; charge; motor seizure duration; electroencephalogram (EEG) seizure duration; administered pre-medications and their dose; and presence or absence of induction medications, and their dose. Seizure duration will be
compared between patients who had scheduled anticonvulsants held, dose reduced, or continued prior to ECT therapy.

Poster Title: Implementation of a pharmacy protocol for intravenous (IV) to oral (PO) conversion between unlike antibiotics in the hospital setting.

Primary Author: Charles Morrison, Rapid City Regional Hospital, SD; Email: cmorrison2@regionalhealth.com

Additional Author(s):
Veronica Lesselyoung
Joe Strain
Chelsea Conway

Purpose: Antibiotic IV to PO conversion protocols have become common practice among hospital institutions. These conversions reduce complications, cost of care, and length of hospital stay. Misconceptions have led to unwillingness to switch patients to oral therapy in a timely manner. Current institutional policy only allows for IV to PO conversion of the same antibiotic. Literature has established that other antibiotics could be converted from the IV form to a therapeutically equivalent PO form. This project will help identify proper exchanges for intravenous agents that do not have an oral dosage form in order to expand an existing antimicrobial conversion protocol.

Methods: This study is pending Institutional Review Board approval. This prospective study will evaluate patients 18 years and older on intravenous ceftriaxone, ampicillin/sulbactam, and cefazolin for conversion therapy eligibility. Evaluation will occur three times weekly for a period of 3 months. If the patient meets criteria for conversion, the provider will be contacted and a suggestion will be made to convert to an oral therapeutically equivalent antibiotic. During the study period, the following data will be collected: age, gender, weight, BMI, indication for antibiotics, IV antibiotic and dose, result of recommendation, PO antibiotic and dose, culture source, identified bacteria, IV, PO and total antibiotic days, length of stay, 30-day readmission, readmission diagnosis, and 30-day reinfection. The electronic medical record and monitoring systems will be used for data collection.

**Poster Title:** Empiric vancomycin use in community-acquired pneumonia in hospitalized Native American patients

**Primary Author:** Jessica Rounds, Rapid City Regional Hospital, SD; **Email:** jrounds2@regionalhealth.com

**Additional Author (s):**
John Kappes

**Purpose:** The prevalence of methicillin resistant staphylococcus aureus (MRSA) in community-acquired pneumonia is not fully identified. A recent study suggested the prevalence is roughly 0.7 percent. This study also found 30 percent of patients are treated empirically with anti-MRSA antibiotics. Currently no studies specifically show the prevalence of MRSA community-acquired pneumonia in the Native American population. The purpose of this project is to evaluate empiric antibiotics and the prevalence of MRSA community-acquired pneumonia the Native American population.

**Methods:** A retrospective, electronic medical chart review of patients hospitalized with community-acquired pneumonia. This study is pending institutional review board approval. Patients will be identified with International Statistical Classification of Diseases (ICD 10) code from October 1st, 2015 to October 1st, 2016. Patients 18 years or older with evidence of community acquired pneumonia will be included. Exclusion criteria are patients who are immunosuppressed or have a history of MRSA. Data collection will include admission date, intensive care unit or medical floor admission, age, gender, race, comorbidities (diabetes, alcoholism, and chronic obstructive pulmonary disease), smoking history, temperature, respiratory requirements, white blood cell counts, lactic acid on the first day of antibiotics, microbiology results, sputum culture quality, serology results, empiric antibiotics started, and CURB-65 scores.

Poster Title: Improved patient care with pharmacist-directed interventions in the emergency department of a community hospital.

Primary Author: Amber Yaeger, Rapid City Regional Hospital, SD; Email: ayaeger@regionalhealth.com

Additional Author (s):
Katie Hayes
Cindy Way

Purpose: Nationwide, emergency departments are known to have the highest rate of medication errors in a hospital facility. This study will quantify the interventions made with a pharmacist present in the emergency department during high volume times. Secondarily, a comparison of the emergency department’s perception of a pharmacist in the emergency department before and after a pharmacist has been available to make interventions for improved patient care will be evaluated. The site-specific information within a community hospital, with no current pharmacist coverage of the emergency department, will guide the future of an emergency department-based pharmacist position.

Methods: This study is pending Institutional Review Board approval. The prospective study will be conducted at a level II trauma center equipped with a 28-bed emergency department, providing care for adult and pediatric patients of Rapid City, South Dakota and surrounding communities. The primary objective will identify the quantity of cumulative interventions posed by a pharmacist while present in the emergency department. Secondary outcomes include the changes in perception of a pharmacist’s presence in the emergency department pre- and post-study period, the change in medication error rate, the associated cost savings of interventions, and the acceptance rate of the interventions suggested. The primary investigator will be available in the emergency department during high volume hours to make real-time interventions to all patients with intended medication administration in the emergency department. For the purpose of this study, orders from an admitting physician will be excluded from analysis. Recommendations will primarily be conducted verbally and occasionally written when unable to locate the physician. Each identified intervention will get recorded in an Excel spreadsheet according to the designated intervention subcategory. The emergency department
staff will complete a short survey to identify the baseline perception of pharmacist presence in the emergency department before the trial begins. The Likert-ranked survey will be repeated at the end of the study period for comparison to baseline.

Poster Title: Comparison of pharmacist-led versus nurse-led discharge medication education on 30-day readmission rates in patients diagnosed with acute myocardial infarction

Primary Author: Matthew Slagle, Confluence Health Central Washington Hospital, WA; Email: matthew.slagle@confluencehealth.org

Additional Author (s):
Joseph Jaspers
Laurel Aaberg

Purpose: In 2013, the Agency for Healthcare Research and Quality reported acute myocardial infarction (AMI) as the fifth most costly condition to our healthcare system. Central Washington Hospital’s current overall 30-day readmission rates are lower than the national average, whereas 30-day readmission rates for AMI were found to be no different. Various studies have found reductions in 30-day readmission rates when pharmacists have an active role in the discharge process. This study will observe whether pharmacist-led medication counseling results in a reduction of 30-day readmission rate in patients with AMI, as standard discharge practice at Central Washington Hospital currently omits pharmacist.

Methods: This study is pending approval from the Washington State University Institutional Review Board. Recruitment for this study will occur for all patients with an AMI meeting study inclusion, upon admission to Progressive Care Unit. Once informed consent has been obtained, patients will be randomized in a five to three fashion to receive discharge medication counseling from a pharmacist or from a nurse, the standard practice at Central Washington Hospital. In the event a pharmacist cannot counsel an assigned patient, that patient will be moved to the nursing cohort for the remainder of the study. A review of the patient’s profile will be conducted to determine AMI risk factors and cardiac medications prior to admission. At the time of discharge, the pharmacist or nurse will complete a standardized form to record time spent discussing medications, and various accepted medication interventions. Patient identifiers will be removed and this information will be inputted into a Microsoft Excel spreadsheet. With the provided phone number, patients will be contacted 31-days post-discharge to determine hospital readmission or emergency department visit in the previous 30-
days. Patients will be asked a standardized questionnaire regarding their discharge counseling experience. The study is expected to last three months.

Poster Title: Clinical pharmacists have the prescription to fix your emergency department: Implementation of an emergency department pharmacist

Primary Author: Michael Zacher, Confluence Health- Central Washington Hospital, WA; Email: michael.zacher@confluencehealth.org

Additional Author(s):
Lauren Wheeler
Greg Stahly
Ben Sharples

Purpose: The American Society of Health-System Pharmacists (ASHP) and Fairbanks et al, have shown that up to 78 percent of medication related adverse events can be prevented by utilization of an ED pharmacist. As of 2003, only about 3 percent of hospitals had clinical pharmacists assigned to the emergency department (ED). This disparity is detrimental to patient safety. The primary aim of this study is to assess the impact of an ED pharmacist, and demonstrate that benefit exists in placing a pharmacist directly in the ED. Secondary aims are to gauge opinions, barriers, and financial constraints that exist for placement.

Methods: This study will seek Institutional Review Board approval from Washington State University. A clinical pharmacist will perform a 6-8 week trial in the ED which will include: review of patient charts, and identifying and making necessary changes as authorized by hospital protocols or providers. The pharmacist will record the following: type and number of interventions, time needed for intervention resolution, and what day and time the interventions took place. Interventions will be categorized as: medication error (wrong drug, dose, or dosage form), administration error, untreated indication, medication without indication, pharmacokinetic consult, cost avoidance, code response, or missing patient information. All data will be tabulated within Excel and a dollar value will be associated with each intervention to determine ED pharmacist impact. The pharmacist will be unblinded to the intervention data collection as it would not otherwise be feasible. Surveys will be distributed to ED staff in order to evaluate their opinion of clinical pharmacists prior to placement within the ED, and after.

Poster Title: Collecting meaningful outcomes in oncology patients: Preliminary analysis of factors and challenges affecting the initiation and completion of chemotherapy in an integrated delivery system

Primary Author: Tiffany Nguyen, Group Health Cooperative, WA; Email: nguyen.tiffany@ghc.org

Additional Author (s):
Andrew Yu

Purpose: Proactively capturing real world clinical outcomes for patients being treated with oral oncology agents is a challenging task, especially outside of clinical trials. The authors are unaware of any comprehensive databases characterizing patient-centered outcomes for cancer therapy: clinical efficacy and tolerability. Thus, a data collection system was created inside of Group Health’s (GH) Electronic Medical Record (EMR) software to aid healthcare providers in understanding factors and challenges that may lead to suboptimal chemotherapy treatment. Using preliminary data, this study assessed a small subset of patients and their characteristics that may impact the initiation and completion of their oral chemotherapy regimen.

Methods: The data set consists of the following information: patient demographics and comorbidities, cancer type, line of therapy, oral oncology regimen, treatment-emergent adverse events and the resulting interventions, and reason for treatment discontinuation. Discrete data was pulled from the EMR for patients with referrals to start oral chemotherapy after April 1st, 2016. Only patients who received services within the GH integrated delivery system were included in the study. Patients who did not discontinue or complete therapy by August 26th, 2016, were excluded from data analysis. Duplicate patients, non-chemotherapy drugs, and referrals that did not indicate the line of treatment were also excluded. Chart reviews were conducted for relevant missing fields that were readily retrievable.

Results: Seventy-one of 792 patients with referrals to start therapy after April 1st met inclusion criteria. Despite plans for therapy, 27 patients did not start treatment, with 9 of 27 (33 percent) deceased or referred to hospice before treatment initiation. Other common reasons for not starting therapy included drug cost (5/27, 19 percent) and services received outside of GH
(5/27, 19 percent). Of 44 patients who started therapy and had early treatment discontinuation, patients on greater than 2nd line therapy were more likely to discontinue treatment due to tumor progression, hospice referral, or death (15/19, 79 percent) compared with those on 1st or 2nd line therapy (12/25, 48 percent). Of 792 patients, 30 were referred for treatment with a baseline Eastern Cooperative Oncology Group (ECOG) performance status of 2 or 3, with 8 patients fitting our study’s inclusion criteria. All 8 patients discontinued treatment due to progression, hospice referral, or death. Compared with those on greater than 2nd line therapy, patients on 1st or 2nd line treatment appeared more likely to stop chemotherapy due to adverse events (24 percent vs. 11 percent), with similar findings for those with an ECOG score of 0 compared with 1 (44 percent vs. 14 percent).

**Conclusion:** Patients on greater lines of therapy or with poor ECOG scores were likely to discontinue therapy early due to tumor progression, hospice referral, or death. Initial results from GH’s oral oncology database are promising, serving as a potential resource for providers and payers to better understand the challenges to initiating chemotherapy. Patient and treatment characteristics may also be used to predict reasons for chemotherapy disruption. Future use of the database may allow clinicians to intervene or provide support to patients in a more strategic manner in anticipation of the potential challenges to treatment.

**Poster Title:** Assessing the implementation of coordinated, multidisciplinary strategies to increase asthma HEDIS quality measures in an integrated healthcare system

**Primary Author:** Bryan Davis, GROUP HEALTH COOPERATIVE, WA; **Email:** davis.ba@ghc.org

**Additional Author(s):**
Lisa Nguyen

**Purpose:** Group Health Cooperative (GHC) identified opportunities for improvement in the HEDIS quality metrics for asthma, the Asthma Medication Ratio (AMR) and the Medication Management for People with Asthma (MMA). The AMR metric was prioritized over the MMA because recent data suggests that it is a better surrogate marker for meaningful clinical outcomes. This data analysis was designed to evaluate the overall effectiveness of various strategies implemented to increase the AMR and explore the strategies with the largest impacts, as well as to identify opportunities to improve GHC’s quality of care for asthma patients.

**Methods:** A pharmacy-led analysis in early 2015 identified opportunities to improve workflow processes, information technology (IT) support, and care team education for asthma quality measures. An Asthma Oversight Team was established to implement and monitor quality improvements, and included multidisciplinary leaders over various work streams. The first major workflow strategy implemented was standardized outpatient pharmacy work for asthma, which included performing Asthma Control Tests (ACT) at point of sale, facilitating dispensing of a controller medication, and counseling on proper technique of inhalation devices. The second major workflow intervention was a chronic disease management (CDM) program, in which clinical pharmacists operating under a collaborative drug therapy agreement (CDTA) manage patients with mild to moderate persistent asthma. Other process improvement strategies involved standardizing patient rooming workflow in primary care settings and creating non-compliant patient lists for outreach attempts by providers. Decision support tools included updating internal asthma guidelines and providing clinician education. IT enhancements included in-clinic alerts to identify poorly controlled asthma patients for the primary care team, defaulting albuterol refills to zero for new asthma orders, patient secure messaging for
obtaining ACT scores, and automated telephone refill reminders for controller medications. Health plan strategies included adding formulary quantity limits for albuterol.

**Results:** GHC provides both an integrated health system and a contracted network option. The strategies implemented did not impact both divisions equally and were evaluated separately. For the evaluation, a run chart was used to assess the performance of the multiple strategies initiated to increase the HEDIS quality measures. A run chart is an analytical tool used in quality improvement to measure trends and shifts of processes implemented over time. The strongest positive trend was observed in the integrated system after the initiation of the clinical pharmacist asthma CDM program, which increased the AMR by 4.4 percent over a 6-month period (approximately 1,300 patients reviewed and 26 percent enrolled in CDM). The increase in AMR was also influenced by an increase in outpatient pharmacy interventions, which was sustained at greater than 80 interventions per month over the 6-month period increase. The overall outpatient pharmacy strategy had greater than 1,200 interventions since inception, where approximately 85 percent performed an ACT and 30 percent dispensed a controller medication at point of sale. No trends were identified in the network. Ongoing subgroup analyses include clinical pharmacist CDM program outcomes, outpatient pharmacy interventions analysis by clinic and type, and changes in asthma-related hospitalizations.

**Conclusion:** The implementation of widespread strategies to improve patient care in asthma has shown positive results, as evidenced by the increase in HEDIS asthma quality measures. The strongest drivers of quality improvement were with pharmacist involvement, both in the CDM program where clinical pharmacists managed patients with mild to moderate asthma, and in outpatient pharmacies where pharmacists made interventions at point of sale. Continual analysis of the workflow process will give insight into the most effective strategies and continue to improve patient care.

**Poster Title:** Pharmacist impact on transition of care in patients with diabetes.  

**Primary Author:** Courtney Strouse, Highline Medical Center, WA; **Email:** cstrouse@highlinemedical.org  

**Additional Author (s):**  
Rebecca Kingsley  
Leigh Channel  
Kristin Peterson  
Jamie Casanova  

**Purpose:** Patients with diabetes commonly face complex barriers to healthcare that may lead to poor control of diabetes and associated comorbidities. Loss to follow up, or delayed follow up is one barrier that exists for some of these patients. The purpose of this research is to evaluate the impact of a newly initiated, pharmacist led transition of care clinic in patients with diabetes.  

**Methods:** This study is pending Institutional Review Board approval. Baseline data will be obtained through retrospective chart review of electronic medical records. Patients admitted with a diabetes diagnosis will be screened for the following inclusion criteria: newly diagnosed diabetes within three months of admission, uncontrolled diabetes indicated by hemoglobin A1c of 8 percent or greater, or patients initiated on insulin therapy at time of discharge. Appropriate candidates will receive an ambulatory care referral, noting diabetes transition of care follow up, by a physician or case manager. The pharmacist will be notified of such referral and will meet with the patient prior to discharge to provide education and clinic information. Outpatient follow up will take place at the transition of care clinic, where a pharmacist will manage diabetes related care under collaborative drug therapy agreements. The primary endpoint will evaluate pharmacist impact on diabetes management by measurement of reductions in quarterly hemoglobin A1c and weekly average blood glucose readings. Secondary endpoints will evaluate reduction in readmission rates and diabetes related adverse events.

**Poster Title:** Optimizing pharmacist driven antimicrobial services in the emergency department

**Primary Author:** Lawrence-Wynner Pajarillo, Highline Medical Center, WA; **Email:** lawrep2@gmail.com

**Additional Author (s):**

**Purpose:** The presence of a pharmacist in the emergency department is vital to improve quality of care and resource efficiency. According to the Center of Disease Control and Prevention, 2 million people become infected with bacteria that are resistant to antibiotics. With the growing need to address patient safety and antibiotic resistance, it will be necessary that pharmacists take an active role in providing services that optimize antibiotic treatment plans. The objective of this study is to enhance antimicrobial stewardship in the emergency department by assessing and implementing pharmacist led antimicrobial services.

**Methods:** The first part of this study will be a retrospective chart review that compares pharmacist led microbiology culture follow-up with the former nursing led culture follow-up. Primary endpoints include total time spent on culture follow-up, number of visits to the emergency department, and appropriateness of antibiotic chosen. A secondary endpoint is documentation of this intervention in the electronic medical records. The second part of the study will be a prospective cohort study that will compare pharmacist led antibiotic discharge counseling versus the current nursing led antibiotic discharge counseling. A guideline for pharmacist driven medication discharge counseling will be developed and implemented to educate the patient on both the indication and drug information for the prescribed antibiotic. Post-discharge interviews will be conducted to gather the primary endpoints of patient satisfaction with the antibiotic counseling, as well as time to antibiotic dispensing at an outpatient pharmacy. Furthermore, the number of interventions done by the pharmacist upon review of the discharge prescription will be recorded as a primary endpoint. Secondary endpoints include potential cost savings and types of interventions.

Poster Title: Implementation and evaluation of a pharmacist-driven training on palliative care medications and infusion devices

Primary Author: Ivan Huang, Multicare Good Samaritan Hospital, WA; Email: ivanjh1239@gmail.com

Additional Author(s):
Steven Larson
Dianna Gatto

Purpose: The goal of palliative care is to provide symptomatic relief from serious illness, while preserving the patient’s quality of life. At MultiCare Good Samaritan Hospital, there is limited specialized training for nurses and pharmacists on palliative care medicines. This lack of standardized training has led to inconsistencies and underutilization of potentially beneficial therapies. The purpose of this project is to design, implement, and evaluate a pharmacy-driven training on palliative care medications and infusion devices to nurses and pharmacists.

Methods: This quality improvement project will be conducted at MultiCare Good Samaritan Hospital. A pre-education assessment will be conducted on palliative care unit nurses and pharmacists to determine baseline knowledge and gaps. The Palliative Care Medication Order Set will be updated and education in the form of oral presentations, reference handouts, and required computer-based learning modules will be created in collaboration with palliative care providers. Education modules and didactic learning sessions will encompass an overview of palliative medicine, palliative medications, palliative sedation, and training on a new infusion device that allows for intravenous or subcutaneous administration of continuous infusions and patient-controlled analgesia. A post-education assessment will be conducted and results will be compared with pre-education assessments.

**Poster Title:** Implementation of pharmacist-driven transitions of care position in an acute care community hospital

**Primary Author:** Margeaux Byrd, Multicare Good Samaritan Hospital, WA; **Email:** maggie.byrd@ multicare.org

**Additional Author (s):**
Michelle Watts
Dianna Gatto

**Purpose:** Pharmacist involvement in the transition of care has been shown to reduce medication discrepancies and improve health outcomes. The objective of this project is to implement a transition of care pharmacist position at MultiCare Good Samaritan Hospital by developing workflows, standards, and responsibilities with targeted outcomes. The ultimate goal is to reduce re-admissions by optimizing discharge medication therapy management with a focus on high risk re-admission disease states.

**Methods:** MultiCare pharmacy has conducted multiple studies demonstrating the effectiveness of pharmacist involvement in medication management during transitions of care. Outside of MultiCare, other institutions have had success in reducing re-admissions by implementing a transition of care pharmacist. By reviewing these past studies, visiting other successful programs, and incorporating literature reviews, a transition of care pharmacist role will be tailored for MultiCare. Workflow, standards and expectations will be developed for the specific population and current staffing at this site. This position will utilize electronic medical record features to triage patients from admission and prioritize them on highest risk for re-admission. This will include but not limited to: a high risk re-admission diagnosis, age 65 years or older, and poor medication adherence upon admission. Responsibilities may include: optimization of discharge medications including review of prior to admission medication and incorporating guideline based therapy review, evaluation of barriers to medication adherence, utilization and referral for medication assistance programs, providing education and medication counseling through teach back, and follow up consult. Data will be collected for the following: number of medications upon admission/discharge, type of medication discrepancy, referral to medication assistance, assessment of patient education on discharge medications, and total time spent
with patient. This data will be analyzed for possible reduction of re-admissions and the number of medication discrepancies intervened by the transition of care pharmacist.

**Poster Title:** Impact of discharge medication reconciliation and patient education strategies on readmission rates of heart failure patients

**Primary Author:** Cris Thach, MultiCare Health System, WA; **Email:** cthach24@yahoo.com

**Additional Author(s):**
Jenny He
Kitty Anderson

**Purpose:** The Center for Disease Control estimates that 6 million Americans have heart failure. Moreover, an analysis of Medicare claims indicate that 24 percent of patients admitted to hospitals for heart failure will be readmitted within a month. Defining strategies to facilitate transitioning these patients to the outpatient setting serves as one of the greatest opportunities to reduce readmission rates. The objective of this project is to implement a pharmacist-driven process to conduct medication reconciliations, provide patient education at time of discharge and assess the impact on readmission rates of heart failure patients.

**Methods:** This project will take place in a 437-bed tertiary care hospital and is a quality improvement project that is exempt from Institution Review Board Approval. Electronic medical record reviews will be conducted for patients admitted due to heart failure. At time of discharge, reconciliation of medications will be completed to determine if the patient is on appropriate therapy. Any recommendations regarding changes to therapy will be made to the discharging physician and data will be collected to assess the impact of pharmacists in optimizing discharge medications. The pharmacist will also provide education on heart failure, lifestyle changes and signs of decompensation to the patient. Filled prescriptions will be delivered to the bedside and the pharmacist will counsel patients on their heart failure medications, reviewing indications and strategies to increase adherence. Time spent counseling the patient will be documented to determine the replicability of this process. Thirty days after the index admission, the patients’ medical profile will be examined and phone calls will be made to determine if they were readmitted within this period. A control group of patients who were admitted to the hospital in relation to heart failure but did not receive the intervention will also be reviewed to determine baseline readmission rates. The two groups will be compared to determine the primary outcome of pharmacist interventions on readmission rates.

Poster Title: Pharmacist impact on the utilization of a rapid diagnostic blood stream test in an antimicrobial stewardship program

Primary Author: Hannah VonWahlde, MultiCare Health System, WA; Email: hannah.vonwahlde@multicare.org

Additional Author (s):
Brittany Marshall
Julianna Van Enk

Purpose: Tailoring empiric broad-spectrum antimicrobial therapy is important to prevent the development of multi-drug resistant organisms as well as adverse effects. However, traditional culture and sensitivity data may take up to several days to produce results. The Verigene System, a gene-based rapid diagnostic test (RDT), allows the identification of specific pathogens and resistance markers in the blood within three hours after a positive gram stain. The purpose of this study will be to evaluate pharmacist utilization of RDT results, time to appropriate antibiotic therapy, and impact on pharmacist workflow.

Methods: This is a quality improvement project and is exempt from Institutional Review Board approval. RDTs are run automatically on all positive blood cultures at our hospital, a 437-bed acute care tertiary Level II trauma center. Baseline data will be collected retrospectively through an electronic infection surveillance program to determine time to appropriate antibiotic therapy without the intervention of a pharmacist. The antimicrobial stewardship pharmacist will begin to receive alerts for positive RDT results and will make recommendations to change therapy if necessary using a standardized decision support tool and clinical judgement. All adult patients with a positive RDT result during the time frame will be included. The results of these interventions will be tracked for an extended period of time. Data points to be collected include patient age, weight, gender, white blood cell count, renal and hepatic function tests, pertinent physical exam findings, RDT results, culture and sensitivity reports, initial and final antibiotic therapy, time to appropriate antibiotic therapy, length of antibiotic therapy, and length of stay. The primary outcome is to determine whether pharmacist intervention reduces the time to appropriate antibiotic treatment. Secondary outcomes include length of stay, physician acceptance of pharmacist recommendations, and duration of antibiotic
treatment. Analysis of these results will assist to further define the role of the antimicrobial stewardship pharmacist in RDT result monitoring.

**Poster Title:** Development and implementation of continuous infusion vancomycin for methicillin-resistant Staphylococcus aureus (MRSA) infections in adult medical and neuro intensive care units  

**Primary Author:** Magda Nowinski, MultiCare Health System, WA; **Email:** magda.nowinski@ multicare.org  

**Additional Author(s):**  
Duane Coffler  
Julianna Van Enk  
Brittany Marshall  

**Purpose:** Early and adequate obtainment of therapeutic vancomycin serum levels for MRSA infections can be challenging in patients admitted to the intensive care unit (ICU) secondary to altered vancomycin pharmacokinetics and the need for higher-dose regimens. Administration of vancomycin by continuous infusion (CI) in the ICU setting has been shown to provide rapid target concentration attainment with lower overall drug exposure and reduced nephrotoxicity. The objective of this study is to assess the impact of CI vancomycin use in the ICU after development and implementation of a CI vancomycin dosing strategy.  

**Methods:** This is a quality improvement project and exempt from Institutional Review Board approval. The study will take place in the adult medical and neuro ICUs of a 437-bed acute care tertiary Level II trauma center. Vancomycin use in the ICU will be determined by examining historical data through an electronic infection surveillance program. Criteria for patients who are candidates for CI vancomycin will be identified by evaluating duration of vancomycin therapy greater than 72 hours, confirmed or suspected MRSA infection, renal function, infection source, time to therapeutic serum concentration, and clinical condition. Collaboration with pharmacists and the infectious disease service will utilize historical data from the institution and published studies involving CI vancomycin to develop an institution-specific CI vancomycin dosing protocol. Patients in medical and neurosurgical ICUs who are eligible for CI vancomycin based on the generated dosing protocol will receive vancomycin by CI for the duration of vancomycin therapy, regardless of transfer to a different service. Demographic and pertinent data regarding the current hospitalization and medication use will be collected. The
primary outcome will be rates of nephrotoxicity in patients receiving CI vancomycin compared to historical controls. Secondary outcomes to be assessed include the following: time to therapeutic serum concentration, duration of vancomycin therapy, total vancomycin exposure, and concomitant nephrotoxic agents.

**Poster Title:** Communicating a pharmacy department’s performance by generating new performance metrics

**Primary Author:** Brian Havens, Multicare Health System, WA; Email: brian.havens@multicare.org

**Additional Author(s):** Tom Rowe

**Purpose:** With the wide-spread use of electronic medical records (EMR), data in healthcare is abundant; however, deriving meaningful information from this data is challenging. For every performance metric or patient outcome that can be easily measured (e.g. readmissions rates), there are multiple leading indicators (medication compliance, appropriate prescribing, etc.) which are often difficult to measure but could be powerful predictors of the outcome in question. The goal of this project is to develop a process to identify key leading indicators, generate reproducible metrics to measure over time, and communicate the findings to pharmacy personnel in an effort to drive performance.

**Methods:** Utilizing multiple databases within the setting of a 437-bed acute care tertiary hospital, performance metrics will be identified based on strategic initiatives of the health-system and measured over time. These performance metrics could include but are not limited to high-spend medication utilization, pharmacist interventions, or chosen patient outcomes. For each of the performance metrics identified, multiple leading indicators will then be developed and tested for correlation against the outcome they are designed to predict. The leading indicator that best correlates with the performance metric will then be put into a dashboard and distributed to the pharmacy department personnel. Ideally multiple performance metrics and their corresponding leading indicators will be from various departments throughout the hospital and combined into a single dashboard. This communication tool will be used to increase transparency throughout the organization, further energize pharmacy personnel involvement, and attempt to measure the strategic direction of the pharmacy department.

**Poster Title:** Appropriateness and safety of warfarin use in atrial fibrillation patients in pharmacist-managed anticoagulation clinics  

**Primary Author:** Brittany Kramer, Multicare Health System, WA; **Email:** kramebr23@gmail.com  

**Additional Author(s):**  
Ashley Van Allen  
Susan Rowe  

**Purpose:** Roughly 2.7 million people suffer from atrial fibrillation (afib), which is more prevalent in the elderly. Afib increases the risk of stroke therefore warfarin is commonly prescribed, but it carries risks such as bleeding. Due to the availability of pharmacist-led anticoagulation clinics, warfarin assessment by physicians of benefit verses risk as the patient ages may be diminished. The object of this study is to assess the appropriateness and safety of warfarin usage in afib patients based on risk stratification to further enrich pharmacist-provider interventions and to assess the outcomes.  

**Methods:** This is a quality assurance project, which is exempt from Institutional Review Board approval. The project will consist of a random sample of afib patients being managed at two pharmacist-led anticoagulation clinics. Data that will be collected are components of the CHA2DS2-VASc score, HAS-BLED score, appointment cancelations, insurance type as a measure of food insecurity, time in therapeutic range, and other anticoagulation or antiplatelet medications. Patients will then be assessed for their risk of stroke and bleeding using an online risk assessment tool in addition to the previously mentioned factors. Data will then be analyzed for appropriateness of warfarin usage in these patients. If interventions are warranted then the data collected will be used to help improve pharmacists’ discussion with providers about the discontinuation of warfarin therapy. The outcome of the pharmacist interventions will be measured.

**Poster Title:** Effects of discharge counseling on readmissions and emergency department visits

**Primary Author:** Shadi Khosravi, PeaceHealth Columbia Network, WA; **Email:** skhosravi@peacehealth.org

**Additional Author(s):**
Ashley Schnee
Austin Horner

**Purpose:** Discharging patients from the hospital is a complex process that has its own challenges. Among Medicare patients, almost 20 percent who are discharged from a hospital are readmitted within 30 days. Preventing avoidable readmissions has the potential to profoundly improve both the quality of life for patients and the financial wellbeing of healthcare systems. During this study, the impact of a discharge education program on 30-day readmissions and emergency department (ED) visits will be evaluated.

**Methods:** An observational pre and post analysis will be conducted at PeaceHealth Southwest Medical Center to compare rates of hospital readmissions and return to the emergency department during one-month period before and after implementation of discharge education for a high-risk subgroup. The study will include patients prescribed with two or more medications for the treatment of chronic diseases. The patients randomized into the intervention group will receive pre-discharge counseling by the clinical pharmacist about each prescribed medication. The control group will receive no counseling. The primary outcome will be rates of readmissions and return to the emergency department (ED) within 30 days of discharge.

**Results:** N/A

Submission Type: Research-in-Progress

Session-Board Number: 10-294

Poster Title: Establishment of policies and procedures for the training, implementation and auditing of the United States Pharmacopeia (USP) 797 and 800 regulations at Peacehealth Southwest

Primary Author: Madison Block, Peacehealth Columbia Network (Southwest), WA; Email: madisonblock40@gmail.com

Additional Author (s):
Ann Anthony
David Castillo
Ryan Parker

Purpose: Every hospital that compounds sterile products must comply with the USP (United States Pharmacopeia) rules and regulations. Peacehealth is not up to code with the current USP 797 sterile compounding regulation nor the USP 800 regulations which discuss hazardous drug best practices. The goal of this project is to develop procedures and protocols to help Peacehealth Southwest Medical Center follow these rules and regulations. Once these policies and procedures have been optimized, they will be used to ensure regulation compliance throughout all Peacehealth system hospitals.

Methods: The goal of this project is to have 100% employee compliance in the various USP 797 and 800 auditable fields by January 2016. These auditable fields include garbing, handwashing, cleaning, aseptic technique and documentation. Employees at Peacehealth Southwest Medical Center (PHSW) will be trained using materials provided by the Washington State regulating body along with those created by Peacehealth pharmacy. Training will include visual, auditory and kinetic methods including videos, reading material and hands on practice. After first round training is complete, audits will be conducted to test compliance and understanding of the regulations. These audits will include written exams, growth medium manipulation testing, and technique observation using an objective rubric in each of the auditable fields. Employees that perform audits will be trained as well to ensure accurate and consistent employee testing. The results collected from each audit field will lead to process improvement interventions to fix any holes in the training or testing. Then a second round of auditing will occur after the appropriate interventions have been integrated into the employee’s training. The results of this second
audit will again provide process improvements until 100% compliance is observed at PHSW. Once training materials are established at PHSW, training will then be conducted at the other Peacehealth hospitals within the system.

Poster Title: Implementation of oncology clinical services provided by pharmacists for reimbursement through provider status

Primary Author: Angela Yuen, PeaceHealth Southwest Medical Center, WA; Email: ayuen@peacehealth.org

Additional Author (s):
Kristen Senyk
Semra Stanley

Purpose: Pharmacists are recognized as providers within Washington State. This law is the first in the nation to require health insurance carriers to include pharmacists as network providers and reimburse for clinical services. Our hospital’s health system oncology pharmacists offer limited clinical services to patients due to the lack of a collaborative practice agreement. This study’s objective is to enroll oncology pharmacists as providers with Washington insurance carriers and bill for clinical services. With the recently approved 1.0 FTE, this will support the creation of additional clinical oncology services that will improve patient care and enhance collaboration within the interdisciplinary team.

Methods: This study was submitted to the Institutional Review Board for approval as an exempt study. Oncology pharmacists within our health system network will be enrolled as providers through our credentialing department with Washington insurance carriers. Each pharmacist will complete a Washington Practitioner application and provide requested supplemental materials. Current procedural terminology (CPT) coding will used to bill according to the amount of time spent on direct patient care. Education will be provided for pharmacists on suitable documentation of visits to qualify for proper billing tiers. Billing processes will be implemented with assistance from our medical staff office and commercial payers. Credentialed pharmacists are anticipated to bill as providers for patient care services beginning in January 2017. The initial oncology clinical service offered to patients as fee-for-service will be chemotherapy patient teaching consults (PTC). PTC parameters will be defined and implemented as a policy to be added to the current ambulatory care collaborative drug therapy agreement. Physicians will be able to refer patients to pharmacists for PTC prior to chemotherapy infusions. Once this service has been established, additional services will be developed to allow physicians to
request consultations for pharmacists to manage therapy and allow for more time to address critical or complicated patients. These services will include breakthrough nausea and vomiting, venous thromboembolism prophylaxis, oral chemotherapy, and diarrhea or constipation management.

Poster Title: Development and implementation of pharmacy driven services to reduce hospital readmissions through medication adherence testing

Primary Author: Amanda Hack, PeaceHealth Southwest Medical Center, WA; Email: ahack@peacehealth.org

Additional Author(s):
Lydia Chang
Kimberly Russell
Victoria Tamis

Purpose: For patients with chronic medical conditions, hospital readmissions are costly and often preventable occurrences. Although many factors play into readmission rates, non-adherence to medications is thought to be a major contributing factor. Technological advances give health care providers various means to monitor medication adherence in this patient population. Through blood sampling, a qualitative medication screening panel is one such tool that can detect adherence to medications used to manage chronic disease states. This project will pilot incorporating screening panel results as an aid in pharmacist driven medication adherence counseling.

Methods: This project will be submitted to the internal institutional review board for approval prior to initiation. Institution specific admission and 30-day readmission rates for heart failure will be collected prior to initiating the pilot to serve as a comparator. The initial phase will include developing a pharmacy driven protocol for ordering and review of a medication screening panel in the inpatient setting. Once this protocol is established, the panel will be ordered for all qualifying patients with a documented or suspected heart failure exacerbation prior to receiving doses of inpatient medications. Results will then be reviewed by clinical pharmacists and/or a pharmacy practice resident to screen for non-adherence to home medications, duplicate medication classes, and to assist in adherence counseling. Results inconsistent with the reconciled medication list will be communicated to the appropriate provider and documented in the patient’s electronic medical record. If indicated, patients will be offered adherence counseling by a clinical pharmacist or pharmacy practice resident. The

**Poster Title:** Implementation of an inpatient education service for patients on warfarin

**Primary Author:** Rupinder Kaur, PeaceHealth St. Joseph Medical Center, WA; **Email:** rupi.kaur@wsu.edu

**Additional Author(s):**

**Purpose:** Pharmacists play an essential role in medication management and adherence; this is especially true when patients receive pharmacist led education. Implementation of a patient education program led by pharmacy students and residents can reinforce the importance of patient education and optimize adherence, and understanding of high alert medications. The primary outcome of this study will be to initialize and implement warfarin education at the medical center. Secondary outcome will be evaluation of Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) scores on selected units.

**Methods:** This study will be submitted to the Institutional Review Board for approval. The study will consist of two phases. The first phase of this study will be implementation of a pharmacy student/resident led educational service. Data collection throughout the study will consist of inpatient specific factors (unit, age, sex, indication for warfarin, goal INR, new start versus continuing, and follow-up plan) to later help determine the impact of the educational intervention and HCAHPS scores. Patients on warfarin will receive an unscheduled visit from student pharmacists or a pharmacy resident prior to discharge. The patient will receive bedside counseling and educational resources (written material) on warfarin. The educator will also be responsible for ensuring there is a referral/ follow-up plan in place for the patient after discharge. The education will be documented in the electronic medical record. All pharmacy students on rotation at the medical center will get individualized instructions on the education process and the standard educational materials. The second phase of the study will consist of a retrospective analysis of HCAHPS performance scores prior to the implementation of discharge counseling to be compared with HCAHPS scores after implementation.

**Poster Title:** Implementation of vancomycin dosing competency program for clinical pharmacists to improve clinical outcomes and confidence  

**Primary Author:** Chelsea Hewitt, PeaceHealth St. Joseph Medical Center, WA; **Email:** chelsea.hocker@gmail.com  

**Additional Author (s):**  

**Purpose:** The safe use of vancomycin requires continuous drug therapy monitoring which is often the responsibility of clinical pharmacists. At many institutions, clinical pharmacists have varying degrees of educational background and experience with dosing and monitoring vancomycin. This project is designed to provide entry-level and on-going vancomycin dosing and monitoring education to all pharmacists on the clinical staff at PeaceHealth St. Joseph Medical Center and determine if clinical outcomes and clinical confidence can be improved by the implementation of a vancomycin learning module.  

**Methods:** This study will be submitted to the Institutional Review Board for approval. Comprehensive and contemporary information regarding the safe and efficacious use of vancomycin as well as institution-specific policy and protocols will be organized into an interactive, computer-based learning module for the clinical pharmacy staff at PeaceHealth St. Joseph Medical Center. The content of the learning module will be designed to ensure correlation with the current approved vancomycin collaborative drug therapy agreement. All clinical pharmacists in the inpatient setting will complete the learning module. Pre- and post-module quizzes and clinical confidence surveys will be used to qualitatively assess the learning material. Annual retrospective vancomycin use evaluations will be used to compare clinical outcomes before and after implementation of the learning module. Specifically, percent of trough levels appropriately drawn and percent of trough levels within the therapeutic range will be assessed to quantitatively determine the impact of this supplemental education.

Poster Title: Transitions of care optimization and expansion for COPD patients

Primary Author: Ashley Morrisey, Providence Centralia Hospital, WA; Email: ashley.morrisey@providence.org

Additional Author(s):
Hilary Smith
Kumar Arulapalam
Terri Byers
Julie McCoy

Purpose: Project team members aim to expand and optimize our transitions of care program to include COPD patients. The goals associated with this project are improving patient compliance with combined education with respiratory therapy, performing admission and discharge medication reconciliation, and communication with the patient’s primary care provider (PCP) upon discharge. This project will utilize a multidisciplinary team to reduce 30-day readmission rates for COPD patients at Providence Centralia Hospital.

Methods: This project is in the process of review by the Institutional Review Board (IRB) as a quality improvement project. Upon receiving IRB approval, data collection will begin. Inclusion criteria for the intervention group consists of patients with a primary diagnosis of COPD who are being followed by the Transitions of Care (TOC) clinical team, and who are discharged between the hours of 0800 and 1600. Medication reconciliation will be completed soon after admission, as well as prior to discharge to ensure guideline-recommended and affordable treatment options are made. Pharmacists will provide patient education, in a joint effort with respiratory therapy, prior to discharge to ensure medication compliance and optimal disease state management. The TOC pharmacist will write a discharge note summarizing the hospitalization, as well as patient specific recommendations for therapy optimization. This information will be sent electronically to the patient’s PCP via EPIC, or other providers at the clinic as appropriate (i.e. pharmacists, RN care coordinators, etc.). Data collection will assess the 30-day readmission rate for COPD patients.

Poster Title: Optimizing antimicrobial stewardship: An education based approach

Primary Author: Tylor Heilman, Providence Centralia Hospital, WA; Email: tylor.heilman@providence.org

Additional Author(s):
Philip Tobias
Julie McCoy
Steven Standaert
Elizabeth Hesselbacher

Purpose: The new antimicrobial stewardship standard set forth by the Joint Commission for hospitals and critical access hospitals effective January 1, 2017 identifies provider education as one of its core elements of performance. In alignment with the new standards, this quality improvement study aims to modify the prescribing behavior of clinicians through an interactive e-learning module centered around specifically designed patient cases in order to optimize antimicrobial stewardship throughout Providence Centralia Hospital and Providence St. Peter Hospital.

Methods: This quality improvement project is pending approval by the Institutional Review Board. A retrospective analysis of hospitalized patients who are 18 years of age or older who received antibiotics during their admission will be conducted in order to create specific patient cases that focus on areas of improvement relating to antimicrobial stewardship. These patient cases will be used to develop an interactive e-learning module that will be shown to new hire clinicians as well as be used to develop a live interactive presentation that will be conducted during a continuing medical education meeting for currently employed clinicians. Subjective data will be collected after the live presentation using a questionnaire to assess current clinician’s opinions on how well the provided information improved their understanding of antimicrobial stewardship practices, appropriate antibiotic usage, and if they anticipate any changes in their antibiotic prescribing behavior. Objective data will be collected before and after the implementation of provider education to assess for significant changes in antibiotic use pertaining to the specifically designed patient cases.

**Purpose:** Despite the prevalence of reported penicillin allergies among inpatients, very few have a true allergy. In most cases, the reported “allergy” is a misclassified prior adverse reaction. Unfortunately, this misrepresentation often leads to the unnecessary avoidance of beta-lactams in patients who could tolerate them and in whom penicillins are indicated as first-line treatment. Alternative antibiotics selected may be clinically inferior and associated with prolonged hospital stays and increased adverse event rates. The purpose of this project is to evaluate the impact of a reported penicillin allergy on clinical outcomes in patients admitted to Providence Regional Medical Center – Everett (PRMCE).

**Methods:** This study will be submitted for Institutional Review Board approval. The electronic medical record system was used to generate a report identifying all patients admitted to PRMCE between September 1, 2015 and August 31, 2016 who had a reported penicillin allergy and received antibiotics. Patients were excluded if they were younger than 18 years of age, were incarcerated, or had a confirmed anaphylactic reaction to a penicillin. Patients charts were reviewed to collect the following data: age, gender, allergy severity, reaction, indication for antibiotics, if beta-lactam was the preferred treatment for infection, antibiotics received, reaction to antibiotics received, duration of treatment, adverse events requiring antibiotic discontinuation, Clostridium difficile infection, readmission for the same infection, length of stay, and antibiotic cost. Data will be analyzed to determine clinical outcomes based on reaction reported and antibiotics received.

**Poster Title:** Evaluation of treatment duration in patients discharged with antibiotics for either acute uncomplicated cystitis or pyelonephritis from the Providence Regional Medical Center Everett emergency department.

**Primary Author:** Debbie Torres, Providence Regional Medical Center Everett, WA; **Email:** dtsf887180@gmail.com

**Additional Author (s):**
Andrea Eberly
Mena Senecal

**Purpose:** The Infectious Diseases Society of America (IDSA) has clinical practice guidelines for the treatment of acute uncomplicated cystitis and pyelonephritis in women. The IDSA states that despite published recommendations, studies have demonstrated a variation in prescribing practices. The objective of this retrospective review is to determine the extent to which the duration of treatment of acute uncomplicated cystitis and pyelonephritis in women discharged from the Providence Regional Medical Center Everett (PRMCE) emergency department complies with the IDSA guidelines.

**Methods:** This is a single center, retrospective chart review that will include female patients 18 to 50 years old who were discharged from the PRMCE emergency department on antibiotics for acute complicated cystitis or pyelonephritis between January and September, 2016. Patients who meet the IDSA criteria for complicated cystitis will be excluded from this study. Data that will be collected include: patient’s age, diagnosis, antibiotic prescribed, duration of therapy, urine culture and microbiology results, and antimicrobial stewardship interventions following sensitivities. In addition, since the IDSA considers pregnant women to be complicated cases of cystitis and pyelonephritis the number of pregnancy tests performed will also be evaluated. The primary outcome is to measure the percentage of patients who were treated for a different duration of therapy than recommended by the IDSA guidelines. Secondary outcomes include percentage of urine cultures taken during admission, number of pregnancy tests performed, and antimicrobial stewardship interventions.

**Poster Title:** Initiating a pharmacist-physician practice care model for opioid-dependent patients using buprenorphine/naloxone in an ambulatory care setting

**Primary Author:** Phu Trinh, Providence Sacred Heart Anticoagulation and Pharmacotherapeutics Clinic, WA; **Email:** phu.trinh@providence.org

**Additional Author(s):**
Tiffany Olson
Jennifer Taylor

**Purpose:** Opioids such as heroin, morphine, and prescription pain medications have been abused and leads to addiction in the United States. The consequences of abuse of opioids have been devastating to the health, social, and economic welfare of all societies, and continues to rise. The purpose of this study is to establish a pharmacist-physician collaborative practice for opioid-dependent patients. The collaboration will allow patients to have greater access to medication treatments, decrease physician burden, improve patient care, decrease overall cost, and prevent medication diversion.

**Methods:** To address this complex issue of opioid abuse, specially registered physicians are frequently referred to manage a patient’s addictions through methadone clinics or prescribing Suboxone. Physicians are often hesitant to become specially registered to manage an opioid treatment program due to the heavy workload involved with patient monitoring, treatment maintenance, and patient follow-up. Physicians must undergo specialized training and registration in order to initiate an opioid treatment practice. There is an opportunity for pharmacists to ease this burden and decrease health care related costs by working closely with buprenorphine-prescribing physicians. Pharmacists will be referred by specially registered physicians after induction and stabilization phase is complete. Pharmacists will be involved in the maintenance phase of Suboxone which consists of weekly monitoring to review urine toxicology, review patient adherence, and assess treatment barriers. Urine toxicology will measure buprenorphine and opioid levels. Buprenorphine levels will indicate adherence to treatment plan and opioid levels will indicate illicit drug use. The specially registered physician will then be notified of the patient’s progress by the pharmacist and continue prescribing Suboxone based on the pharmacists recommendations.

**Poster Title:** Utilizing clinical pharmacists to streamline treatment in patients with hepatitis C in a medical residency teaching clinic

**Primary Author:** Luke Dearden, Providence Sacred Heart Anticoagulation and Pharmacotherapy Clinic, WA; **Email:** luke.dearden@providence.org

**Additional Author(s):**

**Purpose:** The utilization of clinical pharmacists in the management of patients with hepatitis C is emerging as a successful practice option. While the newest medications used to treat hepatitis C virus (HCV) are highly effective, they are exceedingly expensive and often require a lengthy prior authorization process before treatment initiation. Pharmacists may be the best equipped health professional to streamline time-to-treatment in patients with HCV. The primary objective was to evaluate the time from prescription authorization to treatment initiation with and without pharmacist involvement. Secondary outcomes included cost savings and analyses of the total number of patients treated.

**Methods:** After a comprehensive work-up by a physician, patients with hepatitis C were referred by a medical resident at a teaching clinic to a pharmacist-run pharmacotherapy clinic. An appropriate hepatitis C treatment was prescribed by the pharmacist, and the prior authorization process was managed by members of the pharmacotherapy clinic. Time-to-treatment was closely monitored and compared to a cohort of hepatitis C patients previously treated and managed without pharmacist involvement. After medication initiation, pharmacists participated in patient management throughout the entire treatment course in an effort to reduce costs and lighten the load of physicians. Their responsibilities included ordering and coordinating four week labs, contributing to a five week follow up visits, providing medication education, screening for side effects, and promoting adherence. Prior to study initiation pharmacists within the pharmacotherapy clinic were assigned to a team of family and internal medicine residents. While the pharmacotherapy clinic accepted referrals from medical residents outside their team, pharmacists only played a direct role in the identification of hepatitis C patients whose primary care provider was a member of the assigned team. The total number of patients treated with pharmacist identification was compared to the number of patients treated without pharmacist identification.

**Poster Title:** Development and Expansion of the Discharge Medication Bedside Delivery Service

**Primary Author:** Christopher Tong, Providence Sacred Heart Medical Center & Children's Hospital, WA; **Email:** christopher.tong@providence.org

**Additional Author(s):**
Jason Brouillard
Brent Albertson
Jill Miller

**Purpose:** The current discharge medication bedside delivery service delivers medications to the north side of the Orthopedic Post-Surgical floor of Sacred Heart Medical Center and Children’s Hospital. The purpose of this project is to develop and expand the bedside medication delivery service to deliver medications to patients on the south side of the same floor and evaluate the possible benefits and resources required for future expansion. This service will ensure that patients have the medications that they need, such as anticoagulants or pain relievers, prior to discharge.

**Methods:** This expansion program will be continued on the south side of the Orthopedic Post-Surgical floor of Sacred Heart Medical Center. Informational brochures of the bedside delivery program will be handed out to patients prior to discharge. At that time, prescription insurance information will be obtained from any patients wishing to purchase their medications through the bedside delivery service. Any changes to administration directions or issues regarding insurance coverage or authorization will be addressed by the outpatient pharmacy prior to discharge. At time of discharge, medications will be charged to the patient in their room by a concierge pharmacy technician. Each patient will receive counseling for their medications via telephone, or face-to-face interaction with a pharmacist. Surveys will be given to patients after their hospital stay to evaluate their satisfaction on timeliness of prescription filling, quality of pharmacist consultation, and ease of the bedside delivery service. Parameters to be measured include patient and nursing staff satisfaction.
Data previously gathered from the bedside delivery service on the north side of the Orthopedic Post-Surgical floor will be reviewed alongside new data collected from the south side, for possible benefits and resources required for future expansion of this service to other floors.
This project is Institutional Review Board exempt because it is for performance improvement purposes.

Poster Title: Analysis of Excessive Warfarin Anticoagulation in Post Cardiac Surgery

Primary Author: Heather Lowmaster, Providence Sacred Heart Medical Center & Children's Hospital, WA; Email: heather.lowmaster@providence.org

Additional Author(s):
Fritz Nichols
Brenda Graph
Brent Albertson
Jill Miller

Purpose: Excessive warfarin anticoagulation in post cardiac surgery is very common. Patients who are post open heart coronary artery bypass grafting (CABG) or valve replacement are more sensitive to warfarin initiation than those starting warfarin for atrial fibrillation, deep vein thrombosis treatment, pulmonary embolism treatment, and post-stroke. INRs that have risen too rapidly have been associated with bleeding and longer hospital stays as well as increased morbidity and mortality in patients post vascular surgery. The purpose of this project is to provide caregivers with a warfarin dosing guideline to titrate slowly and at lower doses to prevent bleeding.

Methods: Our warfarin and vitamin K dosing guidelines are available for all patients initiated on warfarin at our facility. An evaluation of patients who are post CABG or valve replacement will be completed and warfarin dosing based on the current protocol will be analyzed along with INR values and incidence of bleeding complications. The data will be used to adjust the current protocol specifically for this group of patients. Pharmacists will be educated and will test the changes to the protocol. We will be monitoring the incident of suprathapeutic INRs and bleeding post change. This is a performance improvement project and is IRB exempt.

**Poster Title:** Evaluation of prescribing patterns of critical care providers for ICU patients with the diagnosis of pneumonia at an acute care hospital

**Primary Author:** Genevieve DeLuze, Providence Sacred Heart Medical Center and Children's Hospital, WA; **Email:** genevieve.deluze2@providence.org

**Additional Author(s):**
- Kristen Edgar
- Mariesa Durrant
- Jill Miller
- Brent Albertson

**Purpose:** With the diminishing effects of marketed antimicrobials due to resistance, proper empiric and definitive treatments for pneumonia are vital to the survival for patients admitted to the ICU. This project was designed to evaluate prescribing patterns of critical care providers for the diagnosis of hospital acquired pneumonia (HAP) or aspiration pneumonia in comparison to the IDSA HAP clinical practice guidelines. The purpose of this project is to present the collected data to critical care providers in a de-identified manner and provide education in order to improve and promote antimicrobial stewardship.

**Methods:** The electronic medical record system was used to identify all patients admitted to the ICU with a diagnosis of pneumonia between February and April of 2016. The following data will be collected for evaluation of prescribing patterns: critical care provider consulted, empiric and definitive antimicrobial selection, days of therapy and resulted microbial cultures. Data analysis will focus on appropriateness of antimicrobial selection and duration of therapy per the IDSA HAP clinical practice guidelines and will be presented to the critical care providers in a de-identified manner. Education on the IDSA HAP guidelines will be given to the critical care providers as well. After presentation of the collected data and education, a follow-up patient chart review will be performed between February to April of 2017 to monitor for changes in prescribing practices. This is a performance improvement project and is IRB exempt.

Poster Title: Evaluation of sedation and analgesia use in ventilated pediatric intensive care unit patients and weaning of sedation medications
Primary Author: Stephanie Persaud, Providence Sacred Heart Medical Center and Children's Hospital, WA; Email: stephanie.persaud@providence.org
Additional Author(s):
Brent Albertson
Jill Miller
Sarah Marrinan
Leslie Martin

Purpose: Sedation and analgesia play an integral role in caring for mechanically ventilated children. Both under-sedation and over-sedation may lead to complications with care such as, prolonged intubation, and increased pain, agitation, and length of stay. Increased time on such sedatives and analgesia may lead to withdrawal symptoms and warrant medication weaning. At Providence Sacred Heart Medical Center and Children’s Hospital, there is a protocol that uses methadone and diazepam for treatment of withdrawal from opioid and benzodiazepine tolerance. This current protocol does not address weaning from alpha-2-adrenergic agents, nor does it specifically address the implementation and monitoring of these medications.

Methods: A retrospective chart review will be conducted to evaluate the course of sedation in mechanically ventilated pediatric intensive care unit (PICU) patients for assessing the appropriateness of each sedation and analgesic medication, duration of sedation and analgesia, medication selection for each medication wean, and duration of each wean. The data collected will be used to determine appropriateness of initiating and sustaining sedation in PICU patients, as well as determining a protocol to wean off of alpha-2-adrenergic agonists, which will specifically focus on the addition of dexmedetomidine to be added to the current wean protocol. Physician, nurse, and pharmacist education will be provided for the new protocol. After protocol implementation, another chart review will be conducted to assess the effectiveness of the updated protocol. This is a performance improvement project and is IRB exempt.

Poster Title: Evaluation of hypoglycemic events associated with anti-diabetic agents to identify potential pharmacist initiated interventions to reduce hypoglycemic events.

Primary Author: Stephanie Inouye, Providence Sacred Heart Medical Center and Children's Hospital, WA; Email: stephanie.inouye@providence.org

Additional Author(s):
Hope Tran
Jill Miller
Brent Albertson

Purpose: The purpose of this project is to proactively prevent hypoglycemia by identifying repeat medication issues that could potentially increase a patient’s chance of hypoglycemia. The inpatient glucose range as recommended by The American Diabetes Association is 140-180 mg/dL. Continuing a patient’s home regimen in the hospital can increase the risk of hypoglycemia when combined with other factors such acute illness and not consuming their normal diet. Hypoglycemia can have serious consequences that could potentially be harmful to patients and counterproductive.

Methods: Patients will be identified by using both the electronic medical record and an electronic screening tool who had a blood glucose level of < 70 mg/dL, were admitted to the cardiac unit, and had an anti-diabetic medication on their medication administration record. Each patient will be evaluated for the cause of the event as well as changes made to their anti-hyperglycemia regimen post hypoglycemic event, steroid use, and if their home regimen was resumed inpatient. Once a common issue leading to hypoglycemia is identified, ways by which pharmacists can intervene will be developed. The clinical pharmacist will then intervene based on patient need. After a pilot is completed, the incidence and causes of hypoglycemia will be analyzed to look for improvement. This is a performance improvement project and is Institutional Review Board exempt.

**Poster Title:** Evaluation of institutional proton pump inhibitor use and implementation of a pilot program to reduce utilization within inpatient critical care and non-ICU settings

**Primary Author:** Sarah Lindstrom, Providence Sacred Heart Medical Center and Children's Hospital, WA; **Email:** sarah.lindstrom2@providence.org

**Additional Author(s):**
Brent Albertson
Jill Miller
Mariesa Durrant
Kristen Edgar

**Purpose:** Proton Pump Inhibitors (PPIs) are commonly used within the inpatient setting to treat or prevent gastrointestinal bleeds or reflux conditions. Additionally, in-hospital PPI use has been increasing recently without a specific indication. Emerging data identifies significant risks associated with PPI over-use: increased rates of *Clostridium difficile*-associated diarrhea, pneumonia, and drug-drug interactions. With long-term use, PPIs may lead to hypomagnesaemia, B12 deficiency, and bone fracture. This project aims to target areas of high PPI usage within Providence Sacred Heart Medical Center and Providence Holy Family Hospital and to align PPI usage with recommendations from current guidelines.

**Methods:** A Medication Use Evaluation (MUE) will be performed to analyze high areas of inappropriate utilization of PPIs within Sacred Heart and Holy Family. *Clostridium difficile* rates within each hospital unit will be compared to PPI utilization on those units. Carene data is collected, two ospital unit will be compared to PPI utilization on those units. tionally, pharmacists rounding carene data is collected, two ospital unit will be compared to PPI utilization on those units. tionally, pharmacists rounding Once baseline data is collected, two units will be selected for the pilot project, one Intensive Care Unit (ICU) and a non-ICU unit. Within the selected units, prescribing practices will be analyzed for appropriate indications for PPIs to determine which current practices are discordant from guidelines. Indications for histamine-2 receptor blockers (H2RAs) and no stress ulcer prophylaxis will also be considered. Following this analysis, targeted provider education with presentations, posters, and pocket-cards will be performed. Pharmacists rounding on each unit will reinforce appropriate
indications. After intervention on the pilot units, a follow-up MUE will be performed to determine the effectiveness of the program and future applicability in other inpatient units within the hospitals. This is a performance improvement project and is IRB exempt.

Poster Title: Optimizing nicotine replacement therapy in Providence Southwest Washington Region inpatient facilities

Primary Author: James Myres, Providence St Peter Hospital, WA; Email: james.myres@providence.org

Additional Author(s):
Dominick Caselnova
Danny Veenhouwer
Angela Lam
Ashley Morrisey

Purpose: Project team members aim to enhance patient care and community health by offering nicotine replacement therapy, including education, to admitted patients. Although available to most patients, there exists a potential inpatient population who may not be offered or provided such therapy during their hospital stay. To prevent nicotine withdrawal symptoms, increase patient satisfaction, and promote smoking cessation, it is important to offer nicotine replacement therapy to qualifying admitted patients and promote smoking cessation at discharge. This quality improvement project will assess opportunities for optimization and evaluate subsequent interventions related to provision of nicotine replacement therapy.

Methods: This quality improvement project is currently being reviewed by the Institutional Review Board (IRB) and data collection will begin once approval is received. Adult patients admitted to our inpatient facilities who are users of nicotine products will be included in the project.
A retrospective gap analysis will be performed in an attempt to identify opportunities for qualifying patients to receive access to nicotine replacement therapy while in the hospital. Following the gap analysis, pharmacists and nurses in selected areas of the hospital will cooperate with physicians to intervene and provide nicotine replacement therapy on behalf of patients when nicotine replacement therapy is warranted but not initially provided. Nicotine replacement therapy may include nicotine patches, gum, or lozenges, and patients will be offered materials and resources to support tobacco cessation post-discharge. This intervention process and any resulting changes to the quality of patient care will be documented. An
assessment including, but not limited to, reports of withdrawal symptoms, use of anti-anxiety medications, patient desire to continue with smoking cessation after discharge, and patient satisfaction will be performed retrospectively to evaluate the significance of increased access to nicotine replacement therapy. The information collected during this analysis may be used to construct a collaborative drug practice agreement between pharmacists and physicians within Providence Southwest Washington Region inpatient facilities.

**Poster Title:** Incorporation of a pharmacist-led antimicrobial stewardship program in a skilled nursing facility

**Primary Author:** Kenna Marx, Providence St. Mary Medical Center, WA; **Email:** kenna.marx@providence.org

**Additional Author(s):**
Amy Robisch
Bret Barnes
Somashaker Masuram

**Purpose:** Antibiotics are typically the most frequently prescribed medications in long-term care facilities, and studies have shown that nearly 75 percent of these are unnecessary or inappropriate. Antibiotic misuse is a growing worldwide concern due to its association with bacterial antibiotic resistance and increasing healthcare costs. Recently, Centers for Medicare and Medicaid Services proposed that all skilled nursing facilities (SNF) begin implementing an antimicrobial stewardship (AMS) program that includes prescribing protocols and antimicrobial monitoring systems by the year 2017. This study will expand upon the current AMS services available at Providence St. Mary’s Medical Center to include Regency skilled nursing facility.

**Methods:** The study will be submitted to the Institutional Review Board for approval. It will examine the implementation of an AMS program in a local SNF as a pilot for further implementation in the surrounding community. Baseline data was collected January 1, 2016 through August 31, 2016. The study will focus on residents diagnosed with urinary tract infections, pneumonia, and cellulitis, and who are prescribed fluoroquinolones, amoxicillin derivatives, clindamycin, cephalexin, metronidazole, sulfamethoxazole and trimethoprim, and oral vancomycin either prior to or after admission. The pharmacist will formulate recommendations for antibiotic therapy based on evidence-based infectious disease guidelines and discuss their recommendations with the physician overseeing the patient’s care and the staff infectious disease nurse. The following data will be collected: hospital readmission rates due to infectious causes, antibiotic prescription choice, appropriate dose, frequency, and duration of therapy as primary endpoints. Clostridium difficile infection rates, total antibiotic
use, cost reduction, and perceived value of AMS education in-services will be evaluated as secondary endpoints of this study.

Poster Title: Hospital IV room gap analysis for compliance with United States pharmacopeia general chapters &

Primary Author: Haiden Mohl, Providence St. Mary Medical Center, WA; Email: haiden.mohl@providence.org

Additional Author (s):
Michele Hall
Anita Treis

Purpose: United States pharmacopeia (USP) chapters < 797>& < 800> address sterile compounding practices and regulations. Chapters < 797> “Pharmaceutical Compounding – Sterile Preparations” and < 800> “Hazardous Drugs – Handling in Healthcare Settings” provide standards to ensure high quality product production, personnel safety, and public health and environmental protection. The IV compounding room at Providence St. Mary Medical Center (PSMMC) was recently approved for remodeling to bring it into compliance with these regulations. The study objective is to perform an IV room gap analysis to determine the extent of compliance with USP general chapters < 797>& < 800>, and ensure full USP compliance with both chapters upon remodel completion.

Methods: This study will be submitted to the Institutional Review Board for approval. The pharmacy quality assurance commission sterile compounding [USP < 797>] self-assessment compliance checklist from the Washington State Department of Health will be used to help create a gap analysis. Using the gap analysis, an initial assessment of the IV compounding practice will be conducted to identify areas of noncompliance. With a baseline established, policies, education, and work flow, will all be revised to help achieve full compliance with USP < 797> & < 800>.

Submission Type: Research-in-Progress

Session-Board Number: 10-314

Poster Title: A retrospective study on postoperative spine surgery pain management in patients treated with liposomal bupivacaine

Primary Author: Edward Phan, Providence St. Mary Medical Center, WA; Email: edwardphan@gmail.com

Additional Author(s):
Somasheker Masuram
Amy Robisch

Purpose: Liposome bupivacaine (LB) is a long-acting local analgesic in an encapsulated liposomal formulation developed with the goal of providing a longer duration of anesthesia compared to its counterpart bupivacaine hydrochloride (BH). LB was approved by the FDA in October 2011 for administration into a surgical site for postoperative analgesia in adults. At Providence St. Mary Medical Center, LB was approved for use in total knee and hip arthroplasty, and spinal surgeries. This study is a retrospective review of baseline data to analyze the effect of LB versus traditional local analgesia in spinal surgery patients on pain control and clinical outcomes.

Methods: This study will be submitted to the Institutional Review Board for approval. A literature search was performed on PubMed/Medline (January 2010 to July 2016) using the search terms: bupivacaine liposome, liposomal bupivacaine, and the brand name of LB. The literature search identified many studies involving total knee arthroplasty, hip arthroplasty and non-orthopedic surgical procedures. However, few studies have been published in evaluating the use of LB versus BH as a local anesthetic in spinal procedures. This study will retrospectively examine patient baseline data in spinal surgeries without LB use at Providence St. Mary Medical Center (PSMMC) collected from September 2014 – April 2015, and in spinal surgery patients administered LB from April 2015 - July 2015. The pharmacy resident will conduct patient chart reviews in order to evaluate the data and analyze the effectiveness of LB in the following post-operative primary and secondary endpoints. The primary endpoints assessed in this study include: duration of pain control, patient’s pain scores, use of rescue opiate pain medications, time to first rescue medication, and length of stay. The secondary endpoints assessed will include: adverse drug events and cost. Finally, the study will
partition the data between the different types of spinal surgeries to identify if certain surgeries have increased benefit with use of LB.

**Poster Title:** Implementation of a pharmacist-led transitions of care service for medical oncology patients

**Primary Author:** Tierra Gaillard, Providence St. Mary Medical Center, WA; **Email:** tierra.gaillard@providence.org

**Additional Author(s):**
Monica Verma
Clell Hasenbank

**Purpose:** Transitioning between care settings is a particularly vulnerable period for patients with complex oncology care needs. Breakdown in care is more likely to occur during this time, which could lead to increased hospital readmissions and poor patient outcomes. In 2013, Providence St. Mary Medical Center implemented a transitions of care (TOC) discharge process where the TOC pharmacist aids in transitioning patients with TOC diagnoses (myocardial infarction, COPD, pneumonia, heart failure, or total hip/knee arthroplasty) between care settings. This study will expand TOC services to oncology patients to help improve their overall health outcomes, increase provider revenue, and decrease hospital readmissions.

**Methods:** This study will be submitted to the Institutional Review Board for approval. Patients from Providence St. Mary Regional Cancer Center (PSMRCC) will be identified upon admission by the clinical oncology pharmacist, TOC pharmacist, or PGY-1 resident. Only admitted patients from PSMRCC will be included in the study. Patients that are admitted with TOC diagnoses will be excluded. Once identified, admission medication reconciliation will be performed, and the patient will receive education regarding his or her diagnosis and medications. Upon discharge, the patient will receive discharge plan teaching. The clinical oncology pharmacist or resident will contact the patient via phone within two business days post-discharge. This follow up call will assess the patient’s understanding of his or her admission diagnosis, review his or her health status, perform medication reconciliation, and answer any questions. Patients will also be re-educated about their oncology diagnosis, treatment plan, and any changes resulting from the admission. The clinical oncology pharmacist or resident will schedule the patient for a follow up visit with the oncologist within seven calendar days of discharge. The resident will
track service-related outcomes for these patients, and the clinical oncology pharmacist will track billed services.

**Poster Title:** Collaborative care between a pharmacist and behaviorist to increase patient access to depression and anxiety management in a family medicine clinic

**Primary Author:** Shannon Kelly, Providence St. Peter Family Medicine, WA; **Email:** kelly.shannon@providence.org

**Additional Author (s):**
Steven Elrod
Erica Dennehy
T. Levi Lancaster

**Purpose:** Untreated symptoms of depression and anxiety are a major concern in primary care settings. Time constraints make it difficult for primary care providers to review both the pharmacotherapy and psychological treatment necessary for depression and anxiety symptom improvement. A pharmacist and behavioral health specialist working together can help relieve some of the burden on primary care providers and improve patient access to timely follow-up. The goal of this project is to increase patient access to care by having a pharmacist initiate or modify pharmacotherapy by utilizing a collaborative drug therapy agreement.

**Methods:** A three-month retrospective chart review will be completed to evaluate the time between an initial and follow-up appointment with a primary care provider for depression and/or anxiety. Following collection and evaluation of the background data, a pilot of the service will be conducted at a single family medicine clinic with limited primary care provider access. Patients included in this service will be those with a recent diagnosis or increase in symptoms of depression and/or anxiety, or patients experiencing side effects from depression or anxiety medication therapy, who have been referred to a pharmacist by the primary care provider. The pharmacist will initiate, modify, or discontinue pharmacological therapy for depression and anxiety under a collaborative drug therapy agreement, while the behaviorist will work with the patient to develop coping skills and identify community resources. Subsequent follow-up will include face-to-face meetings and telephone calls. The following data will be evaluated: time between follow-up appointments or phone calls, Patient Health Questionnaire-9 (PHQ-9) scores, Generalized Anxiety Disorder Questionnaire-7 (GAD-7) scores, and comorbid mental health diagnoses. Primary care providers will be surveyed pre- and post-
implementation to identify the perceived impact on patient care, access, and provider comfort level with managing depression and anxiety.

Poster Title: Expansion of primary care health team education by pharmacists

Primary Author: Laura Pahlmeyer, Providence St. Peter Family Medicine
PGY2 Ambulatory Care Pharmacy Residency, WA; Email: laura.pahlmeyer@providence.org

Additional Author (s):
Andrea Corona
Daniela Dandridge
Laura Habib

Purpose: In an era of healthcare reform, primary care is increasingly provided by multidisciplinary care teams. Healthcare professionals are caring for an aging population with increased complexity of medication therapy. A majority of physician office visits involve medication-related decision making, which requires vast knowledge of medication-related issues. New literature and medications are being released on a continual basis, and pharmacists are ideally equipped to help busy primary care providers and team members stay current on medication-related issues. To meet this need for continuing education that supports clinicians in providing collaborative and complex care, pharmacists are expanding and standardizing multidisciplinary healthcare education.

Methods: Survey data will be collected from clinic providers, leadership, and staff to assess current educational needs, logistical constraints, and satisfaction with existing continuing education opportunities. This data will be used to design an educational curriculum to be provided by pharmacists and piloted at six of 11 primary care clinics. Follow-up surveys evaluating satisfaction with available continuing education opportunities will be distributed after the pilot and will be used to measure the success of this service in improving the provision of continuing education in primary care clinics. This pilot will serve as a model for expansion of this education program by pharmacists to all primary care clinics in the region.

Poster Title: Gap analysis assessing pharmacy consults in an inpatient palliative care service

Primary Author: Ryan Nottingham, Providence St. Peter Hospital, WA; Email: ryan.nottingham@providence.org

Additional Author(s):
Mark Ritter
Bogdan Stepchin
Chris Park
Sarah Merrifield

Purpose: The palliative care specialty focuses on life-limiting illness. Palliative care patients frequently present with complex disease states, symptoms, and medication regimens. However, provision of pharmacy services within palliative care is a new and emerging field. With medications playing a critical role in palliative care, pharmacy services may prove beneficial in this specialty. This project is designed to characterize pharmacy consults requested by palliative care and measure palliative care staff satisfaction with the integration of pharmacy services. Through this project, pharmacy consults will become standardized and streamlined. This project will promote efficient interdisciplinary collaboration and improve palliative patient care.

Methods: This quality improvement project will be submitted to IRB for review. The inpatient palliative care team will request pharmacy consults for specific patient cases. Consult requests are done via phone, staff message, or in person. Pharmacists will perform consults including, but not limited to, drug-interaction checking, dose optimization, titration/tapering schedules, converting between different administration formulations, follow up phone calls, hospice transition assistance, and general drug information questions. Pharmacy services will track these consults and categorize them. The results from tracking will be reviewed every 6 weeks to analyze request patterns. Palliative care staff will complete a satisfaction survey every 3 months to examine satisfaction with pharmacy services. This project is set to finish in June 2017.

**Poster Title:** Optimizing antimicrobial stewardship of prescribers: An education based approach

**Primary Author:** Philip Tobias, Providence St. Peter Hospital, WA; **Email:** philtobias1@gmail.com

**Additional Author(s):**
Tylor Heilman
Elizabeth Hesselbacher
Steven Standaert
Julie McCoy

**Purpose:** The objective of this quality improvement project is to try to modify unnecessary antibiotic prescribing behavior with the implementation of an interactive, e-learning module while utilizing clinical patient cases. In addition, we hope to measure specific antibiotic usage data that correlates with each one of our patient cases to monitor for significant changes in antibiotic prescribing across Providence St. Peter Hospital and Providence Centralia Hospital.

**Methods:** This quality improvement project is pending approval by the Institutional Review Board. Patients 18 years of age or older who have been hospitalized and received an antibiotic during their admission will be analyzed retrospectively as an aggregate to see where antibiotic use has been inappropriate and patient cases will be developed to improve antimicrobial stewardship. While the e-learning module will be implemented for the new physicians hired, current physicians will be educated with an interactive presentation with similar patient cases. Subjective data will be collected from the current prescribers after the presentation regarding their thoughts on how the information affected their understanding of antimicrobial stewardship practices, appropriate antibiotic usage and if it will change their ordering habits in the future. Objective data will be collected before and after prescriber education and the e-learning module to assess for any statistically significant changes in specific antibiotic prescribing related to the patient cases.

Poster Title: Opioid overdose prevention initiative at two regional hospitals: Determining the benefit of patient opioid overdose emergency response training and naloxone kit distribution

Primary Author: Amy Yanicak, Providence St. Peter Hospital, WA; Email: amyyanicak@gmail.com

Additional Author (s):
Matthew Gardner
Hilary Smith
James Leonard
Juline McCoy

Purpose: To address the need for preventing opioid overdose fatal events, Providence St. Peter and Providence Centralia hospitals in Washington state have adopted Collaborative Drug Therapy Agreements for pharmacists to prescribe and dispense naloxone to high risk patients. The objective of this quality improvement project is to assess the impact of this new initiative. The hypothesis of the project is that a hospital-based prescribing program for take-home naloxone and overdose education will decrease opioid overdose events and associated fatal outcomes (tracked by emergency department admissions for opioid overdose and county data).

Methods: This project is in the process of review by the Institutional Review Board (IRB) as a quality improvement project. Upon receiving IRB approval, data will be collected on patients receiving naloxone kits and opioid overdose education from a pharmacist from October 1, 2016 to March 31, 2017. These kits and education will be given to patients at two regional hospitals indicated as high risk of opioid overdose as outlines in the naloxone Collaborative Drug Therapy Agreement for the hospitals. Inclusion criteria include all eligible patients over age 18 years old indicated for naloxone and overdose education; exclusion criteria include any patients that decline a prescription/counseling or have a contraindication to naloxone. All pharmacists, trained on naloxone and education workflow, will identify these patients, open intervention documentation in patient charts, write prescriptions for naloxone to the hospital outpatient pharmacy, and then provide the medication and counseling to the patient during an emergency department or inpatient admission. These patients will then have information entered into a secure datasheet for tracking of readmissions for opioid overdose in the following 30 days and
90 days post-intervention. Analysis of the total number of hospital admissions for overdose before and after the intervention, county data on opioid overdose deaths, and cost analysis of cost benefit/impact of the service will be performed for evaluating the impact of this quality improvement project.

Poster Title: Causes of 30-day re-admission in congestive heart failure patients and patient-specific interventions in two acute care community hospitals

Primary Author: Andrea Fernandez, Providence St. Peter Hospital, WA; Email: andreacamille.fernandez@providence.org

Additional Author (s):
Stephen Gunadi
Terri Byers
Chia Wei Liao
Suzanne Upfield

Purpose: Project team members aim to enhance patient care for re-admitted heart failure (HF) patients by providing root cause analysis for 30-day readmission. The interdisciplinary team has been tracking 30-day readmission rates but root causes for these readmissions are not currently being tracked. To further prevent readmissions of HF patients, it is important to fully understand the reasons for readmission. Detailed description of the causes of HF readmission are lacking and gaining insight on this can be helpful in optimizing management of these patients.

Methods: This quality improvement project is currently being reviewed by the Institutional Review Board (IRB) and data collection will begin once approval is received. HF patients who have been re-admitted within 30 days of discharge with a primary diagnosis of congestive heart failure exacerbation will be included in the project. Data will be collected retrospectively through electronic medical record review via Epic. Data collected will primarily focus on investigating the reasons for readmission. 30-day readmission information will also be available to the entire interdisciplinary team through the “flowsheets – readmission information” functionality in Epic. The team can use this information to further assess appropriate interventions for readmitted patients. Assessment of 30 day all-cause readmission rates and comparison of patient interventions done during previous admit and current admit will be performed retrospectively to evaluate the significance of knowing the root causes of 30-day readmission of HF patients.

Poster Title: Collaboration to improve hospital and poison center documentation in intravenous lipid emulsion cases

Primary Author: James Leonard, Providence St. Peter Hospital, WA; Email: james.leonard@providence.org

Additional Author(s):
Curtis Elko
Andrew Tyrrell
Matthew Gardner
Julie McCoy

Purpose: Intravenous lipid emulsion (ILE) is a potential salvage therapy for patients who have not responded to conventional treatments for acute overdose of many substances. This treatment option has become increasingly popular as evidenced by frequency of case report publication. Guidelines published in 2016 gave only neutral recommendations for use as part of standard treatment modalities and highlighted limitations in the available data. The intent of this quality improvement project is to further characterize the effects of ILE in acute overdose and to improve documentation of the effects by the local poison center.

Methods: This project is awaiting IRB designation as a quality improvement initiative. This is a retrospective, sequential case series of all cases of ILE used for overdose in 2 community hospitals since these hospitals have been on their current electronic medical record system. Patients receiving intravenous lipids strictly for nutritional support, receiving ILE for local anesthetic toxicity, and those receiving ILE for completely unknown toxin ingestion will be excluded. After identification of patient cases, the following data will be extracted from both hospital medical records and when available, from poison center documentation: patient age, sex, weight, comorbidities, suspected or actual toxin(s) and dose(s) ingested, other treatments given for the overdose, response to ILE (hemodynamic, charted clinical observations, electrocardiographic), lab values associated with the ingestion and ILE, and patient outcomes. Data will be summarized using descriptive statistics in an attempt to identify trends in onset of effect of ILE and identify positive (improvement in vital signs or laboratory values) or negative effects (interference with labs, pancreatitis, and inability to initiate other supportive therapies).
Documented in both systems will be compared to identify areas for future improvement in the specific data collected by the poison center. Additionally, data will be used to educate emergency department providers throughout our regional hospital system, to develop internal guidelines for our hospital, and to guide use with the local poison center.

**Poster Title:** Pharmacist involvement in new post-discharge clinic targeting patients at high risk of readmission

**Primary Author:** Christine Doran, Providence St. Peter Hospital, WA; **Email:** christine.c.doran@gmail.com

**Additional Author (s):**
Andrea Hall
Romil Wadhawan
Stephen Gunadi

**Purpose:** Reducing hospital readmissions is a goal for many healthcare systems, as reimbursement rates have recently changed based on hospital-specific readmission rates. A new post-discharge clinic will serve patients in Olympia, Washington who are unable to be seen by their primary care provider (PCP) in a timely manner after hospital discharge. The purpose of this project is to attempt to justify pharmacy’s involvement in the post-discharge clinic, determine the scope of involvement, and work to identify the most efficient and efficacious workflow model for patient visits. The ultimate goal of this project is to reduce high-risk hospital readmission rates.

**Methods:** The project team will determine criteria which constitutes high readmission risk. These criteria will be applied to inpatients at Providence St. Peter Hospital in order to prioritize need and ensure efficient and appropriate patient selection for referral to the post-hospitalization visit (PHV) clinic. Financial and market analyses will be performed to justify pharmacy’s involvement within the clinic. The scope of pharmacy’s involvement will be determined based on available resources and results from background research. A visit template will be created, to allow the healthcare provider to track interventions and systematically document clinic visit interventions. An analysis of these interventions will be performed by the project team. Results from this analysis will be used to justify pharmacy’s continual involvement within the clinic. Baseline 30-day hospital readmission rates will be collected and compared to 30-day hospital readmission rates after the opening of the PHV clinic.
Institutional Review Board (IRB) approval is pending for this quality improvement project. The results of this project will be presented at Western States Conference, to medical staff at a continuing education meeting in the spring of 2017, and compiled as a manuscript with the intention of submission for publication.

**Poster Title:** Pharmacist-led protocol to reduce empiric fluoroquinolone use for urinary source infections in the acute hospital setting

**Primary Author:** Matt Glaus, Saint Joseph Medical Center - CHI Franciscan Health, WA; **Email:** matthewglaus@chifranciscan.org

**Additional Author(s):**
Justin Jellison
Serena Von Ruden
Michael Bonck

**Purpose:** Fluoroquinolone antibiotics are often ordered during acute hospitalizations to treat uncomplicated urinary tract infections (UTI). A 2016 FDA review found that, compared to other antibiotics, fluoroquinolones carry a much higher risk for permanently disabling adverse events such as peripheral neuropathy and tendon rupture. Additionally, fluoroquinolones are known to increase the risk of Clostridium difficile infection (CDI) as compared to other antimicrobial agents, such as first generation cephalosporins. The purpose of this project is to develop a protocol to limit the use of empiric fluoroquinolones for UTI by substituting ceftriaxone or cefazolin in the interim period until cultures result.

**Methods:** This project will be submitted to the Institutional Review Board for approval. Pre-intervention data will be collected retrospectively from the months of May to June, 2016. Patients 18 years or older admitted to Saint Joseph Medical Center with a fluoroquinolone ordered for a urinary source infection will be included in the study. Exclusion criteria include diagnosis of severe sepsis/septic shock, pyelonephritis, hospitalization within the past 90 days, nursing home residency, hemodialysis, immunosuppression, and known hypersensitivity to intervention antibiotics. Based on the results of the retrospective data, a protocol will be developed to reduce empiric fluoroquinolone use for urinary infections. Education to the medical and pharmacy staff will be conducted prior to protocol implementation, as well as periodically during the intervention period. Post-protocol intervention data will be collected in the same manner. The primary endpoint is the percentage reduction in empiric fluoroquinolone use for urinary tract infections. Secondary endpoints include length of hospital stay, total
antibiotic days, incidence of CDI, and total number of antibiotics used during the hospitalization.

Poster Title: Pharmacist’s formal role in a team-based approach to opioid abuse mitigation in the emergency department

Primary Author: Brett Lawson, St. Joseph Medical Center, WA; Email: brettlawson@chfranciscan.org

Additional Author(s):
Tony Casanova
Michael Li

Purpose: Prescription opioid abuse has become increasingly detrimental to numerous aspects of healthcare in the United States. Patients who abuse these medications suffer serious consequences, including unnecessary emergency department visits and even death. At the front line of this epidemic, emergency department pharmacists can provide an essential role in managing symptoms from opioid withdrawal and providing long-term treatment options. The implications behind preventing emergency department re-admissions due to opioid abuse are increased patient safety and decreased healthcare-related costs. The objective of this study is to provide treatment for patients who abuse opioids and prevent emergency department re-admissions.

Methods: Patients who abuse opioids will be identified in the emergency department by comparative data including emergency department visits, narcotic prescription utilization, or self-admittance. These data can be found in the Prescription Monitoring Program and the Emergency Department Information Exchange. Once identified and screened, the pharmacist, nurse care manager, and physician will provide the patient with education on the dangers of opioid abuse and the options for symptom management and addiction treatment. Medications for symptomatic relief will be provided along with treatment referral options. Retrospective patient data will then be collected, documented, and compared to follow-up prospective data using the patient prior to intervention as their own control. The primary outcome will be a comparison of emergency department visits before and after the intervention. Secondary outcomes will be post-intervention opioid utilization, number of naloxone prescriptions written, and patient satisfaction based on a short survey assessing the effectiveness of the intervention.

**Poster Title:** Impact of formal Pharmacist-driven education and intervention to encourage single-Pseudomonas coverage for hospital-acquired pneumonia  
**Primary Author:** Melissa Ferguson, St. Joseph Medical Center, WA; **Email:** melissaferguson@chifranciscan.org  
**Additional Author(s):**  
Shannon Fry  
Justin Jellison  
Mike Bonck  

**Purpose:** In recent years, antimicrobial stewardship principles have been heavily promoted throughout health-systems across the country in response to increasing rates of multidrug-resistant pathogens, antibiotic-associated superinfection, and a paucity of new antimicrobial agents introduced to the market. Pharmacists have the opportunity to influence prescriptive practices through formal education and specific therapy recommendations. This project is designed to assess the impact of pharmacist-led provider education and interventions to minimize the usage of double-Pseudomonas coverage in patients without specified risk factors for hospital-acquired pneumonia (HAP) patients, as recommended by the 2016 IDSA Hospital-acquired Pneumonia guidelines.  

**Methods:** Formal education on the guideline-based updates to empiric HAP therapy will be presented to providers at the monthly hospitalist meeting at St. Joseph Medical Center by means of a PowerPoint presentation and a summative handout. Following education, patients admitted for >48 hours with an indication of pneumonia or sepsis entered for antibiotic orders will be screened by pharmacists. Patient exclusion criteria are: IV antibiotic use within the previous 90 days, structural lung disease, history of Pseudomonas infection, ventilator support required due to pneumonia or septic shock, or known history of Pseudomonas infection. If a patient with identified HAP does not meet any exclusion criteria, a standardized therapy recommendation will be made by pharmacists to providers via text page. The primary endpoint is the number of patients, n (%) initiated on single-Pseudomonas coverage or therapy was narrowed to single-coverage directly as a result of pharmacist intervention. Secondary endpoints will be derived from an objective Variance Report, designed to identify patterns in
guideline-based prescribing practices within the provider groups. The control group will be patients meeting criteria treated for HAP from the date the IDSA guideline was published until the date of provider education. The subjective impact of education will be assessed by likert-scale surveys distributed to providers immediately following the formal education, and again at the conclusion of the intervention period.

**Poster Title:** Implementation of a medication therapy management program within the patient-centered medical home

**Primary Author:** Jessica Chung, St. Joseph Medical Center, WA; **Email:** jessicachung@chifranciscan.org

**Additional Author(s):**
- Kristin Peterson
- Eric Wymore

**Purpose:** Eligible Medicare Part D beneficiaries within the Catholic Health Initiatives Franciscan patient-centered medical home (PCMH) are enrolled into a medication therapy management program (MTM) where they may receive an annual comprehensive medication review (CMR) and ongoing targeted medication reviews (TMR). The goals include improving the patient’s knowledge of their prescribed medications, identifying and addressing any discrepancies related to their medications, and ultimately ensuring optimal therapeutic outcomes. The objective of this study is to provide MTM services to demonstrate improved outcomes within chronic disease state management and to evaluate the return on investment generated upon reimbursement of these services.

**Methods:** Patients that are managed within the PCMH clinic will be identified as eligible for an MTM through the OutcomesMTM Connect Platform and will receive an offer for a CMR. A resident or clinic pharmacist will perform the CMRs and provide patients with a personalized medication action plan and updated medication list. If the pharmacist has identified interventions or recommendations about change in therapy that will require physician approval, then the pharmacist will first discuss these potential changes with the patient to assess for willingness and then contact the primary care physician. The primary endpoints assessed will include number of successful CMRs/TMRs completed and the implementation of pharmacist CMR/TMR workflow within the PCMH clinics and subsequent evaluation of return on investment generated with each visit. Secondary endpoints to be assessed include goal achievement of disease state management targets such as hemoglobin A1c, blood pressure levels, serum low-density lipoprotein, and heart failure readmissions; number of pharmacist interventions and/or recommendations; number of patients referred to pharmacist for disease
state management; number of pharmacy interventions accepted by the provider; and patient and/or provider satisfaction with pharmacist involvement with MTM related care. The timeline of the project will occur from October 2016 through March 2017 with an ongoing plan to support MTM and ongoing implementation into scheduled pharmacist workflows. This project is exempt from approval by the Institutional Review Board.

Poster Title: Implementation of a 48-hour antibiotic review

Primary Author: Eno Inyang, St. Joseph Medical Center, WA; Email: eno-abasiinyang@chifranciscan.org

Additional Author(s):
Serena Von Ruden
Ben Michaels

Purpose: According to the Centers for Disease Control and Prevention, 20-50 percent of antibiotics prescribed in U.S. hospitals are unnecessary or inappropriate. The misuse and overuse of antibiotics has led to increased prevalence of antibiotic-resistant bacteria. Antibiotic-resistant bacteria and serious side effects, such as Clostridium difficile infection, pose patient safety and public health concerns. The Joint Commission recently released new antimicrobial stewardship requirements to help reduce the use of unnecessary antimicrobials. These requirements include a mandate for antibiotic review after 48-hours. The objective of this project is to establish standardized policies, procedures, and education for the implementation of this review.

Methods: This project will be submitted to the Institutional Review Board for approval. All patients age 18 years and older, admitted and started on cefepime, ceftazidime, meropenem, or piperacillin-tazobactam will be included. Eligible patients will be identified at 48 hours of antibiotic use, using the electronic health care record. Policies, procedures, and education will be developed based on primary literature and best practice standards. Medical and pharmacy staff will be educated on the 48-hour antibiotic review process. The primary outcome will be implementation of the 48-hour review workflow. Secondary outcomes include frequency of accepted interventions, pharmacy and medical staff satisfaction, and change in antibiotic duration. Antibiotic duration will be evaluated and compared to data from a 6 month time period prior to implementation of the new practice model.

Poster Title: Implementation of a collaborative practice model for oncology pharmacists in a gynecologic oncology clinic

Primary Author: Kayla Grzybowski, St. Joseph Medical Center, WA; Email: kaylagrzybowski@chifranciscan.org

Additional Author(s):
Ferowsi Pecoraro
Eric Wymore
Kara Crane

Purpose: Oncology pharmacists are an integral part of the outpatient infusion center and inpatient cancer care team at St. Joseph Medical Center, but are not yet heavily integrated into the oncology clinic setting. The objective of this study is to develop and implement a practice model to enhance the oncology pharmacists’ involvement in chemotherapy treatment planning and ongoing management of patients in the Franciscan Gynecologic Oncology Associates clinics. Anticipated benefits include improvement of both patient and provider satisfaction and the potential to generate revenue for the clinical services provided by the oncology pharmacist.

Methods: This study will be submitted to the Institutional Review Board for approval. All gynecologic oncologic patients seen by included providers at the Franciscan Gynecologic Oncology Associates clinics will be referred to the oncology pharmacist for an initial assessment and ongoing management throughout chemotherapy. The pharmacist will order the necessary laboratory tests and schedule patients for an initial face-to-face pharmacist visit in the physician’s clinic, which will enable the pharmacist to tailor supportive care needs to the individual patient. The initial visit will encompass medication reconciliation, screening for potential drug-drug interactions, evaluation of laboratory tests, chemotherapy education, and education regarding the management of potential side effects. The pharmacist will continue to follow referred patients throughout the course of their therapy and schedule follow up-visits as needed to manage chemotherapy-induced side effects. The following data will be collected: number of referrals received, patient satisfaction, provider satisfaction, type and quantity of recommendations made and accepted by the providers, and revenue generated by oncology
pharmacists. Additional data that will be tracked includes patient age, gender, type of cancer, and chemotherapy regimen.

Poster Title: Opiate Ordering, Prescribing and Education Prior to Discharge

Primary Author: Kristine Gillas, St. Peter’s Hospital Olympia, WA, WA; Email: kristine.nguyen@providence.org

Additional Author(s):
Megan Pettibone
Mark Ritter

Purpose: Over the past several decades providers were trained to treat pain as the fifth vital sign. Research and studies stated that opioids, when used to treat pain, had a very low incidence of addiction. However, over the past few years new research has emerged showing that opioids have a high potential for dependence, addiction and abuse. This has left prescribers unsure of how to best treat their patients’ pain. This quality improvement project aims to determine best practices surrounding opioid discharge prescriptions.

Methods: A chart review of patients who were prescribed opioids at discharge from our facility will be performed to review patient’s pain level and opioid need while in-patient. Assessments will be done to determine if the amount of opioids prescribed exceeded doses patients were receiving while in-patient, were similar to what they were receiving in-patient with a reasonable taper schedule, or were inadequate compared to what they were receiving while in-patient.
Trends in prescribing, areas for improvement and points of reeducation will be identified. Additionally, concierge filling of prescriptions by our outpatient pharmacy will be offered to patients undergoing planned surgeries. This is intended to reduce the number of pre-surgery prescriptions and lead prescribers to write for quantities reflective of the amount of pain and progress the patient is making.
Data will be collected from pre-intervention and post intervention time periods and assessed to see what, if any, impact the interventions had on the quantity of opioids prescribed.

Poster Title: Evaluating the impact of clinical pharmacy services on diabetes management within four primary care clinics

Primary Author: Karen White, Swedish Medical Center, WA; Email: karen.white4@swedish.org

Additional Author(s):
Nancy Lee
KyAnn Wisse

Purpose: Swedish Medical Group (SMG) consists of 30 + clinics across the Seattle area. Historically, there has been minimal pharmacy involvement within the medical group. Since 2014, pharmacy presence has grown from one to five pharmacists each working in single SMG clinics. Pharmacist responsibilities in the clinics include, but are not limited to, drug information consults, transition of care management, and chronic disease management (diabetes, hypertension, lipids, etc). The impact of these clinical pharmacy services has yet to be assessed. This study aims to quantify the impact of SMG clinical pharmacy services and specifically focuses on changes to diabetes management.

Methods: The following study design will be submitted to the International Review Board for approval. Patients will be retrospectively identified for study inclusion if they were referred to the clinical pharmacist for diabetes management and have had at least 3 follow-up visits with clinical pharmacist within a 4-month period from the dates of June 1st 2015 to September 28th 2016. Patients will be excluded if they did not have follow-up labs since the initial pharmacist contact. Charts will be reviewed retrospectively. Data to be collected will include initial A1c, follow-up A1c values, number of pharmacist visits (in-person or telephone), aspirin therapy, angiotensin-converting enzyme inhibitor therapy, statin therapy, average blood pressure (BP) prior to pharmacist contact (defined as average of 3 office visit BP values prior to initial pharmacist contact), final BP value average (defined as average of most recent 3 office visit BP values), pertinent vaccine history, and initial and final diabetes medications (by pharmacological drug class) from start of pharmacist contact to end of pharmacist contact. Patient data will be de-identified and stored on secure; hospital approved devices.

Poster Title: The Evaluation of Tocilizumab for Cytokine Release Syndrome in Chimeric Antigen Receptor T-Cell Patients.

Primary Author: Courtney Bishop, The University of Washington Medical Center, WA; Email: cbbishop@uw.edu

Additional Author(s):

Purpose: Chimeric antigen receptor (CAR) specific for CD19, a B-cell specific antigen expressed on normal and malignant cells, is a promising new strategy for relapsed/refractory B-cell malignancies. Patients may develop cytokine release syndrome (CRS) due to T-cell activation and release of inflammatory mediators, which can be manifested as fever, hypotension, capillary leak, coagulopathy, and neurotoxicity. IL-6 receptor blockade with tocilizumab has been effective to reduce symptoms without dampening the response of CAR T cell expansion. We seek to characterize patients who developed CRS and received tocilizumab with or without dexamethasone at our institution and its clinical effects in these patients.

Methods: This is a retrospective case series of patients treated with tocilizumab for CRS as a result of CAR T-cell therapy at The University of Washington Medical Center. Data will be collected from the electronic medical record and will include: patient demographics (gender, age); dose of CAR t-cells; malignancy; dose of tocilizumab; ferritin; CRP; IL6; LDH; oxygen requirement; vasopressor support; serum creatinine; liver function tests; CRS grade; fibrinogen; date of CAR t-cell infusion; date of tocilizumab and/or corticosteroid administration; blast percentage prior to t-cell infusion; and death (if applicable). Descriptive data will be used to describe results.

Poster Title: Comparison of two training methods and their effect on immunization delivery in community pharmacy: Project VACCINATE

Primary Author: James Lin, University of Washington / QFC Pharmacy, WA; Email: jlin1709@yahoo.com

Additional Author (s):
Jennifer Bacci
Marci Reynolds
Peggy Odegard

Purpose: Identifying effective training strategies for community pharmacy is critical to expanding patient care services in this setting. Project VACCINATE is a demonstration project in Washington State aimed at increasing adult immunizations administered in and state registry documentation by community pharmacies. The objective of this project, a subset of Project VACCINATE, is to compare the effects of live training strategy versus a train-the-trainer strategy on (1) influenza, pertussis, herpes zoster, and pneumococcal vaccines administered to adults 18 years and older; (2) training costs and immunization revenue; and (3) pharmacist and technician knowledge and confidence in a supermarket chain community pharmacy organization.

Methods: This demonstration project is taking place at eight high performing supermarket chain community pharmacies in Seattle. These eight pharmacies were matched based on immunization sales and performance and sorted into 2 groups. Four pharmacies had all staff pharmacists and technicians attend a 2 hour live training session. The other four pharmacies received a train-the-trainer strategy where one pharmacist and one technician champion attended the live 2 hour training and then returned to their pharmacy to train their complete staff. The number of immunizations administered and revenue generated at each pharmacy will be obtained from pharmacy dispensing records every two weeks post training. Training costs will be derived from both the direct paid time to bring staff to training sessions and the total logged time for the pharmacist and technician champion to train staff members. Training costs will be tallied after the train-the-trainer groups fully train their staff. Knowledge and confidence will be assessed using standardized confidence scales and knowledge exams. These confidence and knowledge assessments were administered before and after the live training sessions and
will also be administered to staff trainees in the train-the-train group before and after training. A repeat set of assessments will also be administered every month afterwards. All data will be analyzed using descriptive statistics and then combined to compare the effects of the two training strategies.

Poster Title: Evaluation of resource utilization of immunotherapy checkpoint programmed death receptor-1 (PD-1) and cytotoxic T-lymphocyte-associated protein (CTLA-4) inhibitors for patients with advanced sarcomas

Primary Author: Kristyn Yemm, University of Washington Medicine, WA; Email: yemm@uw.edu

Additional Author (s):
Katharine Kinsman
Kathryn Hammer

Purpose: There has been a dramatic improvement in the rate and disease-free survival in patients diagnosed with sarcoma since the 1970s, from previous mortality rates of 80-90% with the addition of multimodal therapy including surgery, chemotherapy radiotherapy. However, despite previous advancements there has been a plateau in overall prognosis for sarcoma patients; alternative and more effective options are needed. Recent success of immune checkpoint inhibitors such as PD-1 and CTLA-4 antibodies in melanoma, renal cell carcinoma, prostate, colorectal and non-small cell lung cancer has triggered exploration of these agents in other diseases such as sarcoma.

Methods: Retrospective chart review will be performed for patients diagnosed with advanced sarcoma receiving care at the Seattle Cancer Care Alliance (SCCA) in Seattle Washington from August 1, 2015 to September 28, 2016. Patients will include those 18 years or older with a diagnosis of advanced sarcoma and must have applied for patient assistance to receive an immunotherapy checkpoint inhibitor regimen. The primary objective of this analysis is to quantify the amount of time and resources being used for awarding patient assistance of checkpoint inhibitors, specifically PD-1 and CTLA-4 antibodies, in opposition to last lines of treatment including end of life care in patients with advanced sarcomas. We will specifically examine the number of requests for these immunotherapies compared to actual new initiations of therapy. We will work with our patient assistance coordinator to obtain hours and resources involved in the award of patient assistance for each patient for each targeted agent, time between initiation of patient assistance to initiation of therapy and determine if the total time and resources spent are a wise allocation of institutional resources. Secondary objectives of the
study are to document line of therapy, total time spent on PD-1 and CTLA-4 antibody therapy, time to death after initiating therapy if applicable and toxicities experienced by the patients receiving the antibodies.

Poster Title: Improving medication self-efficacy in patients at high risk for readmission

Primary Author: Crystal Zhou, UW Medicine, WA; Email: crystalzhou88@gmail.com

Additional Author (s):
Lintak Chan
Ying Zhang
Alvin Goo

Purpose: The objective is to evaluate the impact of primary care clinical pharmacist interventions through monthly clinic visits on patients’ medication self-efficacy, using the MUSE (medication understanding and use self-efficacy) scale, a validated tool. Specifically, this study aims to increase medication self-efficacy in patients at high risk for readmission, as identified by the LACE (length of stay, acuity, comorbidities, emergency department visits) index. A secondary aim is to determine the difference in improvement of MUSE score stratified by LACE index of 10-13 and >13. An additional exploratory aim is to compare improvement in MUSE score in English versus non-English speaking patients.

Methods: This is a single-center, prospective study capturing adult patients recently discharged from the hospital with LACE index ≥10. Patients who have had clinical pharmacist visits within the past 12 months and live in a long-term care, skilled nursing or assisted facility will be excluded. Patients admitted for oncological, mental health, or surgery diagnoses will be excluded as well. After obtaining informed consent, patients will be scheduled for 3 face-to-face visits over 3 months with the clinical pharmacist in their primary care clinic for monthly comprehensive medication reviews which will also assess control of chronic disease states such as diabetes, hypertension, dyslipidemia, asthma, or chronic obstructive pulmonary disease. The MUSE survey will be administered at visits 1 (baseline) and 3 (post-intervention). Patient demographics and clinical characteristics will be collected from the electronic medical records. The primary outcome is change in MUSE score from baseline in all patients. Secondary outcomes include change in medication adherence based on refill history and hospital readmission rates. Additional analyses include comparing the change in MUSE score stratified by LACE 10-13 and >13 and between English and non-English speakers. Student’s t-test will be
used to determine the change in MUSE score; Pearson’s chi-square test will be used to determine change in adherence and readmission rates.

**Poster Title:** A retrospective evaluation of the efficacy and toxicities observed with palbociclib in breast cancer patients

**Primary Author:** Alan Chin, UW Medicine, WA; **Email:** alanchin@uw.edu

**Additional Author(s):**
Laura Alwan
Eve Segal
Anne Spengler
Vijayakrishna Gadi

**Purpose:** The primary objective of this study is to assess the duration of therapy and clinical response of patients taking palbociclib for hormone-receptor positive metastatic breast cancer in patients that have also received everolimus for treatment of hormone-receptor positive metastatic breast cancer. Additional objectives include assessing hematologic toxicities and subsequent dose adjustments associated with palbociclib at monthly intervals. This study will benefit the institution by examining prescribing practices and providing additional guidance for monitoring patients receiving palbociclib.

**Methods:** This study will be submitted to the Institutional Review Board for approval. Subjects for this study will be identified using the pharmacy database to search for patients prescribed both palbociclib and everolimus between August 31st 2013 through August 31st 2016 at the Seattle Cancer Care Alliance. Patients who never received everolimus at any point in their treatment history will be excluded. The anticipated total number of patients to be included in this study is between 60-100. The following data will be collected for patients through online chart review of the electronic medical record: age, sex, hormone receptor (HR) status, HER2 status, menopausal status, date palbociclib initiated and stopped, length of treatment with palbociclib, reason why palbociclib stopped, line of therapy of palbociclib, hormone treatment while on palbociclib, changes to hormone therapy while on palbociclib, date everolimus initiated and stopped, length of treatment with everolimus, and toxicities associated with palbociclib therapy such as hematologic abnormalities (neutropenia and thrombocytopenia). The collected data will be used to determine the following: median length of therapy with palbociclib in patients who previously received everolimus compared to patients who never
received everolimus prior to starting palbociclib, rate of dose reductions of palbociclib and if dose reductions were in accordance to recommendations from the package labeling. The data will be analyzed using descriptive statistics by the investigators.

Poster Title: Development of a procedure and evaluation of the effect of switching patients from long-acting insulin to insulin NPH

Primary Author: Stephen Ueng, UW Medicine, WA; Email: sjueng@uw.edu

Additional Author(s):
Greta Sweney
Theresa O'Young

Purpose: To develop and implement a procedure for switching patients from long-acting insulin to insulin neutral protamine Hagedorn (NPH) and to evaluate its safety and efficacy.

Methods: Phase I: A retrospective evaluation of patients’ control of diabetes. Those with type 2 diabetes mellitus currently insulin seen by a clinic pharmacist in the past 6 months (April 2016 – September 2016) will be eligible. They will be identified through EMR reporting.
Data to be collected include:
- Age, gender, race, BMI
- Antidiabetic medications
- Hemoglobin A1c

Phase II: Implementing a process to switch insulin.
Will assess a process for patients seen by clinic pharmacists to switch from long-acting insulin to insulin NPH. A standardized process will be developed for the pharmacist to assess hypoglycemia at every visit.

Phase III: A retrospective evaluation of safety and efficacy.
Those with type 2 diabetes mellitus currently insulin seen by a clinic pharmacist in the past 6 months (November 2016 – April 2017) will be eligible. The safety and efficacy of the procedure to switch from long-acting insulin to NPH will be assessed by looking at any changes in A1c as well as episodes of hypoglycemia. Potential financial benefits will also be examined.
Data to be collected include:
- Age, gender, race, BMI
- Antidiabetic medications
- Hemoglobin A1c
- Episodes of hypoglycemia determined through standardized process

Poster Title: Evaluation of appropriate renal dosing of zoledronic acid in breast and genitourinary cancer patients with metastases to the bone.

Primary Author: Amy Ly, UW Medicine, WA; Email: amyly2813@uw.edu

Additional Author (s):
Laura Alwan
Anne Spengler
Eve Segal

Purpose: The primary aim of this study is to identify the proportion of patients appropriately dosed with zoledronic acid based on renal function in patients with breast and genitourinary cancer with metastases to the bone. Data will also be gathered to evaluate the frequency of hold parameters in the order for zoledronic acid, and to identify the incidence of hypocalcemia in patients who are not appropriately dosed with zoledronic acid based on renal function.

Methods: General study design: Retrospective, descriptive study to identify the proportion of appropriately dosed zoledronic acid based on renal function
Data Collection: Retrospective chart review on approximately 100 patients between January 01, 2015 to August 31, 2016. Data will be collected from the billing department and chart review.
Inclusion criteria: Patient’s with a diagnosis of metastatic breast or prostate cancer with lesions to the bone who receive an initial dose of zoledronic acid for management of metastases to the bone between January 01, 2015 and August 31, 2016. Subsequently, zoledronic acid must be ordered for an every 3-6 week schedule (range of dosing to allow for flexibility of scheduling to align with concomitant chemotherapy orders).
Exclusion criteria: Patients who are receiving zoledronic acid for an indication of hypercalcemia.

Results: Results and conclusion pending.

Conclusion: Results and conclusion pending.

**Poster Title:** Assessment of inpatient pharmacy medication costs over six months to determine opportunities for clinical interventions and cost savings

**Primary Author:** Laura Lavezo, Virginia Mason Medical Center, WA; **Email:** laura.lavezo@virginiamason.org

**Additional Author (s):**
Lacey Boren
Laurel Brown
Lisa Chamberlain

**Purpose:** As the cost of medications continues to rise annually, it is imperative for inpatient pharmacies to have an understanding of how money is currently being spent on medications for use in the hospital. Pharmacists can have a significant role in analyzing medication costs and utilization patterns in order to optimize high cost medications to reduce overall medication expenditure while providing safe and appropriate care. The purpose of this study is to identify high cost medication usage trends over the past six months and investigate opportunities for evidence-based clinical interventions to decrease either cost or usage.

**Methods:** Six months of inpatient medication expense data was provided for a cost-review analysis. Medications were sorted into medication categories according to Cerner software. Information on monthly total costs and total number of doses dispensed was sorted using pivot tables in Microsoft Excel. The six month data was analyzed to find consistencies and variations in spending and utilization over time. Medications were excluded from analysis if only used by a single patient or if the medication was a non-formulary medication. Medications with a monthly cost of over ten thousand dollars, medications with a single-dose cost of over five thousand dollars, or medications that had the potential to not follow current evidence-based practices were targeted for further investigation. This information will be reviewed from a clinical standpoint to determine what areas of opportunities exist to improve medication use and in the inpatient setting. Additionally the data will be used to identify opportunities for medication cost-savings in the inpatient setting. In the future, the information gained from this study will be utilized to analyze prescribing patterns with providers.

Submission Category: Pain Management

Submission Type: Research-in-Progress

Session-Board Number: 10-340

Poster Title: Evaluation of pharmacist involvement on an interdisciplinary team for the management of chronic nonmalignant pain in an ambulatory clinic setting

Primary Author: Lena Perry, Yakima Valley Memorial Hospital, WA; Email: lenaperry@yvmh.org

Additional Author(s):
Nicholas Eckert
Linnea Reed
Christopher Cook

Purpose: In a response to the marked increase of opioid prescriptions and the parallel increase of opioid related deaths over the last decade, the Center for Disease Control and Prevention recently published guidelines for prescribing opioids for chronic pain outside of active cancer treatment, palliative care, and end of life care. These guidelines are intended to optimize care and improve safety among chronic pain patients in outpatient settings. The purpose of this study is to evaluate outcomes after the implementation of pharmacist involvement in the care team for patients in a moderate to high risk group in an ambulatory clinic setting.

Methods: This study is currently pending approval by the institutional review board. An opioid registry, provided by a project funded through a government grant, will be used to identify patients receiving two or more opioid prescriptions over a 90 day period. Pharmacists and pharmacy students will calculate morphine equivalent doses (MED) for each patient using a state approved online calculator. Patients will be stratified according to their risk of overdose and opioid use disorder. The predefined MED scores include, high risk (>90 MED), moderate risk (50-90 MED), and low risk (< 50 MED) groups as described by the health system’s physician opioid prescribing protocol. For patients categorized as moderate or high risk, a pharmacist will evaluate the statewide Prescription Monitoring Program (PMP) and random urine drug screens for signs of potential abuse. Assessments for opioid related adverse side effects and drug interactions will be made through patient interviews. Pertinent results and recommendations will be triaged to physicians based on level of significance. Metrics for efficacy of pharmacist involvement will include: the number of patients evaluated by the pharmacist, time spent to complete each evaluation, recommendations made by the pharmacist for the provider,
decrease in MEDs per patient, patient perspective of pain management and functional status, and potential cost savings.

Poster Title: Implementation of a Pharmacist-Led Chronic Disease Management Program in a Primary Care Clinic

Primary Author: Pearce Engelder, Yakima Valley Memorial Hospital, WA; Email: pearceengelder@yvmh.org

Additional Author(s):
 Nicholas Eckert
 Christ Cook
 Marc Murdock

Purpose: Chronic disease management is imperative to minimizing long-term and irreversible complications. Rural areas, like Yakima, Washington, are often plagued by a shortage of primary care providers. This shortage of primary care providers makes it difficult for current providers to appropriately monitor their patients with chronic diseases. To improve the quality of care and frequency of follow-up for patients with chronic diseases, a chronic disease management pharmacist will be integrated as part of the primary care team within the Memorial Family of Services primary care clinics.

Methods: This study will be submitted to the Institutional Review Board for review as exempt status. Collaborative drug therapy agreements will allow a full-time pharmacist the ability to order labs and prescribe medications for the following chronic diseases: asthma, chronic obstructive pulmonary disease, diabetes, hypertension, and hyperlipidemia. Patients will be referred to the pharmacist by their provider for disease management. A secondary referral process will be utilized to refer patients to the pharmacist based on clinic records of the patient’s prior disease control or with evidence of a recent disease-related hospital admission. The pharmacist’s time will be divided between forty minute initial visits, twenty minute follow-up visits, and follow-up phone calls. Phone calls will be used for the following: assess effects of new drug regimens, adjust dosing and frequency of new medications, provide additional education, and perform motivational interviewing as warranted by the clinical scenario. Visits will be billed using established office patient Evaluation and Management Current Procedural Technology codes 99213, 99214, and 99215. Continuous metrics will be set up to allow the pharmacist to monitor impact on patient’s disease control in relation to chronic disease
management guidelines and provider-set goals. Other measurements will include time spent per patient, number and type of interventions, and reimbursement rate will also be evaluated to determine sustainability of pharmacist involvement.

**Results:** N/A

**Conclusion:** N/A
Purpose: Chemotherapy toxicities are common in cancer patients and cause significant symptom burden and decreased quality of life. Supportive care services are vital for caring for patients through the continuum of care. Literature supports utilization of pharmacists in managing supportive care regimens. Our site was chosen by Centers for Medicare and Medicaid Services to participate in the Oncology Care Model which entails pharmacist involvement in patient care with expanded prescriptive authority. The purpose of this study is to implement and evaluate the pharmacist-led, collaborative method of care delivery and measure improvement in patient outcomes, decreased costs, and increased access of care.

Methods: A team consisting of the clinical pharmacist director, chief medical director and pharmacy resident will develop a pharmacist-managed oncology supportive care clinic. A retrospective chart review will be conducted to assess appropriateness of supportive care regimens prior to clinical pharmacist intervention. A detailed business plan and prescribing and ordering protocols for various types of hematologic toxicities and anti-emetic regimens will be created to support the clinic’s development. Collaborative drug therapy agreements (CDTA) utilizing current evidence-based guidelines will be created and submitted for approval. These protocols will give the pharmacists the ability to initiate or modify drug therapy, order related laboratory tests and assess patient’s response to therapy, providing oncologists more time to spend on treatment of primary disease as well as accept new referrals. The study will be submitted to IRB for approval. This new service is expected to be implemented in January 2017. April 2017 will be used to assess impact of pharmacy interventions on patient outcomes, overall
cost of care, and improved access. Primary outcome measures will be evaluation of physician prescribing practices pre and post implementation which include adherence to NCCN guidelines and appropriateness of ESA use. Secondary outcome measures will include compliance with CMS guidelines, number of hospital admissions for supportive care related issues, percentage of patient encounters by oncologists, overall costs and patient satisfaction compared to pre-pharmacy involvement.

Poster Title: Implementation of medication therapy management (MTM) for high risk patients

Primary Author: Moro Kim, Yakima Valley Memorial Hospital, WA; Email: morokim@yvmh.org

Additional Author (s):
Ryan Taketomo
Christopher Cook

Purpose: Medication Therapy Management (MTM) is health care service provided by pharmacists that has been shown to optimize patients’ drug therapy and improve therapeutic outcomes. Consistent and efficient MTM services can prevent medication errors, enhance medication compliance, active patient involvement in medication management, cost reduction and improve continuity of patient care. The objective of this project is to implement a pilot service that targets high risk patients using predictive analytics and optimize medication use. The final analysis will measure the various intervention made and their acceptance by the practitioners. Lastly, patient and practitioner satisfaction will be recorded for quality measures.

Methods: The project will be a collaborative effort with Signal Health, a clinically integrated health care network with a focus on the Institute for Healthcare Improvement’s Triple Aim, targeting a Medicare patient population. The high risk patients will be identified using the Johns Hopkins Adjusted Clinical Groups Practice Model, a predictive analytics tool, and Patient Activation Measure surveys. Once patients are identified, residents and interns will contact patients via telephone for an appointment. When patients agree for the service, residents and interns will then conduct medication reconciliation, complete a medication use action plan that informs patients about their medication, and document any findings that need to be addressed with their primary care provider in their electronic medical record. The end result of this program will be measured by a 90 day retrospective review that will compare different types of interventions made, such as adverse drug reaction reduction, stop duplicate therapy, cost savings made, identify inappropriate indication, dose adjustment and drug interaction. In addition, the MTM service will also measure how many interventions were accepted by the practitioners with the patient profile review and practitioner responses.

Poster Title: Implementation and assessment of a pharmacological venous thrombosis prophylaxis protocol in obese patients

Primary Author: Lauren Cope, Ascension | Wheaton Franciscan - St. Joseph, WI; Email: lauren.cope@wfhc.org

Additional Author(s):
Diane Erdman
Nadir Hinnawi
Betsy Karli
Anne Toy

Purpose: Obesity and venous thromboembolism (VTE) are on the rise in the United States, with over one-third of the population classified as obese and approximately 900,000 VTE events each year. It has been shown that obesity is a major risk factor for VTE and currently VTE chemical prophylaxis at Wheaton Franciscan hospitals is not standardized in obese patients. The purpose of this study is to design and implement a VTE pharmacist driven dosing protocol for obese patients with a BMI ≥40. Secondary analysis will look at adherence to the protocol and comparison between dosing before and after protocol implementation.

Methods: This study will be submitted to the Institutional Review Board for approval. The proposed protocol will be presented to the P&T committee before education and implementation. Patients included in the pharmacist driven VTE dosing protocol will be: adults >18 years old, BMI ≥40, length of stay ≥48 hours, and requiring chemical thromboprophylaxis. Exclusion criteria will be: CrCl < 30 mL/min, platelet count < 100,000/mL, and pregnant or post-partum patients. Appropriate dosing post-protocol will be defined as enoxaparin 40mg subcutaneous twice daily in patients with a BMI ≥40. Retrospective data will be collected from July 1st – November 30th, 2016 to analyze dosing patterns prior to implementation. Education will be provided to pharmacists, nurses, and physicians about the changes to dosing and ordering in the protocol. After implementation, adherence data will be assessed from December 1st – March 31st, 2017.

Poster Title: Improving adherence to surviving sepsis campaign guideline recommendations for crystalloid bolus administration in the emergency department: a pharmacist quality improvement project

Primary Author: Bobbie-Jo King, Ascension | Wheaton Franciscan Healthcare - All Saints Hospital, WI; Email: bobbie-jo.king@wfhc.org

Additional Author(s):
Erin Napier
Kevin Peterson
Peter DeGroot
Paul Springborn

Purpose: To create and implement an educational intervention in the emergency department (ED) that will increase the compliance to the surviving sepsis campaign guideline recommendations of 30 mL/kg crystalloid fluid bolus in septic patients who are hypotensive with a lactate greater than 2 mmol/L prior to the initiation of a vasopressor.

Methods: This study has been submitted for approval by the Institutional Review Board. The electronic medical record system will identify patients discharged from the hospital for a period of three months who had a lactate level greater than 2 mmol/L drawn in the emergency department (ED). The following data will be collected: systolic blood pressure less than 100 mmHg, age, sex, length of stay, lactate level, weight, amount of fluid received, time span fluid ran over, vasopressor received within six hours, vasopressor used, number of vasopressors used, vasopressor started prior to the completion of fluid bolus administration. The primary end-point of this study is the percent compliance to a 30 mL/kg crystalloid fluid bolus prior to the administration of a vasopressor. Questionnaires will be created and distributed to physicians, nursing staff, and pharmacists who staff the ED. The questionnaires will determine potential barriers in education, workflow, and physical ability to adhere to the guideline recommendations. Based on the results of the questionnaires, educational interventions will be created and implemented in the ED that focuses on improving the primary end-point. Post intervention, three months of data will be collected and analyzed. Results and conclusions will be drawn between pre and post-intervention for rates for compliance.

Poster Title: Review of institutional protocol adherence for the treatment of diabetic ketoacidosis in a community hospital

Primary Author: Angela Zivkovic, Ascension/Wheaton Franciscan St. Joseph Hospital, WI; Email: angela.zivkovic@wfhc.org

Additional Author(s):
Jeffrey Yochum
Jordan Williams
Rahim Mohammadali

Purpose: Diabetic ketoacidosis (DKA) is a serious complication of diabetes. Treatment of this condition includes correction of dehydration, hyperglycemia, and electrolyte abnormalities. The American Diabetes Association (ADA) has developed a guideline with clear goals and recommendations for the treatment of DKA. Despite the protocol approach given in the guideline, studies have shown adherence to the DKA guideline is inadequate. The main objective of this study is to determine if treatment of DKA in a sample of adult patients in the hospital was consistent with institutional protocol.

Methods: This study has been approved by the Institutional Review Board. A retrospective chart review will be conducted using electronic medical records to identify patients who visited the Emergency Department (ED) and were given a diagnosis of diabetic ketoacidosis from May 31st to December 31st, 2016. All patients greater than 18 years of age will be included. The primary outcome will be the adherence to the institutional protocol for the treatment of DKA. The secondary outcome is the comparison of patients treated per protocol to off protocol treatment in regards to time to resolution of DKA, occurrences of hypokalemia and hypoglycemia, time to Critical Care Unit (CCU) discharge and time to discharge from hospital. The following data will be collected: time to CCU discharge, time to discharge from hospital, time to DKA resolution, potassium < 3.3 within 48 hours of admission to ED, appropriate potassium supplementation, initial IV fluid, initial insulin Infusion dose, correct start of subcutaneous insulin post resolution, number of hypoglycemic episodes, correct discontinuation of insulin infusion, restart of insulin infusion after resolution, and correct identification of resolution. All data will be recorded without patient identifiers. The findings of
this review will be used to provide education to both emergency and critical care department staff and implement changes to the institutional protocol if necessary.

Poster Title: Comparison of patient-reported home opioid medications use and opioid prescriptions verified through a prescription drug monitoring database

Primary Author: Taylor Mancuso, Ascension/Wheaton Franciscan-St Joseph, WI; Email: taylor.mancuso@wfhc.org

Additional Author(s):
Andrew Ticcioni
Robert Mueller
Michelle Reichart

Purpose: According to the CDC deaths from prescription opioid overdose have quadrupled since 1999. Prescription drug monitoring programs (PDMP) present an opportunity to track controlled medications through an electronic database. In light of the opioid overdose epidemic, pharmacy staff sought to evaluate the routine review of the PDMP during the medication verification process for continued home opioid medications. Ideally, this could ensure a more accurate admission medication list and guide appropriate inpatient medication therapy.

Methods: The electronic medical record will provide data on patients admitted from May 2016 to September 2016. Adult patients from all floors of the hospital will be included if an opioid is on the home medication list. Patients will be excluded if medication reconciliation isn’t completed or a home medication list isn’t collected. Pharmacist education on PDMP use prior to verification of reordered home opioid medications will be provided in November 2016. Implementation of pharmacist checking, documentation of findings, and physician communication of the PDMP report prior to verification of home opioid medications will take place in November 2016. Data will be collected after implementation from November 2016 to January 2017. The following information will be collected: number of opioids reordered from the home medication list, number of opioid discrepancies, types of opioid discrepancies, number of opioid fabrications, number of opioid omissions, number of physicians/pharmacies utilized by the patient, whether or not information obtained from the PDMP altered inpatient admission orders, whether or not a drug screen was collected, and whether or not drug screen
was positive for opioids. All data will be recorded without patient identifiers. The study has been approved as a quality assurance measure through the hospital's Institution Review Board.

**Poster Title:** Implementation of a pharmacist driven VTE risk assessment tool

**Primary Author:** Roshni Patel, Ascension/Wheaton Franciscan-St. Joseph, WI; **Email:** roshni.patel@wfhc.org

**Additional Author (s):**
Nadir Hinnawi
Betsy Karli
Andrew Ticcioni

**Purpose:** Venous thromboembolism (VTE), which includes deep vein thrombosis (DVT) and pulmonary embolism (PE), is a leading complication among hospitalized patients. Currently pharmacists do not have a standardized approach to addressing pharmacological VTE prophylaxis. The primary objective of this study is to design and implement a pharmacist driven VTE risk assessment tool for medical patients admitted to Wheaton Franciscan St. Joseph Hospital. The secondary objective is to determine the appropriate usage of pharmacologic VTE prophylaxis in hospitalized patients using a pharmacist led VTE risk assessment tool.

**Methods:** The Institutional Review Board has approved this study. The electronic medical record will be utilized to collect patient data. Pre implementation data will be collected for 100 patients from January 2016 –September 2016 and post implementation data will be collected for 100 patients from November 2016 - March 2017. The following data will be collected: Padua risk assessment score, and its components, such as history of VTE, reduced mobility, active cancer, history of thrombophilic condition, recent trauma or surgery, obesity, acute MI/ischemic stroke, ongoing hormonal treatment, heart and/or respiratory failure, lower extremity arthroplasty, and spinal cord injury with paresis. All previously mentioned parameters will be recorded without patient identifiers and maintained confidentially. Pharmacists will use the risk assessment tool to determine the patient’s need for pharmacologic VTE prophylaxis and convey their recommendation to the physician within 24 hours of admission by any form of communication they deem appropriate. This will ensure all patient have optimized pharmacological VTE prophylaxis. Pharmacists will be educated through a competency and they will receive the protocol and instructions for documentation. Statistical analysis will be
performed on the parameters mentioned above using a chi-squared test for categorical data and t-test for continuous variables.

Poster Title: Implementation of a fluoroquinolone prescribing tool in response to recent FDA labeling changes

Primary Author: Abigail Schauble, Ascension/Wheaton Franciscan-St. Joseph, WI; Email: a-schauble@onu.edu

Additional Author (s):
Kyle Piscitello
Ravindra Karmarkar

Purpose: New data suggests that benefits do not outweigh potential risks when using fluoroquinolones for the treatment of certain uncomplicated infections including acute sinusitis, acute bronchitis, and uncomplicated urinary tract infections. The FDA has subsequently released new safety warnings and labeling changes for this drug class. The objective of this study is to create a tool for providers to use when prescribing fluoroquinolones in order to improve adherence to infectious diseases (ID) treatment guideline recommendations.

Methods: This study has been approved by the Institutional Review Board. All patient identifiers will be removed from data. A three-month retrospective chart review will be conducted to assess initial prescribing trends of fluoroquinolones. In collaboration with ID physicians, ID pharmacists and pharmacy clinical managers, this initial data will be used to develop a tool for providers to use when prescribing these agents. The tool will be applicable to patients admitted to the hospital as well as those who are seen in the Emergency Department and receive prescriptions for outpatient antibiotics. It will incorporate guideline-recommended uses of fluoroquinolones including suggested dosages and durations of therapy based on specific infectious indications. Following implementation of the prescribing tool, an additional three-month retrospective chart review will be performed to assess changes in prescribing trends and the use of fluoroquinolones. In addition, a pre- and post-implementation survey will be sent to physicians and pharmacists to understand their opinions on the use of these antibiotics at our institution.

Poster Title: Implementation and evaluation of an electronic pain-agitation-delirium and spontaneous awakening and breathing trial order set in a community teaching hospital

Primary Author: Mingyao Yang, Ascension/Wheaton Franciscan-St. Joseph, WI; Email: ykevin_my@hotmail.com

Additional Author (s):
Rahim Mohanmmadali
Nadir Hinnawi
Betsy Karli
Diane Erdman

Purpose: One third of all intensive care unit (ICU) patients are mechanically ventilated. Poor adherence to standard pain-agitation-delirium (PAD) management recommendations established by the 2013 American College of Critical Care Medicine is associated with negative clinical outcomes. Additionally, prolonged mechanical ventilation may also lead to negative outcomes. Spontaneous awakening and breathing trials (SAT/SBT) have shown to shorten time on ventilation. The objective of this study is to implement a standardized electronic PAD with SAT/SBT order set to improve adherence to current guidelines. The secondary objective is to evaluate the use of the order set and patient outcomes after implementation.

Methods: This study has been approved by the Institutional Review Board. It is a single center, retrospective analysis of a practice improvement project. An electronic PAD order set based on the 2013 ACCM guidelines will be updated from the current paper order set. Also, an electronic SAT/SBT order set based on the trial by Girard, et al. will be built and implemented. The combined order set will be reviewed and approved by an interdisciplinary team of physicians, pharmacists, and nurses with a goal of implementation into the electronic ordering system before 2/2017. Patients in the ICU older than 18 years of age with an ICD-10 code for mechanical ventilation will be enrolled and retrospectively reviewed before and after implementation of the order set from 11/1/2015 to 6/30/2017. Exclusion criteria include patients intubated for less than 24 hours, or with traumatic brain injury, cerebrovascular injury, or receiving paralytic infusions. Monthly education on utilization of order set will be provided to nurses, respiratory therapists, and physicians in ICU. The following data will be collected:
patient demographics, baseline disease, medication usage, order set usage, daily SAT/SBT performance, length of mechanical ventilation, length of ICU and hospital stay, and re-intubation rate within 24 hours of extubation. All data will be recorded without patient identifiers and maintained confidentially.

Poster Title: Education and reinforced use of order set for early onset sepsis improves antimicrobial use in neonates

Primary Author: Eric Augustin, Ascension/Wheaton Franciscan-St. Joseph, WI; Email: eric.augustin@wfhc.org

Additional Author (s):
Luke Palmer
Jeffrey Garland
Kyle Piscitello
Diane Erdman

Purpose: The Vermont Oxford Network (VON) initiative is aimed at reducing the overall antibiotic usage amongst neonates. VON has been enacted at Ascension St. Joseph Hospital to help reduce antimicrobial usage in the Neonatal Intensive Care Unit (NICU). With the implementation of EPIC, an order set was created to help physicians order the necessary therapies for NICU admissions, including commonly utilized antibiotics for Early Onset Sepsis (EOS). To further improve antimicrobial use in the NICU, education will be provided to physicians regarding utilization of the NICU admission order set.

Methods: This study will be submitted to the Institutional Review Board for approval. Education will be provided to physicians on the utilization of the NICU admission order set. The educational in-service will focus on importance of utilization of the order set for safe dosing, as well as pharmacist delegation on when antibiotics can safely be discontinued. Data will be collected pre and post educational in-service. Pre educational in-service data will be collected from October to December. The primary outcome is utilization of the NICU admission order set. The main secondary outcome is reduction in days of antibiotic therapy (measured by Days of Therapy) by 5%. Other specific data that will be collected includes patient demographic data, antibiotic combination used, and blood culture results.

Poster Title: Implementation of a pharmacist-driven discharge medication reconciliation and counseling process: A transitions of care pharmacist service

Primary Author: Kaia Zepke, Aspirus Wausau Hospital, WI; Email: kaia.zepke@aspirus.org

Additional Author(s):
Timothy Nikstad

Purpose: Pharmacist-led services involving discharge reconciliation and counseling have been shown to reduce readmission rates and increase patient satisfaction. The main objectives will be to determine if a pharmacist-driven transition of care service will reduce rates of readmission for high-risk groups and improve HCAHPs scores related to medications.

Methods: This study will be submitted to the Institutional Review Board for approval. The transitions of care pharmacist will identify and follow patients who are at high risk for readmission throughout the hospital (excluding the Emergency Department) based on the readmission risk scoring tool used in-house. When a patient is added to the service, the pharmacist will complete discharge medication reconciliation, update the discharge medication list and send it to the hospital provider for approval. Once discharge orders have been written for a particular patient, the pharmacist will bring any new prescriptions and medication information to the patient and provide education related to their medications, including but not limited to the indication for that medication, dosing, administration, adverse effects, and answer any patient questions. The data collection period will be three months. Primary end points will be readmission to the hospital, either through the Emergency Department or a direct admission, and percent difference in HCAHPs scores related to medications. Secondary endpoints will be number of accepted recommendations made by the pharmacist and time spent per patient.

Poster Title: Implementation of a discharge medication delivery program for high risk patients in a community hospital

Primary Author: Cecilee Rodenkirch, Aspirus Wausau Hospital, WI; Email: cecilee.rodenkirch@aspirus.org

Additional Author(s):
Lynn Halambeck
Patricia Christopherson

Purpose: Patients with multiple comorbidities utilizing prescription medications are at high risk for readmission due to the complexity of their medication regimens. The goal of this study will be to increase the number of patients discharging from the hospital with their essential medications.

Methods: The study will be presented to the Institutional Review Board for evaluation and approval. Eligible patients will include adults (greater than 18 years of age) with LACE Readmission Assessment Tool scores greater than nine on admission who are discharged home with new prescriptions or requiring refills of current prescriptions. Pharmacists will round on this patient population and offer medication dispensing prior to discharge along with appropriate education. The primary objective of this study is to increase the percentage of high risk patients leaving the facility with medications in their possession while attempting to decrease 30-day readmission rates. Secondary objectives will be to increase the raw number of prescriptions captured and revenue in the Aspirus Wausau Hospital Clinic Pharmacy. Participation from an interdisciplinary team is necessary to successfully implement this Discharge Medication Delivery Program at Aspirus Wausau Hospital.

Poster Title: Comparison of morphine and hydromorphone containing patient controlled epidural analgesia solutions in pediatric post-operative patients

Primary Author: Jesse Cramer, Children's Hospital of Wisconsin, WI; Email: jlcramer@chw.org

Additional Author(s):

Purpose: The purpose of this study is to examine whether hydromorphone or morphine provides superior pain relief in the pediatric population post-operatively when administered via patient controlled epidural infusion. Published studies have reported that patient controlled epidural analgesia after surgery in the pediatric population can be both safe and effective for pain management. Hydromorphone and morphine are two commonly used opioids for epidural analgesia. There is little data available on the comparative effectiveness of morphine versus hydromorphone with patient controlled epidural analgesia after surgery in the pediatric population.

Methods: A retrospective chart review will identify patients within the electronic health record who had epidural analgesia post-operatively with either hydromorphone or morphine over a one year period. Patients between the ages of 0 and 18 years will have their charts reviewed. Data collected will include pain scores on post-op days 0-2, type of opioid used in the epidural solution, dosing parameters, changes made to the epidural solution, number of PCEA button demands and deliveries, and length of hospital stay. This study will be submitted to the Institutional Review Board prior to commencement for approval.

Poster Title: Evaluation of clonidine usage and development of a tapering schedule at a large pediatric teaching hospital

Primary Author: Patrick McBride, Children’s Hospital of Wisconsin, WI; Email: pmcbride@chw.org

Additional Author(s):

Purpose: This medication use evaluation will examine enteral and transdermal clonidine usage. In addition a guideline will be developed for a clonidine tapering schedule for use in pediatrics.

Methods: An evaluation of the current literature will be conducted in order to determine usage of clonidine in a pediatric setting with regards to tapering off of sedative and analgesic medications. A medication use evaluation will be performed to collect information about clonidine usage at a large pediatric hospital. Data collected may include patient demographics, presence of withdrawal symptoms, supportive medications taken, length of intensive care unit stay, and length of clonidine therapy. Information related to current clonidine tapering and withdrawal symptoms may also be captured. The electronic medical record will be utilized to retrospectively identify patients receiving clonidine after prolonged exposure to sedative and analgesic medications. This medication use evaluation will be submitted to the Institutional Review Board.

**Session-Board Number:** 10-356  
**Poster Title:** Incidence and risk factors associated with nephrotoxicity in pediatric patients treated with concomitant vancomycin and piperacillin-tazobactam  
**Primary Author:** Ashley Brown, Children's Hospital of Wisconsin, WI; Email: albrown2@chw.org  
**Additional Author(s):**  
Tracy Zembles  
Tom Nelson  

**Purpose:** The primary objective of this study is to evaluate the incidence of nephrotoxicity associated with the concomitant use of vancomycin and piperacillin-tazobactam in pediatric patients and to determine associated risk factors. The published incidence of vancomycin nephrotoxicity is 5% to 35%, however piperacillin-tazobactam is rarely associated with nephrotoxicity. Vancomycin is frequently used in combination with piperacillin-tazobactam in hospitalized patients. This combination has recently been reported in the adult population to increase the risk of nephrotoxicity. Data in the pediatric population are sparse.  

**Methods:** A retrospective chart review of patients greater than 28 days old and less than 18 years old that received concomitant vancomycin and piperacillin-tazobactam treatment for a minimum of 72 hours will be performed. Kidney Disease: Improving Global Outcomes (KDIGO) clinical practice guidelines will be used to assess nephrotoxicity. Serum creatinine values prior to, during, and up to 1 week following concomitant therapy will be reviewed for up to four years from present. Descriptive statistics will be used to evaluate the rates of acute kidney injury associated with concomitant vancomycin and piperacillin-tazobactam therapy. Length of time from initiation of concomitant therapy to acute kidney injury and associated risk factors for the development of acute kidney injury will also be evaluated. Data collected from the electronic health record may include: age, weight, height, serum creatinine values, blood urea nitrogen values, indication for antimicrobial treatment, vancomycin dose and frequency, vancomycin length of therapy, piperacillin-tazobactam dose and frequency, piperacillin-tazobactam length of therapy, hospital length of stay, and concomitant nephrotoxic medications. The study will be submitted to the Institutional Review Board (IRB).

Poster Title: Medication Use Evaluation of Efficacy and Safety of Tocilizumab in Pediatrics

Primary Author: Grace Herr, Children's Hospital of Wisconsin, WI; Email: gherr@chw.org

Additional Author(s):

Purpose: Tocilizumab, IL-6 receptor inhibitor is indicated for juvenile idiopathic arthritis and polyarticular juvenile idiopathic arthritis for patients 2 years of age and greater. The purpose of this study is to determine effectiveness and safety of tocilizumab use in pediatric patients.

Methods: A retrospective chart review of tocilizumab use at a tertiary care pediatric hospital will be conducted to assess efficacy and safety of tocilizumab in children age 2 to 18 years. Data will include patient demographics, baseline disease characteristics, previous exposure to biologics, treatment regimen, patient response to therapy, and adverse events. Descriptive statistics with categorical data represented as frequency will be performed to analyze significance of the finding. Systemic literature review pertaining to labeled and unlabeled use in pediatrics will be completed. Patient information will be obtained through the electronic health record. This medication use evaluation for the hospital system will be submitted to the institutional review board for approval.

Results: N/A

Conclusion: N/A
Purpose: The implementation of diabetic ketoacidosis (DKA) guidelines in healthcare systems has been shown to improve patient outcomes. However, current literature suggests professional adherence to guidelines is not sustainable in many medical settings and protocol fidelity is variable. There are many potential reasons for inconsistency of implementation including the complexity of the patient, clinical status, and differences in health-system strategies for implementation. The purpose of this study was to assess adherence to the Froedtert DKA protocol and to determine if there is an association between protocol compliance and clinical outcomes.

Methods: A retrospective chart review of patients 18 years old or older admitted to a critical care unit with a diagnosis of DKA from January 1, 2015 through May 1, 2015 at Froedtert and the Medical College of Wisconsin was approved by the pharmacy research committee and was conducted. The primary objective was to determine whether compliance to the Froedtert DKA protocol impacted the rate of return to insulin infusions (or rebound DKA). Secondary objectives were to distinguish compliance at the 9 protocol checkpoints, including fluid resuscitation, the rate of insulin infusion, the amount of subcutaneous insulin selected for transition to subcutaneous insulin, the amount of time the insulin infusion is running after the first dose of subcutaneous insulin, and to identify possible reasons for protocol noncompliance, including safety concerns (e.g., hypoglycemia).

Results: Forty-eight patients met inclusion criteria, of which, 38% were male (n = 18) with a mean age of 45 years (ranging from 19-90 years old). There were an equal number of patients
with type 1 and type 2 diabetes mellitus, 52% (n=25) and 48% (n=23), respectively. Of the 48 patients, 25% experienced rebound DKA (n = 12). Of those that had rebound DKA, each patient had at least one deviation from the hospital’s DKA protocol (n=12). Of the patients that did not have rebound DKA, five patients (14%) had care that was consistent with the protocol and compliant at each checkpoint (p = 0.3). The median number of points of protocol non-compliance was three (range 0-5) in the rebound DKA population and two (range 0-6) in those without rebound DKA; p=0.6. The most common protocol deviation was not having their home regimen restarted; 75% (n=9) and 75% (n=27) for rebound DKA and no rebound DKA groups, respectively. Followed by not receiving their first dose of subcutaneous insulin at an appropriate time after transition from insulin infusion, 58% (n=7) vs. 56% (n=20).

**Conclusion:** Only a quarter of the patients experienced rebound DKA despite variability in compliance to the DKA protocol. Failure to comply with the Froedert DKA protocol was observed at similar checkpoints in both groups of patients, irrespective of occurrence of rebound DKA. Further research is needed to determine if improving the protocol for DKA management can promote adherence or if protocol fidelity is not feasible.

**Session-Board Number:** 10-359  

**Poster Title:** Evaluation of the effect acetazolamide has on postoperative intraocular pressure reduction following cataract surgery  

**Primary Author:** Ivana Micanovic, Gundersen Health System, WI; **Email:** micanovicivana86@gmail.com  

**Additional Author(s):**  
Mike Lewandowski  

**Purpose:** Cataract formation is the most common age-related eye disease in the United States. One potential complication of cataract surgery is the development of transient intraocular hypertension. Acetazolamide may be used prophylactically at the conclusion of a cataract surgery to lower postoperative intraocular pressure (IOP). Known risk factors for ocular hypertension include diabetes, dyslipidemia, and systemic hypertension. The objectives are to determine the effect of acetazolamide on postoperative IOP in patients undergoing cataract surgery, and to evaluate if patients with certain comorbid conditions, including diabetes, hypertension, and dyslipidemia, have higher postoperative IOP, and therefore would be better candidates for acetazolamide.  

**Methods:** Approval through the Institutional Review Board will be obtained prior to data collection. A retrospective chart review will be accomplished utilizing the electronic medical record. All data will be recorded without patient identifiers and maintained confidentially. Eligible patients include those 18 years of age and above undergoing cataract surgeries at Gundersen Health System within the predetermined time period. Patients will be excluded if they are on chronic carbonic anhydrase inhibitor therapy, or if they have a past medical history of glaucoma. The study will compare postoperative IOP in patients receiving acetazolamide versus patients not receiving acetazolamide after undergoing cataract surgery. The data collected for each patient will include: age, sex, postoperative IOP, and comorbid conditions including diabetes, hypertension, and/or dyslipidemia. Appropriate statistical analysis will be completed using the student’s t-test. Data collected from this study will be used to determine if postoperative acetazolamide is beneficial for preventing intraocular hypertension after cataract surgery, and if any risk stratification may be made based on comorbid conditions and increases in IOP.

Poster Title: Efficacy of preoperative gabapentinoids as adjuvant therapy in multi-modal pain control following total knee arthroplasty

Primary Author: Sarah Kryka, Gundersen Health System, WI; Email: slkryka@gundersenhealth.org

Additional Author(s):
Alice Johnson
Mike Lewandowski

Purpose: Total knee arthroplasty is one of the most common elective surgical procedures in the United States with approximately 4.7 million people in 2010 having undergone the surgery. The benefits of effective postoperative pain control include decreased length of hospitalization, fewer pulmonary, cardiac, and thromboembolic complications, prevention of chronic pain development, earlier mobilization, and improved patient satisfaction. The objective of this study is to assess postoperative opioid use, pain scores, and hospital length-of-stay in inpatient total knee replacement surgery patients before and after implementing pre-procedural gabapentinoid use for adjunctive analgesia.

Methods: This study will be submitted to the Institutional Review Board for approval. Data gathering will occur within the electronic medical record using samples of total knee arthroplasty patients prior to and after the addition of a gabapentinoid to the order-set. Data collected will include: patient’s age, gender, body mass index, prior to admission opioid and gabapentinoid use, serum creatinine, total opioid use during the first 24 hours after surgery, pain score 24 hours after surgery, length of hospitalization, and the dose and type of gabapentinoid used preoperatively, if any. Patients will be matched according to baseline characteristics. Collected data will be evaluated based on the calculation of average pain score at 24 hours postoperatively using the numeric rating scale, average opioid use in oral morphine equivalents for 24 hours postoperatively, and average length of stay. Patient outcomes pre- and post-addition of a gabapentinoid to the order-set will be compared using a Student’s t-test or Wilcoxon Rank Sum Test for non-normal data to analyze differences for statistical significance.

Poster Title: Optimizing initial empiric antibiotic therapy timing and administration among patients in the emergency department

Primary Author: Claire VanAlstyne, Gundersen Lutheran Medical Center, WI; Email: csvanals@gundersenhealth.org

Additional Author(s):
Melissa Forbes
Lisa Meyer

Purpose: The Surviving Sepsis Campaign has identified the administration of broad-spectrum antibiotic therapy within one hour of the recognition of septic shock and severe sepsis as the goal of therapy to improve outcomes and reduce mortality. Similarly, the Centers for Medicare and Medicaid (CMS) quality measures dictate that antibiotics be administered within three hours of the identification of severe sepsis or septic shock. The purpose of this study is to evaluate if Gundersen Lutheran Medical Center is meeting this goal of timing for antibiotic administration and to identify any potential barriers or trends that are preventing this from being accomplished.

Methods: Approval will be obtained from the Institutional Review Board for retrospective chart review and data collection. Eligible patients include all patients admitted from the emergency department with suspected sepsis or septic shock as identified utilizing the electronic medical record, ICD-9, and ICD-10 codes. The data to be collected include age, antibiotic-related allergies, suspected source of infection, time from determination of suspected sepsis to administration of antibiotic, availability of antibiotic from the automated dispensing system, incompatibility of antibiotics, and antibiotics ordered and administered. All data will be recorded without patient identifiers and maintained confidentially. Data from patients who did not receive antibiotics within the desired three hour window will be analyzed to determine potential barriers to treatment.

**Poster Title:** Evaluation of antibiotic prescribing practices for early-onset sepsis in the neonatal intensive care unit  

**Primary Author:** Jackelyn Roberts, Gundersen Lutheran Medical Center, WI; **Email:** jackelynr13@gmail.com  

**Additional Author(s):**  
Scott Eppley  
Kathryn Richmond  
Luis Ramirez  

**Purpose:** The appropriate prescribing of antibiotics in the neonatal intensive care unit is a current challenge faced by many clinicians. Early-onset sepsis can be difficult to diagnose and is often treated when an infection is not confirmed. The objective of this study is to evaluate antibiotic prescribing for consistency in empiric treatment of early-onset sepsis in the neonatal intensive care unit with a goal of standardizing practice. A guideline will then be proposed with integration into the Antimicrobial Stewardship Program.  

**Methods:** This retrospective study has been submitted to the Institutional Review Board for approval. The electronic medical record system will be used to identify neonates with antibiotic utilization within the first three days of life and neonates not prescribed antibiotics with specific clinical criteria. The criteria include an elevated C-reactive protein (> 1 mg/dL), neutropenia (ANC < 1,000 cells/mm3), thrombocytopenia (< 150,000/microL), or the need for supplemental oxygen within the first three days of life. Patients will be excluded if the medication prescribed was an antifungal or ophthalmic erythromycin ointment. The following data will be collected: gestational age, birth weight, gender, ethnicity, maternal group B streptococci status and antibiotics administered if applicable, timing of rupture of membranes to birth, presence of chorioamnionitis, antibiotic prescribed and any additional antibiotics during hospitalization, total duration of antibiotics, clinical signs and symptoms of infection, including pertinent lab values and vital signs, culture results and antibiotic susceptibility information, and the presence of a confirmed infection identified by the patient’s problem list. All data will be recorded without patient identifiers and maintained confidentially. The percentage of patients prescribed
antibiotics given specific maternal factors and clinical criteria will then be identified and the prescribing consistency will be determined.

**Poster Title:** Novel atorvastatin and rosuvastatin extemporaneously compounded oral suspensions for inpatient use

**Primary Author:** David Dulak, Gundersen Lutheran Medical Center, WI; **Email:** djdulak@gundersenhealth.org

**Additional Author (s):**
Adam Gregg

**Purpose:** HMG-CoA reductase inhibitors (statins) provide many benefits to patients in the acute care setting, especially after acute coronary syndrome events and strokes. Often these patients experience swallowing difficulties that make traditional administration of oral tablets difficult. Currently there are no commercially available liquid formulations for statins. Minimal publications about extemporaneously compounded suspensions of statins exist in the literature, thus developing a validated formula could prove advantageous in this patient population. The objective of this study is to formulate atorvastatin and rosuvastatin oral suspensions and confirm their physical stability and chemical integrity.

**Methods:** As proof of concept, multiple suspensions for both atorvastatin and rosuvastatin will be created with varying concentrations, suspending agents, and vehicles and stored under refrigeration (between 2 and 8 degrees Celsius) for seven days. After initial storage, these formulations will be assessed for their organoleptic properties, pH, and physical stability. Chemical integrity will be further determined using high performance liquid chromatography and defined as maintaining at least ninety percent of the concentration of the active pharmaceutical ingredient. The chromatography samples will be kept at both controlled room temperature (between 20 and 25 degrees Celsius) and under refrigeration and will be analyzed in triplicate after seven and thirty days to assign appropriate beyond-use dating and storage conditions.

Poster Title: Warfarin management in patients with cancer receiving chemotherapy

Primary Author: Katherine Lorson, Marshfield Clinic, WI; Email: lorson.katherine@marshfieldclinic.org

Additional Author (s):
Melissa Mikelson
Adedayo Onitilo
Tonja Larson

Purpose: Patients with cancer are at an increased risk of thrombotic events and warfarin therapy may decrease this risk. Chemotherapy can increase or decrease the anticoagulant effects of warfarin, depending on the specific chemotherapy treatment. Despite these effects on warfarin, current warfarin dosing and international normalized ratio (INR) lab management guidelines do not exist for patients with cancer on specific chemotherapy treatment. The objective of this study is to determine if this institution’s Anticoagulation Service (ACS) is effectively reaching desired anticoagulation for patients with cancer on warfarin who are receiving chemotherapy.

Methods: This is a retrospective cohort study and will include patients 18 years and older treated with chemotherapy for a cancer diagnosis managed on warfarin by this institution’s ACS during the study period May 2016 to November 2016. After Institutional Review Board approval, data will be gathered electronically from subject medical records including age, warfarin management by this institution’s ACS, type of cancer and date of cancer diagnosis, date of chemotherapy treatment, name of chemotherapy medications received during the study period, and major bleeding or thrombotic events. Manual chart review will be performed to gather subjects’ goal INR range and the percentage of time within this goal range. Subjects who have a goal INR range that includes a value less than two will be excluded. Data will be assessed in three subject groups: 1) patients with cancer taking warfarin who are receiving chemotherapy treatment, 2) patients with cancer taking warfarin who are not receiving chemotherapy treatment, 3) patients without cancer taking warfarin who are not receiving chemotherapy treatment. Statistical analysis will be conducted to determine if differences exist between the three subject groups regarding subjects’ INR time in therapeutic range and major
bleeding or thrombotic events. These results will be used to determine appropriate warfarin dosing and frequency of INR lab draws for patients with cancer receiving chemotherapy.

**Poster Title:** Pharmacogenetics in practice: preliminary outcomes and clinician feedback on the Marshfield Clinic electronic medical records and genomics (eMERGE) pharmacogenetics (PGx) study

**Primary Author:** Emili Leary, Marshfield Clinic, WI; **Email:** leary.emili@marshfieldclinic.org

**Additional Author(s):**
Murray Brilliant
Peggy Peissig
Sara Griesbach

**Purpose:** The electronic MEdical Records and GEnomics (eMERGE) pharmacogenetics (PGx) study is a multi-site pilot program focused on integration of patient genetic results into the electronic medical record (EMR), with the goal of providing medication recommendations tailored to the patient’s genotype. The goals of the present study are to determine outcomes of patients enrolled in the eMERGE PGx project who were taking warfarin and had pharmacogenetic (PGx) alerts fire in the EMR when providers were prescribing warfarin between November 2014 – June 2016, and to assess provider feedback regarding comprehension and utility of the EMR PGx alerts.

**Methods:** This study has been submitted to the Institutional Review Board for approval. The eMERGE PGx project at Marshfield Clinic will be evaluated in two phases. Phase I (outcomes) is a retrospective descriptive analysis of the eMERGE PGx cohort with triggered PGx alerts. These alerts will be evaluated via manual and electronic chart review of up to 28 warfarin patients, 4 simvastatin patients, and 1 clopidogrel patient; the latter two groups will be descriptively analyzed. Outcomes assessment will include time to target INR, accuracy of predicted warfarin dosing based upon genotype, incidence of bleeds or clots, as well as hospitalizations and all-cause mortality in the warfarin subgroup. Phase II (clinician feedback) will be a prospective observational – cross sectional internet-based survey. Select Marshfield Clinic clinicians with prescriptive authority will be provided with a case example including the eMERGE PGx alert, and will be asked to complete a short online survey on their perceptions and feedback regarding the PGx alert. Demographic data will be collected in addition to case scenario specific question. Data will be de-identified, summarized
and evaluated. All data analyses will be carried out using commercially available statistical software package SAS (version 9.4, English).

Poster Title: Impact on diabetes control utilizing a multidisciplinary approach to the management of uncontrolled type 2 diabetes involving pharmacist telephonic intervention within an internal medicine clinic

Primary Author: Joshua Lee, Marshfield Clinic, WI; Email: lee.joshua@marshfieldclinic.org

Additional Author (s):
Ravijeta Guddeti
Andrew Jensen
Sara Griesbach

Purpose: Intensification of therapy for diabetes remains suboptimal despite strong clinical evidence to reduce adverse outcomes. This may be due to complicated diabetic management plans, leading to potential confusion about health care related issues and cause patients to feel overwhelmed by these burdens. Pharmacists may be positioned to bridge this gap. Our study seeks to determine the benefit of and will contribute to addressing the issues of uncontrolled type 2 diabetes (T2DM) through the collaboration of a multidisciplinary care model utilizing pharmacist telephonic intervention for T2DM patients well above Hemoglobin A1C (HbA1C) goal seen in an internal medicine clinic.

Methods: This is an Institutional Review Board approved single-center prospective observational study designed to evaluate HbA1C differences in patients 18-79 years of age with uncontrolled T2DM (HbA1c > 9%) who utilize clinical pharmacists in a multidisciplinary team approach compared with patients who receive usual medical care over 9-12 months. Secondary outcomes include change in blood pressure and fasting lipid panel. Exclusion criteria include pregnancy, type 1 diabetics, non-English speaking, cognitive impairment or hospice care. Up to 100 patients will be randomized into either an intervention arm (n=50) or control arm (n=50). Assuming a 20% dropout rate of 20 patients (n=80), we will have 79% power to detect a difference in HbA1C reduction of 0.6% between groups. Using a standardized script, a pharmacist will contact the patient telephonically, obtain consent and perform an initial full medication reconciliation and medication therapy review. Subsequent phone calls will occur every 4-6 weeks until the follow-up period is reached. If a patient is determined to be at goal and adherent to their diabetes regimen after 3 interventions, a qualified support staff member
may facilitate follow-up calls under pharmacist supervision. Patients non-adherent or with out-of-range blood glucose or blood pressure values will be referred back to their providers with drug therapy recommendations. A 6 month interim analysis will determine if study-end will be appropriate at 9 months or 12 months.

**Poster Title:** Evaluation of broad spectrum antibiotic use for skin and soft tissue infections before and after inpatient antimicrobial stewardship interventions

**Primary Author:** Tara Hawley, Mayo Clinic Health System - Eau Claire Hospital, WI; **Email:** hawley.tara@mayo.edu

**Additional Author (s):**
Lisa Sommerfeld  
Kent Gierhart  
Janki Patel

**Purpose:** The Centers for Disease Control and Prevention (CDC) estimates that 20-50% of all antibiotics prescribed in hospitals are unnecessary or inappropriate. Skin and soft tissue infections (SSTIs) are a common indication for the use of antibiotics. The Infectious Diseases Society of America (IDSA) has published guidelines regarding when broad spectrum and narrow spectrum antibiotic agents should be utilized when treating SSTIs. The purpose of this study is to evaluate the use of broad spectrum antibiotics for patients with SSTIs and compare patients where the antimicrobial management team (AMT) intervened to those patients where no intervention was performed by the AMT.

**Methods:** This study will be conducted at Mayo Clinic Health System (MCHS) - Eau Claire Hospital. A retrospective chart review will be completed for hospitalized SSTI patients admitted post-implementation of focused antimicrobial management team (AMT) interventions and physician education. These patients will be compared to patients admitted pre-implementation of the AMT but after the most current IDSA SSTI guidelines (2014) were published. AMT interventions will include having the team specifically discuss SSTI patients, make antibiotic therapy recommendations to the attending physician, and contact physicians to include documentation of SSTI classification and severity in their notes. Physician education about current IDSA guidelines for SSTI treatment and the use of broad spectrum antibiotic agents will be distributed. The primary outcome of this study is length of broad spectrum antibiotic therapy. Secondary outcomes include total days on antibiotic therapy, 30-day readmission rates, Clostridium difficile infection rates, and cost of antibiotic therapy. The collected data will include: age, gender, risk factors for SSTIs, comorbid conditions, days on broad spectrum
antibiotics (piperacillin-tazobactam, cefepime, carbapenems), total days of antibiotic therapy (inpatient and outpatient), days to de-escalation of antibiotic therapy, antibiotic use prior to admission, 30-day readmission or outpatient antibiotic treatment for SSTI within 30 days post-discharge, whether a C. difficile infection developed, and acquisition costs of the medications. This study will be submitted to the Institutional Review Board for approval.

Poster Title: Verification of accuracy of current emergency department medication history process to identify potential areas for improvement

Primary Author: Molly Haferman, Mayo Clinic Health System – Eau Claire Hospital, Inc., WI; Email: haferman.molly@mayo.edu

Additional Author(s):
Sarah Normand
Lee Hraby
Ross Dierkhisng
Noelle Wimer

Purpose: Obtaining accurate and up-to-date medication histories is at the forefront of proper patient care. A comprehensive medication list provides practitioners the necessary information needed to adequately assess, evaluate, and treat patients. Inaccurate medication histories can lead to poor patient outcomes including adverse drug events, increased need for monitoring, and added medical costs. The objective of this study is to determine the accuracy of the hospital’s current medication history process performed by nursing staff and to identify gaps/areas of improvement. The goal is to provide better patient care and enhance overall care transitions by involving pharmacy team members in the process.

Methods: This quality improvement study will be performed on hospitalized patients admitted through the emergency department (ED) in which a medication history was completed by nursing staff. A pharmacy resident will perform a follow-up medication history on these patients within 24 hours of hospital admission to verify the accuracy of medication histories obtained in the ED and to determine where errors are occurring in the current process. Data collected will include: age, gender, race, admitting diagnosis/location, number of medications, number and type of discrepancies found, high-risk medications, and source of medication information (i.e. patient, family, pharmacy). A “discrepancy” will be defined as any of the following: drug omission, duplicate therapy, incorrect medication (i.e. missing drug name, dose, route, frequency), or missing allergy. Definition of “high-risk medications” will be adapted from the Institute For Safe Medication Practices (ISMP) High-Alert Medications List. These include: transplant, cardiology, anticoagulant, and hypoglycemic medications. Percentage of patients...
with incorrect medication histories is the primary endpoint. Secondary endpoints include discrepancies involving high-risk medications, number of changes made to med list, and a breakdown of discrepancies. This study will be submitted to the Institutional Review Board for approval.

Poster Title: Pharmacogenomics educational series and development of clinical decision support

Primary Author: Elizabeth Neumann, Monroe Clinic, WI; Email: beth.neumann@monroeclinic.org

Additional Author(s):
Julie Koch
Dave Grinder

Purpose: Pharmacogenomics is a rapidly growing but often underutilized field. Two common barriers to implementation include clinicians’ limited knowledge and absence of software support. This project will assess the effectiveness of a six-presentation series on clinicians’ knowledge of pharmacogenomics over a period of six months. Additionally, clinical decision support will be created in parallel with the lectures to reinforce knowledge and allow practical application of pharmacogenomics. The combination of these efforts will create a foundation upon which pharmacogenomic services can be expanded in the future.

Methods: Six pharmacogenomics lectures will be provided over six months to a pre-selected group of forty-one clinicians and managers. Presentation topics include: an introduction to pharmacogenomics, neurology, cardiology, oncology, infectious disease/transplant, and barriers to implementation/miscellaneous. Teaching effectiveness will be measured through participant assessments given via an electronic audience response system. Assessments will be provided before, during, and/or after each lecture. To analyze long term knowledge retention, questions from previous lectures will be included in assessments before subsequent lectures. Data will be statistically analyzed upon completion of the lectures. Additionally, an informatics pharmacist and the primary investigator will create standardized clinical decision support using available pharmacogenomic guidelines. The informatics pharmacist will work with the electronic medical record to develop discrete documentation fields for pharmacogenomic test results. Subsequently, alerts with specific criteria will be designed to advise clinicians when ordering an interacting medication for a patient with documented pharmacogenomic results, as well as to suggest recommended alternatives. These alerts will be presented to the Pharmacy and Therapeutics Committee for approval. The
effectiveness and relevance of the alerts will be tracked over time through analysis of alert frequency, and whether these alerts are accepted or overridden.

Poster Title: Evaluating the impact of pharmacy-led admission medication history in pre-operative patients compared to the standard of care at St. Elizabeth Hospital

Primary Author: Karlee Kamps, St. Elizabeth Hospital, WI; Email: karlee.kamps@ascension.org

Additional Author(s):
Annette Siedschlag

Purpose: The purpose of this quality improvement project is to evaluate the impact of a pharmacy-led admission medication history in pre-operative patients on both the accuracy and completeness of the medication list and on pharmacy staffing. At St. Elizabeth Hospital, nurses in the pre-surgery area perform the admission medication history for pre-operative patients during the pre-operative phone call, while pharmacy staff collects and verifies the medication history for all other hospital admissions. There have been multiple occurrence reports filed from the pre-surgical area describing predominantly errors of omission and errors of incorrect medication and dose.

Methods: Background data will be collected on a select number of post-operative total knee or hip arthroplasty patients each week during the period of September 26, 2016 to November 11, 2016 by repeating the admission medication history post surgically. Potential for process improvement will be measured by the number and type of errors or discrepancies found in the medication history completed before surgery compared with that collected by pharmacy staff. After the background data collection is complete, pharmacy will begin a pilot program to collect a pre-procedure medication history on a select number of patients. The goal of this pilot program is to develop a process for pharmacy to record the most complete and accurate medication list possible, prior to the patient’s admission. Outcomes will be measured by comparing the number and type of discrepancies found in the medication history before and after implementation. Time studies will be conducted during implementation to determine the potential impact on pharmacy staffing.

**Poster Title:** Implementation of pharmacy involvement in a discharge medication reconciliation and discharge education process at a community hospital

**Primary Author:** Holly Mercado-Schoessow, St. Elizabeth Hospital, WI; **Email:** holly.mercadoschoessow@ascension.org

**Additional Author (s):**
Annette Siedschlag

**Purpose:** This quality improvement project will pilot a pharmacist–led service to facilitate the reconciliation of medications and provide patient medication education at discharge. Currently there is no formal involvement of pharmacy in the discharge process. The goal of this project is to determine if pharmacist participation will lead to an improved process, measured primarily by the number and type of interventions made by pharmacists and secondarily by patient readmission within 30 days of discharge.

**Methods:** Prior to implementation of the pilot, background data will be collected by performing retrospective medication reconciliation on a randomly selected group of patients who have been discharged with a diagnosis of heart failure, chronic obstructive pulmonary disease, respiratory failure, pneumonia, or acute renal failure/acute kidney injury between July 27, 2016 and August 11, 2016. This patient group was selected based on diagnoses most commonly associated with hospital readmissions as determined by data published by the Agency for Healthcare Research and Quality. After background data collection, a discharge medication reconciliation process that includes pharmacist participation will be created and piloted in the specified patient population. The medication reconciliation process will involve reviewing a patient’s home medications compared with hospital medication therapy to develop an accurate, appropriate, and evidence based medication list upon discharge. After medication reconciliation completion, the pharmacist will notify the provider that the medication list has been reviewed and will provide recommendations for any needed modifications to the home medication list. The pharmacist will also evaluate concerns regarding access to and affordability of the medications and recommend alternatives if necessary. After discharge medications are finalized, the pharmacist will provide medication education and adherence aids to facilitate
patient understanding of the medication regimen, including purpose of the medication, how it will benefit the patient, potential side effects, and things to remember.

Poster Title: Utilization of gabapentin in an alcohol withdrawal protocol at a community hospital

Primary Author: Christopher Leuenberger, Wheaton Franciscan – All Saints Hospital, WI; Email: cleuenberger@msn.com

Additional Author (s):
David Galbis-Reig
Biniam Berhane
Steven Suokko
George Honein

Purpose: Recent literature suggests that gabapentin is effective in the management of alcohol withdrawal. The utilization of gabapentin within withdrawal protocols has shown several benefits when compared with traditional protocols that utilize benzodiazepines. This study will compare the outcomes between patients treated with a lorazepam based protocol, and those treated with a gabapentin based protocol. The primary objective is to implement an optimized alcohol withdrawal protocol that utilizes gabapentin for effective symptom management.

Methods: Wheaton Franciscan Healthcare manages alcohol withdrawal at two different facilities in Racine, WI. Each facility uses a different method for alcohol withdrawal management, and there were anecdotal observations of higher amounts of benzodiazepines being utilized on the general medical units than on a medical managed detoxification unit. Additionally the detoxification unit utilized gabapentin in their treatment protocol. This study will compare differences between alcohol withdrawal management at All Saints a 200 bed hospital and St. Luke’s a 70 bed detoxification unit. This will be a retrospective naturalistic outcomes study design. The data will be gathered from chart review of the electronic medical record for patients treated for alcohol withdrawal between January 2016 - September 2016. The data will include: age, gender, blood alcohol content on admission, total benzodiazepine dosage used, total gabapentin dosage used, clinical institute withdrawal assessment for alcohol score, length of stay, and if the patient experienced any seizures or delirium during treatment. The study will be submitted to the Institutional Review Board for approval. Patients will be risk stratified using the Prediction of Alcohol Withdrawal Severity Score in a retrospective fashion.

**Poster Title:** Evaluation of Alcohol Withdrawal Practices at a Community Hospital  

**Primary Author:** Kaity Erickson, Wheaton Franciscan - St. Joseph, WI; **Email:** kaitlyn.erickson@wfhc.org  

**Additional Author(s):**  
Rahim Mohammadali  
Nadir Hinnawi  

**Purpose:** In 2010, 1.9 million people discharged from the hospital had at least one alcohol-related diagnosis. Mortality rates of alcohol withdrawal syndrome (AWS) are estimated to be as high as 15% in untreated patients versus 2% in treated patients. At Ascension/Wheaton Franciscan-St. Joseph Hospital, an alcohol withdrawal protocol is initiated in patients experiencing AWS, and the Clinical Institute Withdrawal Assessment for Alcohol (CIWA-Ar) scores are used to assess the severity of alcohol withdrawal symptoms. The purpose of this study is to assess the utility of and adherence to the alcohol withdrawal protocol at Ascension/Wheaton Franciscan-St. Joseph Hospital.  

**Methods:** A retrospective chart review will be conducted utilizing electronic health records to identify patients admitted to Ascension/Wheaton Franciscan-St. Joseph Hospital diagnosed with AWS during a three month period. The primary objective is to determine adherence to the alcohol withdrawal protocol. To assess this objective, patient charts will be reviewed to see if the protocol was ordered in patients undergoing AWS, and if the appropriate amount of benzodiazepines were administered in response to CIWA-Ar scores. Secondary objectives include describing the patient population being treated for AWS at Ascension/Wheaton Franciscan-St. Joseph Hospital; discover what, if any, medications patients are being discharged home with to help treat or prevent withdrawal; to identify an optimal medication regimen for alcohol withdrawal. To evaluate these objectives the following information will be collected: patient demographics, previous hospitalizations for AWS in the past 12 months, delirium tremens, number of seizures, adjunct medication utilization, ICU admission, duration of withdrawal, length of stay, complications, and discharge prescriptions for AWS. All information will be maintained confidentially. Data will be analyzed using the appropriate statistical tests. Chi squared test will be used for categorical variables and a t-test will be used for continuous...
variables. Statistical significance will be at p < 0.05. To assess for influence of confounding factors multiple linear regression will be used.

**Poster Title:** Effects of a new initiative to increase probiotic prescribing in the intensive care unit on all-cause diarrhea incidence and probiotic prescribing

**Primary Author:** Meghan Learned, Wheaton Franciscan Healthcare - St Francis Hospital, WI;  
**Email:** meghanlearned@gmail.com

**Additional Author(s):**  
Bruce Berry  
Sonia Rodríguez  
Benjamin Scott

**Purpose:** Diarrhea and clostridium difficile infections are common ailments affecting intensive care unit (ICU) patients. There are several risk factors for these illnesses that ICU patients regularly experience, including antibiotic use, immunosuppression, and changes in nutritional status. The primary purpose of this project is to examine probiotic prescribing habits in the ICU and the incidence of all-cause diarrhea, both before and after the introduction of a new initiative to increase probiotic prescribing.

**Methods:** This study has been submitted for approval by the Investigational Review Board. Data will be collected from the electronic health records of two groups of ICU patients from two community hospitals in Milwaukee, Wisconsin: those prior to and those after the introduction of the new initiative. The percent of probiotic use in the pre-initiative group will be compared to percent of probiotic use in the post-initiative group. This data will be analyzed to determine the primary outcome of change in probiotic prescribing. For the remaining outcomes the post-initiation group will be further divided into those that received probiotics and those that did not receive probiotics. A random sampling of 15 patients per month, per group, will have the following data collected: patient demographics, probiotic use, diarrhea incidence, number of ordered clostridium difficile polymerase chain reaction (PCR) tests and the results of those tests, 30 day readmission, blood culture results, concurrent mechanical ventilation, enteric feedings, or total parenteral nutrition, and use of antibiotics, proton pump inhibitors, histamine-2 receptor antagonists, antidiarrheal medications, or laxatives. Collected data will be analyzed to determine the additional primary outcome of incidence of all-cause diarrhea between the three groups of patients. Secondary outcomes of the study will be the number of...
clostridium difficile PCR tests ordered and the results of those tests. An additional secondary outcome will be 30 day readmissions.

Poster Title: Epic alert reduction efforts for Ascension Wisconsin inpatient hospital providers

Primary Author: Sarah Seward, Wheaton Franciscan Healthcare - St. Francis Hospital, WI;
Email: sarah.seward@wfhc.org

Additional Author(s):
Kyle Sabol
Kylee Albright
Lindsay Cahill

Purpose: Our hospital system transitioned to Epic computer systems in May of 2016. As part of the post-Epic “go-live optimization phase”, hospital administration expressed interest in a team-based targeted effort to identify, customize, and reduce the number of unnecessary fired alerts that came with initial implementation of the new system. Noticeable frustration with the current level of default alerts among inpatient staff in our hospital system has raised concern across multiple departments. Primary analysis has shown over 500,000 alerts were overridden by providers during August alone, so alert reduction efforts would be of great benefit to hospital staff members.

Methods: Prior to the alert reduction phase, a survey will be distributed among staff within our hospital system to determine satisfaction/frustration with alerts appearing immediately after the Epic implementation period. This survey will then be used to guide improvement efforts and target reductions in desired alert categories (drug-drug, drug-disease state, duplicate medication warning). A pivot table report would also be run to measure the override rates before the alert reduction phase, as well as after, to quantify the effect of both helpful and unnecessary alert changes made during the alert reduction phase. Some examples of unnecessary alerts include: prochlorperazine + metoclopramide, glipizide + weakness, ceftriaxone + pyelonephritis, and potassium chloride + dehydration. The alert reduction phase would consist of a coordinated effort between the members of the Epic and our hospital Willow teams to identify, improve the quality of, and reduce the quantity of alerts fired for providers when signing and verifying orders. After completion of the alert reduction phase, a satisfaction survey would once again be distributed to staff to help gauge the hospital and Willow team
improvement efforts. A pivot table report would also be run again to compare the overall number of alerts overridden, as well as quantify the number.

**Poster Title:** Stress ulcer prophylaxis protocol's impact on intensive care unit patients followed through continuum of care: evaluating appropriateness of acid suppression therapy, costs and adverse events

**Primary Author:** Rida Abbasi, Wheaton Franciscan HealthCare - St. Francis Hospital, WI; **Email:** abbasi.rida@gmail.com

**Additional Author (s):**
Jeanne Datka

**Purpose:** Buckley et al, presented that 70% of general medical and intensive care unit (ICU) patients received inappropriate stress ulcer prophylaxis. Additionally, 73% to 90% of patients discharged from the hospital also received inappropriate stress ulcer prophylaxis. Yearly financial burden decreased by $200,000 in their hospital after initiation of a pharmacy driven protocol. Purpose of my project is to implement stress ulcer prophylaxis protocol which aims to reduce inappropriate use on ICU patients and followed to the general floor and/or upon hospital discharge. The impact of financial and potential adverse effects due to initiation of the protocol will also be evaluated.

**Methods:** A submission will be made to the Institutional Review Board for this project. Stress ulcer prophylaxis protocol provides indications (presence of at least one major or two or more minor risk factors) that will qualify patient for stress ulcer prophylaxis agent. Pharmacists will check for appropriateness by evaluating stress ulcer prophylaxis utilization daily. If the patient no longer has risk factors, the pharmacist will discontinue stress ulcer prophylaxis in 48 hours, unless the physician specifically request continuation. Pharmacists will complete a progress note in patient’s chart to notify the physician. The progress note will reiterate the protocol’s major and minor risk factors. Pharmacists will begin implementation of protocol with ICU patients and follow through transitions of care (general floor) and upon discharge. The resident will review the ICU patients throughout the continuum of care and assess the application and impact of the protocol. Additionally, the resident will gather data from medical records including patient demographics, concomitant illnesses, length of stay, duration of therapy, costs, adverse events from stress ulcer prophylaxis discontinuation, bleeding risks, major risk factors and minor risk factors. Data will be compared from this prospective study with two

**Poster Title:** Impact of pharmacist-led medication discharge counseling and follow-up calls on medication adherence rate among patients with cerebrovascular accident, transient ischemic attack, and carotid stenosis

**Primary Author:** Hyesun (Juliette) Kim, Cabell Huntington Hospital, WV; **Email:** juliet.kim@chhi.org

**Additional Author(s):**
Janet Wolcott
Crystal Heise
Mitzi Beckett

**Purpose:** Cerebrovascular accidents (CVA) including ischemic, hemorrhagic strokes and transient ischemia attacks (TIA) are the third most common cause of death in the United States with a recurrence rate of 10 to 20 percent within 90 days from an initial episode. Medication adherence is essential for the secondary prevention of CVA and TIA, and non-adherence to medication is a risk factor for recurring vascular events or death. The purpose of the study is to assess the influence of pharmacist-led discharge counseling and follow-up calls after CVA, TIA and carotid stenosis on medication adherence rate.

**Methods:** The study will be a single-center two-phase study comparing medication adherence before and after implementation of pharmacist-led discharge counseling. The first phase will be a retrospective chart review that will include patients at least 18 years of age who were admitted to Cabell Huntington Hospital (CHH) with primary diagnosis of initial or recurrent CVA, TIA or carotid stenosis episodes between August and October 2016. The prospective phase arm will include patients at least 18 years of age who are admitted to CHH with primary diagnosis of initial or recurrent CVA, TIA or carotid stenosis between November 2016 and January 2017. The patients in the prospective phase will receive pharmacist-led detailed discharge counseling on medications, and a follow-up call 7-days post-discharge. During the follow-up call, the patients will be asked a series of questions regarding their medication adherence. The primary outcome is the rate of medication adherence which will primarily be measured by prescription filled history provided by DrFirst, a medication history data tool, or by information obtained from the patients’ pharmacies. The secondary outcome is the rate of re-hospitalization within 90 days.
post-discharge. The adherence rate from the arms will be compared to evaluate the effectiveness of pharmacist-led discharge counseling and follow-up calls on the medication adherence rate.

**Poster Title:** Alternative dosing strategy of acyclovir in obese patients

**Primary Author:** Christopher Fitzpatrick, Cabell Huntington Hospital, WV; **Email:** christopher.fitzpatrick@chhi.org

**Additional Author(s):**
Derek Evans
Hasan Koc
Todd Gress

**Purpose:** A recent prospective, controlled study published by Turner et al suggested that morbidly obese patients who are treated with IV acyclovir based on current recommendations using ideal body weight (IBW) experience lower systemic exposure compared to normal weight patients dosed by total body weight (TBW). In addition, they suggested that using an adjusted body weight (AdjBW) in morbidly obese patients may result in comparable exposure seen in normal weight patients. The purpose of this study is to compare overall systemic exposure of IV acyclovir in obese patients dosed using AdjBW versus normal weight patients using TBW.

**Methods:** This single-center, prospective, case-controlled study will evaluate a novel dosing strategy in obese patients compared to standard dosing in normal weight patients. Blood samples will be collected prior to administration of acyclovir and at 10 different times following administration. To be included, patients must: be 18 years of age or older, have an expected hospital stay of greater than 24 hours, receive acyclovir as part of their routine care, and have a BMI greater than 30 kg/m² for obese patients or BMI less than 30 kg/m² for normal weight patients. Exclusion criteria includes: patients who received acyclovir or a similar guanosine nucleoside analog in the previous 24 hours, serum creatinine greater than 1.4 mg/dL at time of drug administration, hypersensitivity to acyclovir, requiring vasopressors in the previous 48 hours, receiving medications that interact with acyclovir, pregnant or breast feeding, burns greater than 30 percent, or amputation. The primary outcome to be assessed will be systemic clearance of acyclovir in obese and normal weight patients. Secondary outcomes will include maximum concentration of acyclovir in obese and normal weight patients, time above 50 percent inhibitory concentration (IC50) for varicella zoster virus and herpes simplex virus, time to maximum concentration of acyclovir in obese and normal weight patients, volume of
distribution of acyclovir in obese and normal weight patients, and incidence of acute kidney injury.

Poster Title: retrospective evaluation of osmotic therapy in middle cerebral artery (MCA) ischemic stroke

Primary Author: Temeka Lewis, Charleston Area Medical Center, WV; Email: temeka.lewis@camc.org

Additional Author (s):
Lisa Robinson

Purpose: Currently the only intervention shown to improve functional outcomes in large hemispheric ischemic stroke is a decompressive hemicraniectomy within 48 hours. There are no studies in the primary literature to date evaluating the efficacy of osmotic therapy in MCA ischemic stroke. However, current guidelines recommend the use of osmotic agents for the management of cerebral edema and this is primarily based on the observation of ICP reduction. The objective of this study is to determine the safety and efficacy of osmotic therapy in patients with MCA ischemic stroke.

Methods: This will be a retrospective study of patients who presented to Charleston Area Medical Center (CAMC) General Hospital from September 30, 2015 through September 13, 2016 with a middle cerebral artery (MCA) ischemic stroke identified by ICD-10 diagnosis codes. This primary outcome of this study will be to evaluate if osmotic therapy (hypertonic saline or mannitol) decreases 90 day mortality in patients with MCA ischemic strokes. A secondary outcome of this study will be to evaluate if osmotic therapy improves functional outcomes at hospital discharge. This study will also evaluate the incidence of acute kidney injury, hospital acquired pneumonia (HAP), ventilator associated pneumonia (VAP), central line associated blood stream infection (CLABSI), catheter associated urinary tract infection (CAUTI), deep venous thrombosis (DVT), or pulmonary embolism (PE). The results of this study may better define the role of osmotic therapy in patients with MCA ischemic stroke.

Poster Title: Effects of obesity on treatment outcomes for the inpatient management of skin and soft tissue infections

Primary Author: Brianna Thompson, Charleston Area Medical Center, WV; Email: brianna.thompson@camc.org

Additional Author(s):
John Crowley

Purpose: Skin and soft tissue infections (SSTI) encompass infections of varying severity with different management strategies. Many patients are treated empirically with antibiotics and appropriate use of these antibiotics is necessary for treatment success. With an increasing obesity epidemic and a lack of dosing recommendations for this patient population, providing optimal antibiotic regimens can be challenging. The primary objective of this study is to determine the effects of obesity on the clinical outcomes for patients admitted to a tertiary healthcare system for the inpatient treatment of a SSTI.

Methods: This retrospective study will be submitted to the Institutional Review Board for approval. The electronic medical record will be used to identify patients who were admitted to two hospitals within a tertiary healthcare system with an admitting diagnosis of a SSTI receiving at least one dose of an antibiotic. This study will compare clinical outcomes in obese patients versus non-obese patients. Demographics including age, sex, height, and weight will be obtained for each patient who meets inclusion and exclusion criteria. Additional data collected will include laboratory data at the time of SSTI diagnosis, physical findings of infection, hospital and intensive care unit (ICU) length of stay, antibiotic regimens and durations, incision and drainage documentation if performed, and in-hospital mortality. All patient information will be de-identified during data collection. After data collection, the Body Mass Index (BMI) for each patient will be calculated using the demographic information obtained. Patients with a BMI above 30 kilograms per square meter will be classified as obese. After classifying patients as obese and non-obese, the differences in hospital length of stay and duration of antibiotic therapy, in addition to ICU length of care, in-hospital mortality, readmission for SSTI management, and the appropriateness of antibiotic therapy as determined by adherence to the Infectious Diseases Society of America SSTI guidelines will be assessed.

**Poster Title:** Analgosedation versus conventional sedation in the elderly medical intensive care unit patient  
**Primary Author:** Keesha Kline, Charleston Area Medical Center, WV; **Email:** keesha.kline@camc.org  
**Additional Author (s):** Brian Hodges  

**Purpose:** Analgosedation is the technique of prioritizing pain management for intensive care unit sedation. The use of opioids for analgesia and sedation as opposed to conventional sedative-hypnotic medications has emerged in guidelines, but evidence to support these recommendations is limited. Pharmacokinetic and pharmacodynamic properties play a vital role in the selection of sedation medication. Elderly patients are particularly challenging, as altered renal and hepatic function, hypoalbuminemia, complex comorbidities, and polypharmacy influence the response and ability to tolerate opioid versus sedative-hypnotic medications. This study aims to evaluate the effectiveness and safety of analgosedation compared to conventional methods within the critically-ill elderly population.

**Methods:** This study will be submitted to the institutional review board for approval. The electronic medical record system will identify patients with pharmacy charges for fentanyl, propofol, dexmedetomidine, midazolam, or lorazepam continuous infusion admitted to medical intensive care unit between January 1 and December 31, 2015. Data such as patient demographics, dose, frequency, and duration of medications used for sedation, reversal, agitation, delirium, and pain, home medication lists, renal and hepatic function on admission, and severity of illness will be collected. All data will be de-identified and maintained confidentially. ICU length of stay, time to successful extubation, and hospital length of stay will be analyzed as primary outcomes to determine the effectiveness of analgosedation compared to conventional methods. Secondary outcomes of safety and efficacy will be measured using adjunctive sedation or rescue medication use, as well as percentage of time within Richmond Agitation Sedation Scale goals of -2 to 0 within the first 72 hours of sedation.
**Results:** This abstract is submitted as research in progress; results will be reported as they become available.

**Conclusion:** This abstract is submitted as research in progress; conclusion will be reported as results become available.

**Session-Board Number:** 10-382  

**Poster Title:** Evaluation of medication errors after transition of electronic medical records in a multi-hospital system  

**Primary Author:** Michelle Howerton, Charleston Area Medical Center, WV; **Email:** michelle.howerton@camc.org  

**Additional Author (s):**  
Brian Sayre  
Tracy Hall  

**Purpose:** Electronic medical records (EMRs) are now widely used in healthcare, having transitioned from the use of paper documentation. Other electronic technology accompanied this switch, including computerized prescriber order entry (CPOE) and bar-code scanning technology. Many studies have looked at the relation between the adoption of these systems and a reduction in medication errors but few have evaluated the transition from one EMR to another. The purpose of this study is to examine the impact that transitioning from Soarian/Siemens EMR to the Cerner Millennium integrated EMR will have on medication errors and the impact on CPOE and bar-code scanning systems.  

**Methods:** This retrospective study will be submitted to the Institutional Review Board for approval. Data for medication errors will be collected from employee-submitted error reports from the Quantros reporting system. Data to be collected includes: event date, patient type, medical record/account number, type of event, harm category from system, department involved, hospital, nature of event, medications involved, and error description. Medication errors will be assessed as medication errors per patient hospital days to normalize the number of errors. Bedside bar-code scanning medication administration data, records for CPOE orders entered, and medication written orders will be collected from reports generated from the EMR system being used during each time period. Data will include percentage of charted medications, patient ID overrides, total product overrides, wrong patient scans, patient ID overrides after incorrect scans, total potential saves, total saves, total pharmacy orders scanned, and total pharmacy orders placed via CPOE. All information will be collected for each of the four hospitals in the system. Medication error rates and percent of orders placed by CPOE and scanned to pharmacy will be compared in the 2.5 months before and after the
transition as well as the same time period the previous year. Differences in bar-code administration overrides will also be assessed for those time frames.

**Poster Title:** Impact of pharmacist interventions on potentially inappropriate medications in elderly patients in the outpatient clinic  

**Primary Author:** Daniel Wolverton, Charleston Area Medical Center, WV; **Email:** daniel.wolverton@camc.org  

**Additional Author(s):**  
David Elliott  
Cassandra Legari  

**Purpose:** Elderly patients represent the largest users of prescription medications. Given this fact, it is likely that suboptimal prescribing occurs. Potentially inappropriate medications (PIM) may lead to increased adverse effects, healthcare use and even morbidity. Several methods can be used to identify PIM with one of the more common being the Beer’s Criteria. Another aspect, medication regimen complexity, also affects medication use by making it harder for patients to use their medicines appropriately. This quality improvement project will assess the effectiveness of pharmacist interventions in reducing these medications and improvements in regimen complexity in the ambulatory clinic setting.  

**Methods:** Pending Institutional Review Board approval, this project will be conducted at two outpatient clinics at a large community teaching hospital. One clinic site is a geriatrics primary care clinic and the other an internal medicine primary care clinic. The primary objective will be to measure the effectiveness of pharmacist interventions at discontinuing potentially inappropriate medications via provider recommendations and improving overall regimen complexity. This information will be used to further refine the process to have a greater impact on patient care. Patients over age 65, who use 10 or medications on a daily basis and are seen on a regular basis in either clinic will be included. PIMs will be identified by selecting medications most commonly used in practice from the Beer’s Criteria. Data to be collected and maintained confidentially will include: age, sex, PIMs identified, whether the PIMs are dosed on a scheduled or as needed basis, whether a recommendation was made to change the PIM dosing parameters, presence of PIM and daily dose 30 days after clinic visit. Medication regimen complexity score at baseline and 30 days after clinic visit will also be evaluated.
Descriptive statistics will be used to explore changes in PIMs and regimen complexity after the implementation of the new process.

Poster Title: Evaluation of the safety of NPH and glargine insulin in a mixed ICU population

Primary Author: Kevin Ordons, Charleston Area Medical Center, WV; Email: kevin.ordons@camc.org

Additional Author(s):
Brian Hodges

Purpose: Prior poster abstracts presented at the Society of Critical Care Medicine Annual Congress have compared the use of NPH and glargine insulin among critically ill patients. Results of this research have not been consistent. The objective of this study is to compare the incidence of hypoglycemia in patients receiving NPH as a basal insulin compared with patients receiving insulin glargine in a mixed medical and surgical ICU population at a large, tertiary care center.

Methods: This will be a retrospective study of patients who were admitted to the intensive care units at CAMC Memorial or General hospital from September 2014 to September 2015. Patients who received NPH or glargine insulin (at least 10 units in a 24 hour period) and were admitted to the ICU for at least 72 hours will be included. Patients will be excluded for type 1 diabetes or an ICU admission for a hyperglycemic crisis. The primary objective is to compare the incidence of hypoglycemia in medical and surgical critical care patients treated with NPH and patients treated with glargine. Secondary objectives are to compare the incidence of hyperglycemia, glycemic variability, length of stay, and mortality. Subjects will be identified by medication orders for NPH or glargine insulin. All data will be collected from the electronic health record. Comparison of continuous variables will be evaluated by the Student t-test or the Wilcoxon rank-sum test. Discrete variables will be evaluated by the Fisher exact test or Chi-square test.

Poster Title: Antipsychotic use for the treatment of delirium in elderly ICU patients: The importance of continued assessment for indication

Primary Author: Nishika Patel, Charleston Area Medical Center, WV; Email: nishika.patel@camc.org

Additional Author (s):
Brian Hodges

Purpose: Delirium can have serious ramifications such as long term cognitive impairment and increased mortality. Many clinicians start antipsychotics for elderly patients experiencing delirium in the intensive care setting. The rate at which these are continued beyond care transitions has not been measured. This issue is further compounded by the black box warning for antipsychotics having the propensity to cause an increased risk of death in elderly patients with dementia related psychosis. The objective of this study is to evaluate how often prolonged use of antipsychotics beyond transition from the ICU occurs at Charleston Area Medical Center.

Methods: This study is a retrospective chart review and will be submitted to the Institutional Review Board for approval. Electronic medical records will help identify patients who were 65 years or older and were started on an antipsychotic during their intensive care stay. The following data will be collected: patient age, length of stay in the ICU, home medications, ICU medications, floor medications, discharge medications, admit diagnoses, QTc intervals, and EPS incidence. Patients with a primary CNS pathology as well as patients previously on mood stabilizers, antiepileptics, or antipsychotics will be excluded; this will be done to avoid potential confounders. The addition of an antipsychotic during the intensive care stay will be considered a surrogate for the formal diagnosis of ICU delirium as diagnoses are not always documented.

**Submission Category:** Pain Management

**Submission Type:** Research-in-Progress

**Session-Board Number:** 10-387

**Poster Title:** Pain Management of Sedated Patients within a Critical Access Hospital

**Primary Author:** Seth Lilly, Jefferson Medical Center, WV; Email: seth.lilly@wvumedicine.org

**Additional Author (s):**
Jonathan Kline

**Purpose:** Patients often need sedation to provide comfort and care during recovery. In such situations, strategies to assure adequate pain management are put in place. These types of strategies include pain medication orders being placed before or concurrently as sedation occurs. Because sedation often leaves expressing and assessing pain difficult for both the patient and staff, it is important pain management is placed before the patient is sedated. The purpose of this study is to evaluate pain management put in place before or concurrently with sedation placement within a critical access hospital.

**Methods:** This study will be submitted to the Institutional Review Board for approval. This is a retrospective, observational study looking at patients placed within the intensive care unit starting January 1st, 2016 through September 30, 2016. All patients will be screened for sedation procedures. Information collected from these patients include if a pain medication order was placed, pain assessments made while patient was undergoing sedation, time before or after sedation occurred that a pain management order get placed, type of pain medication given for the patient undergoing sedation, dosing of pain medication, patient allergies, and indication for sedation. Explanation of why a patient was not put on pain medication, if applicable and provided, will also be recorded. Patient identifiers will be removed to assure confidentiality. All data will be analyzed using appropriate statistical tests.

**Poster Title:** Examination of time to first antibiotic administration in patients with sepsis

**Primary Author:** Benjamin Robertson, Marshall Univeristy / King's Daughters Medical Center, WV; Email: benjaminrobertson@cedarville.edu

**Additional Author(s):**
Delilah Navarro
Brittany Riley
Lori-Belle Slone
Jessica Sobnosky

**Purpose:** The surviving sepsis campaign bundle states that antibiotics should be administered within three hours, while the guideline defines the goal of therapy to be antibiotic administration within the first hour after recognition of sepsis. Current literature states that early antibiotic administration improves patient outcomes. However, despite the importance of early antibiotic administration, treatment may be delayed for various reasons. The purpose of this study is to assess the time interval between recognition of sepsis and the administration of the first dose of antibiotics with a goal of identifying barriers to optimal treatment of sepsis patients.

**Methods:** This study protocol was approved by the Institutional Review Board prior to commencement. A retrospective chart review will be performed on patients with a diagnosis of septicemia or severe sepsis, excluding pediatric or pregnant patients. Patients were selected using DRG ID MS870, MS871, or MS872 who were admitted during June and July 2016. All data will be collected from the electronic medical record and will be de-identified. The following data will be gathered: patient age, sex, weight, date of admission, date and location of septicemia or severe sepsis diagnosis, SIRS and qSOFA criteria identified on presentation, initial antibiotics, number of antibiotics, time first antibiotic was ordered, verified and administered, type and amount of fluids patient received, time and type of cultures obtained, ICU admission date if applicable, vasopressors initiated and time started, and adherence to the hospital’s approved sepsis order set. The primary endpoint is the time to first dose of antibiotic and the secondary endpoints are adherence to the sepsis order set and the surviving sepsis bundle.

**Poster Title:** Impact of pharmacy intervention of opioid use associated with fibromyalgia patients in a community pharmacy setting

**Primary Author:** Andre Watson, Marshall University School of Pharmacy/Valley Health, WV; Email: watson154@marshall.edu

**Additional Author(s):**
Brittany Riley
Megan Peterson

**Purpose:** Community pharmacies are aware of the need to establish a standard of care for patients with chronic pain management. Fibromyalgia is described as a chronic, widespread pain that is centrally amplified and associated with hyperalgesia. Opioids are prescribed without concern of published randomized trials that examine the efficacy of therapy, which leads to negative outcomes such as minimum pain relief. The pharmacist direct involvement with fibromyalgia patient care can improve quality of life. The purpose of this study is to determine if the pharmacist modification of therapy is correlated with positive patient outcomes regarding fibromyalgia pain.

**Methods:** This study will be submitted to the institution’s IRB for approval. Fibromyalgia patients that are being seen at a federally-qualified health center will be identified by using a M79.7 ICD10 code search throughout the database as well as other subset codes associated with fibromyalgia. This group of patients will be identified based on opioid use with fibromyalgia. Patients that meet the criteria will be asked to participate in this study and given a survey to complete. Surveys will be given at baseline, 3 months, and 5 months to measure widespread pain and quality of life during the study as primary endpoints. Physicians will be encouraged to initiate changes in therapy per titration protocol developed by the pharmacist to decrease opioid use. Morphine equivalents will be calculated at baseline and during titration to measure change in doses. Alternative therapy will be initiated simultaneously with the titration protocol using serotonin-norepinephrine reuptake inhibitors or tri-cyclic antidepressants. The actual study will be executed from December 1, 2016 through March 31, 2017. The patient therapy will be optimized and tailored towards each patient unique disease state.

Poster Title: Pharmacist role in monitoring patients in a Medication-Assisted Treatment program at risk for developing metabolic syndrome

Primary Author: Chad Butler, Marshall University School of Pharmacy/Valley Health Systems Residency Program, WV; Email: butler71@marshall.edu

Additional Author(s):
Brittany Riley
Megan Peterson

Purpose: Approximately 9.8 million adults suffer from mental illness. Of those, 2.3 million met the criteria for substance use disorder. Medication adherence is vital for treatment success in both patient populations. There are several barriers that contribute to nonadherence. One major problem with mental illness treatment is metabolic syndrome associated with antipsychotic therapy. Metabolic syndrome is defined as a group of risk factors for developing heart disease, diabetes, and stroke. This study is to determine if the role of pharmacy education therapy modification can alleviate the stress of metabolic syndrome in patients taking antipsychotics participating in the Medication-Assisted Treatment program.

Methods: This study will be submitted to the institution’s IRB for approval. Patients being treated with antipsychotic medications will be identified through Valley Health’s Medication-Assisted Treatment (MAT) programs. Once identified patients will be given two questionnaires to complete concerning medication adherence and compliance. Drug Attitude Inventory and the Brief Adherence Rating Scale will be used. Questionnaires will be administered at baseline, three months, and five months. Also, adherence monitoring will be measured by pharmacy refill records provided by Valley Health Intergy software. Patient education will be provided to participants in the MAT program. For patients on antipsychotic therapy monitoring and education for metabolic syndrome will be initiated. Weight, BMI, and waist circumference will be measured at each visit every week. Blood pressure will be measured at baseline and every two weeks. Glucose and lipid panel will be measured at baseline and every three months. If patients develop signs and symptoms of metabolic syndrome, a recommendation to the physician will be made to properly discontinue current antipsychotic therapy, initiate alternate antipsychotic medication, and start appropriate medication to control metabolic risk factor. A
retrospective analysis of the previous three months will be conducted to determine the effectiveness of pharmacy intervention on metabolic syndrome and adherence. The retrospective arm will be completed August 2016-October 2016 and the prospective arm will take place November 2016-March 2016.

Poster Title: Evaluation of a nasal swab methicillin-resistant Staphylococcus aureus (MRSA) polymerase chain reaction (PCR) test for guiding de-escalation in patients with pneumonia

Primary Author: Sarah Dunaway, St. Mary’s Medical Center, WV; Email: sarah.dunaway@stmarys.org

Additional Author(s):
Kara Orwig
Stephanie Giancola

Purpose: A recent retrospective study completed at St. Mary’s Medical Center (SMMC) concluded that the use of nasal swab MRSA PCR testing might be a useful stewardship tool to guide discontinuation of anti-MRSA antibiotics in patients with pneumonia, demonstrating 98.6 percent negative predictive value for ruling out MRSA pneumonia. Subsequently, SMMC added this test to the existing pneumonia protocol (OS270), which allows for vancomycin to be discontinued when the MRSA PCR is negative. The primary objective of this study is to compare vancomycin days of therapy (DOT) before and after the addition of the nasal swab MRSA PCR to OS270.

Methods: This is an Institutional Review Board-approved, single-center, retrospective chart review study. Adult patients admitted to SMMC with healthcare-associated pneumonia or community-acquired pneumonia and OS270 initiated will be screened for inclusion. Additional inclusion criteria will be vancomycin ordered and nasal swab MRSA PCR collected within 24 hours of admission. Patients will be excluded if they have MRSA infection elsewhere (such as a skin infection) when the nasal swab MRSA PCR was collected. Patients admitted prior to and after addition of the nasal swab MRSA PCR to OS270 will serve as the control and intervention groups, respectively. The primary outcome will be vancomycin DOT. Secondary outcomes for assessment will include in-hospital all-cause mortality and length of stay. Data collection from the electronic medical record will consist of age, sex, admit date, discharge date, admit from the community or from a nursing home, comorbidities, allergies, tube feeding status on admission, unit or floor to which the patient was admitted, CURB-65 score, previous antibiotic exposure within 90 days, WBC count, maximum temperature, vancomycin start and stop date, PCR date and result, and respiratory culture results and specimen type if obtained.
Results: N/A

Conclusion: N/A
**Submission Category:** Infectious Diseases

**Submission Type:** Research-in-Progress

**Session-Board Number:** 10-392

**Poster Title:** Impact of procalcitonin on antibiotic exposure, hospital length of stay, and 30-day readmission rate in patients with a chronic obstructive pulmonary disease (COPD) exacerbation

**Primary Author:** Casey Fitzpatrick, St. Mary's Medical Center, WV; **Email:** casey.fitzpatrick@st-marys.org

**Additional Author (s):**
Kara Orwig

**Purpose:** The unnecessary use of antibiotics in COPD exacerbations increases healthcare costs, promotes bacterial resistance, and causes avoidable adverse effects. Previous studies show that procalcitonin guided therapy greatly reduces antibiotic exposure in patients with a lower respiratory tract infection without negatively impacting outcomes. The 2016 GOLD recommendations are vague regarding the utilization of antibiotics in COPD exacerbations but contend that procalcitonin may be valuable in the decision to use antibiotics. The purpose of this study is to evaluate the impact of procalcitonin guided therapy on antibiotic exposure, hospital length of stay, and 30-day readmission rate in COPD exacerbation patients.

**Methods:** This is an Institutional Review Board-approved, single-center, retrospective chart review study. Patients 18 years or older, who were admitted to St. Mary’s Medical Center (SMMC) with a COPD exacerbation, will be included. Patients will be excluded if they were admitted to an intensive care unit or if they had other sources of infection. A pre-intervention group will consist of patients admitted between March and December 2015, before the implementation of procalcitonin at SMMC. An intervention group will include patients admitted between March and December 2016, after implementation of procalcitonin testing. Hospital policy is based on the suggestion that a procalcitonin level less than 0.05 micrograms per liter likely indicates the absence of a bacterial infection and discontinuation of antibiotics is strongly encouraged. The primary outcome to be assessed will be the impact of procalcitonin values on the number of antibiotic days of therapy (DOT). Secondary outcomes will include hospital length of stay (LOS) and 30-day readmission rates.

**Poster Title:** Evaluation of vancomycin use for pediatric patients at a large academic medical center  

**Primary Author:** Sheng Da Ma, West Virginia University Healthcare, WV; **Email:** sma1@mix.wvu.edu  

**Additional Author(s):**  
Jennifer Shahan  
Lisa Garavaglia  
Courtney Sweet  

**Purpose:** Vancomycin is a glycopeptide antibiotic used to treat gram-positive infections. Excessive use can lead to increased healthcare costs, the emergence of resistant organisms, and place patients at increased risk of adverse effects. Patients should be de-escalated to a more specific antibiotic regimen once cultures and laboratory tests identify a particular pathogen. Although a full course of vancomycin therapy is warranted for patients with culture-proven infections, the picture is less clear for those with negative cultures beyond 72 hours. The purpose of this study is to describe the indications for vancomycin use beyond 72 hours at a large academic medical center.  

**Methods:** This study is approved by the Institutional Review Board. This study is a retrospective chart review using electronic medical records in reverse chronological order from June 30, 2016 until 150 patients are accrued. All pediatric patients discharged from WVU Medicine Children's who received greater than 72 hours of vancomycin therapy will be included. Exclusion criteria consist of non-pediatric services, maternal infant care unit patients, pediatric patients with an open chest, and Hematology/Oncology service patients with febrile neutropenia. Data collected included age, weight, gender, unit location, antimicrobial allergies, prescribing service, indication for continued therapy, length of therapy past 72 hours, number of levels, culture results, type of IV line, and infectious disease consult recommendations. Descriptive statistics will be utilized.  

**Results:** This abstract submission is for research in progress.
Conclusion: This abstract submission is for research in progress.

Poster Title: Retrospective Review of Rituximab Utilization and Impact on Reimbursement

Primary Author: Jonathan Angus, West Virginia University Healthcare, WV; Email: jon.h.angus@gmail.com

Additional Author(s):
Megan Bodge
Aaron Cumpston
David Cecere

Purpose: The purpose of this project was to evaluate the use of rituximab throughout our institution and perform a cost analysis specifically focusing on reimbursement for inpatient use. The primary objective of this project was to describe inpatient use of rituximab by service, provider, and indication. Secondary objectives included: the comparison of inpatient versus outpatient utilization among specific indications and providers, assessment of reimbursement amounts according to location (inpatient vs. outpatient) and by insurance provider (Medicare, Medicaid, Private Insurance, and Health Maintenance Organizations), and evaluation of the need for formulary restriction of rituximab prescribing.

Methods: This project consists of a retrospective chart review from October 2015 to July 2016 of adult patients who received rituximab at our institution either in the inpatient setting or in the outpatient infusion center. Patients who were greater than or equal to 18 years old and who had received greater than or equal to one dose of rituximab were included in the chart review. Patients admitted to pediatric services, patients receiving rituximab in the outpatient pediatric infusion center, and patients receiving rituximab as an investigational drug were excluded. The data collected based on these criteria showed the prescribing patterns of rituximab and the associated cost.

Results: Currently, at our institution, the inpatient use of rituximab is unrestricted and its use is seemingly increasing. Rituximab is an expensive medication, with an estimated actual wholesale price (AWP) of $928.88 per 100 mg vial and $4644.42 per 500 mg vial. Reimbursement for this medication varies drastically depending on insurance payer as well as patient location (inpatient versus outpatient). There were 41 inpatient administrations and 457
outpatient administrations. Many of the inpatient administrations were for unapproved indications, ordered by off-service prescribers, and not reimbursed by a carve-out within the DRG.

**Conclusion:** The current inpatient prescribing practices regarding rituximab at our hospital necessitate the implementation of specific ordering restrictions to help facilitate its use. Shifting the majority of inpatient rituximab infusions to the outpatient setting or admitting patients under "observation status" may be ways to mediate the high cost and lack of reimbursement experienced during inpatient administration of this medication. Rituximab remains a powerful therapeutic agent with a variety of applications.

Poster Title: Recognition, monitoring, and treatment of QTc prolongation secondary to selective serotonin reuptake inhibitors and serotonin norepinephrine reuptake inhibitors in medicine and trauma patients.

Primary Author: Bethany Miller, West Virginia University Medicine, WV; Email: bethany.miller@wvumedicine.org

Additional Author(s):
Jay Martello
Karen Petros

Purpose: The purpose of this study is to assess the recognition, monitoring, and treatment of QTc prolongation at J.C. Ruby Memorial Hospital in medicine and trauma patients presenting on selective serotonin reuptake inhibitors (SSRI) and serotonin and norepinephrine reuptake inhibitor (SNRI) therapy.

Methods: This is a retrospective cohort study of adult patients who were admitted to a medicine or surgical service at J.C. Ruby Memorial Hospital between July 1, 2013 and July 1, 2016 and were on an home SSRI or SNRI. Patients were excluded if they had a congenital heart condition, a cardiac abnormality at baseline, or no baseline EKG within 24 hours of admission. A cardiac abnormality at baseline included any patients who had heart failure, coronary artery disease, valvular disorders, or any other abnormality that would affect the heart. Patients were grouped according to admitting service, either medical or surgical, and 50 patients were collected in each arm for a total of 100 patients included in the study. Data collected for this study will be analyzed by descriptive statistics.

Results: This medication use evaluation is still currently being conducted and finalized results will be analyzed and presented.

Conclusion: It is anticipated this project will identify if a problem exists with recognizing, monitoring, and treating QTc prolongation at J.C. Ruby Memorial Hospital and if there is an observed difference in the above parameters between the medicine or the trauma services.

Poster Title: Comparison of regular versus rapid acting sliding scale insulin on the incidence of hypoglycemia

Primary Author: Andrew Allison, WVU Medicine, WV; Email: andrew.allison@wvumedicine.org

Additional Author(s):
Jon Wietholter

Purpose: Sliding scale insulin regimens are often used as the sole method to provide glucose control in hospitalized patients despite being strongly discouraged by the American Diabetes Association. Regular and rapid acting insulin are both commonly used in these regimens. While both products lower blood glucose levels, they have markedly different pharmacokinetic parameters. The primary objective of this study was to determine which insulin product led to higher rates of hypoglycemia within a large academic medical center.

Methods: The institutional review board approved this comparison study. A retrospective chart review was completed from October 1, 2015 to July 31, 2016 of inpatients that received sliding scale insulin. Seventy patients met inclusion criteria. There were 35 patients per group receiving either rapid or regular acting insulin. The following data points were collected: age, sex, weight, hemoglobin A1c, sliding scale intensity, type of sliding scale insulin, use of basal or scheduled mealtime insulin, total dose of basal insulin administered 36 hours prior to a hypoglycemic event, total mealtime insulin dose administered 24 hours prior to a hypoglycemic event, number of hypoglycemic episodes within 2 hours of a sliding scale dose, number of hypoglycemic episodes likely attributable to sliding scale insulin, major attributable adverse events due to hypoglycemia, corticosteroid use while inpatient, and use of other diabetic medications while inpatient or outpatient that could cause hypoglycemia. Data was collected from the electronic medical record and maintained on a spreadsheet. A comparison of demographics was completed to determine if significant differences were present between study groups. Primary and secondary objectives were analyzed using descriptive statistics, comparing the event rates between groups. All identifying patient information was removed from study data to preserve privacy.
**Results:** Seventy patients were included in the study: 44 percent female, 56 percent male. Of all prescribed sliding scale insulin regimens, 81 percent utilized conservative dosing in the regular insulin group and 76 percent utilized conservative dosing in the rapid insulin group. The conservative sliding scale regimen included insulin administrations of two to six units depending on the patient’s blood glucose level. Patients in the rapid insulin group were prescribed basal insulin more often, both inpatient and outpatient, compared to the regular insulin group (66 percent versus 37 percent outpatient respectively, 69 percent versus 31 percent inpatient respectively). Twelve hypoglycemic episodes, defined as blood glucose less than 70 milligrams per deciliter, were identified in the regular insulin group. Eleven hypoglycemic episodes were identified in the rapid insulin group. Of these 23 episodes, only one could likely be attributed to rapid acting sliding scale insulin. No patients experienced coma, death, or seizure due to hypoglycemia in our study.

**Conclusion:** There appears to be no difference in the rate of hypoglycemia due to regular or rapid acting sliding scale insulin regimens in our study population. A similar number of hypoglycemic events were identified in each group, with only one episode likely due to rapid acting sliding scale insulin. The lack of attributable events could be due to any of the following: properly managed sliding scale regimens, choice of regimens that were too conservative, or inclusion of stable patients. Further studies should be completed to evaluate other patient populations that may be more prone to hypoglycemic events.
Conclusions: Evaluation of four-factor prothrombin complex concentrate use in an academic medical center

Primary Author: Robert Walchack, WVU Medicine, WV; Email: robert.walchack@wvumedicine.org

Additional Author(s):
Lisa Moherman
Kelly Thornton
Nicole Kovacic

Purpose: Four-factor Prothrombin Complex Concentrate (4F-PCC) is recommended by the American College of Chest Physicians (CHEST Guidelines) for the rapid reversal of anticoagulation in warfarin-associated major bleeding. Regarding the direct factor Xa inhibitors apixaban, rivaroxaban, edoxaban, and fondaparinux, no FDA-approved antidotes currently exist. Since data are limited, it is unclear whether 4F-PCC is effective treatment in life-threatening bleeds or reversing the effects of factor Xa inhibitor anticoagulants, but it may be a reasonable option given the lack of effective alternatives. The primary objective of this study is to qualify the use of 4F-PCC with or without vitamin K.

Methods: This is a retrospective chart review looking at patients who received 4F-PCC between January 1, 2016 and June 30, 2016. Descriptive statistics are being utilized to analyze the collected data. Collected information includes patient demographics, allergies, 4F-PCC dose and indication, ordering service and treatment floor where patient received 4F-PCC, number of doses given, INR(s) immediately prior to and within 72 hours of 4F-PCC administration, use of vitamin K administration with 4F-PCC, anticoagulant requiring reversal, thrombotic event within 30 days, if antithrombotic medication was used after 4F-PCC, transfusion requirements, and incidence of re-bleeding within 24 hours. Duration of therapy as well as length of hospital stay were assessed.

Results: Research-in-progress.

Conclusion: Research-in-progress.

**Poster Title:** Evaluation of ketamine, propofol, or both for procedural sedation in the emergency department

**Primary Author:** Julianne Yeary, WVU Medicine, WV; **Email:** jy0014@wvumedicine.org

**Additional Author (s):**
Jeffrey Quedado
Kelly Thornton
Nicole Kovacic

**Purpose:** Procedural sedation is the process of utilizing low doses of sedatives or dissociative agents with or without the use of analgesics to improve comfort during painful procedures. Ketamine and propofol for procedural sedation have been a popular alternative to high doses of opioids. The American College of Emergency Physicians clinical policy regarding procedural sedation in the emergency department provided a level A safety recommendation for the use of ketamine in pediatrics and for propofol in pediatrics and adults. Purpose of this study is to evaluate safety and appropriate dosing strategies for these agents alone or in combination.

**Methods:** This is a retrospective chart review of patients admitted to the emergency department between January 2016 to June 2016 and given ketamine, propofol, or both for procedural sedation. Primary outcomes include the rate and type of adverse events associated with each agent or in combination. Safety endpoints are the frequency of significant hemodynamic and respiratory compromise and respiratory intervention when needed. Time to sedation resolution will be evaluated as a secondary outcome. Data points measured will include dosing, repeated doses if needed, time to sedation resolution, procedure, adverse events reported, recorded agitation, respiratory intervention, and vasopressor use.

**Results:** Data collection in process, results pending. Preliminary results include < 1% (3 of 61) patients have experienced an adverse event and ~30% (18 of 61) required respiratory intervention of nasal cannula or non-rebreather.

**Conclusion:** To be determined after completion of data collection.
**Submission Category:** Drug-Use Evaluation/ Drug Information

**Submission Type:** Evaluative Study

**Session-Board Number:** 10-400

**Poster Title:** Evaluation of fosfomycin use at an inpatient academic medical center.

**Primary Author:** Christine Hanks, WVU Medicine, WV; **Email:** christine.hanks122@gmail.com

**Additional Author (s):**
Lisa Keller
John Guilfoose
Hugh Palmer

**Purpose:** In 2012, an institution-specific urinary tract infection (UTI) guideline was implemented. This guideline promoted fosfomycin as one of three preferred first-line antibiotics for the treatment of uncomplicated cystitis. After implementation of the UTI guideline, fosfomycin use has increased. The primary objective of this evaluation was to determine if fosfomycin use was empiric or pathogen-driven. Secondary objectives included determining if a catheter was present and if fosfomycin was given first or as a subsequent antibiotic.

**Methods:** This evaluation was an Institution Review Board-approved retrospective chart review of patients receiving at least one dose of fosfomycin at our institution in June 2016. There were no exclusion criteria. Data collected included age, gender, allergies, presence of a catheter, prescribing service, number and frequency of doses, urine culture results, and antibiotics administered within 72 hours of a fosfomycin dose. Descriptive statistics were used to analyze collected data.

**Results:** One hundred patients were evaluated: 11 male and 89 female. Twenty seven percent of patients were given fosfomycin in the emergency department. Thirty-two percent of patients received pathogen-driven (targeted) treatment with fosfomycin. In those receiving targeted therapy, the most commonly isolated organism was Escherichia coli (37.5 percent). Eighteen percent had a catheter present. Thirty one percent of patients received other antibiotics within 72 hours of a fosfomycin dose. Of these patients, only 6 percent received fosfomycin as the initial agent for a urinary tract infection.
**Conclusion:** This review showed that fosfomycin is being used most commonly in women. The majority of patients received one dose of fosfomycin empirically. Escherichia coli was the most commonly isolated organism in patients receiving pathogen-driven therapy. Few patients had a catheter present on the same day that the fosfomycin dose was administered. If other antibiotics were given within 72 hours, the majority of the fosfomycin doses were given as a subsequent antibiotic.

**Poster Title:** Evaluating intravenous vancomycin dosing in hemodialysis at an academic medical center

**Primary Author:** Meera Mehta, WVU Medicine, WV; Email: meera.mehta@wvumedicine.org

**Additional Author(s):**
Lisa Keller
Douglas Slain
Renee Straight
Micah Butcher

**Purpose:** There is currently no national consensus amongst institutions on the dosing and monitoring of vancomycin in hemodialysis (HD), however, several strategies have been proposed. Dosing should take place after dialysis and frequent monitoring of levels has been recommended due to the varying effects of hemodialysis on drug removal. Current vancomycin dosing guidelines at our institution state that doses should be given after the dialysis session, and levels may not be needed if the patient is clinically improving. The primary outcome was to evaluate IV vancomycin dosing strategies utilized in patients with ESRD on HD at an academic medical center.

**Methods:** The study design was an IRB approved retrospective chart review. Patients must have received ≥2 doses of vancomycin to be included. Intra-operative and one time ED vancomycin doses were excluded. Patients were identified via running a HD report on EPIC in addition to ICD 9 code for end stage renal disease (ESRD). Data was pulled from January to July 2016, and patients were retrospectively reviewed in reverse chronological order until a sample size of 50 was encountered. Data collected included vancomycin indication, number of levels drawn per admission, pre or post dialysis level, level value, vancomycin dose, dose changes after level, days of therapy, missed vancomycin doses, gram positive organism, minimum inhibitory concentration, and patient length of stay. Descriptive statistics was utilized to summarize the data.

**Results:** N/A
Conclusion: N/A

**Poster Title:** Comparison of acute kidney injury in hospitalized patients receiving combination vancomycin and piperacillin-tazobactam versus vancomycin and cefepime  

**Primary Author:** Donna Park, Antelope Valley Hospital, CA; **Email:** annodpark@gmail.com  

**Additional Author (s):**  
Julie Snyder  

**Purpose:** Hospitalized patients who develop acute kidney injury (AKI) have an increased risk of mortality, length of stay, and costs. The combination of vancomycin and an anti-pseudomonal beta-lactam, such as piperacillin-tazobactam or cefepime, is commonly used as empiric antimicrobial therapy in hospitalized patients. The nephrotoxic risk of vancomycin has been well documented in literature, but the incidence of nephrotoxicity occurring with concomitant use of piperacillin-tazobactam or cefepime has been limited in comparison. The purpose of this study is to compare the incidence of AKI occurring in patients receiving the combination of either vancomycin and piperacillin-tazobactam or vancomycin and cefepime.  

**Methods:** This will be a retrospective, cohort study of patients admitted between January 2014 and August 2016. The primary endpoint will be to compare the incidence of AKI in patients who were either treated with a combination of vancomycin and piperacillin-tazobactam or vancomycin and cefepime. Secondary endpoints include time to AKI from initiation of combination antimicrobials, hospital length of stay, mortality, and incidence of AKI in relation to: age, duration of treatment, receiving greater or equal to 4 grams per day of vancomycin, maintaining vancomycin trough greater than 15 mcg/ml, and use of concomitant nephrotoxic agents. Inclusion criteria includes patients 18 years of age and older, who have received treatment with vancomycin in combination with either piperacillin-tazobactam or cefepime for at least 48 hours during admission. This study aims to achieve a total of 150 patients per study group. Exclusion criteria includes: baseline serum creatinine of greater than or equal to 1.5mg/dL, creatinine clearance less than or equal to 60mL/min, history of end-stage renal disease, treatment with more than one dose of intermittent piperacillin-tazobactam infusion (30 minute infusion), pregnant patients, incarcerated patients, and patients with inadequate laboratory data to determine AKI. Paired t-test will be used to compare normally distributed,
continuous data. Pearson chi-squared test will be used to compare nominal data, and Wilcoxon-Signed Rank test will for ordinal data. This study is pending IRB approval.

Poster Title: Clinical outcomes in patients with reported beta-lactam allergy presenting with septic shock

Primary Author: Deanna Quan, Antelope Valley Hospital, CA; Email: deanna.quan@avhospital.org

Additional Author(s):
Laura Celmins

Purpose: Septic shock is the systemic manifestation of infection resulting in continued hypotension despite adequate fluid resuscitation. Delay in the administration of appropriate empiric antibiotics is associated with increased mortality in septic shock, and broad-spectrum antibiotics such as piperacillin/tazobactam are the empiric treatment of choice. Patients with reported allergies to beta-lactams may have a lower likelihood of receiving appropriate empiric therapy, which may lead to adverse outcomes. This study aims to determine if a reported beta-lactam allergy in patients who develop septic shock is associated with worse outcomes versus patients with no reported antibiotic allergies.

Methods: We will perform a comparison of patients with septic shock between reported beta-lactam allergy and no allergy. Data will be collected through a retrospective, systematic chart review at Antelope Valley Hospital from July 2011 through August 2016. The primary endpoint will be survival to discharge. Secondary endpoints will include hospital length of stay, ICU length of stay, cumulative days of antibiotic exposure, development of acute kidney injury (AKI), death within 48 hours, time to death, readmission for the same infection within 4 weeks, and development of Clostridium difficile, Vancomycin-resistant enterococci, or methicillin-resistant Staphylococcus aureus infection within 4 weeks. We will also look at mortality between patients with a reported allergy who receive beta-lactams, who receive alternative therapy, and patients without reported allergy. Baseline characteristics will include demographics, positive cultures, any resistant pathogens, APACHE II score, qSOFA score, allergy descriptions, other allergies, initial lactate, AKI-causing drugs, time from fluid resuscitation to vasopressors, maximum rates, number, and duration of vasopressors, and antibiotic use, indication, and escalation. Inclusion criteria will include septic shock, ICU admission, at least one dose of antibiotics, vasopressor use, and 18 years of age or older. Exclusion criteria will include
pregnancy, prisoners, and other causes of shock. A student t-test will be used to assess numerical variables, and a chi-squared test will be used for nominal variables. IRB approval is currently pending.

Poster Title: Safe Medication Transitions Program (SafeTMed) Timeline: Inspired, Created and Implemented by Residents

Primary Author: Lydia Noh, Cedars-Sinai Medical Center, CA; Email: lydia.noh@cshs.org

Additional Author(s):
Rita Shane
Duong Donna Luong
Katherine Palmer

Purpose: Medication-related readmissions occur in up to 20% of all readmissions. Pharmacists play an important role in ensuring safe transitions to and from the hospital by providing medication reconciliation and education at admission, transfer, discharge, and post-discharge. Cedars-Sinai Medical Center (CSMC) began and expanded its transitions of care program through interdisciplinary collaboration led by pharmacy residents. Through longitudinal research studies and tests of change led by PGY-1 and PGY-2 residents, CSMC’s program was able to grow to 15 full time employees (pharmacists and technicians) in 2016.

Methods: CSMC started focusing efforts on evaluating patient-centered services in transitions of care. In an effort to gather evidence of various types of TOC services, projects were incorporated into the administrative rotation as small-scale projects and were also assigned as longitudinal research projects determined by the Chief Pharmacy Officer when residents expressed interest.

Program Initiation:
CSMC’s first transitions of care (TOC) pilot began on the heart failure unit in 2010. Realizing the need to evaluate multiple TOC services at various phases of care, CSMC implemented small initiatives through resident projects to get quick turn around on potential areas of interest (Etchelles E, et al, 2015). Small test of change with rapid process improvement methods provided a valuable learning experience for both the residents and the leadership team. Resident projects add to the growing body of knowledge of what it takes to grow and scale a program and sustain the services.

Program Expansion and Optimization
With the knowledge gained from small resident projects, CSMC’s TOC program was able to evaluate all phases of a patient’s care and gathered evidence of each phase. Many residents involved in TOC initiatives became TOC pharmacists and continued to help create the tools to continue to expand and optimize the program. They also serve as mentors for the current residents leading TOC projects.

**Results:** CSMC’s TOC program was scaled to various clinical services and hospitalist groups through resident projects. In 2011, the first project was in collaboration with hospitalists in medicine units to provide medication reconciliation on admission and discharge counseling. It was expanded to other units due to its success and resulted in creation of a dedicated TOC pharmacist. In 2012, admission medication reconciliation was integrated into decentralized pharmacist workflow through training modules prepared and conducted by residents. Results of multiple major projects justified the expansion of the program and addition of staff. In 2013, a resident conducted a study evaluating the discharge reconciliation process for skilled nursing facilities (SNF). Study results demonstrated that pharmacist interventions reduced SNF readmissions and justified additional 0.5 full time equivalence (FTE). In 2015, residents developed a methodology toolkit for documenting drug-related problems and potential readmissions avoided, also known as “Medication-related Acute Care Episode (MACEs)”. Results from MACEs study was found to be cost-effective, resulting in an addition of 4 FTEs. Recently in 2016, residents piloted the MACEs methodology as a multi-center study in collaboration with 8 other institutions. This national project demonstrated that the CSMC methodology was applicable to other TOC programs of various sizes and settings.

**Conclusion:** CSMC’s TOC program was inspired by the Chief Pharmacy Officer and implemented by residents. The efforts of the residents highlighted the challenges and led to program growth and lessons learned. Positive results found during each initiative was shared with senior leadership, which provided additional FTE support to continue optimize the program. Resident’s small projects over the years continue to add to the knowledge of safe transitions and will continue to be a methodology used to study future opportunities.
**Submission Category:** Pain Management  
**Submission Type:** Research-in-Progress  
**Session-Board Number:** 11-004  
**Poster Title:** Targeting Patient Pain: a Pharmacist-driven Hospital Pain Management Service  
**Primary Author:** Quinn Wonders, CHA Hollywood Presbyterian Medical Center, CA; **Email:** quinn.wonders@hpmedcenter.com  
**Additional Author(s):**  
Sofia Gezalyan  

**Purpose:** The Joint Commission recommends that all healthcare institutions have a program in place to address patient pain. When reviewing Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) scores for the institution, a need for a pain service was identified, coinciding with the Joint Commission recommendation. The purpose of this study is to compare patient satisfaction scores, length of stay, and opioid usage, before and after the implementation of a pharmacist-driven hospital pain management service.  

**Methods:** This study will be submitted to the hospital Institutional Review Board for approval. The method of identifying patients for pain management will be multi-factorial. The pharmacist will review the surgery schedule of the previous day and visit each patient to address post-operative pain. The pain pharmacist will take pain management requests via phone and from log sheets in nursing units. Patients will be included if they are expected to have a hospital stay of more than 24 hours. Patients that are younger than 18, on a ventilator with sedation, or pregnant, will be excluded. The pain management consult will include the pharmacist assessing patient pain and identifying pain goals. The pharmacist will give the patient a pain information sheet that describes types of pain and how to communicate about pain. Patients will be followed until their pain is at goal for 48 hours or until the patient is discharged. Post discharge calls will be made to assess the patient’s satisfaction of the pain management program and to inquire about post-discharge pain. The following data will be collected: patient demographics, mode of pain management request, pain goals and scores, interventions, and patient satisfaction scores. The data collected will be compared with matched patients that were admitted into the hospital before the intervention was implemented. Pain education will be provided to pharmacists, nurses, and surgeons.

**Session-Board Number:** 11-005

**Poster Title:** Assessing pharmacist involvement in an asthma quality improvement project implemented in a pediatric emergency department

**Primary Author:** Jennifer Nguyen, Children's Hospital of Orange County (CHOC Children's), CA; Email: jenguyen@choc.org

**Additional Author(s):**
Winnie Stockton
Katie Tu

**Purpose:** In a 2006 survey, less than 50 percent of persistent asthmatic children seen in the emergency department (ED) were on controller medications, with less than 20 percent prescribed a controller subsequently. Based on the current literature and the National Institute of Health recommendations on the management of persistent asthma, an interdisciplinary asthma quality improvement project (asthma QIP) was initiated at a 31-bed pediatric ED to improve controller medication prescribing practice, provide proper patient education, and ensure controller medication availability for patients prior to discharge. This report describes the asthma QIP, with a focus on pharmacist activities in this multidisciplinary approach.

**Methods:** Persistent asthmatic patients presenting to the ED are identified and screened by the triage nurse using the Mini Pediatric Asthma Control Tool (MPact). Once an MPact is activated, an alert is populated on the ED tracking board for the physician, respiratory therapist, and pharmacist. The ED team will first address any acute exacerbations of asthma with rapid reliever medications and systemic corticosteroids. After patient examination and confirmed diagnosis of persistent asthma, the ED physician then initiates orders for respiratory and pharmacy consult, a short-acting beta agonist, and controller medications. Upon respiratory consult order, the respiratory therapist provides the first dose of inhaled corticosteroid in-house and educates the patient and family on inhaler technique and asthma action plan. The pharmacy consult order prompts the ED pharmacist to perform patient medication reconciliation, provide patient education on rescue versus controller inhalers, and dispense the properly labeled medications to patients prior to discharge. Due to the high census and acute nature of the ED, the controller inhalers are dispensed as a relabel of the in-house product,
rather than being processed through the patient’s insurance, to avoid delay in patient throughput.

**Results:** There were 4113 ED patients with an ICD-10-CM diagnosis code related to asthma in the first year of asthma QIP implementation. Asthma diagnoses of these patients included mild intermittent, mild persistent, moderate persistent, severe persistent, unspecified, exercise induced bronchospasm, cough variant asthma, and other asthma. As a result of the asthma QIP, 590 controller medications were dispensed from the ED pharmacy directly to the patient prior to discharge. Of those patients, 316 had a pharmacy consult documented in their electronic medical records. Per protocol, a pharmacy consult is required for every activity related to controller medication dispensing. It was observed that a physician may order a controller medication without initiating a pharmacy consult, and that pharmacists would often times give patient education on controller medications without the official consult order. Based on the Pediatric Health Information System (PHIS) data, from October 2015 through March 2016 of the asthma QIP, 41 asthma patients returned to the ED for the same diagnosis within 30 days. The PHIS data also reports that from October 2014 through March 2015, a similar time frame prior to implementation of the asthma QIP, there were 58 asthma patients returning to the ED in 30 days.

**Conclusion:** The public PHIS data suggests that there appears to be a difference in the number of asthma ED revisits during the winter periods before and after the asthma QIP implementation. This absolute reduction in number of ED revisits should be investigated further, as there can be many potential explanations. There is an opportunity for improvement in the documentation of pharmacist involvement in the medication reconciliation, education, and dispensing activities related to controller medications. Further evaluation is also needed to assess the cost effectiveness of direct controller medication dispensing to the patient in the ED, as well as effect of pharmacist involvement in the asthma QIP on the number of ED revisits the asthma management program may reduce.

**Submission Type:** Research-in-Progress  
**Session-Board Number:** 11-006  

**Poster Title:** Effectiveness of vancomycin administered as continuous infusion (CIV) versus intermittent infusion (IIV) for the treatment of methicillin-resistant staphylococcus aureus (MRSA) bacteremia in pediatric patients

**Primary Author:** Abdullah Dakhllallah, Children's Hospital of Orange County (CHOC), CA; **Email:** adakhllallah@choc.org

**Additional Author (s):**
M. Tuan Tran

**Purpose:** The 2011 IDSA guidelines for treatment of MRSA infections in adults and children recommend a target trough of 15-20 mcg/ml to achieve a ratio of area under the curve (AUC) over minimum inhibitory concentration (MIC) greater than 400. However, achieving the recommended trough goals in children has been difficult in clinical settings. The guideline further recommend against CIV due to lack of clear benefit and time above MIC has not been found to be the primary predictor of efficacy. The objective of this study is to compare the effectiveness of vancomycin CIV versus IIV in pediatric patients with MRSA bacteremia.

**Methods:** Pending IRB approval, this retrospective chart review will include randomly selected patients aged 6 months to 18 years old who received vancomycin as either IIV or CIV for treatment of MRSA bacteremia at a pediatric hospital between January 1st, 2012 to June 30, 2016. Data abstraction from patients' electronic health record includes: vancomycin regimen including dose, frequency, timing and method of administration, demographics such as age, height, weight and gender, vital signs including temperature and heart rate, laboratory markers such as serum creatinine, complete blood count, vancomycin serum level, as well as microbiology data including vancomycin MICs. The primary objective of the study is to assess differences in outcome between the different method of vancomycin administration including: duration of bacteremia, duration of fever, hospital length of stay (LOS), intensive care unit LOS. Secondary outcome measures include differences in vancomycin exposure defined as AUC/MIC ratio and highest serum levels collected within 72 hours of initiation. Additionally, differences in treatment-related adverse effects such as nephrotoxicity, defined as an increase in serum creatinine greater or equal to 0.5 mg/dL, or 50% increase from baseline, development of rash, thrombophlebitis, loss of IV access will also be examined. Differences between the study group
will be analyzed using Chi Squared for qualitative data and t-test for quantitative data. Statistical analysis will be performed with Excel, Microsoft Office 2010.

Poster Title: Effect of discharging patients with a prescription for an antipsychotic on alcohol related readmissions in patients suffering from schizophrenia and alcohol use disorder

Primary Author: Johnson Hung, Citrus Valley Health Partners, CA; Email: johung@mail.cvhp.org

Additional Author(s):
Nhi Dinh
Mark Richman
Patrick Chan

Purpose: The rate of alcohol-use disorder (AUD) in the general population is 6.8 percent, a rate which increases to 43 percent in patients suffering from concurrent schizophrenia. The treatment of schizophrenia and AUD individually is challenging and the effect of antipsychotics on alcohol consumption is unclear. The primary objective of this study was to evaluate whether discharging patients, suffering from both schizophrenia and AUD, with a new prescription for an antipsychotic will reduce future alcohol-related readmissions and if antipsychotics will prolong the time between admissions. The secondary objective was identifying potential factors that may influence readmission rates.

Methods: This retrospective cohort study spanned from January 1, 2005 to December 31, 2015 at Olive View Medical Center in Sylmar, CA. After an IRB protocol was approved by both Western University of Health Sciences and Olive View Medical Center, a query based on International Classification of Diseases-9/10 codes for schizophrenia was conducted to identify admissions related to schizophrenia and alcohol-related events. Over 16,000 patients were screened. Inclusion criteria included: documented diagnosis of schizophrenia, current alcohol abuse (either by Alcohol Use Disorders Identification Test-C score greater than 3 for females and 4 for males or chart documentation), and no current use of an antipsychotic medication on admission. Exclusion criteria included: those under the age of 18, those without patient data available, and those without diagnoses of schizophrenia or without readmissions due to alcohol-related events. Data on demographics, patient medical and social history, comorbidities, urinary toxicological screening results, admission date, date of readmission, medications, and discharge diagnoses was collected. Independent t and Mann-Whitney tests were performed on continuous variables and chi-square tests were performed on predictor variables.
variables for readmission such as discharge with an antipsychotic medication, gender, smoking history, homelessness, concurrent depression, and inpatient psychiatric evaluation. Statistical significance was set at a P value less than 0.05.

**Results:** A total of 108 patients met inclusion criteria (n equals 84 for patients discharged with antipsychotics and n equals 24 for patients discharged without antipsychotics). Baseline characteristics (age, gender, social history, comorbidities) were not statistically significant between the two cohorts. For the primary objective, patients discharged with antipsychotics had significantly lower alcohol-related readmissions (13 percent) compared to those who were discharged without an antipsychotic (33 percent, P equals 0.033, OR equals 0.30, 95 percent CI 0.10 to 0.87). Median days between admission and the first alcohol-related readmission were 152 days and 86 days for those discharged with an antipsychotic and those who were not, respectively (P equals 0.66). Subgroup analysis for potential factors that may influence readmission did not reveal any statistical significance: male gender (P equals 0.067) homelessness (P equals 0.26), smoking history (P equals 0.79), concurrent depression (P equals 0.14), cocaine abuse (P greater than 0.99), and amphetamine abuse (P equals 0.65).

**Conclusion:** Alcohol related readmission rates were significantly lower in patients discharged with antipsychotics than those who were discharged without antipsychotics. Time between admission and first readmission was not significant. This suggests antipsychotics upon discharge may have a positive effect on AUD and reduce future alcohol-related readmissions. Prospective studies and the inclusion of multiple institutions are necessary to substantiate these findings.

**Poster Title:** Evaluation of an antimicrobial stewardship program on the utilization of high-cost anti-infectives

**Primary Author:** Michelle Do, Citrus Valley Health Partners, CA; **Email:** mdo050607@gmail.com

**Additional Author(s):**
Mai-Chi Hong
Edward Jai

**Purpose:** Antimicrobial stewardship programs (ASP) have shown a positive impact on healthcare systems by minimizing the rate of antibiotic resistance, reducing healthcare costs, and improving overall patient outcomes. The importance of ASPs has been recognized nationally by a multitude of organizations, including the Centers for Disease Control and Prevention, The Joint Commission, and the Centers for Medicare and Medicaid Service. Previous studies at Citrus Valley Medical Center (CVMC) showed a significant reduction in piperacillin/tazobactam utilization post-ASP. We aim to extend the evaluation of ASP efforts by assessing the utilization of high-cost anti-infectives, focusing on tigecycline and daptomycin.

**Methods:** This is a retrospective chart review that is anticipated to be submitted the Institutional Review Board for approval. Patients will be included in this study if they are 18 years of age or older, were admitted to CVMC, and have received at least one inpatient dose of either tigecycline or daptomycin. Cases will be identified via the electronic medical record system by active orders for the targeted anti-infectives and relevant data will be collected. All data will be de-identified in order to maintain patient confidentiality. Data collected will include: patient age, gender, height, weight, allergies, hematology results, chemistry results, microbiological results, physical examination findings, clinical notes, and current medications. The primary outcome of the study is to compare the pre-ASP (January through March 2014) utilization of tigecycline and daptomycin to the post-ASP (January through March 2017) utilization. The secondary outcomes of the study include clinical response, adverse drug-related events, and all-cause mortality. Data will be analyzed using Microsoft Excel and GraphPad; a p-value of 0.05 or lower will denote statistical significance.

**Results:** N/A
Conclusion: N/A

Poster Title: Evaluation of Antimicrobial Stewardship Program on Levofloxacin Utilization and Patient Outcome

Primary Author: Jennifer Lau, Citrus Valley Health Partners, CA; Email: jelau@westernu.edu

Additional Author(s):
Julie Vuong
Mai Chi Hong
Edward Jai

Purpose: The primary objective of the study is to assess concerted antimicrobial stewardship efforts on levofloxacin utilization. The secondary objectives are to evaluate multifaceted aspects of patient outcome, such as mortality, clinical status, and therapy-related toxicities.

Methods: A retrospective chart review was conducted at Citrus Valley Medical Center, whereby patients were identified via levofloxacin use pre- and post-implementation of the Antimicrobial Stewardship Program, in February 2014 and February 2015 respectively. Patients included were at least 18 years and received inpatient levofloxacin. Patients who received entirely outpatient levofloxacin were excluded. A total of 679 admissions were reviewed, of which 491 patients met the inclusion criteria. Student t-tests, Mann-Whitney, and Chi-Square tests were utilized in the statistical analysis conducted by GraphPad Prism. Statistical significance for two-tailed p-values will be defined a priori p less than 0.05.

Results: There was no statistically significant difference in levofloxacin utilization between pre- and post-implementation of ASP (p equals 0.29). There was also no statistically significant difference in mortality, clinical stability, clinical response, and therapy-related toxicities.

Conclusion: The results from the study did not demonstrate any difference in average levofloxacin utilization or patient outcome post-implementation of ASP. The results may also suggest benefits in targeting initiation of levofloxacin. Further studies should be replicated with other types of high-use antimicrobial agents.
**Poster Title:** Impact of resident pharmacist intervention on acute kidney injury (AKI) progression and patient outcomes

**Primary Author:** Cheree Sosin, Clovis Community Medical Center, CA; **Email:** csosin@communitymedical.org

**Additional Author(s):**
Shao-Ju Chang
Stephen Rettig
Bryan Carlson
Eric Koehler

**Purpose:** To compare the number of interventions and rate of progression to higher stages of acute kidney injury (AKI) with a new pharmacy workflow as compared to our current practice of renal dose adjustments and if this can avoid the associated costs of more advanced renal dysfunction.

**Methods:** This retrospective study will compare a new pharmacy workflow conducted on patients admitted from November 1, 2016 to January 31, 2017 with patients at the same institution admitted from November 1, 2015 to January 31, 2016. As a part of daily workflow, a PGY-1 Resident Pharmacist is responsible for evaluating patients who have had a 0.3 mg/dL increase in serum creatinine (SCr) in the last 24 hours while admitted and determine if an intervention could prevent progression to a higher stage of AKI as defined by KDIGO (Kidney Disease: Improving Global Outcomes). Exclusion criteria includes patients < 18 years old, admitting diagnosis of end-stage renal disease (ESRD) or AKI, receiving dialysis, pregnancy, and receiving chemotherapy, current or received in the last year. The types of intervention include renal dose adjustment, discontinuation of agents based on manufacturer and institution guidelines, alternative therapy, adjustment or addition of IV fluids, and evaluation of concomitant nephrotoxic agents. Identified interventions will be approved by attending physicians on service before recommendations are implemented. Primary outcomes are the number of interventions made and rate of progression to higher stages of AKI (with or without dialysis). Secondary outcomes are length of hospital stay, type of interventions, and transfer to higher level of care.

**Poster Title:** Efficacy and safety of glucagon, high-dose insulin, and intravenous lipid emulsion in beta blocker and calcium channel blocker toxicity  

**Primary Author:** Esther Park, Community Regional Medical Center, CA; **Email:** epark3@communitymedical.org  

**Additional Author (s):**  
- Mallory Cruz  
- Gillian Pineda  
- Katie Trousil  

**Purpose:** Due to the lack of established practice guidelines, studies are warranted to guide the management of cardiotoxicities due to beta blocker and calcium channel blocker overdose. This study will evaluate the efficacy and safety of glucagon, high-dose insulin (HDI), and intravenous lipid emulsion (ILE) as monotherapy or combination therapies for the treatment of cardiovascular toxicities attributed to beta blocker and calcium channel blocker overdose. Findings will be used to develop a treatment algorithm.  

**Methods:** This study is a retrospective chart review and has been submitted to the Institutional Review Board for approval. Patients who presented to the Community Regional Medical Center Emergency Department from January 2013 to December 2016 with cardiotoxicity due to beta blocker or calcium channel blocker overdose, as defined by the International Classification of Diseases, 9th and 10th Revisions, Clinical Modification codes, will be identified through an institutional generated report and included in the data analysis. Primary endpoints include survival to hospital admission and all-cause mortality. Secondary endpoints include the incidence and nature of adverse effects associated with glucagon, HDI, and ILE. Descriptive statistics will be used to summarize the data.

**Poster Title:** Evaluation of vancomycin dosing in critically ill patients receiving continuous venovenous hemodiafiltration

**Primary Author:** Sherif Sharaby, Community Regional Medical Center, CA; **Email:** ssharaby@communitymedical.org

**Additional Author(s):**
Tou Thao
Linda Kimura

**Purpose:** Continuous renal replacement therapy (CRRT) is often used in the management of critically ill patients with acute kidney injury. Vancomycin is an important antimicrobial agent and is commonly used for treatment of gram positive infections. Optimal dosing of vancomycin is essential to avoid treatment failure, development of resistance, and drug toxicities. The objectives of this study are to evaluate the adequacy of current vancomycin dosing practice in critically ill patients receiving continuous venovenous hemodiafiltration (CVVHDF) therapy mode of CRRT in a tertiary medical center and to determine an optimal dosing regimen.

**Methods:** This study was submitted to the Institutional Review Board for approval. A retrospective chart review will be conducted of all adult patients who received intravenous vancomycin therapy in the intensive care unit (ICU) of Community Regional Medical Center while undergoing CVVHDF for at least 48 hours during the period from April 1, 2013 to August 31, 2016. Patients who received vancomycin more than 36 hours prior to initiating CVVHDF, patients with CVVHDF interruptions totalling more than 6 hours in any 24-hour period, those with burns, and pregnant women will be excluded. The following data will be collected: age, weight, sex, main diagnosis, Acute Physiology and Chronic Health Evaluation score, vancomycin dosing regimen, vancomycin doses administered, vancomycin blood level(s), time when blood samples were drawn, indication for vancomycin therapy, the start and stop dates of vancomycin therapy, start and stop dates of CVVHDF, the times of CVVHDF interruptions, dialysate rates, ultrafiltration rates, blood flow rates, replacement fluid rates, results of microbiological tests and cultures, serum creatinine, blood urea nitrogen, 24-hour urine output, serum albumin, total number of days in the ICU, immediate cause of death (if applicable) and
ICU survival data. Data will be analyzed, mean pharmacokinetic parameters will be calculated, and dosing recommendations will be developed.

**Poster Title:** Octreotide medication use evaluation at Desert Regional Medical Center

**Primary Author:** Elaine Jahng, Desert Regional Medical Center, CA; **Email:** elaine.jahng@tenethealth.com

**Additional Author(s):**
Stephanie Diep  
Miko Tuico  
Pisey Long  
Craig Elg

**Purpose:** Octreotide is a somatostatin analog that has been used in patients with gastrointestinal (GI) hemorrhage. There is limited evidence currently to support the use of octreotide in non-variceal GI bleeds due to its vasoconstrictive properties. This vasoconstriction limits splanchnic blood flow that ultimately reduces portal vein hypertension. Additionally, the frequent shortages of octreotide have contributed to increased drug costs. The purpose of this study is to evaluate the appropriateness of octreotide use at Desert Regional Medical Center (DRMC) in order to limit costs and to deliver safe and effective care for our patients.

**Methods:** A retrospective chart review will be performed using Crimson Continuum of Care to identify patients who have been admitted to DRMC with GI hemorrhage between July 2015 - June 2016. Inclusion criteria: patients greater than or equal to 18 years of age with GI hemorrhage due to any cause who have received at least one dose of octreotide. Exclusion criteria: patients less than 18 years of age, patients with acromegaly, carcinoid tumors, vasoactive intestinal peptide tumors, gastroenteropancreatic neuroendocrine tumors, refractory diarrhea associated with chemotherapy or acquired immunodeficiency syndrome, acute graft versus host disease, malignant bowel obstruction, sulfonylurea-induced hypoglycemia, thymic malignancies, congenital hyperinsulinism, ectopic Cushing’s syndrome, hypothalamic obesity, postgastrectomy dumping syndrome, small bowel fistulas, or Zollinger-Ellison syndrome. We will be reviewing appropriateness of indication, dose, route, and duration of octreotide therapy.

**Poster Title:** Retrospective review of a pharmacist led medication refill authorization protocol to improve practice performance

**Primary Author:** Alyssa Yasuda, Desert Regional Medical Center, CA; **Email:** alyssaimiyasuda@gmail.com

**Additional Author(s):**
Mukti Kadiwala
Maureen Fulgencio
Chanh Le
Teresa Hodgkins

**Purpose:** Medication refill requests place a burden on physician practices and consume a large amount of daily workload for staff. The medication refill process involves evaluations that requires clinical expertise and a dedicated time component. This process is universal in primary care offices and represents a predictable point of connection between the patient and healthcare provider that delivers a valuable opportunity to address pertinent patient care needs. We aim to quantify the impact of a pharmacist led collaborative practice platform with a comprehensive management scope to improve quality measures and efficiency, while reducing utilization and cost.

**Methods:** An interdisciplinary team consisting of primary care nursing, support staff, physicians, pharmacists, administration, and information technology (IT) developed an evidence-based protocol for centralized medication refill. This protocol was approved and implemented with a physician champion in March 2015. The protocol was then integrated within our electronic medical record (EMR), NextGen and initially implemented with a physician champion in March 2015. This program is currently scaled to include 16 employee group physicians. The refill clinic process algorithm was adapted from Riege’s study on pharmacy refill clinics within the U.S. Navy. Each refill request goes to the refill team and is evaluated by trained pharmacy technicians working under the supervision of clinical pharmacists. After a thorough profile review, the technicians will authorize the refill per protocol when patient meets all applicable criteria. Concerns or discrepancies found are sent to a pharmacist for further review. Statistical analysis will be performed on all data from the implementation of the protocol to the end of
October 2016. We will analyze the impact of our pharmacist led medication refill authorization protocol on reduction of prescription volume, volume and outcomes of prior authorizations, identification of patients in need of office visit, identification of patients in need of lab work, use of electronic prescription (eRx) prescribing versus other methods, and the driving shift to 90 day supply for chronic medications.

Thanh Nguyen

**Purpose:** Center for Disease Control indicates that COPD affects over 32 million people in the United States and is the 3rd leading cause of death. COPD exacerbations are a common cause of hospitalization and readmission. Improvements in COPD management can produce significant benefits in cost control and enhance quality of life. Center for Medicare and Medicaid Services includes COPD outcomes as a clinical quality measure for hospitals requiring public reporting and affecting reimbursement rates. We aim to quantify the impact a pharmacist led collaborative practice platform with a comprehensive management scope to improve the patient experience, while reducing utilization and cost.

**Methods:** An electronic medical review will be performed to identify patients diagnosed with COPD. The following data will be collected: age, gender, smoking status, level of benefit, insurance, acute bed days, skilled nursing facility (SNF) bed days, comorbid conditions, urgent care (UC) visits, emergency department (ED) visit, and ED diagnosis. Patients will be enrolled into the COPD program by recent utilization or referral and then risk stratified based on acuity for comprehensive assessment and management. Current chronic disease management models require a face-to-face visit followed by need driven follow-up appointment versus telephonic support. All enrolled patients will receive a comprehensive medication review to evaluate appropriateness of current therapy, compliance, adherence, immunization status, smoking history and barriers to regimen optimization. The collaborative drug therapy management (CDTM) follows the 2016 Global Initiative for Chronic Obstructive Lung Disease guidelines, and will dictate treatment and care management recommendations. Statistical analysis will be
performed to identify the impact CDTM has on adherence, pre and post enrollment utilization, patient experience, clinical improvement and cost. In addition, we will analyze the effects that seasonal changes have on utilization.

Poster Title: Evaluation of appropriateness and outcomes of stress ulcer prophylaxis in an intensive care unit

Primary Author: Jing (Sophie) Xia, Eisenhower Medical Center, CA; Email: jxia@emc.org

Additional Author(s): 

Purpose: Stress ulcer prophylaxis is commonly administered to critically ill patients to prevent potential mucosal bleeding from the gastrointestinal (GI) tract. They are beneficial for patients indicated and are at high risk for stress ulcers. Inappropriate usage of stress ulcer prophylaxis may lead to harmful side effects such as nosocomial pneumonia and clostridium difficile infections. This study will evaluate the use of proton pump inhibitors and H2 blockers in patients in the intensive care unit and the corresponding patient outcomes. The values of pharmacist interventions to promote appropriate stress ulcer prophylaxis such as education, protocol development, and in-services will be discussed.

Methods: The retrospective study will extract patient data utilizing Eisenhower Medical Center’s electronic medical record system (McKesson). Adults who were acutely admitted to the intensive care unit in and were treated with pantoprazole or famotidine would be identified and analyzed for appropriateness of prophylactic treatment. The following data will be recorded: patient’s age, gender, admitting chief complaint, stress ulcer prophylactic drug, dose, duration, indication, and risk factors for stress ulcers. Data will be reviewed to determine if compliant with ASHP’s stress ulcer prophylaxis guideline. Outcome measures would include proportion of patients with clinically important GI bleed, nosocomial pneumonia, clostridium difficile infections, and all-cause mortality during hospital stay. All data will be confidential, and recorded without patient identifiers. Data will be analyzed on Microsoft Excel and a stress ulcer prophylaxis protocol will be proposed.

**Poster Title:** Antibiotic de-escalation after culture identification of methicillin sensitive Staphylococcus aureus bacteremia

**Primary Author:** Forrest Ridgway, Eisenhower Medical Center, CA; **Email:** tub78574@temple.edu

**Additional Author(s):**

**Purpose:** The Centers for Disease Control (CDC) cite the inappropriate use of antibiotics as one of the leading actions associated with the development of antibiotic resistance. Antibiotic resistance has emerged as a national healthcare problem. The CDC recommends periodic antibiotic assessment and narrowing of empiric therapy to curb inappropriate use. As beta-lactam antibiotics are preferred over vancomycin in methicillin sensitive Staphylococcus aureus (MSSA) bacteremia, the purpose of this study will be to assess the value of a pharmacist antibiotic intervention program to reduce the inappropriate use of vancomycin.

**Methods:** A retrospective chart review will be conducted including patients 18 years or older on intravenous vancomycin with 2 or more positive blood cultures for MSSA at Eisenhower Medical Center from January 2016 to August 2016 in a group prior to pharmacy intervention implementation and compared to a prospective patient group after intervention implementation. Patients with comorbid infections with other bacterial species or MSSA will be excluded as will patients who were deceased before sensitivity results became available. Data to be collected will include patient name, medical record number, date and time intravenous vancomycin was started, date and draw time for the first blood culture, date and time when culture results were posted, date and time of antibiotic change, and antibiotic chosen for definitive therapy. Statistical analysis will be performed to determine whether a significant difference exists between groups before and after implementation of pharmacy intervention. The expected outcome is a reduction in time to narrow therapy following the implementation of a pharmacy intervention program. This drug use evaluation was exempt from IRB approval.

Submission Category: Clinical Services Management

Submission Type: Research-in-Progress

Session-Board Number: 11-019

Poster Title: Can the implementation of pharmacy-driven transitions of care processes promote adherence to long-acting injectable antipsychotics (LAI-APs) and reduce readmission rates?

Primary Author: Naira Barsegyan, Glendale Adventist Medical Center, CA; Email: barsegn@ah.org

Additional Author(s):
Kenneth Lin

Purpose: Various studies have shown that the use of long-acting injectable antipsychotics (LAI-APs) have improved adherence and decreased hospitalization. Barriers such as cost and lack of appropriate transition and follow-up prevent patients from receiving LAI-APs. The objective of this study is to assess whether pharmacy-driven transitions of care processes can help improve adherence and ultimately, reduce readmission rates.

Methods: This study will be submitted for approval from the Institutional Review Board (IRB). All patients who are prescribed a LAI-AP, which include fluphenazine, haloperidol, paliperidone, risperidone, olanzapine, and aripiprazole, from November 1, 2016 to March 1, 2017 will be included in the study. Prior to discharge, the patient will be educated/counseled on the medication, and efforts will be made to transition the patient to a setting where the medications can appropriately be administered. Currently, patients being discharged from Glendale Adventist Medical Center are given the option to continue receiving their LAI-APs at the Outpatient Infusion Center (OPIC) on campus. For ease of follow-up and administration, patients will initially be referred to OPIC and an appointment will be made prior to discharge. Barriers including cost and adverse events will be assessed and efforts will be made to address them. Patients will be followed on a monthly basis to assess adherence, relapse, and readmission utilizing phone calls and chart reviews. Phone calls will remind patients of their appointment times and re-emphasize counseling points to improve adherence. The data will be reviewed to assess patterns in adherence and readmission.

**Poster Title:** Impact of pharmacist involvement in collaborative heart failure management with updated guideline-directed medical therapy

**Primary Author:** Christine Lee, Huntington Hospital, CA; **Email:** christine.lee@huntingtonhospital.com

**Additional Author (s):**
Michelle Rose

**Purpose:** Pharmacist involvement in heart failure (HF) management has increased across the continuum of care in an effort improve patient outcomes. Recently, opportunities for pharmacist involvement in optimizing HF management have expanded consequent to the release of 2016 guideline updates to pharmacologic therapy. Establishment of pharmacist-physician collaborative care and implementation of an updated guideline-directed medical therapy (GDMT) protocol within a pharmacist-run clinic marks our institution’s most recent endeavor to improve outcomes of HF patients. The objective of this study is to measure the impact of pharmacist involvement in collaborative HF management on healthcare resource utilization, patient morbidity, and adherence to GDMT.

**Methods:** This study will be submitted to the Institutional Review Board for approval. An updated GDMT protocol incorporating latest guideline recommendations will be developed and implemented as the foundation of our institution’s pharmacist-run HF clinic. Thereafter, a retrospective chart review will proceed on patients that were active participants of our clinic post-implementation of the updated GDMT protocol. All patients followed by our clinic will receive comprehensive HF education, medication reconciliation, and close monitoring of relevant laboratory values, vital signs, weight, symptoms, medication-related side effects, and drug interactions. Pharmacist-physician approved adjustments to HF therapy will be based on subjective patient reports and objective findings. The primary outcome measure will be 30-day hospital readmission rates and emergency department visits of patients followed by our clinic compared to that of non-clinic patients of a historical cohort, comprising of patients discharged from our institution with a primary diagnosis of HF one year prior to the present study. Secondary outcome measures will include changes in morbidity status and rate of adherence to GDMT. Clinic patients will be identified as those referred by providers from the cardiology
medical group with an established collaboration with the clinic. Non-clinic patients will be identified via the institution’s electronic medical record system. All data utilized for this study will be maintained confidentially and recorded without patient identifiers.

**Results:** N/A

**Conclusion:** N/A
Poster Title: Impact of age on the management and outcome of urinary tract infection in the emergency department

Secondary Authors: Annie Wong-Berger, Joanne Pang

Author: Mira Zurayk, Huntington Hospital, CA; Email: mirazurayk@gmail.com

Purpose: Urinary tract infections (UTIs) are one of the three most commonly diagnosed and treated infections in the emergency department. However, the data on adherence to the UTI guidelines or on the effect of antimicrobial stewardship interventions for UTI in the emergency department setting is limited. The purpose of this study is to determine the epidemiology, prescribing patterns, and outcomes of patients presenting to the emergency department with UTIs grouped by age (18-50 versus over 50 years old) in order to identify areas for improvement in quality of care for age-specific patient groups.

Methods: Adult patients presenting to the emergency department between July 1, 2015 and June 30, 2016 with a diagnosis of UTI (ICD-9 and ICD-10 codes: 599 for UTI, 595.9 for cystitis, and 590.10 for pyelonephritis) were identified. A total of 500 patients were randomly selected using computer-generated randomization; of those, 150 were admitted to the hospital while 350 were discharged from the emergency department. Patients were excluded if any of the following was met: under 18 years old, transferred to an outside hospital, evaluation or treatment was refused by patient or family, or if the medical chart was not available. The medical records of eligible patients were reviewed for pertinent demographic and clinical data and recorded using a standardized data collection form with specific definitions for each variable. Notable variables collected include patient demographics, illness symptoms and duration, urinalysis results, urine culture and sensitivities, white blood cell count with differential, and presence of sepsis. To evaluate treatment, antibiotics given in the emergency department, inpatient antibiotics, discharge antibiotics, and treatment duration were recorded. Outcome endpoints were return visits to the emergency department within 72 hours and 30
days, and hospital readmissions within 30 days of discharge. Reasons for return within 72 hours or 30 days were documented. Statistical analysis will be performed using GraphPad Prism.

**Poster Title:** Transitions of care: Optimization of home infusion therapy

**Primary Author:** John Khoan, Kaiser Permanente - Fontana, CA; **Email:** john.khoan@kp.org

**Additional Author (s):**
Dennis Kim
Carol Crawford
Guy Ito

**Purpose:** Decreasing days spent in the hospital can help reduce physical, financial, and emotional burden placed upon patients and healthcare organizations. A pharmacist with knowledge of both inpatient services and home infusion therapies are optimally positioned to reduce the length of hospital stay through streamlining home infusion services. Review of the literature shows that a pharmacist’s role in home infusion therapies and transitions of care varies widely and established metrics are needed. The objective of this study is to explore metrics that can establish measurable value to a pharmacist’s role in transitions of care and outpatient parenteral therapies.

**Methods:** This study will be submitted to the Institutional Review Board for approval. Investigators will chart review patients, via electronic medical record, who received intervention from transitions of care pharmacists and a comparator group. The study population includes patients admitted to the inpatient setting who are treated with parenteral antibiotic therapy or parenteral nutrition therapy that have available therapeutically equivalent parenteral therapies for home use. The primary outcomes will be potentially avoidable days, defined as the amount of extra days patients stay in the hospital after they are dischargeable, or length of stay in the hospital. Secondary outcomes to collect and analyze include readmission to emergency department or hospital, cost savings, interventions made, adverse reactions, and appropriate usage of cultures and sensitivities.

**Results:** Not applicable.

**Conclusion:** Not applicable.

Poster Title: Identifying risk factors for involuntary psychiatric holds in the emergency department

Primary Author: Tiffany Nguyen, Kaiser Permanente Medical Care Program - Fontana, CA; Email: tiffany.x.nguyen@kp.org

Additional Author (s):
Sophia Ho

Purpose: Patients presenting to the emergency department for psychiatric crises may have orders written for involuntary psychiatric holds. Patients placed under involuntary psychiatric holds require medical clearance prior to transfer to an outside psychiatric facility. The time required to obtain medical clearance may potentially prevent other patients presenting to the emergency room from gaining timely access to care. It can also lead to increased staffing and security requirements. Oftentimes, these crises may be preventable. The objective of this study is to determine if there are identifiable risk factors for an individual’s likelihood of being placed under an involuntary psychiatric hold.

Methods: This study will be submitted to the Institutional Review Board for approval. Mental Health Services will provide two lists of patients: a list of patients seen by their service in the medical centers' emergency rooms, as well as a list of patients seen in the outpatient Mental Health Clinic. The following information will be collected: patient age, gender, psychiatric diagnosis, reason for psychiatric hold, classes of medication, and percentage of days patient has medication (determined based on frequency of medication refills). If available, the duration of treatment, psychosocial issues, use of oral versus long-acting injectable medication, history of substance abuse, history of previous involuntary psychiatric hold, previously missed or canceled appointments with psychiatry, therapists, or Chemical Dependence Recovery Program, and whether or not the patient is in transition between medications will also be collected. All data will be recorded without patient identifiers in order to maintain confidentiality. The reviewers will analyze and compare patient and treatment characteristics between the two groups to determine factors that may predict risk of involuntary psychiatric holds in the emergency department. The results of this study will be shared with the Psychiatry department in order to attempt to reduce the number of patients placed under involuntary psychiatric holds.

**Poster Title:** Implementation of drug-disease interaction alerts in an integrated electronic health record  

**Primary Author:** Michelle Park, Kaiser Permanente Pharmacy Informatics, CA; **Email:** michelleapark@gmail.com  

**Additional Author(s):**  
Don Ly  
Thong Dang  

**Purpose:** Drug-disease interaction alerts notify providers of potential drug-disease interaction alerts in a health system utilizing computerized provider order entry. This alert category is less utilized than its counterpart, drug-drug interaction alerts. Drug-disease interaction alerts were implemented in an integrated electronic health record. However, large scale implementation of drug-disease interaction alerts would add to the volume of alerts seen by providers and contribute to alert noise. A systematic process utilized to prioritize drug-disease interaction alerts before and after implementation will be described.  

**Methods:** The drug-disease interaction alerts were derived from an interaction knowledge base from a third party vendor. The available drug-disease interactions were screened based on clinical significance. A scoring tool was developed in cooperation with the third party vendor to evaluate the severity and relevance of a drug-disease interaction. The scoring tool was utilized to identify a subset of drug-disease interaction alerts that would be activated. Pre-implementation data was gathered by activating the drug-disease interaction module in the electronic health record, but keeping the alerts invisible to end users. The alerts were then made visible to end users and piloted in a designated region of the health system. Post-implementation data was gathered evaluating the rate of prescriber acceptance and override of the alerts. The overall alert rate (including other alert categories) was also assessed. The data was utilized to further refine the subset of activated drug-disease interaction alerts. The alerts were then activated in additional regions of the health system. An additional post-implementation analysis of the remaining drug-disease interaction alerts will be completed to determine the appropriateness of further refinement of the alerts.

**Poster Title:** Cost impact of pharmacist-managed thyroid cancer monitoring service

**Primary Author:** Annie Tran, Kaiser Permanente Santa Clara, CA; **Email:** annie.tran@tu.edu

**Additional Author(s):**
May Jue  
Lawrence Troxell  
Kali Sommer  
Eric Ip

**Purpose:** Our medical center implemented a pharmacist managed thyroid cancer monitoring service five years ago and now manages 100 percent of the thyroid cancer patients. The service has been shown to improve patient adherence rates, reduce duplicate lab orders, and allow for cost reduction within the medical center. The objective of this study is to determine if there is a greater cost-reduction with our medical center’s pharmacist managed thyroid cancer monitoring service when compared to Northern California Region’s usual care by physician specialists.

**Methods:** This study will be submitted to the Institutional Review Board for approval. It will be a multi-center retrospective observational cohort study on the monitoring of thyroid cancer patients across Northern California. The pharmacist managed thyroid cancer monitoring service from our medical center will be compared to the usual care performed regionally by physician specialists. Regional data pull will be used to obtain Northern California patients who have a diagnosis of thyroid cancer. The following data will be collected: date of thyroidectomy, labs ordered and obtained (includes TSH, free T4, and thyroglobulin), patient adherence (defined as patient making the appropriate lab and office visits within 30 days of the scheduled date), hours a pharmacist or physician specialist spend on thyroid cancer patients weekly, and the number of provider encounters per patient. The number of units of time for each provider will be converted to the national median salary of the specific job title (defined as clinical pharmacists, nuclear medicine specialists, endocrinologists, and head and neck surgeons).

**Poster Title:** Effects of increasing BMI on efficacy of dabigatran

**Primary Author:** Sanam Farokhi, Kaiser Permanente Woodland Hills Medical Center, CA; **Email:** sanam.h.farokhi@kp.org

**Additional Author(s):**

**Purpose:** Current dosing recommendations are dabigatran 150mg BID for all patients, excluding renal adjustments. This agent has a large volume of distribution. To date there has been no study to show that outcomes of breakthrough VTE/stroke will change in overweight patients. Excess body weight has been found to be a factor associated with breakthrough VTE/stroke. It is important to identify if excess weight will need dose adjustments or discontinuation of dabigatran. The purpose of this study is to assess whether in patients currently taking dabigatran, if there is an increased risk of VTE/stroke in higher BMI versus normal weight patients.

**Methods:** Study design is a retrospective cohort. Outcomes will be stratified based on patient’s BMI subgroups ( < 24.9, 25-29.9, 30-34.5, >35). Details of the methodology will be determined after consultation with a Biostatistician. Data source will be the electronic medical record (KP HealthConnect) and patients will be captured based on ICD 9/10 codes in patients currently on or previously treated with dabigatran 150 mg BID. Inclusion criteria includes patients > 18 years old with documented previous VTE or documented history of atrial fibrillation taking dabigatran 150 mg BID. Exclusion criteria excludes any history of clotting disorders, heart valve disorder, CrCl < 30 ml/min, active liver disease, pregnancy, co-administration with P-GP inhibitors, all prophylaxis dosing as they are only on the medication for a short duration of time. The primary objective of this study is to assess the risk of breakthrough VTE/stroke in patients currently on dabigatran 150 mg BID based on BMI. The secondary objective is all cause mortality in patients on dabigatran 150 mg BID based on BMI.

Poster Title: Outcomes associated with oral versus subcutaneous methotrexate in patients with rheumatoid arthritis on biological disease-modifying antirheumatic drugs (DMARDs)

Primary Author: Ericka Huckle, Kaiser Permanente-Woodland Hills, CA; Email: erickahuckle@gmail.com

Additional Author(s):
Robert Deamer
Mitchell Pelter

Purpose: The purpose of the research is to determine whether treatment with subcutaneous methotrexate is associated with greater effectiveness compared to oral methotrexate in patients with rheumatoid arthritis. The primary objective is to determine the effectiveness of subcutaneous methotrexate versus oral methotrexate by assessing the time to initiation of biological DMARD (bioDMARD) therapy, and the use of other concurrent DMARD therapies.

Methods: This is a retrospective, observational cohort study in patients with rheumatoid arthritis currently undergoing treatment with a bioMARD. Patients at least 18 years of age with a history of methotrexate use in the Kaiser Permanente (KP) enterprise pharmacy information management system (ePIMS) will be included and stratified according to route of administration. Data to be collected from the KP electronic medical record will include: information at the time of initiation and termination of MTX therapy: erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), glucocorticoid use, use of other DMARDs, findings from serologic testing and erosive status of the disease. The reason for MTX failure and adverse effects associated with therapy will also be obtained from the electronic medical record. Other covariate data to be collected include age, sex, duration of rheumatoid arthritis, and length of MTX therapy. Prescription data from ePIMS will be used to evaluate the effectiveness of methotrexate. Continuous data will be analyzed using a t-test or ANOVA, categorical data will be analyzed using a chi-squared test, and ordinal data will be analyzed using a Wilcoxon-Rank Sum test. Time to treatment failure will be assessed by a log-rank Kaplan-Meier curve.

Poster Title: Evaluation of perioperative medication safety

Primary Author: Sharanjit Kaur, Kaweah Delta Health Care District, CA; Email: shakaur@kdhcd.org

Additional Author(s):
Sarah Stephens
Christopher Patty

Purpose: The purpose of this study is to evaluate the medication use process in the main operating room at Kaweah Delta Health Care District (KDHCD) using a targeted approach to identify errors in the medication use process, define areas for improvement, and increase interprofessional collaboration.

Methods: Approximately 70 surgeries will be observed during the time period of September 2016 thru January 2017 in the main OR at KDHCD. Data will be collected via observational checklists, interviews with OR staff, and review of current policies. Observational checklists were designed to evaluate both safe medication practices during a procedure as well as evaluate how medications are ordered, stored, and dispensed in general. Current practice will then be compared to best practice recommendations of the 2015 Association of Perioperative Registered Nurses (AORN) Guidelines for Perioperative Practice as the primary outcome of the study. The secondary outcome of this study is the number of observed unsafe conditions or medication errors noted during the study period. Identified gaps in best practice recommendations will be used to define future Medication Error Reduction Plan goals or other targeted strategies as deemed necessary by the organization.

**Poster Title:** Assessment of procalcitonin use in a community, teaching hospital

**Primary Author:** Mee Moua, Kaweah Delta Health Care District, CA; **Email:** mmoua@kdhd.org

**Additional Author(s):**
Benjamin Ereshefsky
Nicole Gann

**Purpose:** The aim of this study is to assess the appropriateness of ordering procalcitonin and how procalcitonin results are used to determine the length of antibiotic therapy. The outcomes of this study will be used to develop a procalcitonin policy to guide and optimize antimicrobial use at our institution.

**Methods:** This is a retrospective, observational single-center study. The research protocol will be submitted to the Institutional Review Board for approval prior to beginning data collection. Subjects will be identified by querying the laboratory database for patients who have a resulted procalcitonin value. The electronic medical records will be used to collect data on patients 18 years of age or greater who have had at least one procalcitonin level drawn between June 2016 and August 2016 and were admitted to the hospital with an inpatient stay of at least 72 hours. The following data will be collected: demographic information, past medical history, past surgical history, number of procalcitonin ordered, location of the patient when procalcitonin was ordered, vital signs, laboratory results, radiology reports, antibiotic use during hospitalization, and length of stay. The data collected will be maintained confidentially using a Research Electronic Data Capture (REDCap) electronic database. These data will be reviewed and analyzed to determine how procalcitonin results are currently used at our institution. The primary outcome of this study is the percentage of procalcitonin labs drawn before or within 24 hours of initiating antibiotics. The secondary outcomes include the number of day(s) antibiotics were continued after procalcitonin results were available and the frequency of antibiotic discontinuation if the procalcitonin level was less than 0.25.

**Poster Title:** Clinical and pharmacoeconomic outcomes of a pharmacist-led diabetes safety-net clinic

**Primary Author:** Elliott Asarch, Kern Medical, CA; Email: elliott.asarch@gmail.com

**Additional Author(s):**
Jeff Jolliff
Everett Yano

**Purpose:** To evaluate the clinical and pharmacoeconomic outcomes of a safety-net diabetes mellitus clinic in which patients received care from pharmacists. While previous quality assurance projects have shown positive clinical outcomes from pharmacist managed clinics, less data is available comparing these clinics to “standard care” clinics that do not incorporate a pharmacist in the healthcare team. This study will also compare drug utilization in pharmacist-led clinics compared to clinics that do not utilize clinical pharmacist services.

**Methods:** The study retrospectively evaluated the charts of patients diagnosed with diabetes mellitus who received care from the pharmacist-led diabetes clinic for a minimum of three months. Patients were included in the study if they had a hemoglobin A1C (HbA1c) level greater than or equal to seven percent. Patients were excluded from the study if they had documented non-compliance or if they did not have HbA1c drawn at baseline and after 3 months of treatment. Primary outcomes evaluated included mean reduction of HbA1c and percent of patients that met National committee for Quality Assurance (NCQA) Healthcare Effectiveness Data and Information Set (HEDIS) HbA1c goals. Secondary outcomes evaluated included cost of diabetes related mediations. Student t test analysis was used to evaluate the HbA1c mean reduction and cost analysis. Chi Square analysis was utilized to evaluate the proportion of patients who met HEDIS goals for HbA1c.

Poster Title: Assessment of enoxaparin thromboprophylaxis dosing and anti-factor Xa levels in low-weight patients

Primary Author: Deepika Mohan, Loma Linda University, CA; Email: dmohan@llu.edu

Additional Author(s):
Lisa Hong

Purpose: Using fixed enoxaparin dose for prophylaxis in low-weight patients may be close to weight-based dosing recommended for VTE treatment in these patients. Dosing low-weight patients with prophylactic doses close to total body weight puts them at an increased risk for bleeding and thus, prolong hospitalization. The objective of this study is to evaluate anti-factor Xa levels in low-weight patients receiving enoxaparin for venous thromboembolism prophylaxis.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients who have had anti-factor Xa level measured following prophylactic enoxaparin dose. The following data will be collected: age, gender, actual body weight, height, body mass index, enoxaparin daily dose, baseline serum creatinine, baseline creatinine clearance, serum creatinine when anti-factor Xa is drawn, creatinine clearance when anti-factor Xa is drawn, anti-factor Xa level, hours between when last dose of enoxaparin was administered and when level was drawn, any adverse events, unit of hospital, reason for admit, duration of therapy and duration of hospital stay. The primary end point of the study is to determine the correlation between body mass index and anti-factor Xa levels in low-weight patients. Secondary end points include determining various factors that are associated with anti-factor Xa levels in low-weight patients and to determine the extent to which body mass index affects anti-factor Xa levels in low-weight patients. Data will be analyzed using Pearson correlation analysis between body mass index and anti-factor Xa level. Linear regression will be used to predict association of anti-factor Xa levels and body mass index.

Results: N/A
Conclusion: N/A
**Purpose:** Best practice alerts and recommendations serve as useful tools to guide medication therapy. When used appropriately, automated electronic alerts utilize relevant patient-specific information to optimize medication safety and efficacy. However, when used inappropriately, automated electronic alerts can cause alert fatigue. In regards to patient care, reducing the use of potentially inappropriate medications in older adults is essential for preventing adverse drug events and medication errors and is a quality measure for healthcare plans. The objective of this study is to implement best practice alerts and recommendations to optimize medication safety and quality in older adults while minimizing alert desensitization.

**Methods:** An analysis of potentially inappropriate medications in older adults at a large 908-bed academic university medical center will be performed to determine current utilization. Best practice alerts and recommendations will be instituted via a coordinated effort to optimize medication safety and quality. In order to avoid alert fatigue, a comprehensive review of potentially inappropriate medications will be completed to determine medications of highest priority by cross referencing multiple sources including the American Geriatrics Society Beers Criteria for Potentially Inappropriate Medication Use in Older Adults, the Screening Tool of Older Person’s Potentially Inappropriate Prescriptions, and the Screening Tool to Alert doctors to Right Treatment. The list of potentially inappropriate medications in older adults to be associated with best practice alerts and recommendations will be presented to medication safety committees to ensure appropriate application to clinical practice. Medication safety pharmacists will work in conjunction with pharmacists specialized in informatics to coordinate relevant clinical parameters for the alerts and recommendations. To direct appropriate therapy, best practice alerts, order routes for recommended alternative medications, and safety alerts for inappropriate indications and maximum doses exceeded in older adults will be implemented into the electronic health record system. After incorporation of the alerts and
recommendations, an analysis of utilization of potentially inappropriate medications in older adults will be performed to observe the impact of the process implementation.

Poster Title: Does One Size Fit All? Partial Dose Pegfilgrastim Use in Adult Oncology Patients

Primary Author: Ying Long, Loma Linda University Medical Center, CA; Email: ylong@llu.edu

Additional Author (s): Michelle Spencer-Safier

Purpose: 1). To assess the prevalence of neutropenia, febrile neutropenia, and hospitalization due to febrile neutropenia of partial dose pegfilgrastim in patients receiving chemotherapy; 2). To assess the prevalence of subsequent chemotherapy cycle delay or dose reduction due to neutropenia in patients receiving partial dose pegfilgrastim; 3). To assess the financial impact of prescribing partial dose pegfilgrastim on a health system and society; 4). To explore patient characteristics that are potentially associated with prescribing partial dose pegfilgrastim.

Methods: This study has been approved by the Loma Linda University Institutional Review Board. Patients ≥ 18 years old who received pegfilgrastim less than 6 mg between 3/1/2013 and 8/31/2016 will be selected and their medical chart will be reviewed via Epic Electronic Health Record. The following data will be collected: patient age, gender, race, weight, cancer diagnosis, chemotherapy regimen, pegfilgrastim doses, white blood cell and absolute neutrophil count before and after each chemotherapy cycle. Provider documentation will be reviewed to determine if bone pain was reported, loratidine was recommended, or if fever, febrile neutropenia, hospitalization due to febrile neutropenia occurred during chemotherapy. Pegfilgrastim cost and reimbursement will also be collected through the pharmacy department finance database. All data will be recorded without patient identifiers and maintained confidentially. The primary outcomes are to assess the prevalence of neutropenia, febrile neutropenia, or hospitalization due to febrile neutropenia in patients receiving partial dose pegfilgrastim. All analyses will be conducted using SAS version 9.4. A one sample test of proportions will be used to determine if significant differences exist in pegfilgrastim 6 mg compared to less than 6 mg. Exact proportions and confidence limits will be obtained using a corresponding confidence level of 0.95. This study will also assess annual cost of pegfilgrastim.
waste on societal and institutional levels, and explore patient characteristics potentially associated with pegfilgrastim dose reduction.

**Poster Title:** Evaluation of thromboembolic and bleeding outcomes of obese patients with atrial fibrillation treated with direct oral anticoagulants (DOACs)

**Primary Author:** Dimpa Choksi, Loma Linda University Medical Center, CA; Email: c.dimpa@gmail.com

**Additional Author (s):**
Huyentran Tran
Rebecca Cheung
Michelle Do
Grace Shinn

**Purpose:** Currently, there are four direct-acting oral anticoagulants (DOACs) approved in the United States. While dabigatran is a direct thrombin inhibitor, rivaroxaban, apixaban, and edoxaban are factor Xa inhibitors. Though DOACs exhibit predominately renal elimination, there is limited evidence regarding safety and efficacy of these agents in the obese population. The American College of Chest Physicians (CHEST) guidelines do not include any recommendations in this unique patient population. The purpose of this study is to add to current literature regarding the safety and efficacy of DOACs in obese patients with atrial fibrillation.

**Methods:** This study will be submitted to the Institutional Review Board for approval. We will perform a retrospective cohort study of patients seen at a multi-disciplinary outpatient atrial fibrillation clinic at a large academic medical center between September 1, 2015 and September 1, 2016. Subjects will be at least 18 years old with body mass index (BMI) of greater than or equal to 30 kg m-2 and documented use of a DOAC for acute management or secondary prevention of atrial fibrillation induced thromboembolic events for at least 3 months. Electronic medical records will be reviewed for history of thromboembolic complications and bleeding complications. The primary objective is to assess the frequency of thromboembolic events in obese patients. Secondary objective is to assess the frequency of bleeding events, as defined by the Bleeding Academic Research Consortium (BARC) definition for bleeding, a validated bleed risk assessment tool. Additional subgroup analysis according to baseline characteristics will be
performed e.g., subjects who have switched anticoagulant agents, CHADS2-VASc score, HAS-BLED score, renal function, and obesity classification.

**Poster Title:** Medication reconciliation in an ambulatory cancer center - Impact of the oncology pharmacist  
**Primary Author:** Ariani Waworuntu, Loma Linda University Medical Center, CA; **Email:** awaworuntu@llu.edu

**Additional Author (s):** Kofi Donkor  
Julie Selim  
Gayathri Nagaraj  
Erika Wass

**Purpose:** The aim of this study is to determine whether the current medication reconciliation process at the Loma Linda University Ambulatory Cancer Center is optimal enough to avoid any adverse patient outcomes or whether there are still loopholes that could potentially lead to adverse outcomes. Another purpose of this study is to evaluate the impact that the oncology pharmacist performing a medication reconciliation can have in reducing medication errors and preventing adverse drug events, adverse drug-drug, and drug-disease interactions in patients who are about to start a new chemotherapy regimen in an ambulatory cancer center.

**Methods:** This study has been approved by the Institutional Review Board. This is a prospective study that includes patients who are new to the ambulatory cancer center and starting a new chemotherapy regimen at the outpatient infusion clinic. New patients prescribed with an oral chemotherapy regimen to be taken at home are also included. Patients who are not new to the ambulatory cancer center are excluded. This study will compare the medication reconciliation performed by a clinic nurse at the time of the patient’s first visit to the medication reconciliation performed by a pharmacist during the time of their chemotherapy patient education. The oncology pharmacist will document any medication errors (such as omissions, duplications, dosing errors, or drug interactions) and any interventions that were found at the time of the medication reconciliation by the pharmacist. The oncology pharmacist will then present all findings, interventions, and documentations to the medical oncologist for review. The medical oncologist will assess its accuracy and authenticate the claim. The primary outcome that will be measured is the percent of medication reconciliation errors documented
by the oncology pharmacist. The secondary outcome that will be measured is the percentage of interventions made by the oncology pharmacist.

**Results:** N/A. To be presented.

**Poster Title:** Identification of post coronary artery bypass graft surgery patients at high risk for 30-day hospital readmission: the development of a risk stratification tool

**Primary Author:** Genevieve Noronha, Loma Linda University Medical Center, CA; **Email:** gnoronha2014@gmail.com

**Additional Author (s):**
Hoang-Oanh Tran
Paul Gavaza

**Purpose:** The Centers for Medicare and Medicaid Services (CMS) have recently implemented a readmission penalty for hospitals that have unexpected coronary artery bypass graft (CABG) 30-day readmission rates higher than the national average. Currently, there is no guidance for pharmacists on how to stratify patients based off of 30-day readmission risk after a CABG procedure. The purpose of this study is to provide further guidance, specifically for transitions of care pharmacists, by offering a risk stratification tool. This stratification tool will aid in identifying and directing resources to patients at high risk for an unplanned 30-day readmission after a CABG procedure.

**Methods:** This study will be submitted to the institutional review board for approval. A pharmacy resident will utilize the electronic medical record system to identify patients from October 2015 to January 2017 who underwent a CABG procedure. Patients will be separated according to readmission status with non-readmitted patients serving as the control group. The resident will retrospectively assess factors such as age, gender, race, body mass index, comorbidities, previous heart procedures, perioperative prophylactic antibiotics, bleeding requiring reoperation, gastrointestinal bleeding, renal failure, respiratory failure, discharge destination, length of stay, days to first follow up appointment and best practice measures for cardioprotective medications. The study will assess each risk factor, utilizing the independent t-test or chi-square test between the two groups based on data type. The next step will involve performing bivariate and multivariate logistical regression analyses to identify the risk factors that influenced 30-day readmission. The data will then be assessed to determine significant predictors of readmission which will be incorporated into a risk stratification tool for use by the pharmacists of the transitions of care team.

Poster Title: Vasopressin use in adult code blue outcomes before and after 2015 American heart association (AHA) guideline updates for cardiopulmonary resuscitation and emergency cardiovascular care

Primary Author: Marym Molki, Loma Linda University Medical Center, CA; Email: mmolki@llu.edu

Additional Author(s):
Christopher Hauschild

Purpose: Inpatient healthcare institutions have emergency response teams, commonly known as code blue teams, that provide advanced cardiovascular life support (ACLS) to unresponsive patients. AHA guidelines for cardiopulmonary resuscitation and emergency cardiovascular care provide standard of care recommendations for code blue management. One of the major changes in the November 2015 guideline was the removal of vasopressin as an alternative to one dose of epinephrine in the ACLS treatment algorithm. The purpose of this study is to evaluate whether there is value in maintaining vasopressin in hospital code carts to administer as an alternative to one dose of epinephrine.

Methods: This retrospective chart review study looks at approximately 300 subjects between 18-89 years of age at a large academic center in San Bernardino county, California. Patients who received epinephrine or vasopressin during a code blue from January 1, 2015 to August 31, 2016. The primary outcome of this study is the difference in hospital survival to discharge between the two arms of the study. The first arm includes patients who received epinephrine only, and the second arm includes patients who received vasopressin with or without epinephrine. The secondary outcome compares the difference in the rate of hospital survival to discharge before and after publication of 2015 American heart association (AHA) guideline updates for cardiopulmonary resuscitation and emergency cardiovascular care. Another secondary outcome looks at percentage change in the use of vasopressin before and after publication of 2015 guideline recommendations update.

Poster Title: Prevention of paclitaxel hypersensitivity reactions: Oral dexamethasone given night before and morning of paclitaxel versus short-course intravenous dexamethasone infusion given 30 minutes prior to paclitaxel

Primary Author: Jade Lee, Loma Linda University Medical Center, CA; Email: jadelee@llu.edu

Additional Author(s):
Kofi Donkor
Julie Selim
Adorina Moshava
Arbella Moshava

Purpose: Administration of paclitaxel is commonly associated with hypersensitivity reactions and as a result, patients receiving paclitaxel must be premedicated with corticosteroids, H1 receptor antagonists, and H2 receptor antagonists prior to infusion. Currently there are no standardized methods for administration of premedications. This study aims to determine the most effective and safest methods of administering premedications, particularly corticosteroids, to cancer patients who are receiving paclitaxel as monotherapy or regimen containing paclitaxel.

Methods: A retrospective chart review of all adult patients treated with paclitaxel, as monotherapy or as part of a combination regimen, for any type and stage of cancer at an ambulatory cancer center between July 2013 and August 2016 will be conducted. Patient demographics, chemotherapy cycle, paclitaxel dose and rate of infusion, premedications, administration schedule of premedications, and occurrence or absence of hypersensitivity reactions will be collected from electronic medical records. The primary outcome of this study is the percentage of patients who experienced hypersensitivity reactions with paclitaxel infusion. The incidence of hypersensitivity reactions will be compared between the different premedication methods. This study was approved by the institutional review board.

Poster Title: Evaluation of clinical outcomes using intravenous immune globulin dosed by ideal body weight

Primary Author: Amanda Golay, Loma Linda University Medical Center, CA; Email: agolay@llu.edu

Additional Author(s):
Norm Hamada

Purpose: Intravenous immune globulin (IVIG) is a weight based medication that is commonly dosed by actual body weight as recommended by the prescribing information. Due to the high cost of the medication, some institutions have started using ideal body weight to dose instead of actual body weight. However, there have not been studies to show that dosing by ideal body weight maintains the effectiveness of IVIG. The purpose of this study is to determine the clinical outcomes of using IVIG based off of ideal body weight.

Methods: The study will be submitted to the health system’s institutional review board. Data collection will be done as a retrospective study of patients who have received IVIG based off of their ideal body weight at an academic teaching hospital from February 13, 2015 to November 18, 2015. Patients will be identified through the use of electronic medical records and each patient will only be included once. The study will be a continuation of a previous study that focused on the impact of selection guideline and ideal body weight dosing on intravenous immune globulin. Clinical outcomes will be determined through documentation in the electronic medical records after a patient has been given IVIG.

Poster Title: Evaluating incidence of bone marrow suppression associated with prophylactic sulfamethoxazole-trimethoprim versus inhaled pentamidine in a pediatric kidney transplant population

Primary Author: Jiten Patel, Lucile Packard Children's Hospital Stanford, CA; Email: jipatel@stanfordchildrens.org

Additional Author(s):
Angela Beadles
Abanti Chaudhuri
Paul Grimm

Purpose: Sulfamethoxazole-trimethoprim (SMX-TMP) is the preferred medication for prophylaxis of Pneumocystis Jiroveci Pneumonia (PJP) for pediatric kidney transplant patients at our institution. Inhaled pentamidine is an alternative to SMX-TMP and is given for the first dose of prophylaxis because SMX-TMP can cause bone marrow suppression. The patients’ white count and renal function are monitored after transplant to assess appropriateness to switch to SMX-TMP. The purpose of this study is to investigate and compare the frequency of leukopenia with SMX-TMP and inhaled pentamidine in a pediatric kidney transplant population and compare the cost-benefits of each regimen.

Methods: This study will be reviewed by our institutional review board. A retrospective chart review will be performed, including pediatric patients from 1 to 21 years old who have undergone kidney transplantation at our institution from January 1, 2010 to June 30, 2016. Patients will be excluded if they are less than 1 year old or greater than 21 years old, have a sulfa allergy, received a previous transplant, prescribed another medication for PJP prophylaxis, or received prophylaxis for any other indication (e.g. rejection, severely immunocompromised). Electronic medical records will be reviewed for patients for the first 6 months post-transplant. White blood cell count (WBC), absolute neutrophil count (ANC), and serum creatinine lab values will be reviewed. Medication adherence will be assessed by refill history. The primary outcome will be assessing the incidence of leukopenia, defined as WBC less than 5.0, associated with taking sulfamethoxazole-trimethoprim. Secondary outcomes include comparing duration of prophylaxis with sulfamethoxazole-trimethoprim versus inhaled pentamidine, agents used
for transplant induction therapy and duration of therapy, cost analysis, and review of hospitalizations in the first 6 months post-transplant.

Poster Title: Frequency of severe infusion reactions associated with rapid infusion of infliximab without pre-medications

Primary Author: Stephanie Hutsell, Lucile Packard Children's Hospital, Stanford, CA; Email: shutsell@stanfordchildrens.org

Additional Author (s):
May Wu
KT Park

Purpose: Infliximab is associated with severe infusion related hypersensitivity reactions. Medications are often administered prior to infusion to prevent reactions. Pre-medications have some benefit in reducing infusion reactions once an event has occurred. It is unclear if pre-medicating in the absence of an infusion reaction serves any additional benefit. We aimed to determine (1) the variability in the standard-of-care that may be associated with increased risk of an adverse reaction during an infliximab infusion; and (2) the number of patients receiving rescue epinephrine and/or rapid response / code blue events as the result of a reaction to infliximab.

Methods: We performed a review of ambulatory infliximab infusions between January 2014 and December 2015. Hospital-wide longitudinal data were available from a total of 427 infusions in 2014 and 466 infusions in 2015. This information was cross-referenced with pharmacy records of epinephrine removal from the automated dispensing cabinets, and with data collected by the hospital code committee regarding rapid response and code blue calls.

Results: During the two year review period, two major practice changes occurred. In 2015 the gastroenterology service converted to a 1 hour infliximab infusion, while the rheumatology maintained their infusions at 3 hours. Also in 2015, one provider omitted pre-medications from all infliximab infusions. Over a 1 year time span, these changes resulted in a 51% decrease in total infusion hours (1281 to 630 infusion hours), despite a 9% increase in total number of infusions. There were no epinephrine administrations associated with infliximab maintenance infusions in 2014 or 2015. Additionally, there were no code blue/ rapid response calls associated with infliximab maintenance infusions.
**Conclusion:** In our experience, the frequency of severe infliximab infusion reactions requiring epinephrine is very low, and corresponds with recently published literature. Infusing infliximab over 1 hour rather than 3 and omitting standard pre-medications did not increase the risk for severe infusion reactions. Our findings highlight a quality-improvement opportunity to standardize infliximab infusions to streamline care in an ambulatory setting.

Poster Title: Implementation of a 48 hours antibiotic time-out in a community hospital

Primary Author: Vivian Nguyen, Palomar Health, CA; Email: vivian.nguyen@palomarhealth.org

Additional Author(s):
John Engelbert

Purpose: Antibiotics that are started empirically are often inappropriate for ongoing therapy. Diagnostic information used in reassessing antimicrobial therapy is usually available between 48 and 72 hours. Regulatory requirements endorsed by the CDC, National Quality Forum, and 2017 Joint Commission Antimicrobial Stewardship Standard will require hospitals to institute a program that will provide for a uniform, systematic, and comprehensive assessment of all antibiotics that are continued beyond 48 hours. The objective of this study is to implement an antibiotic time-out to guide providers to reassess the continuation of antimicrobial therapy past 48 hours and to measure the impact.

Methods: This quality improvement project is currently pending approval from the Institutional Review Board and will be implemented in three phases. The first phase will consist of the pharmacy department collaborating with a team of physicians to develop content for the 48 hours antibiotic time-out. After content is developed, approval from the Antibiotic Subcommittee will be obtained for the development of the time-out. In the second phase, the IT department will begin building the electronic time-out note template into the hospital’s electronic medical record, Cerner. Once implemented, the pharmacy department will provide education to the medical staff on how to complete a time-out. A time-out alert will fire at the primary care team for patients on antibiotics and expectation would be for the physicians to review all components and take action if needed. In the third phase, data on compliance, antibiotic days of therapy and hospital-acquired infections will be collected prior to and after implementation of the time-out. Initial data analysis may be limited to a select disease state such as sepsis, a specific group on antibiotics such as empiric vancomycin, or a care area such as intensive care unit dependent on the timeline for informatics implementation.

Poster Title: Integration of Rapid diagnostics in a Health-system Antibiotic Stewardship Program

Primary Author: Garrett Rueda, Palomar Health, CA; Email: garrett.rueda@palomarhealth.org

Additional Author(s):
Michael Kruse
John Engelbert

Purpose: Rapid diagnostic technology has expedited microbe identification as compared to conventional culturing methods. The objective of this project is to integrate rapid diagnostics with antimicrobial stewardship in a health-system, improve antibiotic de-escalation therapy, and provide pharmacists and medical staff with evidence based algorithms to aid in targeted therapy, and identify measures to justify the use of rapid diagnostic technologies.

Methods: This study will be submitted to the Institutional Review Committee for waiver as an evidence-based practice implementation. A literature search will be conducted to establish the current role of rapid diagnostics in antimicrobial decision making, specifically in the antibiotic stewardship program. The background information will also include contacting institutions who have already implemented rapid diagnostics into their health system and the change it made with their antimicrobial stewardship program, their pharmacy staff’s and physician staff’s antimicrobial choices. An algorithm will be developed that describes the use of rapid diagnostics in decision-making. A clinical education package will describe the background, components and value of these new techniques in antimicrobial stewardship. This will be prepared and distributed to the pharmacy and medical staff. After the education has been completed, the project will propose future quality improvement measures to justify rapid diagnostics and antimicrobial stewardship.

**Poster Title:** Creation of phased PowerPlans for obstetric patients

**Primary Author:** Kristine Carrasco, Palomar Health, CA; **Email:** kristine.carrasco@palomarhealth.org

**Additional Author(s):**
Aaron Weigelt

**Purpose:** Given the unpredictability of patients’ requirements during child birth, obstetricians try to anticipate all the needs that may arise by using multiple order sets, or PowerPlans found in Cerner, an electronic medical record program. However this leads to duplicate orders, confusion among medical staff providing care to the patient, and a potential for medication error. A solution to this problem is using a phased plan which may reduce duplicate orders, confusion, and allow for timely verification of orders by pharmacists.

**Methods:** This study is submitted to the Institutional Review Board for approval. In order to create phased PowerPlans, the first of its kind for this facility, current plans (which include medications, patient care orders, and laboratory testing) used by obstetricians will be evaluated and reviewed during the content development step with input from the obstetrics (OB) department. Once the content development step is complete, the plans will be taken to the OB department committee meeting for approval. The approved content will then go to the informatics committee to begin the build for the phased plan. Prior to the plan going live, there will be one to two weeks of testing period while education on the new workflow will roll out to the obstetric doctors, nurses, and all pharmacists. The following data will be collected prior to and after the launch of the phased PowerPlan: occurrence of duplicate orders for pain, nausea and non-steroidal anti-inflammatory drugs along with time to activation of post-partum pain orders.

Poster Title: Implementation of dose range checking (DRC) in a community hospital electronic health record (EHR)

Primary Author: Taylor Rotunno, Palomar Health, CA; Email: taylor.rotunno@palomarhealth.org

Additional Author(s):
Diana Schultz
Juhi Jain

Purpose: It is well recognized that medication errors cause significant morbidity and mortality each year and that many of these errors are preventable. It has been estimated that up to 60% of medication errors involved incorrect doses or administration frequencies. Clinical decision support (CDS) of drug dosing has the potential to significantly improve patient safety. However, in many cases the drug-dose CDS standard content needs optimization to be effective, as its usefulness is often limited by clinically irrelevant alerts. The study objective is to assess the effectiveness of implementing DRC in a community hospital’s EHR.

Methods: An algorithm will first be created to help aid in the selection of medications in which implementing DRC would be beneficial. A second algorithm will be developed to use as a step by step decision tree that will guide the user in creating patient specific DRC content for any medication. Fifteen to twenty medications will then be selected from a list of top prescribed medications that are regularly implicated in medication errors. DRC will then be implemented into the EHR for these medications using the algorithm that was created. Data will be collected from the EHR to determine what percentage of DRC alerts result in an override, a discontinued order, or in the order detail being changed. This information will be used to assess the relevance of the alert. Additionally dose information for two medications with protocols will be evaluated pre and post intervention to assess whether the implementation of DRC has resulted in a significant increase in adherence to dosing protocols.

**Poster Title:** Development of an Antimicrobial Stewardship Performance Dashboard

**Primary Author:** Natasha Novikova-Miller, Palomar Health, CA; **Email:** natasha.e.novikova@gmail.com

**Additional Author(s):**
Brandon Bailey

**Purpose:** Clinical dashboards are emerging as a valuable tool in assessment of clinician performance and impacting quality by providing relevant and timely information. Literature has suggested that the implementation of well-designed clinical dashboards can favorably impact patient care and outcomes. Antimicrobial stewardship programs play a critical role in promoting the appropriate use of antibiotics, and will likely benefit from dashboards that track performance and outcome data, as well as allow comparison between individual providers. The main objective of this implementation project is to describe the process, requirements and limitations of developing an antimicrobial stewardship performance dashboard for a large healthcare district.

**Methods:** The requirements to create a clinical dashboard will be researched and multiple processes and products will be evaluated based on organizational goals and needs. Key metrics to assess antimicrobial prescribing and related outcomes will be selected and may include the following: a) treatment of bronchitis in the emergency department (avoidance of antibiotic coverage); b) urinary tract infection (avoidance of antibiotics in asymptomatic bacteriuria); c) Clostridium difficile infection (infection rate during hospitalization); d) sepsis (mortality rate); e) febrile neutropenia (mortality rate); f) surgical prophylaxis (avoidance of antibiotics post-closure).

Once key requirements and metrics are identified, the input from key stakeholders will be solicited, at which point the goals will be reviewed, validated and finalized. This project will be submitted to the Institutional Review Board for approval. Data to be displayed within the dashboard will be extracted from the Electronic Medical Record. The most feasible format to present the results will be determined, with options ranging from a simple table format to pie charts and bar graphs. The design of the dashboard will be implemented by the information technology department with the primary goal of displaying metrics and outcome measures as
both aggregate data and at the individual provider level. Throughout the project, the barriers in developing and implementing a clinical dashboard will be identified and reported.

Poster Title: Retrospective comparison of empiric piperacillin-tazobactam therapy and empiric carbapenem therapy in clinical outcomes for patients with extended-spectrum beta-lactamase bacteremia

Primary Author: Christine Choi, Providence Holy Cross Medical Center, CA; Email: christine.choi2@providence.org

Additional Author(s):
Daniel Salas
Snezana Naumovski
Nicole Cho
Jiwon Kim

Purpose: The prevalence of extended-spectrum beta-lactamases (ESBLs) in gram-negative bacteria has increased over the past decade. Existing literature indicates that carbapenems are the drug of choice for treating patients infected with ESBL-producing organisms. However, the use of carbapenem contributes to the increasing emergence of carbapenem-resistant Enterobacteriaceae. This type of resistance may be controlled by reducing carbapenem usage and identifying alternative antibiotics that can be used empirically for suspected ESBL infections, including bacteremia. The objective of this study is to compare treatment outcomes between patients initially treated with piperacillin-tazobactam and patients treated with a carbapenem for ESBL bacteremia.

Methods: This retrospective, multicenter study will investigate patients admitted between January 2013 and September 2016 with confirmed ESBL bacteremia. Patients will be identified using consolidated reports of all patients with ESBL bacteremia. Electronic medical records will be reviewed to categorize patients into one of two cohorts: empiric treatment with piperacillin-tazobactam and empiric treatment with a carbapenem (imipenem-cilastatin, meropenem, or ertapenem). The data points to be collected are demographics and clinical parameters including preexisting medical conditions, organism and time of first positive blood culture, source control status, initial empiric therapy (defined as initial antibiotic(s) received for 48 hours or more), initial effective therapy (defined as agent to which isolated organism is reported susceptible in vitro), days of effective therapy, length of stay, and outcome at day 14. The primary outcome
measure will be mortality within 14 days from the first day of detectable bacteremia, where day 1 will be defined as the day of first positive blood culture.

**Poster Title:** Reducing the number of automated dispensing machine overrides in perioperative areas with the goal of improving patient safety  

**Primary Author:** Robert Ng, Providence Tarzana Medical Center, CA; **Email:** robert.ng@providence.org  

**Additional Author (s):**  
Susan Wee  
Goorgen Boghossian  
Crystal Hung  
John Padgett  

**Purpose:** Regulatory agencies require that all medication orders be reviewed and verified by a pharmacist prior to medication administration. Healthcare providers may perform an automated dispensing machine (ADM) override in emergent situations when the status of the patient’s health might be compromised. Currently, the medication override rate in the perioperative area is above the acceptable threshold. Literature has shown that patient safety is affected if medication administration occurs prior to pharmacy review. The purpose of this study is to identify workflow weaknesses, inadequacies, and gaps. The goal is to reduce override rate through intervention and education.  

**Methods:** This is a prospective study with the goal of improving patient care during the perioperative process. Baseline and prospective data will be collected through automatic cabinet dispensing records and electronic health records. The information collected will include number of overrides, timing of medication ordering processes, and the efficiency of patient transfers. The pharmacy resident will review preliminary information to identify specific deficiency before baseline data will be collected. The pharmacy resident will provide continuous real time education to staff, streamline methods of workflow, and provide information to adjust ADM settings. The primary objective of this study is to reduce the number of ADM overrides in the hospital’s perioperative areas. The secondary objective is to improve workflow efficiency and promote better coordination of care between the perioperative department and pharmacy.

**Poster Title:** Improving nursing compliance with intravenous smart pump drug library usage at a community hospital

**Primary Author:** Marjon Mirmiran, Providence Tarzana Medical Center, CA; **Email:** marjon.mirmiran@providence.org

**Additional Author (s):**
Susan Wee
Goorgen Boghossian
Crystal Hung

**Purpose:** Many hospitalized patients are prescribed a number of intravenous (IV) medications including high risk medications. IV smart pump drug libraries have shown to increase patient safety by generating alerts to reduce the likelihood of adverse drug events associated with IV infusion errors. A review of the IV smart pump system at our facility revealed an underutilization of the drug library and subsequently an area for improvement. The primary objective of this study is to improve drug library compliance through a collaborative interdisciplinary approach consisting of drug library revisions, nursing staff education, and auditing.

**Methods:** This is a prospective quality improvement study. Baseline data will be collected retrospectively from the IV smart pump utilization reports and prospectively through real time auditing to identify areas for improvement in critical care units and the cardiovascular unit. The data collected will include number of infusions using the smart pump drug library, infusions using simple delivery, alerts, and override variance medications. Baseline data will also consist of specific medications that were infused without utilizing the drug library during an allocated period of auditing. Based on this data and nursing staff feedback, revisions will be made to the smart pump drug library. Revisions will include the addition of new medications, and the rearrangement of the medication display list. Drug library limits and infusion units for specific medications will also be revised to match the systemwide titration protocol. In addition, targeted nursing staff education will take place to reinforce the importance of utilizing the drug library with the corresponding limits followed by daily auditing.

Poster Title: Impact of a Guideline-Based Treatment Algorithm and Pharmacy-Driven Education on Clostridium difficile Infections in an Academic Medical Center

Primary Author: Jeremy Price, Riverside University Health System, CA; Email: jeremy.price@ruhealth.org

Additional Author(s):
Nikita Patel
Made Sitjita
Gary Thompson

Purpose: Adherence to Clostridium difficile infection (CDI) treatment guidelines has shown significant improvement in CDI recurrence and mortality, and has been associated with shorter length of stay in previous studies. Unfortunately, adherence is inconsistent and standardized treatment is fairly uncommon. The purpose of this study is to assess adherence to guideline-based treatment for CDI before and after implementation of a standardized, American College of Gastroenterology (ACG) guideline-based treatment algorithm and pharmacy-driven provider education. Additionally, the study will assess the impact of a standardized treatment algorithm on outcomes in patients treated for CDI.

Methods: This prospective, observational study will assess guideline adherence and patient outcomes (clinical cure, length or stay, recurrence, and mortality) in two groups – patients treated for CDI between January and June 2016, prior to implementation of a standardized, guideline-based treatment algorithm and pharmacy-driven education versus patients treated for CDI between January and June 2017, after implementation of the algorithm and pharmacy-driven education. CDI-related drug cost before and after implementation will also be assessed. Patients treated for CDI will be identified through review of electronic and paper medical records and the following data will be collected: demographic information, hospital admission and discharge dates, pertinent vitals and microbiology data, CDI status and 60-day recurrence, prescribed and administered medications, CDI-related surgical intervention, and 60-day all-cause mortality.

Poster Title: Critical Care Pharmacist and Pharmacy Resident Integration into Healthcare Team and Optimization of Drug Therapy in Critically Ill Patients

Primary Author: Tiffany Truong, Santa Clara Valley Health and Hospital System, CA; Email: tiffany.truong@hhs.sccgov.org

Additional Author(s):
Gina Marotto

Purpose: To integrate the critical care pharmacist and pharmacy resident into the critical care healthcare team and to demonstrate their presence optimizes medication therapy management through chart review and rounding with the critical care team.

Methods: This study will be submitted to the Institutional Review Board for approval. Currently at my institution, there is one pharmacist monitoring four intensive care units (trauma, surgical, medical, and coronary). Due to time constraints, this pharmacist is only able to round with the medical intensivists. By adding a second decentralized pharmacist or resident to monitor the trauma and surgical units, the workload will be more evenly split. This allows more time for the pharmacist to better optimize medication management through chart review and expanded multi-disciplinary team rounding with surgeons and intensivists. Patient interventions and clinical monitoring will be documented in the electronic medical record (Health Link) using i-vents, which is a documentation tool used only by pharmacists to document drug related interventions and monitoring. The primary outcome of this study is to measure the number of clinical interventions that were accepted and rejected for antibiotic de-escalation, dose optimization or adjustment, drug-drug interaction, and therapy recommendations before and after de-centralization of the pharmacist or resident. After the two month study period, the pharmacy resident will retrospectively review all intensive care unit patients’ medical records to collect all pharmacist interventions (i-vents). By decentralizing another pharmacist or resident, we hope to increase the number of interventions to optimize medication management and improve relationships with nurses and providers in the trauma and surgical units.

**Poster Title:** Identification of contributing factors leading to 30-day hospital readmissions for patients with heart failure

**Primary Author:** Thuy Hoang, Santa Clara Valley Health and Hospital System, CA; **Email:** thuy.hoang@hhs.sccgov.org

**Additional Author (s):**
Lawrence Dang
Jessica Song
Aravind Swaminathan

**Purpose:** Despite quality improvement campaigns, identifying risk factors and preventing heart failure (HF) hospital readmissions remains a challenge. Santa Clara Valley Medical Center (SCVMC), a county hospital with a diverse patient population commonly underrepresented in the medical literature, has noted an increasing trend in 30-day readmissions. The objective of this project is to identify the top five reasons for 30-day all-cause readmissions in HF patients at SCVMC. Additionally, an effort to increase the use of SCVMC pharmacies is necessary to better manage and monitor patients with HF. This study also aims to identify the top reasons why patients utilize non-SCVMC pharmacies.

**Methods:** This study has been approved by the Institutional Review Board (IRB) at SCVMC. A retrospective chart review will be performed on patients admitted with a primary diagnosis of HF between July 1, 2015 and June 30, 2016. Baseline demographics, social history, hospitalization histories, HF clinical data, comorbidities, medication history, HF clinic enrollment, discharge plans, and pharmacy utilization will be collected. Descriptive statistics will be used for analysis of the data collected. A comprehensive corrective plan will be implemented by January 2017 to address the top reasons for readmissions and external pharmacy usage. A follow-up study pending IRB approval will examine the impact on 30-day all-cause readmission rates and SCVMC pharmacy utilization.

Poster Title: Reducing opioid overdose through implementation of a county-wide naloxone take-home program and creation of an opioid prescribing protocol.

Primary Author: Lawrence Chang, Santa Clara Valley Health and Hospital System, CA; Email: lawrence.chang@hhs.sccgov.org

Additional Author(s):
Khanh Pham
Charmaine Gallego
Jennefer Yoon
Narinder Singh

Purpose: In 2014, a total of 28,647 American lives were taken by opioid overdoses, equivalent to one life every 18 minutes. Unless something is done, both the prevalence and incidence of opioid-related deaths will continue to ravage our communities. The aim of this project is to reduce opioid overdose deaths, first by increasing patient access to naloxone, the antidote to opioid overdoses. Second, we will analyze baseline opioid-prescribing habits of county physicians and address them in a clear, comprehensive and evidence-based opioid-prescribing protocol outlining proper initiation, management and tapering down of opioids.

Methods: Once approval is obtained from the hospital's Institutional Review Board, we will start by implementing naloxone-dispensing protocols in 11 county pharmacies in accordance with regulations set by the California Board of Pharmacy and the Medical Board of California. In addition to targeting pharmacies, we will expand take-home naloxone programs to local community organizations that interact with high-risk patients; these include shelters, drug treatment programs, and clinics. Non-pharmacy dispensing sites will be authorized to distribute naloxone kits through standing orders issued by the sites’ respective medical directors. Next, we plan to promote prescriber education through the assembly of a clear, evidence-based opioid prescribing protocol outlining proper procedures for the initiation, management, and tapering down of opioids in both acute and chronic settings. To identify any high-risk behaviors in need of attention, we will obtain a baseline measure of current opioid prescribing habits by county physicians. To do so, we will first generate a list of patients taking an opioid dose greater than or equal to 90 Morphine Milligram Equivalents per day. (We will target the following
Afterwards, we will undergo retrospective chart review to assess the appropriateness of those opioid therapies using recommendations from the latest 2016 CDC Guidelines on Chronic Pain Management. All physicians' names will be blinded during analysis of the results.

**Poster Title:** Determining the distribution and identifying potential interventions of antibiotic prescriptions in outpatient clinics

**Primary Author:** Nhu Nguyen, Santa Clara Valley Health and Hospital System, CA; **Email:** nhuquynh.nguyen@hhs.sccgov.org

**Additional Author(s):**
Sherman Lau
Phoebe Li
Harleen Sahni
Timothy Ong

**Purpose:** Overuse of antibiotics is a major public health concern that is associated with increased morbidity and mortality from the development of bacterial resistance, secondary infections, and serious adverse drug events. Healthcare and community settings are encouraged to develop an antibiotic stewardship program in order to preserve the efficacy of existing antibiotics. The primary purposes of this study are to characterize and describe the distribution of antimicrobial prescribing practices in the outpatient setting at my institution, and to identify potential interventions to improve antibiotic utilization and reduce the occurrence of antibiotic resistance.

**Methods:** This study will be submitted to the Institutional Review Board for approval. Antibiotic prescriptions information from patients 18 years or older will be collected and a set number will be randomly selected from January 2016 to March 2016 from each class of the most commonly prescribed antibiotics in the outpatient clinics, excluding specialty clinics. Antibiotics will be assessed for clinical appropriateness defined by the Infectious Diseases Society of America (IDSA) guidelines for indication, dosing, frequency, duration, drug-drug, and drug-disease state interactions. Indications that are not addressed by IDSA will require consultation with an Infectious Disease specialist, John Hopkins Antibiotic Guide, or the Sanford Guide. Patient’s specific data will include age, gender, ethnicity, height, weight, allergies, reaction to allergies, most recent serum creatinine, and culture results. Results will be used to educate physicians and pharmacists in the form of in-services, and if necessary, dosing cards, or HealthLink alerts. Primary outcomes of the study include describing the distribution of antibiotics prescribed in
the ambulatory setting, and identifying potential interventions to improve antimicrobial usage through a retrospective evaluation of clinical appropriateness. Secondary outcomes include adverse drug reactions 30-days post-script that require hospitalization, association of patient’s characteristics to frequency of antibiotic prescribing, and number of patients greater than 65 year-old who do not have a baseline serum creatinine in the last 12 months for renally adjusted antibiotics.

**Poster Title:** Evaluation of medication histories collected by pharmacy technicians and pharmacy students in the emergency department

**Primary Author:** Christie Kim, Santa Clara Valley Health and Hospital System, CA; **Email:** christie.kim@hhs.sccgov.org

**Additional Author (s):**
Marcus Dong  
Maily Nguyen  
Kinal Shah  
Narinder Singh

**Purpose:** Traditionally, patient medication histories are collected and documented in the medical record by nurses. Dedicating this responsibility to pharmacy technicians and pharmacy students can provide nurses with more time to focus on other patient care activities. The primary objective of this study is to compare the accuracy of medication histories collected by pharmacy technicians/students to medication histories collected by nurses in the emergency department. If the results are similar between the two groups, we plan to transition the medication history responsibility from nurses to pharmacy technicians/students in the future.

**Methods:** During a 4-week pilot test in the emergency department, a pharmacy resident will observe the technician/student during the medication history process to identify if transcription errors were made during the patient interview, call to the outpatient pharmacy, and documentation of the medications into the electronic medical record. After the pilot test, we will conduct a retrospective study to evaluate the medication histories. The following data will be obtained from each medication history: patient age, gender, preferred language, admission unit, type of outpatient pharmacy (e.g. internal or external), number of documented prescriptions, OTC and high-alert medications, number and type of discrepancies (e.g. incorrect or missing medication, strength, dose, route, frequency, indication, last dose taken, allergy information, days supply, and last date dispensed), and number of accurate medications. After the data is collected from each medication history, the accuracy rate will be determined for the technicians, students, and nurses by identifying the number of accurate medication histories out of the total number of medication histories collected.

**Poster Title:** Evaluation of a medication synchronization program: Impact on adherence and patient satisfaction

**Primary Author:** Yuumi Miyazawa, Santa Clara Valley Health and Hospital System, CA; **Email:** yuumi.miyazawa@hhs.sccgov.org

**Additional Author(s):**
Geary Wong
Belinda Paz
Phoebe Li
Narinder Singh

**Purpose:** Medication synchronization, where all medications are refilled on the same day each month, has been shown to improve medication adherence, especially in patients with low baseline adherence. The objective of this study is to evaluate and describe the impact of a medication synchronization program implemented at one of ten outpatient pharmacies at a 574-bed county hospital, with the intent of offering this service to all patients utilizing the hospital’s pharmacies.

**Methods:** This study will be submitted to the Institutional Review Board for approval. Retrospective and prospective chart review of patients eligible and enrolled in the medication synchronization program will be conducted to collect the following data: age, gender, race/ethnicity, language, zip code, insurance status/type, social history, chronic disease state(s), medication dispense dates, number and drug class of medications synchronized, and method of medication delivery. Eligible patients are defined as any patient who filled two or more chronic medications at the county hospital's pharmacy three months prior to medication synchronization program implementation, any patient referred by providers of the institution, or any patient expressing interest in enrollment. All data collected will be maintained confidentially and only patients who agree to enrollment in the medication synchronization program will be included. Proportion of days covered (PDC), as defined as the proportion of days supplied by at least one drug in the class based on prescription fills during a measurement period, will be calculated to measure medication adherence before and after enrollment in the synchronization program. Collected data will be analyzed using the paired Student's t-test to
compare PDC before and after enrollment. A survey will be sent out to patients at the end of the study period to evaluate patient satisfaction regarding enrollment in the program.

Poster Title: Comparing outcomes following pharmacy-driven interventions to improve patient compliance with laboratory monitoring for chronic medications: A randomized trial

Primary Author: Yunchen Ding, Santa Clara Valley Health and Hospital System, CA; Email: yunchen.ding@hhs.sccgov.org

Additional Author(s):
Oliver Hsu
Phoebe Li
Narinder Singh

Purpose: Improving patient compliance to routine laboratory monitoring for chronic medications is an effort to reduce preventable adverse drug events and promote safe outpatient prescription medication use. Community pharmacists are often the most accessible healthcare providers to patients. Therefore, they are in an optimal position for promoting patient compliance with laboratory monitoring in outpatient settings. This study aims to evaluate and compare the effectiveness of four pharmacy-driven interventions in improving overall patient compliance with routine laboratory monitoring for chronic medications in ambulatory settings at Santa Clara Valley Health and Hospital System.

Methods: This study has been approved by the Institutional Review Board. A retrospective review will be conducted to assess the baseline of overall compliance rate of routine laboratory tests for target chronic medications and identify eligible non-compliant patients. The target chronic medications include angiotensin converting enzyme inhibitors, angiotensin receptor blockers, diuretics, and digoxin. The following data will be collected: age, gender, ethnicity, preferred language, primary care physician location, primary pharmacy location, number of primary care visits within past year, number of emergency department visits within past year, the class and indication of the chronic medication, total treatment days within the past year, comorbidities, and the status of laboratory test. Patients will be randomized into four arms in a 1:1:1:1 ratio to receive letter reminders, automated phone call reminders, phone call consultations by pharmacists, or in-person consultations by pharmacists. The compliance rate of digoxin patients is anticipated to be significantly different from the other target medications. To minimize possible confounders, the four arms will be matched to have the same number of
digoxin patients. The institution Language Services will be utilized for patients whose preferred languages are not English. Patients will be de-identified and coded. Data will be password protected, and only shared among the researchers of this study. The percentage of patients who completed recommended laboratory tests after receiving each intervention will be measured and compared.

Poster Title: Safety and feasibility of rapid infusion rituximab over 90-minutes: a single infusion center, prospective study

Primary Author: Jessica Lu, Santa Clara Valley Hospital and Health System, CA; Email: jessica.lu@hhs.sccgov.org

Additional Author (s):
Fa-Chyi Lee
Navneet Pooni
Gregg Loo

Purpose: Rituximab is FDA approved for 90-minute infusions for two of its indications: follicular and diffuse large B cell Non-Hodgkin's lymphomas. The objective of this study is to determine the safety and feasibility of 90-minute rituximab infusions regardless of indication.

Methods: This study will be submitted to the Institutional Review Board for approval. The electronic medical record system will identify patients who have received at least one rituximab infusion at the standard infusion rate. If these patients meet the inclusion and exclusion criteria for the study, then informed consent will be obtained. The patients will be interviewed by a physician or pharmacist prior to their next rituximab infusion. If informed consent is obtained, the patient will receive their next rituximab infusion in 90-minutes, 20% of the dose will be infused over 30 minutes and the remaining 80% of the dose will be infused in 60 minutes. Vital signs will be recorded every 15 minutes by the registered nurse for the first hour, then every 30 minutes. The nurse will fill out a de-identified data collection form to determine if an infusion related reaction occurred. If patients have signs or symptoms of an infusion reaction, the infusion will be stopped until symptoms are resolved and the infusion will be resumed at 50% of the previous rate and titrated every 30 minutes as tolerated. If needed, rescue medications will be administered to treat the reaction. The primary endpoint of the study is the development of grade 3 or 4 infusion related reactions. Secondary endpoints include the development of grade 1 or 2 infusion related reactions.

Poster Title: Improvement in Medication Adherence for the Emerging Adult Population Using Text Messaging Services

Primary Author: Michael Wong, Santa Clara Valley Medical Center, CA; Email: michaela.wong@hhs.sccgov.org

Additional Author (s):
Mymy Le
Chris Ando
Phoebe Li
Daniela Cohen

Purpose: There have been many studies regarding the use of text messaging on medication adherence and studies involving medication adherence in adolescents and young adults. However, there have been very few studies that examine the emerging adult population (between 18-21 years of age) and the impact of text messaging on their medication adherence. This project aims to address a core problem and prevent future complications related to medication non-adherence.

Methods: The study will be submitted to the Santa Clara Valley Medical Center’s Institutional Review Board for approval. Prior to the study, the Bascom pharmacy staff will be trained with proper procedures and handing of the county provided cell phone. Along with training on the operation of the device, they will also be trained on how to send, respond, and interact via two-way text messaging with patients. Patients will be identified based on their Bascom clinic physician who have agreed to participate in the study. All patients will then be contacted via telephone, mail, or verbally to opt into this study. Patients will then be contacted at least once monthly reminding them of refills or medications that require them to pick up. The data that will be collected for this study includes: missed/ late prescription pick-ups before and after intervention (medication adherence), patient days covered (PDC), patient satisfaction, prescriber satisfaction, and patient perceptions on their own medication adherence (self-reported). The study plans to not include personal identifiers in our text messages or the name of the medication. If the patient would like to know more information about their medications that
are ready for them they will have the option to respond to our message. Once they respond to our message, an algorithm will be followed to ensure the correct patient and confidentiality.

Poster Title: Preemptive oral versus intravenous acetaminophen for postoperative pain in minimally invasive gynecologic surgery: a randomized, double-blinded, controlled trial

Primary Author: Nicole Wachi, Scripps Memorial Hospital - La Jolla, CA; Email: wachi.nicole@scrippshealth.org

Additional Author(s):
Bruce Kahn
Tresa Lombardi

Purpose: This study aims to determine if oral acetaminophen provides adequate post-operative pain relief compared to its intravenous form when given preemptively in minimally invasive gynecologic surgery. Currently, there is no gold standard for preemptive analgesia and, as such, medication route is determined by surgeon preference. Intravenous acetaminophen is significantly more costly than its oral equivalent at a rate of approximately $40/dose versus $0.05/dose, respectively. If appropriate, administering oral instead of intravenous acetaminophen would reduce healthcare costs substantially.

Methods: Women 18 years of age and older undergoing robotic-assisted laparoscopic hysterectomy for benign indications are eligible for enrollment. Exclusion criteria include, but are not limited to, allergy to acetaminophen, inability to take medications by mouth, and intraoperative conversion to laparotomy. Consented patients will be randomized to either the control or intervention group. The control group will receive two placebo capsules 30 minutes prior to surgery and then acetaminophen 1000 milligrams intravenous after anesthesia induction but before first skin incision. The intervention group will receive acetaminophen 1000 milligrams (two 500 milligram capsules) by mouth 30 minutes prior to surgery and then 100 milliliters of saline intravenous after anesthesia induction but before first skin incision. Postoperative pain will be assessed at two hours, four hours, and 24 hours postoperatively using the visual analogue scale (VAS). The mean difference between each group’s VAS score will be compared to assess the non-inferiority of oral acetaminophen to the intravenous form. Other outcomes to be assessed include postoperative opioid use, length of time in the post-anesthesia care unit, and length of stay.

**Poster Title:** Rapid identification of gram-negative bacteremia and impact on anti-pseudomonal antibiotic consumption and patient outcomes at a community-based hospital system

**Primary Author:** Samantha Wong, Scripps Memorial Hospital La Jolla, CA; **Email:** wong.samantha@scrippshealth.org

**Additional Author (s):**
Maggie Box

**Purpose:** The purpose of this study is to determine the impact of Verigene® Gram negative molecular assay implementation in combination with antibiotic stewardship on anti-pseudomonal antibiotic consumption in patients with gram-negative bacteremia. Secondary endpoints will assess differences in hospital length of stay, mortality, pharmacy costs, and overall hospital charges pre- and post- implementation of the Verigene® Gram-Negative Blood Culture test (BC-GN).

**Methods:** This multicenter, quasi-experimental study will analyze patients with Escherichia coli, Klebsiella pneumoniae, Klebsiella oxytoca, and Proteus spp. bacteremia, pre- and post-implementation of the Verigene® Gram-Negative Blood Culture Test (BC-GN). The pre-intervention cohort will include patients from November 1, 2015 through October 30, 2016 and will be compared to the post-intervention cohort from November 1, 2016 through March 30, 2017. Eligible patients include hospitalized patients age 18 years or older with gram-negative bacteremia upon admission, defined as a positive blood culture with a gram-negative pathogen within 72 hours of admission. Exclusion criteria includes patients with polymicrobial bloodstream infections, antibiotic care withdrawn due to hospice or palliative care goals, blood culture organisms identified prior to admission, or positive blood culture > 72 hours after admission. The primary outcome will be days of therapy (DOT) of anti-pseudomonal antibiotics versus DOT of non-anti-pseudomonal antibiotics. Secondary outcomes will include hospital length of stay, mortality, pharmacy costs, and overall hospitalization costs. Data collected will include DOT of antibiotics, blood cultures and susceptibilities, length of hospital stay, mortality, pharmacy and overall hospitalization costs.

**Poster Title:** Beyond the LACE index: Identifying factors associated with 30-day readmissions in a hospital system

**Primary Author:** Gloria Wu, Scripps Memorial Hospital, La Jolla, CA; **Email:** wu.gloria@scrippshealth.org

**Additional Author(s):**
Amy Evenstad
Troy Drysdale

**Purpose:** The LACE index (length of stay, acuity, Charlson comorbidity index, number of ED visits in the preceding six months) is a validated tool used to predict the risk of unplanned readmission in medical and surgical patients within 30-days of hospital discharge. Currently, MTM (Medication Therapy Management) services are provided towards high LACE index patients prior to discharge at Scripps Memorial Hospital, La Jolla. It is hypothesized that factors outside the LACE index can contribute to readmission. The purpose of this study is to identify other factors associated with 30-day readmissions to further screen patients that may benefit from MTM service.

**Methods:** A retrospective chart review will be conducted to identify patients between January 2016 and June 2016 at high risk (11-19 points) for readmission according to the LACE index. Patient demographics and clinical characteristics will be obtained through the Scripps Health Information’s electronic medical records. The following data will be collected: patient age, gender, ethnicity, medications upon admission, where the patient was admitted from, clinical co-morbidities, laboratory values, insurance information, discharge location, hospital service, cause of admission and whether MTM service was provided. Variables will be assessed for relative risk for 30-day readmission in both patients who did and did not receive MTM service. The outcome of interest will be readmission to any of the Scripps hospitals within 30 days of discharge. All data will be recorded without patient identifiers and patient confidentiality maintained. This study will be submitted to the Scripps Institutional Review Board for approval.

**Poster Title:** Use of daptomycin plus ceftaroline versus standard of care for treatment of methicillin resistant Staphylococcus aureus bacteremia

**Primary Author:** Krista Ouellette, Sharp Healthcare, CA; **Email:** krista.ouellette@sharp.com

**Additional Author (s):**
Logan Vasina
Mathew Geriak
George Sakoulas
Marie Yu

**Purpose:** Methicillin resistant staphylococcus aureus (MRSA) bacteremia is a frequent and difficult problem in the hospital setting. The high mortality and clinical treatment failures with current standard of care, vancomycin or daptomycin, leave room for clinical and microbiological improvement. Several studies have demonstrated synergistic activity between daptomycin and ceftaroline for treatment of MRSA, and this combination has been a successful salvage treatment for refractory bacteremia. The purpose of this study is to compare combination treatment with daptomycin and ceftaroline versus standard of care therapy daptomycin or vancomycin monotherapy with respect to microbiological cure and clinical outcomes in patients with MRSA bacteremia.

**Methods:** This study was submitted to the Sharp Healthcare Institutional Review Board for approval. The study is a retrospective chart review of a cohort of patients from Sharp Memorial and Grossmont Hospital. The data collection time period will be from January 1, 2014 to December 31, 2016. Eligible patients will have a diagnosis of MRSA bacteremia treated for at least 72 hours with a combination of daptomycin plus ceftaroline and will be compared to a cohort of patients at the same facilities within the same time frame who were treated with standard of care therapy (vancomycin or daptomycin monotherapy). Combination will be matched to standard therapy in a 1:2 ratio based on the following criteria: 1. Source (1.Primary 2.Secondary 3.Venous Catheter related), 2.Age (+/- 10 years), 3.Creatinine Clearance (>50ml/min, < 50ml/min or End Stage Renal Disease on Hemodialysis). The following data will be collected: Age, gender, height, weight, serum creatinine, comorbidities, Pitt Bacteremia Score, source of infection, level of care, time of first positive and first negative blood culture, antibiotic
regimen, length of hospital stay, in hospital mortality and the number of diagnostic treatments. Time to microbiological cure will be calculated from the time of the first positive to the first negative blood culture. The primary outcome, time to microbiological cure, will be analyzed using time to event analysis. Data will be presented in Kaplan-Meier Curve format.

Poster Title: Evaluation of clinical effectiveness and safety of extended-interval and conventional dosing of gentamicin in postpartum adults

Primary Author: Nhi Dinh, Sharp Healthcare, CA; Email: nhi.dinh@sharp.com

Additional Author (s):
Katie Andonian
Morgan Yancy

Purpose: Although extended-interval dosing of gentamicin has been studied and shown to have equal effectiveness without higher toxicity, there are still populations, such as postpartum adults, that have not been extensively studied. The rare literature that exists for extended-interval dosing in postpartum adults suggests there may be positive outcomes in terms of clinical effectiveness and safety. However, these studies are sparse, dated, and rely on small samples. As such, the purpose of this study is to evaluate the clinical effectiveness of extended-interval dosed gentamicin and conventionally dosed gentamicin in postpartum adults.

Methods: This is a single-site, retrospective, observational control study that will study postpartum adults who received gentamicin for either chorioamnionitis or endometritis. Inclusion criteria include age over 18 years old, diagnosis of chorioamnionitis or endometritis, and use of gentamicin. Exclusion criteria include age less than 18 years old, pregnancy, lack of diagnosis for chorioamnionitis or endometritis and aminoglycoside allergy. The study’s primary outcome is clinical effectiveness as suggested by rates of treatment success, which is defined as fever resolution within 48 hours, between the conventional and extended-interval dosing groups. Safety outcomes such as hearing and renal function will also be assessed. Secondary outcomes include time to fever resolution, length of stay, duration of antibiotic use, time to antibiotic administration and cost of drug usage.

**Poster Title:** Point prevalence study of medication errors using a validated trigger tool versus comprehensive chart review in the medical intensive care unit of a community hospital

**Primary Author:** Anh Nguyen, Sharp HealthCare System, CA; **Email:** anh.nguyen@sharp.com

**Additional Author(s):**
Jill Limberg
Albert Rizos
Alexandra Perreiter

**Purpose:** Many hospitals are dependent upon voluntarily reported medication errors, but the prevalence of actual or potential errors is unknown. Pharmacist-led chart reviews may lead to recognition of errors and allow for interventions, however, this method is labor-intensive and unsustainable. The Institute for Healthcare Improvement (IHI) Global Trigger Tool is validated and may capture potential errors, but is not entirely relevant to the needs of our institution. The objective of the study is to identify medication errors in the medical intensive care unit and to create a customized trigger tool using findings from chart reviews and the IHI Global Trigger Tool.

**Methods:** This study will be submitted to the Institutional Review Board (IRB) for approval. The study will be conducted in a 48-bed medical intensive care unit (MICU) of a community hospital and patients will be selected based on the severity of the Acute Physiology and Chronic Health Evaluation (APACHE) score. A total of 20 hours over 5 days will each be dedicated to the electronic medical record to identify potential and actual errors using 1) the IHI’s “Medication Module Triggers” and “Intensive Care Module Triggers,” then 2) pharmacist-led comprehensive chart review. Records will only be reviewed within the allotted time frame to assess the feasibility of chart review within the pharmacist’s workflow. The number of interventions initiated and accepted will be documented. All errors from both methods will be reviewed and categorized using the National Coordinating Council for Medication Error Reporting and Prevention (NCCMERP) classification. The creation of a customized trigger tool is planned upon analyzing data on frequency and severity of actual and potential errors identified.

Poster Title: Characterization of Exparel Impact Upon Orthopedic Surgery Outcomes

Primary Author: Chong Fang, SHARP HEALTHCARE, CA; Email: chong.fang@sharp.com

Additional Author(s):

Purpose: Liposomal Bupivacaine (Exparel) is approved for surgical site administration to produce postsurgical analgesia. This FDA indication is based on 2 clinical trials: hemorrhoidectomy and bunionectomy. There is no conclusive study that proves its efficacy superior to standard therapy. Acute post-operative pain is a common phenomenon in orthopedic procedures. Due to the high cost of Exparel, we question the efficacy of its use in total knee arthroplasty (TKA). The purpose of this study is to assess the clinical efficacy and safety of liposomal bupivacaine versus standard of practice in patients who have undergone unilateral total knee arthroplasty.

Methods: Multi-site, retrospective, historical control, utilizing the Orthopedic Surgery Service Line’s newly developed database to compare specific outcomes before and after adoption of Exparel in practice. We will collect data of patients who underwent TKA at three different sharp hospitals: Sharp Grossmont, Sharp Memorial, and Sharp Coronado. Data that will be collected include: opioid and naloxone use, which are surrogates of efficacy and safety, respectively. We will include patients ≥18 years old, who has underwent unilateral TKA. We will exclude patients who are opioid tolerant, have opioid/narcotic allergies. Data will be collected using three different data sources: Sharp Healthcare Orthopedic Registry, Sharp Healthcare Billing Records, and Cerner Electronic Health Record. We will include in our data: age, gender, weight of the patients, as well as date/time of admission/discharge. We will collect data pre and post June 2015, since that is when the orthopedic surgeons were trained on Exparel injection techniques. The amount of patients included will be based on our power analysis.

**Poster Title:** Evaluation of the time to therapeutic vancomycin troughs in patients who receive loading doses

**Primary Author:** Daniel Polchinski, Stanford Health Care, CA; **Email:** dpolchinski@stanfordhealthcare.org

**Additional Author (s):**
Mark Klanjac
Lina Meng
Emily Mui

**Purpose:** At several medical institutions, vancomycin loading doses are often given in an effort to reach a therapeutic vancomycin trough level faster than with traditional maintenance dosing. However, it is currently unknown whether this practice leads to a decreased time to a therapeutic trough level. Our study aims to determine if giving a vancomycin loading dose helps achieve a therapeutic trough level faster than if no loading dose is given.

**Methods:** This retrospective, observational study has been approved by the Institutional Review Board. The electronic medical record system will identify patients who have received at least two doses of vancomycin and have had a trough level drawn. Exclusion criteria include patients whose vancomycin troughs were drawn incorrectly, patients on hemodialysis, and peri-operative patients. The following data will be collected: patient age, weight, body mass index, vancomycin dosing regimen, vancomycin trough level(s), serum creatinine measurements throughout hospitalization, and vancomycin indication. The patients’ charts will be reviewed to see whether a vancomycin loading dose was given in order to determine if giving a loading dose increased the percentage of patients who attained an initial therapeutic vancomycin trough level. The reviewers will also determine if giving a vancomycin loading dose is associated with nephrotoxicity, defined as a serum creatinine increase of greater than or equal to 0.5 milligrams per deciliter or an increase of greater than 50 percent from baseline over two consecutive readings from the initiation of vancomycin to 72 hours after the last vancomycin dose was given. Other outcomes looked at will include the percentage of patients with either a supra-therapeutic or sub-therapeutic initial vancomycin trough level, duration of vancomycin therapy,
and the average time to attain a therapeutic vancomycin trough level. All data will be collected without patient identifiers to maintain patient confidentiality.

Poster Title: Impact of transition of care pharmacist interventions in patients with myocardial infarction

Primary Author: Walter Domingo, Stanford Health Care, CA; Email:wdomingo@stanfordhealthcare.org

Additional Author (s):
Noah Fang
Deepak Sisodiya

Purpose: Since October 2012, Centers for Medicare and Medicaid Services began reducing inpatient reimbursement for hospitals with excess readmissions in an effort to encourage improvements in hospital outcomes. Between July 2011 and June 2014, readmission rates for acute myocardial infarction decreased from 17.8 percent to 16.0 percent. To sustain this trend, hospitals are implementing strategies such as transition of care pharmacy programs to decrease readmissions. The objective of this study is to assess the impact of transition of care pharmacy interventions on 30-day readmission rates and medication errors in acute myocardial infarction patients and to track pharmacy interventions.

Methods: This study will be a prospective chart review that will compare 30-day readmission rates and number of medication errors in patients with acute myocardial infarction who received transition of care pharmacy services versus standard of care. Researchers will identify patients admitted to Stanford Health Care’s general cardiology team with a diagnosis of ST elevation myocardial infarction, non-ST elevation myocardial infarction, or unstable angina. The following data will be collected: patient age, gender, admission date, discharge date, admission diagnosis, 30-day readmission status, medication errors, transition of care pharmacy interventions, core measures, and medication compliance.

Poster Title: Hepatotoxicity Associated with Pegasparagase in Adults with Acute Lymphoblastic Leukemia

Primary Author: Jodi Stark, Stanford Health Care, CA; Email: jstark@stanfordhealthcare.org

Additional Author(s):
Eun Kim
Samit Patel
Stephanie Tse

Purpose: Pegasparagase (PEG) is a mainstay component in acute lymphoblastic leukemia (ALL) therapy and is associated with improved survival rates. One of the most commonly observed adverse events is hepatotoxicity. Previous literature has described PEG-induced hepatotoxicity as an increase in aminotransferase levels and bilirubin. Literature further characterizing this hepatotoxicity is needed to improve understanding of the toxicity. Such information could allow for risk stratification of patients and more appropriate monitoring. The objective of this study is to identify risk factors, define the frequency, severity, median onset, reversibility, and time to normalization of pegasparagase-induced hepatotoxicity.

Methods: This study is a retrospective, single-center, chart review of adult patients diagnosed with acute lymphoblastic leukemia age 18 years of age and older who received at least one dose of PEG from July 1, 2008 to July 30, 2016 at Stanford Health Care. These patients will be evaluated to identify possible risk factors associated with hepatotoxicity. Hepatotoxicity was defined using the Common Terminology Criteria for Adverse Events (CTCAE) version 4.03 for evaluating transaminitis and bilirubinemia. Data collection will include age, sex, height, weight, ALL regimen used, dose used, number of PEG doses given, concomitant hepatotoxic medications, albumin level, time to develop grade >1 hepatotoxicity, time to normalize to grade < 1, lipase, amylase, and triglycerides.

**Poster Title:** Pharmacist Impact on Epoetin Usage in CKD Patients in an Acute Care Setting  

**Primary Author:** Austin Wang, Stanford Health Care, CA; **Email:** austinw4002@gmail.com  

**Additional Author (s):**  
Denise Kwong  
Tiffany Wong  
Graham Abra  

**Purpose:** Outpatient pharmacist-led epoetin management has demonstrated clinical and economic benefit but these interventions were not studied in acute hospital settings. A medication use evaluation (MUE) at our facility identified a subgroup of chronic kidney disease (CKD) patients on epoetin for greater than 30 days that could benefit from pharmacist intervention to optimize epoetin. Specific opportunities include reduction in overall red blood cell transfusion (RBC), cost savings due to epoetin dose rounding to appropriate vial size, optimization of epoetin therapy with package insert based dose adjustments, and appropriate utilization of iron supplementation.  

**Methods:** This longitudinal study will begin with the retrospective chart review of patients with hospital length of stay greater than 30 days on epoetin to establish a starting reference level of dosing frequency, RBC usage, baseline characteristics, and clinical response. This information will further identify specific steps that can be taken to optimize epoetin therapy and a dosing algorithm will be developed in collaboration with the nephrology department. This prospective pharmacy-managed epoetin algorithm will be proposed at a pharmacy and therapeutics committee meeting to gain approval prior to initiation and will run over 6 months. The prospective arm of this study will include pharmacist intervention based on collaborative guidelines to optimize patient care. Patients on epoetin for greater than 30 days will be evaluated based on these guidelines and the pharmacist will provide recommendations to optimize clinical outcomes and minimize cost. For this group of patients on epoetin therapy, the primary outcome will be defined as the number of RBC ordered and appropriate dosing interventions recommended by pharmacists per collaborative guideline. The secondary outcomes will be defined as the number of iron panels ordered in hospital admission, appropriateness of iron therapy, adverse events, and pharmacy expenditures on epoetin.

**Poster Title:** Rates of BK virus in highly sensitized kidney transplant recipients receiving rituximab  

**Primary Author:** Jane Kim, Stanford Health Care, CA; **Email:** janekim@stanfordhealthcare.org  

**Additional Author(s):**  
Reid Imai  
Roy Lee  
Mark Klanjac  
Uerica Wang  

**Purpose:** BK virus is a clinically significant infectious complication in kidney transplant recipients (KTRs). This trend is more prevalent in KTRs requiring human leukocyte antigen (HLA) desensitization, who require lymphocyte depleting induction and are at high risk for rejection. Some studies suggest mycophenolate mofetil (MMF) dose reduction in this population to decrease the rates of BK virus infection. This study aims to evaluate the rates of BK viremia in highly sensitized kidney transplant recipients that receive different doses of MMF.  

**Methods:** In this retrospective, single-center study, highly sensitized KTRs greater than 18 years of age who received rituximab and Thymoglobulin at Stanford Health Care will be evaluated for rates of BK viremia. Highly sensitized KTRs receive up to five doses of Thymoglobulin 1.5 milligram per kilogram as induction therapy post-kidney transplant along with a dose of rituximab 500 milligram intravenously prior to discharge. Two cohorts will be evaluated. Cohort A will include patients who received standard dose of MMF 1000 milligram by mouth twice daily. Cohort B will include patients who received reduced dose of MMF 500 milligram by mouth twice daily. Surveillance of BK viremia is done using quantitative polymerase chain reaction (PCR), and BK viremia is defined as BK virus load of 1,000 to 60,000,000 copies per milliliter (3.00 to 7.78 Log10 copies per milliliter) in the plasma. The following data will be collected: patient demographics, donor type and source, HLA match, kidney donor profile index (KDPI), calculated panel reactive antibodies (cPRA), infections, presence of other viruses, and transplant rejection and type, if applicable. This study will be submitted to the Institutional Review Board for approval. Comparisons of incidence of BK viremia between two cohorts will be analyzed using chi-squared test and Fisher's exact test.

**Session-Board Number:** 11-072

**Poster Title:** Safety of peri-operative lidocaine infusion for pain in cardiac surgery patients

**Primary Author:** Benny Yau, Stanford Health Care, CA; **Email:** byau@stanfordhealthcare.org

**Additional Author(s):**
Mark Klanjac
Denise Kwong

**Purpose:** Lidocaine infusion for pain control is commonly used in peri-operative settings to optimize therapy and reduce opioid use. Atrial fibrillation is the most common post-operative arrhythmia to occur, especially in cardiac surgery patients. Lidocaine along with its antiarrhythmic properties can also increase the risk of developing arrhythmias. There is a gap in literature evaluating the risk of arrhythmias associated with lidocaine use in cardiac surgery patients. The objective of this study is to evaluate the safety of utilizing lidocaine infusion for pain in cardiac surgery patients and clarify whether it correlates to new onset post-operative atrial fibrillation (POAF).

**Methods:** This study has already been submitted to the Institutional Review Board for approval. It is a retrospective chart review in which the Society of Thoracic Surgeons database is used to identify cardiac surgery patients who had an elective coronary artery bypass graft or valve surgery and subsequently were infused with lidocaine for pain control post-procedure. Patients excluded from the study will comprise of emergent cardiac surgeries, history of arrhythmia prior to surgery, use of lidocaine not indicated for pain, patients on other antiarrhythmic medications besides lidocaine prior to the diagnosis of new POAF, and children. A comparison arm will be a cohort of the same time frame with patients not utilizing lidocaine for pain. To determine the contribution of lidocaine to new onset POAF, baseline characteristics will be analyzed for confounding factors that increase the risk of POAF independent of lidocaine. The following data will be collected: baseline characteristics (age, sex, body mass index, cardiac surgery type, past medical history, peri-operative medications, operative and post-operative data, length of hospital stay, 30-day mortality, and readmission), lidocaine regimen, indication, lidocaine blood level, new POAF diagnosis, diagnosis date, and electrolytes on the day of diagnosis (calcium, potassium, and magnesium). Protected health information will be de-
identified and recorded confidentially. The primary objective is to evaluate the presence of new onset POAF in post-cardiac surgery patients utilizing lidocaine for pain.

Poster Title: Evaluation of daratumumab infusion-related reactions at a single academic medical center

Primary Author: Nicole Lee, Stanford Health Care, CA; Email: nicolelee@stanfordhealthcare.org

Additional Author(s):
Magdalena Seyer
Eun-Jeong Kim
Samit Patel
Abraham Chang

Purpose: Daratumumab has recently emerged as a promising treatment approach for patients with multiple myeloma. Daratumumab is well tolerated, and the most common adverse event is infusion-related reactions. Risk factors for infusion-related reactions such as disease burden or premedication use are not well defined for daratumumab. Evaluating for risk factors that may predispose patients to infusion-related reactions and management of reactions is important for better prevention and treatment of these adverse events. This study aims to evaluate potential risk factors associated with daratumumab infusion-related reactions and its management in patients with multiple myeloma or amyloidosis at a single academic medical center.

Methods: This study is a single academic medical center, retrospective chart review that has been approved by the IRB. Patients with multiple myeloma or amyloidosis who receive their first and all subsequent evaluable doses of daratumumab between November 16, 2015 and December 31, 2016 will be included. Patients under 18 years of age or treated with daratumumab for indications other than multiple myeloma and amyloidosis will be excluded. Infusion-related reactions will be graded as defined by CTCAE version 4.03. Other information that will be collected include: age, gender, height, weight, allergies, history of allergic reaction, history of cardiac or pulmonary disease, serum creatinine, complete blood count, clonal plasma cell percent on bone marrow biopsy prior to daratumumab therapy, CD38 percent in bone marrow biopsy prior to daratumumab therapy, serum or plasma M protein and immunoglobulin levels, serum free light chain levels, beta-2 microglobulin levels, lactate dehydrogenase, number of prior multiple myeloma therapies prior to daratumumab therapy,
transplant status, premedication used, daratumumab dose, daratumumab infusion duration, and use of concomitant chemotherapy. The primary objective will be to evaluate for specific patient and disease characteristics that may be associated with an increased risk or severity of daratumumab infusion-related reactions. Secondary objectives will be to describe and evaluate management of these infusion-related reactions. Informed consent will not be required for this study.

Poster Title: Implementation of patient assistance program in a not-for-profit health system in northern California

Primary Author: Ahmad Saad, Sutter Health, CA; Email: ahmadnsaad@gmail.com

Additional Author(s):
Heidi Rens

Purpose: New innovative medicines are emerging to treat complex autoimmune and cancer conditions. With the current heterogeneity of governmental and commercial health insurance coverage, patients are facing financial hardships to access such innovative medicines. The objective of this study is to evaluate the effect of a patient assistance program on affordability to medications for patients receiving their care in infusion centers in a not-for-profit health system in northern California.

Methods: Webinars will be coordinated with the drug manufacturers that offer patient assistance program (PAP) to financial counselors in each infusion center. The webinars will help the financial counselors to understand the eligibility criteria of the PAP and the application process. A web-based resource will be created and made accessible to financial counselors. The web-based resource will include a list of the medications that are offered through a PAP, and information guides that are drug or diagnosis specific to be distributed to patients to help them through the PAP application process. The outcomes of this study will be assessed by recording the number of approved PAP applications, out-of-pocket payments, uncompensated care costs, and number of patients on payment plans before and after implementing the PAP. All data will be recorded without participant identifiers and maintained confidentially. This study will be submitted to the Sutter Health Institutional Review Board for approval.

Poster Title: Duration of therapy and concomitant risk factors for vancomycin nephrotoxicity in pediatric patients

Primary Author: Henock Woldu, UC DAVIS MEDICAL CENTER, CA; Email: henockw@gmail.com

Additional Author(s): Bernard Guglielmo

Purpose: Purpose: With an adjustment and more aggressive vancomycin dosing, the risk of vancomycin induced nephrotoxicity has become a subject of interest in children receiving intravenous vancomycin. To determine the true risk of vancomycin nephrotoxicity in children at high risk and to secondarily determine whether a relationship exist between nephrotoxicity, duration of therapy and concomitant risk factors including receipt of nephrotoxic medications.

Methods: Method: After an institutional IRB approval, a retrospective cohort analysis was conducted from June 2012 to June 2015 at the University of California San Francisco Benioff Children’s Hospital. Patients 3 months to less than 19 years who were admitted and received intravenous vancomycin therapy for greater than or equal to 48 hours were evaluated. The incidence of nephrotoxicity was defined as an increase in serum creatinine greater than or equal to 0.5 mg/dL or greater than or equal to 50 percent increase in baseline serum creatinine persisting for at least two consecutive levels. The primary outcome was incidence of nephrotoxicity. Secondary outcomes include duration of vancomycin therapy and concomitant risk factors including receipt of concomitant nephrotoxic medications. Univariate and multivariate analysis were conducted to identify factors contributing to nephrotoxicity.

Results: Results: Of 291 pediatric patients included, nephrotoxicity occurred in 19 (6.5 percent) patients. In a univariate analysis, weight, vancomycin initial and final dose, nephrotoxic factors including hypotension, respiratory failure, serum vancomycin trough concentration greater than or equal to 15 and concomitant receipt of nephrotoxic medications were significantly associated with nephrotoxicity. The median duration of therapy was 4 days and 3 days in the non-nephrotoxicity and nephrotoxicity groups respectively. Multivariate analysis identified final
serum vancomycin trough concentration greater than or equal to 15mg/dL and piperacillin/tazobactam as significantly associated with nephrotoxicity (odds ration 3.49, 95% confidence interval 1.20-10.1, p=0.021) and (odds ratio 3.138, 95% confidence interval 1.02-9.6, p=0.046).

**Conclusion:** Conclusion: Little to no nephrotoxicity takes place in high-risk pediatric patients receiving vancomycin. While vancomycin does not appear to be associated with nephrotoxicity, its concomitant use with known nephrotoxic medications and other risk factors may be associated with an increase in serum creatinine.

Submission Type: Research-in-Progress

Session-Board Number: 11-076

Poster Title: Evaluation of vancomycin dosing in adult obese patients

Primary Author: Ryan Ferren, UC Irvine Health, CA; Email: rsferren10@gmail.com

Additional Author(s):
Helen Lee

Purpose: The American Society of Health-System Pharmacists recommends dosing vancomycin 15-20 mg/kg every 8-12 hours using total body weight (TBW) in individuals with normal renal function with severe Methicillin-resistant Staphylococcus aureus infections. However, it is a common practice to use adjusted body weight (ABW) for obese patients due to difficulty determining the appropriate dosing weight. Using TBW to dose obese patients can increase the risk for nephrotoxicity and supratherapeutic trough levels. The purpose of this study is to evaluate the rate of therapeutic troughs attained in obese patients and attempt to determine the appropriate threshold for using ABW for vancomycin dosing.

Methods: A retrospective chart review will be conducted at a tertiary care academic medical center which has an institutional vancomycin dosing guideline. Patients admitted between November 2013 and October 2016 will be evaluated for this study. The inclusion criteria are patients at least 18 years of age, obese, defined as total body weight greater than 130% of ideal body weight, received at least 36 hours of vancomycin, creatinine clearance of at least 25 mL/min, and had a vancomycin trough level measured. A therapeutic vancomycin trough will be defined as a level between 10 to 20 mcg/mL. Patient information will be obtained utilizing the institution’s electronic medical record. Data collection will include patient age, gender, total body weight, ideal body weight, and height. Dose of vancomycin, trough levels, date and time of trough levels, number of trough levels obtained, indication for vancomycin therapy, comorbidities and receipt of other nephrotoxic agents will also be gathered for analysis. The primary endpoint will be the rate of therapeutic vancomycin trough levels attained in obese patients. Secondary endpoints include time to therapeutic trough levels, number of subtherapeutic and supratherapeutic trough levels, incidence of nephrotoxicity and treatment failure.

Poster Title: Evaluation of Naloxegol Use for Opioid-Induced Constipation

Primary Author: Christine Tran, UC Irvine Medical Center, CA; Email: chrit12@uci.edu

Additional Author(s):
Rosene Pirello
Soloman Liao

Purpose: Currently, there are no published literatures regarding the use of naloxegol in cancer patients. The purpose of this study is to evaluate the efficacy and safety of naloxegol in all patients at UC Irvine Medical Center and to determine if the results are consistent with current literature.

Methods: This study will be submitted to the Institutional Review Board for approval. A retrospective chart review will be performed using the electronic medical record to identify patients who have taken at least one dose of naloxegol. The following data will be collected: medical record number, admission/discharge date, age, sex, primary diagnosis, presence or absence of abdominal processes, history of constipation, and concurrent opioid use. Collected data such as pain scores before and after use, dosage used, stool consistency, and time to laxation will be used to determine the efficacy of naloxegol. Results will be compared the data found in literature. No patient identifiers will be used and confidentiality will be maintained.

Poster Title: Effect of Transitions of Care Pharmacist Intervention on Heart Failure Mortality, Readmissions, and Emergency Department Visits at an Acute Care Hospital

Primary Author: Conor Bowman, University of California Irvine Medical Center, CA; Email: c Bowman@uci.edu

Additional Author(s):
Lan Vu

Purpose: Primarily, this study's purpose is to evaluate the effect of a pharmacist’s medication education during heart failure hospital admission and post discharge phone call on 30 day all-cause hospital readmission, 30 day mortality, and 30 day emergency department (ED) visits to standard of care. Secondarily, to identify factors associated with readmission or ED visits for this population, to track type of pharmacist intervention made to the primary team prior to discharge and to demonstrate whether pharmacist intervention is a cost-effective means to improve quality of care and reduce hospitalization costs associated with higher mortality and readmission rates.

Methods: This will be a quality improvement project comparing pharmacist intervention to standard of care. The study's population will include adult patients with heart failure diagnosis as primary cause for admission and followed by UC Irvine as outpatients. Patients less than 18 years old or who are mentally disabled will be excluded. Pharmacist will perform education with intervention-arm patients prior to discharge. This session's focus will be on adherence to and understanding of critical heart failure medications. Pharmacist may also provide interventions to care team regarding medication issues prior to discharge. A note will be recorded in the Electronic Medical Record (EMR) regarding the details of this patient education session and any interventions made. Patients will be contacted by phone within three days by the pharmacist. These encounters may include topics such as verification of patient’s medications, patient’s understanding of medications, medication storage, or adherence. This session will be recorded in EMR as well. 30 day readmission rates, mortality, and ED visits will be tracked afterwards through EMR. A parallel set of standard-of-care patients not followed by the pharmacist will also be tracked to determine if there is any difference in primary outcomes. Risk factors such as baseline ejection fraction, sex, ethnicity, renal impairment status, and other
comorbidities collected during patient’s initial hospital visit will also be reviewed to determine whether these affected primary outcomes.

**Poster Title:** Effects of sirolimus on thrombosis risk after lung transplant in patients with interstitial lung disease

**Primary Author:** Georgina Waldman, University of California San Diego Health System, CA; Email: gwaldman@ucsd.edu

**Additional Author (s):**
Ashley Feist
Linda Awdishu
Gordon Yung
Mark Mariski

**Purpose:** Sirolimus is associated with an increased risk of venous thromboembolism (VTE) in lung transplant patients. Interstitial Lung Disease (ILD) is associated with high risk of thrombus after lung transplant, irrespective of sirolimus use. Practitioners may avoid sirolimus in ILD patients to minimize this risk; however, there are significant benefits when using sirolimus in lung transplant patients. The purpose of this study is to assess the risk of thrombus in ILD lung transplant patients treated with sirolimus versus a non-sirolimus based immunosuppression.

**Methods:** The primary objective of the study is to assess the risk of VTE in ILD lung transplant patients treated with sirolimus versus non-sirolimus based immunosuppression. The secondary objective is to determine if there is an association of sirolimus levels with the risk of VTE in ILD lung transplant patients. This study has been submitted to the Institutional Review Board for approval. There will be a retrospective chart review of all ILD patients transplanted from January 1, 2010 to August 31, 2016, estimated to be 48 patients. They will be divided into 2 groups based on history of sirolimus use. The following data will be collected: basic patient demographics, transplant, sirolimus use, sirolimus trough concentrations, anticoagulation use, VTE occurrence before and after transplant, VTE occurrence before and after sirolimus, risk factors for development of VTE and events. All data will be recorded without patient identifiers and maintained confidentially. VTE events will be assessed using the Narajo Adverse Drug Reaction Probability Scale to determine relation to sirolimus. A multi-variable regression model will be used to analyze occurrence of VTE in lung transplant patients with ILD taking sirolimus.

**Submission Type:** Research-in-Progress  

**Session-Board Number:** 11-080  

**Poster Title:** Utilization of a Bayesian clinical decision support tool to improve initial dosing and subsequent dose adjustments of vancomycin in the pediatric population  

**Primary Author:** David Hughes, University of California, San Francisco (UCSF) Medical Center, CA; **Email:** David.Hughes@ucsf.edu  

**Additional Author (s):**  
Jonathan Faldasz  

**Purpose:** Clinical data supporting the use of vancomycin is offset by its narrow therapeutic window and need for therapeutic drug monitoring (TDM). Clinical decision support (CDS) tools have been developed to aid clinicians in optimizing vancomycin dosing, yet there is a paucity of data assessing the extent to which these CDS tools may improve dosing of vancomycin as compared with a pharmacist alone. This two-part retrospective observational cohort study will compare standard protocols for dosing vancomycin at UCSF Benioff Children’s Hospital to model-based recommendations using Insight-Rx, a software tool utilizing a pediatric-specific pharmacokinetic model and Bayesian clinical decision support for optimal dosing.  

**Methods:** The study will include approximately 200 pediatric patients between the ages of 1 and 18 years (excluding those with end-stage renal disease receiving hemodialysis or those receiving continuous renal replacement therapy). Patients were admitted to UCSF Benioff Children’s Hospital from July 1, 2015 to July 1, 2016 and received intravenous vancomycin and had at least one vancomycin level measured. In the first part of this study, pharmacokinetic parameters will be calculated for all patients, and the initial dosing regimen based on a UCSF protocol will be compared to a model-based regimen based on a published pharmacokinetic model recommended by the Insight-Rx CDS tool. The ability to achieve pharmacokinetic targets of interest (AUC24, Ctrough,ss) will be assessed. Patients with more than one vancomycin level obtained will be included in the second part of the study, wherein actual level-based dosing adjustments made by pharmacists will be compared to recommendations made by the Bayesian-driven CDS tool with regard to achieving pharmacokinetic targets.
The outcomes of this study will contribute to the optimization of vancomycin dosing in the pediatric population and will aid in assessment of the value of incorporating software-driven TDM into general practice.

Poster Title: Pharmacist impact on reducing hospital readmission rates and length of stay; integrating pharmacists into the transition of care team

Primary Author: Nikhil Sangave, University of Southern California, CA; Email: nsangave@gmail.com

Additional Author(s):
Sheila Salamunovich
Jofel Yan
Steve Kawahara

Purpose: Avoidable hospital readmissions lead to decreased patient quality and cost the healthcare system billions of dollars each year. According to Centers for Medicare and Medicaid Services (CMS), in 2013 the national average for 30-day hospital readmission rates was 17.5%. Medication related problems are factors identified as leading to hospital readmissions. The 30-day hospital readmission rate at the medical groups 75 bed contracted skilled nursing facility (SNF) is currently at 25%. The objective of this study is to evaluate the impact on reducing hospital readmission rates and length of stay by integrating a pharmacist into the transition of care team.

Methods: This study will be submitted to the Institutional Review Board for approval. A pharmacist will be integrated into the SNF care team to perform a comprehensive medication review on enrolled, capitated (at risk) patients in the medical group. Following the comprehensive medication review, the pharmacist will consult with the SNF physician to resolve any medication related problems (MRPs) or gaps in care before patients are discharged. The pharmacist will also meet with the patient prior to discharge to provide medication counseling. Following discharge, a member of the pharmacy team will contact the patient by phone at approximately 24-48 hours, 7 days, and 30 days to identify and resolve any additional MRPs, assess medication adherence, and update the medication list in the electronic health record. For any MRPs identified 24-48 hours post discharge the pharmacy team will consult with the SNF physician to resolve. Any MRPs identified at 7 days or 30 days post discharge, the pharmacy team will consult with the patient’s primary care physician to resolve. At each interaction with the patient, the pharmacy team will track MRPs, interventions, and
intervention implementation in a database. SNF length of stay and hospital readmission rates at 7 days and 30 days will be calculated from medical claim data.

**Poster Title:** Evaluating implementation of pharmacist services in an underserved primary care clinic to optimize reductions in 30 day readmissions, associated health system costs, and medication discrepancies

**Primary Author:** Brittany Dougherty, Mercy Medical Center, IA; **Email:** bdougherty@mercycare.org

**Additional Author(s):**

**Purpose:** Evidence shows that integrating a pharmacist into a multidisciplinary team within a primary care clinic improves patient outcomes. These improvements include decreased readmissions; improved medication literacy; improved adherence; and achieved health goals (i.e. blood pressure, hemoglobin A1c targets). Limited evidence exists in literature to support the benefits of a clinical pharmacist in a complex underserved primary care clinic. The objective of this study is to determine the impact of clinical pharmacist interventions in this patient population to achieve a reduction in 30-day readmission rates, associated health system costs, and medication discrepancies.

**Methods:** This study will be submitted to the Mercy Medical Center Institutional Review Board for approval. Using the electronic medical health record, patients will be recruited based on the following inclusion criteria: age 18 years or greater, and one or more of the following; visit(s) to the underserved clinic in the previous six months, pharmacist documented interventions, and 30-day readmission to Mercy Medical Center’s emergency department in the preceding 12 months. Exclusion criteria include: less than 18 years of age, no visits to underserved clinic, and zero 30-day readmission visits to the emergency department in the preceding 12 months. The data will be correlated retrospectively at the end of the six month study with a control group to assess potential 30-day readmissions prevented through pharmacist encounters (chart interaction or personal encounter), potential cost avoidance from emergency room visits, total number of medications incorrectly documented, and total number of therapy interventions. The control group will be assessed to account for variation between groups. Patient information collected will include age, gender, primary diagnosis, vitals, laboratory values, pain scores, medication lists, intervention notes, and provider notes. The data will be recorded with patient identifiers and be password protected for confidentially of patient information.

**Poster Title:** Implementation of pharmacist-led medication reconciliation for pre-operative total knee and total hip replacement patients  

**Primary Author:** Elizabeth Glynn, Mercy Medical Center - Cedar Rapids, IA; **Email:** elizabeth.glynn.10@gmail.com  

**Additional Author(s):**  

**Purpose:** Medication reconciliation for pre-operative patients is currently being performed by five different nurses at this institution. Surgeons have expressed interest in having the pharmacy department manage medication reconciliation for these patients due to issues with inaccurate and incomplete medication lists prior to surgery. The objective of this study is to determine if pharmacy-led medication reconciliation for pre-operative total knee and hip replacement patients prior to surgery would result in decreased medication-related hospital readmissions, adverse drug events, and missed education opportunities.

**Methods:** Pharmacists and pharmacist interns will be a part of the medication reconciliation process. The pharmacist interventions will include: implementing a standard form to follow when performing medication reconciliation, conducting the medication reconciliation, documenting any changes that were made to the medication list, providing medication education if requested or deemed necessary for the patient, and contacting the patient’s pharmacy if adequate medication information cannot be collected from the patient. Patients who have undergone total hip or knee replacement surgery four months prior to pharmacist intervention and those who will be receiving these surgeries four months after pharmacist intervention is implemented will be identified by the electronic medical record. The two patient groups will be compared and the following data will be collected: patient age, gender, number of medications prior to medication reconciliation, number of medications after medication reconciliation, number of changes made to the patient’s medication list, addition of an anticoagulant, reported adverse drug events, and education regarding medications received. Provider documentation post-operatively will also be reviewed for medication-related information. All data will be recorded without patient identifiers and maintained confidentially. Data will be reviewed and compared to determine the impact of the pharmacist interventions. This study will be submitted to the Institutional Review Board for approval.

Poster Title: Low dose naloxone for opioid induced respiratory depression in the emergency department

Primary Author: Michael Thiefault, Mercy Medical Center - Des Moines, IA; Email: mthiefault@mercydesmoines.org

Additional Author(s):
Catherine Defino

Purpose: The purpose of this study is to determine the safety and efficacy of low dose naloxone (0.04mg) compared to standard doses previously given in the ED. When patients present to Mercy Medical requiring naloxone administration, they will receive a provider specific dose to reverse respiratory and CNS effects. High doses in chronic abusers can cause acute mania, hypertensive crisis, pulmonary edema and more. This study would look at the safety/efficacy of 0.04mg, as well as the incidence of AWS when compared to previous naloxone doses given (0.4mg-2mg)

Methods: Using accudose dispensing data, I will identify retrospectively the patients who received naloxone 6 months prior to the study start date. Prospectively we will identify patients receiving naloxone by printing accudose dispensing data weekly. The provider will have the option to follow study protocol if the patient presents without being apneic or in respiratory arrest. The pharmacy Department has developed naloxone dilution kits to be placed inside the ED accudose to help with the timely administration of naloxone. The 0.04mg/mL naloxone solution will be made by drawing up 9mL of NS in a 10mL syringe, then drawing up 1mL of 0.4mg/mL naloxone. The initial dose will be 0.04mg and doubled every 2-3 minutes until desired response. The primary endpoint is the proportion of subjects with reversal of respiratory and CNS reversal within 1 hour of initial naloxone administration. Reversal defined as; O2 sats > 95%, RR >12, GCS >12. Secondary endpoints include; proportion of subjects developing acute withdrawal symptoms post naloxone. Defined as; RASS greater than or equal to +1 plus one of the following; HR>100, BP >140/90, diaphoretic. Other secondary endpoints include length of hospital stay, ED stay and total naloxone dose given. Date collection will be started after the next emergency medicine provider meeting, and the appropriate statistical analysis will be performed once all data collection is final.

**Poster Title:** Surviving sepsis quality improvement  

**Primary Author:** Olivia Lehman, Mercy Medical Center - North Iowa, IA; **Email:** olivia.lehman@mercyhealth.com  

**Additional Author(s):**  
Abbey Pitzenberger  
Jennifer Thoe  

**Purpose:** Severe sepsis and septic shock are major health concerns that require prompt treatment. The Surviving Sepsis Campaign highlights speed and appropriateness of therapy as influencers of positive outcomes. The 3 and 6 hour bundles were created as guidelines to help practitioners treat septic patients appropriately. As of October 2015, the Centers for Medicare and Medicaid Services has established the updated 3- and 6-hour bundles from the Surviving Sepsis Campaign as a core measure. The objective of this quality improvement project is to assess compliance with the entire 3-hour bundle with the primary objective being increased rate of compliance.  

**Methods:** These objectives will be assessed through retrospective chart review to establish all areas of the bundle that we are falling out on. Patients who meet criteria for severe sepsis and septic shock will be included in this study. The Surviving Sepsis guidelines are specific to adult patients and diagnoses of severe sepsis and septic shock, so patients under age 18 as well as those with simple sepsis who do not progress to severe sepsis or septic shock will be excluded. Patients will also be excluded if comfort care directives are placed either prior to or within 3 hours of meeting sepsis criteria. Due to skip logic, current data abstraction stops as soon as a metric is not passed. The first intervention will be providing education to the Emergency Department (ED) physicians on what antibiotics meet the CMS core measure. Because the sepsis bundles are all or nothing, if retrospective chart review reveals that we are also not meeting other metrics in the bundle, secondary interventions will be implemented at that time. The antibiotic intervention will begin in October 2016. From October through December 31, data will be monitored concurrently through daily sepsis alerts to provide guidance and feedback to ED physicians. Beginning January 1, chart review will begin to assess if compliance with the 3 hour bundle is increasing.

**Poster Title:** Evaluation of pharmacist involvement in discharge medication reconciliation

**Primary Author:** Britney Stillmunkes, Mercy Medical Center - North Iowa, IA; **Email:** britney.stillmunkes@mercyhealth.com

**Additional Author(s):**
Shana Brunsvold
Michael Williams

**Purpose:** A pharmacist’s impact on health care by reducing medication errors may result in better patient outcomes and decreased hospitalizations. By fully reviewing patient medication regimens before hospital discharge, pharmacists are able to identify medication discrepancies before they occur. This study is to determine if involving a pharmacist in discharge medication reconciliation could reduce medication errors and hospital readmission rates within 30 days of patient discharge.

**Methods:** An observational analysis of all patient discharges from the hospital to affiliated long-term care facilities will be recorded between October 1, 2016 and December 31, 2016. The collection time may be extended to achieve a goal of 50 patients. Pharmacists at the long-term care pharmacy will track patients discharged from the hospital to a facility and document medication errors that occurred on discharge. Inpatient hospital pharmacists will simultaneously document the patient discharge medication reconciliations in which they participated in. Patients will be placed into one of two groups based on discharge medication reconciliation with or without pharmacist involvement. The primary objective is comparison of reported medication error rates between the two groups. The secondary objectives include hospital readmission rates within 30 days of discharge and the time pharmacists spend on medication error resolution.

**Poster Title:** Outpatient pharmacist-led anticoagulation management in patients with left ventricular assist devices: A pilot study

**Primary Author:** Talli Smith, Mercy Medical Center-Des Moines, IA; **Email:** tallismith78@gmail.com

**Additional Author(s):**
Emily Moen
Jennifer Maki

**Purpose:** Patients with left ventricular assist devices (LVADs) require close monitoring of warfarin therapy due to their increased risk of both thrombosis and bleeding. Numerous studies have demonstrated the efficacy of pharmacist-managed anticoagulation services in both the inpatient and outpatient setting, but less data is available in LVAD patients. The objective of this study is to describe and compare the safety and efficacy of a center-based pilot study, which provides pharmacist-led warfarin management to a small cohort of LVAD patients.

**Methods:** This study will be submitted to the Institutional Review Board for approval. Patients with a left ventricular assist device and anticoagulation managed by an advanced heart failure cardiology team will be approached for inclusion in the pilot study. If patient consent is granted, a pharmacist will lead warfarin management in collaboration with the cardiology team in a pilot group of patients over a three month period. The majority of INR values will be collected via point of care devices in the patient home and electronically transmitted to the clinic for review. After each reading, patients will be interviewed over the telephone by a pharmacist. The pharmacist will develop and finalize a management plan with a cardiologist before communicating with the patient and documenting the encounter. The objective of the study is to compare time in therapeutic range between patients managed by a pharmacist to those receiving standard care. Secondary objectives to be evaluated include the percentage of recommendations accepted, incidence of thrombosis and bleeding, and patient and staff satisfaction with pharmacist-led services.

Poster Title: Development and Implementation of a Hospital Discharge Medication Reconciliation Process Assisted By Student Pharmacists at a Family Medicine Clinic

Primary Author: Rachel Lienemann, Northeast Iowa Medical Education Foundation, IA; Email: rlienemann@neimef.org

Additional Author (s):
Jim Hoehns
Matthew Witry
Adam Roise

Purpose: Approximately 60% of all medication errors occur during times of care transitions. Pharmacist integration in the transitional care has been shown to reduce preventable readmissions and improves health outcomes. At Northeast Iowa Family Practice Center (NEIFPC), pharmacists are not currently involved in the transition of care for clinic patients who are being discharged from the hospital. This project aims to improve the discharge process currently performed at the Northeast Iowa Family Practice Center through the implementation of a new medication reconciliation service, largely administered by student pharmacists with management by licensed pharmacists.

Methods: A templated discharge medication reconciliation note was created in the NEIFPC electronic medical records. Template elements include the following: hospital stay synopsis, a list of the patient’s current medications while inpatient on day of planned discharge, medications that have been started, stopped and/or adjusted while they were inpatient, drug therapy problems identified by the pharmacist or pharmacy student while inpatient and drug therapy recommendations the pharmacist or pharmacy student made to the inpatient physicians, and for the patient’s primary clinic physician to address.

Eligible patients include adult patients (≥18 years old) from NEIFPC who are admitted to a local hospital and receive inpatient care from the NEIFPC inpatient team. Patients who are discharged on Saturday or Sunday are excluded. Pharmacists and pharmacy students will perform bedside rounds with eligible patients and round with the NEIFPC inpatient team. When an eligible patient will be discharged from the hospital the pharmacist or pharmacy student will complete the templated discharge medication reconciliation note in the NEIFPC electronic
medical record and reconcile the clinic medication list. The study will measure time requirements of the pharmacist and pharmacy students as well as physician acceptance of drug therapy recommendations. Descriptive statistics will be utilized. The project has been reviewed by the NEIFPC Ethics Committee and satisfies criteria to be considered a quality improvement project.

**Poster Title:** Evaluation of behavioral health patient readmission rates before and after treatment with the once-monthly injectable antipsychotic paliperidone palmitate

**Primary Author:** Christopher Brockert, St. Luke's Regional Medical Center, IA; **Email:** christopher.brockert@unitypoint.org

**Additional Author(s):**
Fekadu Fullas  
James Stratton  
Lesleigh Ailts  
Corey Thieman

**Purpose:** Patients with chronic mental illness and a history of symptom relapse due to medication non-compliance are ideal candidates for long-acting antipsychotic treatment. Paliperidone palmitate (Invega Sustenna) is the most frequently used long-acting antipsychotic at a local community hospital. The primary objective of this study is to evaluate patient readmission rates to the behavioral health unit before and after receiving paliperidone palmitate.

**Methods:** This is a retrospective study that compares readmission rates for behavioral health unit patients before and after treatment with paliperidone palmitate. Patients admitted or transferred to the behavioral health unit between March 2014 and May 2016 with a medication order for paliperidone palmitate were eligible for this study. Medical profiles were reviewed on each admission/transfer for age, gender, purpose for admission/diagnosis, and antipsychotic medications used before and during inpatient stay. Patients who received the 234 mg dose but did not receive or were not scheduled to receive the 156 mg dose within seven days were excluded. Dates of each behavioral health unit admission were recorded for analysis. Admission data were compared before and after treatment and were analyzed using appropriate statistical methods. This study will be reviewed by the Institutional Review Board for approval.

**Poster Title:** Compliance with the Surviving Sepsis Campaign 3-hour bundle: a retrospective review of sepsis management

**Primary Author:** Nhut Nguyen, St. Luke’s Regional Medical Center, IA; **Email:** nhut.nguyen2@unitypoint.org

**Additional Author (s):**
Fekadu Fullas
James Stratton
Kristel Nelson

**Purpose:** The Centers for Medicare and Medicaid Services recently released its core measure for sepsis management, which aligns with the Surviving Sepsis Campaign guidelines. Sepsis management is complex, and promptness of therapy can impact patient outcomes. The 3-hour bundle includes initiating broad spectrum antibiotics, obtaining blood cultures prior to antibiotics, measuring initial lactate level, and administering 30 ml/kg of crystalloid fluids for indicated patients. This study’s objective is to assess compliance with guideline-directed recommendations from the 3-hour bundle to identify potential barriers to early sepsis management.

**Methods:** A single-center, retrospective chart review will be performed on patients diagnosed with sepsis from March 2016 to August 2016. Patients transferred from other hospital facilities will be excluded from the study. The electronic medical record system and International Classification of Diseases (ICD-10) codes will be used to obtain a roster of septic patients. Data on patient demographics, sepsis diagnosis, emergency department admission date, sepsis triage time, and sepsis order set utilization will be collected. Elements from the 3-hour bundle will be analyzed, which include time to first antibiotic administration, time of blood culture draw, time of lactate draw, initial lactate level, proper fluid administration (i.e. 30 ml/kg) for indicated patients and time of fluid administration. Guideline-recommended compliance with the 3-hour bundle will be evaluated. The study will be submitted to the Institutional Review Board for approval.

Poster Title: Analysis of gastrointestinal bleeds and proton pump inhibitor prophylaxis in patients requiring dual antiplatelet therapy at Allen Hospital.

Primary Author: Jacob Peterson, UnityPoint Health - Allen Hospital, IA; Email: jacob.peterson@unitypoint.org

Additional Author (s):
Elizabeth Nichols
Adam Wilcox

Purpose: The Clopidogrel and the Optimization of Gastrointestinal Events Trial (COGENT) supported using proton pump inhibitors for patients prescribed dual antiplatelet therapy in an effort to reduce gastrointestinal bleeding. This study will have two arms. In the retrospective arm, the objective is to determine the percentage of patients at this hospital receiving an appropriate proton pump inhibitor in addition to dual antiplatelet therapy after stenting. In the prospective arm, interventions to increase appropriate therapy will be implemented. Upon conclusion, both groups will be compared to determine if a decrease in gastrointestinal bleeding occurred after intervention without increasing cardiac events.

Methods: This study has been submitted to the Institutional Review Board for approval. Patients undergoing percutaneous coronary intervention at Allen Hospital during the period from August 2014 to July 2016 will be included in this study. The electronic medical record will be used to identify medication regimens, diagnosis codes, and cardiologists covering each case. All data will be collected without patient identifiers to maintain protected health information. Patients meeting inclusion criteria will be categorized by the specific dual antiplatelet regimen and proton pump inhibitor prescribed. The percentage of patients receiving appropriate therapy will be recorded as well as the occurrence of any gastrointestinal bleeding or cardiac events post-procedure. After determining initial prescribing rates of proton pump inhibitors, education will be provided to the cardiologists. The order set in the electronic medical record will be updated to include a proton pump inhibitor as a default order to increase the rate of prescribing. Patients undergoing procedures for three months after these interventions will be included in the prospective arm. After the prospective data has been collected, the two study groups will be compared and differences in prescribing habits will be documented. The
incidence of patients who present with gastrointestinal bleeding will be recorded for each group to determine if the intervention resulted in a significant decrease in admissions due to gastrointestinal bleeding.

Poster Title: Implementation of vancomycin dosing protocol specific for obese patients

Primary Author: Michael Jacobsen, UnityPoint Health- Allen Hospital, IA; Email: mchljcbsn13@gmail.com

Additional Author(s):
Jeffrey Martin
Nupur Chopra

Purpose: Vancomycin requires therapeutic drug monitoring for optimal antibacterial effect. Higher incidence of supratherapeutic troughs occur in obese patients as vancomycin demonstrates two-compartment distribution. The purpose of a vancomycin dosing protocol specific for obese patients aims to reduce the occurrence of supratherapeutic troughs, acute kidney injury, dialysis or extended hospitalization after administration of a loading dose of vancomycin. This institution’s current protocol utilizes a 25mg/kg loading dose with subsequent 20mg/kg dosing at intervals determined by estimated creatinine clearance. The modified protocol divided the initial loading dose into two doses given six hours apart.

Methods: This study will be submitted to the Institutional Review Board for approval. Patients included in this study will be adults 18 years of age or older, have a BMI greater than or equal to 35 kg/m2 and pharmacy consulted to dose vancomycin. Patients that do not meet criteria are pre-op/intraoperative vancomycin dosing, patients on hemodialysis, or physician managed vancomycin dosing. A six-month, retrospective sample of patients who met this study’s inclusion criterion will be identified to determine a baseline occurrence of supratherapeutic troughs. Prospectively, a six-month data collection of obese patients receiving divided loading doses of vancomycin will be completed. The primary outcome measure is the percentage of obese patients that receive divided loading doses of vancomycin and have a therapeutic trough within goal range of 15-20 mcg/mL. Secondary outcomes included percentage of troughs that are above or below goal range of 15-20 mcg/mL.

Poster Title: Utility of traditional severity markers in Clostridium difficile infections in solid organ transplant patients

Primary Author: Tiffany Lee, Beth Israel Deaconess Medical Center, MA; Email: tlee11@bidmc.harvard.edu

Additional Author(s):
Monica Mahoney
Christopher McCoy
Elizabeth Hirsch
Carolyn Alonso

Purpose: Solid organ transplant (SOT) patients are at a high risk of contracting Clostridium difficile infections (CDI) due to chronic immunosuppression and a propensity to receive multiple courses of antimicrobials. Management of CDI in SOT patients poses a unique challenge since this population generally has disease-altered laboratory parameters. As a result, commonly utilized laboratory variables for classifying CDI severity may not be accurate, putting patients at risk for inappropriate therapy. This project aims to analyze the differences in severity categorization using traditional markers of CDI in SOT patients.

Methods: The study will be submitted to the Institutional Review Board prior to commencement. This is a retrospective cohort study of SOT versus non-SOT patients experiencing their first episode of CDI at Beth Israel Deaconess Medical Center between 2008 and 2016. Patients will be identified through a report of all patients with a positive Clostridium difficile stool toxin assay or PCR result. Only first cases of CDI will be included. The SOT-cohort will be those with CDI following transplantation. A comparator cohort of non-SOT patients will be included from the same time period. All patients will be included in they were deemed infectious and treated for CDI, and will be excluded if they have an active malignancy and are receiving chemotherapy or are being treated for a recurrent CDI. Data collection will include demographics, transplant history, CDI characteristics, and variables to assess severity based on multiple scales. The primary study endpoint is the rate of concordance for all patients considered severe or severe complicated in existing CDI scales. Secondary endpoints include the initial CDI treatment received and rates of clinical success by cohort group. Variables will be
analyzed using McNemar’s and t-test, as appropriate. A multivariate logistic regression analysis will be used to determine which laboratory parameters and CDI-related characteristics may be more clinically useful in determining true CDI severity in the SOT population.

Poster Title: Impact of a new computerized provider order entry vancomycin dosing nomogram on target trough attainment

Primary Author: Ryan Chapin, Beth Israel Deaconess Medical Center, MA; Email: rchapin@bidmc.harvard.edu

Additional Author(s):
Christopher McCoy
Monica Mahoney

Purpose: The effect of vancomycin exposure on treatment has driven many institutions to implement complex dosing protocols for initiation of therapy. Previous reviews at our institution demonstrated that a simplified protocol resulted in a 48% rate of initial target trough attainment. A new computerized order entry protocol was initiated this year with the goal of improving the rate of initial target trough attainment. The type of infection, weight and estimated renal function are the primary determinants. The purpose of this study is to determine if a new vancomycin dosing nomogram improves achievement of initial therapeutic trough compared to the previous nomogram.

Methods: This study will be submitted to the Institutional Review Board for approval. Patients will be identified using clinical databases to generate a report for inpatients treated with vancomycin at Beth Israel Deaconess Medical Center with initial troughs documented for the months prior to and the month following nomogram implementation. Inclusion criteria are patients dosed appropriately per nomogram, treated for at least 72 hours with vancomycin, and not on hemodialysis dosed by the Nephrology service. Data to be collected include patient demographics, estimated renal function at the time of dosing, stability of renal function, indication for vancomycin therapy, and concomitant nephrotoxic agents. The goal trough range will be determined from the indication entered during order entry and/or documentation in care notes. Levels drawn greater than 2 hours from a true trough time will be extrapolated using population based pharmacokinetic calculations. The primary outcome will be the frequency of target range attainment at the time of the first steady state trough between the groups pre and post nomogram. Those values outside the range will be described as either supertherapeutic or subtherapeutic with a percent discrepancy. Given that weight and
estimated renal function are two primary fixed variables for the nomogram, other contributing patient factors that may affect performance such as unstable renal function, extremes of age, or weight will be assessed for impact on the primary outcome.

**Poster Title:** Fosaprepitant for the prevention of chemotherapy-induced nausea and vomiting in allogenic and autologous hematopoietic stem cell transplant patients

**Primary Author:** Nora Alkhudair, Beth Israel Deaconess Medical Center, MA; **Email:** noura.alkhudair@gmail.com

**Additional Author (s):** Zaven Norigian

**Purpose:** Chemotherapy-induced nausea and vomiting (CINV) is a common complication of cancer therapy. Patients undergoing hematopoietic stem cell transplant (HSCT) have a higher risk of developing CINV, due to the administration of multi-day moderately and highly emetogenic chemotherapy regimens, in addition to the emetic response associated with the infusion of cryopreserved stem cells. There are limited data evaluating the use of fosaprepitant (FOS) in the HSCT setting. In 2012, Beth Israel Deaconess Medical Center converted to a fosaprepitant antiemetic protocol. A review is warranted to evaluate the efficacy of the addition of FOS to autologous and allogeneic HSCT antiemetic regimens.

**Methods:** Prior to commencement, this retrospective medical record review will be submitted to the Institutional Review Board for approval. The study will include patients 18 years and older, who received conditioning regimens for allogeneic or autologous HSCT from 2009 to 2016. Patients will be divided into two groups: the control group will comprise patients who received standard antiemetic regimens without FOS from 2009 to 2011, and the FOS group will comprise patients who received standard antiemetic regimens plus FOS from 2012 to 2016. The primary endpoint is no emesis during and after the conditioning period in each group. Secondary outcomes include reduction in the amount of supplemental anti-emetics (total number of breakthrough antiemetic doses per patient), percentage of patients with no delayed emesis, total number of emetic episodes per patient, and complete response rate (defined as no emesis and no breakthrough antiemetic use). Pertinent demographics, chemotherapy regimen, emesis reported, timing of emesis (acute versus delayed) and as needed anti-emetic use will be collected. Based on earlier trials, we estimate that the absence of emesis in the FOS arm will be 65%. Therefore, a sample size of 79 patients per group will provide 80% power at an alpha of 0.05 to...
detect a 25% reduction of emesis. Categorical variables will be analyzed using Fisher’s exact test and continuous variables will be analyzed using t-test and Mann-Whitney test.

Poster Title: Impact of a steroid free immunosuppressive regimen on patient and graft outcomes in pancreas transplant recipients

Primary Author: Mariesa Cote, Beth Israel Deaconess Medical Center, MA; Email: cote.mariesa@gmail.com

Additional Author(s):
Khalid Khwaja
Katelyn Richards
Christin Rogers

Purpose: For decades, steroids have been a component of immunosuppressive regimens in solid organ transplant for prevention and treatment of rejection. There are concerns regarding long term steroid use, due to their association with hypertension, hyperlipidemia and post-transplant diabetes. For these reasons, the use of steroid free immunosuppressive regimens following pancreas transplant has increased over the past decade. Most studies to date involving pancreas transplant recipients had short term follow-up, evaluating outcomes six months to one-year post-transplant. The purpose of this study is to evaluate the risks and benefits of steroid withdrawal in pancreas transplant recipients at three years post-transplant.

Methods: This study will be submitted to the Institutional Review Board for approval. It is a retrospective chart review of patients who underwent a pancreas transplant at Beth Israel Deaconess Medical Center (BIDMC) between May 1989 to October 2013. Prior to 2004, steroid maintenance therapy following pancreas transplant was standard at BIDMC. After 2004, a steroid free maintenance immunosuppressive regimen was adopted. Patients who received a pancreas transplant will be identified from a data repository and screened for age over 18 years and the absence of graft failure within two weeks of transplant for inclusion. The primary outcome is a composite outcome of pancreas graft survival, patient survival and rejection rates at three years post-transplant. Secondary outcomes include readmission rates at one month and three years post-transplant, need for antibiotics within 30 days of transplant, immunosuppression levels at 14 days, 3 months, 6 months, 1 year and annually post-transplant, rates of infection, rates of malignancy and the number of patients who resumed prednisone in the steroid free group. Patients included in the steroid free group are those who did not receive
steroids after postop day seven. Graft loss will be defined as a sustained return to insulin (greater than 30 days of use) or graft removal. Acute rejection will be defined as biopsy proven rejection that was treated or rejection that was treated without biopsy results.

**Results:** N/A

**Conclusion:** N/A
Purpose: Fentanyl is the cornerstone of intensive care analgesia and sedation at the Beth Israel Deaconess Medical Center (BIDMC). A subset of patients develop tolerance to fentanyl, leading to higher dose requirements (greater than 400 mcg per hour) and diminished effects. Switching these patients to lower dose hydromorphone intravenous infusions may lessen opioid burden and improve pain management. Opioid equianalgesic conversion is complicated in critically ill patients given their altered kinetics and functional impairment. The objective of this study is to evaluate a fentanyl to hydromorphone infusion conversion, assessing dose equivalence, tolerability, and efficacy.

Methods: This study will be submitted to the Institutional Review Board for approval. It is a single center retrospective chart review of patients who underwent an opioid conversion from a fentanyl to hydromorphone infusion between July 2014 and July 2016 in the intensive care units (ICU) of BIDMC. All patients aged 18 years and older who received fentanyl at an infusion rate greater than 400 mcg per hour and were transitioned to hydromorphone will be evaluated for inclusion. Patients who received non-ICU or comfort-focused infusions will be excluded. The primary outcome is pain scores, measured as an average of the patient’s pain levels over 48 hours, 24 hours before and after the opioid conversion. Secondary endpoints include respiratory rate, sedation level, and blood pressure values. Secondary endpoints will be measured as averages over a 48-hour interval, 24 hours pre and post conversion. Data collection will also include indication for conversion and patient demographics. Data will be analyzed using Fisher’s exact test and chi-squared test for categorical data, Student’s t-test for continuous data, and univariate and multivariate logistic regression for clinical outcomes.

Poster Title: Analysis of missed doses of venous thromboembolism prophylaxis medication in hospital inpatients

Primary Author: Eun Ko, Brigham and Women's Hospital, MA; Email: ejko@partners.org

Additional Author(s):
Catherine Ulbricht
Marc Pimentel
Robin Heafey

Purpose: Venous thromboembolism (VTE) is the most common preventable cause of in-hospital mortality, and proper VTE prophylaxis has been shown to prevent VTE. There is a gap in the literature regarding the reasons for missed doses of pharmacological VTE prophylaxis. Missed doses of VTE prophylaxis medications in the inpatient setting may lead to an increased risk of thrombotic events and readmissions. The objective of this study is to quantify and describe the most common reasons for missed doses of VTE prophylaxis.

Methods: All clinical research represented in this abstract was approved by the Brigham and Women’s Hospital Institutional Review Board. A report of ordered medication doses for VTE prophylaxis for inpatients over an eight month period (January 1, 2016 to August 31, 2016) was compiled from the electronic inpatient medication administration record. The raw data included all ordered doses of unfractionated heparin and low molecular-weight heparin, excluding doses with non-subcutaneous route of administration, non-inpatient areas, unknown administration status, subcutaneous heparin doses other than 5,000 units, and subcutaneous enoxaparin doses other than 40 mg. The report included documentation of given and missed doses obtained from the electronic medication administration record (MAR), reasons for the missed doses and free text comments about the missed doses. The proportion of missed doses was calculated. The reasons for missed doses were categorized and tabulated. Free text comments for missed doses were also reviewed.

Results: A total of 106,730 VTE prophylaxis doses ordered for admitted patients over a 8-month period were analyzed. The proportion of ordered doses that were not administered was 9.89% (10,551/106,730). The four most common reasons for missed doses were “patient/family
refusal” (60.5%, 6,381/10,551), “contraindicated” (15.4%, 1629/10,551), “per MD order” (11.7%, 1230/10,551), and “patient not available” (4.8%, 504/10,551). These reasons accounted for more than 90% of missed doses. Comments about missed doses were added in 759 of the 6,381 refusals, and included comments such as, “patient ambulating frequently”, “patient educated about VTE risks”, “patient being discharged home” and “MD aware”. VTE Prophylaxis doses given in ICU vs. non-ICU settings were also analyzed to assess if different settings affect the data. Out of 5645 doses given in ICU, missed doses (335/5645) only accounted for 6% whereas in non-ICU settings, 10% (10216/101085) doses were missed. The two most common reasons for missed doses in ICU settings were “doses held for various reasons” (7.8%, 26/335), and “going to OR” (5.7%, 19/335).

**Conclusion:** Missed doses of VTE prophylaxis medication often occur for non-medical reasons, such as patient/family refusal and unavailability of the patient at the scheduled time of dose. Education to prevent patient/family refusal of VTE prophylaxis medication is a significant area of focus for improved healthcare outcome and opportunity for pharmacy-led counseling interventions. Implementing VTE prophylaxis education led by pharmacy for patients and family members, including review of the risks of missing doses, may help reduce the number of missed doses, thereby reducing the risk of VTE and readmissions. Supplemental anticoagulant education efforts can also help assure compliance with the medication safety Joint Commission as a National Patient Safety Goal.

Jimmy Gonzalez  

**Purpose:** Direct oral anticoagulants (DOACs) have shorter half-lives compared to warfarin; therefore, missed doses can lead to significant gaps in anticoagulation coverage and a high risk of thrombotic events. Previous studies have demonstrated improved adherence to DOACs in patients who were monitored and educated by pharmacists. The objective of this study is to determine if a pharmacist-run anticoagulation service, monitoring patients for adverse events as well as appropriate use and providing education on the importance of anticoagulation therapy, leads to an improved adherence and lower rates of bleeding, thrombosis, and mortality.  

**Methods:** This study will be submitted to the Institutional Review Board for approval. Cardiovascular specialists at a cardiology clinic affiliated with a community hospital will provide a list of patients who were on a DOAC from September 2015 to August 2016 (historical control group) and a list of patients who are presently on a DOAC (observation group). The latter group meeting the inclusion criteria will be contacted via telephone and invited to participate in a DOAC clinic. Patients 18 years or older receiving DOAC therapy from the cardiology clinic will be included. Vulnerable and/or protected populations will be excluded. The initial appointment with the pharmacist will be in person and at least monthly thereafter in person or via telephone. The pharmacist will assess the DOAC therapy (indication, drug, and dose based on renal and hepatic functions) and screen for drug-drug interactions. All patients seen in the DOAC clinic will be provided with a print-out of patient drug information. The data that will be collected include demographic information, past medical and medication history, prescription and safety data. All data will be secured and maintained confidentially. The primary endpoint of adherence rate will be reported as a dichotomous variable for the proportion of days covered.
(PDC) of 80% or more and analyzed using the chi-squared test. Thrombosis, bleeding, and mortality will be analyzed with Fisher’s exact test.

Poster Title: Restricting meropenem use in a community hospital: a retrospective review of clinical and economic outcomes

Primary Author: Jillian O'Keefe, Cooley Dickinson Hospital, MA; Email: jillian.okeefe@wne.edu

Additional Author(s):

Kaylee Maynard

Purpose: Amidst the growing prevalence of bacterial resistance and concern for patient safety, antimicrobial stewardship has become a national priority. Monitoring and decreasing unnecessary and/or inappropriate use of broad-spectrum antibiotic agents, like carbapenem antibiotics, is vitally important to preserving the efficacy of these agents in the years to come. The objective of this study is to evaluate meropenem utilization pre- and post-stewardship audit interventions.

Methods: This study will be submitted to the Institutional Review Board for approval. Meropenem utilization at a 140 bed community hospital will be audited by pharmacists within 24 hours of order entry from October 2016 through March 2017. The primary outcome will be appropriateness of meropenem use based on documented indications, including, but not limited to, empiric treatment of health-care associated infections in patients with recent exposure to extended-spectrum beta-lactam agents and prior infection or colonization with a resistant gram-negative bacteria. If pre-determined utilization criteria are not met, the pharmacist will contact the prescriber to suggest appropriate changes. Secondary outcomes measured will include Days of Therapy (DOT) per 1000 patient days, number of unique patients, length of stay (LOS), and the cost of meropenem doses administered, each reported as a monthly average. Appropriateness of meropenem use as well as meropenem consumption and cost data from January 2015 through September 2016 will be reviewed for comparison; both pre- and post-intervention data will be obtained through MIDAS and the electronic medical record. Statistical analyses will utilize T-test for continuous variables and Fisher’s Exact test or Chi-square test (depending on sample size) for nominal variables.

**Poster Title:** Impact of pharmacy driven intervention to meet the Paul Coverdell National Acute Stroke Registry Consensus Measures

**Primary Author:** Brandon Huxley, Hallmark Health, MA; **Email:** bhuxley@hallmarkhealth.org

**Additional Author (s):**
Edward Harney
Nicole Clark

**Purpose:** Per the Center for Disease Control, stroke is a leading cause of death and serious, long-term disability in the United States. Roughly one in four strokes is recurrent. For patients admitted to the hospital with a stroke, medication management both during their stay and upon discharge is crucial to preventing these recurrences and promoting positive long term outcomes.

**Methods:** Pharmacy driven intervention will be founded in active flagging of admitted stroke patients through computer database. Pharmacists will actively perform a standardized quality assurance check based on study endpoints throughout patient hospital stay. Primary endpoints: percent of patients with ischemic stroke or TIA who receive antithrombotic therapy by end of hospital day two, percent of non-ambulatory patients with ischemic stroke or hemorrhagic stroke who receive DVT prophylaxis by end of hospital day two, percent of ischemic stroke or TIA patients with LDL > 100, or LDL not measured, or on cholesterol-reducer prior to admission, who are discharged on statin medication, percent of patients with ischemic stroke or TIA prescribed antithrombotic therapy at discharge, percent of patients with ischemic stroke or TIA with a-fib/flutter who are discharged on anticoagulation therapy. Secondary endpoints: percent of stroke or TIA patients or their caregivers who were given education during hospital stay about stroke-related warning signs, risk factors and medications.

All patients with ischemic, hemorrhagic stroke or TIA admitted to hospital will be included in the study. 4 months of pre and post intervention data will be collected from the Quality Department for included patients. Percentage of patients who meet the defined study endpoints will be calculated for both control and intervention data sets. Statistical analyses of each data endpoint will be conducted through calculated p-value and 95% confidence intervals.

Poster Title: Implementation of a pharmacy driven basal-bolus insulin protocol within a community hospital setting

Primary Author: Michael Courage, Hallmark Health System, MA; Email: mcourage@hallmarkhealth.org

Additional Author(s):
William Thornton
Nicole Clark

Purpose: The ADA and the AACE recognize that glycemic outcomes are optimal in patients managed on a basal-bolus insulin regimen. In hospitalized patients, glycemic outcomes are related to the length of hospital stay and costs associated with hypoglycemic or hyperglycemic events. Since pharmacists can make an impact on related outcomes, the objective of this research is to determine the efficacy of a pharmacy driven basal-bolus protocol as compared to non-protocol managed patients. Secondary objectives are to determine the cost justification of the protocol in relation to length of hospital stay and decrease in the cost of hyperglycemic and hypoglycemic events.

Methods: This study will be submitted to the Institutional Review Board for approval. Patients ordered sliding scale insulin with two or more blood glucose readings less than 70 mg/dL and/or greater than 200 mg/dL in 24 hours will be identified via pharmacosurveillance software. Pharmacists will then intervene by contacting providers and recommending those identified patients be placed on an insulin by pharmacy basal-bolus protocol. Additionally, the protocol can be ordered by a provider for any non-critically ill hospitalized patient. The protocol will be developed by the pharmacy department and approved by the Pharmacy & Therapeutics Committee and the Endocrine Committee of the Hallmark Health System. It will guide pharmacists in determining the optimal basal-bolus regimen and adjusting the regimen based on glucose readings. From January 2017 through April 2017, blood glucose readings during hospital stay will be collected for patients ordered the protocol and for patients not ordered the protocol. A head to head comparison of the average blood glucose readings between the two groups will be analyzed using the student’s t-test. The primary endpoint is to conclude if blood glucose outcomes were optimally controlled (between 140-200 mg/dL) in the protocol
group versus optimally controlled in the non-protocol group. As secondary endpoints, cost justification of the protocol will be determined by comparing hyperglycemic and hypoglycemic events and length of stay for patients in each group, respectively.

**Session-Board Number:** 11-103  
**Poster Title:** Impact of post-operative intravenous acetaminophen on opioid consumption within twenty-four hours after orthopedic surgery in a community hospital setting: A retrospective cohort study  
**Primary Author:** Caitlin Barker, Hallmark Health System, Inc., MA; **Email:** cbarker@hallmarkhealth.org  
**Additional Author (s):**  
Christine McCluskey  
Nicole Clark  

**Purpose:** Multi-modal analgesia is becoming increasingly important for the treatment of post-operative pain. The Pharmacy and Therapeutics Committee of a two-community hospital system approved intravenous (IV) acetaminophen for a one-time dose within 24 hours post-operation. This was mainly due to the high cost of the medication which is only available as a brand name product. The primary objective of this study is to evaluate the effects of IV acetaminophen in orthopedic surgery patients on opioid use, while the secondary objective is to evaluate its effect on pain control.
