Methods: The institutional review board approved this observational study of an educational initiative to expand health professional knowledge through pharmacy student-led teaching on an international medical mission trip. Participants included doctors, medical residents, and nurses working in the Dominican Republic. The verbal, case-based education was provided by five doctor of pharmacy students on their advanced pharmacy practice experience rotation. A medical Spanish translator was used to interpret the presentation. Study participants received a 10 question multiple choice pre and post assessment. They were asked to complete the pre assessment prior to the education and the identical post assessment after the completion of the education to evaluate knowledge gained. Questions were written to equally represent material from the four topics that were covered throughout the educational initiative: antibiotic resistance, medication safety, hypertension and diabetes. Assessments were graded with one point awarded for each correct answer, with a maximum possible score of 10.

Results: The average score on the pre assessment was 6.14 (standard deviation of 1.52) out of 10, which increased to an average score of 7.59 (standard deviation of 1.53) out of 10 on the post assessment. When the data was analyzed using a paired samples T-test, the difference in the means between the pre and post assessments was 1.45 questions (95 percent confidence interval, -2.03 to -0.88, P value less than 0.05). The greatest increase in knowledge was observed with questions relating to antibiotic resistance, hypertension and diabetes.

Conclusion: On a short-term medical mission trip to the Dominican Republic, pharmacy student-led teaching demonstrated an increase in health professional knowledge. Based on the findings of this study, short-term medical mission trips should include a student-led teaching component. This innovative addition could benefit not only the students in their training to become competent healthcare providers, but also the providers, patients, and communities that these medical mission trips serve.

Poster Title: How to explain cancer to a child and the effects of coloring therapy in children with cancer

Primary Author: Alexandra Mauer, Butler University College of Pharmacy, Indiana; **Email:** amauer@butler.edu

Purpose: It has been studied and proven that art therapy can help with anxiety, depression, and even some diseases such as cancer. When a child who has cancer is waiting to be seen in a doctor's office, a coloring book can keep his or her mind off of the diagnosis, provide entertainment, and elicit a relaxing mindset. The purpose of this thesis is to determine if we, as an inter-professional team after studying the current body of literature, can create a children's book to address an unmet need in educating children on cancer while at the same time incorporating art therapy.

Methods: Today, art therapy is widely practiced in a variety of settings including hospitals and in patients who have adverse physical health conditions such as cancer. Art can encourage emotional expression, improve relationships, encourage self-confidence, help to control anxiety or depression, and help to take your mind off pain or discomfort. Children's coloring books are an important aspect of children's healthcare that should be utilized for every child that has cancer in order to put them at ease and hopefully explain some questions that they may have about cancer.

Results: Research was conducted on the effects of art therapy in cancer and on the current availability of children's books about cancer. Ultimately this resulted in the co-writing of a children's book focused on incorporating art therapy for cancer patients through coloring, which addresses an area of unmet need. Writing a children's book was a group effort that consisted of two college of pharmacy majors, two business majors, two college of education majors who have experience in children's literature, and an illustrator. The storyline includes a young character with leukemia to help explain cancer to children. The children's book was designed as a coloring book in order to provide entertainment, relaxation, and therapy to those who choose to heal through art.

Conclusion: Art therapy should be utilized to calm cancer patients and provide them with a distraction, while simultaneously offering children dealing with serious illnesses a chance to express their feelings. Additionally, a coloring book with a storyline could help explain unanswered questions a child might have and equips parents with a helpful resource for explaining cancer. This type of book could be utilized in children's hospital waiting rooms and patient rooms, or could be sold simply as a coloring book with an educational storyline.

Poster Title: Implementation of a student-developed electronic medical record in a Dominican Republic underserved health clinic

Primary Author: Bethany Feitshans, Butler University College of Pharmacy, Indiana; **Email:** bfeitsha@butler.edu

Additional Author (s):
Thomas Muma
Ryan Barton
Trish Devine

Purpose: In 2009, Congress passed the Technology for Economic and Clinical Health Act (HITECH), which emphasized the "meaningful use" of health technology. Research has shown that electronic medical records can increase patient safety, increase documentation accuracy, and improve outcome measures. However, there has been difficulty expanding this technology to smaller populations of underserved patients, such as international medical mission trips, due to cost. The purpose of this study was to implement a student-developed electronic medical record in a Dominican Republic underserved health clinic and to assess the perceived improvement of patient care attributed to the technology.

Methods: Three doctor of pharmacy students collaborated with a team of students from the "Engineering Projects in Community Service" undergraduate course at Butler University to design and develop an electronic medical record for non-profit organization Barnabas Task. It was specialized to meet the demand of clinic work flow and was based off of previous paper medical records used by Barnabas Task. Six iPads were purchased using a 1500 dollar grant. The institutional review board approved this cross-sectional study in which a survey was sent out via email to the students and trip leaders who attended the May 2016 medical mission trip to the Dominican Republic. One multiple choice and two free response questions were included to assess the participant's perception of the electronic medical record's impact on patient care and potential improvements for the future. Multiple choice question data was analyzed using frequencies and percentages. Qualitative responses were organized to look at trending themes.

Results: The electronic medical record was successfully developed and implemented in the underserved Dominican Republic health clinic during four clinic days seeing 329 total patients. Out of 23 possible participants, 18 completed the survey. Over 60 percent of participants either agreed or strongly agreed that the electronic medical record improved patient care. Additionally, 22.22 percent of participants were neutral and 16.67 percent had other responses to the impact on patient care. No participants disagreed or strongly disagreed that the electronic medical record improved patient care. Qualitative feedback showed that establishing a medical history for the patients and helping with organization of the clinic were the largest perceived impacts on patient care. Participants agreed that fixing basic maintenance issues and improving the prescription entry could enhance patient care at future clinics.

Conclusion: Student-developed, specialized electronic medical records can successfully be implemented into international medical mission clinics at a low cost to the non-profit organization. Overall, there was a positive perception of the electronic medical record's impact on quality of patient care during the underserved clinic in the Dominican Republic.

Poster Title: Adult antimicrobial renal dosing policy evaluation: A retrospective chart review

Primary Author: Sarah Lowry, Butler University College of Pharmacy & Health Sciences, Indiana;
Email: slowry@butler.edu

Additional Author (s):
Kelly Davidson
Colleen Scherer
Melissa Neglia
Alison Walton

Purpose: Renal dosing adjustments have been found to lessen the prevalence of antibiotic dosing errors in renally impaired patients. With the increase of acute kidney injury, there is a need to review appropriate medication dosing in order to prevent adverse outcomes while maintaining disease treatment. This study evaluates the compliance to an adult antimicrobial renal dosing policy where specific antimicrobials were adjusted based on patient renal function, change in renal function during therapy, and adverse events.

Methods: An IRB-approved retrospective chart review was conducted on patients 18 years of age and older who received one of seven antimicrobials while at St. Vincent Indianapolis, St. Vincent Carmel, or St. Vincent Fishers hospitals from March 1, 2016 through May 31, 2016. The seven target antimicrobials evaluated were intravenous acyclovir, intravenous ciprofloxacin, oral ciprofloxacin, intravenous levofloxacin, oral levofloxacin, intravenous piperacillin/tazobactam, and intravenous cefepime. Baseline demographics and antimicrobial agent, dose, and length of therapy were collected and patient creatinine clearance and change in creatinine clearance were determined using the Cockcroft Gault formula per serum creatinine lab values. Patients who were less than five feet in height, not given the ordered antimicrobial, or did not have a measured serum creatinine within three days of admission were excluded. The primary outcome of this study was to evaluate overall compliance to the renal dosing protocol. The secondary outcomes included examining documented adverse effects or clinical worsening of renal function.

Results: There were 1,504 patients that had at least one target antimicrobial during the study time period. Per a random number generator, 100 patients were randomly selected from this group for analysis. Ninety-five patients met inclusion criteria, resulting in 126 antimicrobial orders for evaluation. Intravenous cefepime and piperacillin/tazobactam accounted for 63.5% of the antimicrobial orders. The overall compliance to the antimicrobial renal dosing policy for the initial dose was 68.3%, with cefepime being the least at 45.5%. For subsequent doses, 15% of incorrect orders and 30% of orders with renal function change during therapy were appropriately changed. An antimicrobial dosing alert was fired for 33 orders, but 27 of those orders had no intervention documented. However, no adverse events were documented for any patients.

Conclusion: Adult antimicrobial renal dosing policies may prevent dosing errors in patients, especially the renally impaired. This study identifies the need to improve renal dosing adjustments for antimicrobials, specifically with intravenous cefepime and worsening renal function. Although no adverse events were reported, future studies' further investigation may help determine the significance made by renal dosing policies.

Poster Title: Cronobacter sakazakii pneumonia in a burn patient requiring mechanical ventilation.

Primary Author: Ryan Schneck, Butler University College of Pharmacy and Health Sciences, Indiana; **Email:** rschneck@butler.edu

Additional Author (s):
Todd Walroth
Megan Fleming

Purpose: This case report describes a Cronobacter sakazakii infection in a burn patient requiring mechanical ventilation. Cronobacter sakazakii, formerly categorized as an Enterobacter spp., is a gram-negative, non-spore forming rod. It is most commonly associated with neonatal meningitis secondary to food contamination from breast milk or dry powder. This organism has been previously reported in the wound of a burn patient but has been unreported in a burn patient's lungs. The patient is a 38-year-old female who sustained 39 percent Total Body Surface Area full thickness and deep partial thickness burns to her lateral trunk, bilateral upper extremities, bilateral thighs, and face after her clothes ignited while smoking a cigarette. She was electively intubated at an outside hospital due to increased oxygen requirements and transferred via helicopter where she was admitted to our Burn Center. She presented afebrile with a WBC of 9.7 k/mm3. Her past medical history was significant for an underlying neurological condition that was unknown at the time, multiple sclerosis, and chronic necrotic wounds on bilateral thighs. On Post Burn Day (PBD) 1, a bronchoscopy showed no evidence of inhalation injury, a nasojejunal tube was placed for enteral nutrition, and she was initiated on Assist Control Ventilation Control mode mechanical ventilation. On PBD2, she received debridement, escharotomies, and a homograft placement in the operating room. On PBD4, she was transitioned to Continuous Positive Airway Pressure-Pressure Support ventilation mode. A chest x-ray on PBD5 showed a small left pleural effusion with bibasilar atelectasis, sputum cultures were obtained, and cefepime 2 grams IVPB every 8 hours was started empirically. Vancomycin was added on PBD6 for empiric coverage of ventilator-associated pneumonia after the patient developed a fever of 102F. A loading dose of Vancomycin 2000mg (24mg/kg) IVPB was given followed by 1500mg (18mg/kg) IVPB every 12 hours. On PBD8, her WBC was 18.1 k/mm3, Tmax was 103.6F, and she began producing thick, yellow sputum. In response to these

symptoms, a bronchoscopy was performed. Quantitative cultures of bronchoalveolar lavage (BAL) fluid and blood culture were collected. The sputum culture and BAL culture both grew gram-negative rods, later identified as Cronobacter sakazakii. Blood cultures became positive in two out of four bottles, later identified as a Streptococcus spp. and Enterobacter cloacae. Cronobacter sakazakii was found to be susceptible to cefepime with an MIC less than or equal to 1 on PBD9, so therapy was continued. The patient's clinical status improved on PBD9 with successful extubation to room air and decreased sputum production despite an increase in WBC to 20.6 k/mm3. On PBD10, she continued to respond clinically to cefepime as her WBC decreased to 18.2 k/mm3 and she became afebrile. The decision to move to comfort care with symptom-only management was made by the patient, her family, and the medical team during a meeting on PBD11 due to her underlying neurologic condition, associated life expectancy, and quality of life concerns. At that time, all antibiotic therapy was discontinued with no further cultures obtained. To our knowledge, this is the first reported case of successful treatment of a ventilator-associated Cronobacter sakazakii pneumonia in a burn patient.

Poster Title: Scopolamine transdermal patch medication use evaluation at St. Vincent Indianapolis Hospital

Primary Author: Alexandria Hissong, Butler University College of Pharmacy and Health Sciences, Indiana; **Email:** ahissong@butler.edu

Purpose: Scopolamine transdermal patches are widely used in the pre- and post-operative areas of St. Vincent Hospital to prevent nausea and vomiting associated with anesthesia in surgery. Guidelines recommend scopolamine as an adjunct to other antiemetic therapies since up to 80 percent of surgical patients may be affected. However, reports suggest that if patch removal does not occur within 72 hours of placement, a withdrawal syndrome may cause symptoms consistent with rebound cholinergic activity. The documentation for the actual scopolamine order, patch placement, and patch removal at St. Vincent was identified as a potential opportunity for improvement to prevent scopolamine withdrawal.

Methods: This is a retrospective medication use evaluation of patients at St. Vincent Indianapolis Hospital with a documented charge for a scopolamine patch and a charge for a Level 1 through 10 surgery between September 1, 2014 and August 31, 2015. There were 1,475 patients identified based on these criteria. Patients were arranged in order by birth date to separate children (less than 18 years of age) and adults (greater than or equal to 18 years of age) into two separate lists. These two different patient populations were then arranged in order of the date of service and assigned numbers to be used in a random number generator. The patients were randomized, identifying 10 pediatric patients and 61 adult patients for evaluation. The patients were individually evaluated based on scanned images of their paper charts and their electronic medical record to collect the following scopolamine data points: documentation of administration, complete drug order (drug, dose, route, and frequency), administration documentation and removal task fired in the Sunrise Clinical Manager electronic medical record, completion of removal task, discharge within or after 72 hours of patch placement, and written discharge removal instructions. Data was evaluated using mean and percentage difference between groups.

Results: In the adult and pediatric populations, the results proved to be similar regardless of outpatient or inpatient status. Approximately 94 percent of all of the patients included in this evaluation had documentation of administration of the scopolamine patch within their chart or electronic medical record. Of these patients, approximately 69 percent of patients had a complete order including the drug name, dose, route, and frequency. Approximately 61 percent of patients had administration documentation and a removal task fired within the electronic medical record, with only 7 percent having completion of the removal task. In the adult patients, 34 patients were discharged prior to the full 72 hours of the scopolamine patch administration, yet only 2 of these patients (6 percent) had written discharge instructions to remove the patch. On the other hand, in the pediatric population, no patients had completion of the removal task or written discharge removal instructions in their paperwork.

Conclusion: The results of this medication use evaluation demonstrates that a majority of anesthesiologists are documenting the placement of the scopolamine patch on their anesthesia records and/or writing a complete order for scopolamine patches, but there is still room for improvement. There needs to be a focus on removal order documentation for the task and/or documentation that the patient was instructed how and when to remove the patch if they were discharged prior to removal. Proper documentation is essential in order to ensure that transitions of care are effectively communicated to reduce the risk of scopolamine withdrawal syndrome.

Poster Title: Outcomes of extended infusion cefepime in pediatric patients

Primary Author: Lauren Beauchamp, Butler University College of Pharmacy and Health Sciences, Indiana; **Email:** lkarmire@butler.edu

Additional Author (s):
Kristen Nichols
Chad Knoderer

Purpose: The use of extended infusions of cefepime has been shown to optimize pharmacokinetic and pharmacodynamic parameters. Optimization improves clinical outcomes in adults with infections secondary to gram-negative pathogens, but there are no studies demonstrating benefit in pediatric patients. The objective of this study was to compare clinical outcomes in pediatric patients receiving extended and traditional infusion cefepime.

Methods: This was a retrospective cohort study of patients aged 30 days to 17 years receiving extended versus traditional infusion cefepime at a tertiary care children's hospital from January 1, 2007 to April 30, 2016. Patients were included if they received cefepime for at least 48 hours for a susceptible gram-negative bacteremia with no concomitant gram-positive or fungal infections. Patients were excluded if they received both regimens, did not receive active antimicrobial therapy within 24 hours of the first positive blood culture, or received more than 24 hours of empiric therapy with a beta-lactam other than cefepime. The primary outcome was a composite clinical outcome comprised of infection-related mortality within 14 days of antibiotic initiation, bacteremic relapse with the same organism within 30 days of culture clearance, and treatment failure. Treatment failure was defined by lack of defervescence, normalization of white blood cell (WBC) count, or negative follow-up blood cultures. Patients who failed to meet the criteria for defervescence, WBC normalization, or culture clearance or any single component when no other information was available were considered treatment failures. Secondary outcomes included bacteremia duration, hospital and intensive care unit (ICU) length of stay (LOS), infection or colonization with a multi-drug resistant (MDR) organism, and adverse effects of cefepime.

Results: Thirty-nine patients were included in the analysis; 12 patients (30.8 percent) received extended infusion, and 27 patients (69.2 percent) received traditional infusion. Traditional infusion patients were significantly younger with a median (interquartile range [IQR]) age of 0.4 (0.2-3) years compared to 5 (1.1-9.8) years amongst extended infusion patients (p equals 0.023). The median initial mg/kg doses were similar between groups (approximately 50 mg/kg intravenously every 8 hours). The most common infectious organism was Escherichia coli (10/39 cultures) followed by Klebsiella pneumoniae (9/39 cultures). The most common minimum inhibitory concentrations (MICs) amongst organisms were less than or equal to 1 (36/39 cultures), though 1 organism within traditional and extended infusion had MICs equal to 2 mcg/ml, and 1 traditional infusion organism had an MIC of 4 mcg/ml. The primary outcome occurred in one patient in each group (p equals 1). Development of MDR infection did not differ. Clearance of bacteremia within 24 hours was observed in 4 patients (33.3 percent) receiving extended infusion versus 6 patients (22.2 percent) receiving traditional infusion (p equals 0.693). Length of stay was similar between groups. One adverse effect was reported with extended infusion compared to 3 adverse effects with traditional infusion.

Conclusion: Use of extended infusion cefepime in pediatric patients with documented gram-negative bacteremia led to similar clinical outcome as traditional infusion in this cohort of children with low bacterial MICs. Larger studies including patients that are infected with organisms with higher MICs may be more likely to detect significant difference in outcomes.

Session-Board Number: 3-125

Poster Title: Outlining Medicare Part B versus Part D coverage for outpatient medications in Indiana

Primary Author: Andrea Baker, Butler University, College of Pharmacy & Health Sciences, Indiana; **Email:** ajbaker@butler.edu

Additional Author (s):
Carriann Smith

Purpose: Most outpatient medications are covered by Medicare Part D. Medicare Part B also provides coverage for outpatient prescriptions. Due to special circumstances, unique dosage forms, and an unclear definition of 'usually" self-administered, determining if a product is covered under Part B or D is difficult. Patients and advocates utilizing the Medicare Plan Finder to compare Part D plans must enter the list of medications covered only by Medicare Part D. This project was developed to assist with accurate Medicare Part D lists for the plan finder. Created for Indiana, it may also serve as a guide for other states.

Methods: The first step in developing a tool to compare Medicare Part B and D coverage was to list outpatient medications covered by Medicare Part B. Resources provided by the Centers for Medicare and Medicaid Services (CMS) were used to start the list. Most of these medications have specific requirements for coverage under Medicare Part B. The specific requirements for each medication were carefully evaluated using several detailed documents from the Centers for Medicare and Medicaid Services (CMS) and WPS Local Coverage Determination and consolidated billing documents.

Results: The results are provided in a PDF document with three parts. First is a summary table outlining all the Medicare Part B covered outpatient medications by medication category. Following this is a detailed bulleted list outlining the coverage requirements for each medication. Finally, a separate appendix was created for injectable medications that are excluded from Medicare Part B coverage and are therefore covered under Part D.

Conclusion: This tool has been used by pharmacists and patient advocates to create an accurate Medicare Part D list for patients using the plan finder in Indiana.

Poster Title: Analysis of corticosteroid prescribing patterns following ICU transfer

Primary Author: Barbara Suh, Manchester University, Indiana; **Email:** bmsuh2017@manchester.edu

Additional Author (s):
Tung Nguyen
Dustin Linn
Sarah Gordon

Purpose: Corticosteroids are administered in patients with acute exacerbations of chronic obstructive pulmonary disease (COPD) as they may shorten recovery time and improve lung function. Literature describing the use of corticosteroids for COPD exacerbation specifically in critically ill patients is limited. Patients in the intensive care unit (ICU) commonly receive intravenous methylprednisolone initially with subsequent dose tapering and/or conversion to oral prednisone. Following ICU transfer, missed opportunities during care transition may occur resulting in prolonged intravenous or oral corticosteroid therapy and inadvertent adverse drug events. This study aims to evaluate corticosteroid prescribing patterns following ICU transfer.

Methods: This retrospective cohort study was approved by the Institutional Review Board at Parkview Health. Male and female patients aged 18 years and older, who had a coded diagnosis for acute respiratory failure or COPD exacerbation and received intravenous methylprednisolone were included. Patients who not admitted to the ICU, received an initial daily dose of methylprednisolone more than 500 mg per day, completed the entire course of corticosteroid therapy while in the ICU, expired while in the ICU or were directly discharged from the ICU, or had chronic corticosteroids listed on their home medication list were excluded. Data was collected from electronic medical record for patients who met the inclusion criteria from January – December, 2015. Data collected included total dose and duration of corticosteroid therapy before, during and after ICU transfer, discharge medication list containing corticosteroid therapy, incidences of hyperglycemia following ICU discharge, and post-ICU discharge length of stay. Two groups of patients were specified for comparison, those with a discontinuation/taper plan set for corticosteroid therapy following ICU transfer by critical care providers and those without a set discontinuation/taper plan. The primary outcome is the

difference in the duration of corticosteroid therapy following ICU transfer in the two treatment groups. The Mann-Whitney U test was used to compare differences in post-ICU duration of corticosteroid therapy between the two groups.

Results: We identified 102 patients admitted to the ICU during the specified timeframe. Of these 102 patients, 41 patients were included for analysis, 23 of whom had an intensivist-initiated corticosteroid discontinuation/taper plan and 18 patients who did not. There was no difference in the duration of corticosteroid therapy prior to transfer (5.0 vs. 5.0 days), dose (in prednisone equivalents) before transfer (770 vs. 512 mg), or post-ICU length of stay (3.0 vs. 3.5 days) between those who had an intensivist-initiated corticosteroid discontinuation plan and those who did not. Patients who had an intensivist-initiated corticosteroid discontinuation plan had a shorter duration of corticosteroid therapy after transfer from the ICU (8.0 vs. 14.5 days; p=0.023) and a shorter total duration of corticosteroid therapy (15 vs. 20 days; p=0.035). There was no difference in dose of corticosteroids following ICU transfer or days with hyperglycemia following ICU transfer.

Conclusion: An intensivist-initiated corticosteroid discontinuation plan is associated with reductions in duration of corticosteroid therapy following transfer from the ICU and total duration of corticosteroid therapy. Targeted interventions during transition out of the ICU may help reduce unnecessary exposure to corticosteroid therapy. Further studies are warranted to evaluate the impact of these findings on clinical outcomes including adverse effects, hospital length of stay, and readmission rates.

Submission Type: Evaluative Study

Session-Board Number: 3-127

Poster Title: Effect of pharmacist intervention during transitions of care on heart failure patient readmission rates

Primary Author: Tung Nguyen, Manchester University, Indiana; **Email:** tanguyen2017@manchester.edu

Additional Author (s):
Teresa DeLellis

Purpose: The impact of poor medication reconciliation, patient education, and medication-related problem interventions upon admission, during hospitalization, and at discharge has increased adverse drug events and healthcare costs. Studies of pharmacist interventions in each of these areas separately have yielded conflicting results for multiple disease states, including heart failure. The primary aim of this study is to evaluate the effect of bundled interventions (medication reconciliation, discharge education, and multiple post-discharge follow-up phone calls) on reducing readmission rates for heart failure patients. The secondary aim is to describe this novel practice in terms of types and number of interventions made per patient.

Methods: The institutional review board approved this retrospective chart review comparing two groups: those who have had pharmacist intervention during transitions of care and a historical control group without pharmacist intervention. Patients 18 years and older with a discharge diagnosis of heart failure admitted between the dates of June 1, 2015 to August 31, 2015 (historical control) and June 1, 2016 to August 31, 2016 (intervention group) were included in this pilot analysis. Patients transferred to hospice care or another hospital were excluded. The pharmacist intervention consisted of three stages: admission medication reconciliation, discharge medication education, and follow-up phone calls. The follow-up calls were series of at least 4 phone calls over the first 30 days after discharge: the first within 24-72 hours of discharge, then once weekly thereafter for three more calls (for a total of four calls in four weeks). The pharmacist had the option to provide more frequent and numerous calls for some patients, where deemed necessary based on professional judgement. The primary outcome, 30-day readmission rates, was analyzed using the chi square test. Baseline demographic differences between groups were analyzed using student t test for continuous

variables and chi square for nominal variables. Secondary outcomes were analyzed using descriptive statistics.

Results: Twenty-seven patients were identified for analysis: 16 in the intervention group and 11 patients in the control group. Patients in the control group were older (mean age 84.7 vs. 74.5 years, p-value 0.036), while the average number of medical conditions was greater in the intervention group (8.1 vs. 5.5, p-value less than 0.001). There was no statistically significant difference between groups in gender, location admitted from (home vs. skilled nursing facility [SNF]), discharge disposition (home vs. SNF), number of home medications, or hospital length of stay. There was no statistically significant difference between groups in 30-day readmission rates (12.5 percent intervention group vs. 27.3 percent control group; p-value greater than 0.05). In the intervention group, admission medication reconciliation was completed for 88 percent of patients, with an average of 4.2 discrepancies in the initial admission medication list uncovered per patient. The most common discrepancies identified were missing prescriptions, prescriptions that the patient was no longer taking, and incorrect directions on over-the-counter products. Discharge education was completed for 14 percent of patients; post-discharge follow-up phone calls were completed for all patients. Each patient was successfully reached an average of 2.5 times, with an average of 1.6 interventions per patient.

Conclusion: Bundled pharmacist services during transitions care helped identify and resolve multiple medication-related problems. Pharmacist involvement in transitions of care can prevent drug adverse events, potentially reducing the rate of hospital readmissions although this study was not sufficiently powered to accurately detect a difference in this outcome. Larger and longer timeframe studies are warranted to evaluate the impact of multiple pharmacist transition of care interventions on 30-day readmission rates in heart failure patients. Ongoing studies of this practice are in process with the objective of evaluating larger numbers of patients to accurately assess for a statistically significant difference in readmission rates.

Poster Title: Impact of serum chloride levels on kidney function in patients receiving vancomycin and piperacillin/tazobactam

Primary Author: Morgan Gilbert, Manchester University College of Pharmacy, Indiana; **Email:** mngilbert2015@manchester.edu

Additional Author (s):
Kacie Knapp
Jeffery Thurston
Trent Towne
Dustin Linn

Purpose: Previous studies have indicated that the use of vancomycin in combination with piperacillin/tazobactam concomitantly and hyperchloremia are independent risk factors for the development of acute kidney injury. The primary objective of this study is to determine if hyperchloremia impacts the rate of acute kidney injury in critically ill patients receiving the combination of intravenous vancomycin and piperacillin tazobactam. Secondary objectives will assess if chloride levels are in these patients impact ICU length of stay, hospital length of stay and hospital mortality.

Methods: This study is a retrospective chart review cohort study to evaluate the impact of chloride level on renal function in patients who are receiving concomitant piperacillin/tazobactam and vancomycin. Data will be collected from the electronic medical records for any patient > 18 years of age who were admitted to the Intensive Care Unit or Progressive Care Unit of Parkview Health Systems (Allen County Hospitals) between January 1, 2016 and June 30, 2016 with the diagnosis of sepsis or pneumonia and received both vancomycin and piperacillin/tazobactam for > 24 hours. . Data to be collected includes: age, sex, weight, height, BMI, ICU and hospital length of stay, inpatient mortality, length of vancomycin and piperacillin/tazobactam therapy, baseline SCr and chloride level, peak SCr and chloride level following initiation of vancomycin and piperacillin/tazobactam, length of time to peak SCr and chloride level (days), presence of acute kidney injury requiring hemodialysis, and the requirement of mechanical ventilation or vasopressor medications within the first 24 hours of hospitalization. Patient's categorization of kidney function will be defined by the Acute

Kidney Injury Network (AKIN) criteria. For all primary and secondary endpoints, with the exception of hospital length of stay, a Chi-squared test will be utilized for statistical analysis. For hospital length of stay, the Mann-Whitney U test will be used. Multivariate logistic regression will be used to determine confounding variables.

Results: 145 patients met criteria for entry into the study. Of these patients, 13 (8.9%) met AKIN criteria during their hospitalization and treatment with piperacillin/tazobactam and vancomycin. Among those patients with hyperchloremia (serum chloride > 111 mmol/L), 7% (n =5) developed AKI. In contrast, those patients without elevated chloride levels developed AKI in 12% (n = 8) of cases. In those patients with hyperchloremia who developed AKI, the overall hospital length of stay was much longer than those who met AKIN criteria who were not hyperchloremic (13 days vs. 7 days). Mortality among those with and without hyperchloremia was similar (24% vs 25%) and was not significantly influenced by the presence of hyperchloremia.

Conclusion: Overall rates of acute kidney injury with the combination of vancomycin and piperacillin/tazobactam were lower than seen in previous studies. The influence of hyperchloremia on the development of acute kidney injury and mortality was not observed in this population.

Poster Title: Quantifying services provided by the pharmacy team in a family medicine clinic

Primary Author: Trung Nguyen, Manchester University College of Pharmacy, Indiana; **Email:** tnguyen2017@manchester.edu

Additional Author (s):
Nathan Stuckey

Purpose: Services provided by pharmacists in an outpatient setting have expanded beyond the role of dispensing medications. Pharmacists are now involved in direct patient-care and medication therapy management. Services provided by the pharmacy team have been available at the family medicine clinic since 2012, but no analysis of services provided by the team have been described. Services provided by the pharmacy team at the clinic include medication therapy management, identification of drug-related therapy problems, and assistance with transition-of-care. The purpose of this retrospective study is to quantify and characterize the interventions made by the pharmacy team in the family medicine clinic.

Methods: All services rendered by the pharmacy team over a period of four months will be analyzed. The pharmacy team will use a paper tracking tool to record details of each patient encounter. Documentation of each encounter will be completed by the end of each business day. The information recorded on the paper form will be entered into an excel spreadsheet. Data to be collected includes the type of intervention or recommendation performed by the pharmacy team and whether or not the recommendation was accepted by the physician. Patient demographic information (age, sex, language and ethnicity), co-morbidities, number of medications prescribed, and identification of high risk medications will also be recorded. The pharmacy team member performing the intervention, type of patient encounter, and physician associated with the intervention or encounter will also be collected.

Results: The pharmacy team had a total of 232 patient encounters from the June 2016 thru September 2016. The mean age of the patients was 56 years, and males represented 40 percent (93/232) of the sample. There were 663 interventions that were made by the pharmacy team. Medication reconciliation, detection of drug discrepancies, and drug therapy

recommendations were the most frequent interventions, with 180, 153 and 121 interventions respectively. Ninety-two percent of the recommendations were accepted by the physicians.

Conclusion: The pharmacy team made many interventions, which may be associated with improved outcomes and cost avoidance. Most drug therapy recommendations were accepted by the physicians. Services provided by the pharmacy team are an essential part of patient care at the family medicine clinic.

Poster Title: An evaluation of sources of fluid intake in medical ICU patients

Primary Author: Jessica Western, Manchester University College of Pharmacy, Indiana; **Email:** jlwestern2015@manchester.edu

Additional Author (s):
Jason Eakins
Dustin Linn

Purpose: Patients admitted to the ICU often receive large volumes of intravenous fluid to help restore end organ perfusion. Recent evidence has suggested a positive fluid balance during an ICU stay may be associated with diminished organ function and increased mortality. The objective of this study was to focus on sources of intravenous fluid administration in the first 24 hours in patients admitted to the medical ICU. We recorded all intravenous fluid administration, including those volumes specified by physicians and volumes administered from other sources.

Methods: This retrospective cohort study was approved by the Institutional Review Board at Parkview Regional Medical Center located in Fort Wayne, Indiana. The admission log in the medical ICU was used to identify patients over a 6-week period in June and July of 2016. The electronic medical record was used to extract data included in this analysis. Patients were excluded if they died or were discharged from the ICU within 24 hours of admission or if they were transferred to the medical ICU from another ICU within the same facility. Volume of all fluids administered in the first 24 hours of ICU admission was recorded and specified as discretionary fluid or non-discretionary fluid. Discretionary fluids included volumes specified by the treating physician and included bolus and maintenance intravenous fluids, enteral feedings, and blood products. Non-discretionary fluids included those in which the volume was not set by the treating physician. This included fluid from antibiotics, sedatives, analgesics, vasopressors, electrolytes, and intravenous flushes. The primary objective was to describe the volumes of intravenous fluids administered to patients in a medical ICU, comparing volumes specified by a treating physician and those not specified and their contribution to fluid intake at 24 hours. We also compared fluid volumes in patients with confirmed or suspected sepsis to those without sepsis to evaluate the impact of this diagnosis on fluid administration.

Results: During the specified timeframe, 195 patients were admitted to the ICU and 169 patients remained after exclusions. The mean age of the patients was 63 years and 99 (58.5%) were male. The mean volume of fluid administered in the first 24 hours of ICU admission was 4,412 mL in all patients. The average discretionary and non-discretionary fluid administration during the first 24 hours was 3,144 mL and 1,268 mL, respectively. Patients with confirmed or suspected sepsis received higher discretionary fluid volumes in the first 24 hours (4,175 vs. 2,735 mL); however, the non-discretionary fluid volumes were similar between septic and non-septic patients (1,307 vs. 1,253 mL). Mean volumes of non-discretionary fluid from different sources were as follows: "other" intravenous medications (528 mL), antibiotics (295 mL), sedatives/analgesics (150 mL), vasopressors (138 mL), electrolytes (115 mL), and intravenous flushes (43 mL). Patients with sepsis tended to receive more maintenance fluid and fluid boluses as well as more fluid from antibiotics and vasopressor agents compared to those patients without sepsis.

Conclusion: Fluid administration from non-discretionary intravenous fluids contributes more than 1 liter to total fluid intake in the first 24 hours of ICU admission. Patients with sepsis patients receive higher volumes of discretionary fluids; however these patients received similar volumes of non-discretionary volumes compared to non-septic patients. Healthcare providers should consider the volume of fluid administration from non-discretionary sources for patients admitted to the medical ICU and the impact on fluid balance and patient outcomes. Further evaluation of the impact of non-discretionary fluid administration on clinical outcomes including organ function, length of stay, and mortality is warranted.

Submission Category: General Clinical Practice

Submission Type: Descriptive Report

Session-Board Number: 3-131

Poster Title: Evaluating management strategies for peripherally inserted central catheter-associated thrombosis

Primary Author: Alyssa Petry, Manchester University College of Pharmacy, Natural and Health Sciences, Indiana; **Email:** anpetry2017@manchester.edu

Additional Author (s):
Daniel Rafael
Nancy Luu
Dustin Linn

Purpose: Peripherally inserted central catheters (PICCs) are useful in hospitalized patients that require the infusion of multiple intravenous medications. PICCs are less complicated to insert than other central venous catheters. Associated complications include infection and venous thrombosis. The true incidence of PICC-associated venous thromboembolism (VTE) is unknown, as diagnosis and testing modality vary between institutions. The CHEST guidelines do not provide specific recommendations on management of PICC-associated superficial venous thrombosis (SVT). The purpose of our study was to examine current management strategies for PICC-associated SVT and evaluate management strategies and outcomes associated with their use.

Methods: We conducted a retrospective cohort analysis looking at patients admitted to Parkview Regional Medical Center between January 1, 2014 and December 31, 2015 who had a Current Procedural Terminology (CPT) code for PICC-line insertion and an ICD-9 code for superficial vein thrombosis in the basilic or cephalic veins during the same hospitalization. We evaluated patient demographic data including age, weight, reasons for admission, location of admission (floor vs. ICU), use of mechanical ventilation, and past medical history which may predispose the patient to VTE. We also evaluated the use of pharmacologic VTE prophylaxis at the time of diagnosis. We evaluated SVT management strategies implemented for these patients including removal of the PICC-line or initiation of therapeutic doses of anticoagulant therapy. We also evaluated the use of follow-up ultrasound to determine if SVT progressed to a DVT and observed the proportion of patients who were discharged on anticoagulant therapy

without an indication other than SVT. Descriptive statistics were utilized to report data obtained from this analysis.

Results: We identified 64 patients in the specified timeframe with PICC-associated SVT who met inclusion criteria. The majority of excluded patients were excluded due to concomitant deep vein thrombosis at the time of recognition of SVT leaving 35 patients for evaluation. The average age of patients was 58.1 years and 54% were male. Patients were more commonly admitted for a medical diagnosis (63%) than a surgical diagnosis (37%). 74% of patients were receiving pharmacologic VTE prophylaxis at the time of recognition of superficial vein thrombosis. The PICC-line was removed in 43% of patients in response to superficial vein thrombosis and therapeutic anticoagulation was initiated within 24-hours of recognition in 40% of patients. A repeat duplex ultrasound of the upper extremities was ordered in 11 patients (31.4%) at a median of 9 days following initial recognition and in 2 patients the superficial vein thrombosis had progressed to DVT. Ten patients (28.6%) were discharged on anticoagulant therapy without an obvious indication other than SVT.

Conclusion: We observed significant variation in practice in the management of patients with PICC-associated SVT including PICC-line removal and use of therapeutic anticoagulation. The use of pharmacologic VTE prophylaxis did not appear to be protective against PICC-associated thrombosis. We observed a low rate of follow-up duplex ultrasound and progression to DVT so it is difficult to discern how management strategies may impact progression of thrombosis. These findings highlight the need for more research into prevention and management strategies for PICC-associated SVT.

Poster Title: Impact of an interprofessional team-based approach for providing transitional care management (TCM) services on 30-day readmission rates among Medicare beneficiaries

Primary Author: Ashley Montgomery, Manchester University College of Pharmacy, Natural and Health Sciences, Indiana; **Email:** aemontgomery2017@manchester.edu

Additional Author (s):
Nathan Stuckey

Purpose: This study sought to determine the effectiveness of post-discharge TCM services with an interprofessional team in reducing rates of hospital readmission at 30-days following an index hospitalization compared with patients who did not complete post-discharge TCM services.

Methods: TCM services at this study site are furnished by a transitional care coordinator, a pharmacist, and a physician at an academic patient-centered medical home (PCMH). Complying with the requirements set forth by the Centers for Medicare and Medicaid Services, the following three components for a TCM encounter in this study includes: an interactive contact, certain non-face-to-face services, and a face-to-face post-discharge visit. The effectiveness of an interprofessional team-based approach in providing TCM services on 30-day readmission rates was assessed through a retrospective chart review. Convenience sampling of Medicare beneficiaries aged 18 years or older with an acute care admission to a local hospital were identified by the transitional care coordinator from April 2015 to February 2016. Using the electronic medical record a total of 226 hospitalizations were included in the study, demographic data was collected on the corresponding patients in addition to hospital length of stay (LOS), number of chronic medications prescribed, functional health literacy status, and calculation of the Charlson comorbidity index. Baseline characteristics will be evaluated by descriptive statistics. Pearson's chi-square test and an odds ratio (OR) will be utilized to analyze the comparison rates of 30-day readmission based on patient's completion of post-discharge TCM services. Ethics committee approval was obtained for the study at the site.

Results: Of 181 patients identified during the specified timeframe, 226 total hospitalizations were analyzed. It was found that 75 hospitalizations (33 percent), accounting for 68 patients, completed the post-discharge TCM services. The remaining 151 hospitalizations (66 percent) in 113 patients did not complete post-discharge TCM services. The odds ratio for readmission when participating in post-discharge TCM services was 0.49 (p=0.181). Rates for readmission for any cause at 30 days were 6.7 percent in patients who completed the post-discharge TCM services and 12.6 percent in patients who did not (p=0.174). The two groups demonstrated balanced baseline demographics (age, race, ethnicity, language spoken, employment status, hospital LOS, and average number of medications). Differing baseline characteristics in patients who completed post-discharge TCM services compared to patients who did not participate included a higher female population 53 percent vs. 45 percent, respectively, and a lower average Charlson score of 2.74 vs. 3.04, respectively. Functional health literacy status also differed, in patients who received post-discharge TCM services it was found that 16 percent demonstrated low functional health literacy, while 40 percent demonstrated high functional health literacy. Patients who did not complete post-discharge services demonstrated equal rates of both low and high health literacy at 4.6 percent.

Conclusion: Nearly 1 in 10 hospitalizations during the specified timeframe was followed by a repeat hospitalization within 30 days, of which more than half were in patients who did not receive discharge TCM services. In this analysis the 30-day any cause readmission rate was reduced by 51 percent among patients who participated in an interprofessional team-based transition care management services. Reducing readmission rates allows for better patient care, better outcomes, and enhanced billing opportunity.

Poster Title: Evaluation of radiochemical purity of technetium-99m mertiatide and technetium-99m tetrofosmin stored at 30 degrees Celsius during the shelf-life

Primary Author: Stephanie Pitman, Purdue College of Pharmacy, Indiana; **Email:** spitman@purdue.edu

Additional Author (s):
Neil Hartman
Russell Soanes

Purpose: The summaries of product characteristics for technetium-99m mertiatide and technetium-99m tetrofosmin recommend refrigeration of radiolabelled products at 5 plus or minus 3 degrees Celsius after manufacturing. However, these products are not typically refrigerated during transportation to various end-point hospitals. The vehicles used to transport radiopharmaceuticals are designed to limit radiation exposure but not refrigerated. The purpose of this project was to evaluate the radiochemical purity of technetium-99m mertiatide and technetium-99m tetrofosmin at 30 degrees Celsius for up to 12 hours in order to determine whether transport in an unrefrigerated vehicle would affect radiochemical purity and stability of the radiolabelled products.

Methods: One kit each of technetium-99m mertiatide and technetium-99m tetrofosmin was prepared on three separate dates. The kits were prepared within manufacturer reconstitution limits. After preparation, the radiolabelled kits were placed in a heated water bath set to 30 degrees Celsius for 12 hours. The products were subject to radiochemical purity testing in triplicate at times 0, 2, 4, 6, 8, 10, and 12 hours after preparation. Thin layer chromatography (TLC) was used to determine radiochemical purity. A radiochromatogram scanner was used to trace the radioactivity profile of each TLC strip, and a chromatography integrator was used to measure the areas of radioactive peaks in order to calculate radiochemical purity. In order to meet the minimum requirements for clinical use, as per the manufacturer's summary of product characteristics, radiochemical purity was required to be greater than 90 percent for technetium-99m tetrofosmin and greater than 94 percent for technetium-99m mertiatide. The mean radiochemical purity with a 95 percent confidence interval was calculated for each time point evaluated.

Results: For technetium-99m mertiatide, 57 out of 60 quality control tests met the minimum radiochemical purity. For technetium-99m tetrofosmin, 62 out of 63 quality control tests met the minimum radiochemical purity. For all four tests that failed, the others strips tested at the same time points passed for each product, suggesting operator error. The lower limit of the 95 percent confidence interval for mean radiochemical purity at each time point did not fall below the minimum percentage required to pass, indicating that these products remain stable for up to 12 hours when stored at 30 degrees Celsius. The radiochemical purity did not appear to decrease over time for either product.

Conclusion: Although the respective manufacturer guidelines for these radiopharmaceuticals recommend refrigeration after preparation, both remain stable at 30 degrees Celsius for up to 12 hours. These results suggest that both products can be safely transported in an unrefrigerated vehicle at temperatures up to 30 degrees Celsius. Although this project showed that these two products maintain radiochemical purity under these conditions, they may not maintain sterility. It is important to continue to consider antimicrobial integrity and refrigerate these products whenever possible once transportation has been completed.

Poster Title: Zoledronic acid use analysis and renal adjustment and monitoring protocol development at an urban, safety-net hospital

Primary Author: Alison Switzer, Purdue University, Indiana; **Email:** aswitzer@purdue.edu

Additional Author (s):
Heather Dossett
Monica Macik

Purpose: Zoledronic acid is a bone resorption inhibitor in the bisphosphonate class used intravenously for the treatment of hypercalcemia of malignancy along with multiple myeloma and bone metastases from solid tumors. This project was designed to assess the use of zoledronic acid at an urban, safety-net hospital in regards to indication for use, doses used, monitoring of renal function via serum creatinine, patient demographics, and administration setting.

Methods: A retrospective chart review was conducted on 40 patients that received zoledronic acid from November 2015 to May 2016. The sample of 40 patients was randomly selected from a total of 75 patients. Patients were selected who had received at least one dose of zoledronic acid in the inpatient or outpatient setting at an urban, safety-net hospital in which they were billed for the medication. The primary endpoint was the indication for receiving zoledronic acid. Secondary endpoints included strength and number of doses administered, appropriateness of doses adjusted for renal impairment, administration setting, patient demographics, and days elapsed since last serum creatinine level was drawn.

Results: The primary endpoint revealed that 100 percent of zoledronic acid doses administered in the inpatient setting were given for hypercalcemia of malignancy. Indications for outpatient use included osteoporosis, lytic lesions from multiple myeloma, metastatic bone lesions from solid tumors, prevention of aromatase inhibitor-induced bone loss in breast cancer, and prevention of androgen deprivation-induced bone loss in prostate cancer. Of the 79 doses received by the 40 patients, 74 were appropriately administered based on renal function, and 72.2 percent of all doses were 4 mg. Unlike the 4 mg doses, the 3, 3.3, and 3.5 mg doses had more episodes of inappropriate dose adjustments associated with them, with the amount of

incorrect dosages totaling 6.3 percent. The incorrect dosages were dosed lower than necessary based on renal function, but no harm resulted. Of the 40 patients, 36 received zoledronic acid in the outpatient setting. For demographics, 65 percent of patients were female, and the age of the patients ranged from 30 to 89 years. Excluding serum creatinine levels drawn the same day in which the dose was administered to the patient, 0-60 days had elapsed since the last serum creatinine level had been drawn in 80 percent of the patients.

Conclusion: Zoledronic acid usage was appropriate in 74 of 79 total doses administered. Inappropriate underdosing occurred in 5 of 79 patients. Because 20 percent of patients had a serum creatinine level drawn more than 60 days from dose administration, a renal dosing and serum creatinine monitoring protocol was created within a standardized order set. This allowed for serum creatinine to be ordered at the time of the next dose to obtain a level within 60 days. Zoledronic acid 5 mg was capped at 4 mg versus the labeled dose for osteoporosis and Paget's disease due to lack of state reimbursement.

Submission Type: Evaluative Study

Session-Board Number: 3-135

Poster Title: Vancomycin Therapeutic Dosing Evaluation

Primary Author: Taylor Hebenstreit, Purdue University, Indiana; **Email:** thebenst@purdue.edu

Additional Author (s):
Lisa Ribble-Fay

Purpose: The American Society of Health-System Pharmacists (ASHP) and the Infectious Diseases Society of American (IDSA) have recommended an increased vancomycin trough range of 15-20 mg/L for most indications in order to achieve optimal therapeutic outcomes in patients. Published primary literature suggests that the percentage of patients who achieve initial vancomycin troughs of 15-20 mg/L from using various dosing strategies and nomograms is around 50 percent. The purpose of this project is to present a retrospective chart review of a change in vancomycin dosing practice.

Methods: The institutional review board approved this project. Adults greater than or equal to 18 years old who were on vancomycin treatment regimens in the pharmacy dosing service were included. Those patients with a calculated creatinine clearance of less than or equal to 30 mL/min were excluded. One month of data was retrospectively collected via a computer generated report. This data was evaluated by identifying initial vancomycin concentrations in therapeutic regimens, mg/kg of maintenance doses, age, initial serum creatinine, and calculated creatinine clearance. The pharmacy dosing service subsequently initiated a vancomycin dosing nomogram similar to one noted in the literature. The same data parameters were collected seven weeks after implementation.

Results: A total of 192 patients were evaluated. Sixty-two patients were evaluated in the initial one month data collection and 130 patients were evaluated in the seven weeks following the dosing change. The percentage of patients who obtained vancomycin concentrations between 15-20 mg/L in the one month data was 18 percent, compared to 39 percent in the seven week data. The percentage with initial concentrations less than 15 mg/L was 63 versus 21.5 percent, and the percentage with initial concentrations greater than 25 mg/L was 13 versus 24 percent in the one month and seven week data collections, respectively. Additionally, 5 percent of patients in the one month collection had concentrations between 21-25 mg/L, compared to 15

percent in the seven week collection. One article evaluated patients with concentrations of 13-22 mg/L. Data collected in this project showed 41 percent (one month data) and 58 percent (seven week data) of patients were in this range. Regarding average age, average maintenance dose mg/kg, average initial serum creatinine, and average creatinine clearance in the one month and seven week collections, respectively, the values are as follows: 56.4 versus 57.6 years, 16.3 versus 15.3 mg/kg, 0.9 versus 0.9 mg/dL, and 84.3 versus 84.5 mL/min.

Conclusion: After the implementation of a dosing nomogram, patients were more likely to present with initial vancomycin serum concentrations in the 15-20 mg/L range and substantially less patients fell in the less than 15 mg/L range. It was also noted that a higher percentage of the patients had concentrations greater than 20 mg/L after the dosing change. Further evaluation of subgroups will be pursued for future reference.

Poster Title: Quality assurance assessment and pharmacist perception of a five day antimicrobial stop date program at a community teaching hospital

Primary Author: Ashley Boone, Purdue University, Indiana; **Email:** boonea@purdue.edu

Additional Author (s):
Michelle Brenner
Sara Weidert

Purpose: Recently the Centers for Disease Control and Prevention summarized recommended core elements for hospital antibiotic stewardship programs (ASP) to help improve antibiotic prescribing. The increased focus on stewardship has prompted many healthcare systems to implement initiatives to help improve antimicrobial prescribing and reduce antimicrobial resistance and hospital-acquired infections. One initiative implemented was a five day automatic stop date program for all antimicrobial agents. Pharmacists worked with providers to define antibiotic drug regimens, including clarifying durations of therapy. This project was designed to assess the quality and accuracy of the program, while also evaluating pharmacy perception.

Methods: Pharmacy staff added a stop date of five days for all antimicrobial orders without a provider entered stop date (excluding chronic or suppressive therapy). In the 24 hours preceding the automatic-stop date, pharmacists were to call the primary provider to discuss the therapy plan and clarify further duration of the antimicrobial agent when indicated. Clinical surveillance software was used to collect the following data daily: a report of all antimicrobial orders in the hospital, a report of antimicrobial orders that were expiring that day, and a report of antimicrobial orders that were to expire the next day. All reports were compared for accuracy at one month regarding the input of stop dates, as well as made sure that no antimicrobial agents were being discontinued without discussion with the providers. The following resources were provided to pharmacy staff to promote antimicrobial stewardship and conversation between pharmacists and providers regarding durations of therapy and appropriate antimicrobial use: Sanford Guide to Antimicrobial Therapy 2016, durations of therapy document, and electronic drug information references. Four months after the initiation of the program, a survey was conducted to assess pharmacists' perceptions of the program.

Results of the study have been shared with site leadership for ongoing process improvement planning.

Results: One month after the initiation of the program, the average number of antimicrobial agents without stop dates each day was 19 (18.82 percent of all antimicrobial agents being ordered in the hospital). Additionally, an average of 56.87 percent of antifungal medications and 60.11 percent of antiviral medications were without stop dates each day. A quality assurance assessment showed that no antimicrobial agents were being discontinued without a discussion with the primary provider. Survey results from 11 pharmacists regarding perception of the program showed that 81.81 percent felt that the program was beneficial in reducing the duration of antimicrobial therapy, and 90.91 percent felt that providers were either somewhat receptive or very receptive to the program. Furthermore, 60 percent felt that they were able to make recommendations regarding durations of therapy most of the time when they were calling providers, and 100 percent utilized one of the resources provided to guide their recommendations.

Conclusion: The five day antimicrobial automatic stop date process was successfully implemented into the daily pharmacist workflow. After one month, the number of antimicrobial medications without stop dates was low, suggesting that antimicrobial stewardship efforts were taking place. The majority of surveyed pharmacists supported the program and felt it and the resources provided were beneficial.

Poster Title: Assessment of safe prescribing of low molecular weight heparin treatment across Barts Health National Health Service (NHS) Trust

Primary Author: Catherine Zhang, Purdue University, Indiana; **Email:** zhang742@purdue.edu

Additional Author (s):
Jagjot Chahal
Viktoria Vakulenko
Kyung Lee
Sotiris Antoniou

Purpose: The use of low molecular weight heparin (LMWH) retains a significant role in many disease states that require anticoagulation. As high-risk medications, LMWHs may produce adverse events such as major bleeds, resulting from inappropriate dosing. Assessing the clinical prescribing patterns for LMWHs is important in reducing adverse events. This audit was designed to evaluate the safe prescribing of LMWH treatment doses in a large UK National Health Service (NHS) Trust, in accordance to patients body weight, renal function and concomitant therapeutic anticoagulation.

Methods: All four sites within the Trust were audited for the purpose of this study. From August 15th to 26th, 2016, data was collected prospectively from a total of forty-three wards across two hospital sites and the respective outpatient pharmacies. From August 30th to September 9th, data was collected prospectively from an additional thirty-one wards from the remaining two hospital sites, and the respective outpatient pharmacies.
A data collection tool was developed to track the hospital, date, patient demographics, dose and indication of the LMWH prescribed, renal function (both creatinine clearance and estimated glomerular filtration rate were collected and compared), latest INR readings for patients taking concurrent warfarin, and concurrent direct oral anti-coagulant (DOAC) use. Pharmacists and nursing staff at each site were notified of the audit and requested to identify eligible patients. Patient identification forms from each ward were checked daily during the collection, and relevant patient information was recorded on the data collection tool. Eligible patients included current inpatient or outpatient patients on treatment regimens of a LMWH.

Patients were excluded if they were on pediatric, obstetrics, gynecology, or acute assessment wards.

Results: There were 162 patients on treatment dose LMWH across the trust, with 109 (67%) of the patients receiving all doses in the safe and recommended range. Forty-one (25%) patients were prescribed enoxaparin and 120 (75%) patients were prescribed tinzaparin. Fifty-three (33%) patients were not dosed appropriately according to their body weight at some point during the data collection time frame. Forty (25%) patients were on concurrent warfarin at some time during the study, with no patient at therapeutic INR. Also, no patient was on concurrent DOAC, which would indicate inappropriate prescribing. Six (4%) patients had received LMWH doses that were not appropriate for their renal function. For fifteen (9%) patients, the difference between the renal function estimations impacted clinical dose adjustments. After reviewing the electronic medical records and drug charts for all patients not dosed appropriately, it was noted that inaccurate information were contributing heavily to the dosing errors (both overdosing and underdosing).

Conclusion: Thirty-three per cent of patients received inappropriate doses of LMWHs based on either their weight or renal function translating to either inadequate cover (thrombosis risk) or excessive dosing (bleeding risk). In order to ensure patients are receiving an appropriate LMWH dose, weight, height and renal function need to be obtained and updated in a timely manner. Frequent INR checks should be performed, and INR results assessed prior to administering LMWHs for patient concurrently on warfarin. With the recent introduction of DOACs, this may offer a safer alternative to LMWHs as well a potentially being preferable to patients being oral therapy.

Poster Title: Efficacy of transdermal clonidine patches in difficult-to-treat hypertension patients attending a specialist blood pressure clinic in the United Kingdom.

Primary Author: Jessica Louthan, Purdue University, Indiana; **Email:** jlouthan@purdue.edu

Additional Author (s):
Rahana Alom
Melvin Lobo
Vikas Kapil
Sotiris Antoniou

Purpose: Hypertension is a major risk factor for cardiovascular morbidity and mortality. Control rates in treated patients are sub-optimal despite availability of numerous medication classes. This may reflect poor adherence to anti-hypertensive medications with persistence rates at one year estimated to be less than fifty percent. Poor adherence is often related to medication posology and adverse drug reactions. Transdermal clonidine applied once-weekly, although unlicensed, could be useful for patients who report difficulty with taking daily medication or report intolerances to oral medication. The purpose of this study was to determine the effectiveness of clonidine patches in real-world patients with difficult-to-treat hypertension.

Methods: A retrospective analysis of patients in a specialist Hypertension Centre outpatient service between January 2015 – August 2016 was performed. Patients prescribed transdermal clonidine (TTS-1, delivery 100 micrograms daily) were identified by hospital pharmacy records. Data regarding demographics, co-prescribed medications, and blood pressure values were extracted from electronic health records. Patients were included for analysis if: clinic systolic blood pressure greater than 140 mmHg or diastolic blood pressure greater than 85 mmHg immediately prior to transdermal clonidine prescription; prescription was continued for more than one month; patient was wearing transdermal clonidine patch at follow-up; follow-up clinic blood pressure was recorded. Patients who initiated clonidine TTS-1 with an additional anti-hypertensive medication were excluded. Final clinic blood pressure was used from the last clinic visit prior to: additional anti-hypertensive medication prescription; transdermal clonidine cessation; increase in weekly dose of transdermal clonidine. All clinic blood pressures were measured in triplicate by trained nurses according to national guidelines using validated blood

pressure machines and the lowest value was considered as clinic blood pressure. Data are presented as mean plus or minus standard deviation unless otherwise specified and statistical analysis was performed as paired t-test as data exhibited Gaussian distributions (D'Agostino and Pearson omnibus normality tests). Study was approved by trust research and development office.

Results: Of the 79 patients that received any dose of transdermal clonidine since January 2015, 36 patients satisfied inclusion and exclusion criteria and data were extracted for analysis. Mean age was 57 (plus or minus 13) years and 86 percent were female. Self-reported intolerance was to 3 (plus or minus 4) classes of medications and 4 (plus or minus 3) individual anti-hypertensive medications used previously. Baseline clinic blood pressure was 186 mmHg (plus or minus 21) over 101 (plus or minus 13) mmHg on 4 (plus or minus 2) medications. The addition of transdermal clonidine TTS-1 was associated with reduction of blood pressure by 23 mmHg (plus or minus 33) over 10 (plus or minus 18) mmHg (p less than 0.001 and p equals 0.002 respectively) over median 11 weeks (mean 18 weeks; range 4-134 weeks). Twenty-five (69 percent) patients were deemed to be responders (clinic systolic blood pressure reduction of greater than 10 mmHg). Transdermal clonidine was stopped in a small number of patients due to: reversible dermatological reactions (n=2); fatigue (n=2); diarrhoea (n=1); headache (n=1) and insomnia (n=1). Additionally, transdermal clonidine was also stopped due to perceived ineffectiveness (n=2) and excessive effect (n=1).

Conclusion: These are the first contemporary data in a real-world setting demonstrating the sustained blood pressure lowering efficacy of transdermal clonidine at the lowest available dose in patients with significant history of intolerance to standard oral anti-hypertensive medications. There was a robust blood pressure response in greater than two-thirds of patients but there was an appreciable adverse drug event rate of almost 1-in-5. These data confirm the potential of transdermal clonidine as an effective non-oral anti-hypertensive formulation. This may have utility in specific populations of patients with medication intolerance, resistant hypertension, or where oral dosing may not be possible.

Susie Crowe

Purpose: In 2003 Purdue University College of Pharmacy (PUCOP) established an eight-week global health advanced pharmacy practice experience (APPE) in Eldoret, Kenya. Historically students have found it difficult to summarize their growth in clinical knowledge, professional skills, and emotional maturity into a concise, articulate response when asked about their APPE in Kenya during job and residency interviews. Typical responses sound oversimplified, generic, and lack connection to the skills needed in US-based positions. This project aimed to strengthen students' confidence and ability to create articulate responses about the skill set developed while in Kenya during interviews.

Methods: A preceptor-led topic discussion was developed that allowed students the opportunity to reflect on all aspects of their APPE and put it into the context of commonly asked interview questions. To assess students' ability prior to the discussion they were asked to provide a brief response about their time in Kenya as if asked about it during an interview. Then they were lead through the topic discussion and asked to repeat this exercise. The content of the discussion included brainstorming on ways the students have grown as clinical practitioners during the rotation, applying their thoughts to commonly asked interview questions, and then finally providing feedback on what they learned through the activity and what could be improved about it. After completion of the topic discussion, students completed an online survey to assess the impact the activity had on their ability to articulate answers during interviews. The 19 question survey was distributed electronically using Qualtrics (Provo, UT) online survey software one month after graduation for two classes of students (in 2015 and 2016). A 5-point Likert scale was used for most questions. Demographics were also collected.

Results were extrapolated from the data collected and the institutional review board approved of this study.

Results: Over a two-year period there were 37 students who completed the interview preparation topic discussion. There were 24 students who completed the online survey to assess the activity. The students reported participation in a total of 97 interviews. Of those 97 interviews, 71 (73 percent), had asked about Kenya during the interview. More than half of the students, 13 of the 24, were asked about Kenya in every interview they participated in. The survey asked students questions about their confidence during interviews after going through the topic discussion and ranked questions based on a 5-point Likert scale. Based on the survey, 18 of the 24 students "strongly agreed" that they were able to apply their experience in Kenya to typical interview questions after completing the topic discussion and having completed interviews. The majority of the students, 23, either "strongly agreed" or "agreed" that the topic discussion prepared them well enough to defer interview questions away from the topic of safari. Additionally, 14 of the students either "strongly agreed" or "agreed" that the discussion helped them overall be more successful with interviews. Seventy five percent of students "strongly agreed" that the topic discussion should be continued for future students.

Conclusion: Students who participated in the interview preparation topic discussion had improved confidence and ability to articulate their experience in Kenya when asked about their APPE experience during an interview. Additionally, students felt more comfortable steering discussion about Kenya away from safaris and adventures and shifting it towards discussion about skills and personal strengths acquired during that APPE that are desirable skills in a candidate. Overall, this topic discussion helped student pharmacists be better prepared for successful interviews. Future plans include expanding this topic discussion to include other international APPE experiences offered at PUCOP.

Poster Title: Expansion of pharmacy students' involvement in global health and international clinical rotations

Primary Author: Alice Chang, Purdue University, Indiana; **Email:** chang260@purdue.edu

Additional Author (s):
Monica Miller
Ellen Schellhase

Purpose: According to the international migration survey conducted by the UN in 2015, more than 14%, increasing from 12.3% in 2000, of the entire US population were born in another country. Student pharmacists' global engagement has demonstrated positive patient impacts; however, limited opportunities exist for student pharmacists at Purdue University College of Pharmacy (PUCOP). As a result, identifying the needs and expanding student pharmacist access to global engagement experiences are critical to meet the changing needs of the US population. The aim of this study was to identify the needs for increasing global engagement experiences offered at PUCOP.

Methods: A survey was developed using Qualtrics online survey software (Provo, UT) and distributed to all first, second, and third year student pharmacists at PUCOP. This survey was distributed via email and data collection occurred between August 31, 2016 and September 22, 2016. Survey responses were anonymous. The specific locations of interest included existing programs in Kenya and the United Kingdom (UK) and potential future sites in Colombia and Tanzania. The survey questions were classified into 5 categories: (1) participation interests, (2) preferences in locations, (3) reasons to participate, (4) reasons not to participate, and (5) interests towards an elective or course focusing on international pharmacy practice. The survey utilized a five-point Likert scale and allowed participants to type in their own responses for certain questions. Lastly, demographics were collected to differentiate whether students' background influenced their interest in participating in global pharmacy experiences. Descriptive statistics were computed to analyze the results. The study was approved by the Institutional Review Board.

Results: The survey was sent to a total of 460 students and 148 of them participated. One hundred and thirty-two students (89.2%) were interested in global health and/or international clinical rotations or an elective course coupled with an experience abroad. The majority of students were interested in going to London, UK (56.2%) whereas 23.1% for Eldoret, Kenya, 13.1% for Colombia, and 7.7% for Kilimanjaro, Tanzania. The top three reasons for participation were "to explore differences in medical care outside of the US" (13.0%), "challenge myself" (12.5%), and "work in an interdisciplinary team including attending physicians, residents and medical students" (11.5%). On the other hand, the least likely motivations for participation were "to provide patient care to underserved patient populations in resource constrained settings" (9.8%), "broaden pharmaceutical knowledge about diseases not endemic to the home region" (8.1%), and "go on weekend travel excursions" (7.9%). For students who were not interested, top reasons were "time away from family and friends" (40.0%), "scheduling conflicts" (20.0%), "safety" (20.0%), and "financial constraints" (20.0%). Lastly, 78.0% of the students reported prior experience abroad.

Conclusion: This study demonstrated PUCOP student pharmacists desire participation in global engagement opportunities. In additional to expanding current partnerships in Kenya and the UK, there is necessity to explore opportunities for partnerships with key universities in Colombia and Tanzania. The advancement of global engagement opportunities will promote students' cultural awareness and sensitivity, expose students to treatment of diseases not commonly seen in modern Western medicine, and cultivate future leadership for the growth of global pharmacy practice.

Poster Title: Analysis of the cost-effectiveness of low molecular weight heparin (LMWH) treatment across a large National Health Service (NHS) Trust in the United Kingdom

Primary Author: Viktoria Vakulenko, Purdue University, Indiana; **Email:** vvakulen@purdue.edu

Additional Author (s):
Catherine Zhang
Jagjot Chahal
Kyung Lee
Sotiris Antoniou

Purpose: This study was designed to examine the potential cost-savings to the Barts Health NHS Trust, in switching eligible inpatients, outpatients and discharges from a treatment dose of LMWH to a direct oral anti-coagulant (DOAC). DOACs are licensed alternative treatments for venous thromboembolism (VTE) and non-valvular atrial fibrillation (AF). Unlike LMWHs, which require a subcutaneous (SC) injection and subsequent patient discomfort, DOACs are administered orally. District nurse visits are also not needed post-discharge, leading to further cost-savings with DOACs, in addition to the direct savings from drug-cost as some DOACs are less expensive than LMWHs.

Methods: Data was collected across each site of the Trust from August 15 to September 9 of 2016, excluding weekends, encompassing 74 wards. Ward pharmacists identified patients on treatment doses of LMWHs. Study data was collected from paper drug-charts and electronic medical records. Additional patients on LMWH treatment were identified by screening the discharge summaries. The exclusion criteria were current cancer treatment/active cancer, poor renal function (defined as a creatinine clearance (CrCl) less than 15mL/min), major surgery within the last 14 days and indications other than VTE or non-valvular AF. LMWH administration post-discharge was examined for the administrative needs of district nurse visits, as patients may also self-administer. Cost was calculated per dose, as LMWH varies with patient weight, which in turn affects costs. Cost-comparisons were made to edoxaban for VTE treatment and rivaroxaban for non-valvular AF treatment based on present costs of these medications to the Trust.

Results: One-hundred and sixty-one patients on treatment doses of LMWHs were identified. Fifty-six patients (34.78 percent) were eligible to switch to a DOAC, of which 51 (91.07 percent) were inpatients. Of the eligible patients, 40 (71.43 percent) were on VTE treatment and 16 (28.57 percent) on non-valvular AF treatment. In total 253 LMWH doses, costing £1,120.06 to the Trust, were dispensed to patients eligible to be on DOACs. The cost of the DOACs would have been £401.60. Therefore, in that ten-day period there was a £718.46 cost-savings potential. This is approximately £26,000 per year in cost-savings. Nineteen patients were also discharged, of which five (26.32 percent) were advised for district nurse visits to support administration of LMWH at the patient's home, adding additional unnecessary costs to the health system.

Conclusion: Prescribing DOACs in accordance to licensed indications as opposed to LMWHs offers a conservative financial cost-saving for the Trust of just over £26,000. As restrictions were placed on inclusion criteria, cost-savings are likely greater than the estimates presented. A prior Trust audit found safety reasons to prescribe DOACs. This current study adds to the evidence that the Trust adopt new guidelines in which DOACs are given in preference to LMWHs in the treatment of VTEs and non-valvular AF at the point of diagnosis.

Poster Title: Evaluating the appropriateness of weight-based sugammadex dose utilization at an urban, safety-net academic medical center

Primary Author: Ashley Brost, Purdue University, Indiana; **Email:** ashleyvbrost@gmail.com

Additional Author (s):
Thernell Anderson
Evan Zahn
Todd Walroth
Health Dossett

Purpose: Sugammadex was approved in December 2015 as a selective reversal agent for rocuronium and vecuronium. By binding these agents at the neuromuscular junction, sugammadex provides immediate reversal. Food and Drug Administration-indicated doses are two milligrams per kilogram (moderate routine blockade), four milligrams per kilogram (deep routine blockade) or 16 milligrams per kilogram (immediate reversal of blockade). When evaluating sugammadex for addition to formulary, effectiveness and cost were both compared to its alternative, neostigmine with glycopyrrolate. With a significant volume of use over the previous five months, a retrospective chart review was conducted to evaluate the appropriateness of sugammadex dosing.

Methods: A retrospective chart review was conducted to evaluate all patients over the age of 18 who received sugammadex at Eskenazi Health from May 11, 2016 to September 9, 2016. Demographic, dosing, administration and outcome data were evaluated. The primary endpoint was the appropriateness of the weight-based dosing of sugammadex. This was defined as a dose of two to four milligrams per kilogram (plus or minus 10 percent). Secondary endpoints included indication (routine versus immediate), location of administration, efficacy, and adverse drug events.

Results: One hundred and thirteen patients were initially included, and 91 patients were over the age of 18 with documented administration of sugammadex. Lack of documentation related to weight-based dosing (height, weight, sugammadex dose given) excluded 10 patients. The average age was 46.1 years (14.01) with 41 male patients (48.4 percent). The mean ideal body

weight was 63.1 (13) kilograms. The median (IQR) dose of sugammadex was 200 (200, 200) milligrams. All doses ranged from 100 to 600 milligrams. The primary outcome (patients who were dosed appropriately) occurred in 38.5 percent of patients (n equals 35). Subgroup analysis showed a statistical difference between patients who received appropriately dosed sugammadex versus those who did not (median (IQR)) (2.0 milligrams per kilogram (1.923, 2.120) versus 2.535 milligrams per kilogram (2.326, 2.941); (95 percent confidence interval -0.663, -0.293; p less than 0.001). Neostigmine and glycopyrrolate administration occurred in nine patients prior to receiving sugammadex; no patients received these after sugammadex. Only two of 91 (3.3 percent) patients experienced an adverse event after sugammadex; two patients required a second dose, one patient required a medication for respiratory depression.

Conclusion: This retrospective chart review observed only 38.5 percent of patients received an appropriate dose of sugammadex and a statistically significant difference was identified when comparing the weight-based dose of sugammadex in appropriately and inappropriately dosed patients. This data indicates that providers were more likely to round to a vial size than draw up a patient specific dose, potentially leading to more adverse events and unnecessary resource utilization. Future steps will be needed to be taken to address the misutilization within the institution using the electronic medical system.

Poster Title: Risk Factors and Prevalence of QT Interval Prolongation in Adult Burn Patients Receiving Methadone

Primary Author: Allison Hester, Purdue University, Indiana; **Email:** hestera@purdue.edu

Additional Author (s):
Todd Walroth
Rajiv Sood
Marilyn Schoenle

Purpose: Previous studies support methadone use in burn patients as a means to decrease opioid use, ventilator days, and delirium development. The American Pain Society recommends electrocardiogram (ECG) monitoring for patients on methadone with certain risk factors for prolonged rate-corrected QT interval (QTc). There is a lack of data regarding methadone-associated QTc prolongation in burn patients. A QTc monitoring protocol for burn patients receiving methadone was implemented at the study institution to optimize care for high-risk patients. The purpose of this study was to determine the prevalence, risk factors, and cardiac outcomes related to methadone-associated QTc prolongation in burn patients.

Methods: This retrospective cohort study included 91 adult patients admitted to our Burn Center from 06/01/10-05/31/16 with at least one dose of methadone for pain, a baseline ECG prior to the first dose, and at least one follow-up ECG after initiation. Baseline QTc and maximum QTc after methadone initiation were recorded, and patients were divided according to those who had a prolonged QTc (> 470 for males; > 480 for females) versus those who did not (controls). Primary outcomes were incidence of cardiac events and change from baseline to longest QTc.

Results: Prolonged QTc was found in 27% of patients (n = 25). Median (IQR) maximum QTc was 458 (442,477) overall, 492 (479,520) in the prolonged QTc group, and 450 (437,462) in the control group. Both primary outcomes were significant: more patients had cardiac events in the prolonged QTc group (44%, n=11) than in the control group (9%, n=6) (p < 0.001), and median (IQR) change from baseline QTc was higher in the patients with QTc prolongation [61 (18,88), n=23)] than in the control group [233(13,38), n=43] (p < 0.001). The following risk factors for

prolonged QTc were similar between groups: age (p=0.5519, female gender (p=0.262), black race (p=0.388), number of QT-prolonging medications (p=0.181), number of CYP inhibitors (p=0.061), prior stimulant use (p=0.876), history of QTc prolongation (p=0.393), history of cardiac disease (p=0.945); history of CHF (p=0.572), and history of liver disease (p=1.000). Patients in the prolonged QTc group had higher TBSA [n (%)] [43.0 (21.7) versus 31.4 (14.9), p=0.005] and required higher total daily doses of methadone [milligrams; median (IQR)] [90.0 (52.5,97.5) versus 52.5 (30.0,75.0), p=0.004]. A post-hoc analysis revealed a moderate correlation between total daily dose of methadone and overall change in QTc from baseline [Pearson correlation coefficient = 0.498 (p < 0.001)].

Conclusion: Patients with prolonged QTc had a higher TBSA, longer LOS, and experienced a significantly higher rate of adverse cardiac events versus control patients. Of the risk factors studied, only total daily dose of methadone was significant. This study demonstrates the need for a standardized approach to routine ECG monitoring for QTc prolongation in burn patients receiving methadone. Regardless of presence or absence of other known risk factors for prolonged QTc, larger doses of methadone may correlate to longer QTc and higher rates of adverse cardiac outcomes in burn patients.

Submission Type: Descriptive Report

Session-Board Number: 3-144

Poster Title: Analyzing adverse drug event reports to improve patient outcomes: Twitter versus FAERS data

Primary Author: Rachel Wilson, Purdue University College of Pharmacy, Indiana; **Email:** wilso227@purdue.edu

Purpose: Utilization of social media as a data resource is increasing, especially as this information pertains to market research. Patients and consumers frequently post on Twitter regarding medications and use thereof. Similarly, the SafeRx database was created by the Purdue University Center for Medication Safety Advancement as a source of meaningful data, including data from the Food and Drug Administration Adverse Event Reporting System (FAERS). This current study was designed to collect and compare reported adverse drug events (ADEs) for Cymbalta (duloxetine) from Twitter to ADEs from the FAERS database, in order to highlight potential areas of improvement regarding medication safety.

Methods: Cymbalta (duloxetine) was selected for this study because it is the #21 drug in the Food and Drug Administration Adverse Event Reporting System (FAERS) database as listed by "number of reaction reports by drug." Tweets mentioning "cymbalta" from 6/9/16 to 7/11/16 were collected, analyzed, and compared to FAERS data from the same time period in 2015 (6/9 to 7/11), for the top 20 FAERS adverse drug events (ADEs) for Cymbalta. Three hundred tweets mentioning the search criterion "cymbalta" from the time period of 6/9/16 to 7/11/16 were manually collected from Twitter. Retweets and tweets containing internet links mentioning "cymbalta" were excluded from collection. Tweets classified as containing an ADE were required to contain both person reporting the event and person experiencing the event, as required by the FDA event reporting system. Tweets containing an ADE were then classified with a one or two-word, author-determined ADE description, such as "insomnia." FAERS data from the same time period in 2015, 6/9/15 to 7/11/15, was collected via the SafeRx database entitled "Common Reactions for Drug," for "Cymbalta." FAERS data from this time period in 2016 was unavailable when data was collected. There were 411 FAERS reaction reports for Cymbalta during this time period.

Results: 96 ADEs were reported in 300 collected tweets (32%) which mentioned "cymbalta," spanning a timeframe from 6/9 to 7/11 in 2016. 82 of 300 tweets (27%) contained at least one ADE. 14 of 300 tweets (5%) contained more than one ADE. Withdrawal syndrome was most commonly-reported, with 22 ADEs, and confusional state was second, with 7 ADEs. 1227 reactions affiliated with Cymbalta were collected from the SafeRx database for the "Top 20 ADEs" for Cymbalta, contained in 411 FAERS reports from the 6/9 to 7/11 time period in 2015. 140 ADEs (34%) were classified as "drug withdrawal syndrome," the most-commonly reported ADE. Of note, "suicidal ideation" was listed as the #12 reported reaction in the FAERS database with 46 reports from 6/9 to 7/11 in 2015. Percentages for each of the top 18 ADEs, of the total number of reports both from Twitter and FAERS data, respectively, were determined and compared. The top 18 Twitter ADEs, based on frequency, were included because 18 ADEs were mentioned more than once in the selection of 300 tweets, with the exception and addition of "suicidal ideation" due to the significance of this event, as it had only 1 report in 300 tweets.

Conclusion: Similar ADEs were reported to Twitter and the FDA. However, 6 of the top 18 ADEs were only reported on Twitter, and 7 of the top 20 FAERS ADEs were not reported on Twitter. Consequently, both Twitter and the SafeRx database are beneficial for collecting medication use data which may positively impact patient safety. Withdrawal syndrome was the most commonly-reported ADE for Cymbalta, both on Twitter (7%) and in the FAERS database (34%). Accordingly, tapering regimens should be emphasized to provide better therapeutic results for patients. Mood-related ADEs and suicidal ideation were also commonly-reported, indicating a need for further surveillance.

Submission Category: Small and Rural Pharmacy Practice

Submission Type: Descriptive Report

Session-Board Number: 3-145

Poster Title: Using the Bridging Income Generation with GrouP Integrated Care (BIGPIC) model as a method for addressing chronic disease management in a peri-urban, resource-limited setting.

Primary Author: Mario Hoyos, Purdue University College of Pharmacy, Indiana; **Email:** mhoyos@purdue.edu

Additional Author (s):
Ellen Schellhase
Chelsea Pekny
Sonak Pastakia
Samuel Kimani

Purpose: Prevalence of non-communicable diseases (NCDs) is rising in low and middle income countries. Adoption of sedentary, calorie rich lifestyles contribute to the rise in NCDs. Urban areas are highly impacted by this lifestyle shift, but have accessible healthcare. Peri-urban and rural areas are also impacted, but present barriers to addressing NCDs due to lack of accessible healthcare infrastructure. The Bridging Income Generation with GrouP Integrated Care (BIGPIC) model was developed for and has been proven to work in rural settings in western Kenya. This project evaluated the adaptation and acceptance of the BIGPIC model in a peri-urban slum.

Methods: Purdue University faculty and student pharmacists worked with providers from Moi Teaching and Referral Hospital (MTRH) and the AMPATH Consortium to establish a BIGPIC program at the Tumaini Center to serve the Munyaka slum and neighboring communities outside of Eldoret, Kenya. The program follows the 6 pillars of the BIGPIC model. 1) find patients portably, 2) link to peer/microfinance groups, 3) integrate education, 4) treat portably, 5) enhance economic sustainability, and 6) generate demand for care through incentives. Student pharmacists and faculty procured the supplies and medications necessary for screening events and care groups and created a sustainable work plan for the establishment of a new BIGPIC care program. They also brought together leaders of the Munyaka community, Tumaini Center administration, and AMPATH and MTRH providers to ensure community and provider support of the program.

Results: Munyaka and surrounding community chiefs and elders have been engaged and are in support of the establishment of these care programs. Screening events for hypertension and diabetes have been set for January 2017 and the microfinance team from AMPATH will create BIGPIC groups from the patients who screen positive. The providers who will care for patients in the groups at the Tumaini Center have been identified and group care has been put into their work assignments starting in February 2017.

Conclusion: The BIGPIC model, which has been proven in rural areas to effectively manage diabetes and hypertension, can be adapted and accepted in economically vulnerable populations in peri-urban areas in western Kenya. Future studies will compare patient care metrics and results from the establishment of this program outside of Eldoret to care results from rural populations to measure success of this program in peri-urban areas. This model may be replicable for other underserved populations in similar regions around the world.

Submission Category: Practice Research/ Outcomes Research/ Pharmacoeconomics

Submission Type: Evaluative Study

Session-Board Number: 3-146

Poster Title: Evaluation of the effectiveness of a veterinary pharmacotherapy elective to prepare pharmacy students for handling veterinary prescriptions in the community setting

Primary Author: Allison Grana, Purdue University College of Pharmacy, Indiana; **Email:** agrana@purdue.edu

Additional Author (s):
Lauren Eichstadt Forsythe
George Moore

Purpose: As a result of the cost savings and convenience community pharmacies can provide, an increasing number and complexity of animal-related prescriptions are being referred to community pharmacies. Pharmacists' knowledge and education can be used to develop working relationships with veterinarians so that community pharmacists can properly dispense animal medications. However, many pharmacy schools do not incorporate veterinary pharmacology into their required courses and only some offer a veterinary pharmacology elective. The objective was to determine if a veterinary pharmacy elective offered to pharmacy students improved their ability to address veterinary-related questions compared to classmates who did not take the elective.

Methods: A one-credit veterinary pharmacotherapy elective course was offered at Purdue's College of Pharmacy for second and third professional year students. The course consisted of 7 two-hour meetings, a one-hour recorded lecture and a written final exam. Thirty-two students (5 third year, 27 second year) enrolled in and completed the course. A 17 question survey was used to assess the competence and confidence with which students answered veterinary pharmacy questions. The survey consisted of three demographic questions, seven multiple choice clinical questions focusing on veterinary scenarios a pharmacist may encounter in the community setting, and seven questions assessing respondent's confidence in answering each clinical question. The survey was administered using Qualtrics. It was distributed to students in the veterinary pharmacotherapy course and students were asked to complete the survey prior to the first class session. At the end of the semester the survey was distributed to all second and third professional year students. Survey responses were anonymous at all stages. This research was exempted by the Purdue University Institutional Review Board. The primary

endpoints of this study were number of correct responses to the seven clinical questions and the respondents' confidence in their answers between responses at the beginning and end of the course and between students who had taken the course versus those who had not.

Results: Thirty-two students took the course. Thirty-one students took the survey before the start of the course (second year: 87 percent, third year: 13 percent). Twenty-four of these students took the second survey at the end of the course. After the elective, 93 students took the survey (second year: 59 percent, third year: 41 percent), including the 24 students who had taken the course and 69 students who had not taken the course. Students who took the survey at the end of the elective chose the correct answers a higher percentage of the time than when they took the survey at the beginning of the elective, yielding statistically significant results for 4/7 questions. Additionally, students who took the survey after the elective answered questions with more confidence than when they took the survey at the beginning of the elective, yielding statistically significant results for 7/7 questions. Students who took the elective consistently chose the correct answers a higher percentage of the time versus students who did not, yielding statistically significant results for 4/7 questions. Additionally, students who took the elective were more confident in answering the survey questions than their counterparts who did not, yielding statistically significant results for 7/7 questions.

Conclusion: This particular elective course did significantly increase the knowledge of students with regards to veterinary pharmacy topics that may be common in a community setting. However, the universally significant increase in confidence regardless of correct answer could be a potential cause of concern. These results are also applicable to other specialty electives. Because such courses are only foundations, it is important to emphasize that drug information resources and/or specialists may still need to be consulted when there is any uncertainty about veterinary prescriptions to ensure patient and caregiver safety.

Submission Category: Pharmacy Law/ Regulatory/ Accreditation

Submission Type: Evaluative Study

Session-Board Number: 3-147

Poster Title: United States Food and Drug Administration advisory committee outcomes and agency approval analysis from 2010 - 2015

Primary Author: Zachary McCormack, Purdue University College of Pharmacy, Indiana; **Email:** zmccorma@purdue.edu

Additional Author (s):
Lauren Tesh
Christina Thompson

Purpose: Advisory committee meetings hosted by The United States Food and Drug Administration (FDA) are part of the pre-market approval process for many pharmaceuticals in which the opinion of external experts is solicited to help address areas of uncertainty. Advisory committee meetings are of substantial importance to sponsors as they come after significant time and financial investment and can have a large influence in a drug's ultimate approval. Given such implications, this analysis sought to quantify voting behavior and other characteristics of advisory committee meetings and compare that with the FDA's approval decisions in the years of 2010 - 2015.

Methods: An analysis of the Center for Drug Evaluation and Research (CDER) advisory committee meetings for the years of 2010 – 2015 was conducted by utilizing publicly available information. Information pertaining to the advisory committee (number of voting sessions, votes, and meetings; percent of meetings that were joint meetings; percent of committee members voting yes, no, abstain, or non-voting; breakdown of voting question) was obtained from the FDA's website, particularly from available meeting minutes and transcripts for each advisory committee. Information regarding the FDA's decision for approval and rationale for issuing a complete response letter was based on material gathered from drugs@fda or directly from the sponsor's website.

Results: There were 163 voting sessions, 207 votes, and 229 meetings. 25 percent of meetings were joint meetings. Voting patterns remained fairly constant with an aggregate voting pattern of 64 percent yes, 34 percent no, 2 percent abstain, and 0 percent non-voting. These percentages changed when assessing voting patterns relative to instances of favorable voting

(86 yes, 12 no, 2 abstain, 0 non-voting) and unfavorable voting (17 yes, 81 no, 2 abstain, 0 non-voting). The advisory committee voted favorably 67 percent of the time and unfavorably 33 percent. Voting questions assessed approval (63 percent), acceptable risk-benefit profile (19 percent), efficacy (8 percent), safety and efficacy (7 percent), and safety (3 percent). The FDA's approval decision supported the committee's decision in 90 percent of cases. When such agreement didn't occur (21 cases), this was due to differences in clinical opinion (43 percent), manufacturing deficiencies (14 percent), lack of manufacturing data (14 percent), and a post advisory committee event (5 percent). There wasn't enough information to determine why there was a differing opinion in 24 percent of cases. In instances in which the FDA had a differing opinion, the agency typically didn't approve a substance in which the committee recommended approval (81 percent).

Conclusion: The results support past research examining a comparable subject matter from 2001 – 2010. Voting patterns were relatively constant and generally heavily favored one outcome. The FDA's ultimate approval decision was in line with the advisory committee vote in the vast majority of cases. When it wasn't, available information indicated this was usually due to the FDA having a differing opinion on presented material's clinical importance, furthering the notion that advisory committee insight is heavily considered but not the final determinant in agency action.

Submission Category: Oncology

Submission Type: Evaluative Study

Session-Board Number: 3-148

Poster Title: Retrospective review of ifosfamide associated encephalopathy for patients admitted to the inpatient oncology unit at the Indianapolis University (IU) Health, University Hospital, Simon Cancer Center

Primary Author: Rachel Bubik, Purdue University College of Pharmacy, Indiana; **Email:** rbubik@purdue.edu

Additional Author (s):
Patrick Kiel
Kellie Weddle

Purpose: Ifosfamide is an alkylating agent metabolized by CYP3A4 into its active form and two inactive metabolites, one of which is neurotoxic and can lead to encephalopathy. Aprepitant, a neurokinin-1 receptor antagonist, is known to be a moderate inhibitor of CYP3A4 and is used as an anti-emetic prior to administration of ifosfamide. Anecdotal reports have suggested a possible interaction between ifosfamide and aprepitant although this idea has not currently been supported by clinical trials or recent pharmacokinetic data. This study aimed to evaluate the incidence of ifosfamide-induced encephalopathy.

Methods: All patients admitted to the inpatient oncology unit from 5/1/15-3/31/16 who had received ifosfamide were included. Patients with multiple visits were only included in the analysis one time. The primary objective of this study was to evaluate the incidence of ifosfamide-induced encephalopathy in patients receiving aprepitant versus those not receiving aprepitant as antiemetic prophylaxis. Secondary objectives compared patient characteristics among patients that developed encephalopathy versus patients who did not including: cancer diagnosis, chemotherapy regimen, dose of ifosfamide, day and cycle number when encephalopathy occurred, cisplatin use, serum creatinine level, and albumin level. An additional secondary objective was to identify other potential factors that could have exacerbated the symptoms of encephalopathy such as drug interactions, presence of brain metastases, use of opioids, benzodiazepines, or other anti-emetics. As this was a retrospective review, encephalopathy cases were categorized into "no encephalopathy" and "proven/probable encephalopathy" cases based on the description of symptoms in the medical records. They were also classified by the common terminology criteria for adverse events (CTCAE) and

separated into grades 1/2 and grades 3/4 encephalopathy. This study was approved by the Indiana University Institutional Review Board.

Results: Fifty-one unique patients received ifosfamide during this time period and 14 of 51 (27.5 percent) developed encephalopathy. Of the 51 total patients, 34 patients received aprepitant and 17 did not. The incidence of proven or probable encephalopathy was 17.6 percent (6 out of 34) in patients receiving aprepitant and 47.1 percent (8 out of 17) in patients not receiving aprepitant (p equals 0.045). Based on these data, the interaction between aprepitant and ifosfamide was not found to be statistically significant in regards to increasing the incidence of encephalopathy and there were no appreciable differences in the baseline characteristics between the groups. Of the 14 patients that developed encephalopathy, 6 were classified as CTCAE grade 1/2 and 8 were classified as grade 3/4. Encephalopathy occurred during the first cycle for 12 of the 14 patients (85.7 percent) and occurred on the second day of the cycle for 7 of the 14 patients (50 percent). Notably, there were no significant differences in any of the secondary outcomes analyzed.

Conclusion: The results of this study suggest that patients who received aprepitant were actually less likely to develop encephalopathy, therefore the use of this effective anti-emetic may not need to be avoided when using ifosfamide.

Poster Title: Board of pharmacy practices related to medication errors and the impact on patient safety

Primary Author: Michael Peters, Purdue University College of Pharmacy, Indiana; **Email:** peter100@purdue.edu

Purpose: Individual state boards of pharmacy are responsible for developing regulations to govern the practice of pharmacy. Individual rules for governing practice may vary by state, but the primary premise for these regulations is to protect the public health. All boards must deal with reported medication errors and determine the most appropriate course of action with regard to each individual case. Actions taken as a result of an error may not always be in the best interest of public health. This study evaluated the policies and procedures of boards of pharmacy in response to medication error cases.

Methods: This study was approved as exempt from full review by the Purdue University Institutional Review Board. The primary objective of this study was to identify and compare "error response" practices among 54 boards of pharmacy that are members of National Association of Boards of Pharmacy (NABP). The survey was distributed to state boards of pharmacy contacts. The contact list was obtained from NABP. Survey responses included an electronic survey with phone follow up for clarification or non-responders. All complete responses were included in final data analysis. The survey was administered using the Qualtrics (Provo, Utah) survey software and consisted of 15 closed response questions, of which 3 questions were case-based. The case-based questions presented responders with a medication error event occurring and the subsequent response that their board of pharmacy would have taken depending on the level of harm (no harm, temporary harm, permanent harm, or death). The survey remained open from August 20, 2015 to September 24, 2015. The survey questions were designed to collect demographic information, information regarding various disciplinary options, and specific improvement plans associated with any board action. Comparator data was also collected, including: board composition (i.e., size, practitioner expertise, and public involvement), state population or state geography (US region). Collection of survey responses occurred automatically through the Qualtrics survey manager.

Results: The survey was completed by 24 individuals representing different state boards of pharmacy, representing a 44.4% response rate. The majority of respondents were the state executives of the board of pharmacy (80%), were pharmacists (63%), and had more than 5 years of experience on the board of pharmacy (54%). A majority of responders (63%) reported that their state does not require medication safety or medication error training of its licensees or registrants. The survey also revealed that a majority of responders (71%) indicated that board members are not provided orientation materials related to medication safety or medication errors. When a medication error is reviewed, 42% of responders stated that their board of pharmacy does not require performance improvement or system re-design strategies to be employed. Ninety-one percent of respondents reported that actions taken against pharmacists who commit errors are developed on a case by case basis. The cases showed similar levels of actions levied against pharmacists depending on the severity of harm to the patient among the different situations without much regard to the actual action taken by the pharmacist and whether or not the case represented negligence and recklessness, natural human error, or a flawed system.

Conclusion: This study demonstrates an opportunity for boards of pharmacy to improve consistency of practice. Current opportunities for improvement are error reporting, safety training, and process improvement. This study demonstrated that boards of pharmacy make punitive decisions based on outcome to a patient in response to a medication error without regard to the nature of the error and make minimal efforts to avoid similar problems for future patients. Aiming to protect public health, boards of pharmacy should strive to be proactive and prevent future errors instead of punishing an action of the past.

Poster Title: Exploratory comparison of the PRIMROSE-LDL and PRIMROSE-BMI equations versus the Pooled Cohort equation for cardiovascular risk prediction in patients with serious mental illness

Primary Author: Luke Smedley, Purdue University College of Pharmacy, Indiana; **Email:** lsmedley@purdue.edu

Additional Author (s):
Jasmine Gonzalvo
Muirisha Lavender
Valerie LeGacy

Purpose: Studies have shown that patients with serious mental illness (SMI) are at a higher risk for cardiovascular mortality and metabolic disorders than the average population. Interventions in these patients can reduce cardiovascular risk factors, however, a significant amount of patients are not optimally managed to reduce these risk factors. Various risk calculations have been established to predict cardiovascular risk, but it is unknown how accurate these predictions are in patients with SMI. The purpose of this study was to describe the correlations between calculations with PRIMROSE-LDL and PRIMROSE-BMI equations and the pooled cohort equation in patients with SMI.

Methods: The institutional review board approved this retrospective chart review. We identified patients using schedules of providers at the clinic. We included patients if they had a diagnosis of schizophrenia, schizoaffective disorder, bipolar disorder, or other mental illness with a component of psychosis (e.g., major depressive disorder with psychotic features), and were between the age of 40 and 79. We recorded sex, age, home medications, race, high-density lipoprotein (HDL) level, total cholesterol (TC) level, most recent systolic blood pressure (SBP), weight, height, current diagnoses, alcohol use history, smoking status, and Area Disparity Index quintile for each patient. We used these values to calculate and record 10-year risk of a cardiovascular event using the PRIMROSE-LDL, PRIMROSE-BMI, and Pooled Cohort equations for each patient. We tested the results for normality using the Shapiro-Wilk Test. We tested for differences in values from each equation using Friedman's ANOVA, and then the Wilcoxon signed-rank test if the results from Friedman's ANOVA was significant. The significance level for

Friedman's ANOVA was set a priori at α=0.05. To decrease bias from multiple comparisons for the Wilcoxon signed-rank test, we adjusted the significance level to α=0.0167 using the Bonferroni correction.

Results: We identified a total of 39 patients. The average ten-year risk of cardiovascular events was 12.4% (95% CI 9.2 – 15.6%) with the Pooled Cohort equation, 8.0% (95% CI 5.8 – 10.2%) with the PRIMROSE-LDL equation, and 11.8% (95% CI 9.1 – 14.5%) with the PRIMROSE-BMI equation. After evaluating the data using Friedman's ANOVA, there was a statistically significant difference in risk predictions between the three equations ($\chi2$=25.436, $p < 0.001$). After evaluating using the Wilcoxon signed-rank test, there was a statistically significant increase in risk prediction with the PRIMROSE-BMI equation than the PRIMROSE-LDL equation (r=-0.78, $p < 0.001$), and statistically significant decrease in risk prediction with the PRIMROSE-LDL equation than the Pooled Cohort equation (r=-0.53, p=0.001). There was not a statistically significant difference between the PRIMROSE-BMI and Pooled Cohort equations (p=0.989).

Conclusion: Use of the PRIMROSE-LDL equation gave a lower ten-year risk of cardiovascular events than the Pooled Cohort equation and the PRIMROSE-BMI equation. This raises questions of whether different populations have different correlations and differences in risk prediction when using one equation over another. The results from this study spurred the interest of the investigators to perform another study with a larger sample size, to better describe these correlations.

Poster Title: Retrospective review of adult patients with solid tumor cancers receiving rivaroxaban therapy: Assessment of associated bleeding risks

Primary Author: Parth Patel, Purdue University College of Pharmacy, Indiana; **Email:** patel163@purdue.edu

Additional Author (s):
Kellie Weddle

Purpose: Oral direct factor Xa inhibitors such as rivaroxaban are used to prevent venous thromboembolic events. The current National Comprehensive Cancer Network guidelines do not recommend rivaroxaban therapy for acute and chronic management in patients with cancer. However, the use of this agent has increased in the oncology population. The purpose of this study is to evaluate toxicities associated with rivaroxaban anticoagulation therapy in oncology patients at Indiana University Health University Hospital and the Simon Cancer Center.

Methods: This retrospective review was conducted at the Indiana University Health University Hospital, the Simon Cancer Center, and their associated outpatient oncology clinics in Indianapolis, Indiana. The electronic medical record system identified patients from these sites who had received rivaroxaban for anticoagulation management. Patients were included if they were eighteen years of age or older, had cancer listed in their past medical history, and received rivaroxaban for anticoagulation management from January 2013 to February 2016. The exclusion criteria included patients with hematological cancers, benign tumors, basal cell carcinomas, multiple cancers, and unknown indication for rivaroxaban. Data was collected from one hundred and forty-four patients who met the inclusion criteria. The data collection sheet included the following: age, gender, weight, cancer type, cancer stage, cancer treatment history, rivaroxaban indication, rivaroxaban dose, rivaroxaban duration of therapy, major bleeding (any bleeding requiring treatment or hospitalization), minor bleeding (any bleeding not requiring treatment or hospitalization), recurrent thrombosis, previous anticoagulation therapy, smoking status, history of atrial fibrillation, and survival status. All data were collected without patient identifiers. This study was approved by the Indiana University Institutional Review Board.

Results: Sixty four (44 percent) out of one hundred and forty-four patients experienced bleeding while receiving rivaroxaban therapy. There were six cancer types that had a higher incidence of bleeding: bladder, breast, melanoma, pancreas, prostate, and renal cell. Six out of fifteen bladder cancer patients (40 percent) experienced bleeding with 26.7 percent and 13.3 percent classified as major and minor bleeding, respectively. Seven out of thirteen breast cancer patients (53.8 percent) experienced bleeding with 46.2 percent and 7.7 percent classified as major and minor bleeding, respectively. Five out of ten melanoma patients (50 percent) experienced bleeding with 10 percent and 40 percent classified as major and minor bleeding, respectively. Eleven out of nineteen pancreas cancer patients (57.9 percent) experienced bleeding with 36.8 percent and 21.1 percent classified as major and minor bleeding, respectively. Ten of out twenty-two prostate cancer patients (45.5 percent) experienced bleeding with 13.6 percent and 31.8 percent classified as major and minor bleeding, respectively. Lastly, five out of nine renal cell cancer patients experienced bleeding (55.6 percent) with 44.4 percent and 11.1 percent classified as major and minor bleeding, respectively. No other data collected identified any increased risk of bleeding in these patients.

Conclusion: Patients on rivaroxaban therapy with bladder, breast, melanoma, pancreas, prostate, or renal cell cancers were at higher risk for bleeding than other solid tumor cancers. Major bleeding incidences were higher in patients with bladder, breast, pancreas, and renal cell cancers. Minor bleeding incidences were higher in patients with melanoma and prostate cancer.

Poster Title: A study of medication disposal practices through a state-wide collection project

Primary Author: Adam Smith, Purdue University College of Pharmacy, Indiana; **Email:** smith673@purdue.edu

Additional Author (s):
Patricia Darbishire

Purpose: Demand for prescription medications is on the rise, with 4.4 billion prescriptions filled by pharmacies in the United States in 2015. Of those, one third, or about 200 million pounds of medication are unused and often accessible for misuse. In 2014, more people died from drug overdoses than ever before. Additionally, improper medication disposal poses a threat to our environment, contaminating our land and water. The purpose of this study is to describe disposal practices and attitudes of patrons using the Yellow Jug Old Drugs medication disposal program in an attempt to address these growing concerns.

Methods: In the fall of 2015, a Purdue pharmacy faculty member and an advanced pharmacy student led a duel initiative in the Purdue University Pharmacy to begin a medication disposal program (Yellow Jug Old Drugs - operated by Great Lakes Clean Water Organization) in addition to an IRB-approved survey research project to study the practices and attitudes of patrons bringing in medication for disposal. In the spring of 2016, additional Indiana-based pharmacies participating in the same disposal program agreed to collect and share information. These include an independently owned pharmacy, as well as outpatient clinics affiliated with Eskenazi Health in Indianapolis - a Level I trauma center and teaching hospital serving vulnerable populations in Marion County, Indiana. The anonymous, voluntary paper survey involved 20 multiple choice and yes/no questions about the participants' demographics, reason(s) for participation, who the medication owners were, where the medications were obtained, knowledge on opportunities for disposal within their community, willingness to pay for a disposal service, as well as other questions. The number of medications returned per participant were tracked as well. Descriptive statistics were performed using Excel 2016 and the data were analyzed for frequencies and trends.

Results: Forty seven medication disposal surveys were completed by pharmacy patrons utilizing the disposal service. In total, approximately 400 different types of medications were collected for disposal by those completing the surveys. Eighty-five percent of medications collected were prescription and obtained from a local pharmacy. Eighty-seven percent indicated their primary reason for visiting the pharmacy was for medication disposal and almost 45 percent first learned about the take-back program while visiting the pharmacy for another purpose. Sixty-two percent indicated that their medication had expired and 36 percent indicated their medication regimen had changed. Fifty-one percent noted that their primary motivation for using this service was to protect the environment, with 43 percent indicating a concern of theft/abuse. Prior to using this service, approximately 60 percent of participants reported disposing of unwanted medications either by flushing them down the toilet/sink, or placing them in the trash. Twelve participants reflected in writing on barriers to properly disposing of medications with the majority (67 percent) listing "limited access" to opportunities as the greatest barrier. Sixty-six percent indicated it was their first time disposing of medications through a service, with 85 percent stating they are likely to recommend this program to a friend.

Conclusion: Each year, more than one billion medications go unused in the United States. Medication consumers are concerned that improper disposal is harmful to the environment and may promote medication misuse and abuse. Results suggest that consumers want to properly dispose of medications, but do not know best practices for medication disposal, or have limited access to medication disposal programs. The Yellow Jug Old Drugs medication disposal program is one method of providing a convenient, accessible option for consumers to safely dispose of unwanted medications in an environmentally friendly manner.

Poster Title: Calibrated Peer Review to Introduce the Pharmacists' Patient Care Process: Student Perceptions Survey

Primary Author: Lindsay Moreland, Purdue University College of Pharmacy, Indiana; **Email:** lmorela@purdue.edu

Additional Author (s):
Zachary Weber
Alex Isaacs

Purpose: Pharmacists' patient care process (PPCP) is an approach used to optimize health outcomes using patient-centered care with collaboration from other healthcare professionals. However, activities related to these are difficult to implement and assess in large enrollment healthcare courses. Calibrated peer review (CPR) is a tool that allows students to practice PPCP skills and interprofessional communication through cases. CPR provides an advantage over multiple-choice because students have the opportunity to develop clinical skills, and evaluate themselves and peers using rubrics. The purpose of this study was to assess pharmacy student perceptions of CPR to introduce and assess aspects of the PPCP.

Methods: A voluntary survey was administered to first year professional doctor of pharmacy students during the fall semester. The survey focused on outcomes related to the PPCP: collecting information, assessing available information, creating a patient-specific plan, implementation of the plan, and follow-up. Students were asked to complete the survey prior to completing the first PPCP assignment. Since students tend to struggle with the subjectivity of the PPCP, the survey assessed first year professional students' confidence in their ability to use CPR. Students ranked their confidence levels using a five-point Likert scale to rate their confidence: as very confident (extremely sure of his or her decision and no need for further guidance), confident (sure of his or her decision with limited guidance needed), somewhat confident (sure to some extent of his or her decision requires some guidance), slightly confident (unsure of his or her decision and requires much guidance), and not at all confident (completely unsure of his or her decision and unable to do on his or her own).

Results: The survey was administered to first year professional students and received 165 responses with 100% of students responding. 65.5% of students (108/165) reported previous use of CPR with non-pharmacy assignments. When asked about patient-specific tasks, over 50% of students were less than confident on each task with the exception of writing a SOAP note. Only 35.2% (58/165) were less than confident in their ability to prepare a SOAP note. Students reported their ability to create a ranked problem list as 67.9% (112/165) less than confident. Students responded with 64.8% (107/165) being less than confident in determining pertinent patient specific factors. When asked their ability to recommend patient-specific recommendations, 75.2% (124/165) were less than confident in their ability to provide recommendations with 59.4% (98/165) less than confident about being able to provide supporting evidence for their recommendation. When then asked about their confidence to develop written communication to another healthcare professional, 66.7% (110/165) were less than confident in their ability to do so. Finally, 75.8% (125/165) were less than confident in their ability to prepare a care plan.

Conclusion: The survey found many first year professional students were not confident in their ability to perform PCPP skills. In addition to current curricular activities, CPR is a tool that can develop and enhance students' ability to make patient specific decisions and improve patient outcomes. By practicing skills and evaluating themselves and peers, CPR enables students to apply and reinforce the necessary PCPP skills to enhance patient care.

Poster Title: Outcomes of empiric urinary tract infection (UTI) management versus empiric treatment with ampicillin and gentamicin

Primary Author: Madeline Miller, Purdue University College of Pharmacy, Indiana; **Email:** maddy@purdue.edu

Additional Author (s):
Jon Hiles

Purpose: Urinary tract infections (UTI) are a common problem in the United States. Treatment options are relatively well-studied for acute uncomplicated cystitis in the outpatient setting; however, there is less data regarding treatment of complicated UTIs in the hospital. Local susceptibility data has shown that commonly used agents, such as ciprofloxacin and ceftriaxone, cover less than 70 percent of organisms seen in the urine. The purpose of this study is to evaluate the agents currently used at Methodist Hospital for efficacy and susceptibility rates of urinary pathogens to compare with a newly implemented initiative treating UTIs empirically with ampicillin and gentamicin.

Methods: The institutional review board approved this prospective evaluative study. A data reporting system, MedMined, was used to generate a report of patients with positive urine cultures between October 1 and December 31st, 2015. Patients were included if they were greater than 18 years of age, and showed at least 105cfu/mL white blood cells on urinalysis if un-catheterized, and 103cfu/mL if catheterized. Patients were excluded if they did not receive antimicrobial treatment for a UTI during their hospital stay, received antimicrobials for another infection, were never inpatient, died or were admitted to hospice within 48 hours of positive urine culture. Patient's culture and susceptibility were recorded, as well as the length of initial therapy and the need for a change in therapy. Time of total active therapy was calculated, as well as time without active antibiotics. Active therapy agents were reported, and the patient was evaluated for clinical success. Primary endpoint was clinical success defined as a combination of not needing to change therapy to cover identified organism, no readmission for UTI and no repeat urine culture with same organism. Secondary outcomes will be percentage of urinary pathogens covered by selected antimicrobial(s), time to initiation of active therapy and microbiological cure in patients with repeat culture data available.

Results: Preliminary results represent a sample group of 80 patients, 45 of whom met inclusion criteria. This preliminary data showed a clinical success rate of 58 percent. 27 percent of patients required a change in therapy. Ceftriaxone and ciprofloxacin were the two most commonly selected systemic agents for initial therapy (24 percent and 15 percent respectively). Unfortunately, ceftriaxone covered only 42 percent of pathogens, and ciprofloxacin covered only 44 percent. By comparison, these preliminary findings showed that ampicillin with gentamicin would cover 70 percent of pathogens. The most common pathogen was Escherichia coli, making up 36 percent of infections. Klebsiella pneumoniae was the second most common, followed by Enterococcus species. On average, patients went 24 hours without appropriate antibiotic coverage.

Conclusion: Initial antimicrobial therapy for UTIs is often based solely on susceptibility rates of Escherichia coli. Our preliminary findings show that there are other organisms commonly identified and the majority of patients were initially treated with antibiotics that have poor coverage for most UTI pathogens. Low rates of clinical success and the need to change therapy often with current practice support the initiative to empirically treat UTIs with the combination of ampicillin and gentamicin.

Poster Title: Adherence to spironolactone

Primary Author: Julie Kippenbrock, Purdue University College of Pharmacy, Indiana; **Email:** jkippen@purdue.edu

Additional Author (s):
Rachel Hasty
Sarah Lynch
Michael Murray

Purpose: Spironolactone is a potassium-sparing diuretic and an aldosterone antagonist. While this medication can contribute to reduced cardiovascular risk and mortality, patient adherence to this medication is usually lower than other anti-hypertensive medications without documented reasons. The study objective is to observe adherence rates and side effects among patients prescribed spironolactone considering gender and race.

Methods: We conducted an observational study using electronic medical record data from the Indiana Network for Patient Care (INPC). This patient population is representative of patients in the state of Indiana, USA. The population of interest for this study includes patients 18 years of age and older taking spironolactone and/or other antihypertensive medications at some point during 2003-2014. We assessed reported side effect rates from prescriber notes using text mining technology and assessed adherence from pharmacy fill records. This study was approved by Indiana University institutional review board and all analyzed data was de-identified.

Results: According to proportion of days covered (PDC) at 180 and 365 days, patients taking spironolactone had lower adherence rates when compared to all other anti-hypertensives combined. Whites had higher adherence rates at 90 and 180 days compared to blacks and males had higher adherence rates than females. After text mining of patient charts was used to determine potential causes for this difference, it was shown that blacks had higher rates of documented adverse events than whites, which is reflected in the lower adherence rates for black patients. When examining text mining results for gender, males had higher rates of

documented adverse effects than females, yet adherence rates for males were higher than females.

Conclusion: Adherence rates and adverse events for patients taking spironolactone need to be examined further in order to determine the reason(s) for these differences.

Poster Title: Creating a Play Area for Shoe4Africa Pediatric Hospital: A Purdue University College of Pharmacy Service Learning Project

Primary Author: Katherine Curtis, Purdue University College of Pharmacy, Indiana; **Email:** curtisk@purdue.edu

Additional Author (s):
Karolina Grzesiak
Sarah Ellen Mamlin
Ellen Schellhase
Monica Miller

Purpose: Opened in 2015, Shoe4Africa is East Africa's first public pediatric hospital. With just over 100 beds, the hospital provides quality inpatient and outpatient care to hundreds of children daily. Purdue University student pharmacists participate in patient care activities at the hospital. During this experience, a need was identified for a play area for the children and their families. Therapeutic play has been shown to improve outcomes for hospitalized children. The purpose of this project was to develop an area for therapeutic play at this hospital and provide an opportunity for student pharmacists to address patient needs outside of the pharmacy.

Methods: While in Kenya, student pharmacists explored ways to further their involvement at the local practice sites and impact the local community. Building a safe play area for the pediatric patients at Shoe4Africa was identified as an opportunity for growth and further engagement for Purdue students. An extensive literature search was performed to identify the needs for therapeutic play and improved patient health outcomes. Student pharmacists further researched appropriate equipment to maximize the benefits children are able to gain through therapeutic play. A meeting with child-life leaders at Shoe4Africa was arranged to discuss and determine the location-specific needs and requirements. Plans were tailored to build a stimulating, safe, and inclusive playground for the local pediatric population. Existing equipment was evaluated and it was decided that some could be repurposed. The need for new equipment was crucial to provide an appropriate and safe area. The cost of the additional parts and equipment was researched to develop a plan for the play area. A service learning grant application was submitted to obtain the funds to support this project.

Results: Literature shows support of therapeutic play as a method to improve health outcomes in pediatric patients. According to the Child Life Council Evidence-Based Practice Statement on therapeutic play in pediatric healthcare, "Research provides evidence for the effectiveness of therapeutic play in reducing psychological and physiological stress for children facing medical challenges." This statement is based on nine quantitative and one qualitative studies. Additionally, over ten professional organizations throughout the globe are strong supporters of therapeutic play. To finance the project a service learning grant for $1,500 was obtained through the Purdue University Office of Engagement. These funds were used to purchase the materials needed to build new equipment and refurbish the existing pieces in order to provide an appropriate environment for children to play. The area is providing a creative outlet for hundreds of children that walk through the doors of Shoe4Africa each day. Six student pharmacists were directly involved in the initiation of the project. Additionally, each year 24 student pharmacists on an 8-week advanced pharmacy practice experience in Eldoret will continue the project involvement by enhancing the equipment, building cross-cultural bonds with pediatric patients through play, and expansion of the current services provided.

Conclusion: This project and grant provided a foundation for child-life services and therapeutic play at Shoe4Africa. Participation in this project allowed student pharmacists to learn about patient care and community engagement outside of the pharmacy, develop communication skills, and break cultural barriers. Student pharmacists are now given the opportunity to develop skills beyond their pharmacy training though engaging in therapeutic play that can later translate to interactions with other pediatric populations. Future plans for the play area include incorporating medication education for the parents conducted by student pharmacists and promoting healthy activities for children and their families.

Poster Title: Retrospective review of the safety and efficacy of everolimus use post liver transplantation in patients with hepatocellular carcinoma

Primary Author: Anne Rodino, Purdue University College of Pharmacy, Indiana; **Email:** arodino@purdue.edu

Additional Author (s):
Rachel Bubik
Allison Grana
Jenna Kolb
Hillary McNamee

Purpose: Liver transplantation is the most effective treatment for hepatocellular carcinoma (HCC); however, recurrence is common. One prevention strategy uses mammalian target of rapamycin (mTOR) inhibitor based immunosuppressive regimens due to their direct antitumorigenic effect. Since everolimus gained Food and Drug Administration approval for liver transplant in 2013, it has replaced sirolimus at Northwestern Memorial Hospital (NMH) as the primary mTOR inhibitor used in liver transplant recipients. Clinicians at NMH have reported everolimus intolerance and subsequent discontinuation in this patient population. The purpose of this study was to determine discontinuation and adverse effect rates of everolimus in liver transplant recipients.

Methods: This was a single-center, retrospective study conducted at NMH in Chicago, Illinois. Patients 18 years of age and older with a diagnosis of HCC who received everolimus at any point post-liver transplant from January 1, 2007 to August 17, 2016 were included in this study. Patients were excluded if they were on sirolimus at any time prior to everolimus initiation or if they had a history of human immunodeficiency virus. A chart review was performed to collect basic demographics, duration of everolimus use, concurrent immunosuppression and drug levels, adverse effects, incidence of rejection, treatment of rejection, and graft and patient survival. The primary objective of this study was to determine the discontinuation rate in patients using everolimus. Secondary objectives included identifying reasons for discontinuation, duration of everolimus therapy prior to discontinuation, adverse effects related to everolimus, average everolimus and tacrolimus levels during therapy, rate and type

of rejection episodes, and graft and patient survival. Further endpoints examined the need for additional drug therapy required to treat adverse effects such as hypertriglyceridemia and neutropenia. This study was approved by the NMH institutional review board.

Results: Thirty-nine liver transplant recipients with a diagnosis of HCC were included in this study. Everolimus was started a median of 84 days after transplant with a median exposure of 387 days for all patients. Twelve patients (30.8 percent) discontinued therapy due to adverse effects after using everolimus for a median of 95 days. The most common reasons for discontinuation were mouth sores (n equals 3, 25 percent) and lung toxicities (n equals 3, 25 percent). Median everolimus levels for those who continued and discontinued therapy were 4.43 ng/ml and 4.93 ng/ml, respectively, and were not statistically different (p equals 0.92). Most patients experienced at least one adverse effect (n equals 33, 84.6 percent). Common adverse effects among all patients included infection (n equals 13, 33.3 percent), diarrhea (n equals 12, 30.8 percent), elevated liver enzymes (n equals 10, 25.6 percent), and neutropenia (n equals 10, 25.6 percent). Rejection was seen in four patients (10.3 percent); three episodes of acute-cellular mediated rejection and one episode of antibody-mediated rejection. Concurrent immunosuppression most often included tacrolimus (n equals 36, 92.3 percent) and mycophenolate mofetil (n equals 12, 30.8 percent). There were no episodes of HCC recurrence, graft failure or mortality reported.

Conclusion: Everolimus remains a viable immunosuppression option for HCC patients undergoing liver transplant. This study demonstrated that overall adverse effects secondary to everolimus were common, and approximately one-third of patients discontinued therapy due to adverse effects. Our findings were consistent with those seen in a pivotal trial with everolimus for liver transplant, where 96.3 percent of patients reported any adverse reaction and the discontinuation rate was 28.6 percent. Whether the risk of adverse effects outweighs the potential benefit of preventing HCC recurrence will still need to be determined in a larger, randomized controlled study with long term follow-up.

Patricia Darbishire

Purpose: To develop, pilot, assess and describe a new interdisciplinary game-based phone application intended to help healthcare students learn medication/medical terminology, as well as enhance their ability to communicate this information to a variety of audiences, including patients, healthcare providers, preceptors and insurance companies. The research question is: Do students believe this application increases their knowledge of medication/medical terminology, and understanding of the importance of assessing the audience's health literacy and adapting communication style? Originally designed as a teaching tool, user feedback will also help the researchers determine the utility of the application as a study tool.

Methods: This IRB-approved project called "PharmPhrase" was developed using an application-development software program. The pilot involved multiple groups of competing teams composed of volunteer, first professional year pharmacy students randomly assigned into teams of three to five. Each group of two teams required one cell phone loaded with the application. Players within each team have defined roles: "user" (person explaining the term from the app), "responders" (team members deducing the term), and "scorekeeper" for the opposing team. The first user begins the timed game by selecting from categories of pre-loaded medical terms and presses "GO" to randomly generate the first term. The user explains the term to team members based on assumptions of medical literacy within the team. If team members do not understand/identify the term, the user must rephrase their explanation in order to "win" the play. Teams rotate play until time is up. Scores, including the number and reasons for skipping terms, were recorded for future analysis. Following the game, players were asked to complete an electronic survey that asked for demographic information, perceptions, and feedback on the app in order to answer the research questions.

Results: Thirty-one first-year professional pharmacy students participated in the pilot of this application and completed a retrospective pre- and post-survey by indicating their level of agreement with statements using a five-point Likert scale with 1 indicating strongly disagree and 5 indicating strongly agree. Following use of PharmPhrase, the participants' understanding of the importance of assessing health literacy did not significantly change from pre to post (mean 3.94, SD 0.772; mean 3.97, SD 0.752, respectively; P equals 0.813). Slightly more than half (58 percent) of participants agreed or strongly agreed that they were familiar with the medical terms in the application on the pre-survey (mean 3.55, SD 1.06); however, after using PharmPhrase, nearly 81 percent agreed or strongly agreed that they better understood these terms (mean 4.10, SD 0.79, P equals 0.03). Fifty-eight percent of students agreed or strongly agreed that they routinely adapted their style of communication to their audience's needs prior to use of the app (mean 3.52, SD 0.626). After using PharmPhrase, 90 percent of the students agreed or strongly agreed that they are more likely to adapt their communication style to meet the needs of their audience in future healthcare interactions (mean 4.06, SD 0.772, P equals 0.001).

Conclusion: This application is intended to be an additional active-learning teaching tool to help move students' conceptual knowledge to that of understanding and application. The researchers will conduct additional pilots with other healthcare disciplines so students can learn how best to communicate with one another. Pilot results with pharmacy students demonstrated increased perception of knowledge and an increased ability to adapt communication style to the audience. Students viewed the app as a fun and engaging education tool, with promise for use as a study tool.

Poster Title: Drug screening policies and procedures at colleges and schools of pharmacy

Primary Author: Alexa Proctor, Purdue University College of Pharmacy, Indiana; **Email:** aproctor@purdue.edu

Additional Author (s):
Wesley Horner
Patricia Darbishire

Purpose: Substance abuse is on the rise, and healthcare students are at risk due to a rigorous curriculum, knowledge of and easy access to drugs, and social and extracurricular pressures. Pharmacy administrators, more than ever before, are in the position of safeguarding the welfare of students and patients they serve, as well as protecting the integrity of their programs and the reputation of the pharmacy profession. The purpose of this study was to explore the drug screening policies and procedures in U.S. colleges and schools of pharmacy, frequency of drug-related incidents, and types of substances most frequently abused among pharmacy students.

Methods: The institutional review board approved use of this web-based survey. The survey was reviewed and tested by 9 individuals, including a Dean of Student Affairs and Academics/Assessment, Experiential Program Director, Associate Professor of Pharmacy Practice, and Clinical Associate Professor of Pharmacy Practice from four schools prior to implementation. Topic areas included administrative perspectives on drug screening students, determination of the entities which create and administrate drug screening policies and procedures, types and frequencies of incidents, and methods to address inappropriate drug use following positive test results for both incoming and current students. The survey instrument used skip logic and consisted of 4 to 26 questions, depending on responses, plus 6 demographic questions. An email describing the research project and an invitation to complete the survey was sent to 129 Accreditation Council for Pharmacy Education (ACPE) accredited and 6 candidate status school of pharmacy administrators, including deans, experiential education, and student services personnel. A reminder email was sent two weeks later. Lastly, a paper copy of the survey was sent to non-responding schools. Responses to questions were

confidential and not linked to any individual or school, but were combined and analyzed collectively to provide a national perspective.

Results: An administrator from 98 schools of pharmacy responded to the survey for a 73 percent national response rate. Fifty-eight percent have a drug screen program and 42 percent do not. Approximately 71 percent of schools that identified as private, drug screen students, compared to only 44 percent of schools that identified as public. Schools with a program provided initial motivation(s) for the implementation of their program and primary reasons included experiential site requirement (68.5 percent), pharmacy school admission requirement (32.9 percent), protection of the profession (23.3 percent), deterrence of drug abuse/addiction (16.4 percent), and/or a specific drug-related incident (6.8 percent). Known incidents involved the following substances: alcohol (79.5 percent), marijuana (61.1 percent), amphetamines (42.3 percent), opiates and heroin (26.9 and 7.7 percent, respectively), benzodiazepines (14.1 percent), cocaine (7.7 percent), and others (16.9 percent). On average, schools that drug screen students are aware of 0.85 (standard deviation equals 1.06) drug-related and 1.44 (standard deviation equals 1.95) alcohol-related incidents per year, compared to 0.95 (standard deviation equals 1.2) drug-related and 2.47 (standard deviation equals 2.47) alcohol-related incidents at those that do not. Approximately 76 percent of administrators responded that they feel random drug screening would deter pharmacy students from substance abuse.

Conclusion: The results of this national survey are one consideration when evaluating the need to institute or enhance a drug screening program in a school of pharmacy. A drug screening program can assist in safeguarding students' health and welfare while in the school's charge, promote compliance with federal and state laws/regulations, help ensure optimal patient care, and protect the integrity of the school and the profession of pharmacy.

Poster Title: Impact of cardiovascular comorbidities on healthcare costs in patients with diabetes

Primary Author: Dee Lin, Purdue University College of Pharmacy, Indiana; **Email:** lin451@purdue.edu

Additional Author (s):
Suyuan Zhang
Joseph Thomas

Purpose: Cardiovascular (CV) disease is two to four times more prevalent in patients with diabetes compared to people without diabetes. Among diabetes patients age 65 or older, more than half die from some CV condition and 16 percent die of a stroke. Since CV disease is a common diabetes complication, this study sought to quantify the impact of CV comorbidities in diabetes patients on the total healthcare expenditure.

Methods: A sample was drawn from 2014 Medical Expenditure Panel Survey (MEPS), a survey of a nationally representative sample of the U.S. population. Adults aged 18 years and older with self-reported diagnosis of diabetes that was confirmed by a follow-up question asking patients if the diagnosis was from a healthcare professional were included in the sample. Individuals with any missing data on study covariates were excluded. Patients were classified as having cardiovascular comorbidity if they reported having ever been diagnosed with any of the following conditions: hypertension, coronary heart disease, angina or angina pectoris, heart attack or myocardial infarction, stroke, or other kind of heart disease. Due to skewed distribution of healthcare expenditures, a generalized linear model with gamma distribution and log link were used to assess association between CV comorbidity and healthcare costs among patients with diabetes. The model adjusted for age, gender, race, education, family income, insurance coverage, self-perceived health status and duration of diabetes. The MEPS sampling weights were used to adjust for the complex survey design. An a priori alpha of 0.05 was used to determine significance. Data analyses were performed using SAS version 9.4 and STATA version 14.1.

Results: A total of 2,022 individuals met study criteria, of which 1,656 (81.9 percent) had one or more CV comorbidities. Patients with CV comorbidity were older, 62.3 mean years (standard deviation equal to 13.0 years) compared to those without CV comorbidity, 52.2 mean years (standard deviation equal to 14.4 years), p-value less than 0.001. There was no significant difference in prevalence of cardiovascular comorbidity among males (83.6 percent) and females (80.6 percent), p-value equal to 0.091. Non-whites had higher prevalence of CV comorbidity (85.2 percent) than whites (80.0 percent), p-value equal to 0.004. Patients with CV comorbidity had longer duration of diabetes, 12.9 mean years (standard deviation equal to 9.9 years) than those without CV comorbidity, 9.7 mean years (standard deviation equal to 8.7 years), p-value less than 0.001. The unadjusted cost associated with CV comorbidity was 7,454 U.S. dollars (USD) per year (95 percent confidence interval, 5,541 USD to 9,366 USD), p-value less than 0.001. After adjusting for study covariates, the estimated cost associated with CV comorbidity decreased to 5,606 USD per year (95 percent confidence interval, 3,282 USD to 7,931 USD), p-value less than 0.001.

Conclusion: Cardiovascular comorbidity is a significant contributor to healthcare expenditure in patients with diabetes with an annual associated cost of 5,606 USD. Subjects with older ages and longer duration of diagnosis tended to have a higher risk of CV comorbidity.

Poster Title: Perceived roles of community pharmacists and pharmacy technicians in patient referrals to community-based health resources: A study from the Medication Safety Research Network of Indiana

Primary Author: Rebecca Miller, Purdue University College of Pharmacy, Indiana; **Email:** mille857@purdue.edu

Additional Author (s):
Cassie Perras
Caitlin Frail
Margie Snyder

Purpose: Community pharmacists are ranked among the most trusted healthcare providers. Pharmacies often serve as informal community health access points with pharmacy staff as the first point of care for many patients. Given their accessibility and affordability, community pharmacists are a significant link between patients and information relevant to their health. The purpose of this study was to explore the attitudes of community pharmacists, pharmacy technicians, and patients regarding their perceptions of pharmacist referrals of patients to community-based health resources.

Methods: Community pharmacies were recruited through the Medication Safety Research Network of Indiana: Rx-SafeNet, a practice-based research network of community pharmacies in Indiana. A purposeful sample of pharmacists and pharmacy technicians was recruited to allow for a balanced and maximized perspective of the pharmacy environment, and patients were recruited using convenience sampling at the participating pharmacies. Three interview guides were designed to elicit information from pharmacists, pharmacy technicians, and patients. Face-to-face, semi-structured interviews were audio-recorded with permission from participants. Audio recordings were transcribed verbatim, and interview transcripts were coded and analyzed by two members of the study team using an open-coding approach to qualitative thematic analysis. A comprehensive codebook was compiled from identified trends and themes, with more specific and descriptive sub-codes accompanying broader main codes. MAXQDA, a qualitative data analysis software program, was used to systematically organize, code, and evaluate data. Cross-tabulation analyses were conducted according to participant

type and pharmacy site to assess trends across different participant groups. This study was approved by the Purdue University Institutional Review Board.

Results: Interviews were conducted with seven pharmacists, fifteen pharmacy technicians, and fifteen patients recruited from four different independent community pharmacy locations. Pharmacists were acutely aware of lapses in patient health literacy and awareness of available resources, and they identified pertinent barriers to expanding the promotion of community programs. General follow-up after referrals was lacking, and most pharmacy staff reported not knowing the impact of their recommendations on patients' health. A large segment of participants recognized the pharmacy technician as underutilized in the provision of pharmacy services; pharmacy technicians often described their own roles as limited due to lack of knowledge or fear of overstepping the confines of their positions. Patients were generally aware of the pharmacist's day-to-day responsibilities but were unaware of the pharmacist's role in referring patients to community health resources. While many patients were able to name general community-based resources, fewer were able to accurately identify specific health-related resources. Despite the lack of follow-up, patients reported strong satisfaction with their pharmacists, placing significant value on pharmacist-patient interactions. While demographic differences existed between the four locations, cross-site responses were consistent in nature. In contrast, trends in responses differed strongly based on participant type, as described previously.

Conclusion: Patient perspective of the pharmacist role may need to be expanded beyond the traditional function in filling prescriptions to allow for a larger pharmacist role in patient referrals. Additionally, opportunities appear to exist to improve patient awareness of available community resources. Further education is necessary to expand the pharmacy technician role. Increased utilization of the pharmacy technician role may allow for pharmacists to take on additional responsibility in the promotion of community programs. Strong, positive relationships with patients already exist, but increased follow-up is needed to maximize the role of pharmacy staff in increasing access to community services.

Submission Category: Pediatrics

Submission Type: Evaluative Study

Session-Board Number: 3-162

Poster Title: Evaluation of piperacillin-tazobactam adverse effects in pediatric cystic fibrosis patients

Primary Author: Erika Hauenstein, Purdue University College of Pharmacy, Indiana; **Email:** ehauenst@purdue.edu

Additional Author (s):
Rebecca Pettit

Purpose: Piperacillin-tazobactam is used in the treatment of cystic fibrosis for acute pulmonary exacerbations. Cystic fibrosis patients are commonly colonized with Pseudomonas aeruginosa making piperacillin-tazobactam an important drug; however, there has been concern regarding a high incidence of adverse effects in cystic fibrosis patients. The purpose of this study is to determine the incidence of adverse effects in pediatric cystic fibrosis patients treated with piperacillin-tazobactam and identify potential risk factors.

Methods: An institutional review board approved this retrospective chart review evaluating cystic fibrosis patients hospitalized and treated with piperacillin-tazobactam for a cystic fibrosis exacerbation. Patients who received at least one dose of piperacillin-tazobactam between January 1, 2007-December 31, 2015 were included in the analysis. Patient charts were reviewed for an adverse drug reaction after administration of piperacillin-tazobactam; the type of adverse reaction and time in days, to the onset of the reaction, were recorded for each adverse reaction. The Naranjo Scale was used to calculate scores for all patients with an adverse reaction to determine the probability of a valid attribution of the adverse reaction to piperacillin-tazobactam administration. Allergies to beta-lactams, carbapenems, and sulfa drugs were tracked for all patients, to evaluate these allergies as potential risk factors for developing an adverse reaction to piperacillin-tazobactam. Chi-square analysis was used to evaluate nominal data and student's t-test was used to analyze continuous data.

Results: The analysis included 204 patients; of which, 24 patients (11.7 percent) experienced an adverse reaction after administration of piperacillin-tazobactam. Patients in the reaction group were older and heavier with an average age of 12 years (standard deviation 4.6) and weight of 36.5 kilograms (standard deviation 14.8) compared to 7.2 years (standard deviation 4.82) and

21.7 kilograms (standard deviation 14.4) in the non-reaction group (p less than 0.001, p less than 0.001). The two groups did not differ on gender, reaction group 37.5 percent male and non-reaction group 46.7 percent male (p equals 0.39). Of the patients with a reaction, 8 patients' reactions were classified using the Naranjo Scale as possibly related to piperacillin-tazobactam and 16 reactions as probable. The average Naranjo score was 4.8 (standard deviation 1.8). 3.9 days (standard deviation 4.4) was the average days from piperacillin-tazobactam start to the onset of an adverse reaction. The presence of a concurrent beta-lactam allergy was more prevalent in the reaction group at 66.67 percent versus 0.1 percent (p less than 0.001). There were 3 patients with carbapenem allergies, all in the reaction group. The number of patients with sulfa allergies was not significantly different between the two groups (p equals 0.15).

Conclusion: The incidence of adverse effects with administration of piperacillin-tazobactam was 11.7 percent in this pediatric cystic fibrosis population. This is similar to other reported adverse effects rates for piperacillin-tazobactam in this population. Patients with a piperacillin-tazobactam adverse reaction were more likely to have beta-lactam and carbapenem allergies. The difference in prevalence of carbapenem allergies between the two groups may be related to patient exposure. Sulfa allergy rates do not seem to be associated with piperacillin-tazobactam reactions.

Poster Title: Pediatric counseling: Assessing student pharmacists' skill, competence, and confidence within a controlled environment

Primary Author: Marissa Stoffel, Purdue University College of Pharmacy, Indiana; **Email:** mstoffel@purdue.edu

Additional Author (s):
Monica Miller
Emily Israel

Purpose: Children are a vulnerable patient population that pharmacists encounter in most community pharmacies and health systems. Although pharmacists interact with children in practice these interactions are not frequently simulated in the didactic pharmacy curricula. Due to the known benefit of simulated interactions for other patient populations, incorporating these activities focused on pediatrics into curricula should better prepare student pharmacists for situations they will encounter. The study aims are to evaluate the students' effectiveness in communicating accurate inhaler technique and side effect information to a child and guardian pair and perceived value of the experience.

Methods: In 2015 a pediatric focused asthma counseling activity was implemented within the first year professional program lab at Purdue University College of Pharmacy. In 2016, 154 students and 11 child (aged 1 to 10 years) and guardian pairs participated in the activity. Students provided patient education on either a rescue inhaler or inhaled corticosteroid (ICS). After the session, the parent (and child, if old enough) utilized a dichotomous yes/no evaluation for each student on completeness and accuracy of the clinical information provided and the ability to interact with the child. They evaluated the student on knowledge and confidence using a 5-point likert scale. Students completed individual reflection assignments, which allowed them to discuss their prior experience working with children and level of confidence interacting with them before and after lab. Students addressed whether they would recommend keeping the exercise in the curriculum. IRB approval was obtained for this study. Both the parent evaluations and student reflections were analyzed to assess overall student performance, confidence, and perceived value of the counseling activity. The quantitative and

qualitative data was analyzed for mean values, significance, and overall themes and Wilcoxon rank sum test was used for non-parametric data.

Results: Ninety-four percent of students interacted with the child at least once during the session. For the students who counseled on the rescue inhaler, 81 percent correctly stated how to administer it while 59 percent remembered to address tremor or shakiness as a side effect. For the students who counseled on the ICS inhaler, 89 percent correctly stated twice daily administration and 91 percent correctly discussed oral thrush as a side effect. Most students (72 percent) clearly differentiated the difference between a rescue inhaler and controller medication to the patient during the exercise. Only 39 percent of students demonstrated how to use the inhalers and repeated key points to ensure understanding. The majority of guardian/children pairs (91 percent) stated they would return to their student pharmacist to fill another prescription. The mean values for overall knowledge and confidence as assessed by the parent were 4.35 and 4.4, respectively. There was a statistically significant improvement in student perceived confidence for counseling a child with an average of 2.5 prior and 3.92 after (p-value less than 0.01). When reviewing students' confidence levels, 89 percent increased 7 percent remained unchanged, and 4 percent decreased. Almost all students (99 percent) recommended keeping the activity.

Conclusion: Overall, the activity was deemed successful by faculty and students. Child/guardian pairs had a positive interaction with the students and the majority of students self-reported an increase in confidence after the conclusion of the activity. The data revealed areas for continued improvement in students' knowledge retention and effective communication skills for this vulnerable patient population. This activity will continue to be refined and utilized for future classes. Due to the success of this activity, future plans are to continue incorporating pediatric patient simulations in more labs throughout the entire didactic curriculum.

Submission Category: Emergency Medicine/ Emergency Department/ Emergency Preparedness

Submission Type: Evaluative Study

Session-Board Number: 3-164

Poster Title: An exploratory, retrospective evaluation of clinical pharmacist implementation in a community hospital emergency department and its effect on intravenous antibiotic utilization

Primary Author: Shaylyn Vogler, Purdue University College of Pharmacy, Indiana; **Email:** svogler@purdue.edu

Additional Author (s):
Brian McCrate

Purpose: Selection and timing of appropriate antibiotic therapy has become more challenging, especially with the increasing rates of resistance and acuity level of patients. This is even more challenging in the emergency department for practitioners due to large patient volumes, limited time and lack of information. Benefits of pharmacist implementation in the emergency department are well-studied and have shown decreased medication errors, improved antibiotic stewardship and decreased administration time of time-sensitive medications. The purpose of this study was to assess intravenous antibiotic utilization prior to and after pharmacist implementation in the emergency department of a community hospital.

Methods: A retrospective chart review was completed for patients who received at least one dose of IV antibiotics in the emergency department prior to clinical pharmacist implementation (January 2015 to June 2016) and post-implementation (January 2016 to June 2016). Data was randomly collected for 100 patients in each group. Randomization was performed by a computer generator. Data that was collected included diagnosis, arrival time of patient, antibiotics ordered, order entry time, pharmacist verification time, antibiotic administration time, number of septic patients, number of admissions, length of stay, 30-day readmissions and number of pharmacist interventions. Additionally, demographic data, which included patient sex, age and nationality, was collected for all patients who were studied. The study was approved by the Institutional Review Board.

Results: When comparing pre-pharmacist implementation to post-pharmacist implementation, a decrease in the average antibiotic order time (151.75 minutes vs. 135.12 minutes), verification time (14.81 minutes vs. 3.75 minutes) and administration time (195.32 minutes vs. 173.90 minutes) was observed after pharmacist implementation. Additionally, a trend of

decreased prescribing of fluoroquinolones (22 vs. 12) and meropenem (6 vs. 1) was observed after pharmacist implementation. However, pharmacist implementation was not observed to have a noticeable impact on length of stay or 30-day re-admittance rate.

Conclusion: Implementation of a clinical pharmacist in the emergency department may decrease times to antibiotic ordering and administration. Additionally, this implementation may decrease prescribing of broad-spectrum antibiotics. However, because of our small sample size, further research is warranted to assess the true clinical significance of the implementation of a pharmacist in the emergency department.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Session-Board Number: 3-165

Poster Title: Occurrence of hospital-acquired clostridium difficile infection in patients admitted to a community hospital on proton pump inhibitor therapy

Primary Author: Lauren Jackson, Purdue University College of Pharmacy, Indiana; **Email:** jacks168@purdue.edu

Additional Author (s):
James Hatter

Purpose: Widespread and overuse of proton pump inhibitor (PPI) therapy has become increasingly common in patients across the healthcare system in the United States. Evidence continues to show patients receiving PPIs are at an increased risk of short-term and long-term adverse effects, including gastrointestinal infections such as Clostridium difficile colitis. The purpose of this study is to evaluate a correlation between the incidence of hospital-acquired Clostridium difficile infection (HA-CDI) in patients receiving PPI therapy compared with patients who developed HA-CDI without PPI use. The results of this study will then be used to optimize the hospital's PPI protocol.

Methods: This study has been approved by the Sullivan University Institutional Review Board. A retrospective chart review will be performed for hospitalized adult patients admitted from July 1, 2014 to June 30, 2016 to identify patients with HA-CDI utilizing International Classification of Diseases (ICD) 9 and 10 codes for Clostridium difficile colitis. Patients with community-acquired Clostridium difficile colitis (CA-CDI) or admitted to the study hospital with Clostridium difficile infection, admitted from an outside hospital, and /or prisoners will be excluded from this study. The following data will be collected: patient age, sex, length of stay, reason for admission, number of days post-admission of CDI diagnosis, if the patient received at least one dose of a PPI or histamine-2 receptor antagonist (H2RA) and if it was a home medication, the clinical indication for the PPI or H2RA, if the PPI or H2RA was discontinued upon HA-CDI diagnosis, if the patient received any dose of antibiotics and the classes of antibiotics received. The percentage of patients who developed HA-CDI and received at least one dose of a PPI or H2RA will be compared to the percentage of patients who developed HA-CDI without any PPI or H2RA therapy, respectively.

Results: Results to be presented at ASHP Midyear Clinical Meeting.

Conclusion: Conclusion to be presented at ASHP Midyear Clinical Meeting.

Poster Title: Current pharmacy employer views on curriculum vitaes (CVs) and resumes of new graduates

Primary Author: Robert Wozniak, Purdue University College of Pharmacy, Indiana; **Email:** rwoznia@purdue.edu

Additional Author (s):
Jamie Reed
Monica Miller
Alex Isaacs

Purpose: Employer requirements for CVs and resumes are continually evolving to reflect the advancing role of pharmacists and their needed qualifications. These views are not always transparent to new graduates which may ultimately affect job placement. This study aimed to identify what current employers value in new graduate CVs and resumes to enhance successful job application and placement.

Methods: An electronic survey was created that posed questions regarding individual portions and format aspects of CVs and resumes. IRB approval was obtained from Purdue University. Survey participants identified areas of value for those documents in relation to their hiring criteria and respective fields of pharmacy. Questions allowed participants to highlight requirements for their particular area of pharmacy including: value of GPA, specific sections of importance, and reflection on format requirements. The anonymous survey was administered via Qualtrics and sent out by email to 100 randomly selected current hiring pharmacists in various fields of pharmacy throughout Indiana and surrounding areas, including post-graduate training directors. Descriptive statistics were used to examine the quantitative data. Specifically, responses were measured using percentages for each question. Participants' feedback to open-ended questions on the survey were analyzed using thematic analysis and key quotes were provided to illustrate recurring responses.

Results: Of those selected for participation, 41 completed the survey from twelve different areas of pharmacy practice. The majority (95%) were involved with reviewing new graduate pharmacists' applications. Employers found the following to be the most important information

to include on an applicant's resume or CV: professional education (100%), professional work experience (93%), licensure (93%), professional leadership (64%), and professional involvement (64%). From the sites that were surveyed, only 14% identified a GPA cutoff at their practice site. Of this group, the cutoff existed between 2.8 and 3.0 on a 4.0 scale. Other items that were encouraged and influential, but not necessarily required included: leadership within professional pharmacy organizations (93%), descriptions of advanced pharmacy practice experience (APPE)/professional work experience (71%), teaching experience (68%), awards/honors (32%), and community service involvement (29%). Leadership within non-pharmacy, collegiate organizations (86%) was slightly less valuable to employers when compared with collegiate pharmacy organizations (93%). Presentations were also considered very valuable to an applicant's CV or resume: in-services (73%), formal pharmacy presentations (73%), and pharmacy-related extracurricular presentations (63%) made the top of the list, respectively. Optional experience, such as prior research (53%) or technology experience (59%) (Cerner/Epic) was considered highly valuable.

Conclusion: Other than pharmacy education and certifications, which are expected, leadership through teaching, work experience, and professional organization involvement is considered valuable. Awards, honors, and community service are also very appealing to hiring employers. Evaluating employers' thoughts and suggestions about new graduate pharmacists' CVs and/or resumes identified the most important sections and formatting requirements for new graduate pharmacists' application materials. Overall, this study met its objective of identifying key areas of interest for current employers which will help guide new graduates in the preparation of their application materials.

Poster Title: Implementation of a low-cost unna boot alternative as adjunctive treatment for Kaposi Sarcoma in Kenya.

Primary Author: Alexander Mills, Purdue University College of Pharmacy, Indiana; **Email:** mills24@purdue.edu

Additional Author (s):
Edith Tonui
Rakhi Karwa
Aileen Chang
Sonak Pastakia

Purpose: Globally 36 million people live with HIV, with 70% residing in Sub-Saharan Africa (SSA). Furthermore, 1.1 million deaths occur due to opportunistic infections (OIs) that can be minimized by initiation of antiretroviral therapy. In Kenya, the OI Kaposi Sarcoma (KS) is especially debilitating physically and psychosocially; magnifying the stigma that patients with HIV already fear. Research has begun to evaluate the effectiveness of an Unna boot as adjunctive therapy to speed healing of these lesions, yet this product is too expensive and not commercially available in SSA. This project was designed to develop a cost-effective alternative "kit" with local resources.

Methods: A literature review was conducted to understand the utility of the Unna boot for leg ulcers in KS and other causes. After gathering the data, including the Unna boot components, locally available materials were obtained. The modified kit was created and piloted on a healthy leg. Piloting was done to test ease of use, durability, and shelf life. After completing successful pilots, production of the modified kits began for implementation within an HIV clinic affiliated with the Academic Model Providing Access to Healthcare (AMPATH).

Results: To date, 25 modified kits have been created. Continuous local acquisition of all components has been present and sourced for lower prices than originally quoted. The kit is currently being implemented in a rural AMPATH clinic in Turbo, Kenya, where a provider with a special interest in wound care has been trained by a US-trained dermatologist to use the modified unna boot. Patients with venous ulcers or KS lesions will begin utilizing the kit weekly

for a nominal cost of 2 USD/kit. In addition, the provider will assess for changes in clinical status of the wounds and changes to quality of life with use of the kit. Feedback after implementation of the kit has suggested decreasing the width of the gauze for improved ease in wrapping of leg ulcers. Future plans include implementation at larger clinics providing care to patients with KS in order to understand its use in that population.

Conclusion: Assembly of a locally-sourced, low cost Unna boot kit has led to its use in one clinic with anticipated scale-up throughout the AMPATH system in Kenya. Further observation and data collection from its current use may show potential for this modified kit to undergo additional review as a potential change in standards of care for patients living with HIV and KS.

Poster Title: Rivaroxaban-induced alopecia

Primary Author: Briana Colizzi, Massachusetts College of Pharmacy & Health Sciences University, Massachusetts; **Email:** briana.colizzi@gmail.com

Additional Author (s):
Elisaveta Dedo
Minh Nhut Vo
Erika Felix-Getzik

Purpose: This case report illustrates one incident among the increasing number of incidents of direct oral anticoagulant induced alopecia. Historically, we have seen alopecia occur as an adverse effect of anticoagulation therapy; in unfractionated heparin, low molecular weight heparin, and warfarin. This is based on numerous published case reports and patient reports. This discussion of drug-induced alopecia requires an explanation of the 3 stages of the hair growth process, namely the anagen, catagen, and telogen phases. During the anagen or growth phase there is rapid mitotic activity of the hair matrix, and hair grows continuously for months to years. The catagen or cessation phase is when the hair matrix stops growing as its cells undergo apoptosis. In the telogen or rest phase, hair follicles shorten as the mature hair moves upward and awaits shedding through friction (shampooing or combing) or displacement by newly growing hair. At any given time, 85 to 90 percent of scalp hair is in the anagen phase, 9 to 14 percent is in the telogen phase, and 1 percent is in the catagen phase. These estimates vary depending on the individual. Hair loss can be exacerbated by medications via 2 mechanisms; anagen effluvium and telogen effluvium, which both affect hair growth in the anagen phase. Anagen effluvium is caused by chemotherapy and other cancer treatments, and hair loss progression is typically more rapid, within days to weeks of drug exposure. Telogen effluvium results from hair growth shifting prematurely from the anagen to catagen phase, and is seen in traditional anticoagulants like heparin and warfarin, and hair loss progression is slower, around 2-3 months after drug initiation. The observation that both heparins and coumarins cause a similar pattern of hair loss suggests a shared mechanism related to their anticoagulant activity. Therefore, this implies that alopecia can be seen as an adverse effect of direct oral anticoagulants like rivaroxaban and dabigatran. To date, the World Health Organization has received 405 reports of direct oral anticoagulant-associated alopecia, and the real-world

Dresden direct oral anticoagulant registry calculated an alopecia incidence of 4.4 out of 100 patient years. In our case report, a 71 year old female presented to our clinic with significant alopecia a few weeks after she was initiated on rivaroxaban for atrial fibrillation. She claimed that clumps of her hair were falling out, especially while showering, and she noticed visible bald spots. She took biotin supplements to attempt to slow the alopecia symptoms and expressed a strong desire to switch to a different agent. After 5 months of being on rivaroxaban, the patient was switched to apixaban, and after taking the apixaban for 1 month, the patient reported less significant hair loss, although it did not completely resolve. Her past medical history included paroxysmal atrial fibrillation and atrial flutter, dyslipidemia, hypertension, gastroesophageal reflux disease, sciatica, and hypothyroidism. Her medication list included Xarelto 20 mg PO daily, flecainide 100 mg PO BID, levothyroxine 25 mcg PO 3 times every week, lorazepam 0.5 mg PO at bedtime as needed for insomnia, metoprolol succinate 25 mg PO daily, omeprazole 20 mg PO daily, Klor-Con 20 mEq PO 3 times every week, Dyazide 37.5-25 mg PO daily, senna-docusate 8.6-50 mg PO as needed for constipation, metronidazole 0.75% vaginal gel as needed, Epipen 0.3 mg/0.3mL IM as needed for anaphylaxis, biotin 10,000 mcg PO daily. This case report demonstrates the need for more data and larger controlled studies in order to establish a causative link between rivaroxaban, and possibly other direct oral anticoagulants like dabigatran and apixaban, and alopecia, and to determine if an FDA-labeled adverse effect is warranted.

Poster Title: Future health care professionals' perspectives on direct to consumer advertising

Primary Author: Jessie Liu, Massachusetts College of Pharmacy and Health Sciences, Massachusetts; **Email:** tong@bu.edu

Additional Author (s):
Michael Steinberg

Purpose: The purpose of this study is to gather information on future health care professionals' opinions on direct to consumer advertising of prescription medications.

Methods: This project was approved by the Institutional Review Board of MCPHS University. Students in select health care programs at our University, including pharmacy, nursing, and optometry, were solicited voluntary written surveys regarding their opinions on direct to consumer advertising of prescription medications. The survey included questions concerning demographics of participants such as program of study, expected year of graduation, gender, and age. The remaining questions focused on student knowledge and opinions of direct to consumer advertising of prescription medications such as whether they felt it influenced patients, whether it guides patients to medications they need, and whether information regarding risks and benefits of prescription medications is balanced, clear, truthful, accurate, misleading, or confusing. The survey also asked questions about the role of health care professionals in providing product information and whether direct to consumer advertising should be adjusted or eliminated.

Results: A total of 600 students responded to the written survey, most of which were female pharmacy students between the ages of 21-30 years in our accelerated Doctor of Pharmacy program. Twenty percent of students were unfamiliar with the term "direct to consumer advertising", but recognized the practice when provided with a description. More than 90% of participants agreed current direct to consumer advertising of prescription medications was influential but did not guide patients to products they need and left gaps in fully informing patients about medications. More than 70% of students either disagreed or strongly disagreed that direct to consumer advertising was clear, truthful and accurate, or balanced risks with benefits, which could all lead to a good chance for confusion among patients. As future health

care professionals, students felt the need existed for practitioners to re-educate and fairly present information to facilitate safe medication selection rather than relying on direct to consumer medication advertising. However, there were mixed views about how FDA regulations for direct to consumer advertising of prescription medications should be adjusted or even eliminated.

Conclusion: Future health care professionals, especially pharmacy students, do not view direct to consumer advertising of prescription medications positively. Instead, students feel that health professionals should be the primary informants for patients regarding their medications.

Poster Title: Similarities between the Alzheimer and diabetes hippocampus: A comparison of gene expression profiles

Primary Author: Trusha Daya, Massachusetts College of Pharmacy and Health Sciences, Massachusetts; **Email:** m0276203@stu.mcphs.edu

Purpose: Patients with Alzheimer's disease (AD) undergo structural changes resulting in the loss of gray matter in the hippocampus, which is associated with learning and memory. Patients with Diabetes mellitus [DM] (Type 1 and Type 2), have been associated with the same deterioration in the hippocampus as AD. Both diseases are characterized by cognitive decline, oxidative stress, and insulin resistance. The purpose of the study is to explore the similarities between AD and DM by identifying common gene expression patterns in the hippocampus among patients with AD versus those with DM.

Methods: Three data sets were analyzed: A diabetes model data set of the hippocampus (GSE34451) in which streptozotocin-treated Wistar rats were compared to controls was used for DM type I. For DM type II, Goto-Kakizaki rats were used. A second data set included human autopsy AD of the hippocampus with non-AD controls (GSE36980). The third data set used consisted of samples from the hippocampi of triple-transgenic AD mice, which bear the PS1(M146V), APP(Swe), and tau(P301L) transgenes, characteristic of AD. This triple-transgenic dataset (GSE32536) consisted of mice treated with pioglitazone and non-treated controls. The various data sets were normalized and background-corrected using the gcrma method. Differentially expressed (DE) genes were identified using the siggenes package of Bioconductor. DE genes were analyzed for over-represented pathways/processes using the Reactome database.

Results: Gene Set Enrichment Analysis results show that innate immune genes are enriched in the control verses DM type 1. Ten genes downregulated in the DM type 1 hippocampus have their orthologues also downregulated in the AD hippocampus. They are: SLC6A17, PRKCB, SYP, HCN2, STX1A, LDB2, CAMLG, MMP17, TTC9B, and L1CAM. Similarly, ten genes downregulated in the DM type 2 hippocampus have their orthologues also downregulated in the AD hippocampus: PRKCB, XYLT1, PRPF8, NPTX2, GRB14, PRKCG, DGKZ, CHRM1, SEPT3, and CFL1.

Certain genes, with suppressed expression in DM or AD, had increased expression in the Pioglitazone treatment model. They are: Plag1, which was suppressed in the DM type 1 model, Cul3 was suppressed in DM type 2, and NRSN2, MCFD2 and NOV which were suppressed in AD.

Conclusion: Genes with suppressed expression in AD or DM are associated with the innate immune system and hemostasis, both of which are linked with cognitive decline. Pioglitazone reverses the decline in some, but not all those genes, underscoring the similarity between AD and DM.

Poster Title: Evaluation of pharmacy intern awareness regarding the accessibility and use of emergency naloxone

Primary Author: Alison Cronin, Massachusetts College of Pharmacy and Health Sciences, Massachusetts; **Email:** acron1@stu.mcphs.edu

Additional Author (s):
Mehrnaz Sadrolashrafi
Katherine Carey
Aimee Dietle

Purpose: The growing opioid crisis in the United States is starting a nation-wide conversation about opioid abuse prevention and treatment. The September 2015 standing order in Massachusetts for the dispensing of emergency naloxone in community pharmacies is paramount in combating opioid overdose deaths. With this current opioid epidemic, it is vital that future pharmacists are aware of the standing order and are competent in naloxone use and counseling. This study aimed to assess the knowledge and comfort level of pharmacy interns regarding emergency naloxone before and after a student-led educational session.

Methods: Pharmacy interns were asked to complete an anonymous, voluntary pre- and post-survey. Informed consent was obtained from all participants and the study design was approved by the institutional review board. The pre-survey, administered prior to the educational session, was comprised of 7 questions. The post-survey was comprised of 5 questions (questions 3-7 from the pre-survey). This allowed for a direct before versus after comparison of responses to identify the impact of our educational session. Questions 1 and 2 of the pre-survey were demographic information questions. The educational session discussed what naloxone is, how to recognize an opioid overdose, overdose intervention steps, components of the "orange" box, how to assemble and administer intranasal naloxone, what to expect with precipitated withdrawal, and how and where to obtain naloxone. An opportunity was provided for interns to practice with placebo naloxone kits after the presentation. The survey questions examined knowledge about the standing order, where emergency naloxone is available, confidence in naloxone counseling, and what components are in a standing order dispensed intranasal naloxone kit.

Results: A total of 47 interns completed the pre-survey and 41 interns completed the post-survey. Overall intern knowledge significantly improved in all questions on the post-survey. Intern confidence in counseling patients on how to use emergency naloxone was reported on a scale of 1-5, 5 being most confident. Using Student's t-test, the reported confidence level significantly improved from 1.96 to 3.59 on the pre- and post-survey, respectively (p value less than 0.0001). Using Fisher's exact test, the post-survey results showed a significant improvement in the knowledge of pharmacy interns about the absence of the nasal atomizer in the "orange" box (p value equals 0.030), access to naloxone without a prescription (p value less than 0.0001), places where members of the public can obtain naloxone (p value equals 0.026), and proper billing of patient insurance (p value equals 0.031).

Conclusion: Evaluation of pre- and post-survey results showed increased confidence in counseling and knowledge of using naloxone in an emergency situation and obtaining naloxone via standing order. It is hoped that pharmacy intern knowledge and awareness about emergency naloxone may increase dispensing via the standing order and its use in emergency situations.

Poster Title: Burden Medicare patients face with COPD medications

Primary Author: Kennya Costantino, Massachusetts College of Pharmacy and Health Sciences, Massachusetts; **Email:** kcost1@stu.mcphs.edu

Additional Author (s):
Trusha Daya
Donna Bartlett

Purpose: Since 2004, the World Health Organization stated that Chronic Obstructive Pulmonary Disease (COPD) has inflicted over 64 million people and by 2030 will be ranked as the third leading cause of death. With a closing doughnut hole, one would expect a decrease in out of pocket expense and a push for more generics on the market to increase adherence and limit out of pocket costs. The purpose is to analyze the costs associated with current inhaler treatment of COPD on the market for various Medicare Part D Plans and evaluate changes in cost and drug development from 2012-2017.

Methods: Three common insurance plans, AARP, Blue Cross Blue Shield, and First Health were analyzed from 2012 to 2017. Data such as full cost of the drug, initial monthly copays, formulary changes, cost during the coverage gap and catastrophic coverage were obtained from www.medicare.gov and q1medicare.gov. Differences from 2012-2017 were reviewed and costs associated with brand name COPD medications were tracked.

Results: Data showed with each passing year the cost and out-of-pocket burden that Medicare beneficiaries with COPD faced was actually increasing. Looking at the three insurance plans, in 2012, the initial monthly copayment of brand name COPD medications were lower than in 2017. Over a 6-year period, the nineteen medications listed specifically for COPD had no generic on the market to date. Besides the annual total medication cost increase, Medicare beneficiaries with COPD are also faced with limited options when seeking alternative affordable medication forms. The three insurance plans show an upward trend in costs with brand name medications each year, and some medications have been completely removed from insurance formulary plans leaving the patient paying the full price upfront. Over a 6-year period the percent increase from 2014-2017 on total cost of medication has spiked by 142 percent and the

cost in the doughnut hole has increased by 42 percent. While the manufacturer covers 50 percent of the cost during the doughnut hole the percent difference between the doughnut hole and the total cost of medication correlates with negative savings outcomes.

Conclusion: Medicare beneficiaries are faced with increased burden with costs associated with COPD treatment. Armed with this knowledge pharmacists can work with pharmaceutical and insurance companies to push for feasible pricing options and alternative medications to possibly help bring down treatment costs.

Poster Title: Emergency intranasal naloxone education for addiction healthcare providers

Primary Author: Pia Clive, Massachusetts College of Pharmacy and Health Sciences - Worcester, Massachusetts; **Email:** pcliv1@stu.mcphs.edu

Additional Author (s):
Jessica Hauger
Susie Nguyen
Aimee Dietle
Katherine Carey

Purpose: Professionals in the setting of addiction recovery management play a crucial role in educating patients and their families on intranasal naloxone for bystander administration. Their role is crucial for both the teaching of proper administration technique as well as for spreading awareness of this resource, which is now available to the public via standing order in Massachusetts' community pharmacies. The purpose of this study was to determine gauge the effect of a pharmacy student-led training program on the use and procurement of emergency naloxone delivered to an audience of addiction healthcare professionals.

Methods: Researchers delivered an educational presentation to a group of healthcare professionals practicing in addiction rehabilitation centers in Massachusetts. The primary presentation medium was a PowerPoint slideshow with virtual animations of the steps required for device assembly and drug administration. Also covered in the presentation was information regarding the procurement of naloxone at community pharmacies under its recently established standing order. Following the presentation, attendees asked questions and practiced assembling a sample device. Consenting attendees were administered surveys prior to and immediately following the program. The surveys had been preapproved by the MCPHS University institutional review board and contained one question gauging self-reported confidence in providing patient education on the topic as well as four knowledge-based questions pertaining to either the specifics of the intranasal naloxone device or its procurement. Both surveys were identical with the exception of an additional two demographic questions on the pre-survey (seven questions total). The change in performance was then evaluated based on questions answered correctly before versus after the presentation in order

to gauge the effectiveness. Fisher's exact test and unpaired t-test were performed to determine the significance of the results using $p < 0.05$.

Results: Twenty-one behavioral healthcare professionals participated in the study. The audience was composed of professionals specializing in addiction rehabilitation in both inpatient and outpatient programs. On average, subjects reported having daily interactions with opioid addicts and having previously had 2-3 discussions with patients on the topic of naloxone prior to the educational session. The level of confidence in providing naloxone training was assessed on a five-point scale, with a change from pre and post intervention showing improvement from 3.14 to 4.48 ($p < 0.0001$). Subjects showed significant improvement in their understanding of the contents of the emergency naloxone kit. Pre-intervention, only 6 (4.76%) subjects accurately asserted that the nasal atomizer attachment is an additional piece that must be supplied, whereas afterwards, 17 (80.95%) answered correctly ($p < 0.0004$). The audience proved to have adequate baseline knowledge of the procurement of naloxone as 19 (90%) before the presentation and 21(100%) after were able to correctly assert that emergency naloxone does not require a prescription in Massachusetts ($p=0.488$). The audience demonstrated a similar unremarkable improvement from an already elevated baseline level of knowledge for the other questions pertaining to insurance billing and locations that provide naloxone kits to the public.

Conclusion: Behavioral healthcare professionals working in an addiction medicine setting have frequent interactions with opioid addicts and are thus instrumental in promoting the education and awareness of emergency naloxone. Participants had a high baseline knowledge in certain aspects of emergency naloxone, but deficiencies in knowledge regarding familiarity with delivery system and confidence in their own ability to train on its use. Overall, the intervention met its objective of improving these deficiencies. Expanding healthcare professionals' knowledge and confidence in training for bystander naloxone administration may improve public access to this drug, but future studies are needed to confirm.

Poster Title: Pharmacy, nursing, and physician assistant students' perspectives on interprofessional collaboration using a patient case simulation activity

Primary Author: Michael McAlister, Massachusetts College of Pharmacy and Health Sciences - Worcester/Manchester, Massachusetts; **Email:** mmcal1@stu.mcphs.edu

Additional Author (s):
Megan Grigas
Karyn Sullivan
Helen Pervanas

Purpose: Interprofessional education (IPE) includes four core competencies for interprofessional collaboration (values and ethics, roles and responsibilities, communication, and teamwork), and promotes improved patient care. IPE is an accreditation standard for Doctor of Pharmacy programs, and embedding IPE activities into the curriculum can be instrumental in introducing students to the concept of collaborative care. These activities may be used to assess student perceptions and the similarities/differences regarding interprofessional care. The purpose of this project was to simulate interprofessional collaboration among nursing, pharmacy and physician assistant students and identify differences, by profession, in their perceptions related to interprofessional collaboration.

Methods: Approval from the University's Institutional Review Board was obtained prior to beginning this study. Student participants from the University's pharmacy, physician assistant, and nursing programs participated in the activity. Participants in the activity were organized into interdisciplinary groups and included students from each of the respective programs. Faculty members from each program were also present to facilitate the case simulation activity and administer the survey that followed. After viewing a video case simulation, students had the opportunity to work together and create an action plan for the patient. Following the activity, a thirteen-question survey using a five-point Likert scale was administered to the participants. Survey questions asked participants about demographics, prior IPE experience, and perceptions on collaborative care. Student responses to the Likert scale questions were sorted by the students' academic program, and whether or not the student had participated in prior IPE experiences, either at work, on a clinical rotation, or as part of their academic studies.

Results: A total of 311 students participated in the IPE case simulation activity and were comprised of 40 percent physician assistant, 33 percent nursing, and 27 percent pharmacy. Prior IPE experience was reported by 81 percent of participants. Responses to the question, "I prefer to work within my own profession," differed between each of the academic disciplines. Of the 134 students that answered either undecided, agree, or strongly agree, 40 percent were from physician assistant studies, 35 percent from nursing, and 25 percent from pharmacy. When asked whether working in an interprofessional team involves more time and effort than working alone, 41 percent of students agreed or strongly agreed. These responses represented 38 percent physician assistant, 34 percent nursing, and 29 percent pharmacy. When asked whether interprofessional teamwork allows for more effective and enhanced patient care, 94 percent of students agreed or strongly agreed. When asked for specific examples of what they learned from other cohorts, students commonly reported the following: physician assistant students reported medication dosing/adjustment and monitoring (31 percent) and medication selection (21 percent), nursing students cited medication selection (51 percent), and pharmacy students reported the use of visiting nurses and home care (27 percent).

Conclusion: The case simulation activity identified differences, by discipline, in perceptions related to interprofessional collaboration. Students contributed their own expertise and knowledge to the activity which supports the incorporation of IPE into health professional curricula. Many participants agreed or strongly agreed that interprofessional collaboration provides enhanced patient care, yet they also felt that interprofessional collaboration requires more effort. Increasing the number of IPE activities offered to students may enhance their ability to work more easily together as a collaborative interdisciplinary healthcare team.

Poster Title: Sensitizing refractory prostate cancer cells to combination cytotoxic and targeted therapies.

Primary Author: Kyung Hyun Chung, Massachusetts College of Pharmacy and Health Sciences (MCPHS University) - Worcester Campus, Massachusetts; **Email:** kchun2@stu.mcphs.edu

Additional Author (s):
Min Jae Lee
Terrick Andey

Purpose: Prostate cancer is the second leading cause of cancer-related deaths among men. By the end of 2016, an estimated 180,890 new prostate cancer cases and 26,120 deaths will be recorded. Treatments that combine chemotherapy with targeted therapy are more effective compared to single treatments in many tumors. However, adverse effects and acquired tumor resistance limits their full clinical benefits. The study evaluated the sensitization of drug resistant prostate cancer cells upregulated with the epidermal growth factor (EGFR) and the SOX2 oncogene using a combination of low dose cytotoxic (docetaxel, camptothecin) and EGFR-targeted therapy (gefitinib).

Methods: DU145 and PC3 prostate cancer cells were treated with different concentrations of gefitinib, docetaxel, and camptothecin alone and in combination. Cells were investigated for effect of treatment on cell viability, cell migration, apoptosis, and expression of SOX2 and EGFR proteins.

Results: Gefitinib, camptothecin, and docetaxel demonstrated varying anticancer activities on PC3 (concentrations that inhibited 50 percent of cell population were: greater than 10.0 micromolar, 3.334 micromolar, and 0.081 micromolar respectively) and DU145 (concentrations that inhibited 50 percent of cell population were: greater than 29.241 micromolar, 7.677 micromolar, and 0.355 micromolar respectively). Gefitinib (1.0 nanomolar) reduced PC3 cell viability by 24.80 percent, 29.65 percent, and 36.95 percent as combination treatment with 10 nanomolar camptothecin, 10 nanomolar docetaxel, and 20 nanomolar docetaxel respectively. In DU145 cells, gefitinib (10 nanomolar) in combination with 1.0 nanomolar, 10.0 nanomolar, and 20.0 nanomolar docetaxel reduced cell viability by 19.89 percent, 14.40 percent and 16.82

percent respectively. Gefitinib (5 micromolar and 10 micromolar) and camptothecin (0.1 micromolar) combination treatments inhibited cell migration and induced apoptosis in DU145 cells. SOX2 and EGFR proteins were upregulated in DU145 and PC3 cells and combination treatment with gefitinib and docetaxel reduced their expression following a 48-hour treatment.

Conclusion: DU145 and PC3 cells demonstrated varying degrees of sensitivities to different concentrations of gefitinib, docetaxel and camptothecin, and their combinations at the cellular and molecular level. Importantly, low doses of combination gefitinib with either docetaxel or camptothecin inhibited cell viability, migration, and the expression of EGFR and SOX2.

Session-Board Number: 3-176

Poster Title: Series of unfortunate drug-induced events

Primary Author: Tanya Martins, Massachusetts College of Pharmacy and Health Sciences University, Massachusetts; **Email:** tmart1@stu.mcphs.edu

Additional Author (s):
Briana Colizzi
Anjali Bharadwaj
Judy Cheng

Purpose: Adverse drug events (ADE) account for 2 million hospital stays in America per year. Elderly patients (>65 years) are at an increased risk of ADE due to their heavy medication burden. The incidence of hospital admission due to ADE in the elderly is one in three. ADE worsen patient outcome and increase cost of care. This case depicts a patient who experienced a sequence of three well described, inter-related ADE over 2 months. A 71-year-old male with a past medical history significant for ischemic cardiomyopathy, ventricular tachycardia (VT), chronic kidney disease and transient ischemic attack was admitted into the hospital for refractory VT. His home medications included: apixaban 5mg twice daily, carvedilol 3.125mg twice daily, digoxin 0.0625mg daily, hydralazine 100mg every 8 hours, isosorbide mononitrate 120mg daily, pravastatin 20mg daily, ramelteon 8mg at bedtime as needed, torsemide 100mg twice daily and amiodarone 200mg daily. The patient underwent ventricular ablation and his chronic amiodarone dose was increased to 600mg daily; however, intermittent VT continued to be significant. Thyroid function test obtained 3 days after the amiodarone dose increase reviewed low TSH levels of 0.09 mIU/L, and high total T4 of 11.8 ug/dL. Amiodarone thyrotoxicosis was diagnosed. Methimazole 40mg daily and prednisone 40mg daily were initiated for treatment, while Amiodarone was discontinued. After 8 weeks of treatment, the methimazole was discontinued and the steroid regimen was tapered to a maintenance dose of dexamethasone 2mg daily. Two weeks later, the patient was readmitted for shortness of breath. He was treated initially for presumed decompensated heart failure. However, the patient continued to have significant dyspnea despite successful diuresis. A chest X-ray reviewed a classic pattern of pneumocystis pneumonia (PCP), presumably due to immunosuppression by the corticosteroid. The patient was treated empirically with trimethoprim 160mg/sulfamethoxazole 800mg four times daily for 21 days and discharged

home. Five days later, the patient was readmitted to the hospital due to extreme fatigue. He was found to have potassium level of 6.8mEq/L. His medication regimen and renal function had not changed. He was treated for possible trimethoprim induced hyperkalemia. His PCP treatment therapy was changed to atovaquone 750mg twice daily to complete the course. Amiodarone induced thyrotoxicosis occurs in 3% of patients. Amiodarone contains iodine atoms, which acts on the pituitary and liver as a thyroid hormone analog. Amiodarone induced thyrotoxicosis is usually reversible with discontinuation of therapy, as well as treatment with corticosteroid and anti-thyroid therapy for 2-3 months. PCP induced by immunosuppressant therapy has been reported. The threshold of "how much for how long" regarding steroids and risk for PCP is unclear, and the critical amount of immunosuppression necessary to increase the risk for PCP is not measurable. Prophylaxis has generally been suggested in patients who receive corticosteroid therapy for longer than 4 weeks at a dose equivalent to 20mg of prednisone daily. This patient has been receiving an equivalent prednisone taper regimen of 40mg for 30days, 26mg for another 30 days, 13mg for 21 days, 6mg for 7 days and 3mg for 7 days. In this patient's scenario, PCP prophylaxis might have helped prevent the episode. Hyperkalemia is a rarely reported ADE of trimethoprim, mostly occurring in patients with other risk factors. Trimethoprim is structurally similar to amiloride. It competitively blocks the sodium channels in the distal nephron, which impairs renal potassium excretion. Our patient has chronic kidney disease and was on PCP treatment doses of trimethoprim/sulfamethoxazole, which may have increased his risk of developing hyperkalemia. This case illustrates the importance of therapeutic drug monitoring in elderly patients who are at high risk of developing ADE, even for low incidence side effects.

Poster Title: Vancomycin-induced nephrotoxicity in neutropenic oncology patients: A retrospective review

Primary Author: Kayla Najafipour, Massachusetts College of Pharmacy and Health Sciences University, Massachusetts; **Email:** knaja1@stu.mcphs.edu

Additional Author (s):

Purpose: Historically, vancomycin has been associated with causing nephrotoxicity. However, there are limited studies saying that an increase in vancomycin's serum concentration directly leads to a decline in renal function. The purpose of this study was to determine the effect of neutropenic oncology/hematology patients receiving vancomycin on renal function. A correlation between the vancomycin dose given, serum trough concentrations obtained, serum creatinine, and a decline in renal function were analyzed. Secondary outcomes such as drug-drug interactions, other nephrotoxic drugs, co-morbid conditions, contrast dyes received, and length of treatment were also assessed.

Methods: Participants in this study included patients admitted into the hematology/oncology unit at Beth Israel Deaconess Medical Center in Boston, Massachusetts who have received vancomycin from January 1st 2015- September 30th 2015. Patients were included if they met this criteria. Patients were excluded if vancomycin was discontinued within 48 hours of initiation, received vancomycin per institutional hemodialysis protocol, and received only vancomycin oral liquid. Patients were included more than once if multiple orders met this criteria. Baseline serum creatinine was recorded on the day of vancomycin initiation. Concomitant nephrotoxic drugs that were assessed were tacrolimus, cyclosporine, amphotericin, cidofovir, foscarnet, and the aminoglycosides. Results were analyzed using descriptive statistics.

Results: Out of 194 patients admitted, 104 vancomycin patients met the inclusion criteria. 17 patients were included more than once therefore 87 patients were evaluated overall. The age range was 21-89 years old (mean age, 59 years) with 38 [44%] being female. Among the 104 vancomycin patients evaluated, 12 patients [12%] developed unstable renal function with either an increase in serum creatinine greater than 50% from baseline or an increase of 0.5

mg/dL or greater from baseline. 10 out of these 12 patients with unstable renal function had a recorded trough level >20 ug/mL at least once during treatment. Of these 12 patients with unstable renal function, 1 patient was on concurrent use of tacrolimus and none were on cyclosporine. The patient on tacrolimus also had a recorded trough level >20 ug/mL during treatment.

8 of the 12 patients received contrast dye during their course of vancomycin therapy. Out of these 8 patients, 6 patients had a recorded trough level >20 ug/mL at least once during the course of treatment. 3 out of the 8 patients had an increase in serum creatinine within 48 hours of contrast.

Conclusion: Using the Naranjo algorithm, there is a possible chance that the serum creatinine increase in the 12 patients that developed unstable renal function was due to vancomycin. The results show that there are other factors that may have affected the serum creatinine increase such as contrast dyes and nephrotoxic drugs. More studies are needed to assess the correlation between nephrotoxicity and vancomycin's serum concentration in oncology patients. Electronic medical records should be utilizied in the future, the time difference between vancomycin dose given and trough recorded should be calculated, and a more robust review of nephrotoxic drugs should be included.

Poster Title: Relapsing and remitting multiple sclerosis: a review of recently and soon to be approved monoclonal antibodies

Primary Author: Anna Kerimov, Massachusetts College of Pharmacy and Health Sciences University, Massachusetts; **Email:** akeri1@stu.mcphs.edu

Additional Author (s):
Jessica McKenna
Mira Khatib
Amanda Morrill

Purpose: Monoclonal antibodies are used to decrease the pathological inflammatory processes occurring in patients with relapsing-remitting multiple sclerosis (RRMS). Until recently, there were two approved monoclonal antibodies in the RRMS treatment guidelines: alemtuzumab, and natalizumab. Recently daclizumab was approved by the FDA as well. Additional agents are in various stages of investigation. Ocrelizumab has recently been granted priority review by the FDA, and Phase III clinical trials studying the use of ofatumumab have commenced. The purpose of this report was to explore the newly approved and emerging monoclonal antibodies for relapsing-remitting multiple sclerosis.

Methods: A literature search was conducted in Embase and Medline (1996 to Week 2 2016) using keywords multiple sclerosis, relapsing-remitting multiple sclerosis, daclizumab, alemtuzumab, ocrelizumab, natalizumab and ofatumumab. Randomized controlled trials and review articles in English were selected for analysis to determine efficacy benefits and any safety risks associated with the newly approved monoclonal antibodies as well as any currently planned Phase III clinical trials scheduled for this year.

Results: Analysis of daclizumab trials both compared to placebo and to interferon beta-1a showed significant decreases in relapses as well as in new brain lesion growth monitored through MRI, however showed some increases in adverse events such as liver damage. Daclizumab is also a monthly injection, which may be preferred by patients over the current daily injection therapies. When comparing ocrelizumab monotherapy with placebo and interferon beta-1a monotherapy, ocrelizumab was associated with reduced total brain lesion

growth. The interferon beta-1a group and placebo group had significantly more adverse events such as infections as compared to the treatment group. Ofatumumab, currently approved for chronic lymphocytic leukemia, is currently scheduled for Phase III clinical trial beginning during the later half of 2016 due to significant Phase II findings that it decreases the number of new brain lesions without increasing the number of serious adverse events. There are no studies as of yet comparing ofatumumab to a placebo or to one of the approved medications.

Conclusion: The recently approved and currently studied monoclonal antibody therapies for RRMS show great promise and efficacy data proving they may be potential drug therapy alternatives to the currently available therapies. The clinical significance of the studies evaluated within this report must be taken into account when new treatment guidelines for MS are released to determine how these new monoclonal antibodies will fit into an updated treatment algorithm. Further studies into long-term risks and benefits of each of the drugs presented will need to be analyzed before these medications can be recommended for use any higher than alternative third line therapies.

Poster Title: Smart connected insulin pens and caps: A digitalized approach to diabetes management

Primary Author: Shivani Shah, Massachusetts College of Pharmacy and Health Sciences University, Massachusetts; **Email:** sshah2@stu.mcphs.edu

Purpose: Current insulin pens have improved diabetes care in regards to increasing patient adherence. However, these pens do not address issues such as unreliable documentation of therapy and delayed patient care. With innovative health technologies emerging, smart connected insulin pens and caps can enhance existing modalities of care. This poster will gather and compare information on the known commercialized devices with the goal of communicating promising new advances in diabetes care and determining the prospective role of these devices in practice.

Methods: A total of five source categories were used to gather information on smart connected insulin devices, and include: proprietary information, press release statements, case studies, periodic publications, and current news. Proprietary information was the primary source of data. However, all of the resources were utilized to: determine the products that constitute the current landscape of smart connected devices, gather information on product design and function, or both. Additional evidence regarding product availability was retrieved from the FDA 510(k) database.

Results: Search results revealed information about seven commercialized smart connected insulin pens and three commercialized smart connected insulin caps. Of these, the only FDA approved devices include InPen, a Bluetooth-enabled insulin smart pen, and Timesulin, a timer-enabled cap for insulin pens. However, other devices are seeking US market approval and expect FDA clearance in the near future. Smart connected insulin pens function by automatically recording and transmitting insulin dosing data to a device. Data can be transmitted via one of three ways: Bluetooth, short-range radio interface, or by USB. Documented data can then be accessed in real-time by physicians, caregivers, or both. Additionally, the majority of these pens can accommodate all U-100 insulins in 3 mL cartridges. Smart connected insulin caps function by either displaying the time since the patient's last dose or by logging and transferring data to a device, similar to the previously discussed smart pens.

However, compared to smart pens, these devices are smaller and more convenient in regards to transport. Most of these smart caps are also compatible with most major insulin pen brands. Individual product specific design further distinguishes these smart pens and caps from one another.

Conclusion: Smart connected insulin pens and caps offer a promising solution for diabetes management. Through an interactive platform, these devices simplify communication between the patient and clinician. This allows for real-time therapeutic interventions, reliable self-management of diabetes, and reduced disease-state complications. Although this pioneering technology has apparent benefits, limitations do exist. Further investigation of HIPAA compliance, health insurance reimbursement, and user accessibility is paramount to launching this idea to its full potential.

Submission Type: Case Report

Session-Board Number: 3-180

Poster Title: Serotonin syndrome following up-titration of paroxetine: a case report

Primary Author: Maleeha Shaikh, Massachusetts College of Pharmacy and Health Sciences University, Massachusetts; **Email:** maleehashkh2@gmail.com

Additional Author (s):
Sadia Minhas
Timothy Hudd
Yahaida Rimola-Dejesus

Purpose: The purpose of this abstract is to describe the development of serotonin syndrome following up-titration of paroxetine after two months of therapy. Serotonin syndrome is an adverse drug reaction caused by excess activation of mainly central and peripheral 5-HT2A serotonergic receptors. 5-HT1A receptors may also be involved in a pharmacodynamic intercalation that synaptically increases concentrations of serotonin agonists. Symptom onset and progression can be rapid and potentially life threatening. Diagnostic symptoms include: spontaneous clonus, inducible or ocular clonus with agitation and/or diaphoresis, tremor with hyperreflexia, hypertonia, and temperature above 100.4 degrees Fahrenheit. Serotonin syndrome is largely under diagnosed due to variable onset, nonspecific symptoms, evolving diagnostic criteria, and lack of awareness amongst prescribers. A 21-year-old female with a past medical history of mononucleosis, generalized anxiety disorder, headaches, cervicalgia, arthralgia, acute pharyngitis, myalgia, and depression presented to clinic with a chief complaint of widespread burning sensation accompanied by hot flashes without sweating. The patient had a history of rash to amoxicillin and intolerance to metoclopramide (panic attack). Her medication history consisted of sertraline, hydroxyzine, naproxen, cyclobenzaprine, doxycycline hyclate, and levonorgestrel/ethinyl estradiol. Sertraline 25mg daily was used for depression over an eleven-month period before being switched to paroxetine due to increased anxiety. Paroxetine was initiated at a dose of 20mg. After 1 week of therapy, depressive and anxiety symptoms intensified, and the patient reported tremors and an inability to sleep more than 2 hours a night. Melatonin 5mg was added at bedtime and the paroxetine dose was increased to 30mg daily. At the patient's request, her primary care physician ordered Lyme titers. In addition, a sedimentation rate, comprehensive metabolic panel, C-reactive protein, thyroid panel, complete blood count with differential, B12 level, iron profile, rheumatoid factor,

antinuclear antibody screen (ANA), drugs of abuse screen-9, and sexually transmitted disease panel was ordered. Results were unremarkable except for an elevated C-reactive protein of 0.73mg/dL and low positive ANA titer of 1:320. An Epstein Barr viral (EBV) antibody test and TB Quantiferon Gold test were also performed, both of which were negative. Two weeks later, the patient was scheduled for an acute office visit due to generalized body aches, weakness, and dizziness. Upon examination, the patient complained of fatigue, weakness, uncontrollable twitching, hand aches, increasing frequency of resting hand tremors, and random sweating. Review of systems was normal except the patient had an elevated heart rate (103 beats/min). Other baseline vital signs and laboratory values were within normal limits. Serotonin syndrome was diagnosed using the Hunters Criteria because the patient was taking a serotonergic agent and presented with tremor plus hyperreflexia. Consequently, the patient was instructed to reduce the dose of paroxetine to 10mg to minimize serotonergic withdrawal symptoms before completely discontinuing therapy. The next day the patient reported headaches, myalgias, nausea, and confusion. Symptoms were attributed to withdrawal and the patient was monitored, requiring no supportive care. Upon follow up eighteen days later, the patient's primary care physician learned that the patient had completely self-discontinued paroxetine on her own and reported complete resolution of symptoms within a week of discontinuing the paroxetine. A score of 4 on the Naranjo scale classifies this as a possible adverse drug reaction. In conclusion, clinicians should be vigilant regarding the development of serotonin syndrome following initiation or up-titration of serotonergic agents by identifying symptoms early on.

Poster Title: Evaluation of the efficacy of medium chain triglyceride oil in patients with mild cognitive impairment or Alzheimer's disease

Primary Author: Michael Roy, Massachusetts College of Pharmacy and Health Sciences University, Massachusetts; **Email:** mike.roy.jr@live.com

Purpose: Medium chain triglyceride oil has been utilized as a supplement for its role in enhancing metabolism; medium chain triglycerides are broken down into medium chain fatty acids and are used readily by the liver to provide energy. Recently, medium chain triglyceride oil has been utilized in various clinical trials, investigating its uses in the setting of cognitive impairment and Alzheimer's disease and its ability to improve memory and cognitive function. The purpose of this presentation is to evaluate the results of these trials and introduce potential areas of exploration for medium chain triglyceride oil in healthcare.

Methods: A literature search was performed utilizing Pubmed, Medline (Ovid), and Science Direct databases for clinical trials that utilized medium chain triglyceride oil with the purpose of improving cognition in the treatment groups. The following Medical Subject Heading terms were utilized in the Ovid Database combined with the following Boolean search terms: cognition OR memory OR Alzheimer's disease AND medium chain triglycerides. In the Pubmed and Science Direct databases the key words medium chain triglyceride oil, beta hydroxybutyrate, and Axona were used in various combinations with cognitive impairment, memory, cognition, and Alzheimer's disease. The searches were limited to English, clinical trials, involving humans only. Three articles were found to meet these criteria.

Results: In the setting of mild cognitive impairment, a pilot study by Rebello et al. revealed that when given 6 doses of medium chain triglyceride oil over 24 weeks, patients experienced improvement in memory when assessed by Alzheimer's disease Assessment Scale – cognitive subscale score. In the setting of Alzheimer's disease, two clinical trials demonstrated the effect of medium chain triglycerides. The first study, by Henderson et al., provided 10 grams of medium chain triglycerides daily and increased to 20 grams after one week for 90 days. This study assessed the effect of continued medium chain triglycerides administration on cognition. The second study, by Reger et al., administered 40ml of emulsified medium chain triglycerides

once per visit, for two visits. A baseline assessment of cognitive status was done at the beginning of each visit and again 90 minutes after medium chain triglyceride administration; the effect of the oil on cognition in an acute setting was assessed with this study. Each study also recorded the patient's serum beta hydroxybutyrate levels as a biomarker for ketone levels and included subgroup analyses regarding apolipoprotein-E genotype status. Both studies demonstrated a statistically significant improvement Alzheimer's Disease Assessment Scale – cognitive subscale score.

Conclusion: Aside from its uses in digestion and metabolism, medium chain triglyceride oil has shown promise in other areas of healthcare. It is currently being explored for its effectiveness in improving the cognitive function in patients and has shown promise in Alzheimer's both in the acute setting and with consistent administration. Currently, the biggest limitation with the use of medium chain triglyceride oil for this application is the trial sizes are relatively small. Larger trials are still required to help reinforce the efficacy of medium chain triglyceride oil in the setting of Alzheimer's disease and cognitive impairment.

Poster Title: Evaluation of Glucagon-like peptide-1 agonists and their weight loss properties in patients with type 2 diabetes mellitus.

Primary Author: Argeta Dhroso, Massachusetts College of Pharmacy and Health Sciences University, Massachusetts; **Email:** adhro1@stu.mcphs.edu

Additional Author (s):
David Schnee
Cal Murphy
Kayla Najafipour

Purpose: Glucagon-like peptide-1 (GLP-1) receptor agonists mimic the naturally occurring incretin hormone which is released in the small intestine. These agents regulate blood glucose by increasing insulin release after glucose load and inhibiting glucagon secretion. Additionally, GLP-1 receptor agonists induce weight loss in patients through their activity in the brain and gastrointestinal tract. The primary action of weight loss activity is thought to be mainly due to an increase in satiety. The purpose of this study is to evaluate each GLP-1 receptor agonist by comparing their efficacy for weight loss in patients with type 2 diabetes mellitus.

Methods: Randomized controlled trials and review articles comparing weight loss outcomes in patients with type 2 diabetes taking GLP-1 agonists were retrieved using EMBASE, Cochrane Library, Ovid Medline and PubMed. Publications were considered from 2009 to 2016 and were searched by using the MESH words "weight loss" and "GLP-1", as well as the brand and generic names of each drug in the GLP-1 agonist class. The GLP-1 agonists that were reviewed included: liraglutide, exenatide twice a day, exenatide once weekly, albiglutide and dulaglutide. Trials that were included reviewed weight loss in patients as a primary or secondary endpoint and weight loss comparison was done among the dugs in the class or compared to placebo. Most articles were meta analysis comparing GLP-1 agonists with placebo and compiled the information together to display a comparison between each GLP-1.

Results: GLP-1 agonists assessed in this review produced a variety of results. In patients with type 2 diabetes, participants taking liraglutide 1.2 mg and metformin had a mean weight loss of −2.6 ± 0.2 kg at 26 weeks and exhibited an increase in weight loss with an increase dose of 1.8

mg. Exenatide 10 μg twice daily and metformin, however, had an average weight loss of -2.8 ± 0.5 kg at 30 weeks. Whereas the trial assessing exenatide once weekly compare to placebo revealed a greater weight loss of -4.00 kg at the end of a 52 weeks period. Alternatively, albiglutide had an average weight gain of 0.26 kg after 12 weeks based on information compiled from 6 studies with a 95% confidence interval of –0.66 to 1.3 kg. Dulaglutide had an average weight loss of -0.88 kg after 12 weeks with information compiled from 7 studies with a 95% confidence interval of –1.80 to 0.03 kg. Both albiglutide and dulaglutide did not show a statistically significant difference in weight loss compared to placebo.

Conclusion: A comparison on the effect of weight loss of the GLP-1 agonists in patients with type 2 diabetes revealed that different formulations in the class have variable effects. Liraglutide and exenatide showed significant weight loss in patients while albiglutide and dulaglutide did not. When recommending GLP-1 agonists to patients for diabetes management who may also benefit from their weight loss effect, either exenatide twice daily or liraglutide should be recommended as adjunct therapy to lifestyle modifications.

Session-Board Number: 3-183

Poster Title: New combination insulin containing pens: a guide for pharmacists and pharmacy students

Primary Author: Vibhuti Shah, Massachusetts College of Pharmacy and Health Sciences University, Massachusetts; **Email:** vshah1@stu.mcphs.edu

Additional Author (s):
Stephanie Mui
Susan Jacobson

Purpose: There are many new innovative therapies currently marketed for the treatment of diabetes. Two combination insulin pens IGlarlixi(lixisenatide, a glucagon-like peptide-1 receptor agonist, and insulin glargine) and IDeglira(liraglutide, a GLP-1 receptor agonist, and insulindegludec, a long-acting insulin) are currently awaiting FDA approval. Combination insulin pens are useful for patients to help ease the burden of injections and to help them achieve a better quality of life while living with diabetes. This poster describes the dosing, safety, efficacy, and comparison of these products that was presented to pharmacists and pharmacy students to enhance their knowledge of Type II diabetes treatment.

Methods: Primary literature and clinical trials were researched to investigate two prefilled insulin pens, IGlarixi and IDeglira. Data was gathered from clinical trials to show adverse effects with these combination medications, initial dosing, adjusting dose, and their respective advantages and disadvantages. Tertiary literature was utilized to provide the initial dosing and titration of the long acting insulins, as well as the glucagon-like peptide-1 receptor agonists.

Results: IGlarixi is available in two different types of prefilled insulin pens. One pen can be utilized in insulin naïve patients, while the other pen can be used in patients who were currently prescribed a low dose basil insulin. These pens differ in the ratio of GLP-1 agonist and long-acting insulin which presents one disadvantage. However, it offers good postprandial coverage and it is dosed once a day. Clinical trials revealed that there are no cardiac risks with the pen dose of lixisenatide,and although there were markedly lower rates of nausea and vomiting, there is still a risk of gastrointestinal symptoms in GLP-1 naïve patients. Though there was weight loss associated with IGlarixi, it was not as significant as when compared to

lixisenatide alone. IDeglira comes as a once daily injection from prefilled insulin pen. Ease of dosing was a clear advantage of using IDeglira, however, potentially sub-therapeutic doses of liraglutide used in IDeglira was a major disadvantage. Furthermore, although we do not see a significant weight loss as seen with liraglutide alone, there is a potential -2.5 in weight decrease when compared to insulin degludec.

Conclusion: IGlarixiand IDegliraare two new insulin containing pens awaiting FDA approval. Because these new medications will soon be available for patients, it is important for pharmacists and pharmacy students to be able to help physicians and patients make informed decisions on which medication would be best suited for them. This poster was presented to help educate pharmacists and students learn about these two products, by comparing dosing, side effect profiles, efficacy, advantages, and disadvantages.

Session-Board Number: 3-184

Poster Title: Evaluation of the Safety of an IV Electrolyte Replacement Protocol for Critically Ill and Oncology Patients at Beth Israel Deaconess Medical Center

Primary Author: Emily Motola, Massachusetts College of Pharmacy and Health Sciences University, Massachusetts; **Email:** emoto1@stu.mcphs.edu

Purpose: A new sliding scale electrolyte replenishment protocol for critically ill and oncology patients was recently established at Beth Israel Deaconess Medical Center. The protocol specifies a low and a high dose corresponding to each endpoint on the scale to be given when a patient's electrolyte level falls within a certain range. There are three separate sliding scales corresponding to Potassium, Magnesium and Calcium (ionized and unionized). The primary objective of this study is to evaluate the safety of this protocol by analyzing the rates of overcorrection in those patients who received sliding scale orders for Potassium, Magnesium, and Ionized Calcium.

Methods: 1,870 ICU patients who received orders for sliding scale Potassium, Magnesium, and Ionized Calcium between October 1st and January 31st were included in this study. Using electronic medical records patients who reported high values were extracted and separated into three cohorts corresponding to each scale. This equaled 1,046 patients who received orders for Magnesium, 150 patients for Potassium, and 674 for Ionized Calcium. Those patients who reported high values that were due to a lab and/or reporting error or resulted from a lipemic, icteric, or hemolyzed specimen were excluded from further analysis. After application of exclusion criteria this left 163 patients and 386 total values to be analyzed in the Magnesium group, 31 patients and 56 total values to be analyzed in the Potassium group, and 21 patients and 38 total values to be analyzed in the Calcium group. Reasons for high values were assessed and those due to overcorrection were identified.

Results: The rates of overcorrection due to following the protocol was 3/150 (2.0%) in the Potassium group, 2/674 (0.02%) in the Calcium group, and 51/1046 (4.9%) in the Magnesium group. When high values were analyzed in the Potassium group, 11/150 patients reported high values due to overcorrection. Of these patients, three received the dose per protocol and eight were given an inappropriate dose (i.e. patients' level prior to receiving the dose was already in

therapeutic range or the dose given was too high). In the Calcium group, 3/674 patients reported high values due to overcorrection. Of these patients two received the dose per protocol and one was given an inappropriate dose. In the Magnesium group, 75/1,046 patients reported high values due to overcorrection. Of these patients, 51 received the dose per protocol and 24 were given an inappropriate dose.

Conclusion: The sliding scale electrolyte replacement protocol proves to be safe in the Critical Care setting and leads to minimal rates of overcorrection in this patient population. The greatest rate of overcorrection was seen with Magnesium when patient levels were in the upper ranges of the protocol, perhaps suggesting a less aggressive approach when levels are greater than 1.7 mg/dL.

Submission Category: Pain Management

Submission Type: Evaluative Study

Session-Board Number: 3-185

Poster Title: Buprenorphine/naloxone for chronic pain management in patients with a history of opioid use disorder.

Primary Author: Jessica Andrade, Massachusetts College of Pharmacy and Health Sciences University, Massachusetts; **Email:** jandr2@stu.mcphs.edu

Additional Author (s):
Mark Iskander
Michele Matthews

Purpose: Buprenorphine/naloxone is FDA-approved for the treatment of opioid use disorder (OUD) and has a unique mechanism of action as a partial mu-agonist with high receptor affinity, which has made it an ideal drug for the management of OUD. New formulations of buprenorphine have been marketed for the management of chronic pain; however, buprenorphine/naloxone has been used off-label for chronic pain management in patients with past or current OUD. The purpose of this study is to evaluate the role of buprenorphine/naloxone for the management of chronic pain in patients with a history of OUD.

Methods: This retrospective review was conducted at a primary care clinic within a large, urban teaching hospital and was approved by the Institutional Review Board. Patients that were currently receiving buprenorphine/naloxone for chronic pain management within the primary care clinic were considered for inclusion if they met the following criteria: age 18 years or older, in recovery from OUD, history of chronic non-cancer pain, baseline numeric pain rating score of greater than or equal to 7, and had at least two documented clinic visits within the past 12 months. The following parameters were obtained through comprehensive chart reviews for visits occurring within the past 12 months: age, gender, pain diagnosis, details related to the history of OUD, current analgesic regimen, current buprenorphine/naloxone dose, number of clinic visits related to chronic pain, baseline average daily pain, function, and quality of life scores assessed using the PEG scale, current average daily pain, function, and quality of life scores assessed using the PEG scale, number of urine drug tests (UDTs), number of abnormal UDTs, average UDT concentrations for buprenorphine and its metabolites, co-prescribing of benzodiazepines, co-prescribing of naloxone, and adverse effects from therapy. Descriptive

statistics were used to summarize all data. The percent change in baseline and current scores was calculated for each parameter within the PEG scale.

Results: Among the 30 patients currently receiving buprenorphine/naloxone, a total of four patients met the inclusion criteria (3 females and 1 male). The mean age of patients was 65.5 years old (range 56 to 78) and all patients were prescribed greater than or equal to 24 mg of buprenorphine per day. The most common pain diagnoses were chronic low back pain and chronic abdominal pain. Half of patients had a history of heroin abuse, and the remainder of patients had a history of prescription opioid abuse. The calculated mean baseline pain scores, activity scores, and life-enjoyment scores were 10, 9.5, and 9.5, respectively. Calculated percent change in mean pain scores was -30%, activity score was -25.63%, and enjoyment of life score was -25.63%. It is important to note that 75% of the patients were receiving at least one additional analgesic. One patient reported nausea/vomiting, but this was not a reason for treatment discontinuation. The average number of UDTs performed over the past 12 months was 9, and the average number of abnormal urine results was 1.5 per patient. The most common substance identified within the UDT was marijuana. The average ratio of norbuprenorphine to buprenorphine was approximately 10 to 1.

Conclusion: The review has concluded that the use of buprenorphine/naloxone, when combined with adjuvant analgesics, is associated with improvements in pain, function, and quality of life scores in patients with chronic noncancer pain and a history of OUD. This treatment also appeared to be well-tolerated. This demonstrates that an opioid with a unique pharmacokinetic and pharmacodynamic profile can be used safely and effectively in this population. Due to the small nature of the study, a larger randomized controlled trial is needed to further investigate the use of buprenorphine/naloxone in this population.

Submission Type: Case Report

Session-Board Number: 3-186

Poster Title: The successful transition of an extremely insulin resistant patient to regular human insulin 500 units/ml

Primary Author: Zaid Baara, Massachusetts College of Pharmacy and Health Sciences University, Massachusetts; **Email:** zaid.baara@gmail.com

Additional Author (s):
Mario Ibrahim
Rachelle St. Fleur
Jennifer Goldman

Purpose: This abstract will describe a patient's case that was successfully transitioned to human regular insulin 500 units/ml (regular U500) once it was apparent that his insulin resistance required greater than 200 units daily of insulin. The patient is a 61 year-old male with a past medical history of diabetes mellitus type 2, hypertension, dyslipidemia, neuropathy, obesity, chronic renal failure, and congestive heart failure class I-II. He was first referred to Pharmacy in November 2013 with an A1C of 9.3%. He was taking insulin glargine 100 units/mL80 units twice daily and insulin lispro 100units/ml, 10-40 units before meals. Both medications were discontinued and regular U500, 100 units twice daily with meals was initiated due to both, its basal and prandial properties using a tuberculin syringe dosed in both volume and units. Titration was successful and he instituted a better diet and exercise. His medical history precluded the use of other medications besides insulin. His A1C two months later was 7.8%. Over time, he stopped exercising and resumed a poor diet and his A1C elevated. In February 2015, insulin detemir 100 units/mL, 60 units in the morning was added to his regimen and prandial insulin dose was subsequently reduced to 80 units twice daily to diminish hypoglycemia risk. Because insulin detemir effects did not last the entire 24 hours, dose was changed to 50 units twice daily in March 2015 and then increased to 60 units twice a day. He experienced occasional nocturnal hypoglycemia determined to be due to diet when he skipped a meal.. In June 2015,insulin detemir 100 units/mL was switched to insulin glargine 300 units/mL, 80 units every morning to try to reduce the number of injections, but was associated with significant peripheral edema, prompting discontinuation and the re-initiation of insulin detemir at previous dose. Consequently, FBG levels rose and after splitting dose to 60 units twice daily in September 2015 and maintaining the prandial insulin at 130 units twice daily. His

basal insulin regimen required a dose greater than dialing capacity, warranting the transition to insulin degludec 200 units/mL, 120 units once in the evening in February 2016. This basal insulin's pen dials up to 160 units per injection and can be given once a day. The regular U500 dose was decreased to 125 units at breakfast and 50 units at dinner. A trial of lispro 200 units/mL with meals was attempted instead of regular U500 but doses required exceeded 60 units, the max per injection on the pen and regular U500 was resumed. In May 2016, he was switched to the regular U500 insulin pen instead of using tuberculin syringes. His doses have since been titrated to insulin degludec 200 units/mL, 160 units once daily and human regular insulin 500 units/mL 100 units twice a day. His blood sugars are closer to goal when he eats properly and elevates significantly when making poor choices. Due to the risk of hypoglycemia as he refuses to alter his dietary habits, increasing his doses further is not appropriate. It is critical for pharmacists to understand insulin resistance and the use of concentrated insulins. This poster will describe the successful transition of an extremely insulin resistant patient with uncontrolled diabetes to concentrated human regular insulin 500 units/mL and review the available concentrated insulins.

Poster Title: The role of a pharmacist in transitional care of heart failure patients.

Primary Author: Faris Alhalwan, Massachusetts College of Pharmacy and Health Sciences University - Worcester, Massachusetts; **Email:** m0246194@stu.mcphs.edu

Purpose: Medication related errors upon the transition of care are the main cause of lengthy hospital stays and re-admissions after discharge. According to the Healthcare Cost and Utilization Project, Medicare patients accounted for 55% of all re-admissions and 58.2% of the costs associated with readmission. In 2011, it was reported that most Medicare re-admissions were due to complications of congestive heart failure. In 2012, the Affordable Care Act implemented the hospital readmission reduction program, which reduced payment to hospitals that have readmission within 30 days. Therefore, there has been an increased effort directed towards implementing interventions that reduce medication related errors.

Methods: Pharmacists have a crucial role in to identifying, preventing, and correcting medication errors related to transition of care in patients with heart failure. This review will identify common challenges posed by multiple studies associated with transition of care in the scope of pharmacy. We will further target these challenges by implementing key interventions to ensure effective and accurate completion of transition of care. This in turn will lead to improved quality of care as well as cost-reduction related to readmission and lengthy stays.

Results: Most medication errors upon transition of care arise due to lack of effective communication, which may lead to incomplete or outdated medication lists. It was reported that these errors may also occur during an acute attack of heart failure due to unintentional discontinuation or inappropriate initiation of chronic medications. There are many challenges that can emerge in regards to medication therapy. These challenges include: abiding by the hospital specific formularies, inter-professional communication between staff from different shifts, lack of understanding from the patient perspective, and missing patient information due to numerous medical records.

The use of standardized forms during the transition process has been helpful in reducing medication errors. These forms provide a template that can be used by the pharmacist in order to extrapolate all of the necessary information from both the patient and their health-care

providers. It is important to provide medication reconciliation in order to obtain an accurate and updated medication list. Upon patient discharge it is beneficial to provide patient centered education, scheduling of outpatient visits, and telephone follow up calls. These steps can all be lead to reductions regarding drug-related problems.

Conclusion: Clinical pharmacists have a beneficial role in the improvement of care in heart failure patients. Their involvement has been proven to reduce medication related errors upon transition of care.

Poster Title: Assessment of 4-factor prothrombin complex concentrate (4-FPCC) dosing practices in patients within neurocritical care unit at UMass Memorial Medical Center (UMASS)

Primary Author: Mehrnaz Sadrolashrafi, Massachusetts College of Pharmacy and Health Sciences-Worcester, Massachusetts; **Email:** msadr1@stu.mcphs.edu

Additional Author (s):
Faris Alnezary
Jeffrey Fong

Purpose: 4-factor prothrombin complex concentrate (4-FPCC) is indicated for reversal of bleeding associated with the use of vitamin k antagonists in cases of abnormally elevated international normalized ratio (INR). Since 4-FPCC is dosed by body weight, clinicians will often round doses up or down to the next closest vial size for clinical convenience. It is unknown if this practice will lead to differences in clinical or laboratory outcomes.

Methods: This is a retrospective cohort study using data collected from UMass' database from May 2015 to May 2016 and was approved by the institutional review board. Patients who received a dose of 4-FPCC for the reversal of warfarin-related intracranial bleeding were enrolled in the study. Patients were included if they had received warfarin prior to hospital admission, had an intracranial bleed (spontaneous or traumatic), and had an elevated INR (greater than or equal to 2). Exclusion criteria included receipt of non-warfarin anticoagulants or an extracranial hemorrhage. The primary endpoints were to characterize the current dosing strategies employed for patients admitted to the neurocritical care unit needing reversal of anticoagulation and compare the safety and efficacy of various dosing strategies for 4-FPCC. The secondary endpoints were to determine if there is a correlation between location of intracranial hemorrhage, dose of warfarin taken by the patient, or use of aspirin on patient's outcome based on modified Rankin score upon discharge. We defined clinical success as modified Rankin score upon discharge of 0 to 3 and laboratory success as INR reversal to less than or equal to 1.4 within the first twelve hours after administration of 4-FPCC. We calculated the time spent in ICU/hospital, modified Rankin score upon hospital discharge, and discharge disposition. T-test and Fisher's exact test were utilized for statistical analysis.

Results: Forty two patients were included in this study. The mean age was 75.2 years old. The majority of the patients were male (57.1 percent), who were mostly taking warfarin for atrial fibrillation (66.7 percent). Most of the patients received 4-FPCC for intracerebral hemorrhage (52.4 percent) and had intra-axial hemorrhage (52.5 percent). The mean baseline Glasgow Coma Score and Charlson comorbidity index were 11 and 3.5, respectively. Patients who received rounded down dosing of 4-FPCC had better laboratory success compared to those who received rounded up dosing (95.7 percent versus 55.5 percent, p value equals 0.04). There was no significant difference in clinical success between those who received rounded down or rounded up dosing of 4-FPCC (56.5 percent versus 44.4 percent, p value equals 1). None of the patients experienced myocardial infarction, deep vein thrombosis, pulmonary embolism, or ischemic stroke. Overall, ten patients (23.8 percent) died due to complications of their injury unrelated to 4-FPCC administration. In subgroup analyses, no significant difference was observed in clinical outcomes when intra-axial hemorrhage was compared to extra-axial hemorrhage (38.1 percent versus 75 percent, p value equals 0.07). No significant difference was observed in subgroup analyses of warfarin dosage taken or concurrent use of aspirin.

Conclusion: Laboratory success was achieved more successfully in patients who received rounded down dosing of 4-FPCC. However, rounded down dosing seems to be as effective as rounded up dosing of 4-FPCC in achieving clinical success. Our study does not suggest that warfarin dose or aspirin use, location of intracranial hemorrhage, and dose-rounding of 4-FPCC has an impact on the clinical success/outcomes defined as modified Rankin score of 0 to 3 upon discharge. Future larger studies are needed to identify optimal and safe dosing strategy of 4-FPCC in practice.

Poster Title: Successful transition from U100 insulin glargine to U200 insulin degludec

Primary Author: Rachelle St.Fleur, MCPHS University, Massachusetts; **Email:** rstfl1@stu.mcphs.edu

Additional Author (s):
Jennifer Goldman

Purpose: This abstract will describe a case of a patient who was successfully transitioned to degludec U200 insulin when it was suspected that U100 glargine was not lasting 24 hours and missed doses due to shift-work was identified. The patient is a 57- year-old male with a past medical history of type 2 diabetes mellitus, hypertension, dyslipidemia, nephropathy, retinopathy, and glaucoma. His current medications are metformin XR 500mg two tablets in the morning and two tablets in the evening, empagliflozin 25 mg daily, insulin degludec U200 98 units daily. He works approximately 70 hours per week with shift work,gets no purposeful exercise, and eats a relatively poor diet. He is 6'2, weighs 296 lbs, and his BMI is 38 kg/m2. He was first referred to Pharmacy in June 2012 with an A1C of 14.4%. At this visit his regimen included taking metformin XR 2000 mg, glipizide 20 mg twice daily, and insulin glargine 24 units in the morning. Glipizide was discontinued and glargine 24 units was continued with a titration schedule to increase by 2 units every 3 days until his FBS was 70-130 then stay at that dose. Metformin ER 500mg 2 tablets in the morning and 2 tablets in the evening was continued. Discussed adding liraglutide at a future visit but he refused. Four months later his A1C was 7.5% on the following regimen metformin XR 2000 mg daily and insulin glargine 52 units every morning. He missed follow up appointments and was not seen again until June 2013 when his A1C was 9% and he was taking metformin XR 2000 mg daily and insulin glargine 62 units in the morning. Mealtime insulin was initiated but he was non-adherent and did not follow up with Pharmacy again until March 2016 when his A1C was 10.5%. His regimen at that time was metformin XR 2000 mg daily and insulin glargine 80 units in the morning. It was identified that he was often late or may miss his insulin dose when he wasn't working and it was suspected that insulin was not lasting 24 hours. He also required larger doses of basal insulin that could not be accommodated with a single injection of U100 glargine. His U100 glargine was changed to U200 degludec 90 units and metformin XR 2000 mg daily was continued. He was educated on the need for adding mealtime coverage via a GLP-1 receptor agonist (RA) or mealtime insulin

when dose is stable. There is a 1:1 conversion from U100 glargine to U200 degludec which is easy for the provider and not confusing for the patient to understand. The half-life of insulin degludec is 25 hours and duration of action is 42 hours. The efficacy of U200 remains the same after 8 and 40 hours allowing for a more flexible dosing schedule. Hypoglycemia rates and other adverse effects were the same also. This allows for U200 degludec to be used in patients who require more than 80 units daily, who have variable work schedules, who are often non-compliant, and anyone who may have trouble injecting at the same time every day. With the addition of U200 degludec to his regimen his glycemic control and compliance has improved. Two months later his A1C was 8.5% and he was injecting 98 units of U200 degludec. He refused any additional medications. Three months later his A1C rose to 9.3% and he refused a daily injection of GLP-1RA but was willing to inject a weekly agent that was initiated.

Poster Title: Role of Desmopressin (DDAVP) and prednisone in acquired hemophilia A: a case report

Primary Author: Nidhi Nivarthi, MCPHS University, Massachusetts; **Email:** nniva1@stu.mcphs.edu

Additional Author (s):
Susan Krikorian

Purpose: This case illustrates the role of desmopressin (1-amino-8-D-arginine vasopressin, DDAVP) and prednisone in managing acquired factor VIII deficiency associated with hemophilia A, a congenital bleeding disorder. An 80-year-old Caucasian female with a past medical history including atrial fibrillation on warfarin and low-dose aspirin presented to the emergency room at our institution with increasing weakness, bruising, nausea, and an eight pound weight loss in two months. On examination, the patient had significant bruising of her hands and lips. She was taking warfarin and aspirin at home and upon presentation her INR and PTT were at 2.8 and >150, respectively. Warfarin was held. On hospital day 4, the INR rose to 3.4. Other significant laboratory values included hemoglobin 7.9 and hematocrit 24.0, dropping to 6.1 and 21.5, respectively, within 24 hours. She was given two units of packed red blood cells. The measured activity levels of Factor VIII (less than 1% of the expected value) and factor IX (50% of the expected value) were reported. Ultimately, a PTT mixing study demonstrated there was evidence of factor VIII inhibitor with hexgonal phase lupus anticoagulant. It was determined her clotting cascade was not functioning appropriately. On hospital day 3, she was diagnosed with new onset mild hemophilia A and intravenous DDAVP 15mcg daily was prescribed to help control bleeding. After 4 days of DDVAP therapy, the serum sodium level dropped to 126 mEq/mL. One of its adverse effects is hyponatremia. DDAVP was discontinued. Prednisone 50mg daily for 21 days was started. On the day of discharge, the PTT level dropped to 90 with an improvement of symptoms. She was discharged off her usual warfarin to complete a 21-day course of high dose prednisone. Continued management of her acquired hemophilia A included close monitoring for signs and symptoms of bleeding and a prednisone taper after completion of a 21 day course of high dose drug.
This report describes a case of new onset acquired hemophilia A in an elderly woman, a disease state that is so uncommon, only an estimated 20,000 individuals in the United States have it.

Desmopressin shortens prolonged PTT and bleeding time, by promoting the release of von Willebrand factor with a subsequent increase in factor VIII survival, and is indicated to treat mild hemophilia A. First-line therapy for eradication of factor VIII inhibitors includes methylprednisolone 1mg/kg/day or an equivalent dose of prednisone. Adding oral cyclophoshamide 50-150mg/day can increase response rate. In our patient, DDAVP successfully controlled active bleeding initially. It is noteworthy all bleeding indices improved after initiation of daily high dose prednsione. Initial therapy with DDAVP to control bleeding followed by daily high dose prednisone may be an option in patients with hemophilia A who are not candidates for combination therapy with cyclophosphamide and prednisone.

Poster Title: Use of anakinra for the management of refractory pericarditis.

Primary Author: Mark Iskander, MCPHS University, Massachusetts; **Email:** iskander.mark@hotmail.com

Additional Author (s):
Muneerah Aleissa
Victoria Phan
Judy Cheng

Purpose: Pericarditis is the inflammation of the pericardium. Though the primary cause of pericarditis is idiopathic in most cases, there are a number of disease states that have shown to be associated with pericarditis (e.g. viral infection, tuberculosis, neoplasms, myocardial infarctions, or autoimmune disorders). Aside from treating the underlying cause, treatment of pericarditis involve the use of non-steroidal anti-inflammatory drugs (NSAIDs), colchicine, and corticosteroids to reduce inflammation, pain and prevent recurrence. The use of high dose NSAIDs and colchicine concurrently is the mainstay of therapy, as they both significantly decrease inflammation, and has been demonstrated to reduce recurrence as compare to NSAIDs alone. Corticosteroids although relieve symptoms, has been demonstrated to increase recurrence as compare to NSAIDs and colchicine. Despite proper treatment, recurrent idiopathic pericarditis is a common, problematic complication of acute pericarditis, occurring in approximately 30% of cases. Other immunosuppressive therapy may have to be considered. We present a patient case of refractory pericarditis successfully managed with anakinra, an interleukin-1 receptor antagonist.

The patient is a 61 year old female with past medical history significant for ischemic cardiomyopathy (left ventricular ejection fraction 25%), and coronary artery disease with stent placement. She was admitted for management of a device pocket hematoma after a recent admission for a cardiac resynchronization pacemaker and defibrillator (CRT-D) placement. During her first hospitalization, the CRT-D was removed and patient was treated empirically with a course of antibiotics (clindamycin 600 mg every 8 hours for 7 days). Patient was readmitted a few weeks later to have a new CRT-D placed via epicardial lead approach. Three weeks after the epicardial lead has been placed, the patient presented to the hospital complaining of fever, fatigue and chest tightness. CT scan showed circumferential thickening of

the pericardium consistent with pericarditis. Additionally, her erythrocyte sedimentation rate (ESR) was elevated to 98 mm/hr, C-reactive protein (CRP) to 244 mg/L, and a friction rub was noted on physical examination. She was initiated on ibuprofen 800mg three times daily and colchicine 0.6mg twice daily. Her laboratory tests and fever both improved after a week of treatment and patient was discharged with colchicine only to be continued for 4 weeks (ibuprofen discontinued on discharge due to gastrointestinal upset and improvement of pain and fever). Two weeks later, patient presented with recurrent pericarditis symptoms (fever, ESR 100 mm/hr, CRP 300 mg/L). Patient was restarted on ibuprofen and continued on colchicine. Another two weeks later, patient presented once again with recurrent symptoms (fever, ESR 113 mm/hr, CRP 354 mg/L). Due to symptoms appearing to be refractory to ibuprofen and colchicine, decision was made for a trial of anakinra 100mg daily subcutaneously. The following morning the patient reported decreased chest pain. Repeated ESR and CRP after 4 doses anakinra were 91 mm/hr and 33 mg/L, respectively. The plan was initially to discharge the patient on anakinra daily for 4 weeks, then re-evaluate. However, due to insurance denying payment, patient was initiated on prednisone 30mg daily instead with plan to consider methotrexate therapy after symptoms further improved.

Anakinra is an interleukin-1 receptor antagonist currently approved for treatment of rheumatoid arthritis. Small number of case reports and case series (mostly in pediatric patients) have been published in its use for management of recurrent pericarditis. Anakinra appeared to be well-tolerated in these case reports. Treatment duration in these case reports average from 2 months to 3 years. Recurrence rate after anakinra discontinuation varies in different reports and remains a concern. Controlled clinical trials are necessary to support the use of anakinra in recurrent pericarditis refractory to traditional therapy.

Poster Title: Surgical weight reduction by vitamin/mineral consumption

Primary Author: Ryan Batchelor, MCPHS University, Massachusetts; **Email:** rbatc1@stu.mcphs.edu

Additional Author (s):
Sajin John
Rebecca Couris

Purpose: This abstract describes the development of a PowerPoint presentation, poster, and brochure designed to educate healthcare professionals, patients and members of the community about the nutrients that are compromised in bariatric surgery. Obesity is a growing public health concern making bariatric surgery common in practice today. A greater understanding of the risks of vitamin and mineral deficiencies post-bariatric surgery is crucial for effective interventions. The purpose of this information is to describe the growing prevalence of obesity and bariatric surgery, the risk of vitamin and mineral deficiencies and how to manage proper interventions to prevent complications.

Methods: Under the direction of faculty, students conducted a literature search on all aspects of bariatric surgery and the associated nutrient deficiencies following each procedure. Incidence of obesity and bariatric surgery, screening for vitamin and mineral deficiencies, and recommended management for interventions were all included in the literature search. The informational resources consisted of peer-reviewed articles as well as other reliable sources such as the National Institutes of Health (NIH) and the American Society of Metabolic and Bariatric Surgery (ASMBS). The information was collected, organized, and evaluated to create a comprehensive informational resource for medical practitioners, patients and members of the community. A thorough analysis of a review article authored by research done by NIH and presented by the Health and Human Services as well as basic literature searches were utilized to find the desired information. The search was preformed to understand the prevalence of obesity in our population, to evaluate the increasing popularity of bariatric surgery in common practice, and how to identify and manage vitamin and mineral deficiencies post-surgery.

Results: An educational PowerPoint presentation, poster and brochure were developed to present the incidence of vitamin and mineral deficiencies commonly seen post-bariatric surgery, the physiological mechanisms by which these deficiencies occur, their signs and symptoms, screening parameters, and recommendations for management and interventions. The information will be presented in charts and diagrams to depict the current estimated cases of bariatric surgery annually and the recommended management and prevention of each vitamin and/or mineral deficiency. Approximately 26% to 32% of Americans are considered obese in our population today with a growing increase in prevalence. It is estimated that 43% of Americans will be considered obese in 2018. Cases of bariatric surgery have been increasing exponentially since the 1990s, growing from about 20,000 procedures in 1992 to 120,000 procedures in 2008. The growing incidence of bariatric surgery has led to greater incidences of nutritional deficiencies. The most common vitamin and mineral deficiencies include a variety of B vitamins (thiamine, pyridoxine, folate and cobalamin), vitamin A, vitamin D, vitamin E, vitamin K, iron, calcium and several proteins. Supplementation of these vitamins and minerals are vital to avoid complications associated with these deficiencies.

Conclusion: The presentation, poster and brochures provide a guide to evaluate the overall impact of nutritional deficiencies commonly found in post-bariatric surgery and how to provide effective management of these complications. These materials will serve as a source of recommendations for providers and patients to raise awareness of this problematic issue. Despite great advances in the last few decades of weight loss management with bariatric surgery, nutritional deficiencies still pose a major problem post-surgery to the public health. Effective education regarding the management and prevention of vitamin and mineral deficiencies is necessary to decrease the risk of these complications.

Poster Title: The development to an alternative method to testing your blood glucose testing.

Primary Author: Mario Ibrahim, MCPHS University, Massachusetts; **Email:** mibra1@stu.mcphs.edu

Additional Author (s):
Zaid Baara
Danny Patel
Rachelle St Fleur
Jennifer Goldman

Purpose: This abstract will describe the development of a blog, brochure, and poster designed to educate healthcare professionals and patients on alternative site blood glucose testing. Alternative site testing provides an alternative method to finger stick testing for patients with diabetes to test their blood sugar that is less painful and may result in better compliance for those that do not test due to pain.

Methods: Under the supervision of faculty, the research of alternative site testing was conducted. The research involved reviews and clinical trials from various sources such as American Diabetes Association, PubMed, Becton Dickinson, then information was organized for an internet blog, brochure, and poster to further educate healthcare providers and patients.

Results: An informational blog, brochure and poster were designed to include the value and use of alternative site blood glucose testing, appropriate sites where patients can test and several concerns regarding this method. This information on the blog and poster provide healthcare professionals and patients additional insight on an additional technique for blood glucose testing to those who have and deal with patients with diabetes. A brochure was designed as an at home teaching tool for both healthcare providers and patients/caregivers so they can further read about the method and reinforce the information told to them at the office.

Conclusion: In conclusion, this project is meant to serve as an educational tool for both healthcare providers and patients/caregivers on alternative site testing. It provides them education on when they should and should not use the various sites and which sites should be

used when. The poster will further educate healthcare professionals and patients to better understand what alternative site testing. Additionally, a brochure will serve as a take home tool so the information is reinforced. Overall goal is to increase patient blood glucose testing compliance and reduce pain cessation from fingertip testing.

Poster Title: Liposomal doxorubicin: Infusion reactions in different cancers

Primary Author: William Ho, MCPHS University, Massachusetts; **Email:** who1@stu.mcphs.edu

Additional Author (s):
Matthew Girgis
Christy Harris

Purpose: Liposomal doxorubicin is used in the treatment of a number of cancers. Infusion reactions related to liposomal doxorubicin have been reported to occur in about 10% - 12% of cases, something not seen with regular doxorubicin. Corticosteroids, histamine-1 and histamine-2 antagonists are generally used in the prevention of infusion reactions. However, there is currently no standardized premedication protocol for liposomal doxorubicin at our institution. The purpose of this study was to estimate the percentage of patients that develop an infusion reaction to liposomal doxorubicin, and to identify any factors that may be associated with the development of these reactions.

Methods: This was a retrospective medical chart review and drug-use evaluation, which was approved by the institutional review board (IRB). Patients who received liposomal doxorubicin at our institution between January 2015 and August 2016 were identified using Dana Farber's pharmacy dispensing records and electronic medical records (EMR). These patients were then retrospectively assessed for any documented infusion reactions during cycle 1 or cycle 2 of their treatment, and the description of such reactions, based on the nursing and provider notes from the institution's EMR. Data collected from each patient included their medical record number, initials, age, gender, type of cancer, cycle, cycle date, cycle dose (mg/m2), total administered dose (mg), and administered pre-medications/doses. Patients who had documented hypersensitivity symptoms during liposomal doxorubicin infusion were considered to have had an infusion-related reaction.

Results: A total of 300 patients were identified and retrospectively analyzed for infusion related reactions when receiving liposomal doxorubicin. Fourteen patients were male, while 286 were female. The median age of all patients was 62 years old. Six different types of cancers were observed, the three main ones being gynecological (167 patients), breast (87 patients), and

sarcoma (33 patients). A total of 32 infusion reactions were documented among all 300 patients. Fourteen patients (42%) with sarcoma had an infusion reaction. Patients with gynecological and breast cancers had reaction rates of 7% and 8% of their subgroup population, respectively. There were no infusion reactions documented in the lymphoma (11 patients), gastrointestinal (1 patient), or myeloma (1 patient) subgroups.

The pre-medications administered before each infusion were also analyzed. Among the breast and gynecological cancer subgroups, no patient received all 3 pre-medications (corticosteroid, H1-antagonist or H2-antagonist), while 8 patients received all 3 medications in the sarcoma subgroup. In the breast cancer subgroup, there were 4 infusions that received no pre-medications that resulted in a reaction, while there was 5 in the gynecological subgroup, and only 1 in the sarcoma subgroup.

Conclusion: The results of this study suggests that patients with sarcomas have a disproportionate incidence of infusion-reactions to liposomal doxorubicin when compared to patients with other cancers. Among 300 patients and 32 documented reactions analyzed in this study, almost half the reactions occurred in sarcoma patients. Despite this disproportionate incidence in sarcoma patients, they were also more pre-medicated when compared to patients with other cancers. There is currently minimal data that indicates why sarcoma patients have higher rates of infusion reactions, and further studies should be conducted to identify other risk factors for infusion-reactions as well as the optimal pre-medication regimen.

Session-Board Number: 3-195

Poster Title: Evidence based protocol for icatibant use in the treatment of angiotensin converting enzyme (ACE) inhibitor-induced angioedema (ACEI-AE)

Primary Author: Noor Almakabi, MCPHS University, Massachusetts; **Email:** nalma1@stu.mcphs.edu

Additional Author (s):
Oussayma Moukhachen

Purpose: ACE inhibitors induced angioedema (ACEI-AE) is defined as a swelling of the face, lips, tongue, or larynx that occurs subcutaneously and progresses rapidly with high risk for severe respiratory compromise, and in some cases death. After encountering a patient with ACEI-AE, we recognized that there is a paucity of information on the optimal treatment of ACEI-AE. Therapies like C1esterase inhibitor concentrate, kallikrein inhibitor, and bradykinin receptor type 2 inhibitor (Icatibant) have been the center of new studies for the treatment of ACEI-AE. We will provide clinicians with a protocol based on the evidence available associated with icatibant.

Methods: Literature was accessed through MEDLINE search using the following MeSH terms: ACEI induced angioedema AND icatibant, non-allergic angioedema AND icatibant, ACEI angioedema management, Angioedema AND asymmetric swelling, C1 esterase inhibitor concentrate AND angioedema. Searches were limited to English language, human subjects, and publication dates within the past 10 years. The search focused on the ACEI induced angioedema that is non-allergic and derived by the accumulation of bradykinin that leads to increased vascular permeability and interstitial edema. Additional studies referenced in the retrieved articles were also reviewed. Two controlled clinical trials, one case series, and several case reports were included in the background literature that was used to develop the evidence base protocol. Based on the evidence available and the cost of the 30mg (3ml)-prefilled syringe averaging about 8825 dollars, icatibant would not be considered a first line agent for ACEI-AE and it should be reserved for severe cases refractory to current standard treatment options such as corticosteroids, antihistamines, fresh frozen plasma, and epinephrine.

Results: For our protocol, icatibant use will be reserved to patients: 18 years of age or older, with at least a moderate severity of angioedema, and clinical presentation of tongue swelling, difficulty breathing, difficulty swallowing, voice change, and refractory to current standard treatment options. Patients should be admitted to the intensive care unit (ICU) for proper management and close monitoring. Protection of the airways is very critical due to the high risk of airway obstruction requiring intubation. A 30mg-Icatibant dose should be administered as a subcutaneous injection. If response is inadequate, or symptoms reappear, an additional injection of 30mg may be administered at intervals of at least 6 hours. No more than 3 injections in 24 hours should be given. Patients should be closely monitored for signs of visible decrease in angioedema, which occur slowly within 15-30minutes with the first dose. Near complete resolution of symptoms is expected to occur within 4-10 hours on average. Erythema and injection site reactions are mild self-limiting side effects associated with icatibant. No additional icatibant-specific monitoring parameters are required. Finally, along with permanent discontinuation of ACEI, proper documentation of the reaction should be updated in the patient medical record.

Conclusion: Our patient was managed supportively in the ICU by giving methylprednisolone and famotidine. Given the cost of the product, icatibant was considered but not administered. Other institutions would probably face the same dilemma and would need to create their own protocol for the management of ACEI-AE using icatibant. In addition, we suggest conducting a cost-benefit analysis to determine the suitability of icatibant before it may be considered as an economically and pharmacologically effective option for the treatment of ACEI-AE.

Submission Type: Evaluative Study

Session-Board Number: 3-196

Poster Title: Aztreonam: Retrospective utilization evaluation and cost assessment of a penicillin skin testing (PST) as an alternative approach

Primary Author: Matthew Girgis, MCPHS University, Massachusetts; **Email:** girgismatthew@gmail.com

Additional Author (s):
Oussayma Moukhachen

Purpose: Aztreonam is a monobactam antibiotic that is prescribed for patients with a severe allergy to β-lactam antibiotics for empiric treatment of an infection caused by gram negative pathogens. Often times, inappropriate prescribing occurs because of incomplete documentation of true allergies to penicillins, leading to an increased use of unnecessary and expensive broad spectrum antibiotics. The purpose of this evaluation is to assess the appropriateness of aztreonam utilization and to assess whether a penicillin skin testing protocol is a cost minimizing alternative approach.

Methods: Pharmacy Meditech database was used to identify patients who were prescribed aztreonam from January 1st, 2015 to May 3rd, 2016. Using a standardized sheet, patients' electronic medical records were reviewed to collect the following baseline and clinical characteristics: age, length of stay, penicillin allergy documentation (timing, causative agent, description of reaction, tolerance of other β-lactams), serum creatinine, clinical indication, microbiological culture results and sensitivities, aztreonam regimen, and occurrence of a side effect attributed to aztreonam.
Utilization of aztreonam was deemed appropriate if dosed according to the package insert, used in a patient with a pathogen only sensitive to aztreonam or in a patient requiring gram negative coverage, or if the patient had an appropriately documented severe allergic reaction to penicillin/β-lactam such as anaphylaxis, angioedema, or hives.
Documentation of the penicillin/β-lactam allergy reaction was deemed absolutely appropriate if it included a clear documentation of the causative agent, and a clear description of the reaction and the specific time of its occurrence. If a patient had a mild or moderate allergy to penicillin (mild rash, diarrhea, nausea/vomiting, itching), or listed as unknown reaction with unknown severity, the patient was deemed a candidate for a Penicillin Skin Testing (PST). The cost of the

aztreonam regimen was compared to the total cost of a suitable per indication predefined alternative β-lactam regimen along with the cost of PST.

Results: 40 patients received aztreonam and were included in this analysis. 199.5g/355.5g (56%) of aztreonam given was considered to be administered inappropriately based on incomplete allergy documentation. No aztreonam usage was deemed inappropriate based on indication and dosing. Three patients did not have allergies to β-lactam antibiotics. The most common allergy causing agent was amoxicillin, causing 6 events (16%). Of the 37 patients who had a documented allergy to penicillin, eight (22%) were found to have absolutely appropriate allergy documentation. We found that only 10 patients (27%) of the 37 with allergies had a recorded specific time of the allergic event occurring. 18 patients (45%) were determined to be appropriate candidates for a skin testing protocol. The total cost of aztreonam therapy among these patients was $5120. The total cost of penicillin skin testing would have been $1871, and the cost of alternative therapy to aztreonam would have been $3,113.49 if ceftazidime was used as the alternative agent for bacteremia, pneumonia and sepsis, or $1154.18 if piperacillin/tazobactam was used. A potential cost saving of $136 when comparing aztreonam regimen to ceftazidime and of $2095 compared to piperacillin/tazobactam.

Conclusion: Overall, aztreonam utilization was not optimal given the lack of appropriate allergy documentation. A penicillin skin testing protocol appears to be a cost minimizing approach in addition to allowing a judicious usage of aztreonam. A hospital wide pharmacist-driven allergy clarification initiative may improve the allergy documentation and may help minimize aztreonam usage based on unclear allergy history. Finally, electronic health record software system should be built to encourage the clear documentation of allergy to avoid vaguely stated allergic reaction such as "unknown", or "allergic to penicillins/β-lactams" without specifying a causative agent.

Session-Board Number: 3-197

Poster Title: Evaluation of nutritional supplements as adjuncts to statin therapy for hypercholesterolemia

Primary Author: Cal Murphy, MCPHS University, Massachusetts; **Email:** cmurp1@stu.mcphs.edu

Additional Author (s):
Simran Bimrah
Tanya Martins
Erika Felix-Getzik
Anelsa Beqo

Purpose: Despite the long-term benefits of cholesterol-lowering agents, many patients struggle to reach their therapeutic goals due to statin intolerability. To overcome this barrier, patients will often seek over-the-counter (OTC) alternatives. Unfortunately, there are several medications on the market that may not have a definitive place in therapy for the treatment of hypercholesterolemia. The purpose of this review is to provide guidance regarding the safe and effective use of OTC supplements as adjunct to statin therapy for the treatment of hypercholesterolemia.

Methods: Relevant primary literature and review articles were collected regarding nutritional supplements in relation to cholesterol and cardiovascular disease. Various supplements were chosen based on high media prevalence or published controversial evidence regarding benefits for cardiovascular health. The different supplements researched were red yeast rice, niacin, omega-3 fatty acids, garlic, coconut oil, psyllium, flaxseed, coenzyme Q10 , and vitamin D. Articles were identified by searching a total of seven databases with publications from 1996 to the present (2016), and key articles were obtained primarily from Ovid Medline, Embase, PubMed, Natural Medicine and Pharmacotherapy. The MESH terms "cholesterol," "cardiovascular disease," and "myalgia" in addition to the name of each supplement were utilized for the literature search. A comprehensive search was made of Internet resources, primarily the use of PubMed through the National Library of Medicine. Finally, studies were eligible for consideration in this review if they reflected changes in cholesterol levels.

Results: The supplements assessed during this drug literature review were evaluated based on their efficacy in decreasing cholesterol levels, as well as their ability to mitigate statin-induced adverse effects. Of the products reviewed, omega-3 fatty acids, red yeast rice and psyllium were proven to reduce cholesterol levels along with most formulations of flaxseed due to their soluble fiber content. There was conflicting results regarding the benefits of garlic and coconut oil and their effect in reducing cholesterol levels, however use did not warrant any safety concerns. Regardless of the lack of safety concerns, garlic and coconut oil do not largely reduce cholesterol levels. Despite the fact that niacin and red yeast rice have shown to be effective in reducing cholesterol levels, both agents have negative safety profiles when used long-term. Due to these concerns, it is typically not recommended for these agents to be utilized without the supervision of a provider. Lastly, vitamin D showed significant benefits in mitigating the adverse effect of statin-induced myalgia, while coenzyme Q10, on a large scale, did not reveal many benefits.

Conclusion: Several supplements have demonstrated benefit as adjuncts in the treatment of hypercholesterolemia. Although some products showed a reduction in overall cholesterol levels, none proved to have any long-term cardiovascular benefit. Despite the lack of concrete mortality benefits with the use of these agents, most may be utilized in therapy without interfering with cholesterol-lowering agents. Omega-3 fatty acids, psyllium, flaxseed, garlic, coconut oil and vitamin D are routinely utilized in moderation with sound clinical reasoning. However, niacin, red yeast rice and coenzyme Q10 lack substantial data regarding their overall benefit, and may potentially be harmful to a patient.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Descriptive Report

Session-Board Number: 3-198

Poster Title: Comprehensive drug utilization review: Liposomal amphotericin b

Primary Author: Chirlie Silver, MCPHS University, Massachusetts; **Email:** chirlie.sabbah@gmail.com

Purpose: This drug utilization evaluation aims to review current evidence on safety and efficacy of using liposomal amphotericin B (AmBisome) in newborns with candidiasis, and compare it to the conventional preparation. Conventional amphotericin B (Fungizone) is more commonly used in newborns, but dose limiting adverse effects may compromise its efficacy. This review will go over the advantages and disadvantages of liposomal amphotericin B and define its place in current practice.

Methods: A literature search was carried out to include relevant data available on the liposomal formulation of amphotericin B. The search included studies dating as far back as 1988, comparing the conventional and the liposomal formulations in newborns as monotherapy. Additional pharmacokinetic studies were reviewed to look at available data. The terms 'AmBisome' or 'liposomal amphotericin B' and 'neonatal candidiasis' were entered on both PubMed and Ovid; studies included focused on safety and efficacy of liposomal amphotericin B in newborns with candidiasis. Single case reports were not included in the review due to the limitations of relying on single cases for conclusions. This literature search was done to provide anti fungal therapy guidance in a newborn infant who developed signs of renal and hepatic adverse events following conventional amphotericin use.

Results: The results of this drug utilization review provided insight on the efficacy and safety of liposomal amphotericin B to treat neonatal candidiasis. Most of the studies used in this evaluation did not have statistically significant results due to size and design of the study, however the reported results are consistent with the other studies evaluated. Overall, current studies support liposomal amphotericin B (AmBisome) as an efficacious option, equivalent to the conventional formulation, with no statistically significant in mortality. Additionally, data supports increased safety including decreased incidence of hepatotoxicity and nephrotoxicity, which was statistically significant when comparing to conventional amphotericin B. Studies also reported a shorter duration of therapy needed in patients not previously exposed to the

conventional formulation, which suggests an increased efficacy of the liposomal formulation over the conventional formulation. There is a lack of data regarding the kinetics of the medication, which will limit its use as a first line agent, specifically in the context of fungal meningitis, as CNS penetration data is insufficient. Moreover, there is a reported lack of renal penetration, which prevents its empiric use, as it requires ruling out infectious renal involvement.

Conclusion: Although liposomal amphotericin B seems to be better tolerated and as efficacious as the conventional formulation based on published literature, the limitations of the studies available on the subject cannot be overlooked. Randomized controlled trials are needed in order to determine the place in therapy of this medication. This medication evaluation contributed to get a more in depth understanding of the medication and led to the addition of liposomal amphotericin b to NICU formulary at Brigham and Women's Hospital, pending Pharmacy and Therapeutics Committee approval.

Submission Type: Descriptive Report

Session-Board Number: 3-199

Poster Title: Gluten: to wheat or not to wheat

Primary Author: Krishna Rana, MCPHS University, Massachusetts; **Email:** krana1@stu.mcphs.edu

Additional Author (s):
Ryan Batchelor
Sajin John
Rebecca Couris

Purpose: This abstract describes the development of a PowerPoint presentation, poster and brochure designed to educate healthcare professionals, patients and members of the community about a food component, gluten, that is incorporated in many food products found on supermarket shelves. The incidence of gluten-related disorders or gluten sensitivity is currently increasing each year with an estimated worldwide prevalence of about 5% while the estimated occurrence of diagnosed celiac disease remains at 1%. The purpose of this information is to describe the differences between celiac disease and non-celiac gluten sensitivity and how to properly manage interventions to prevent complications of these conditions.

Methods: Under the direction of faculty, students conducted a literature search on all aspects of gluten ingestion as it relates to celiac disease and non-celiac gluten sensitivity including epidemiology, pathophysiology, the types of reactions and the management of such reactions. The informational resources consisted of peer-reviewed articles and other reliable sources such as the National Institutes of Health (NIH) and the American Gastroenterological Association (AGA). A thorough analysis of the research conducted at the Celiac Disease Center and the Institute of Human Nutrition at Columbia University was cited as well as other pertinent literature to supplement this information. The information was collected, organized and evaluated to create a comprehensive informational resource for medical practitioners, patients and members of the community. The information consisted of the epidemiology, pathophysiology, characteristics, classification, cross sensitivities and management of gluten allergies and sensitivities.

Results: An educational PowerPoint presentation, poster and brochure were developed to present the differences between celiac disease and non-celiac gluten sensitivity, their pathophysiology, clinical manifestations, biomarkers, histology, screening parameters and recommendations for management and interventions. The information will be presented in charts and diagrams to depict the differences between celiac disease and non-celiac gluten sensitivity and the recommended food items to consume and avoid for proper management and treatment of both conditions. The incidence of celiac disease is 1% worldwide compared to non-celiac gluten sensitivity, which effects up to 5% of the worldwide population. A thorough knowledge and understanding of the signs, symptoms and clinical presentation of celiac disease and non-celiac gluten sensitivity is vital for a differential diagnosis. Symptoms may be mild as bloating and diarrhea to severe complications such as osteopenia, osteoporosis and peripheral neuropathy. Not only do affected individuals have to observe a life long gluten-free diet, screening for nutritional deficiencies with special attention to iron, folate, vitamin B12 and vitamin D is required.

Conclusion: The presentation, poster and brochures provide a guide to evaluate and differentiate between celiac disease and non-celiac gluten sensitivity and how to review clinical histories, symptoms, serological and histological tests to effectively manage complications. These materials will serve as a source of recommendations for providers and patients to raise awareness of this problematic issue. The incidence rates of these conditions are increasing and lack of knowledge could possibly lead to life long complications. Therefore, proper knowledge of the differences among gluten related disorders is vital for proper recommendations, interventions and treatments.

Submission Type: Descriptive Report

Session-Board Number: 3-200

Poster Title: Retard the flame without environmental and health risk blame

Primary Author: Sajin John, MCPHS University, Massachusetts; **Email:** sjohn1@stu.mcphs.edu

Additional Author (s):
Rebecca Couris
Ryan Batchelor

Purpose: This abstract describes the development of a presentation designed to educate the general public about cancer risk in firefighters. Despite years of intervention efforts, cancer rates in firefighters continues to be a major problem, with an abundant number of firefighters developing cancers due to the exposure of carcinogens found in building materials. A greater understanding of carcinogens is crucial for the effective intervention and safety in exposure-response relationships for firefighters. The purpose of investigating current information regarding the most common carcinogens encountered by firefighters during their high-risk exposure will heighten public awareness and provide valuable recommendations to better protect firefighters.

Methods: Under the direction of faculty, students conducted a literature search on all aspects of types of cancer rates in firefighters, including the incidence of exposure, contributing factors, and recommendations for prevention. The informational resources consisted of primary literature as well as other reliable sources such as the National Institute of Occupational Safety and Health (NIOSH), the International Agency for Research on Cancer (IARC) at the World Health Organization (WHO) and the International Association of Fire Fighters (IAFF). The information was collected, organized and evaluated to create a comprehensive informational resource for medical practitioners, patients and members of the community. An analysis of data was conducted based on the number of cancers in firefighters from 1950 to 2004 through the IAFF website. Exposures were classified by most prevalent types of cancer, causes or routes of exposure, and identified substances that are classified as carcinogens. A literature search was then performed to identify contributing factors and recommendations under the following search terms: firefighter AND cancer AND prevention.

Results: According to studies from NIOSH and IAFF, firefighters have been shown to be at a higher risk for multiple types of cancer compared to the general population. Several studies have found a statistically significant increase in specific types of cancer in firefighting including testicular cancer, malignant melanoma, prostate cancer, lung cancer, leukemia and breast cancer. The higher risks of developing cancer (exposure-response relationships) are due to the extended periods of exposure to carcinogens that firefighters face during a fire run. The most common routes of carcinogenic exposure during a fire run are dermal absorption and inhalation. Another major reason for carcinogen exposure is due to the improper removal and decontamination of firefighter equipment, which include turnout gear and self-contained breathing apparatus (SCBA). Studies have also indicated that building materials contain many chemicals that are known carcinogens. These chemicals when inhaled or dermally contacted during a fire may cause carcinogens to enter the body. The most common substances in building materials that cause cancer include arsenic, asbestos, benzene, bisphenol A, formaldehyde, aromatic hydrocarbons, chlorinated plastics (PVCs) and dioxins. A literature search revealed the persistent incidences of cancer among firefighters despite substantial evidence proving this exposure-response relationship and advancement in technology

Conclusion: The presentation, poster and brochures provide a guide to evaluate the increased dangers for firefighters, contributing risk factors and recommendations for improved safety. These materials will serve as a source of recommendations for providers and patients to raise awareness of this problematic issue. Despite great advances in the last few decades, development of cancers in many retired firefighters and the well being of all firefighters remains a crucial concern to public health. Better safety protocols, initiative and research are vital to provide more effective prevention and increased awareness of exposure-response cancers in firefighters.

Session-Board Number: 3-201

Poster Title: Evaluation of antithrombotic management in patients with atrial fibrillation at a tertiary care academic medical center

Primary Author: Jordan Lacoste, MCPHS University, Massachusetts; **Email:** jlaco1@stu.mcphs.edu

Purpose: Atrial fibrillation (AF) is a common arrhythmia, which affects approximately 5 million people in the United States. While management of heart rate or rhythm is of importance, the single largest concern is the increased risk of stroke. Oral anticoagulation (OAC) is the gold standard for stroke risk reduction in these patients, but published data suggests OAC is under prescribed in patients with AF. The purpose of this study is to assess the antithrombotic management of AF patients at Beth Israel Deaconess Medical Center (BIDMC) and its concordance with recommended evidence-based practices.

Methods: The institutional review board approved this retrospective chart review. Patients with a diagnosis of AF who were admitted to BIDMC between June 1- December 31, 2015 were included. Patients with AF were identified using ICD-9 and ICD-10 codes, where applicable. Pertinent exclusion criteria included patients with a CHA2DS2-VASc and/or CHADS2 of 0 as guideline recommend no antithrombotic therapy, patients with a first episode of AF < 48 hours, and first episode of AF patients receiving cardioversion who remain in sinus after 30 days. Identified patients' medical records were reviewed for pertinent information: age, gender, body-weight, and comorbidities. From these data, risk for stroke was calculated using the CHA2DS2-VASc score. Medical records were reviewed for documented reasons for not prescribing anticoagulation. Pharmacy systems were used to identify therapies prescribed for stroke prevention, therapy start date, discontinuation date (if applicable), any changes in dosing or switching of therapies, and any potential drug interactions. Medical records were reviewed to identify reasons for switching therapy, discontinuations if applicable, and any major adverse outcomes while receiving therapy, such as ischemic or hemorrhagic strokes, and any bleeding events.

Results: Of the 1201 candidates eligible to receive anticoagulation, only 57.9% of patients were prescribed OAC. Subjects in the cohort had a mean CHA2DS2-VASc score of 4.2. Warfarin was used most commonly, accounting for 74% of all OAC use, followed by apixaban with 15.4%, rivaroxaban with 11.2% and. dabigatran with 4%. Most common identifiable reasons for non-prescribing included 2% due to an active bleed, 2% due to patient declining therapy, and lastly 0.5% due to high risk of fall.

Conclusion: Stroke prevention with OAC is underused in AF patients who are at high risk for stroke. Among patients receiving OAC, warfarin is still being utilized more often than the newer agents. Further exploration is needed to identify how to increase anticoagulation use in these vulnerable patients.

Session-Board Number: 3-202

Poster Title: Explaining the consolidation of the health care industry and its' future implications for consumers and pharmacists

Primary Author: Sandeep Singh, MCPHS University, Massachusetts; **Email:** ssing1@stu.mcphs.edu

Additional Author (s):
Francis Melaragni

Purpose: Over the past ten years there has been a large amount of acquisitions and mergers among pharmaceutical companies, retail pharmacy chains, hospital systems, and Insurance companies. These mergers combined with the implementation of the affordable care act in 2010 has caused a contraction across the health care industry. The aim of this research project is to predict whether or not consumers and pharmacists will be affected in a positive or negative manner when navigating the dynamic health care market.

Methods: A multimodal approach was taken when synthesizing and analyzing data for this project. A primary literature search was first performed on PubMed with an emphasis on finding articles that explained: Basic tenants of the affordable care act, different aspects of the health care industry such as the definition of a pharmacy benefits manager and the role they play in negotiating drug pricing, and incentives for pharmaceutical companies to merge with one another. Data was also collected by analyzing annual fiscal earnings of top retail pharmacy chains, insurance conglomerates, hospital systems, and pharmaceutical companies' year over year prior to and after completed acquisitions. Current and archived editorials from The New York Times, Washington Post, and Forbes Magazine were also utilized to understand the financial burden undertaken by companies looking to complete mergers and acquisitions. We also researched the cost of insurance premiums for single coverage patients as well as family coverage over the past fifteen years to learn if insurance premium costs had been rising and if so, what was the root cause that precipitated these increases. A primary literature search was also conducted to obtain data on the job satisfaction rate of retail pharmacists within the past two years and we then compared that to the job satisfaction rate from close to fifteen years ago.

Results: After compiling and analyzing the data, we noted several results. When we looked at year over year profits prior to and after acquisitions it was very clear that for most companies, after making a large acquisition, their profits and stock prices would see financial increases. We also noted that over the past ten years the amount of Pharmacy Benefit Managers that have been acquired either by pharmacy retail chains or insurance companies has skyrocketed. We also saw that since the Affordable Care Act was signed into law in March of 2010, hospital mergers and acquisitions have also start to increase at an exorbitant pace due to the notion that the larger a company is, the more favorable a deal they can make with drug manufacturers and insurers. We also analyzed the cost of insurance premiums for single coverage and family coverage on a yearly basis and we learned that every year since 1999, the cost of premiums have gone up considerably. The last piece of data that was analyzed was a survey commissioned by The American Association of College of Pharmacy in 2014 which showed that retail pharmacists were experiencing the worst job satisfaction rates since 2000.

Conclusion: The amount of mergers and acquisitions occurring in the health care market will continue to increase over the coming years. With this continued contraction, we will see customer choices from which retail pharmacy chains to fill prescriptions at to which insurers they choose for medical and prescription coverage all continue to decrease. From a pharmacist's perspective, with these mergers occurring, they will more than likely experience increased stress while having to deal with increasing workloads. They may even be relieved of their jobs because of a lack of positions that may occur after a merger.

Poster Title: The use of inhaled epoprostanol to treat acute pulmonary hypertension (PAH) in the intensive care unit (ICU)

Primary Author: Nadia Noormohamed, MCPHS University, Massachusetts; **Email:** nadia.noormohamed@gmail.com

Additional Author (s):
John Marshall

Purpose: Epoprostanol is a synthetic prostacyclin conventionally used in the management of chronic pulmonary arterial hypertension (PAH). Inhaled nitric oxide (iNO) is the standard of care for acute PAH, however could be cost-prohibitive. The use of inhaled epoprostanol over iNO for acute PAH carries the potential of being a more cost-effective therapy in the intensive care unit (ICU). The purpose of this study is to evaluate the safety and efficacy of inhaled epoprostanol used to treat acute pulmonary hypertension (PAH) in a select cohort of patients treated in the intensive care units at Beth Israel Deaconess Medical Center (BIDMC).

Methods: Data from patients treated with inhaled epoprostanol were retrospectively reviewed via electronic medical records (EMRs) from March 2013 to November 2015. 48 patients were included who had received inhaled epoprostanol. Data was collected as pre- and post-administration of epoprostanol. Efficacy endpoints included changes various hemodynamic parameters such as the partial pressure of oxygen (PaO2), the ratio of arterial oxygen partial pressure to fractional inspired oxygen (PaO2/FiO2), pulmonary vascular resistance (PVR), and hematocrit (HCT). Safety endpoints included cardiac output (CO), platelet counts, and patient survival. Available data was then graphed or tabulated for each parameter using significance intervals derived from previous literature, and conclusions were drawn from these results.

Results: Most patients who derived benefit from inhaled epoprostanol did so 12-60 hours after the first administration. The median change in PaO2 was 12.5 mmHg (millimeters of mercury), while 37 percent of patients experienced significant improvements in their PaO2/FiO2. The efficacy of epoprostanol was modest due to patients' severe status in the ICU, and each patient had different reasons for admission with various comorbidities, rendering a heterogeneous patient population. All patients who experienced a significant change in cardiac output had

levels above the normal limit, and almost half of patients experienced a significant decrease in platelet counts.

Conclusion: Inhaled epoprostanol may be an effective therapy for acute PAH in the ICU that should be used with caution and monitored carefully. Further research with a larger, more homogenous patient population is needed to better delineate inhaled epoprostanol's place in acute PAH therapy.

Poster Title: Impact of matrix-assisted laser desorption/ionization time-of-flight (MALDI-TOF) rapid organism identification technology on time to antibiotic de-escalation in Gram-negative pneumonia

Primary Author: Sofiya Sovalska, MCPHS University, Massachusetts; **Email:** ssova1@stu.mcphs.edu

Additional Author (s):
Philip Grgurich
Khaled Elsaid

Purpose: Typical methods of microbial identification rely on phenotyping characteristics, Gram staining, and other biochemical reactions, which are costly and time consuming. A novel method of microorganism identification, Matrix-Assisted Laser Desorption/Ionization Time-of-Flight (MALIDI-TOF), can rapidly identify pathogens and potentially facilitate a shorter time to antimicrobial de-escalation. Faster organism identification with MALDI-TOF may also result in decreased time to appropriate antimicrobial therapy. The purpose of this study was to assess how changing microbial identification methods would affect the time to antibiotic de-escalation in Gram-negative pneumonia.

Methods: The local institutional review board approved this retrospective study. Per institutional policy, respiratory cultures collected prior to July 1, 2015 were assessed via conventional laboratory identification methods and those obtained after July 1, 2015 were evaluated using MALDI-TOF. Subjects 18 years and older with culture-positive pneumonia caused by a Gram-negative organism from April 1, 2015 to December 31, 2015 were enrolled. Subjects were excluded if: the organism was considered a colonizer or contaminant as determined by the microbiology laboratory, the infection was not treated, the subject expired or was transferred prior to therapy, or the subject had been previously treated for pneumonia during the hospital admission. Data collection was completed via electronic chart review and was documented in an Excel spreadsheet. Data points included age, gender, past medical history, social history, medication history, patient location, length of stay, severity of illness, duration of invasive and non-invasive ventilation, pathogen, antibiotic(s) utilized, timing of antibiotic de-escalation, duration of antimicrobial therapy, mortality, 30-day readmission, and

antibiotic-associated adverse effects. The primary outcome was the time to de-escalation of empiric therapy. Secondary outcomes included: time to appropriate antibiotic therapy, duration of invasive ventilation, length of stay, 30-day readmission, duration of antibiotic therapy, cumulative drug-specific antibiotic hours, development of Clostridium difficile colitis during antibiotic therapy, and antibiotic-related adverse effects.

Results: A total of 91 subjects were included. The mean difference in time to de-escalation was statistically significantly shorter after implementation of MALDI-TOF technology (pre-MALDI-TOF 6.4 hours vs post-MALDI-TOF 1.9 hours, p less than 0.001). However, the use of MALDI-TOF was not associated with a significant reduction in duration of antibiotic therapy (pre-MALDI-TOF 6.4 days vs post-MALDI-TOF 7.6 days, not significant), or cumulative drug-specific antibiotic hours (pre-MALDI-TOF 78.4 hours vs post-MALDI-TOF 91.9 hours, not significant).

Conclusion: Use of the rapid organism identification technique MALDI-TOF was associated with a decreased time to antimicrobial de-escalation. It was not associated with a decreased duration of antibiotic therapy.

Poster Title: IV acetaminophen use at a tertiary care medical center

Primary Author: Anelsa Beqo, MCPHS University, Massachusetts; **Email:** abeqo1@stu.mcphs.edu

Additional Author (s):
John Marshall

Purpose: Beth Israel Deaconess Medical Center (BIDMC) aimed to address the issue of frequent intravenous (IV) acetaminophen use at the medical center through an electronic alert, which was implemented on October 2015. This project sought to evaluate the effectiveness of the alert in reducing the rate of inappropriate prescribing of IV acetaminophen. The purpose of this study was to compare the use of IV acetaminophen before and after the implementation of the clinician alert.

Methods: All patients who received an order for IV acetaminophen in the target units from November-2014 – March 2016 were evaluated for appropriateness of therapy. Appropriateness of therapy was defined as a patient not receiving any other oral medication within 8 hours of the receipt of IV acetaminophen. Additional outcomes were assessed, including if IV acetaminophen was given within 8 hours of IV Zofran, IV opioids, or oral acetaminophen. A list of all patients with IV acetaminophen orders were provided and then further narrowed to the nine floors which were previously studied. A thorough search of the patients' history was performed and data was collected from all admissions.

Results: There were 130 patients in the pre-alert group and 307 patients in the post-alert group. The primary outcome of IV acetaminophen use within 8 hours of receiving other oral medications was seen in 39% of the patients in the before group and 73% of patients in the post-alert group, showing no effect of the electronic alert. When evaluating the use of IV opioids in these patients, 50% of patients in the pre-intervention group received opioids compared to 75% in the post intervention group. Concomitant oral acetaminophen use within 8 hours was 39% in the pre-intervention group versus 73% in the post-intervention group.

Conclusion: The implementation of an electronic alert notifying providers of the high cost of IV acetaminophen did not affect prescribing practices. Overall, there was a significant increase in use of IV acetaminophen in conjunction with IV Zofran, oral acetaminophen, as well as IV opioids and oral medications. Additional means of controlling the use of IV acetaminophen are warranted and will be pursued.

Submission Type: Descriptive Report

Session-Board Number: 3-206

Poster Title: Know your food allergies to prevent life threatening tragedies

Primary Author: Elena Karski, MCPHS University, Massachusetts; **Email:** ekars1@stu.mcphs.edu

Additional Author (s):
Ryan Batchelor

Purpose: This abstract is designed to educate healthcare professionals, patients and members of the community about common food allergies, cross-reactivity of common allergens and the characteristics of the allergic reactions that may occur in response to exposure to these allergens. Food allergy is a growing public health concern because the response to allergic reactions may be fatal. Educating both patients and practitioners is vital to avoid and prevent life-threatening tragedies. The purpose of this information is to describe the incidence and epidemiology of food allergens, identify the pathophysiologic reactions that occur upon exposure to food allergens

Methods: Under the direction of faculty, students conducted a literature search on all aspects of food allergies including the most common food allergens, epidemiology, pathophysiology, the types of reactions, and the management of such reactions. The informational resources consisted of peer-reviewed articles and other reliable sources such as the National Institutes of Health (NIH) and the American Academy of Allergy, Asthma and Immunology (AAAAI). A thorough analysis of the Mayo Clinic Proceedings was cited as well as other pertinent literature to supplement this information. The information was collected, organized, and evaluated to create a comprehensive informational resource for medical practitioners, patients and members of the community. This information consisted of the epidemiology, pathophysiology, characteristics, classification, cross sensitivities, and management of common food allergy. An educational PowerPoint presentation, poster and brochure were developed to present the incidence of food allergies, specific food-induced allergic reactions, how to identify cross sensitivities and their relative risk to allergens that cause life-threatening tragedies. he information will be presented in charts and diagrams to depict the current status of food allergies. According to systematic reviews, food allergy affects between 2% to 10% of the population, including millions of Americans. The National Health and Nutrition Examination

Survey (NHANES) reported that between 2007-2010, the overall prevalence of food allergy was 8.96%, with food allergy affecting 6.53% of children and 9.72% of adults.

Results: The most common foods that cause allergic reactions include milk, tree nuts, shellfish, fish, peanuts, eggs, wheat and soy. Allergic disorders induced by exposure to food are categorized into IgE-mediated allergies, which are more common, and Non-IgE-mediated allergies. IgE-mediated allergies trigger the release of cell mediators such as histamine, prostaglandins, and leukotrienes and include disorders such as angioedema/urticaria, immediate gastrointestinal hypersensitivity, and anaphylaxis. Non-IgE-mediated allergies involve a T-cell response and include disorders such as food protein induced enterocolitis syndrome, allergic proctocolitis, contact dermatitis, and Heiner syndrome. The symptoms of an allergic reaction may be life threatening and often occur quickly after exposure, every time there is an exposure, and can occur even when the amount of exposure is limited. These symptoms include rash and/or hives, itchy skin, shortness of breath, trouble swallowing, chest pain and sudden drop in blood pressure. A food intolerance is not life-threatening, may take hours to onset and does not always occur with exposure. The symptoms of food intolerance include gas, cramps, bloating, heartburn, headache and irritability. Once an allergic reaction is confirmed, first line treatment is epinephrine auto-injector followed by close monitoring and symptomatic interventions

Conclusion: The presentation, poster and brochures provide a guide to evaluate the overall incidence of food allergies, how to identify causative factors and proper management of allergic reactions. These materials will serve as a source of recommendations for providers and patients to increase awareness of food allergies and associated reactions. Despite the increasing awareness of food allergies, exposure to suspected allergens and cross sensitivities still occur, posing risk to the patients and health. In order to decrease this public health concern, effective education on prevention and management is needed to prevent these allergic reactions that may be life-threatening.

Poster Title: Administration of digoxin-specific antibody fragments in an acute overdose of a digitalis-like substance, Pong-Pong: A case report

Primary Author: Michelle Plum, MCPHS University - Boston, Massachusetts; **Email:** mplum1@stu.mcphs.edu

Additional Author (s):
Esther Yamashita
Noor Almakabi
Oussayma Moukhachen
Farin Azadeh

Purpose: This case report describes the management of an acute overdose with a digitalis like substance, called pong-pong. A 37yr old man attempted suicide at 6:45am by ingesting five 25mg-diphenhydramine tablets, along with an unspecified amount of "Pong-Pong" powder, which he bought off the internet. He presented to the emergency department (ED) at approximately 11:00am, accompanied by his cousin, and reported feeling nauseous. However, he was alert and oriented and able to answer questions. He was bradycardic with a heart rate in the 40's, while all other vital signs were normal. Electrocardiogram (EKG) revealed abnormal results. The first EKG showed sinus bradycardia with complete right bundle branch block and non-specific T wave abnormalities. The second EKG revealed complete heart block, with ST wave abnormality. Laboratory data were significant for serum digitoxin level of 57 ng/mL, and serum digoxin level of 1.6 ng/mL. After consulting the poison control center at 11:35am, 10 vials (400mg) of intravenous Digibind were infused over 30 minutes. Normal sinus rhythm was immediately restored. The patient was discharged four days later with no residual symptoms. Pong-pong is the common name for the seeds produced by the Cerbera odollam tree, commonly known as the suicide tree, which belongs to the poisonous Apocynaceae family. This plant grows mainly in salt swamps along the coast of Madagascar and countries in Southeast Asia, such as Kerala in India, Vietnam, Cambodia, Sir Lanka, and Myanmar. The tree is identified by several common names such as nyan, kisopo, samanta, tangena, othalanga maram, kattu arali, or famentana in Southeast Asia, and as pong-pong or buta-buta in Madagascar. Cerebrin is a potent poison found within the tree's seeds, and is an active glycoside with a chemical structure similar to that of digoxin, an antiarrhythmic medication. The ingestion of cerebrin

containing seeds causes severe cardiotoxiciy that can potentially lead to death, thus it has been known to be used as a poison and for suicide.

The laboratory test used to measure serum digoxin levels relies on cross-sensitivity between cardiac glycosides and digoxin, thus an elevated digoxin level only confirms exposure to cardiac glycosides and does not correlate with the severity of toxicity.

Digibind / DigiFab, or digoxin-specific antibody (Fab) fragments, is an antidote for use in digoxin toxicity. However, due to structural similarities, it can also be used to treat poisoning caused by natural cardiac glycosides, such as pong-pong. Digibind / DigiFab binds to the cardiac glycoside preventing it from further exerting its toxic effect. This case report demonstrates the use of Digibind / DigiFab in a symptomatic patient expressing signs of digitalis toxicity after pong-pong ingestion.

Poster Title: The efficacy of using dolutegravir once daily in patients with known raltegravir resistance

Primary Author: Kevin Lee, MCPHS University - Boston, Massachusetts; **Email:** gahwinglee10@gmail.com

Additional Author (s):
Michael Nguyen
Abimbola Cole
Tulip Schneider

Purpose: This case report evaluates the use of dolutegravir (DTG – Tivicay) in a patient with raltegravir (RAL – Isentress) resistance. A 47 year old, treatment-experienced male who was diagnosed with HIV in 1997 was initiated on lopinavir/ritonavir (LPV/r – Kaletra) and lamuvidine/zidovudine (3TC/AZT – Combivir). Due to self-reported non-adherence and personal request, the patient was switched to RAL plus Combivir. Within 6 months of starting the RAL-containing regimen, he developed RAL resistance due to poor adherence. At that time, the patient was immediately switched to a boosted darunavir-containing regimen, but was eventually switched to rilpivirine (RPV – Edurant) plus dolutegravir/abacavir/lamivudine (DTG/ABC/3TC – Triumeq) once daily and has remained undetectable since switching to this simplified regimen. Although RPV (non-nucleoside reverse transcriptase inhibitor – NNRTI) and DTG (integrase inhibitor – INSTI) are both cytochrome P450 (CYP) 3A4 substrates, there are no drug-drug interaction between the two medications. Of greater concern is the use of once daily DTG in the presence of documented RAL resistance in this patient. When the INSTI genotype assay was performed, the version of the assay did not report the exact mutations in the resistance pathway, which was a limitation at the time of switching to the current DTG-containing regimen. According to the VIKING trial, which compares the use of DTG once daily versus twice daily in patients with RAL resistance, there is a notable difference in virological suppression (HIV RNA viral load (VL) less than 50 copies/mL) between DTG twice daily versus once daily at the week 24 response. These response rates are 74% and 41%, respectively. In the single-arm VIKING-3 trial, which is an extension of the VIKING trial, authors investigate the use of DTG twice daily in RAL-resistant patients. This study further confirms the efficacy of the DTG twice daily in patients with known RAL resistance. However, the VIKING trials emphasize that

the efficacy of DTG in patients with RAL resistance is mostly dependent on a patient's baseline resistance to INSTI, despite the area under the curve (AUC) of DTG increasing from 53.6 mcg.h/mL to 75.1 mcg.h/mL when given twice daily versus once daily. Based on the VIKING data and the Stanford University HIV Drug Resistance Database, there are currently no resistance mutations that confer absolute resistance to DTG. Instead, the data provides evidence that it is actually the presence of RAL or elvitegravir resistance mutations that decreases the susceptibility of the virus to DTG. According to the VIKING trial, across both cohorts (once daily and twice daily), a virus with Q148 plus additional RAL resistance mutations was more likely to have a greater DTG fold change and thus a lower response to DTG. Furthermore, the VIKING-3 trial reported that for every two-fold increase in DTG resistance, the odds of achieving a VL less than 50 copies/mL were 63% lower. The odds of achieving this same endpoint were 96% lower in subjects with a virus that had Q148 plus two or more secondary mutations compared to the response in those with no evidence of the Q148 mutation. Based on the clinical evidence and the current HIV guideline, the clinical pharmacy team recommends that his current regimen be changed to DTG twice daily plus RPV and Epzicom (ABC/3TC) once daily. However, the patient's preference is for a once daily regimen. Therefore, despite the team's recommendation, the patient continues on his current regimen of RPV plus Triumeq once daily. At this time, he remains virologically undetectable and immunologically above 900 cells/uL. Additionally, the team recommends to monitor VL and CD4 count more frequently, every 3 months, to ensure efficacy. (References for articles will be provided on the poster)

Poster Title: Evaluation of Cidofovir Use at an Academic Medical Center

Primary Author: Jennifer Wagner, MCPHS University - Boston, Massachusetts; **Email:** jwagn1@stu.mcphs.edu

Additional Author (s):
Christopher McCoy
Carolyn Alonso
Monica Mahoney

Purpose: Cidofovir is an antiviral FDA approved for the treatment of cytomegalovirus (CMV) retinitis, but also has in vitro activity against adenovirus and BK virus. Over the past few years, cidofovir use has increased at our institution. The main purpose of the study was to determine the indications for cidofovir use at BIDMC. Secondary objectives were to quantify doses used and safety parameters.

Methods: The Institutional Review Board approved this retrospective review. Patients receiving cidofovir from January 1, 2008 through December 31, 2015 were identified via pharmacy databases. All patients who received cidofovir were included, regardless of dose or route. Patients were included multiple times if they received cidofovir on subsequent admissions. Data gathered included: cidofovir indication and dose received, viral levels, patient co-morbidities, and concomitant therapy.

Results: Thirty patients were included: 26 (86.7 percent) were male, with an average age of 55 years. All patients were immunocompromised: 18 (60 percent) stem cell transplantation, 10 (33.3 percent) solid organ transplantation, and 2 (6.7 percent) HIV patients. Cidofovir was prescribed for BK virus in 16 (53.3 percent) patients, adenovirus in 10 (33.3 percent) patients, and CMV in 4 (13.3 percent) patients. Intravenous (IV) therapy was used for all adenovirus and CMV indications. For BK virus, 7 (43.8 percent) patients received IV therapy and 9 (56.3 percent) received intravesicular therapy. Probenecid was co-administered in 16/21 (76.2 percent) of patients receiving IV therapy. Cidofovir dosing varied among indications. For CMV, 5 mg/kg weekly was most common (n equals 4). For adenovirus, 5 mg/kg weekly was most common (n equals 4), followed by 0.5 mg/kg thrice weekly (n equals 3). BK virus dosing widely varied: for IV

therapy, 3 patients received 0.5 mg/kg weekly and 2 patients received 5 mg/kg weekly. For intravesicular therapy, most patients received 5 mg/kg (n equals 6) with different re-dosing intervals. Twenty-one patients (70 percent) had 22 documented adverse reactions: proteinuria (n equals 8), nephrotoxicity (n equals8), and rash (n equals 2) were most common.

Conclusion: The most frequent indication for cidofovir therapy was for BK virus. Cidofovir doses and intervals were highly variable among the cohort. A cidofovir utilization guide would help standardize doses and therapy.

Poster Title: The role of a diabetes blog for patient education

Primary Author: Ellie Kang, MCPHS University - Boston, Massachusetts; **Email:**
ekang1@stu.mcphs.edu

Additional Author (s):
Jennifer Goldman

Purpose: This abstract will describe the role of a blog in patient education in relation to diabetes. A pharmacist's role far exceeds just verifying prescriptions and making phone calls. One of many big impacts a pharmacist can make is providing education to patients about not only their medications but their acute or chronic conditions; one of which is diabetes. Blogs are an accessible resource for a majority of patients. Given the growing incidences of patients diagnosed with diabetes, this project serves to be a resource for patients to better understand the many components that come with having diabetes.

Methods: Under the supervision of their preceptor, students were instructed to compose a blog entry in relation to diabetes. These blog entries were written at an 8th grade level to address any potential barriers with literacy for the varying population. Students conducted research on their topic and compiled a list of resources to analyze. Students would submit the blog entry to preceptor for further review for accuracy, proper referencing and content. Blog entry would be submitted for potential publishing to provide easily accessible information to patients about potential concerns that arise with having diabetes.

Results: A diabetes blog entry is posted on a diabetes-focused blog for easy patient access. It provides information to the general public about diabetes as a whole and the various concerns a patient face, especially when first diagnosed. This includes information about potential vitamin B12 deficiency with metformin, importance of checking blood sugar levels, or considerations for when patients are sick and have diabetes. Diabetes and its management are always changing; there is consistently a need to educate our patients about the changes that arise. This blog provides easy-to-access and easy-to-read guides for patients to understand their diabetes.

Conclusion: This blog serves to further educate our patients with the knowledge from current and future pharmacists about the varying matters of diabetes. It also serves as a tool for providers to direct patient to resources that can help them further understand their conditions.

Submission Category: Cardiology/ Anticoagulation

Submission Type: Case Report

Session-Board Number: 3-211

Poster Title: Anticoagulation in the setting of antithrombin iii deficiency, antiphospholipid syndrome, recurrent DVTs/PEs, and neoplasm (in remission): a case report

Primary Author: Amit Hirani, MCPHS University - Boston, Massachusetts; **Email:** amit.hirani@outlook.com

Additional Author (s):
Chioma Aigbedo
Katelyn Gilman
Ricky Thumar

Purpose: This case report describes the outpatient use of warfarin in a 53 year-old African American male for the management of antithrombin iii (AT3) deficiency, antiphospholipid syndrome (APS), and history of neoplasm (in remission) and recurrent DVTs/PEs. Each of these pathophysiologies independently increases a patient's risk for future thromboembolic events. There is limited evidence to guide clinical decision-making in a patient with all of the aforementioned co-morbidities. This report adds to the body of literature suggesting difficulty with maintaining a patient's INR in therapeutic range. It also illustrates the complexity in managing multiple hypercoagulable states in a single patient. As the healthcare team progressively managed his anticoagulation therapy, additional barriers were discovered and will be discussed.

Upon inheriting this patient from a different health center, it was discovered that his documented INR goal was 3.0 - 4.0. Upon reviewing available literature, the clinical pharmacy team inquired as to the appropriateness of this goal as opposed to 2.5-3.5 or 2.0-3.0, which is what much of the available literature seems to favor based on outcomes and bleeding episodes. It remains unclear as to the rationale for this higher goal range as the patient's previous cardiologist was not open to changing the goal but did not provide his reasoning despite multiple inquiries. The patient's new primary care provider agreed with the clinical pharmacy team's literature review but opted to proceed as the cardiologist advised. All interactions were noted in the patient's electronic health record.

After reviewing the patient's INR results dating back to 2006, it was found that his Time in Therapeutic Range (TTR) was 28 percent. Literature suggests warfarin use is associated with an average TTR of 60 percent. Numerous barriers were found to impact the patient's compliance

and the medication's efficacy. First, the INR results may fluctuate simply due to the nature of his co-morbidities. The patient also has mental health disparities along with a history of alcohol and substance abuse. His financial and living situations are variable and he is a poor historian. The patient is however very consistent with getting regular and timely INR checks when prompted. Though the care team has benefitted from the patient's frequency and regularity of INR checks, it did not translate to clinical success as demonstrated by the relatively low TTR. Furthermore, communication gaps within the healthcare team along with intermittently suboptimal documentation of patient encounters led to confusion about the patient's comprehensive care plan.

Some literature suggests the use of low-dose vitamin K therapy in conjunction with warfarin can stabilize a fluctuating INR. As such, the care team decided to trial a 100mcg daily dose with the patient's warfarin in the fall of 2015. Early on, the concomitant use seemed to stabilize the patient's INR well. However, cost, access, patient understanding/education, and poor communication within the healthcare team were the likely culprits for the combination's ultimate loss-to-follow-up and subsequent discontinuation.

Today, the patient remains on warfarin with the same INR goal of 3.0-4.0. Genetic testing is not available for this patient to determine any possible pre-disposition to an impaired warfarin response. There are no data to guide use of any of the direct oral anticoagulants (DOACs) in this type of patient and so outpatient management options are understandably limited. A core improvement area that has been determined through caring for this patient relates to optimizing communications within and across the healthcare team while enhancing documentation efforts with regard to patient interactions. While changes in concurrent medications, co-morbidities, and adherence patterns affect anticoagulation in a relatively predictable way, it remains apparent that intra-individual responses to warfarin cannot always be explained.

Poster Title: Challenge of argatroban monitoring in a critically ill patient with liver failure

Primary Author: Akshar Patel, MCPHS University - Boston, Massachusetts; **Email:** apate3@stu.mcphs.edu

Additional Author (s):
Oussayma Moukhachen

Purpose: JC is a 77 year old man, with ischemic cardiomyopathy with a left ventricular ejection fraction of 25%, atrial fibrillation on apixaban, diabetes mellitus type 2, and hypertension who was admitted intensive care unit with a clinical diagnosis of shock and multi-organ failure: lung, liver, heart and kidneys. His Initial work up has suggested shock with unclear etiology of cardiogenic shock secondary to either a pulmonary embolism, or heart failure or septic shock secondary to pneumonia. His acute kidney injury required continuous veno- venous hemofiltration; and he was supported with an intra-aortic balloon pump. Given suspicion of pulmonary embolism, heparin continuous infusion was started. On day 3 of heparin infusion, his platelets suddenly dropped from 108,000 cells/mm3 to 36,000 cells/mm3. Heparin induced thrombocytopenia (HIT) was suspected and Argatroban infusion was started at a rate of 0.5mcg/kg/min given his liver failure and critical illness. His activated partial thromboplastin time (aPTT) was 32.7 seconds prior to start of the Argatroban infusion. 16 hours into the infusion, one of the aPTT drawn showed an aPTT of 104.7 seconds; accordingly, the infusion was stopped. It took 48 hours for the aPTT to drop to 70.5 seconds and another 24hrs for the aPTT to drop to 48.8 seconds. HIT work-up returned negative, Argatroban order was stopped and the patient was resumed on heparin.

Argatroban is a direct, highly selective thrombin inhibitor. It reversibly binds to the active thrombin site of free and clot-associated thrombin. It inhibits fibrin formation, platelet aggregation, and activation of coagulation factors V, VIII, XIII, and protein C. It is hepatically metabolized via hydroxylation and aromatization as a major pathway and via Cytochrome P450 isoenzyme 3A4 as a minor pathway. The elimination half-life of about 39-51 minutes is extended to 181 minutes in hepatically impaired patients. Similarly, clearance decreases to 1.9ml/kg/min in hepatic impairment from 5.1 ml/kg/min for normal individuals. Even though patient may not be at steady state, it is recommended to check aPTT 2 hours after start of therapy to adjust dose to a target steady state aPTT of 1.5-3 times the initial baseline value

without exceeding 100 seconds. Managing Argatroban or other anticoagulants in patients with liver dysfunction is a certain challenge as seen in JC's case. Liver dysfunction alters the pharmacokinetics of the drugs, and prolongs aPTT values. This poses a challenge when determining a patient's therapeutic range because the elevated aPTT level could be due to the patient's Argatroban treatment or the liver dysfunction.

Currently, package insert and tertiary dosing references recommend a starting dose of 0.5mcg/kg/min. A case report describes a dose of 0.05mcg/kg/min to maintain stable therapeutic aPTT. Hence, our suggestion, based on our experience with JC, is to initiate Argatroban infusion at 0.05mcg/kg/min in critically ill patients with liver impairment and to monitor closely every 2hours and adjust dose as necessary. Further research needs to be conducted with anticoagulation therapy, especially with patients who display liver dysfunction to help clinicians optimize therapy and minimize side effects.

Poster Title: Process evaluation of 4-factor prothrombin complex concentrate versus fresh frozen plasma for acute warfarin reversal

Primary Author: Maria Stratton, MCPHS University (Massachusetts College of Pharmacy and Health Sciences University), Massachusetts; **Email:** mstra1@stu.mcphs.edu

Additional Author (s):
Philip Grgurich

Purpose: Therapeutic options for rapid reversal of vitamin k antagonist (VKA) therapy include 4-factor prothrombin complex concentrate (PCC4) and fresh frozen plasma (FFP). These agents have unique requirements for preparation, potential adverse effects, and cost-effectiveness considerations. . To ensure appropriate use and timely administration of PCC4, we optimized the ordering and dispensing process at our institution to require approval of a blood bank attending physician and preparation in the pharmacy sterile products area. We hypothesized this process change would facilitate timely VKA reversal agent administration versus FFP.

Methods: This retrospective, single center study was approved by the institutional review board and informed consent was waived. Data were gathered for patients requiring VKA reversal for life-threatening bleeding or urgent procedures from 4/2015-6/2016. Data include: demographics, laboratory results, indications for VKA therapy and reversal, dosing, time of ordering and administration, use of phytonadione, INR values and adverse events. We primarily assessed time from ordering of reversal agent (PCC4 or FFP) to administration, measured at time of initiation and completion of infusion.

Results: 258 patients were identified and screened for inclusion. Of 90 patients included, 72 received FFP and 18 got PCC4. 77.8% were taking VKA therapy for atrial fibrillation. VKA reversal was indicated for life threatening bleeding in 50% and 77% of FFP and PCC4 patients, respectively (p=0.03). The mean time from ordering to administration for FFP and PCC4 was 100 and 50.2 minutes, respectively (p=0.004). Mean time from ordering to end of infusion was significantly shorter for PCC4 than FFP (60 vs. 171 minutes, respectively) (p=0.0001). Data was analysis was performed using Minitab Express™.

Conclusion: In routine clinical management of patients requiring acute warfarin reversal, PCC4 was associated with faster infusion initiation and completion as compared to FFP.

Poster Title: Use of continuous venovenous hemodiafiltration in critically ill patients receiving high-dose aminoglycoside therapy for the treatment of multi-drug resistant organisms

Primary Author: Mickayla Clark, MCPHS University (Worcester Campus), Massachusetts; **Email:** mickaylaclark@yahoo.com

Additional Author (s):
Candice Bautista
Jayne Lepage

Purpose: Aminoglycosides are potent antibiotics that are used to treat various infections. One limitation associated with their use is nephrotoxicity, which is more frequently seen in critically ill patients due to the presence of certain risk factors for aminoglycoside-induced nephrotoxicity. As resistance to antibiotics is a growing concern, it is imperative that new methods to treat multi-drug resistant (MDR) organisms be considered. A recent study has shown that utilizing continuous venovenous hemodiafiltration (CVVHDF) in combination with high-dose aminoglycoside therapy in critically ill patients when treating MDR organisms is effective in eliminating organisms refractory to other treatments without causing nephrotoxicity.

Methods: An analysis of a study was conducted involving critically ill adults with sepsis or septic shock being considered for treatment if an infection with a gram-negative organism exhibited resistance to beta-lactam antibiotics and combination therapy, but was susceptible to aminoglycosides. Samples were taken from each patient in order to determine susceptibility and the minimum inhibitory concentration (MIC) of the organism. The patients were administered a high-dose aminoglycoside followed by CVVHDF once the peak concentration (Cpeak) of the aminoglycoside was reached and left on CVVHDF until the end of their treatment. Patients that were already receiving continuous renal replacement therapy (CRRT) when treatment began were converted (if not already receiving) to CVVHDF. Amikacin was administered as a loading dose of 25-30 mg/kg and both tobramycin and gentamicin were administered as an 8-10 mg/kg loading dose. The goal Cpeak/MIC was 8-12. If a patient fell below this level, their dose was increased and if they were above this level, their dose was

decreased. The primary endpoints were clinical efficacy, expressed as response or failure, and microbiological response, defined as eradication or failure.

Results: A total of fifteen critically ill patients were infected with a MDR organism that was refractory to other treatments. The mean age was 61 years and the majority of the patients were male. Four of the patients had sepsis, eleven had septic shock, twelve were mechanically ventilated, and six were receiving CRRT at the start of therapy. Eleven patients received amikacin, three received gentamicin, and one received tobramycin. Doses were adjusted, if necessary, based on the patient's Cpeak/MIC ratio. A clinical response was observed in eight of the fifteen patients, with three of these patients achieving eradication of the offending organism. Six of the eight patients were transferred out of the ICU. Post transfer, the renal function of all patients was assessed. It was seen that one patient who was already dependent on CRRT remained on CRRT and only one of the other patients had a decline in renal function, but did not require CRRT. Five of these six patients were discharged from the hospital. Although the data shows most of these observations to be statistically insignificant, these outcomes are clinically significant in that these patients had failed all other possible treatments and this was used as salvage therapy.

Conclusion: Aminoglycosides are potent antibiotics, however, they are associated with nephrotoxicity, which is more commonly seen in critically ill patients. The risk for nephrotoxicity also increases as the dose increases, which can be problematic as aminoglycosides' bactericidal effects are concentration-dependent. This study provides insight into the use of high-dose aminoglycosides in combination with CVVHDF and shows promise in the treatment of MDR organisms refractory to conventional treatments in critically ill patients. However, since the sample size was so small, larger studies should be performed in order to further investigate the safety and efficacy of this novel treatment method.

Poster Title: Not getting enough sleep may raise your blood sugars: the development of an informational blog for patients and clinicians

Primary Author: Calvin Nguyen, MCPHS University Boston, Massachusetts; **Email:** calvinnguyen93@yahoo.com

Additional Author (s):
Jennifer Goldman

Purpose: The following abstract will describe the development of an online blog to further educate healthcare professionals as well as patients on the implications of their blood glucose and insulin resistance based on the amount of sleep they get. With exercise and good eating habits being the main front runners of living a healthy lifestyle for patients with diabetes, many people discard how important sleep is when taking care of themselves. This project reviewed what the effects of having less than an optimal amount of sleep are on glycemic control. It also reviewed sleep hygiene strategies.

Methods: Under the direction of a faculty member in an ambulatory care practice with a specialty in diabetes, research was done by a student regarding the effects of lack of sleep on insulin resistance. The data was then collected from multiple studies that tested these effects on people. A blog was then written about the impact of sub optimal sleep on glycemic control targeting education for patients and health care providers. After being revised for mistakes and worded for ideal patient understanding, it was then posted on a free to access online diabetes information website as well as on the practice's website. Ways to improve sleep hygiene was also researched and added in the blog so readers could utilize the information given and potentially increase their quality of sleep and improve glycemic control.

Results: An educational blog and poster was created in order to review the consequences of lack of sleep on insulin resistance and glycemic control. Studies show that getting four hours or less of sleep has a negative impact on insulin resistance, which results in hyperglycemia. Results showed that a healthy patient's insulin resistance lacking sleep was similar to that of a patient with diabetes on a normal night's sleep. These study results were explained on the blog, along with methods to get a full night's rest and education on sleep hygiene.

Conclusion: This poster outlines the online post regarding adequate sleep and insulin resistance. It hopes to educate both health care professionals as well as patients on how important it is to get a full night's sleep, as well as the consequences of losing sleep. It is a useful resource that is easily accessible for patients. This educates on other factors involved with improved glycemic control in addition to medications, healthy eating habits and daily exercise.

Submission Type: Case Report

Session-Board Number: 3-216

Poster Title: Role of amitriptyline in irritable bowel syndrome with ulcerative colitis

Primary Author: Kendalyn Thompson, MCPHS University Boston, Massachusetts; **Email:** kthom1@stu.mcphs.edu

Additional Author (s):
Susan Krikorian
Nidhi Nivarthi

Purpose: A 45 year-old Caucasian female with a past medical history of ulcerative colitis (UC) presented to our community teaching hospital emergency room after a bout of excruciating abdominal pain, reporting she was no longer able to tolerate food intake. Prior to admission she underwent a barium study that revealed rapid transit time of 15 minutes in her gastrointestinal tract and an upper endoscopy that was unremarkable. No clear diagnosis was made. Her history is significant for a twenty-pound weight loss in the past two months and bouts of epigastric discomfort consisting of severe sharp abdominal pain that lasted four to five hours after eating and included nausea and vomiting. During the last six to eight months, she has also experienced intermittent episodes of diarrhea, passing undigested food in her stool. Two days prior to admission she was prescribed ondansetron and OxyContin™ by her gastroenterologist. She was also taking maintenance dose mesalamine (Delzicol DR). During this admission, the patient was diagnosed with irritable bowel syndrome (IBS). In the absence of an objective biomarker for diagnosing IBS-type symptoms, the diagnosis of IBS was symptom-based in our patient. The antispasmodic, dicylcomine twenty milligrams four times daily, and the antidepressant, amitriptyline, were prescribed for IBS. Amitriptyline is effective in diarrhea dominant IBS. She was prescribed amitriptyline ten milligrams once, then the directions were changed to ten milligrams three times daily as needed. During her three day stay she only took one more dose. Subsequently, amitriptyline was discontinued. The pharmacy team was able to intervene and note to the medical team, the amitriptyline dosing strategy that has been studied is scheduled nightly, not as needed, with a statistical difference in symptoms seen approximately six to eight weeks after initiation for the treatment of diarrhea associated with IBS. The patient presented in this case is unique compared to previous case studies examining the use of amitriptyline for IBS, as this patient has a past medical history of UC. She was subsequently readmitted to the hospital for continued symptoms and inadequate nutrition one

week after hospital discharge. This patient's suboptimal therapy demonstrates the importance of utilizing evidence-based medicine (EBM). The rationale for all treatment should be well understood before administration to a patient. Inappropriate dosing of amitriptyline in the management of IBS may have affected the patient's response to therapy and outcome. This could lead to an incorrect assessment of treatment failure. Additionally, this case report provides a new perspective of using tricyclic antidepressants to treat IBS in patients with UC. The importance of EBM is emphasized in this case report and adherence to the strategies of determining the best treatment for a patient should be utilized prudently. Pharmacists have an important role in implementing EBM to help prescribers make an informed decision and improve patient outcomes.

Poster Title: Evaluating the evolution of pharmacists' role as accessible and key immunizers and their expanding impact on public health in the United States

Primary Author: Nisha Joseph, MCPHS University Boston, Massachusetts; **Email:** njose1@stu.mcphs.edu

Additional Author (s):
Anusha Sekhar
Catherine Taglieri

Purpose: Immunizations in the United States have been one of the primary achievements in public health and have led to the eradication and reduction of numerous disease epidemics. The profession of pharmacy has experienced significant change since the development of the first vaccinations, and as a result, pharmacists have taken on a more clinical role to become further involved in the delivery of immunizations. The clinical roles acquired by pharmacists can have a significant impact on the availability, rates, and patient education on immunizations, which in turn can lead to better public health outcomes.

Methods: In order to determine the impact of the evolving role of pharmacists on vaccinations in the United States, an online literature review was conducted to identify sources that evaluated the growing profession. Clinical studies, surveys, news articles, textbooks, and other sources of media were reviewed that described the history of the profession of pharmacy, key points in the timeline of the development of vaccines, as well as the current expanding role of pharmacists as immunizers. The progression of the required degrees to practice pharmacy was also assessed through these sources in order to support the notion of clinical responsibility advancements within the profession. The relevance of vaccines has been analyzed through data across the country in regards to improving the health of the population.

Results: The first discovery of a live vaccine against smallpox was by Edward Jenner in 1798. During this time, apothecaries were primarily responsible for compounding and distributing medications to physicians and patients. By the mid 1800s they expanded their role through aiding in the distribution of smallpox vaccines that extended into the 20th century. The late 1800s showed a shift in pharmacy education requirements, which included mandatory

examinations and registration to practice. A four-year Bachelor of Science Degree was mandated by 1923 and increased to five years in 1960, although pharmacists were only permitted to dispense medications without any counseling. The establishment of pharmacists as immunizers began in 1993 followed by the implementation of the Doctor of Pharmacy degree in 2005. Immunization training programs were incorporated by 1999 into schools of pharmacy. Since then, pharmacists are able to administer various vaccines, such as influenza and pneumonia, in all 50 states. With this integral role as health care providers, they have increased immunization rates by about 20 percent throughout the decade, which in return can decrease the predicted 90,000 vaccine preventable deaths per year. The convenience and knowledge that pharmacists can provide will help achieve the Health People goal of 2020.

Conclusion: The evolution of the profession of pharmacy has had a substantial impact on the delivery and availability of immunizations. From apothecary, to druggists, to now clinically advanced professionals who are key players in immunization administration and education, pharmacists have transformed the profession to have a greater impact on public health. These advancements leave hope that there is still room for exponential growth in the profession within the next few decades.

Submission Category: General Clinical Practice

Submission Type: Evaluative Study

Session-Board Number: 3-218

Poster Title: Validation of a medication adherence assessment tool in heart failure patients

Primary Author: Muneerah Aleissa, MCPHS University- Boston, Massachusetts; **Email:** malei1@stu.mcphs.edu

Additional Author (s):
Danielle Carter
Stevens Craig
Lina Matta
Judy Cheng

Purpose: Heart failure (HF) is a leading cause of hospitalization in the US. Medication adherence is a vital component in heart failure management, as poor medication adherence is associated with a higher risk of hospital re-admission. The 8-item Morisky Medication Adherence Scale (MMAS-8) is a simple and efficient method to evaluate medication adherence at bedside. While the MMAS-8 has been validated in many disease states, its use has not been fully evaluated in HF population. The purpose of this pilot study was to evaluate the psychometric properties of MMAS-8 in HF patients presenting to HF ambulatory infusion treatment and education center.

Methods: Over a 4 month period, patients were invited to participate in the study if they were 18 years or older, on a loop diuretic for heart failure management, and are able to self-manage medications at home. Subjects who provided a verbal informed consent were administered MMAS-8 questionnaire to assess his or her medication adherence. A total medication adherence score of all items was calculated, ranging from 0 to 8. The MMAS-8 scores correlate to the following three levels of adherence: high adherence (scores equals 8), medium adherence (scores between 6 to less than 8), and low adherence (scores less than 6). Additionally, the loop diuretic was used as the index medication for calculating medication possession ratio, which ranges from 0 to 1, with 1 corresponding to 100% adherence. Internal validity was assessed using Cronbach's alpha coefficient. An alpha of 0.7 or greater indicates an acceptable internal validity. Additionally, convergent validity was evaluated using Spearman's coefficient to assess the correlation between MMAS-8 scores and the medication possession ratio. Correlation coefficients less than 0.50 are considered to be low, while correlation

coefficients between 0.50 to 0.7 are moderate, and correlation coefficients greater than 0.70 are high. This project was approved by the Institutional Review Board.

Results: Twenty-seven patients were included in the study. The mean age of the subjects was 73.2 years (standard deviation equals 8.3), and 70.4 percent were male. Fifteen had high adherence, 9 had moderate adherence, and 3 had low adherence with a mean score of 7.17 (standard deviation equals 1.36). Strong internal consistency was found (Cronbach's alpha equals 0.71), and convergent validity was moderate (Spearman's coefficient equals 0.54; P equals 0.00397). The MMAS-8 sensitivity, specificity, positive and negative predictive values were 60.87 percent, 75 percent, 93 percent, and 25 percent respectively.

Conclusion: Psychometric analyses indicated that MMAS-8 has acceptable internal validity and moderate convergent validity when used to evaluate medication in adherence in the HF population. Therefore, MMAS-8 can be an appropriate way of measuring medication adherence in HF patients given its ease of use.

Poster Title: Bone mineral density adverse effects of tenofovir disoproxil fumarate/emtricitabine HIV pre-exposure prophylaxis and their reversibility after discontinuation of therapy

Primary Author: Jamie Nguyen, MCPHS University Boston (Massachusetts College of Pharmacy and Health Sciences), Massachusetts; **Email:** jnguy1@stu.mcphs.edu

Additional Author (s):
Anela Stanic

Purpose: Truvada (tenofovir disoproxil fumarate/emtricitabine) is the only FDA-approved medication for HIV pre-exposure prophylaxis (PrEP) in combination with safer sexual practices in the United States. Bone mineral density (BMD) decreases have been reported in individuals receiving tenofovir disoproxil fumarate (TDF) products for HIV PrEP due to alterations in gene expression. However, limited research evaluated reversibility of decreases in BMD and increasing numbers of young, healthy individuals are being prescribed PrEP. Thus, we conducted a literature search aimed to review studies which assessed this adverse effect, its risk factors, and reversibility after TDF product is discontinued in the setting of HIV PrEP.

Methods: PubMed and Ovid databases were searched using different synonyms of tenofovir, bone mineral density, reversibility, HIV PrEP, and Truvada. Additional abstract and presentation searches were conducted through the Conference on Retroviruses and Opportunistic Infections and the International AIDS conference using the same synonyms as above. As we limited our search to BMD adverse effects of HIV PrEP therapy, we included only studies with HIV-negative participants. Our search was also limited to papers written in English. A total of three studies were identified that met criteria for review. Two of the studies discussed BMD loss with tenofovir disoproxil fumarate/emtricitabine (TDF/FTC) for HIV PrEP, while one of the studies discussed BMD loss with TDF alone. One study had an extended follow-up that specifically assessed reversibility of BMD loss from TDF/FTC after HIV PrEP therapy discontinuation. One study that investigated TDF/FTC and the study that investigated oral TDF for HIV PrEP did not assess reversibility of BMD loss. Studies were conducted multinationally, in San Francisco, California, and in Botswana.

Results: The three randomized, placebo-controlled clinical trials assessed 902 (498, 184, and 220) subjects. Median age ranged from 18 to 60 years; therapy duration was 0.5, 2 and 2.5 years. Significant BMD loss was defined as more than 3% from baseline. More subjects on TDF experienced significant spinal or hip BMD loss compared to placebo. Net differences included -0.91%(95%CI -1.44,-0.38, P=0.001), -0.7%(95%CI -1.3,-0.3, P=0.003), and -1.62%(95%CI -2.46,-0.78, P < 0.001) in the spine and -0.61%(95%CI -0.96,-0.27, P=0.001), -0.8%(95%CI -1.3,-0.3, P=0.003), and -1.51%(95%CI -2.49,-0.54, P=0.003) in the hip, respectively. Low BMD was associated with recreational drugs, vitamin D deficiency, and genetic factors. Amphetamine and inhalant use was associated with low baseline BMD in one study. One study found that low BMD was associated with increased blood urea nitrogen, high alkaline phosphatase, and decreased creatinine clearance. TDF metabolite plasma levels showed significant inverse relationship with spine and hip BMD changes in two studies. Subjects taking calcium and vitamin D reported less BMD loss. Ninety six trauma-related fractures were deemed not related to TDF. The extended follow-up of one study assessed reversibility within 24 weeks after HIV PrEP discontinuation; spine and hip BMD loss reversed at annualized rate of 1.13%(⊡0.27, p=0.002) and 1.81%(⊡0.36, p=0.01), respectively.

Conclusion: Several studies have found a link between BMD loss and TDF when prescribed for HIV PrEP. BMD loss was reported in the hip and spine and patient demographic factors were associated with the extent of the BMD loss as well as with its reversibility once TDF was discontinued. Longer TDF exposure was associated with slower reversibility of BMD loss. Patient demographics as well as the length of time on TDF varied across the studies thus possibly contributing to difference in rate of BMD loss. More long-term follow-up and data on reversibility of BMD loss after prolonged TDF exposure is needed.

Poster Title: Cost reduction strategy to replace regadenoson as a pharmacologic cardiac stress agent

Primary Author: Anthony Villanova, MCPHS University Worcester, Massachusetts; **Email:** anthony.villanova@me.com

Additional Author (s):
John Vlahopoulos
Shanti Maheshwari
Jennifer Raltz

Purpose: Yankee Alliance, a national GPO (group purchasing organization), identified high spend among member institutions for Lexiscan (registered trademark) (regadenoson) during 2016's fiscal year. The purpose of this study is to identify cost savings through consideration of other alternative pharmacologic cardiac stress agents while maintaining clinical and diagnostic efficacy and safety.

Methods: A review of member data identified that Yankee Alliance members were spending approximately 6.5 million dollars on Lexiscan (registered trademark) (regadenoson) during fiscal 2016. The American Society of Nuclear Cardiology (ASNC) lists three drugs as first-line agents for myocardial perfusion imaging: Lexiscan (registered trademark) (regadenoson), dipyridamole, and adenosine; no agent is noted as preferred. A literature search was performed, yielding 12 results to determine differences between their efficacy and safety. These results combined with the ASNC Guidelines on SPECT imaging, medication package inserts, and public drug price figures from Lexicomp Online Database were reviewed. These references were relevant to determine the comparative efficacy and safety of Lexiscan (registered trademark) (regadenoson), dipyridamole, and adenosine.

Results: A cost analysis was performed to determine approximately 5.7 million dollars or 4.3 million dollars in potential savings from switching from Lexiscan (registered trademark) (regadenoson) to dipyridamole or adenosine, respectively. Published data show equivalent clinical and diagnostic efficacy when using these three drugs. Safety data between the three differ, but when proper precautions are taken for at-risk patient populations like COPD and

asthmatics, all have similar incidence and types of adverse events with no agents showing overall superiority.

Conclusion: Dipyridamole and adenosine are safe, effective, and cost-saving alternatives for Lexiscan (registered trademark) (regadenoson) for use as pharmacologic stress agents in myocardial perfusion imaging.

Poster Title: An evaluation of the frequency of prescribing concomitant benzodiazepines and opioids in geriatric patients upon hospital discharge.

Primary Author: Raymond Melika, MCPHS UNIVERSITY, Boston, MA, Massachusetts; **Email:** m0165615@stu.mcphs.edu

Additional Author (s):
Jessica Andrade
Michael Angelini
Kenneth Eugenio

Purpose: Benzodiazepines and opioids are both commonly used in hospitalized patients to help manage a variety of acute illnesses. However, concomitant therapy is not without risks and official product labeling was recently updated to require a black box warning about the combination. Opioids have been shown to induce respiratory depression with an increased risk when used with a benzodiazepine. A variety of untoward events may result from the combination, especially if patients are discharged on the duo to an unmonitored setting. The purpose of this study was to evaluate co-prescribing patterns of these drug classes to geriatric patients at discharge.

Methods: An institutional review board waiver was obtained for completion of this retrospective review in a 350 bed community hospital. Demographics recorded included patient age and gender. Hospital information collected included dates of hospitalization, underlying pulmonary conditions, discharge disposition, and specific benzodiazepine and opioid medications prescribed at discharge. Records were included if patients were > 65 years of age, and included at least one benzodiazepine and one opioid prescribed concomitantly while in the hospital. For patients admitted more than once, only data from the first admission were counted. Information was collected on all patients fitting this criteria and admitted between January 1st and March 31st, 2016. Information was recorded ensuring patient anonymity using Microsoft Excel and descriptive statistics were applied to the data.

Results: There were 141 patients that met the inclusion criteria; 63 males (44.7%) and 78 (55.3%) females. The average age of patients included was 76.6 years (range: 66-101) and 51/141 (36.2%) had a persistent baseline condition compromising pulmonary function. Of the study population, 60/141 patients (42.6%) were discharged on a benzodiazepine and opioid combination. Of patients discharged on the combination, 27/60 (45%) also had a persistent pulmonary condition. Those discharged to home or self care represented 27/60 (45%) of the population discharged on the combination. The benzodiazepine most frequently prescribed was lorazepam and oxycodone was the most frequently prescribed opioid.

Conclusion: While adverse events were not evaluated, this review found that geriatric patients are routinely being discharged on concomitant benzodiazepine and opioid therapy. In addition, almost half of these patients had compromised pulmonary function due to underlying pathology. These patients are at risk for a broad sequelae of adverse events, including respiratory depression, falls, mental status changes, and hospital re-admissions. These adverse effects may be especially harmful in patients being discharged to settings without direct healthcare provider oversight. Staff education about the risks of concomitant therapy and procedural safeguards should be evaluated to help keep patients safe.

Session-Board Number: 3-222

Poster Title: Instructions for administering brand and generic naloxone: Are they easy to follow?

Primary Author: Afeefa Bhatti, MCPHS University, School of Pharmacy – Worcester/Manchester, Massachusetts; **Email:** abhat1@stu.mcphs.edu

Additional Author (s):
Bridgette Tran
Monina Lahoz

Purpose: In 2014, opioid overdose deaths nationwide totaled nearly 14,000. To deal with the crisis, 34 states have authorized pharmacies to dispense a rescue medication (generic naloxone or Narcan®) without a prescription under a standing order, along with printed instructions on how to administer it, which are also available online. There is limited research regarding the ease of use of these instructions by the public. When print material is written at a grade reading level higher than 7th grade, reader comprehension is compromised. This study aims to assess the readability, understandability, and actionability of naloxone instructional materials.

Methods: Three naloxone instructional materials were downloaded from the websites of a state government (SG), a pharmaceutical company (PC), and a non-profit organization (NPO). The three authors assessed these written materials for the following: (1) readability, using the Fry Readability Formula, (2) understandability, using the Patient Education Materials Assessment Tool for Printable Materials (PEMAT-P), and (3) actionability, using the PEMAT-P. The Fry Readability Formula assigns a reading difficulty level based on vocabulary and sentence structure. The average numbers of sentences and of syllables per 100 words are plotted on the Fry Readability Graph. Longer sentences and words yield higher grade reading levels. The PEMAT-P is a validated instrument that helps determine whether readers will be able to understand and act on written materials. It yields two percentage scores, one for understandability and one for actionability. The higher the percentage score, the more understandable or actionable the written material. Understandability is assessed using 17 items in 6 categories: Content, Word Choice/Style, Use of Numbers, Organization, Layout/Design, and Visual Aids. Actionability is assessed using 7 items.

Results: The Fry readability results were 7th, 10th, and 17th+ grade reading level for the PC, SG, and NPO materials, respectively. The PEMAT-P understandability scores were 87.5%, 62.5%, and 50% for the PC, NPO, and SG materials, respectively. For the 6 understandability categories, the PC material achieved a score of 100% in Content, 100% in Word Choice/Style, 100% in Use of Numbers, 75% in Organization, 100% in Layout/Design, and 75% in Visual Aids. The NPO material achieved a score of 0% in Content, 0% in Word Choice/Style, 100% in Use of Numbers, 75% in Organization, 100% in Layout/Design, and 100% in Visual Aids. The SG material achieved a score of 0% in Content, 66% in Word Choice/Style, 100% in Use of Numbers, 100% in Organization, 0% in Layout/Design, and 0% in Visual Aids. The PEMAT-P actionability scores were 100%, 100%, and 80% for the PC, NPO, and SG materials, respectively.

Conclusion: Of the three naloxone instructional materials, the PC version had the best readability, understandability, and actionability scores, while the SG material had the worst scores. The three materials had high actionability percentage scores. However, all fell short of the 4th to 6th-grade reading level standard recommended by experts for readability of health care related materials. Reader comprehension is compromised when readability exceeds a 7th-grade reading level. The three naloxone instructional materials must be refined in order for the public to follow the instructions and administer naloxone effectively when responding to an opioid overdose.

Poster Title: DNA repair genes are suppressed in breast cancer treated with anastrozole relative to breast cancer treated with tamoxifen

Primary Author: Alwaleed Alharbi, MCPHS University-Worcester, Massachusetts; **Email:** wele9009@gmail.com

Additional Author (s):
Omar Alkhezi
George Acquaah-Mensah

Purpose: Regardless of race or ethnicity, breast cancer is ranked the most common type of cancer among women. Anastrozole, an aromatase inhibitor, and tamoxifen, a selective estrogen receptor modulator, have been widely used in treating breast cancer. Per National Comprehensive Cancer Network guidelines, anastrozole is considered the first line treatment in postmenopausal women, whereas tamoxifen goes second except in certain cases. Nonetheless, current practice does not depend on genetic information for drug selection. Thus, our research project was conducted to deeply investigate the effect of the two drugs on gene expression profiles in breast cancer.

Methods: The TCGA Assembler package was used to process genetic data of patients' samples obtained from The Cancer Genome Atlas (TCGA). For the analyses, samples from 109 and 137 patients treated with anastrozole and tamoxifen, respectively, were used. Gene expression profiles from the two groups were compared to each other to determine gene expression profile changes associated with each drug. Differentially expressed genes were examined for over-represented biological pathways (reactome.org).

Results: Relative to samples from patients treated with tamoxifen, samples from patients treated with anastrozole had suppressed expression of genes associated with DNA pairing and strand exchange. Further, genes such as FANCI, NELFCD and CDK13, which are associated with TP53 regulation of transcription of DNA repair genes were suppressed. Also, genes associated with signal transduction and cell cycle, such as ARHGAP11B, PSMD12, POGLUT1, PSMD12, BLM, and RPN2, were suppressed in the anastrozole-treated group.

Conclusion: Our results show the changes in gene expression profiles in breast cancer induced by anastrozole and tamoxifen treatments. Critical processes, such as DNA repair and cell cycle are affected differently. Thus, our study is a step towards understanding the molecular effects of adjunctive hormone therapy in breast cancer.

Poster Title: Proposal for pharmacist-led refill authorizations

Primary Author: Riza Usta, Northeastern University, Massachusetts; **Email:** usta.r@husky.neu.edu

Additional Author (s):
Nazmin Khalifa
Todd Brown

Purpose: The United States healthcare system has been marred by a disparity between healthcare costs and health quality. The nation's shortage of primary care physicians and subsequent discontinuity in patient care has contributed to the current problems in healthcare. Pharmacists' involvement in authorizing refill renewals for maintenance medications has shown to both improve management of chronic disease states and contribute to reduced healthcare costs. The purpose of this project was to advocate for implementation of pharmacist-led refill authorizations within community pharmacies.

Methods: A literature review of randomized control trials and retrospective cohort studies was performed to assess the impact of pharmacist-led refill authorizations. Studies conducted within community pharmacies and outpatient refill clinics were included for analysis. Primary endpoints of interest included cost-savings data, quality of disease management, physicians' time saved on refill authorizations and physician satisfaction with refill programs. A review of state legislatures was also performed to establish the legal permissibility of community pharmacists' involvement in patient care. Current limitations in implementing pharmacist-led refill services and solutions to overcome these limitations were identified as well.

Results: A 21-month study of a Navy Hospital showed a total 70,691-dollar savings for the 573 patients whose refills were managed by a pharmacist rather than a physician. Another 30-day study serving 32 patients in a pharmacist refill evaluation clinic calculated a 1,235-dollar cost-savings, amounting to 38.59 dollars saved per patient per month. Moreover, this study revealed that more drug-related problems were found, follow-ups were ordered, and medications were optimized when pharmacists authorized refills versus usual care. A Kaiser Permanente experiment demonstrated that pharmacist-led refill authorizations yielded a greater percentage

of patients with adequate medication monitoring compared to physician-led authorizations (49 percent versus 29 percent). This study also demonstrated that intervention physicians spent 17 minutes per day performing refill authorizations compared to 23 minutes in the usual care group. Furthermore, 80 percent of intervention physicians were very satisfied with their refill request duties compared to 27 percent of control physicians. As demonstrated in another refill evaluation clinic, physicians agreed with 99 percent of the refill renewal decisions made by pharmacists. Per legislative review, pharmacists may implement refill renewal services in retail pharmacies by establishing Collaborative Drug Therapy Management agreements with physicians.

Conclusion: Pharmacists have the ability to make a significant impact on healthcare through their involvement in authorizing refills for chronic medications in accordance with Collaborative Drug Therapy Management laws. A multitude of evidence demonstrates that pharmacist-led refill authorizations not only optimize patients' therapies, but also yield cost-savings. These programs also benefit physicians by allowing them time to better focus on more concerning patient cases. Hence, expanding pharmacists' role in authorizing prescription refills is the next reasonable step in resolving the shortcomings of our current healthcare system.

Poster Title: Impact of antibiotic use on chronic obstructive pulmonary disease (COPD) exacerbation readmission rates

Primary Author: Jennifer Hum, Northeastern University, Massachusetts; **Email:** hum.j@husky.neu.edu

Additional Author (s):
Cyrille Cornelio
Yestle Kim
Ann Phung
Kevin She

Purpose: COPD exacerbations requiring hospitalization increase morbidity, mortality, and health care costs. Antibiotics are one of the therapies frequently used in the management of COPD exacerbations. However, controversy remains as to whether or not antibiotics impact patient outcomes. This study evaluates their role in the management of COPD exacerbations in hospitalized patients and explores the impact that antibiotics have on 30-, 90-, 365-day readmission rate, length of stay, hospital mortality, and time to next exacerbation. The purpose of this study is to elucidate whether or not antibiotics impact clinical outcomes for patients requiring hospital admission for the management of COPD exacerbations.

Methods: This retrospective IRB-approved study assessed patients admitted to a 335-bed academic medical center between January 2008 and December 2014 for a COPD exacerbation. Patients were enrolled if they were at least 18 years-old and admitted to a non-intensive care unit. Study subjects were excluded if they had a co-diagnosis of pneumonia/influenza, lung disease or lung cancer/active malignancy, immunocompromised states, acute decompensated heart failure, were previously hospitalized within the preceding 90 days, transferred from an outside hospital, had code status of comfort measures only or expectation of death within 48 hours of admission, were pregnant/lactating, incarcerated, and/or had miscoded records. The primary outcome was the rate of 30-day readmission rate in those who did, and did not, receive antibiotic therapy during their admission. Secondary outcomes included 90- and 365-day readmission rates, hospital mortality, length of hospital stay, and time to next COPD exacerbation. Non-parametric data were analyzed using the Kruskal-Wallis or Chi-square tests.

Results: 305 patients met inclusion criteria. The included patients had an average age of 74 years, were predominantly of the female gender, were active smokers with an average Forced Expiratory Volume (FEV1) of 50 percent predicted, and had an average Charlson Comorbidity Index of 2. There was no difference in baseline characteristics between the two groups. Of those included, 73 percent (n equals 223) received antibiotics while 27 percent (n equals 82) did not. For the primary endpoint, no difference in 30-day readmission rate was detected between the two groups (12.6 percent versus 12.2 percent, P equals 0.9). Additionally, there was no statistical difference in 90 or 365-day readmission rates, nor was there a statistical difference in hospital mortality and length of stay. However, a nonsignificant trend toward delay in time to next exacerbation was noted.

Conclusion: According to these findings, antibiotics did not significantly impact readmission rates, inpatient mortality, hospital length of stay, or time to next COPD exacerbation. More research is recommended to comparatively assess the effectiveness of different antibiotic classes and further explore the relationship between antibiotic use and exacerbation recurrence. In addition, further investigation should be considered in order to determine the specific patient population that may most benefit from antimicrobial therapy as part of COPD exacerbation management.

Submission Type: Evaluative Study

Session-Board Number: 3-226

Poster Title: Incidence of neurotoxicity with cefepime versus piperacillin-tazobactam in renally impaired intensive care unit (ICU) patients

Primary Author: Lauren Reis, Northeastern University, Massachusetts; **Email:** reis.la@husky.neu.edu

Additional Author (s):
Anna Schegoleva

Purpose: Cefepime is often chosen as empiric therapy for concern of multidrug resistant gram negative pathogens. There is debate over associated rates of neurotoxicity versus other beta lactams, based on recent publications. Multiple providers in this institution have interpreted this to mean any use of cefepime may lead to neurotoxicity, and, therefore, request piperacillin-tazobactam for high risk patients. This study was conducted to identify and describe the relative incidence of neurotoxicity with use of cefepime versus piperacillin-tazobactam in patients with impaired renal function in the intensive care unit (ICU) at a large university affiliated tertiary care medical center.

Methods: As a quality assurance investigation, institutional review board approval was waived. A retrospective chart review of 40 adult ICU inpatients with a creatinine clearance less than 60 milliliters per minute consecutively treated with either cefepime (n equals 20) or piperacillin-tazobactam (n equals 20) intravenous for at least 72 hours between June 2016 and August 2016 was performed. Patients were identified from the computerized prescriber order entry (CPOE) database and medical records were reviewed to establish and compare baseline characteristics. The initial dose of each therapy was reviewed to determine whether it was appropriately optimized for weight, estimated renal function, and site of infection. To assess for drug related neurotoxicity, any reports of altered mental status (AMS) or new onset seizures were reviewed during the course of therapy. Additionally, if performed, the confusion assessment method (CAM-ICU) score was recorded to assess delirium. The primary outcome was the relative incidence of new onset drug related neurotoxicity between cefepime and piperacillin-tazobactam. The secondary outcomes were risk factors for neurotoxicity other than the primary antibiotic, and the number of patients appropriately dosed for their renal function, weight, and site of infection.

Results: Patients were evenly matched except patients in the cefepime group had an average age of 78 versus 68 years in the piperacillin-tazobactam group (P equals 0.01). No patients in either group had a seizure or stroke history, however, at baseline, there were more patients in the cefepime group with delirium, with a trend towards significance (3 versus 0, P equals 0.07). Four (20 percent) and five (25 percent) patients in each group had a baseline psychiatric disorder. There were no documented seizures in either group during therapy. The incidence of AMS with cefepime compared with piperacillin-tazobactam was similar (10, 50 percent versus 7, 35 percent; P equals 0.33) respectively as was the frequency of ICU delirium between the two groups (5, 25 percent versus 7, 35 percent; P equals 0.49). None of the baseline patient characteristics were demonstrated to have an effect on outcomes that met statistical significance. Dosing was appropriate in 17 (85 percent) patients in the cefepime group and 18 (90 percent) in the piperacillin-tazobactam group based on renal function, weight, and site of infection. The use of an inappropriate dose was not significantly associated with neurotoxicity in either group (P greater than 0.05).

Conclusion: The relative incidence of neurotoxicity did not differ between renally impaired ICU patients that received cefepime versus piperacillin-tazobactam. The presence of risk factors did not have a statistically significant effect on outcomes. As this was a small retrospective chart review, this study may not have been powered sufficiently to detect a difference. The clinical significance of these outcomes should be further investigated in a larger study.

Poster Title: Compliance with metformin dosing based on four guidelines

Primary Author: Alice Margulis, Northeastern University, Massachusetts; **Email:** margulis.a@husky.neu.edu

Additional Author (s):
Aakansha Bhalla
Alexa Carlson
May Adra

Purpose: In April 2016, the Food and Drug Administration (FDA) released recommendations to avoid initiation of metformin in patients with an estimated glomerular filtration (eGFR) less than 30 mL/min/1.73 square meters and weigh the risks versus benefits of continuing metformin in patients with an eGFR 30-45 mL/min/1.73 square meters. The purpose of this study was to determine whether the dosing of metformin was in accordance with the new recommendations. Additionally, dosing was assessed to determine if it was compliant with the old FDA recommendations, American Diabetes Association (ADA) guidelines, Canadian labeling, and National Institute of Health and Clinical Excellence (NICE) recommendations.

Methods: This retrospective observational study, approved by the institutional review board, assessed patients admitted to a Boston teaching hospital with an order for metformin identified by the inpatient pharmacy system. A total of 302 patients with orders for metformin between May 1, 2016 and July 31, 2016 were screened for inclusion, of which 156 patients were included in the study. Inclusion criteria consisted of hospitalized adult patients who received at least one order of metformin. Patients who were over the age of 89, prisoners, or those experiencing an acute kidney injury (defined as a rise in serum creatinine of 0.3 mL/min in the past 24 hours or 50 percent from baseline serum creatinine) during their hospital visit were excluded. Exclusion criteria also involved patients who had no documentation of height or weight and patients without a serum creatinine (Scr) available 24 hours prior to receiving the first metformin dose. Per the hospital's renal dosing guidelines, serum creatinine was rounded to 0.8 mg/dL for patients over 70 years of age. Additionally, in patients who weighed over 150 percent of their ideal body weight, creatinine clearance (CrCl) was calculated based on adjusted body weight.

Patient weight, height, age, gender, race, serum creatinine, eGFR, and metformin dosing were collected from corresponding electronic medical records.

Results: Of 146 excluded patients, 13 were excluded due to evidence of acute kidney injury, 126 were excluded due to an unavailable Scr or eGFR, and 7 were excluded due to undocumented height or weight. Of 156 included patients, 66.6 percent were white, 19.9 percent were black, 5.8 percent were Asian, and 7.7 percent were of unknown race. The mean age was 63 years (plus or minus 10.80 years) and 56.4 percent were male. Median calculated eGFR was 88.2 and median CrCl was 82.2. Adjusted body weight was used in the CrCl calculation in 64 patients, while ideal body weight was used in 92 patients.

The metformin order was changed during hospitalization in 26 patients. Of the 6 documented pharmacist interventions, 2 recommended for Scr to be checked.

Metformin dosing was in accordance with the ADA recommendations and the old FDA recommendations in 100 percent of patients. Dosing was compliant with the new FDA recommendations in 99.4 percent of patients and fell into the risk versus benefit category for 0.6 percent of patients. Dosing was in accordance with NICE guidelines in 99.4 percent of patients and with Canadian labelling in 74.4 percent of patients.

Conclusion: The majority of the metformin dosing was in accordance with the new recommendations from the FDA. Additionally, the dosing was mostly compliant with the old FDA recommendations as well as recommendations from the ADA, NICE, and Canadian labeling. The lowest rates of compliance were observed with the Canadian labeling.

Submission Type: Evaluative Study

Session-Board Number: 3-228

Poster Title: Influence of IV Vasopressin (IVP) Generic Rebranding on ICU Clinician Practices and Perceptions

Primary Author: Jennifer Corapi, Northeastern University, Massachusetts; **Email:** corapi.j@husky.neu.edu

Additional Author (s):
John Devlin
Russel Roberts

Purpose: While generic medication rebranding is a recognized cause for higher ICU drug costs, the impact of rebranding on the practices and perceptions of ICU clinicians remains unclear. Generic parenteral vasopressin (GPV) [AWP= $8.67/d] has been used on an off-label basis for years to treat septic shock. In April 2014, Par Pharmaceuticals rebranded GPV as Vasoconstrict [AWP=$416/d]. We hypothesize that GPV replacement with Vasostrict has altered the practices & perceptions of ICU clinicians re: IVP use in septic shock.

Methods: A validated, IRB-approved, written survey was administered in March 2016 to a senior critical care pharmacist from 32 of the 50 largest academic and community hospitals across the six New England States. Practices were compared between Jan/14 GPV-only and Jan/16 Vasoconstrict®-only periods.

Results: Respondents (academic 51%;large community 49%), reported running out of GPV, on average, in 08/15. Between 2014 GVP-only and 2016 Vasostrict®-only periods, respondents perceived the proportion of septic shock patients managed with vasopressin to be identical (25vs. 25%,p=0.99) and the use of focused strategies to reduce vasopressin use similar: 1) More dilute (≤40u/bag) infusions (63vs. 59%,p=0.99); 2)Restriction to patients having a norepinephrine infusion ≥15mcg/min (88vs. 100%,p=0.12); 3)Mandatory approval by an ICU pharmacist (25vs. 28%,p=0.99) or ICU MD (25vs. 28%,p=0.99); 4)Formal education to clinicians re:appropriate use (41vs. 47%, p=0.81); and 5)a DUE conducted or planned (13vs. 19%, p=0.73). Most mistakenly perceived evidence supporting vasopressin use in septic shock to be of moderate strength (86%) and that the Surviving Sepsis guidelines provide a recommendation of

moderate strength supporting its use (89%). Likelihood of IV vasopressin use decreased as the cost of IVP increased across 5 theoretical AVP scenarios.

Conclusion: Despite ICU clinicians reporting to be highly 'AWP-sensitive', a 50-fold increase in the AWP of IV vasopressin due to generic rebranding does not appear to have influenced the way in which they use or administer it to patients with septic shock.

Session-Board Number: 3-229

Poster Title: Characteristics of dementia patients using antipsychotics in programs of all-Inclusive care for the elderly (PACE) program

Primary Author: Elizabeth Shih, Northeastern University, Massachusetts; **Email:** shih.e@husky.neu.edu

Additional Author (s):
Katie Woolford

Purpose: Antipsychotics are commonly used in long term care facilities for the treatment of dementia and off-label reasons, like agitation and aggression, in elderly patients. Antipsychotics have a black box warning for increased risk of mortality when used for the treatment of behavioral symptoms in elderly patients with dementia. This has motivated providers to specify whether the antipsychotic is used for psychosis or behavioral symptoms. The purpose of this study is to assess if patients using antipsychotics at Harbor Health Services, Inc (HHSI) Program of All-inclusive Care for Elderly (PACE) have a psychosis diagnosis or are experiencing behavioral symptoms of dementia.

Methods: This retrospective study looked at antipsychotic use in dementia patients over a 1 year period. Patient charts were obtained from the Harbor Health Services PACE program through online patient profiles on Citrix receiver. The inclusion criteria for this study was a diagnosis of dementia with concurrent use of an antipsychotic medication. The exclusion criteria included patients in nursing homes, since there would not be an accurate documentation timeline for these patients. Patient charts were evaluated based on International Classification of Diseases (ICD) 9 and (ICD)10 codes utilized between January 2015 and February 2016. The ICD 9 and 10 codes search included ones for dementia, psychotic diagnosis, and behavioral symptoms. From our inclusion criteria, 88 patients had a dementia diagnosis and were on antipsychotic medications. For this study, a smaller sample size of 40 patients were used. We used a representative sample size due to time constraints to ensure adequate data collection for each patient. Once the patient sample was defined, we collected data from the patient profiles. The information collected included demographic information, psychosis diagnosis, and behavioral symptoms. From the data collection, we analyzed the results based on the sum of those patients that met a certain criteria. Our primary end point

was behavioral symptoms of dementia without other psychotic manifestation. Our secondary endpoint was the prevalence of behavioral symptoms and which dominated.

Results: Demographic data includes 25 females and 15 males, age ranging from 64-98 (median 81), 37 non hispanic or latino, 2 hispanic or latino, and 1 unreported. Of the 40 patients, 4 had a concurrent diagnosis of schizophrenia, 7 had a concurrent diagnosis of bipolar disorder and 5 had another psychotic manifestations. The behavioral symptoms included: 16 patients with agitation, 1 with apathy, 19 with depression, 14 with anxiety, 2 with mania, and 8 with hallucinations.

Conclusion: Our results show more patients with behavioral symptoms and no psychosis diagnosis than patients with a psychosis diagnosis alone or a diagnosis with concurrent behavioral symptoms. This is aligned with our hypothesis that dementia patients using antipsychotics have more behavioral symptoms then a true psychosis diagnosis. Although we cannot make a direct correlation between behavioral symptoms of dementia and the use of antipsychotics, we feel as our results show the need for more research into the exact nature the the use of antipsychotics.

Poster Title: Impact of clinical pharmacist involvement in transitions of care in a long-term care setting

Primary Author: Elaina Rosario, Northeastern University, Massachusetts; **Email:** rosario.el@husky.neu.edu

Additional Author (s):
Jay Bornstein
Gabriella Pugliese

Purpose: Transitions of care are common occurrences for older adults with acute or chronic illnesses. Although such transitions are designed to accommodate patients' changing health care needs during various stages of illness, many transfers are associated with errors in communication and preventable adverse events. The Joint Commission introduced medication reconciliation as a National Patient Safety Goal in 2005 to protect patients from adverse events related to medication discrepancies that might occur during patient transfers between health care settings. The purpose of this study was to show the importance of clinical pharmacists in the medication reconciliation process in a long-term care setting.

Methods: The study was designed as a single-center, prospective, observational study conducted in a multifaceted long-term care facility, servicing predominantly male veterans. Patients were included if the individual was being admitted to the long-term care facility from home or other nursing home facilities or if the individual was transferred out of the facility for acute care then readmitted. Medication reconciliation data were collected for five weekday intervals over a twelve-week period (July 1, 2016 to September 23, 2016) during dayshift hours. Pharmacy interns and clinical pharmacists performed the data collection. Data collection included the patient's age, where and when they were admitted, if the patient had diabetes, hypertension, congestive heart failure, chronic kidney disease, myocardial infarction, chronic obstructive pulmonary disease, and/or if they were on warfarin, and number of medications the patient was currently taking. The clinical pharmacists and pharmacy interns identified discrepancies after reviewing the patient's chart and comparing the data to what was provided in the admission paperwork. All medication discrepancies identified, following pharmacist evaluation, were documented. Medication discrepancies included orders for incorrect dose,

duration, frequency, route of administration, drug and/or dosage form. Other discrepancies included duplication of therapy, omissions, and/or therapeutic substitutions. Identified discrepancies were discussed with the physician, and any unintended medication discrepancy was documented using Microsoft Excel 2013. Descriptive statistical methods were performed for all data analyses.

Results: A total of 45 patients with an average age of 83 and involving 584 medications were included in this study. Greater than 72 percent (n equals 32) of patients included had diabetes, hypertension, congestive heart failure, chronic kidney disease, myocardial infarction, chronic obstructive pulmonary disease, and/or were on warfarin. This information was collected for quality measure and outcome tracking. More than 62 percent (n equals 28) of patients had at least one error associated with a medication ordered on facility admission. Pharmacists and pharmacy interns resolved a total of 73 admission medication discrepancies. The most common type of intervention was stopped medications, which was defined as either a medication being stopped at an outside facility but continued at the long-term care facility or a medication that was active on an outside medication list that the physician deemed inappropriate or unnecessary to continue at the long-term care facility, (n equals 19). The second most common intervention type was therapeutic substitution (n equals 18). In regards to severity, 26 percent (n equals 19) of medication errors were considered significant or serious, which was defined as a discrepancy that required immediate pharmacist intervention.

Conclusion: Medication discrepancies were common at this long-term care facility on admission. Clinical pharmacist involvement during the admission medication reconciliation process at this facility had a significant impact on reducing the number and severity of potential medication errors. The results of this study demonstrated the vital role of pharmacy interns and clinical pharmacists within the medication reconciliation process and the value of having a multidisciplinary team in a long-term care setting. Although cost savings was not tracked during this study, there is potential for cost savings due to direct pharmacy involvement and reduction in medication discrepancies.

Poster Title: Evaluation of P3 pharmacy students' perceptions and knowledge regarding herbal supplements

Primary Author: Janelle Boehm, Northeastern University, Massachusetts; **Email:** boehm.j@husky.neu.edu

Additional Author (s):
Lianne Chan
Andrew Skirvin

Purpose: Herbal supplements are widely available to consumers in the United States and with uses ranging from the common cold to dementia, they appeal to a variety of people. As herbal supplement use is becoming more common, this emphasizes the importance of pharmacists having sufficient knowledge in order to serve the needs of their patients. The education that pharmacy schools provide on these products is inconsistent and overall remains relatively minimal. The purpose of this study was to assess pharmacy students' perceptions and knowledge regarding patient use of herbal supplements, given the current Northeastern University School of Pharmacy curriculum.

Methods: This study was reviewed by the Northeastern University Institutional Review Board. The pharmacy students' perceptions and knowledge were collected via a voluntary, anonymous electronic survey. The survey invitation was sent out to all Northeastern University P3 pharmacy students in the Spring 2016 semester, a few months before the start of Advanced Pharmacy Practice Experience (APPE) rotations. To gather perceptions, the survey included many statements regarding patient use of herbal supplements, the pharmacist's role in patient use of herbal supplements, and the students' own current level of knowledge on herbal supplements. Each statement corresponded to a four-point Likert scale from strongly agree to strongly disagree. To assess knowledge, the survey asked students to identify the common uses, adverse effects, and drug interactions of herbal supplements in a multiple choice format. The knowledge assessment questions focused on the top 10 most commonly used herbal supplements in the United States.

Results: Out of the 113 students who received a survey invitation, 42 students participated, resulting in a 37% response rate. Based upon survey data, students believe that herbal supplements are frequently used by patients and recognize that there is a role for pharmacists and their knowledge on herbal supplements. However, the students' perceived knowledge did not necessarily match up with their actual knowledge. For example, 62% of students agreed or strongly agreed they would be able to identify herbal-drug interactions; however, only 52% of students were able to do so when given a multiple choice format. When identifying common uses, 62% agreed or strongly agreed they would be able to correctly identify; however, only 45% were able to do so when given a multiple choice format. Also of note, the students' perceived knowledge did not equate to a level of comfort with talking to patients about herbal supplements. Even though 63% of students agreed or strongly agreed that they could identify and describe the uses, drug interactions, and adverse effects of herbal supplements, 68% percent of students disagreed and strongly disagreed to feeling comfortable talking to patients about herbal supplements.

Conclusion: The students of the Northeastern University P3 pharmacy class that participated in the survey recognized a role for pharmacist knowledge on herbal supplements, yet often overestimated their own current knowledge. It is also important to take into account that these students were in their last semester of class and still have a year of APPEs to build up a solid knowledge base on herbal supplements that is necessary to keep up with the increasing amount of patients utilizing these products.

Submission Category: Infectious Diseases

Submission Type: Evaluative Study

Poster Title: Antimicrobial resistance and empiric treatment patterns in multidrug-resistant gram-negative monomicrobial bacteriuria based on presenting location: community versus non-community

Primary Author: Aakansha Bhalla, Northeastern University, Massachusetts; **Email:** aakanshabhalla@gmail.com

Additional Author (s):
Carolyn Darcy
David Kubiak
Kalpana Gupta
Elizabeth Hirsch

Purpose: As antimicrobial resistance continues to be a worldwide threat to public health, studies investigating areas for potential antimicrobial stewardship practices are of utmost importance. Few studies have evaluated antimicrobial resistance and empiric treatment patterns in patients with bacteriuria caused by multidrug-resistant organisms (MDRO) presenting from the community and non-community. The current literature is limited and has been focused on evaluating risk factors associated with MDRO, rather than treatment patterns. Our objective was to compare antimicrobial susceptibilities and patterns in empiric therapy among patients with monomicrobial bacteriuria from MDRO presenting from community vs. non-community settings.

Methods: Retrospective clinical data associated with consecutive gram-negative urine cultures from 173 adults who presented with monomicrobial bacteriuria caused by MDRO (non-susceptible to at least 1 drug in at least 3 classes) in the emergency department or inpatient floors of 2 Boston hospitals between 8/2013-1/2014 were collected. Demographics, past medical history, urinalysis and urinary culture, antimicrobial therapy, and documented urinary symptoms were also collected. Empiric antimicrobial therapy, given within 72 hours for the positive urine culture, was assessed for appropriateness based on symptomatology. Concordance of empiric therapy with eventual organism susceptibility was analyzed based on presenting location. Patients presenting from a skilled nursing facility, long-term care facility, or an outside hospital were included in the non-community group.

Results: One-hundred eighteen (68.2 percent) patients presented from the community while 55 (31.8 percent) presented from non-community settings. Escherichia coli was the most frequently isolated organism (n equals 128; 74 percent) followed by Pseudomonas aeruginosa (n equals 16; 9.2 percent). Patients who presented from the community with E. coli bacteriuria had isolates with significantly lower resistance rates to 3rd and 4th generation cephalosporins (22.8 vs. 52.8 percent, p equals 0.001) and fluoroquinolones (54.3 vs. 77.8 percent, p equals 0.02) compared to those presenting from non-community; both groups had isolates with high rates of resistance to trimethoprim-sulfamethoxazole (62 vs. 58.3 percent, p equals 0.8). Patients presenting with P. aeruginosa had isolates highly resistant to fluoroquinolones (90 percent in community, 100 percent non-community, p equals 1.00), carbapenems (70 vs. 66.7 percent, p equals 1.00), and aminoglycosides (60 vs. 50 percent, p equals 1.00). Overall, patients from the community were more frequently prescribed empiric antimicrobials which were eventually determined to be active against the MDRO (57.6 vs 30.6; p equals 0.01). Seventy-five (43.4 percent) total patients presented with asymptomatic bacteriuria caused by MDRO; both groups had high rates of antimicrobial treatment (75.6 in community, 73.3 percent in non-community, p equals 1.00).

Conclusion: Patients who presented with bacteriuria from non-community settings had isolates with higher resistance rates compared those from the community. High resistance rates can make it challenging for clinicians to select active antimicrobial therapy for the empiric treatment of MDRO. In addition, a high proportion of patients with asymptomatic bacteriuria were treated with antimicrobials though clinical guidelines recommend against this practice. Antimicrobial stewardship initiatives for patients presenting with bacteriuria are needed to better assist clinicians with assessment of risk factors for MDRO and initiating appropriate empiric antimicrobial therapy when indicated.

Poster Title: Wearables: use of commercially available actigraphy devices in clinical trials for patient-centric outcomes research

Primary Author: Ruthvik Malladi, Northeastern University, Massachusetts; **Email:** ruthvikmalladi@gmail.com

Additional Author (s):
Alex Wei
Nathan Cheng

Purpose: Wearable devices combine hardware and software into well designed products such as wristbands, watches, glasses, belt clips, jewelry, etc. Wearables devices paired with analytics software are capable of collecting massive amounts of continuous and objective data enabling consumers and clinicians to closely monitor numerous parameters of health. Wearable devices enable researchers to design innovative clinical trials to conduct patient friendly real world evidence generating studies. Clinically validated wearable devices may allow improved monitoring of patients by pharmacists. This project was designed to analyze the adoption and incorporation of commercially available actigraphy devices in clinical trials.

Methods: We conducted a database analysis of ClinicalTrials.gov national registry for clinical trials using commercially available actigraphy devices on August 30th, 2016. All clinical trials registered in ClinicalTrials.gov registry between January 2011 to September 2016 were included. The top 5 wearable device manufacturers based on market share in the 4th Quarter of 2015 were identified and search queries were conducted on ClinicalTrials.gov using their respective brand names as the search terms. A programmable web scrapper was used to extract data from the Study Record Detail of the 121 clinical trials. The data was checked for quality and clinical trials not using actigraphy devices were removed from the final analysis. Extracted data was organized and analyzed using Microsoft Excel, MySQL and Tableau Desktop software.

Results: Wearable devices have been used in interventional (94% of total studies analyzed) and observational study designs. The adoption of wearable devices into clinical trial design for outcomes has surged in the past four years. In 2015, there were forty-nine total studies using wearable devices registered on ClinicalTrials.gov versus two studies in 2011. The adoption is being primarily led by Universities sponsoring seventy-two studies (33%), followed by hospitals with thirty-nine studies (28%), and pharmaceutical industry with six studies (5%). The top sponsor of clinical trials with wearable devices is University of British Columbia with six studies. Out of the 121 studies we analyzed, Fitbit devices were used in 101 studies (97% of studies). Apple Watch, Garmin Vivofit, and Xiaomi devices were used in one clinical trial each. Wearable devices were used in over 24 different types of conditions. The top three conditions using wearable devices are obesity/physical activity, oncology, and cardiovascular disease states.

Conclusion: Increase in specialty drugs and drug prices led to a greater focus on outcomes and value-based payments. Tracking patient's outcomes data for all medications in every disease state is not scalable. Wearable devices provide a scalable solution to gathering patient outcomes data in a variety of disease states. The increasing adoption of wearable devices into clinical trials may lead to validated wearable dependent outcome measures and monitoring parameters. Pharmacists will have an increasing variety of devices to monitor the health of their patients and greater ability to coordinate care with a patient's primary care team.

Submission Type: Descriptive Report

Session-Board Number: 3-234

Poster Title: Impact of alternative payment models on healthcare quality, efficiency, and accessibility

Primary Author: Lucia Zhu, Northeastern University, Massachusetts; **Email:** zhu.lu@husky.neu.edu

Additional Author (s):
Julia Kholina
Juliette Muszka

Purpose: Despite spending more on healthcare, the United States produces poorer health-related outcomes, such as shorter life expectancy and greater prevalence of chronic diseases, relative to other high-income countries. Part of the problem stems from the current reimbursement model, fee-for-service, where providers are compensated based on quantity of services rather than quality of care. Payers are looking for solutions that will improve healthcare quality while containing costs. The purpose of this analysis was to evaluate the effectiveness of alternative payment models on improving healthcare quality, efficiency, and accessibility.

Methods: A systematic literature review was conducted as of September 2016 and relevant published sources were analyzed from 2006-2016, including the following MESH terms: alternative payment model, bundled payments, efficiency, accessibility, and healthcare costs. Research revealed pertinent information from Centers for Medicare and Medicaid Services, Institute for Clinical and Economic Review, The Commonwealth Fund, Association of Bone and Joint Surgeons, and the Society for the Study of Addiction.

Results: In 2006, 4095 patients of the Geisinger Health Plan participated in a pay-for-performance model of reimbursement, where providers were rewarded if their diabetes patients met a set of quality measures. Cumulative hazard ratios measured over a 3-year period for myocardial infarction, stroke, macrovascular disease, and retinopathy were significantly lower among patients in the pay-for-performance program compared to fee-for-service. In 2009 Blue Cross Blue Shield of Massachusetts implemented an Alternative Quality Contract model, where providers were paid a fixed amount for a defined scope of services as well as

bonuses for meeting quality metrics, in the outpatient setting for substance use disorder. During the first 3 years, there were no differences in substance use disorder service use, total spending, or performance metrics between enrollees in Alternative Quality Contract organizations and those that were not. From October 2013 to March 2015, 91 of 216 patients who underwent revision total joint arthroplasty in one health system participated in a bundled payments arrangement. The bundled payment group had a shorter hospital length of stay compared to the non-bundled group. There were no differences in total episode-of-care costs, costs of post-discharge rehabilitation, rate of discharge to rehabilitation facility, or 90-day readmission rates.

Conclusion: Studies analyzing the effect of alternative payment models on certain health-related measures demonstrate contradictory results. Although alternative payment models show promise in improving the quality of healthcare and reducing the length of stay for certain conditions, their benefits on the efficiency and accessibility of healthcare remain questionable. Additional studies are required to further evaluate the impact of alternative payment models on the healthcare system.

Poster Title: Reported incidence of adverse drug reactions of furosemide in patients with broad documentation of a sulfonamide allergy using data from a large-scale electronic health record

Primary Author: Victor Lei, Northeastern University, Massachusetts; **Email:** victor.j.lei@gmail.com

Additional Author (s):
Kaitlyn Zheng
Joo Hyun Chae
Li Zhou

Purpose: There is a concern of hypersensitivity to sulfonamide nonantibiotic agents in patients with prior history of allergic reaction to a sulfonamide antibiotics (e.g. sulfamethoxazole/trimethoprim). Often, providers document drug allergies within a whole class instead of particular agents. Providers, for example, will document a patient with a "Sulfa" allergy. Are these broad classifications justified? Should there be concern for use of sulfonamide nonantibiotic agents? The purpose of this study was to examine the incidence of adverse drug events of furosemide in patients who have previously been documented with broad documentation.

Methods: The study was conducted on data from 2,796,073 patients using 13 years of Electronic Health Records (EHR) data from a large multi-hospital academic health system. 11,005 patients who were documented to have a "Sulfa" allergy and subsequently received furosemide were included in this study. Of the patients included, patients who experienced an adverse drug event were included in the final analysis. Patients with a previous allergy documentation of furosemide were excluded. Of all patients with adverse drug events, patients with hypersensitivity reactions were extracted. Adverse drug events were labeled as hypersensitivity reactions if they were reactions related to an overactive immune system. This retrospective cohort study was approved by Partners Institutional Review Board.

Results: Of 159,581 patients with a documented "Sulfa" allergy, 11,005 (6.9%) patients were prescribed furosemide. Of the patients prescribed furosemide, 81.9% patients were over the age of 60, 77.9% patients were females, and 49.7% were Caucasian. Also, of the 11,005

patients, 125 (1.1%) patients experienced an adverse drug event. 75 (60%) of the adverse drug events were hypersensitivity reactions. Dermatological manifestations (70.7%) were the most common hypersensitivity reaction. Other relevant hypersensitivity reactions found were edema, vasculitis, and respiratory compromise.

Conclusion: Utilizing data derived from a large-scale EHR database, this study was able to examine the incidence of adverse drug reactions associated with furosemide in patients who were previously documented to have broad documentation of "Sulfa" allergies. This study also highlights the importance of using big data to better analyze adverse drug events that have low incidence rates. Additional research is needed to understand the relationship between prescribing furosemide in patients with sulfonamide allergies, ADRs, and their associated risk factors to influence prescribing practice changes.

Submission Type: Case Report

Session-Board Number: 3-237

Poster Title: Use of leucovorin for the management of drug-induced pancytopenia in a patient infected with Toxoplasma gondii

Primary Author: Eleanor Broadbent, Northeastern University School of Pharmacy, Massachusetts; **Email:** broadbent.e@husky.neu.edu

Additional Author (s):
Elizabeth Hirsch
Alexa Carlson

Purpose: This case illustrates the potential use of increased doses of leucovorin to manage hematologic effects induced by sulfonamide and/or dihydrofolate reductase inhibitor administration in a patient infected with Toxoplasma gondii. The patient presented to the emergency department from an outside hospital with altered mental status, presumed to be a result of viral meningitis. Her past medical history is significant for HIV-2 (nadir CD4 count 41 cells/uL at diagnosis) treated with abacavir-dolutegravir-lamivudine and prophylactic sulfamethoxazole/trimethoprim. Empiric therapy started upon arrival at the hospital consisted of vancomycin, ampicillin, cefepime, and acyclovir. Cerebrospinal fluid from a lumbar puncture was positive for Epstein-Barr virus, Varicella Zoster virus, and T. gondii. An MRI revealed innumerable ring-enhancing lesions and leptomeningeal enhancement, suggestive of CNS toxoplasmosis. Intravenous sulfamethoxazole/trimethoprim was initiated as an alternative treatment for toxoplasmosis due to difficulty obtaining pyrimethamine. Over the following three weeks, the patient's hemoglobin, hematocrit, white blood cell, and platelet levels trended downward. On day 21 of hospitalization, the patient's treatment was changed to pyrimethamine, sulfadiazine, and leucovorin, the first-line therapy for toxoplasmosis, from intravenous sulfamethoxazole/trimethoprim. The patient's blood counts continued to decrease. Due to the risks associated with pancytopenia, the team assessed how to best manage the decreased blood counts without discontinuing the first-line regimen. Leucovorin is utilized in the treatment of toxoplasmosis to counteract the hematologic effects of pyrimethamine. Opportunistic Infections guidelines recommend dosing leucovorin at 10-25mg daily, with the potential to increase to 50mg daily or twice daily. Further expert opinion states that hematologic effects can often be reversed by increasing the dose of leucovorin to 10, 25, or 50mg four times daily. A thorough literature search was completed and no evidence was found

regarding the management of pancytopenia induced by dihydrofolate reductase inhibitors or sulfonamides with leucovorin. After weighing the risks and benefits of continuing the therapy, the team decided to increase the leucovorin dose to 50mg daily on day 27, 50mg twice daily on day 29, and then to 50mg three times daily on day 34. No improvements in the patient's blood counts were noted. On day 35 of hospitalization, the team switched the patient to oral sulfamethoxazole/trimethoprim from pyrimethamine/sulfadiazine/leucovorin due to worsening pancytopenia. Over the following week the patient's blood counts improved, however it was unclear whether this was a result of the increase in the leucovorin dosing or the discontinuation of the pyrimethamine/sulfadiazine/leucovorin due to the short timeline in which these interventions were made. It was unable to be elucidated which medication was the offending agent. Though further investigation is necessary in order to establish leucovorin's safety and efficacy in high doses in this population, its mild adverse event profile, high dose use for methotrexate rescue, and lack of pharmacodynamic interactions with pyrimethamine and sulfadiazine could be reasons to justify its use in the management of drug-induced pancytopenia in a patient infected with T. gondii.

Poster Title: Assessing the interpretation and implementation of USP chapter 797 in institutions throughout New England

Primary Author: Michele Moura, Northeastern University School of Pharmacy, Massachusetts; **Email:** moura.mi@husky.neu.edu

Additional Author (s):
J. Andrew Skirvin

Purpose: Adherence to USP chapter 797 is essential in maintaining sterility and patient safety in the compounding of sterile products. While these guidelines provide a general set of standards that need to be upheld in operating a cleanroom, not all hospitals operate under a standard set of identical practices. The purpose of this study was to detect any discrepancies in terms of deciding beyond use dating in unclear circumstances throughout sterile products areas within various institutions in the New England region, as well as determine the level that USP chapter 797 has been implemented in these institutions.

Methods: The project and survey tool were reviewed by the IRB at Northeastern University. The survey assessed activities performed in each institution's sterile products area. Survey questions covered staffing in the sterile products area, resources utilized by pharmacists, products compounded, as well as pharmacists' understanding of CMS guidelines regarding stability and beyond use dating. The survey was aimed to be completed by a registered pharmacist who works in the IV room regularly, ideally the sterile products area manager. If neither of these personal could be contacted, the survey was sent to the institution's director of pharmacy. Contacts were acquired through calling each institution's central pharmacy and asking for the e-mail addresses of the desired recipients. The survey was then distributed using Qualtrics and results were collected and analyzed using the Qualtrics survey software from March through July of 2016.

Results: Seventeen pharmacists completed the survey of the fifty-one who were requested to complete the survey (33.3% response rate). Through analysis of each question, it became clear that each pharmacist consults different resources when confronted with unclearly defined instructions regarding preparation of sterile products. Each pharmacist stated relative comfort

in the regulations implemented by USP chapter 797, yet not all required practices have been fully executed in each institution. On average, pharmacists were 84.4% comfortable with the CMS interpretive guidelines regarding storage and beyond use dating of parenteral admixtures. Forty percent of pharmacists have implemented USP chapter 797 in its entirety, while 50% stated that there are still a few procedures to be fully implemented. Ten percent of responding pharmacists acknowledged that it has been loosely implemented in their institution. USP chapter 800 has yet to be implemented by most all institutions, with 60% of pharmacists responding that they intend to employ the corresponding procedures and practices in the near future.

Conclusion: Even with the standard set of guidelines for the preparation of sterile products that is USP chapter 797, numerous discrepancies still exist in the operations of sterile products areas among different institutions. In terms of sterility guidelines and beyond use dating, pharmacists would benefit from more universal, evidence-based recommendations. Further evaluation of sterile compounding practices with a larger cohort of responses in a wider geographic area is warranted.

Submission Category: Ambulatory Care

Poster Title: Evaluation of interventions by a pharmacist in a renal clinic: a pilot project

Primary Author: Farbod Khaleghi, Western New England University, Massachusetts; **Email:** farbod.khaleghi@wne.edu

Additional Author (s):
Chelsea Thompson
Marissa Wolff
Jared Ostroff
Michael O'Shea

Purpose: Diabetes affects over 29 million Americans and is the most common cause of renal failure, accounting for 44% of new diagnoses. Previous studies have demonstrated that pharmacist-led diabetes management improves patient parameters, such as hemoglobin A1c. Maintaining better control of A1c, blood pressure, and cholesterol, and preventing progression of renal parameters, such as serum creatinine and estimated glomerular filtration rate, helps prevent long-term complications related to diabetes, such as chronic kidney disease. The purpose of this project is to quantify and qualify the impact of a pharmacist, based upon number and type of documented pharmacist interventions in a renal clinic.

Methods: This study investigated the renal clinical pharmacist's impact on patients with type 2 diabetes and chronic kidney disease in an ambulatory setting, by reviewing the number of diabetes-related, hypertension-related and polypharmacy-related interventions. This pilot project was approved by the institutional review board and was a retrospective chart review of patients identified from the pharmacy clinic schedule from January 2016-February 2016. All patients seen in the renal pharmacy clinic for medication reconciliation, hypertension, or diabetes had their charts reviewed for the pharmacy clinic note; interventions recommended in the note, such as dose increase/decrease, change of medication or dose, hold of medication or monitoring recommendations, were all documented in a data collection form. Age, visit type and number, gender, most recent A1c, most recent serum creatinine, and estimated glomerular filtration rate were also gathered. After the information was organized and collected, it was reported in an aggregate table to describe the general frequency of each documented

intervention, as well as to describe the comprehensive services provided by the pharmacist in the renal clinic.

Results: Overall, 33 patients had scheduled visits at the renal pharmacy clinic from January 1st 2016-January 31st 2016. Thirty-two of these patients were included, as one missed their scheduled appointment. For gender, 43.75% of patients were female, and 56.25% were male. Patients' visit number to clinic ranged from their 1st-13th visit at the clinic, with an average visit number of three. For all patients assessed: the average serum creatinine was 2.08 mg/dl; average estimated glomerular filtration rate was 38.74 mL/min; and average HbA1c was 8.57%. The clinical pharmacist made interventions for 27 of the 32 patients, for a total of 67 interventions. Forty-nine of these interventions were diabetes-related, four were hypertension-related, and eight were related to polypharmacy issues identified among the patients. These interventions were further extrapolated into medication related problems. There were five adjustments to medication doses; three medications were changed to an alternative medication and one medication was held. In total, 56 monitoring recommendations were implemented by the pharmacist, making up the majority of the intervention types seen. These monitoring recommendations included specific instructions for testing blood glucose, education on hypoglycemia, proper glucometer use, suggested lab draws for A1c to the physician, diet recommendations, and medication side effect management.

Conclusion: Pharmacist-led disease state management in a renal clinic is a novel approach to managing co-morbidities among this patient population. As diabetes is one of the leading cause of renal failure, adequate diabetes and disease state management is essential in chronic kidney disease patients. Our data shows a pharmacist plays a critical role in this setting. Of patients screened, 84% required pharmacist intervention. These crucial interventions, including dose titrations, glucose monitoring, and diabetes education, may not have been otherwise provided. These results highlight the expected benefit of a clinical pharmacist in this setting and encourage future studies looking at measured outcomes.

Submission Category: Ambulatory Care

Submission Type: Descriptive Report

Session-Board Number: 3-240

Poster Title: Evidenced-based medicine interventions in a pharmacist led hypertension clinic

Primary Author: Brittney Amaral, Western New England University College of Pharmacy, Massachusetts; **Email:** brittney.amaral@wne.edu

Additional Author (s):
Desirae Daniels
Courtney Doyle-Campbell

Purpose: Evidenced-based medicine applies knowledge gained from large clinical trials directly to patient care and has shown benefit in reducing important health outcomes in patients with hypertension. Pharmacists' expertise in medication management can be an asset when managing hypertension. This project was designed to assess the impact of medication-related interventions on overall trend towards evidenced-based medicine in patients seen within a pharmacist led hypertension clinic and to also recognize additional non-medication related interventions within the clinic which may benefit patient care.

Methods: Primary care physicians, midlevel practitioners and cardiologists refer patients with hypertension to the pharmacist-led clinic for education, counseling and medication management. A retrospective patient chart review was conducted for new patients seen by the clinic between 1/1/2016-6/1/2016, which reviewed the number and types of antihypertensive medications, comorbidities, pharmacist interventions regarding blood pressure medications and comparison to 2014 JNC8 evidenced based guidelines. Additional (non-blood pressure medication related) interventions were also reviewed, including ambulatory blood pressure monitoring (ABPM) (in which patients wore blood pressure monitors for twenty-four hours and blood pressure trends were later analyzed by the pharmacist to help guide hypertension management decisions), over the counter (OTC) counseling and management (education and recommendations for discontinuation, based on side effects and/or lack of benefit), pulmonology referrals for obstructive sleep apnea (OSA), smoking cessation counseling (including recommendations for nicotine replacement therapy) and total medication therapy management (MTM).

Results: Thirty-eight patients were seen for an initial consultation in the hypertension clinic. Of those patients, thirty-three returned for a 1st follow-up visit; twenty-three patients returned for a 2nd follow-up. At the initial consultation, twenty patients were on evidenced-based medicine in accordance with 2014 JNC8 guidelines. Fourteen patients were on blood pressure medication that was not evidence-based and four patients were not on blood pressure medication. Of the patients that were not on evidenced-based medicine or not on blood pressure medication, 44.4 percent (8 patients) were converted by 2nd follow-up. There was a 7.9 percent increase in patients on evidence-based medicine after the initial consult, another 5.3 percent increase after the 1st follow-up and 7.9 percent increase after the 2nd follow-up for a total change of twenty-one percent. Overall, there were sixty-three blood pressure-related medication interventions that occurred in patients between the initial consultations, up until the 3rd follow-up visits, including medication initiation, discontinuation, dose increases and dose decreases. There were thirty-one additional (non-blood pressure medication related) interventions. Fourteen were related to over the counter medications, eight ambulatory blood pressure monitoring assessments, five referrals to pulmonology for obstructive sleep apnea, two smoking cessation counseling sessions and two medication therapy management sessions.

Conclusion: A pharmacist-led hypertension clinic focusing on education, counseling and medication management is beneficial to patient care in a variety of ways. Pharmacists' expertise in therapeutics can effectively contribute to evidenced-based medicine in the management of patients with hypertension.

Poster Title: Retrospective chart analysis evaluating the impact of a pharmacist led hypertension clinic

Primary Author: Desirae Daniels, Western New England University College of Pharmacy, Massachusetts; **Email:** desirae.daniels@wne.edu

Additional Author (s):
Brittney Amaral
Courtney Doyle-Campbell

Purpose: Hypertension is the most common condition seen in primacy care, and is often asymptomatic. If not well controlled complications can include heart attack, stroke, or renal failure. The purpose of this study was to assess the improvement in blood pressure control after visiting a pharmacist led hypertension clinic within a level three medical home.

Methods: The institutional review board approved this retrospective chart review of hypertension clinic patients seen from January 1, 2016 through June 1, 2016. Patients with difficult to control hypertension are referred to the clinic by primary care providers for medication management, lifestyle counseling, and disease state education. The initial consultation is an hour long appointment where the pharmacist reviews all medications over-the-counter and prescription to emphasize their importance and identify barriers to adherence. Evidence based medicine is implemented at the clinic and lifestyle modifications are emphasized. The subsequent follow up appointments are 30 minutes and reinforce personalized plans to achieve blood pressure control. Manual blood pressure readings were analyzed at consult, first, and second follow up. Inclusion criteria for this study included having a blood pressure >140/90 at consultation and one follow up appointment within the time frame.

Results: Fifty one patients were seen for an initial consultation. Of these patients sixteen did not follow up and thirteen had a blood pressure at consultation < 140/90. The remaining 23 patients had a mean blood pressure of 149/88 with a standard deviation of 13/12. At the first follow up the mean was 151/87 with a standard deviation of 12/11. A paired sample t-test determined there is no statistically significant change in SBP or DBP from consult to first follow

up p=0.71 (SBP) p= 0.58 (DBP). When evaluating the data based on percentage of patients at their 2014 JNC8 determined goal blood pressure, 14% of patients had a blood pressure below their goal by their first follow up and 31% by their second follow up.

Conclusion: Patients benefit from the opportunity to have specialized counseling, education, and medication therapy management provided by a pharmacist at the hypertension clinic. This is shown by the increasing percentage of patients at their 2014 JNC8 Blood pressure goal with each follow up appointment. In order to show statistical significance a larger study must be conducted to further reinforce the benefit of these specialized pharmacist provided services. A subgroup analysis to identify factors determining the cause of patients not reaching their goal may also be beneficial.

Poster Title: Implementation of a pharmacy based care transitions program targeting high-risk diabetic patients in a community hospital

Primary Author: Chelsea Thompson, Western New England University College of Pharmacy, Massachusetts; **Email:** chelsea.thompson@wne.edu

Additional Author (s):
Sarah Stevens
Jacqueline Klee

Purpose: One-third of patients with diabetes are hospitalized annually, accounting for twenty percent of health care spending. Reducing readmission rates of diabetic patients has the potential to significantly reduce healthcare costs while concomitantly optimizing patient outcomes. Studies suggest that high-risk diabetic patients will gain long-term benefit from a coordinated inpatient hospital transitions of care program. Two recent studies have demonstrated that pharmacist telephone interventions reduce thirty-day hospital readmissions and emergency department visits. The aim of this project is to assess the impact of a pharmacist driven transitions of care program within a community hospital that targets high-risk patients with diabetes.

Methods: Diabetic patients admitted to Heywood Hospital on the medical-surgical and intensive care units of the hospital over a ten week period were screened for eligibility into the transitions of care program. Screening occurred Monday through Friday. Patients were included if: they presented with a new diagnosis of diabetes mellitus; diabetic ketoacidosis/hyperosmolar hyperglycemic state; severe hypoglycemia of less than 40 milligrams per deciliter; a HbA1c greater than or equal to 9; or a previous hospital admission within the last 30 days. Patients who refused to participate, did not manage their own medications, without phone access, or were discharged to a place other than home were excluded from the study. Qualifying patients were offered enrollment during their hospital stay. Patients who chose to participate in the program signed a consent form. Patient interviews during hospitalization potentially included medication reconciliation, medication and disease state counseling, and barrier identification. A project specific questionnaire was developed and attempted with enrolled patients to assess medication adherence, literacy, and numeracy.

Enrolled patients were contacted by phone 2-4 times following discharge depending on the needs of the patient, to assess for any health or medication related issues. Data collection on all screened patient included HbA1c, co-morbidities, number of medications on admissions, pharmacist interventions, and questionnaire results. All data was recorded in a confidential data sheet for analysis.

Results: Thus far, 126 patients were screened from August 10th to September 26th 2016. Demographics include: mean age of 69; 92% Type 2 diabetes; 2.4% Type 1 diabetes; 5.6% pre-diabetes; 46.8% were female. Also, the mean HbA1c and number of medications on admissions were 7.48% and 15.97 respectively. The clinical pharmacist completed 99 medication reconciliation interventions and 44 glycemic control interventions among these patients. Of the screened patients, 27 were eligible for the transitions of care program and 8 were enrolled. Reasons for non-enrollment included 3 declines and inability to reach patients prior to discharge. 66.7% of enrolled patients had a HgA1c greater than 9% and 29.6% had a previous hospital admission within 30 days and 3.7% presented with diabetic ketoacidosis. Of enrolled patients: 87.5% had type 2 diabetes, average age was 62, and average HbA1c was 10.2%. From the 8 enrolled patients, 3 enrollees completed the questionnaire and 7 were contacted for phone interviews, the 8th patient remained inpatient when data was collected. On average, phone interviews took place 6.6 days post discharge. Overall, 7 glycemic control interventions and 7 medication reconciliation interventions were completed among enrolled patients.

Conclusion: Proper diabetes management and education to inpatient high-risk diabetics is essential to their outpatient success. We successfully made numerous clinical interventions among enrolled patients. Furthermore, phone interviews have identified patient barriers post discharge; such as lack of transportation, inability to understand healthcare material, and misplacement of prescriptions and medical devices. We have been able to assist the enrollees in overcoming these barriers while promoting self-management of their diabetes. Of enrolled patients, none have thus far been readmitted to Heywood Hospital within 30 days, highlighting the benefit of a pharmacist led transitions of care program in this patient population.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Descriptive Report

Session-Board Number: 3-243

Poster Title: Incorporation of pharmacy and nephrology collaboration into daily pharmacy care team activities to ensure efficacy and safety in tacrolimus and cyclosporine patients

Primary Author: Christopher Krupa, Western New England University College of Pharmacy, Massachusetts; **Email:** christopher.krupa@wne.edu

Additional Author (s):
Erin Naglack

Purpose: Allogeneic transplant patients are a population that offers a unique subset of variables that impact medication outcomes in patient care. Dosing strategies of the immunosuppressive agents, required to maintain transplant longevity, rely on the experience of the nephrologist, but adjustments are currently being made retrospectively from existing levels rather than prospectively based on predetermined factors. Thus, this project looked to develop a formal method to both monitor and adjust immunosuppressive agents with outlined considerations for variables that may directly impact drug levels in a subtherapeutic or supratherapeutic manner.

Methods: A pharmacist, with advanced training in the transplant population, within a 760 bed tertiary hospital identified a lack of a defined protocol for dosing the calcineurin inhibitors tacrolimus and cyclosporine. With the assistance of a pharmacy intern, a curbside rounding protocol was developed to guide adjustments and to draw focus to potential risk factors for depression or elevation of levels. The development of this dosing tool first sought to examine the impact patient history plays in guiding dose adjustments. This includes transplant type or other calcineurin inhibitor indications, history/status of rejection, as well as time since transplantation to assess desired levels. Next, concurrent medications were examined to determine potential interactions and severity of impact to tacrolimus and cyclosporine levels. These interactions were first weighed according to the hospital's formulary in the interest of succinctness, then broadened to include commonly used medications not on the formulary weighed by the level of potential interaction severity.

Results: With the development of this guided dosing protocol, a quality improvement curbside rounding initiative can thus be implemented. Driven by pharmacists and nephrologists, daily rounding will evaluate patient-specific factors such as length of time since transplant as an indicator of goal levels and impact of concurrent medications. Individual patient kinetics as well as pertinent medical history, such as history of BK virus and rejection status, will also be utilized in rounding evaluation. The developed protocol will seek to guide providers to examine medication interactions that may precede subtherapeutic or supratherapeutic levels. These listed medications may be utilized to examine both the severity and incidence on tacrolimus and cyclosporine levels in a more guided dosing rationale.

Conclusion: With the development of a guided dosing protocol in the daily assessment of admitted transplant patients, a more formalized approach to an often vaguely defined strategy may be achieved. With further assessment and data collection, a retrospective analysis may yield a more defined correlation between level fluctuation and specific interaction type, further guiding and developing the protocol into a more concretely defined algorithm in the future.

Poster Title: Efficacy of an Inpatient Pharmacist Managed Warfarin Protocol

Primary Author: Kimberly Han, Western New England University College of Pharmacy, Massachusetts; **Email:** kimberly.han@wne.edu

Purpose: Warfarin is a high risk medication which requires close International Normalized Ratio (INR) monitoring and can be a challenge to manage in the acute care setting. One of the Joint Commission's National Patient Safety Goals regarding warfarin therapy, NPSG.03.05.01, outlines the importance of anticoagulation therapy as it relates to patient outcomes. It also endorses the use of approved protocols for the initiation and maintenance of anticoagulant therapy. The purpose of this study is to assess the efficacy of an inpatient pharmacist managed warfarin protocol.

Methods: This study is a retrospective chart review of patients admitted to a small community hospital between February 1, 2016 and July 31, 2016 who were prescribed warfarin and managed according to a pharmacist driven warfarin protocol. Per hospital protocol, institutional review board (IRB) approval was not required, due to the nature of the study. Patients were excluded if younger than 18 years of age, admitted with an active bleed, admitted for surgery, admitted for two days or less, or if warfarin therapy was discontinued indefinitely. The primary outcome was the time in therapeutic range (TTR). Secondary outcomes included the time to reach therapeutic range and the incidence of bleeding and thromboembolic events.

Results: Of the 86 patient charts reviewed during the study period, the average TTR was 42%. A subgroup analysis of patients who were started on warfarin prior to hospital admission revealed an increase in the mean TTR to 51%. Of the patients studied, 56% were discharged with a therapeutic INR and an average time to therapeutic range of 2.9 days. One patient experienced a thrombotic event and one patient experienced a bleeding event. Patients admitted for CHF exacerbations had a mean TTR of 56% and reached their goal INRs in an average of 1.9 days, while patients without a history of CHF had a mean TTR of 40% and reached their goal INRs in an average of 3 days. Patients who were prescribed warfarin for atrial fibrillation treatment had a mean TTR of 44% and reached their goal INRs in an average of 2.5 days, while patients prescribed warfarin for PE/DVT treatment had a mean TTR of 27% and

reached their goal INRs in an average of 3.8 days. Patients who were administered warfarin without interacting antibiotics had a mean TTR of 46%, while patients receiving interacting antibiotics had a mean TTR of 35%.

Conclusion: An inpatient pharmacist managed warfarin service yielded an average TTR of 42% and provided 56% of patients with a therapeutic INR upon discharge. A successful inpatient anticoagulation service requires close monitoring by pharmacists in addition to support from other health care professionals. The results of this study provide the foundation for possible improvements to an inpatient pharmacist managed warfarin protocol. More specifically, using this information, pharmacists can identify specific patient populations which may require closer management in order to improve these patients' warfarin therapies.

Poster Title: Evaluation of antibiotic susceptibilities of gram-negative isolates in oncology patients

Primary Author: Rebecca Marcinak, Western New England University College of Pharmacy, Massachusetts; **Email:** rebecca.marcinak@wne.edu

Additional Author (s):
Erica Housman
Seth Housman

Purpose: Oncology patients are susceptible to infections because of neutropenia (often chemotherapy-induced) and other host factors. Gram-negative pathogens are associated with higher morbidity and mortality among neutropenic patients, necessitating early and appropriate antimicrobial treatments. Clinical Practice Guidelines recommend empiric IV antibiotic therapy with an antipseudomonal beta-lactam [cefepime, a carbapenem (meropenem or imipenem/cilastatin), or piperacillin/tazobactam]. Antibiograms specific to the organization are beneficial, providing local susceptibility rates. Due to increasing resistance and the multiple treatment options, our objective was to determine the best empiric treatment in this population.

Methods: This study was conducted at Baystate Medical Center, Springfield, MA. All patients admitted to the oncology ward at Baystate Medical Center, Springfield, MA with any positive culture from January 2015 to July 2016 were obtained from TheraDoc, an electronic data mining system. Cultures with Gram-negative pathogens were included. Date of specimen collection, type of specimen, and pathogen were obtained. From this information, a chart review was performed to obtain susceptibilities, empiric antimicrobial regimen, and indication. A unit-specific antibiogram was developed, in addition to looking at the susceptibility rates of all pathogens against broad spectrum antimicrobials (piperacillin/tazobactam, meropenem, and cefepime). For patients with multiple cultures from a single admission, only the first isolate was included. Susceptibility was reported for each antibiotic against each pathogen. Other data collected, including indication and empiric therapy, were summarized utilizing descriptive statistics.

Results: A total of 349 unique Gram-negative isolates were reported during this time period. To date, 139 isolates have been analyzed. The most common indications for antimicrobial therapy were community acquired UTI (37/139, 27 percent), healthcare associated pneumonia (16/139, 12 percent), healthcare associated UTI (15/139, 11 percent). The most utilized empiric treatments were piperacillin/tazobactam (57/139, 45 percent), ceftriaxone (35/139, 28 percent), and cefepime (12/139, 10 percent). The most common organisms isolated were Escherichia coli (64/139, 46 percent), Klebsiella spp. (30/139, 22 percent), and Pseudomonas aeruginosa (14/139, 11 percent). Susceptibility rates for piperacillin/tazobactam, cefepime, and meropenem against E. coli were 95, 100, and 100 percent, respectively. Susceptibility rates for piperacillin/tazobactam, cefepime, and meropenem against Klebsiella spp. were 97, 93, and 100 percent, respectively. Of the 102 Klebsiella spp. and E. coli isolates, 8 were positive for the ESBL phenotype. Susceptibility rates of piperacillin/tazobactam, cefepime, and meropenem to the organism Pseudomonas aeruginosa were 93, 71, and 93 percent, respectively. Of the entire cohort of pathogens, susceptibility rates of cefepime were 92 percent versus 93 percent for piperacillin/tazobactam versus 99 percent for meropenem.

Conclusion: Meropenem provided the best in vitro, susceptibility against all Gram-negative organisms causing infections in patients on the oncology ward. Susceptibilities among the broad-spectrum agents to both E. coli and Klebsiella spp. were quite similar. Piperacillin/tazobactam and meropenem have higher susceptibility rates compared to cefepime against P. aeruginosa. For empiric treatment, meropenem provides the best susceptibility against pathogen isolates, though cefepime and piperacillin/tazobactam have greater than 90 percent susceptibility as well. Meropenem sustains this high susceptibility as it provided an advantage over the other agents against ESBL producing pathogens.

Poster Title: Identifying opportunities for de-escalation of vancomycin on general medicine and hospitalist services at an academic medical center

Primary Author: Nathan Goad, Campbell University, North Carolina; **Email:** ntgoad0408@email.campbell.edu

Additional Author (s):
Amy Loken
Jim Johnson
John Williamson
Jim Beardsley

Purpose: Vancomycin is frequently used as empiric therapy due to its bactericidal activity against gram positive organisms, including methicillin resistant Staphylococcus aureus (MRSA). However, to minimize resistance, efforts to de-escalate therapy should be the focus of health care institutions and individual providers. The purpose of this study is to identify clinical scenarios in which vancomycin was initiated inappropriately or continued inappropriately beyond 3 days in patients on a general medicine or hospitalist service.

Methods: This study was a retrospective chart review conducted at an 885-bed academic medical center with a mature antibiotic stewardship program. Patients were included if they received at least one dose of vancomycin while on one of four general medicine services or on the hospitalist service during May through July 2016. Patients were excluded if vancomycin was a continuation of home therapy, used as prophylaxis, administered 3 days or more while the patient was on another service prior to transferring to a general medicine or hospitalist service, or if the patient was transferred from a general medicine or hospitalist service prior to receiving 3 days of vancomycin. A list of patients receiving 1 or more doses of vancomycin during the study period was reviewed in random order to assess for study inclusion. Data collected included renal function, medication allergies, culture data, MRSA risk factors or colonization status, indication for vancomycin at day 1 and day 3, and duration of vancomycin treatment. Three pharmacists with experience in general medicine and infectious disease reviewed the cases to evaluate both the appropriateness of the initial indication for vancomycin and its continuation beyond 3 days of therapy. Vancomycin use was judged to be appropriate if the

patient's condition justified its use and indeterminate if appropriateness could not be determined with certainty.

Results: Data were collected for 74 patients, 52.7 percent were female, mean age was 57.2 years, and median duration of vancomycin use was 3 days. 5 indications were considered to be inappropriate, and 4 indications were indeterminate. The median duration of treatment with vancomycin in those who had appropriate indications was 4 days (range 2 to 17) compared with 2 days (range 1 to 4) in those who did not have an appropriate indication. 36 patients continued treatment for more than 3 days. 5 of these continuations were determined to be inappropriate, and 3 were indeterminate. The median duration of treatment in cases of appropriate continuation was 5 days (range 4 to 17). All 5 patients that received vancomycin inappropriately beyond 3 days of therapy were treated for 1 additional day. After removing indeterminate cases, vancomycin was used inappropriately for 12 days (4.1 percent) of 295 total days of vancomycin therapy.

Conclusion: Although there were opportunities to improve initial selection and de-escalation of vancomycin in certain patients, eliminating inappropriate use would not have a dramatic impact on vancomycin exposure in the general medicine and hospitalist services at our institution.

Poster Title: Saccharomyces usage in the treatment of Clostridium difficile infection in hospitalized patients: A retrospective cohort study

Primary Author: Andrew Darkow, Campbell University College of Pharmacy & Health Sciences, North Carolina; **Email:** atdarkow1013@email.campbell.edu

Additional Author (s):
Phillip DeVillier
Riley Bowers
Kim Kelly

Purpose: Clostridium difficile infection (CDI) is the most common cause of antibiotic associated diarrhea in health systems. Over the past few decades, healthcare professionals have speculated on the efficacy of oral probiotics in the prevention and treatment of CDI. However, the 2010 Society for Healthcare Epidemiology of America (SHEA) Clinical Practice Guidelines for CDI do not recommend probiotic use in the treatment of CDI due to limited evidence to support their addition to standard therapy. The purpose of this study was to determine if the addition of Saccharomyces boulardii to standard antibiotic therapy improves patient outcomes.

Methods: This study was a retrospective cohort study comparing Saccharomyces usage in addition to standard therapy to standard therapy alone. The study was approved by the Campbell University College of Pharmacy & Health Sciences Institutional Review Board. Data was collected on patients admitted as inpatients to a small, rural hospital system. We assessed 150 patients to determine the potential effect of Saccharomyces probiotics on CDI therapy. For inclusion in this study, subjects had to be at least 18 years of age and possess a diagnosis of CDI. Patients were excluded from this study if they had a length of stay less than 24 hours or did not receive treatment for CDI as an inpatient. Cases were evaluated on the use of Saccharomyces probiotics, antibiotic therapy initiated, duration of inpatient treatment, readmission within 30 days for CDI, need for escalation of therapy, and the use of inciting antibiotics prior to diagnosis of CDI. Data was collected by the primary investigators of this study using Microsoft Excel, analyzed using descriptive statistics, and reported as proportions and percentages. JMP was then used to compare patients who received Saccharomyces probiotics in addition to standard therapy versus standard therapy alone in: length of hospital stay using t-test, readmission for

CDI within 30 days using chi-squared test, the need for escalation of therapy using chi-squared test, and inciting antibiotics using chi-squared test.

Results: The average length of hospital stay for the Saccharomyces group versus standard therapy was significantly longer than patients receiving standard therapy alone (6.61 days versus 4.70 days, p equals 0.0116). The percentage of patients readmitted within 30 days following discharge for patients who received Saccharomyces in addition to standard therapy was not significantly lower than patients who received standard treatment alone (6.49 percent versus 16.44 percent, p equals 0.1221). The percentage of patients requiring an escalation of therapy was not significantly higher for patients treated with Saccharomyces versus standard therapy alone (27.27 percent versus 21.92 percent, p equals 0.5606). Significantly more patients in the Saccharomyces group received inciting antibiotics prior to CDI diagnosis than the standard treatment group (54.55 percent versus 34.25 percent, p equals 0.0294). The most common inciting antibiotics were ceftriaxone (29 patients), levofloxacin (18 patients), and piperacillin-tazobactam (11 patients).

Conclusion: With similar readmission rates between the Saccharomyces boulardii and standard treatment groups as well as the increased length of stay that was seen in the Saccharomyces group, Saccharomyces probiotics do not appear to provide additional benefit, and may cause potential harm in the treatment of CDI. Therefore, the potential risks should be weighed against the potential benefits in each patient for Saccharomyces use. Future areas of study could assess the utilization of probiotics in CDI caused by inciting antibiotics, or follow patients prospectively to establish causality between probiotic use and an increased length of stay.

Poster Title: Subtherapeutic anti-Xa levels in a patient with cirrhosis receiving low molecular weight heparin for deep vein thromboses

Primary Author: Katherine Cook, Campbell University College of Pharmacy & Health Sciences, North Carolina; **Email:** krcook1213@email.campbell.edu

Additional Author (s):
Kevin Cowart
April Cooper
Talal Dahhan
Catherine Wente

Purpose: Cirrhosis is associated with both procoagulant and anticoagulant states, creating a unique challenge when initiation of pharmacologic anticoagulation is required. Reduction in coagulation cascade proteins, such as protein C and antithrombin, create this therapeutic dilemma. Because of this coagulopathy, several studies have attempted to establish new ways to address this challenge. Overall, studies have identified low molecular weight heparin (LMWH) as the treatment of choice in cirrhosis patients. We present a case of a 35 year old male who was admitted for severe bilateral lower extremity cellulitis and a past medical history significant for alcoholic cirrhosis, hepatic encephalopathy, esophageal varices, and gastrointestinal bleeding. He was noted to have moderate ascites, significant hyponatremia, acute kidney injury (AKI), and systemic inflammatory response syndrome (SIRS), with an elevated white blood count (WBC) and tachycardia. On the day following admission, he was also found to have bilateral deep vein thromboses (DVTs). Treatment of the DVTs with LMWH was initiated at 1mg/kg subcutaneously every 12 hours. Due to the AKI, monitoring of anti-Xa levels was warranted to assess and adjust the LMWH dosing. Peak anti-Xa levels were consistently subtherapeutic, despite appropriate LMWH dosing per acute DVT treatment guidelines. When the patient was transitioned from LMWH to treatment dose unfractionated heparin (UFH) for a procedure, an activated partial thromboplastin time (aPTT) in excess of 300 seconds prompted discontinuation of the UFH and investigation of the aforementioned subtherapeutic anti-Xa levels. During a literature review, it was discovered that the severity of liver disease is negatively correlated with anti-Xa levels. According to one study, cirrhosis patients who received LMWH never reached appropriate peak anti-Xa targets. These findings

suggest that dosing LMWH based on anti-Xa levels may have been an inaccurate method of monitoring anticoagulation in our patient. Since several studies question the utility of anti-Xa levels in this population, assessment of therapeutic efficacy must be accomplished via evaluation of other hematologic monitoring parameters such as hemoglobin, hematocrit, and platelet counts. Based on our analysis of the literature, we began dosing LMWH by renal function and discontinued monitoring peak anti-Xa levels. Our case demonstrates that despite use of LMWH as the DVT treatment of choice in this population, monitoring of anti-Xa levels is not recommended.

Poster Title: Incidence of steroid refractory (SR) graft versus host disease (GVHD) in allogeneic stem cell transplants

Primary Author: Joseph Arminger, Campbell University College of Pharmacy & Health Sciences, North Carolina; **Email:** jmarminger0220@email.campbell.edu

Additional Author (s):
Kelli Ferguson
LeAnne Kennedy

Purpose: Peripheral blood stem cell transplantation (SCT) is a common therapy following chemotherapy for hematologic malignances. Allogeneic stem cells are collected from a donor and matched to the patient based on major and minor histocompatibility complexes. Variations can result in immune activation of the host against the graft, termed GVHD. Primary therapy of GVHD includes systemic steroids with intravenous methylprednisolone or oral prednisone. However, limited data exists in the treatment of SR- GVHD. The purpose of this study was to determine the prevalence of SR-GVHD as well as commonly used second-line treatment options.

Methods: The institutional review board approved this retrospective chart review performed on patients aged 18 years and older who received peripheral blood allogeneic SCT from January 2013 through April 2016. Potential study subjects were evaluated and excluded if they were diagnosed with aplastic anemia or myelofibrosis, received an autologous or haplo-identical SCT, or utilized bone marrow as the source of stem cells for transplant. Relevant research variables included age during time of transplant, type of hematologic disease, preparative regimen prior to transplant, GVHD prophylactic therapy, classification of acute GVHD, primary GVHD treatment, as well as secondary GVHD treatment. The primary outcome was the incidence of SR-GVHD within 100 days of allogeneic SCT. Acute SR-GVHD was defined as the use of additional treatment within six weeks following primary treatment with either oral prednisone or intravenous methylprednisolone. Secondary outcomes included incidence of acute GVHD, identification of therapy for SR-GVHD, time to disease relapse, and time to death.

Results: One-hundred and twenty-five patients received allogeneic SCT during the study evaluation period with 113 patients meeting inclusion criteria. Sixty-nine patients (61.1 percent) were male and the mean age at time of transplant was 52.9 years. Thirty-nine patients (34.5 percent) received a matched related donor SCT and 59 patients (52.2 percent) received matched unrelated donor SCT. Methotrexate and tacrolimus was the primary prophylaxis for GVHD. Seventy-two patients (63.7 percent) developed acute GVHD. Of the confirmed acute GVHD cases, 29 patients (40.3 percent) received systemic steroids (oral prednisone or intravenous methylprednisolone) and 42 patients (58.3 percent) received local steroid treatment (budesonide or topical steroid creams) as the primary treatment of choice. After evaluating patients who developed GVHD and received primary treatment with systemic steroids, 10 patients (34.5 percent) developed SR-GVHD. When identifying secondary therapy for SR-GVHD, 7 patients (70 percent) received infliximab, 2 patients (20 percent) received basiliximab, and 1 patient (10 percent) received rituximab. Four patients (40 percent) received mycophenolate as additional therapy given in combination with one of the previously discussed therapies. Time to disease relapse and time to death were variable based upon disease severity and development of GVHD.

Conclusion: Development of acute GVHD is common in patients who received allogeneic SCT, but the occurrence of SR-GVHD was clinically non-significant when compared to the total study population and the proportion of study subjects who received first-line systemic steroid treatment. Of the study subjects who developed acute SR-GVHD, infliximab was the most prevalent drug of choice. Treatment options may vary among institutions, thus the most effective primary and secondary treatment options for acute GVHD should be further analyzed for efficacy in larger, long-term retrospective studies.

Poster Title: Dapagliflozin associated euglycemic diabetic ketoacidosis

Primary Author: Suzanne Shearin, Campbell University College of Pharmacy and Health Sciences, North Carolina; **Email:** scshearin0223@email.campbell.edu

Additional Author (s):
Riley Bowers
Catherine Wente

Purpose: Dapagliflozin associated euglycemic diabetic ketoacidosis
Dapagliflozin is an oral anti-diabetic medication used to improve glycemic control in type 2 diabetes mellitus in addition to diet and exercise. Dapagliflozin is a sodium glucose co-transporter (SGLT-2) inhibitor which prevents the reabsorption of glucose in the kidneys. SGLT-2 is responsible for 90% of the reabsorption of glucose. This class of anti-diabetics is typically used in addition to other first line agents. The most common adverse reaction seen with SGLT-2 inhibitors is genital mycotic infections, however more concerning is ketoacidosis. On May 5th, 2015, the FDA issued a statement regarding the use of these medications leading to euglycemic diabetic ketoacidosis (DKA). We report a case of euglycemic DKA in a patient taking dapagliflozin for type 2 diabetes. A 45-year-old female was sent to the emergency department from her physician's office after lab results showed ketones in her urine. The previous week she had presented to her physician with complaints of foot pain, polyuria, polydipsia, and polyphagia. At that time, the patient's glucose was found to be over 300 milligrams per deciliter and she also had ketonuria. She was initiated on sitagliptin-metformin 50-1,000 milligrams once daily and dapagliflozin 10 milligrams once daily. At the follow-up visit four days later, she was normoglycemic, however still had ketones present in her urine. She was advised to go to the emergency department, where she was then admitted for euglycemic DKA. The patient had a beta-hydroxybutyrate of 5.75 millimoles per liter, anion gap of 16, and glucose of 118 milligrams per deciliter. Dapagliflozin and sitagliptin-metformin were discontinued immediately and she was started on intravenous fluids. Insulin was held due to blood glucose being between 90-110 milligrams per deciliter. After three boluses of normal saline and lactated ringers, the anion gap normalized, however ketones were still present. Following another liter of lactated ringers and subcutaneous insulin initiation, the beta-hydroxybutyrate level had dropped to 0.45 millimoles per liter. The patient was then discharged with insulin glargine 15 units in the

morning and metformin 1000 milligrams twice daily. Dapagliflozin was not reinitiated in the patient, however it is unknown whether it is safe for them resume therapy when DKA has resolved. According to European articles, it is not advised to restart SGLT-2 inhibitor unless there is a another clear cause to the patient developing DKA. Patients taking dapagliflozin should be aware of the potential risk for euglycemic DKA. This likely occurs due to dapagliflozin preventing glucose reabsorption without stimulating pancreatic beta cells to secrete insulin leading to decreased ketone removal. Further research is needed to determine the exact mechanism of euglycemic DKA and how it can be prevented. At this time, patients should understand the signs of DKA, how they can check for ketones, and when to present to emergency department.

Poster Title: Sub-therapeutic rivaroxaban concentrations in a 20-year old female (30 kilograms) despite standard adult rivaroxaban dosing

Primary Author: Shasta Grotewiel, Campbell University College of Pharmacy and Health Sciences, North Carolina; **Email:** s_cernea0914@email.campbell.edu

Additional Author (s):
Tara Bell

Purpose: Deep vein thrombosis in younger patients is not as common as adults and is typically due to an underlying condition. Current anticoagulation therapies such as warfarin and enoxaparin, involve frequent monitoring or injections. The direct oral anticoagulation agents, such as rivaroxaban, are appealing due to their ease of use and infrequent monitoring. The pharmacokinetics and dosing of rivaroxaban has not been studied in the pediatric patients, or patients < 40 kg. Two case reports demonstrated that pediatric patients may require more frequent dosing of rivaroxaban to achieve levels similar to that of an adult. We report obtaining subtherapeutic rivaroxaban assay despite the standard adult dose of rivaroxaban at steady state for the treatment of a provoked DVT in an adolescent female who weighs 30kg. A 20 year old female with spina bifida weighing 30.4 kg was admitted for urosepsis related to multi-drug resistant E.coli. Due to the patient's rapid decline in weight, a Nasogastric -tube was placed to achieve adequate nutritional support. Unfortunately due to the PICC line for the intravenous antibiotics, the patient developed a thrombus of the left subclavian vein. The patient was initiated on enoxaparin therapy 30 mg subcutaneous every 12 hours with the intention of transitioning to oral anticoagulation therapy that could be continued on an outpatient basis. Rivaroxaban 15 mg via Nasogastic-tube every 12 hours with food, the standard adult dose for deep vein thrombosis, was initiated and enoxaparin therapy discontinued. A sub-therapeutic rivaroxaban assay level (0.08 micrograms per mL) was obtained following three doses of rivaroxaban, resulting in the re-initiation of enoxaparin therapy. We conclude, the standard adult dose (15 mg enteral twice a day) of rivaroxaban, may not be adequate in achieving therapeutic rivaroxaban levels in younger patients with lower body weight (30 kg). Further studies are needed in order to determine an ideal dosing range in this patient population.

Poster Title: Interprofessional analysis of the factors affecting achievement of adequate statin use in a multidisciplinary family medicine clinic

Primary Author: Jennifer Ku, UNC Eshelman School of Pharmacy, North Carolina; **Email:** jk763@email.unc.edu

Additional Author (s):
Trang Leminh
Payal Patel
Meg Zomorodi
Nicole Pinelli

Purpose: The purpose of this study was to identify factors affecting statin underuse in a multidisciplinary family medicine clinic using an interprofessional student team-based quality improvement approach. There is a need for health professionals trained in population health in most healthcare settings. Given that healthcare is advancing towards interprofessional team-based practice, there is also a need for health professional students to be trained and educated within interprofessional models. However, there is limited evidence demonstrating the success of training an interprofessional student team to perform quality improvement interventions expected in a population health management practice.

Methods: An interprofessional team of three students in pharmacy; two in nursing; two in medicine, one in public health; and one in social work completed a new 13-week population health management course at the University of North Carolina at Chapel Hill as part of the Healthcare PROMISE (Populations: Reformed Outcomes Management from Inter-professional Systems-Based Education) initiative and a 13-week immersion period to analyze statin use at a family medicine clinic. During the immersion, students shadowed and interviewed 13 healthcare providers from multiple professions and support staff using the Ottawa Decision Guide. Interprofessional team members conducted a community needs assessment to determine intervention priorities. Data was collected through interviews, subjective observational notes, and statistics on statin use. Data was then analyzed by determining themes, discussing factors that impeded statin use, and utilizing the Primary Care Collaborative

Quality Measures Reporting Guide to prioritize which factors could be most influenced by the team.

Results: The needs assessment indicated that patient and provider knowledge on statin use benefits were the primary concerns. The team recommended a 4-component effort targeting patient education that included a check-in survey, informational posters and brochures, a provider script, and a personalized "statin choice tool." All of these, except the "statin choice tool", were implemented in April 2016. Two months after implementation, statin use in patients with diabetes increased 9 percent (from 57.3 percent to 66.3 percent).

Conclusion: This study demonstrates the effectiveness of a quality improvement plan developed by an interprofessional team of students as part of a population health management course. Continued efforts are needed to further address provider resistance towards statin prescribing. Overall, the 13-week pilot course proved successful in training an interprofessional team to partake in a quality improvement project within the community.

Poster Title: Impact of clinical pharmacists' interventions on pain management in cancer patients referred to palliative care

Primary Author: Stephanie Rusin, UNC Eshelman School of Pharmacy, North Carolina; **Email:** rusin@email.unc.edu

Additional Author (s):
Issam Hamadeh
Connie Edelen
Rebecca Edwards
Jai Patel

Purpose: Approximately 70% of cancer patients report uncontrolled pain. Although early palliative care (PC) has become an integral component of comprehensive cancer care and has been shown to improve quality of life and survival, one of the greatest challenges busy clinicians face is timely follow ups for pain and symptom assessment. One strategy to help improve practice efficiency is to engage qualified clinical pharmacists in the provision of PC. The aim of this study is to investigate the impact of clinical pharmacists' interventions on pain management in ambulatory cancer patients referred to the PC clinic.

Methods: Cancer patients ≥ 18 years old receiving treatment through the PC clinic and referred for a pharmacy assessment between 07/01/2016-09/23/2016 were included in the observational study. At the baseline visit, the PC specialist performed a symptom assessment using the Edmonton Symptom Assessment Scale (ESAS) (0-10 scale; e.g. 0=no pain and 10=worst pain). Pain medications were initiated or modified by the PC specialist and a list of patients requiring intervention within approximately one week was sent to the pharmacist for follow up. The pharmacist performed a pain and symptom assessment using ESAS either in person (e.g. during scheduled infusion) or via phone call. If needed, drug/dose modifications were sent to the referring PC specialist for approval (Assessment #1). Patients who required any intervention had another assessment (#2) performed within seven days to assess clinical response. The primary end point is the proportion of patients who achieved ≥ 2-point reduction in pain score from baseline to assessment #2, which was compared to historical control rates for pain improvement in cancer patients (~32%) using a Chi-square test. A paired t-test was

used to compare the mean pain scores at baseline and assessment #2. Secondary endpoints include: a description of changes in pain scores longitudinally between each assessment; mean duration of pharmacist assessments; and, the reason and type of each pharmacist intervention in patients requiring a therapy modification.

Results: Of 36 patients referred, 23 (64%) required an intervention and were included in the final analysis. The mean age was 55 ± 15 years, 65% were female, 50% had solid tumors, 65% had stage IV disease, and 61% had an ECOG performance status of 0 or 1. Approximately 52% and 48% of patients presented with nociceptive pain only or both nociceptive and neuropathic pain, respectively. Eighteen patients (78%) had ≥ 2-point reduction in pain score from baseline to assessment #2, which was significantly greater than the historical control rate of 32% (p < 0.0001). The mean pain scores at baseline, assessment #1, and assessment #2 were 6.3 ± 2.9, 4.9 ± 2.4, and 3.5 ± 2.3, respectively (p=0.0007 for assessment #2 vs baseline). The mean time spent for each pharmacist intervention was 18 and 16 minutes at assessment #1 and #2, respectively. The most common reasons for intervention at assessment #1 were uncontrolled pain (52%), lack of response to non-pain related medications (primarily laxatives) (17%) and adverse events (17%). The most common types of interventions performed by the pharmacist were dose adjustments (32%), patient education (e.g. incorrect administration, noncompliance, etc.) (32%), and medication addition (29%).

Conclusion: Clinical pharmacists' interventions occurring after the baseline PC clinic visit resulted in a significantly higher proportion of patients achieving ≥ 2-point reduction in pain scores. Although pain reduction occurred from baseline to assessment #1, the difference was not statistically significant (p=0.08). Importantly, implementation of pharmacists' interventions further reduced pain scores at assessment #2, resulting in statistically significant and clinically improved pain scores. The most common reason for intervention was uncontrolled pain and the most common types of interventions were dose adjustments and education. Pharmacists play a pivotal role in pain management and are critical members of the palliative care team.

Submission Type: Descriptive Report

Session-Board Number: 3-254

Poster Title: Assessment of Factors Affecting Adherence of Hepatitis C Direct Acting Antiviral Therapy

Primary Author: Brittney Roberts, UNC Eshelman School of Pharmacy, North Carolina; **Email:** brittney_roberts@unc.edu

Additional Author (s):
Ellina Max
Jane Giang

Purpose: Treatment of hepatitis C virus (HCV) requires high adherence to new direct acting antiviral (DAA) regimens in order to achieve sustained virologic response (SVR) (i.e. "cure"). High treatment costs and the potential of HCV to develop resistance to these medications add to the impetus of identifying factors in order to optimize patient outcomes. The need to re-examine factors influencing patient adherence to these new medications is imperative. The purpose of this study was to determine what factors affect the rate of adherence to DAAs for HCV patients treated at the University of North Carolina Liver Center.

Methods: Data was collected from adult patients at the UNC Liver Center who qualified for treatment with a DAA for hepatitis C genotypes 1a, 1b, 2, 3, or 4 and had DAA therapy initiated between 1/1/16 – 3/21/16. The impact of (a) face-to-face counseling (FTFC) with a pharmacist, (b) telephone counseling with a pharmacist, (c) age, (d) duration of treatment (8 vs. 12 vs. 24 weeks), (e) daily pill burden (DPB), (f) prior treatment experience (TE) and (g) disease severity (fibrosis) on the rate of adherence of HCV-infected patients treated with DAAs were examined. Adherence was determined by pill counts and self reported during various follow up calls with the pharmacist or clinic visits throughout the duration of treatment. FTFC typically covers indication, administration, common side effects and management strategies, drug-drug interactions and the importance of adherence. The percentage and number of patients with a given characteristic in the "No Missed Doses" (NMD) group was compared to the prevalence of that characteristic in the group of patients that missed at least one dose (MD).

Results: 91 patients were enrolled. 45 patients (50%) had no missed doses compared to 24 patients (26%) that had missed at least one dose. 22 (24%) patients were unable to provide pill counts and were excluded for the data analysis. NMD group had more FTFC (27%[12/45]) prior to initiating therapy than the MD group (17%[4/24]). However, both groups had the same percentage of combined FTFC/phone interventions at 96% (43/45 in NMD vs 23/24 in MD). 12-week duration patients had a higher percentage of missed doses compared to NMD group (67%[16/24] vs 51%[23/45]). MD group had more patients born between 1951-1970 (88%[21/24]) and had received previous treatment (29%[7/24]), compared to NMD group (67%[30/45], 20%[9/45] respectively). MD group had 63%[15/24] patients with DPB of 1 while NMD had 67%[30/45] patients. MD group had a slightly higher percentage of patients with fibroscan scores F2-F4 at 75% (18/24) compared to NMD group of 67% (30/45). NMD group had a slightly higher percentage of patients achieve documented SVR compared with MD group (61% [22/36] vs. 57% [12/21]). Not all patients had reached post treatment week 12 at the conclusion of the study.

Conclusion: Of patients with known pill counts, a majority of patients had no missed doses. However, we found a significant number of patients had missed doses of their DAAs. There was a trend that showed patients with FTFC had higher adherence. Patient characteristics including 12-week duration of therapy, born between 1951-1970 and previous TE were associated more with the MD group. DPB and disease severity did not seem to affect adherence. SVR was higher in NMD group, which highlights the importance of adherence. Pharmacists can use patient characteristics to identify patients that would benefit most from FTFC counseling.

Poster Title: Evaluation of continuous intravenous infusion (CIVI) heparin use at Vidant Medical Center

Primary Author: Marina Snellings, UNC Eshelman School of Pharmacy, North Carolina; **Email:** msnellin@email.unc.edu

Additional Author (s):
Michelle Herrmann
Kacy Whyte
Carol Labadie

Purpose: Continuous intravenous infusion (CIVI) heparin accounts for approximately 40 percent of the anticoagulation errors at Vidant Medical Center (VMC) despite protocols in place for monitoring and titration. There are several alternatives to heparin when anticoagulation is required, including low molecular weight heparin (LMWH), warfarin, and the direct oral anticoagulants (DOACs). The purpose of this study was to evaluate the use of CIVI heparin at VMC to identify opportunities to recommend alternative anticoagulation therapy. This is a quality improvement initiative to proactively address ways to decrease medication errors associated with CIVI heparin at VMC.

Methods: Patients admitted to VMC from May 1, 2016 to June 30, 2016 and on CIVI heparin for at least 24 hours were identified through an electronic health record medication report for CIVI heparin. Patients who were less than 18 years old, pregnant, or incarcerated were excluded. Selected patients were evaluated for age, gender, race, height, weight, length of stay, renal function, anticoagulation indication, heparin indication, prior to admission anticoagulant use, and transition to an oral anticoagulant. Appropriate use of CIVI heparin was defined as indications for heparin in which alternative anticoagulation therapy would not be selected. Safety was evaluated through assessment of appropriate activated partial thromboplastin time (aPTT) lab draws and heparin titration according to approved nurse-driven protocols. The primary endpoint was the percentage of patients with appropriate utilization of CIVI heparin for which alternative anticoagulants would not be indicated.

Results: A total of 100 patients were included in the analysis. Four patients were excluded due to indeterminate heparin indication. Heparin utilization was found to be appropriate in 92 percent of patients. The most common indications for appropriate use of heparin were acute coronary syndrome (ACS) (47 percent), anticipation of a procedure (23 percent), and bridge to an oral anticoagulant (12 percent). Heparin was selected in cases of renal dysfunction in 7 percent of patients. In the safety assessment, only 28 percent of patients had no medication errors with the use of CIVI heparin. An error with the timing of collection of aPTT labs occurred in 32 percent of patients, and an error with heparin titration occurred in 7 percent of patients. An error with both aPTT lab collection and titration of heparin occurred in 33 percent of patients.

Conclusion: Overall, CIVI heparin is being used appropriately for situations in which alternative anticoagulation would not be indicated in patients at VMC. However, there continues to be significant numbers of both lab and titration errors associated with the use of CIVI heparin. Targeting nursing education on the proper use of CIVI heparin may be the most effective method to decrease medication errors due to heparin at VMC.

Poster Title: Management of patients undergoing evaluation for heparin-induced thrombocytopenia in a large academic medical center

Primary Author: Tanner Hedrick, UNC Eshelman School of Pharmacy, North Carolina; **Email:** tlhedric@live.unc.edu

Additional Author (s):
Kalynn Rohde
Sheh-Li Chen
Marian Rollins-Raval
Raj Kasthuri

Purpose: Heparin-induced thrombocytopenia is a rare, but potentially lethal, complication of heparin administration and occurs in approximately 1-5% of patients. Given the numerous clinical services and providers evaluating for heparin-induced thrombocytopenia, management strategies for these patients are complex. These strategies include discontinuation of all heparin products, performing appropriate laboratory testing, initiating alternative anticoagulants, documentation of heparin allergy, and providing patient education prior to discharge. The purpose of this study was to evaluate the current management strategies for patients evaluated for heparin-induced thrombocytopenia within a large academic medical center.

Methods: This study was approved by the Institutional Review Board at the University of North Carolina Hospitals and Clinics. A retrospective chart review was performed to identify patients who fulfilled the following criteria: (1) at least 18 years of age, (2) admitted between 4/4/2014 and 5/31/2016 and (3) had heparin-induced thrombocytopenia panel (heparin-PF4 antibody ELISA and Heparin-induced platelet aggregometry) ordered during their hospitalization. Charts were reviewed to (1) identify the incidence of continued heparin administration during heparin-induced thrombocytopenia panel testing, (2) identify the incidence of continued heparin administration to patients with a positive heparin-induced thrombocytopenia panel and (3) determine the percentage of patients with appropriate heparin allergy documentation upon discharge. A positive panel was defined as a heparin-PF4 antibody ELISA optical density of ≥0.4 and positive heparin-induced platelet aggregometry OR a positive serotonin-release assay.

Results: A total of 636 heparin-induced thrombocytopenia panels were ordered for the 542 patients included in the study. Forty of 636 panels (6.3%) were positive, and 30 patients were diagnosed with heparin-induced thrombocytopenia. Five panels were indeterminate and deemed to require additional testing. Heparin administration was continued during 50.3% of pending heparin-induced thrombocytopenia panels. Out of 30 heparin-induced thrombocytopenia positive patients, 4 patients (13.3%) received heparin while testing was pending. Out of 512 heparin-induced thrombocytopenia negative patients, 33 (6.5%) currently have a heparin allergy incorrectly documented in their electronic health record. Out of 30 heparin-induced thrombocytopenia positive patients, 2 patients (6.7%) did not have heparin allergy documentation in their record.

Conclusion: Our study found a large number of patients suspected to have heparin-induced thrombocytopenia continued to receive heparin while testing was pending. Further, we found incorrect documentation of patients of heparin allergy was also a significant clinical issue, which could result in inappropriate heparin exposure among patients with heparin-induced thrombocytopenia or withholding of heparin in patients in whom heparin-induced thrombocytopenia was ruled-out. Implementation of institutional guidelines on the approach to evaluation and monitoring of patients with suspected or confirmed heparin-induced thrombocytopenia could help ensure patient safety and promote appropriate management in these complex patients.

Poster Title: Evaluation of a pharmacy-to-dose vancomycin protocol in non-morbidly obese patients

Primary Author: Allison Stilwell, UNC Eshelman School of Pharmacy, North Carolina; **Email:** amstilwe@email.unc.edu

Additional Author (s):
Megan Petteys
Kelly Pillinger

Purpose: Despite extensive experience with vancomycin, achieving therapeutic trough concentrations with empiric dosing remains a significant clinical challenge, especially in morbidly obese patients. Retrospective, observational studies within Carolinas HealthCare System (CHS) have evaluated vancomycin dosing in morbidly obese patients, but the effectiveness of the CHS pharmacy-to-dose vancomycin protocol in achieving therapeutic trough concentrations in non-morbidly obese patients is unknown. Therefore, an evaluation of the effectiveness of the CHS pharmacy-to-dose vancomycin protocol in non-morbidly obese patients, which is consistent with the vancomycin dosing guidelines by ASHP, IDSA, and SIDP, can provide a standard we should strive to achieve in morbidly obese patients.

Methods: The institutional review board approved this single-center, retrospective, observational study conducted at Carolinas Medical Center in Charlotte, North Carolina. Patients identified through pharmacy-to-dose vancomycin consultations ordered from June 1st, 2013 to June 30th, 2016 were included if they were greater than or equal to 18 years but less than 60 years of age, non-morbidly obese (defined as less than 100 kg or greater than or equal to 100 kg but total body weight is less than 140 percent of ideal body weight), had a creatinine clearance (CrCl) greater than 90mL/min, and had at least one vancomycin trough concentration drawn at steady state within 25 percent of the dosing interval (i.e., up to 3 hours before a dose in a patient being dosed every 12 hours). Reasons for exclusion included: unstable renal function in the first 48 hours of vancomycin therapy, pregnancy, dosing strategies outside of the protocol, initiation of vancomycin therapy prior to admission, or if a dose had been rescheduled by more than 50 percent of the interval between doses. The primary outcome was the frequency of the attainment of therapeutic vancomycin trough concentrations of 10 to 20

mcg/mL extrapolated from the first measured trough at steady state. Secondary outcomes included the frequencies of subtherapeutic (less than 10 mcg/mL) and supratherapeutic (greater than 20 mcg/mL) trough concentrations and the frequency of nephrotoxicity.

Results: After screening a total of 396 patients, 45 patients were enrolled, representing an inclusion rate of 11 percent. The median age was 39 years old (interquartile range, or IQR, 28 to 50), the median CrCl was 129 mL/min (IQR, 112 to 138) and the median total body weight was 81.1 kg (IQR, 72.1 to 90.7). The majority of patients had no comorbidities (55.6 percent, n equals 25), and 18 patients (40 percent) were in the intensive care unit. The most common indication for therapy was pneumonia (35.6 percent, n equals 16). Most patients had a goal trough concentration of 15 to 20 mcg/mL (73.3 percent, n equals 33). Nineteen patients (42.2 percent) received a loading dose. The median loading and maintenance doses were 25.3 mg/kg (IQR, 24.4 to 25.7) and 15.2 mg/kg (IQR, 14.7 to 15.9), respectively. The median duration of therapy was 4 days (IQR, 4 to 5). Of the 45 patients included, 12 (26.7 percent) achieved a therapeutic vancomycin trough concentration. Subtherapeutic trough concentrations were observed in 33 patients (73.3 percent) and no supratherapeutic trough concentrations were observed. The median extrapolated vancomycin trough concentration was 7.3 mcg/mL (IQR, 5.1 to 10.1). Nephrotoxicity occurred in three patients (6.7 percent).

Conclusion: This study demonstrates that the current CHS pharmacy-to-dose vancomycin protocol led to the attainment of therapeutic vancomycin trough concentrations in only 26.7 percent of non-morbidly obese patients. The majority had subtherapeutic vancomycin trough concentrations, which potentially places patients at risk for treatment failures and the development of vancomycin-resistant organisms. On the other hand, no patients had supratherapeutic trough concentrations. This study reveals that adjustments to the protocol may be needed in order to increase the frequency of non-morbidly obese patients who attain therapeutic vancomycin trough concentrations, which will, in turn, serve as a standard for dosing in morbidly obese patients.

Submission Type: Evaluative Study

Session-Board Number: 3-258

Poster Title: Evaluation of vitamin K utilization at a tertiary care medical center

Primary Author: Brian Kurish, UNC Eshelman School of Pharmacy, North Carolina; **Email:** brian_kurish@unc.edu

Additional Author (s):
Kacy Whyte
Rena Beth Morse

Purpose: Warfarin is an anticoagulant used for a variety of indications including therapeutic anticoagulation or thromboprophylaxis. In severe overanticoagulation, major bleeding, or need for emergent surgery, reversal of warfarin is indicated. Vitamin K is a mainstay in warfarin reversal given its low cost and prolonged suppression of anticoagulation. The primary risk associated with warfarin reversal is thrombosis. Given the thrombotic risks associated with vitamin K use, it is critical to ensure that vitamin K is being used appropriately. The purpose of this investigation is to assess the prescribing practices of vitamin K for warfarin reversal at a tertiary care medical center.

Methods: Adult patients age 18 and older who received vitamin K for the reversal of warfarin at a tertiary care medical center between 04/01/2016 and 06/30/2016 were included in this retrospective analysis. All data points were collected via an electronic health record. Items recorded included demographics, indication for warfarin, indication for reversal, dose and route of vitamin K, INR before vitamin K administration, administration of blood products to supplement reversal, the use of concomitant medications which affect bleeding or hemostasis, and incidence of stroke or systemic embolism. Determination of appropriate use for vitamin K was based on an algorithm derived from recommendations from the 2012 CHEST guidelines for Evidence-Based Management of Anticoagulant Therapy: Antithrombotic Therapy and Prevention of Thrombosis and the 2014 ACC/AHA guidelines for the Management of Patients with Valvular Heart Disease. The primary outcome was the incidence of appropriate vitamin K administration, defined as valid indication, route, and dose according to national guidelines.

Results: Within the study period 74 patients received vitamin K for warfarin reversal. The average age of these patients was 72 years. Most common indications for anticoagulation were atrial fibrillation (48 percent), pulmonary embolism secondary prophylaxis (19 percent), and deep vein thrombosis secondary prophylaxis (12 percent). Indications for reversal included supratherapeutic INR (45 percent), major bleeding as described in ROCKET-AF (30 percent), surgery (24 percent), and one patient had no identifiable indication (1 percent). For the primary outcome, vitamin K administration was considered appropriate per guidelines in 16 patients (22 percent). Of the 58 inappropriate administrations, 31 (53 percent) were not indicated, 2 (3 percent) used an incorrect dose, 20 (35 percent) used an inappropriate route, and 5 (9 percent) used an incorrect dose and route. Of the 74 doses of vitamin K administered, 51 (69 percent) were given intravenous, 21 (28 percent) were given by mouth, and 2 (3 percent) were given subcutaneously. The median dose was 7.5 mg. Of the 28 patients who received concomitant blood products, 7 received 4-factor prothrombin complex concentrate, 21 received fresh frozen plasma, and no patients received 3-factor prothrombin complex concentrate or factor VIIa. There were no recorded incidents of stroke or systemic embolism.

Conclusion: Despite well-established guidelines detailing the management for warfarin reversal, vitamin K is often used inappropriately. One limitation to our study is the incomplete assessment of vitamin K utilization. Since our evaluation included only patients who received vitamin K, patients who would be appropriate candidates for reversal with vitamin K but did not receive it were excluded. Given the significant deviations in practice from guideline recommendations, a protocol will be developed and implemented to promote evidence-based utilization of vitamin K for warfarin reversal at our institution.

Poster Title: Medication bags provided at hospital discharge increase the number of patients that bring medication bottles to follow-up clinic appointments

Primary Author: Catherine Buckthal, UNC Eshelman School of Pharmacy, North Carolina; **Email:** cabuck@email.unc.edu

Additional Author (s):
Carla Sueta
Sabrina Vereen
Becky Van Valkenburgh
Zachariah Deyo

Purpose: Reviewing medication bottles aids in the detection of medication discrepancies. A 1-week pre-implementation review of all clinic encounters at the University of North Carolina (UNC) Cardiology Clinic indicated that only 14 percent of patients brought medications to their clinic appointment. This quality initiative aimed to determine the feasibility of distributing a cloth medication bag to patients discharged from inpatient cardiology services to increase the number of patients bringing medication bottles to hospital follow-up visits. For patients with follow up at UNC's Cardiology Clinic, we also aimed to determine patient satisfaction with the bag and assess medication discrepancies.

Methods: UNC's institutional review board approved this prospective, cohort study as a quality improvement project. Therefore, informed consent was not obtained from patients followed in the study. Patients discharged from UNC Hospitals' inpatient cardiology services (Cardiology (MDC), Heart Failure (MDD), Cards Procedures (MDS)) were included in the study. UNC's inpatient cardiology nurses provided a high quality cloth bag to patients in the cohort from October 26th, 2015 through February 6th, 2016. The inpatient nurses recorded the name and MRN of patients who received a bag at discharge. The bags were labeled with directions to bring all medication bottles to the hospital follow up visit. Outpatient clinic nurses at UNC's Cardiology Clinic documented in the electronic health record (EHR) if patients brought the medication bag with their medication bottles to clinic. If patients used the bag, clinic nurses provided a brief questionnaire to assess patient satisfaction with the bag and recorded the response in the EHR. Additionally, clinic pharmacists recorded and categorized all identified

medication discrepancies. The primary outcome was the percentage of patients who received a medication bag and brought medication bottles to the first visit at UNC's Cardiology Clinic after discharge. Secondary outcomes included patient satisfaction with the provided bag, the number and type of medication discrepancies found, time to clinic visit (7-14 days), and 30-day readmission rate.

Results: We distributed bags to 314 of 512 unique patients discharged (61 percent) from the inpatient cardiology services. Forty-three percent of patients were female, 58 percent were Caucasian, and the average patient was 62 years old. Of the 117 patients with follow-up at UNC's Cardiology Clinic (37 percent of total cohort), 66 patients (44 percent) brought their bag to clinic, of which 86 percent brought their medications. Notably, 41 patients received the satisfaction survey and 90 percent reported the bag helped them remember to bring their medications, 98 percent plan to continue to use the bag, and 98 percent highly or somewhat agree that bringing medications to clinic is important to their care. Clinical pharmacists saw 14 patients (27 percent) with medication bags. Clinical pharmacists identified medication discrepancies in 67 percent of these 14 patients. Eighty-nine percent of medication discrepancies were categorized as having a probable or possible clinical impact. Patients who used the bag were associated with a 4 percent 30-day readmission rate, as compared to 12 percent in patients who did not use the bag.

Conclusion: Providing medication bags to patients at hospital discharge was feasible and increased the percent of patients who brought medication bottles to clinic visits. Additionally, the medication bags helped patients to remember to bring their medications to clinic appointments. Although our results indicate a positive finding, a large number of patients in the initial cohort had follow-up appointments at other locations and could not be analyzed. Future studies may consider following patients discharged to a broader range of clinics to further analyze the benefit of providing medication bags at discharge, including identifying medication discrepancies and the impact on readmissions.

Poster Title: Evaluation of carbapenem utilization in a community hospital.

Primary Author: Margaret Marshall, UNC Eshelman School of Pharmacy, North Carolina; **Email:** margaret_marshall@unc.edu

Additional Author (s):
Amanda Gorman
Shannon Holt

Purpose: Carbapenems are the antimicrobial treatment of choice for extended-spectrum beta-lactamase producing Enterobacteriaceae (ESBL) infections. It is important to preserve these agents for complicated infections requiring broad spectrum coverage as greater exposure contributes to increasing numbers of resistant pathogens, most notably carbapenem resistant Enterobacteriaceae (CRE). Currently at our institution only ertapenem has restrictions in place for utilization. With reported pseudomonal resistance increasing over the last 3 years, the purpose of this retrospective review was to evaluate meropenem utilization in an institution with no restrictions.

Methods: The institutional review board approved this retrospective single center observational study. All adult patients who had an active order for meropenem at the site from January to June 2016 were included in the study. Patients who were not administered a dose or not admitted to the hospital were excluded. The primary outcome was to evaluate prescribing trends for indication and provider. A secondary outcome was to identify potential initiatives to optimize and reduce meropenem usage. This was determined by the percentage of patients on meropenem when an alternative beta-lactam agent could have been utilized. Alternative beta-lactam therapy was determined for the following scenarios: a non-type 1 penicillin allergy (rash or no reported allergy), no documented history of ESBL infection, and no current ESBL infection. Data analysis was completed with descriptive statistics.

Results: 108 were included in the study and consisted of mainly female (56 percent) patients with no reported PCN allergy (76 percent), and no history of ESBL infections (90 percent). The majority of patients were receiving meropenem for intra-abdominal infections (35 percent) and urinary tract infections (UTI) (32 percent). Predominant prescribers included hospitalists (41

percent) and surgeons (26 percent). The mean duration of meropenem therapy was 6 days (range 1 to 22 days). Of those with positive cultures (n equals 50), only 21 (19 percent) patients had a reported ESBL positive organism. The potential for alternative beta-lactam therapy to reduce carbapenem exposure was identified in 62 (75 percent) patients.

Conclusion: Patients were predominantly on meropenem therapy with no documented ESBL infection (81 percent) for coverage of intra-abdominal infections and UTIs. 75 percent of patients, not on the infectious disease service, could have potentially been on a non-carbapenem treatment regimen. Restrictions are needed to preserve the utilization of this broad spectrum agent and prevent future resistance.

Poster Title: Prescriber adherence to guideline recommendations for ACE Inhibitors, ARBs, and aldosterone antagonists in patients with reduced ejection fraction heart failure

Primary Author: Kai Kang, UNC Eshelman School of Pharmacy, North Carolina; **Email:** kangk@email.unc.edu

Additional Author (s):
Abby Hendricks
Timothy Ives
Betsy Shilliday
Jamie Cavanaugh

Purpose: The 2013 ACCF/AHA guidelines recommend certain first-line agents for patients with reduced ejection fraction (≤40%) heart failure (HFrEF), including angiotensin receptor converting enzyme inhibitors (ACEI), angiotensin II receptor blockers (ARB), and aldosterone antagonists. The 2016 QUALIFY trial showed that these agents are often under-prescribed or under-dosed in outpatient adults with recent heart failure hospitalizations. One third of patients in QUALIFY were not prescribed their theoretical guideline recommended regimen. Furthermore, most medications were at target dose less than half the time. Our study assessed the prescriber adherence to evidence-based pharmacotherapy for patients with HFrEF in a general internal medicine clinic.

Methods: The Institutional Review Board approved this study. This is a descriptive, retrospective observational study of outpatients from a single academic based internal medicine clinic at the University of North Carolina Medical Center. Participants were included if they were: 1) ≥18 years old; 2) Established UNC internal medicine clinic patient with a provider visit from January 2015-July 2016; and 3) Had a diagnosis of HFrEF. Patients who were pregnant, in hospice, or in palliative care were excluded. The primary measure of this study was a composite of the following two points: 1) Proportion of patients prescribed to target doses of guideline recommended medications and 2) Proportion of patients not prescribed to target doses of a guideline recommended medication due to contraindication to initiation or titration of an agent. Secondary measures looked at the prescribing patterns of individual drug classes and contraindications to initiation or titration of each class. Contraindications investigated

included co-morbidities, intolerable side effects, high serum potassium levels, high serum creatinine levels, and hypotension. Data was collected from the electronic medical record and analyzed utilizing descriptive statistics.

Results: 157 patients were included with a mean age of 63 years, a mean ejection fraction of 29.7%, and an average of 3.9 visits to the internal medicine clinic in the preceding 12 months. 38 patients (24.2%) met the definition for the primary measure. Of these 38 patients, 10 patients were at target doses of both a guideline recommended ACEI or ARB and aldosterone antagonist. 5 patients were only at target dose of an ACEI or ARB, but were not indicated for an aldosterone antagonist. The other 23 patients had contraindications to initiation or titration of either the ACEI, ARB, or aldosterone antagonist. The reasons for contraindication to an ACEI or ARB included high serum creatinine and allergy history. The reasons for contraindication to an aldosterone antagonist included high serum creatinine, hyperkalemia, low GFR, and allergy history. 17.2% (27/157) of patients were not prescribed any ACEI, ARB, or aldosterone antagonist. 25.5% (40/157) of patients were prescribed both an ACEI/ARB and aldosterone antagonist any dose.

Conclusion: The percentage of patients who met the definition for the primary measure was low and similar to percentages seen in previous studies. Furthermore, the majority of patients who met the definition did so due to a contraindication to one or more drug classes. Although a majority of the patients were on some dosage of at least one agent, this gap in prescriber adherence to guideline recommended therapy suggests an opportunity for optimizing medication use.

Poster Title: Projected impact of genotype-guided optimization of medication use: an opportunity for preemptive genotyping in cardiac catheterization laboratory patients

Primary Author: Amy Li, UNC Eshelman School of Pharmacy, North Carolina; **Email:** amli@email.unc.edu

Additional Author (s):
Olivia Dong
Akinyemi Oni-Orisan
Tim Wiltshire
Craig Lee

Purpose: Preemptive genotyping is a strategy that tests for multiple pharmacogenomic variants before a drug is prescribed. Although pharmacogenomic information currently appears in 165 FDA-approved drug labels, the clinical utility of preemptive genotyping remains uncertain. Many medications have an FDA boxed warning and/or available Clinical Pharmacogenetics Implementation Consortium (CPIC) guideline that recommend action, such as selecting a different drug or dose, in patients with certain genotypes if the genetic test result was available. This study assessed the projected number of actionable genotype-guided interventions that could have been made to optimize medication use through preemptive genotyping in cardiac catheterization laboratory patients.

Methods: This single-center, retrospective study of an established cohort included patients referred for coronary angiography between September 2012 and February 2014 who consented to participation in a biorepository. An institutional review board approved this study. Patient demographics, clinical information, and medication use were abstracted from the electronic medical record. A list of 20 drugs with genetically actionable FDA boxed warnings and/or CPIC guidelines was established a priori to guide medication collection. Oncology and immunomodulatory drugs were not considered. Medication information was collected at discharge and at the first follow-up clinic visit or hospitalization after the catheterization procedure. The analysis included 122 patients that had their first follow-up within 180 days. Drug prevalence at discharge or first follow-up was calculated using descriptive statistics. Projected genotype frequencies for 7 genes with actionable pharmacogenetic

recommendations (HLA-B, CYP2C19, CYP2D6, CYP2C9, SLCO1B1, VKORC1/CYP2C9, and DYPD) were estimated based on published literature for Caucasian-dominated populations. The primary endpoint was the projected number of genotype-guided interventions at discharge or first follow-up that could have occurred if genotype information was available at the time of patient encounter. The projected number of interventions for each drug was calculated by multiplying the observed drug frequency, projected at risk genotype frequency, and number of patients in the study population. The overall number of interventions was summed. The secondary endpoint was the distribution of total interventions by gene.

Results: The study population was on average 63 years old, 57 percent male, and 73 percent Caucasian. Approximately 14 percent had a history of depression and 38 percent underwent a percutaneous coronary intervention during the catheterization procedure. The most prevalent genetically actionable drugs at discharge or first follow-up were clopidogrel (48.4 percent), antidepressants (20.5 percent), simvastatin (13.9 percent), and warfarin (9.0 percent). Corresponding at-risk genotypes of interest and projected frequencies were CYP2C19 intermediate or poor metabolizers (28.9 percent) for clopidogrel, CYP2C19 ultra-rapid or poor metabolizers (32.5 percent) for antidepressants, SLCO1B1 C allele carriers (23.6 percent) for simvastatin, and VKORC1/CYP2C9 sensitive or highly sensitive responders (38.3 percent) for warfarin. The total projected number of genotype-guided interventions at discharge or first follow-up in the study population was 32. The distribution of total interventions by gene was as follows: 71.9 percent CYP2C19, 12.5 percent SLCO1B1, 12.5 percent VKORC1/CYP2C9, and 3.1 percent CYP2C9. There were no projected interventions involving drugs actionable for CYP2D6, HLA-B, and DYPD. Assuming each intervention is unique to one patient, a genotype-guided medication intervention could have been made in 26.2 percent (32 of 122) of the study population within 6 months of their presentation to the cardiac catheterization laboratory.

Conclusion: A preemptive genotyping strategy in cardiac catheterization laboratory patients would result in an immediate genotype-guided intervention in approximately 1 out of every 4 patients, which could optimize medication use in accordance with FDA boxed warnings and CPIC guideline recommendations. Almost 30 percent of interventions involved non-CYP2C19 drugs, suggesting the potential benefit of a multiplexed genotyping approach that extends beyond CYP2C19 testing. The study's limitations include its small sample size, short follow-up, assumption of Caucasian-dominated population, and exclusion of actionable oncology and immunomodulatory drugs. Additional studies are required to determine whether preemptive genotyping in this population improves outcomes and lowers cost.

Poster Title: Risk factors associated with first incidence of hospital acquired Clostridium difficile infection in non-critically ill patients

Primary Author: Lynsi Collins, UNC Eshelman School of Pharmacy, North Carolina; **Email:** lynsi_collins@unc.edu

Additional Author (s):
Ashley Moody
Bobbi Jo Eberwein
Olivia Morgan

Purpose: Clostridium difficile is one of the most common causes of healthcare associated diarrhea, resulting in increased patient morbidity and hospital length of stay. The continued problem of C. difficile emphasizes the need for astute infection prevention and improved antibiotic management. A better understanding of the risk factors associated with C. difficile is needed to facilitate further interventions of disease reduction. The primary purpose of this retrospective review was to evaluate the risk factors associated with first incidence of hospital acquired Clostridium difficile infection (CDI) at a large tertiary academic medical center.

Methods: This study was an institutional review board approved retrospective chart review. All patients aged 18 or older upon admission with a confirmed diagnosis of CDI who were not directly admitted to an intensive care unit were included in the study. Hospital acquired CDI as defined by the presence of diarrhea and a positive stool C. difficile cytotoxin assay greater than or equal to 48 hours after hospital admission was also required for inclusion. Patients with recurrent CDI or diagnosis of CDI less than 48 hours after hospital admission were excluded. Patient data was collected via hospital electronic medical records from January 1, 2015 to December 31, 2015. The primary objective of this evaluation was to identify risk factors that predispose patients at high risk for acquiring CDI in the hospital setting. Data was analyzed through use of descriptive statistics.

Results: The analysis included 53 patients, of which 40 patients met inclusion criteria. Six patients were excluded due to recurrent CDI and seven patients were excluded due to symptom onset occurring less than 48 hours after inpatient admission. The median age was 60 years (range: 18-88) and 53 percent of patients were female. The majority of patients (95 percent) were on at least one antibiotic before developing CDI with 56 percent of patients taking a beta-lactam antibiotic. The average duration of antibiotic use prior to CDI diagnosis was five days and the mean length of hospital stay was 36.55 days. It was found that 65 percent of patients were immunocompromised with 93 percent of those patients receiving antibiotics before a confirmed diagnosis of CDI.

Conclusion: The results from this study demonstrate that the use of antibiotics trend towards the development of CDI in the hospital setting. Patients who are immunocompromised may also be at an increased risk for developing CDI. This risk may be further increased when immunocompromised patients receive antibiotics during their hospitalization. Patients who present with these risk factors during their hospital stay should be provided with antimicrobial stewardship and carefully monitored for the development of CDI.

Poster Title: Assessment of Four-Factor Prothrombin Complex Concentrate Dosing Practices within Neurocritical Care

Primary Author: Molly Merz, UNC Eshelman School of Pharmacy, North Carolina; **Email:** mmerz@email.unc.edu

Additional Author (s):
Denise Rhoney
Kathryn Morbitzer
Aaron Cook

Purpose: Four-factor prothrombin complex concentrates are used to urgently reverse vitamin K antagonists in adult patients with major bleeds. The recommended dosing of four-factor prothrombin complex concentrates is based on Factor IX units, which can range from 20 to 31 units/ml in each vial. This variability in potency has led to differences in how four-factor prothrombin complex concentrates are dispensed. This study was designed to examine the current dosing practices of four-factor prothrombin complex concentrates in neurocritical care unit patients across the United States and evaluate the effect these practices have on patient response and safety.

Methods: This was a multi-center, retrospective, observational study of patients, aged 18 and older, receiving four-factor prothrombin complex concentrates for reversal of warfarin-related, intracranial bleeding between January 1, 2014 and December 31, 2015. A total of 10 centers collected patient data from each center's patient information database or paper medical record. Collected data was categorized into basic demographics, labs, hospital stay and medications. Data collected included age, gender, height, weight and past medical history of each patient. Baseline labs as well as up to eight repeat INR values were collected. Hospital stay information included patient's length of stay in the hospital, length of stay in the ICU, intracranial hemorrhage characteristics and patient discharge information. Patient's reason for vitamin K antagonist use, other reversal agents administered, antiplatelets taken prior to admission and NSAIDs taken prior to admission were collected from medication information. The initial four-factor prothrombin complex concentrate dose given in units, repeat doses and adverse effects experienced were also collected and included in the medication category. The

patient data gathered from each center was then compiled into an online data collection form (operated by REDCap). Each center obtained approval from their local institutional review board (IRB) and was subject to the regulation of the primary governing IRB at the University of North Carolina at Chapel Hill.

Results: A total of 217 patients were entered into the database. Average age was 70.6 years (standard deviation equals 14). Males comprised 56% of the patient population (number equals 121). The majority of patients, 62%, were taking warfarin for atrial fibrillation (number equals 126). In terms of intracranial hemorrhage location, 34% of patients had a subdural hematoma (number equals 63), 14% had an intracranial hemorrhage with intraventricular hemorrhage (number equals 27) and 12% had a supratentorial intracranial hemorrhage (number equals 23). The mean dose of the four-factor prothrombin complex concentrate administered to patients was 2303 units (standard deviation equals 802). The mean dose in units/kg was 28 (standard deviation equals 9). After receiving the four-factor prothrombin complex concentrate, 93% of patients achieved an INR less than 1.4 (number equals 202) and 99% of patients achieved an INR less than or equal to 1.5 (number equals 214). The time from baseline INR to INR less than 1.4 was 7 hours (interquartile range equals 4 to 14 hours). Adverse events included DVT in 4% of patients (number equals 8), stroke in 1% of patients (number equals 3) and hypersensitivity reactions in 1% of patients (number equals 2).

Conclusion: This study was a real-life evaluation of how four-factor prothrombin complex concentrates are used in intracranial bleeding. The majority of patients normalized their INR after treatment with a four-factor prothrombin complex concentrate and few patients experienced adverse reactions associated with dosing.

Poster Title: Impact of a pre-discharge pharmacy concierge service on 30-day hospital readmissions

Primary Author: Caroline Welles, UNC Eshelman School of Pharmacy, North Carolina; **Email:** welles@email.unc.edu

Additional Author (s):
Kayla Waldron

Purpose: Primary non-adherence, defined as the rate at which patients fail to fill new prescriptions, is associated with increased mortality. A pharmacy concierge service provided to patients prior to discharge eliminates primary non-adherence as patients leave the hospital with newly prescribed medications in-hand. A reduction in primary non-adherence rates should theoretically correlate with decreased readmission rates. The purpose of this study is to evaluate the impact of a pre-discharge pharmacy concierge service on unplanned readmissions within 30 days.

Methods: The institutional review board approved this retrospective chart review. An informed consent waiver and HIPAA authorization waiver was obtained from the institutional review board. This study was completed through retrospective chart review and compared patients enrolled in a pre-discharge pharmacy concierge service to patients not enrolled in a pre-discharge pharmacy concierge service over a period of one year. The primary endpoint was the 30 day unplanned hospital readmission rate. Patients were matched 1:2, enrolled versus not enrolled, based on date of admission, UNC hospital-defined "transitions of care" status, hospital service upon discharge, and insurance status. Patients had to be discharged within the same month to be matched. "Transitions of care" status was defined as "low-risk", "moderate-risk", or "high-risk" of readmission. Additional patient information collected included 90-day unplanned readmissions, age at admission, and patient race.

Results: Chart review of a preliminary 2,883 patients resulted in identification of 183 patients (61 enrolled, 122 not enrolled). Of the 61 patients enrolled in the pre-discharge pharmacy concierge service, 11 (18%) were readmitted within 30 days compared to 44 (36%) for non-enrolled patients. A similar trend was seen for 90 day readmission rates with 20 (32%) enrolled patients and 62 (50%) non-enrolled patients readmitted.

Conclusion: Preliminary results suggest that patients enrolled in a pre-discharge pharmacy concierge service have lower rates of readmission compared to patients not enrolled, both at 30 and 90 days.

Poster Title: Impact of a multi-modal antimicrobial stewardship program on outcomes in patients with Clostridium difficile infections

Primary Author: Alyssa Stewart, UNC Eshelman School of Pharmacy, North Carolina; **Email:** aps17@email.unc.edu

Additional Author (s):
Shannon Holt
Ryan Tabis

Purpose: Clostridium difficile infection (CDI) is the most common cause of infectious diarrhea in hospitalized patients. Management of active CDI needs to be optimized to decrease morbidity, mortality, and health care costs. Existing literature indicates that therapy selection for CDI is suboptimal and exacerbating medications such as concurrent antibiotics and acid-suppressing agents increase the risk of CDI recurrence or complications. Outside of primary CDI treatment, there is no current literature on antimicrobial stewardship programs (ASP) optimizing CDI therapy from a multi-modal approach. The objective of this retrospective study is to evaluate the impact of an ASP CDI initiative in CDI patients.

Methods: This is an IRB-approved retrospective cohort study conducted at a large community hospital. In March 2013, the ASP launched a CDI initiative to optimize the management of CDI. Each patient with a newly documented CDI was reviewed utilizing a site-specific checklist, which includes assessment of appropriate CDI treatment based on disease severity, concurrent antibiotic therapy, pro-motility agents, acid suppression therapy, and anti-diarrheal therapy. If areas for optimization were identified, a standard CDI recommendation form that included supporting literature was placed in the medical record. Written recommendations not accepted within 48 hours prompted verbal communication with the provider. To evaluate the impact of this initiative, all adult patients treated for active CDI between March 2011 and February 2015 were included in the study. Patients were excluded for CDI diagnosis prior to admission or CDI documented in the previous 90 days. Patients were randomly selected to include 200 from each of the control (March 2011-February 2013) and post ASP initiative (March 2013-February 2015) groups. The primary endpoint was a composite of unfavorable outcomes, defined as treatment failure or documented CDI recurrence within 90 days after the index infection. Secondary

endpoints were severe CDI treated with vancomycin within 72 hours after onset, acid suppression therapy discontinued within 72hrs after onset, concurrent antibiotics discontinued within 72 hours after onset, 30-day readmission rate, and inpatient mortality.

Results: During the ASP CDI initiative, 225 recommendations were made to improve CDI management with the predominant interventions on discontinue acid suppressive therapy (n equals 57), optimize treatment based on CDI severity (n equals 47), and discontinue concurrent antibiotic therapy (n equals 40). The ASP CDI initiative was associated with a significant decrease in unfavorable outcomes (30 versus 17, p equals 0.043). The largest impact was seen in documented CDI recurrence with 23 events in the control group and 11 in the post ASP group (p equals 0.03). There was no significant difference seen in 30 day readmission (17 percent versus 15 percent) or all-cause inpatient mortality (9 percent in both groups). Appropriate therapy for severe CDI increased from 33 percent to 60 percent. Concurrent acid suppression therapy after onset decreased from 81 percent to 60 percent. The post ASP group had a higher number of patients on concurrent antibiotics for more than 72 hours after onset (48 percent versus 61 percent) as well as increased infection length of stay (mean 9 days versus 12 days).

Conclusion: An ASP CDI stewardship initiative was successfully implemented at a large community hospital with over 200 recommendations targeting both CDI therapy and exacerbating medications. This resulted in a significant decrease in unfavorable outcomes. In the future, this standardized process will be expanded to all decentralized pharmacists in an effort to decrease time to optimization of therapy.

Submission Type: Evaluative Study

Session-Board Number: 3-267

Poster Title: Evaluation of statin medication therapy for the prevention and treatment of cardiovascular disease within an accountable care organization

Primary Author: Amanda D'Ostroph, UNC Eshelman School of Pharmacy - Chapel Hill, North Carolina; **Email:** dostroph@email.unc.edu

Additional Author (s):
Dawn Pettus
Rachel Henderson
Elisabeth Dhalla

Purpose: The primary objective is to evaluate the impact of pharmacists' intervention on the use of statin medication therapy in patients for prevention and treatment of cardiovascular disease within an accountable care organization (ACO) and to evaluate the impact of the ACO's fulfillment of the quality metric. Secondary objectives include evaluating cost savings and the number of pharmacists' recommendations that are approved by providers.

Methods: Patients within the ACO who fall into any of the quality measure's three defined categories will be identified from the ACO database. Each patient will be reviewed to assess if the quality metric was met. The five Triad HealthCare Network (THN) practices with the lowest quality metric scores will be targeted for on-site education by a pharmacist. The pharmacist will contact the THN provider and visit the practice to share recommendations for initiation or change of therapy. The quality metric will be evaluated pre- and post- physician practice education, and the metric for the first quarter of 2016 will be compared to the metric for the final quarter of 2016. This study was approved by the Institutional Review Board at our institution.

Results: Out of 22,256 patients identified by a targeted medication review from the first quarter of 2016, 1,752 (7.9%) patients in the ACO have an indication for statin therapy but are not on it. The five THN practices with the lowest quality metric scores have scores of 68.75%, 73.26%, 75.68%, 75.74%, and 78.95%. The pharmacist educated these practices on the quality metric and made recommendations to providers to consider initiating statin therapy or switching to a generic statin therapy. Practice A resulted in a quality metric score of 85%, a

6.05% increase, after the pharmacist appropriately documented patients who met exclusion criteria. The pharmacist recommended initiating a statin for treatment for 39 patients and for prevention for six patients. Practice B resulted in a quality metric score of 81.53%, an 8.27% increase, after the pharmacist appropriately documented patients who met exclusion criteria. The pharmacist recommended initiating a statin for treatment for 12 patients and for prevention for five patients. Research is ongoing to assess data following additional on-site practice education.

Conclusion: The medication review highlighted areas where pharmacists can help guide THN providers in the prescribing of statin therapy in order to help minimize cost to the patient and insurance plan and to optimize patient care. Pharmacists' intervention on the use of statin medication therapy for prevention and treatment of cardiovascular disease made a positive impact on the ACO's quality metric.

Session-Board Number: 3-268

Poster Title: Process of Chemotherapy Administration - A Quality Improvement Project

Primary Author: Felicia Charles, University of North Carolina - Chapel Hill Eshelman School of Pharmacy, North Carolina; **Email:** felicia_charles@unc.edu

Additional Author (s):
Evelina Kolychev
Jami Moss

Purpose: Prompt administration of chemotherapy to patients who require inpatient treatment is imperative to ensure that patients receive medication during the day shift when the most highly trained pharmacy, nursing and physician staff are readily available. This quality improvement project aims to identify areas for improvement of chemotherapy administration for adults admitted to Vidant Medical Center (VMC).

Methods: The VMC Cancer Committee approved this quality improvement project and the VMC institutional review board was notified of this approval. Researchers analyzed the chemotherapy ordering process for patients receiving inpatient treatment. The primary endpoints were the time from patient admission to time of first dose (for elective chemotherapy admissions) and the time from order written to time of first dose (for prolonged admissions requiring continuation of therapy). Data were collected for six weeks. Most data collected were obtained from the electronic health record. Two additional data points collected were time the pharmacy notified nursing that chemotherapy was ready for pick up and time that chemotherapy was picked up by nursing staff. Data were evaluated to determine the percentage of patients that received chemotherapy between 5 am to 5 pm vs 5 pm to 5 am. Time of discharge was utilized to calculate length of stay (LOS).

Results: Thirty-six patients were evaluated for a total of 52 treatments. Six of 11 (54.5 percent) orders for elective chemotherapy were written by a physician prior to admission and the average time from admission to first dose for these patients was 16.96 hours. The average time from time of admission to doctor signed orders was 4.8 hours. The average time from time attending ordered medication to time nurse released order was 3.11 hours. The average time from time nurse released order to time first pharmacist checked the order was 6 minutes (0.1

hours). Thirty-one of 52 (59.6 percent) orders were first-checked by a pharmacist prior to the nurse releasing the order. The average time from time pharmacy called to notify nursing staff that chemotherapy is ready to time nurse picked up the compounded chemotherapy was 0.51 hours. The average time from time nurse pick up of medication to time chemotherapy was hung was 3.22 hours. Orders administered during the hours of 5 am to 5 pm represented 32.69 percent of treatments compared to 67.3 percent administered during the hours of 5 pm to 5 am. Of the 11 admissions for elective chemotherapy, LOS was prolonged in six patients (54.5 percent).

Conclusion: The research suggests that improving time from nurse pick up of medication to time chemotherapy hung could decrease LOS for adults admitted for chemotherapy. The data also suggests that the pharmacy often completes the first check before the nurse releases the order. Improving time from attending signing the order to time nurse releases the order could further streamline the ordering process. Additional evaluation of the ordering process for inpatient chemotherapy will help identify other areas for improvement. These opportunities for advancement will be implemented at a later date and help to improve the process of care for these patients.

Poster Title: Optimal dosing of unfractionated heparin and low molecular weight heparin for the treatment of venous thromboembolism in the morbidly obese

Primary Author: Thomas Johnston, University of North Carolina at Chapel Hill Eshelman School of Pharmacy, North Carolina; **Email:** thomas_johnston@unc.edu

Additional Author (s):
Ali Piacentini
Bobbi Jo Walston
Olivia Morgan

Purpose: Approximately 15.5 million people in the United States have a body mass index (BMI) greater than or equal to 40 kg/m2, classifying them as morbidly obese. Obesity can present a problem when dosing drugs that are dependent on pharmacokinetic parameters, such as volume of distribution or creatinine clearance. Two such drugs are the heparin anticoagulants, unfractionated heparin and low molecular weight heparin. The purpose of this study is to identify and evaluate current dosing strategies in non-critically ill morbidly obese patients who are being treated with unfractionated heparin or low molecular weight heparin for a venous thromboembolism (VTE).

Methods: This retrospective chart review was approved by the institutional review board and conducted at The University of North Carolina Medical Center in Chapel Hill, NC (UNCMC). The data search targeted patients greater than or equal to 18 years of age with a BMI greater than or equal to 40 kg/m2 who were admitted to UNCMC with a diagnosis of VTE and treated with unfractionated heparin or low molecular weight heparin between January 2015-May 2016. The electronic medical records of the 31 eligible patients were searched for information on unfractionated heparin and low molecular weight heparin dosing, heparin and low molecular weight heparin monitoring, and incidences of bleeding. The primary objective of this study was to identify a weight-based dosing strategy that achieved a therapeutic level of drug. The secondary objectives included the time to therapeutic level and major and minor bleeding events.

Results: The initial search returned 65 possible patients, 34 patients were excluded. The eligible patient population was 42 percent male, averaged 57 years in age, and had an average BMI of 44.6 kg/m2. 74 percent of patients received unfractionated heparin and the mean duration of treatment was 74 hours. Enoxaparin was used in 26 percent of patients and the mean duration of treatment was 61 hours. The majority of patients were dosed based on actual body weight (86.96 percent in the unfractionated heparin group, and 75 percent in the low molecular weight heparin group). Dosing unfractionated heparin based on actual body weight led to non-therapeutic initial heparin correlations in 52.4 percent of these patients, with 42 percent being supratherapeutic. The mean final dose in this group was 15.1 units/kg/hr. 62.5 percent of patients in the enoxaparin group had a documented Anti-Xa level, with all 5 having a therapeutic level. The median initial dose for this group was 120 mg and the final median dose was 120 mg. There were no occurrences of bleeding in the low molecular weight heparin group and two occurrences of minor bleeding in the unfractionated heparin group.

Conclusion: This data demonstrates that most patients will require dose-reduction when initiated on actual body weight unfractionated heparin dosing. Actual body weight dosing may be appropriate for low molecular weight heparin, but several patients did not receive Anti-Xa monitoring. With the small number of patients receiving low molecular weight heparin and a lack of patients dosed on adjusted body weight, we cannot conclude whether adjusted body weight dosing decreases time to a therapeutic level. Further study is needed to determine an optimum dosing weight for the administration of unfractionated heparin and low molecular weight heparin for VTE in morbidly obese patients.

Poster Title: Impact of clinical, unit-specific guidelines on dornase alfa use in critically ill pediatric patients without cystic fibrosis

Primary Author: Carson Tester, University of North Carolina Eshelman School of Pharmacy, North Carolina; **Email:** carson_tester@unc.edu

Additional Author (s):
Travis Heath
Robert Raiff

Purpose: While compelling evidence exists for improved outcomes with the use of dornase alfa in pediatric patients with cystic fibrosis, the evidence in patients without cystic fibrosis is lacking. Because dornase alfa has a large pharmacoeconomic impact on the health system, replacing it with other mucolytic agents, such as hypertonic saline or acetylcysteine, in patients without cystic fibrosis may help to decrease the impact.
The purpose of this study was to evaluate the impact of unit-specific, evidence based guidelines on dornase alfa in the pediatric intensive care unit and pediatric cardiac intensive care unit.

Methods: This single center retrospective review was approved by the Institutional Review Board. The use of dornase alfa in critically ill pediatric patients without cystic fibrosis was evaluated. Subjects were included if they were admitted to the PICU or PCICU and had received at least one dose of dornase alfa during the data collection period. Potential subjects were excluded if they had a medical history of cystic fibrosis. All data was collected retrospectively via electronic medical record review and hospital purchasing reports. Data was evaluated using descriptive statistics to determine the percentage change in number of dornase alfa doses administered and related expenditure during the nine-month period before and after guideline implementation. The Mann-Whitney U test was used to compare the median number of days subjects from the pre- and post-guideline implementation groups stayed on the ventilator.

Results: Between February 1, 2015 and October 31, 2015, 1074 doses of dornase alfa were administered to 53 patients located in the PICU or PCICU. In November 2015, dornase alfa guidelines were implemented, placing significant restrictions on the use of dornase alfa in these units. Post-guideline implementation data collection began on December 1, 2015 and ended

August 31, 2016. During this time period, 239 doses of dornase alfa were administered to 23 patients in these units. Across the nine month data collection periods before and after guideline implementation, there was a 77.7% reduction in the use of dornase alfa in the PICU and PCICU. The reduction of the use of 835 doses of dornase alfa over a nine month period had a profound pharmacoeconomic impact on the health system. With the Wholesale Acquisition Cost of dornase alfa at $96.46 a dose, the implementation of these guidelines generated a $80,544 decrease in expenditure.

Conclusion: The implementation of evidence-based, unit-specific dornase alfa guidelines significantly reduced the number of dornase alfa doses administered in the PICU and PCICU. The reduction in dornase alfa doses administered in the PICU and PCICU had a considerable pharmacoeconomic impact on the health system over the course of nine months. It is predicted that the future implementation of these guidelines across health system could substantially impact the number of dornase alfa doses administered in other units, having an even more profound pharmacoeconomic impact on the health system.

Poster Title: Evaluation of thromboxane A2 as a biomarker for predicting adverse cardiovascular outcomes in patients with stable coronary artery disease

Primary Author: Nan Wang, University of North Carolina Eshelman School of Pharmacy, North Carolina; **Email:** nan_wang@unc.edu

Additional Author (s):
Kimberly Vendrov
Brian Simmons
Craig Lee

Purpose: In patients with stable coronary artery disease (CAD), low-dose aspirin is indicated to suppress cyclooxygenase-mediated thromboxane (TxA2) biosynthesis in platelets and reduce risk of major adverse cardiovascular events (MACE). However, approximately 30 percent of TxA2 is produced by extraplatelet sources, which may contribute to CAD progression. Preclinical studies have demonstrated that TxA2 has pro-inflammatory effects in the cardiovascular system that promote the development, growth and destabilization of atherosclerotic plaques. The clinical implications, however, remain unclear. The purpose of this study is to investigate whether there is an association between elevated TxA2 levels and MACE outcomes in patients with stable CAD.

Methods: A cohort of angiographically confirmed stable CAD patients, defined as at least 50 percent stenosis in one or more major coronary arteries, were identified in the Cardiac Catheterization Laboratory from 2007-2011. The study protocol was approved by the institutional review board. Informed consent was obtained in all participants, and a spot urine sample was collected. Urinary 11-dehydro-TxB2 concentrations, the stable metabolite of TxA2 (TxA2-M), were quantified by ELISA in 112 participants, normalized to urinary creatinine, and expressed as pg per mg Cr. The incidence of major adverse cardiovascular events (MACE) was ascertained by retrospective review of electronic medical records. MACE was defined as a composite of death from any cause, hospitalization for a non-fatal acute coronary syndrome event (defined as unstable angina, non-ST segment elevation myocardial infarction [NSTEMI], or ST segment elevation myocardial infarction [STEMI]), or hospitalization for a non-fatal cerebrovascular event (defined as ischemic stroke or transient ischemic attack). TxA2-M levels

were log-transformed and compared across patients with and without MACE by one-way analysis of variance. Baseline TxA2-M levels were grouped into tertiles, and the frequency of MACE was compared across tertiles by chi-square. The relationship between TxA2-M tertiles and time to occurrence of first MACE was evaluated using proportional hazard regression. Secondary stratified and multivariable adjusted analyses were conducted to account for potential confounders. A P-value less than 0.05 was considered statistically significant.

Results: The study population was, on average, 60 years old, 28 percent female, 17 percent African American, 23 percent had comorbid diabetes, and 64 percent exhibited multivessel CAD. During a median follow-up of 5.7 years, 33 patients (29.5 percent) experienced MACE. Urinary TxA2-M levels at baseline appeared to be higher in those experiencing a future MACE compared to those without a future event (median [IQR] 792 [438] versus 579 [469]); however, these differences were not statistically significant (p equals 0.098). When baseline TxA2-M levels were grouped into tertiles, a significantly higher rate of MACE was observed across the lowest (18 percent), middle (33 percent) and highest (48 percent) TxA2-M tertiles (p equals 0.0386). Compared to the lowest TxA2-M tertile, the highest tertile was associated with a significantly higher risk of MACE (hazard ratio 2.65, 95 percent CI 1.09 to 7.39, p equals 0.031); the middle tertile, however, did not exhibit a significantly higher risk of MACE (hazard ratio 1.61, 95 percent CI 0.61 to 4.68, p equals 0.338). Similar results were observed after adjusting for covariates (age over 65, sex, race, diabetes, multivessel disease, aspirin dose), and after excluding three patients not on aspirin therapy (who had the highest TxA2-M levels).

Conclusion: Elevated TxA2-M levels were associated with worse cardiovascular prognosis in patients with stable CAD, and this association was independent of aspirin use and dose at baseline. This suggests that extraplatelet sources of TxA2 may be an important driver of CAD progression and poor cardiovascular outcomes. Limitations of this study include its retrospective design and limited sample size. Future studies in a larger population are needed to validate these results, investigate the causes of increased extraplatelet TxA2 biosynthesis in certain individuals, and develop therapeutic interventions that mitigate the risk of elevated TxA2 levels in CAD patients on aspirin therapy.

Poster Title: Characterization and usage evaluation of long-acting injectable antipsychotics within a large academic medical center

Primary Author: Charlotte Wells, University of North Carolina Eshelman School of Pharmacy, North Carolina; **Email:** charlow@email.unc.edu

Additional Author (s):
Adam Root

Purpose: Schizophrenia is a chronic, often progressive disease with recurrent episodes of relapse. A major contributor to relapse is medication non-adherence, which has led to the development of long-acting injectable formulations. A class review and formulary recommendations of long-acting injectable (LAI) antipsychotics were approved by the Pharmacy and Medication Management Committee (PMMC) in June 2014. This quality improvement project was designed to assess how the health system currently utilize LAI antipsychotics in order to have a better understanding of the prescribing patterns and patient population with the end goal to improve the system's quality of care and adherence to the formulary.

Methods: A retrospective chart review for patients who received LAI antipsychotics at the primary medical center or affiliate hospital from January 1, 2015 to December 31, 2015 was performed. Included patients were 18 years or older and received at least one dose of a LAI antipsychotic while at the primary medical center or affiliate hospital within the specified one year period. An electronic medical record database identified 146 eligible patients. Of the 146 total patients, 100 were randomly selected to be included in the analysis. A retrospective chart review was conducted on the selected 100 patients with the first administration of a LAI antipsychotic between January 1, 2015 and December 31, 2015 serving as the admission date where the primary data was collected. A review 6 months pre-LAI administration and 6 months post-LAI administration was performed to capture prior and re-admissions. In the case of multiple admissions during the year timeframe, the first admission of the calendar year was captured as the primary encounter and subsequent admissions were counted up until 6 months post primary discharge date.
Patient information regarding gender, age, diagnosis, prior hospitalizations, psychiatric co-morbidities, and concurrent psychiatric medications were collected. Length of stay and time to

readmission were calculated using date of admission and discharge dates. The data was analyzed using descriptive statistics.

Results: 100 patients were included in the analysis. Mean overall age was 38.8 years with 62 percent males, 65 percent African American, and 39 percent with at least one prior hospitalization in the previous 6 months. Of the 100 patients, 69 were diagnosed with schizophrenia, 18 with schizoaffective disorder and 13 with bipolar disorder. The majority of patients were initiated on a LAI while admitted (57 percent initiated vs 43 percent continuation of therapy). Paliperidone palmitate was prescribed most frequently and olanzapine least frequently (39 percent vs 5 percent respectively). While admitted, the mean number of concurrent psychiatric medications administered was approximately 4. The average length of stay was 15.53 days with a standard deviation of 14.32. 25 percent of patients had at least 1 readmission within 6 months post-LAI administration. The median time to readmission was 48 with a range of 2 to 222 days.

Conclusion: Based on the LAI antipsychotic usage evaluation, the health system was able to gain insight into the patient population as well as determine adherence to the formulary. Data collection was limited to the retrospective aspect of the project and results might be health system specific.

Poster Title: Association of the Medication Regimen Complexity Index (MRCI) with readmission rate and time to readmission in a high-utilizer, adult psychiatric population

Primary Author: Stephanie Jean, University of North Carolina Eshelman School of Pharmacy, North Carolina; **Email:** stephanie_jean@unc.edu

Additional Author (s):
Suzanne Harris
Ina Liu
Alyson Aldridge

Purpose: In recent years, increased attention has been brought to hospital readmissions, leading to nationwide efforts to reduce their incidence. Few studies have examined psychiatric readmissions and the role that medication-related factors may play, specifically the complexity of the medication regimen. The objective of this retrospective study is to assess the impact of the Medication Regimen Complexity Index (MRCI) on psychiatric readmission rate and time to readmission in a high-utilization cohort. The findings of this study will aid in informing avenues for future research and the development of targeted interventions to reduce the risk of readmissions and associated costs.

Methods: The Institutional Review Board approved this retrospective study. Patient data was collected through the use of the electronic hospital and pharmacy databases and the electronic medical record system. Patients admitted between July 2012 and March 2014 were identified if they were age 18 years or older and had been discharged from an adult inpatient psychiatry service with greater than or equal to five psychiatric readmissions or at least one 30-day readmission in this time frame. Demographics, number and time to readmissions, length of stay, and number and type of medications on each discharge and readmission were collected. Dosage form, frequency of dosing, and additional usage directions for each medication on each discharge were collected from the electronic pharmacy database, and complexity of the medication regimen was determined using the Microsoft Access Medication Regimen Complexity Index (MRCI) tool by Libby, et al. Separate MRCI scores were computed for psychotropic medications, other prescription medications, and over-the-counter medications. The three scores were combined to calculate the total MRCI score. Statistical analysis was

conducted using statistical software R, version 3.2.2, and Pearson's correlation was used to calculate correlations. The primary objective of this study was to determine if an association exists between the MRCI score and time to readmission as well as readmission rate.

Results: A total of 168 patients were identified. MRCI score for psychotropic medications and total MRCI score at first discharge were both found to be unrelated to the days between first discharge and first readmission (r=0.065, p=0.40 and r=0.0054, p=0.94, respectively). In addition, average total MRCI score was unrelated to average days between each readmission (r=0.064, p=0.41), but a statistically significant association was found between average MRCI score for psychotropic medications and average days between each readmission (r=0.16, p=0.044). Both average MRCI score for psychotropic medications and average total MRCI score were found to be unrelated to readmission rate (r=0.11, p=0.16 and r=0.14, p=0.07, respectively). Average psychotropic medication count was found to be unrelated to readmission rate (r=0.11, p=0.17) but had a statistically significant association with average time to readmission (r=0.18, p=0.019).

Conclusion: Although the total MRCI score was found to be unrelated to time to readmission or readmission rate, statistically significant correlations were found between average time to readmission and average MRCI score for psychotropic medications as well as average psychotropic medication count. These results suggest that a more complex psychotropic medication regimen and a higher psychotropic medication count at discharge may result in a shorter time to readmission in a high-utilizer, adult psychiatric population. The impact of other medication-related factors and the clinical significance of the use of the MRCI score must be determined in larger, long-term clinical trials.

Poster Title: Vancomycin pharmacokinetic parameters in critically ill patients with central nervous system infection

Primary Author: Alvin Ong, University of North Carolina Eshelman School of Pharmacy, North Carolina; **Email:** acong@email.unc.edu

Additional Author (s):
Kathryn Morbitzer
Denise Rhoney

Purpose: Critically ill patients with central nervous system (CNS) infections are of significant concern as these patients often display altered pharmacokinetic parameters that provide challenges in achieving therapeutic vancomycin serum concentrations. Use of vancomycin as empiric therapy should be dosed at 15 to 20 milligrams per kilogram every 8 to 12 hours with a goal trough concentration of 15 to 20 micrograms per milliliter. The hypothesis is that vancomycin dosing utilizing population pharmacokinetics would be suboptimal for treating CNS infections. The primary objective of this study was to determine the pharmacokinetic parameters of vancomycin in critically ill patients with CNS infections.

Methods: The institutional review board approved this single-center, retrospective chart review of critically ill patients with acute brain injury and CNS infections who were at least 18 years of age and between May 1, 2010 and June 1, 2016. Patients who were on vancomycin as empiric therapy or for specified CNS infections were included. Patients who were on vancomycin for non-CNS related infections, whose troughs were not recorded, or whose vancomycin data was missing, were excluded. Data collected included patient demographics, severity of injury, infection sources and organisms, concomitant medications, pertinent laboratory values, and vancomycin regimen and serum concentration information. The primary outcome measure was the difference in the measured trough concentrations, half-life, and elimination rate constant of vancomycin compared to the predicted values using population pharmacokinetics. The difference was assessed using a two-sample Wilcoxon rank-sum test where p less than 0.05 was considered statistically significant.

Results: A total of 30 patients with a median age of 56 years old were included in this analysis. The majority (67 percent) of patients were being treated for meningitis or ventriculitis. The median calculated creatinine clearance was 119 milliliters per minute at the time the vancomycin trough was drawn. For the first vancomycin level, the median dose was 16.6 milligrams per kilogram every 8 hours, with a predicted median serum vancomycin concentration of 13.2 micrograms per milliliter compared to the measured serum vancomycin concentration of 13.3 micrograms per milliliter (p equals 0.535). The measured elimination rate constant, 0.12 inverse hours, led to a half-life of 5.7 hours, compared to a predicted half-life of 6.7 hours (p equals 0.544). The second vancomycin level was drawn in 67 percent of patients with a median dose of 21.3 milligrams per kilogram every 8 hours. The predicted median serum vancomycin concentration was 17.6 micrograms per milliliter compared to the measured serum vancomycin concentration of 19.2 micrograms per milliliter (p equals 0.534). The measured elimination rate constant, 0.11 inverse hours, led to a half-life of 6.2 hours, compared to a predicted half-life of 6.5 hours (p equals 0.935).

Conclusion: Using population pharmacokinetics to calculate the initial vancomycin dose for critically ill patients with CNS infections led to subtherapeutic levels, although the predicted vancomycin serum trough concentrations were not statistically different than the actual measured concentrations. The low vancomycin levels could be due to altered clearance evidenced by the shorter half-life in these critically ill patients. Future vancomycin studies need to be conducted to ensure the most appropriate initial dosing is done in patients with CNS infections.

Poster Title: Novel genetic marker of diarrhea in metastatic renal cell carcinoma patients treated with sorafenib

Primary Author: Allison Karabinos, University of North Carolina Eshelman School of Pharmacy, North Carolina; **Email:** akarabin@email.unc.edu

Additional Author (s):
Amy Etheridge
Carol Peña
Daniel Crona
Federico Innocenti

Purpose: Sorafenib, the first oral anti-angiogenic multikinase inhibitor, is primarily used in the treatment of advanced renal cell carcinoma, hepatocellular carcinoma, and thyroid cancer. Common toxicities experienced by patients treated with sorafenib include diarrhea, hand-foot skin reaction, hypertension, and rash. These toxicities limit sorafenib's use and affect adherence to treatment, reducing sorafenib efficacy. The purpose of this study was to identify, for the first time, genetic markers of sorafenib toxicity in order to optimize its efficacy and minimize toxicity. No novel genetic biomarkers are currently available to identify patients at risk of sorafenib-induced toxicity.

Methods: Metastatic renal cell carcinoma (mRCC) patients (N=153) treated with sorafenib, as part of the TARGET study (Escudier B et al. N Engl J Med. 2007;356(2):125-34), were genotyped for common germline genetic variants in 50 candidate genes. Associations between 5846 variants and sorafenib-induced grade 2-4 toxicities were analyzed. Patients treated for less than or equal to 28 days were excluded from the analysis. Toxicities analyzed included diarrhea, hypertension, hand-foot skin reaction, and/or rash or desquamation. For each toxicity, the worst grade event for each patient was used in the analysis. After linkage disequilibrium-based pruning, 685 variants were utilized in case/control association testing for analysis of each toxicity via a chi-squared test to compare allele frequencies between cases (patients with toxicity) and controls (patients without toxicity).

Results: Of the 153 patients, 28 (18 percent) experienced grade 2 or greater diarrhea. The A allele of rs917881 (G/A), an intronic variant (17 percent allele frequency) in the epidermal growth factor receptor (EGFR) gene, was associated with an increased risk of grade 2 or greater diarrhea (P=0.00006; P=0.04 after Bonferroni's correction; odds ratio 3.6). The frequency of grade 2 or greater diarrhea was 50 percent (3/6) in AA, 33 percent (15/45) in AG, and 10 percent (10/102) in GG patients. The frequency of grade 3 diarrhea was 8 percent (4/51) in patients with the A allele (AA+AG) versus 2 percent (2/102) in patients with the GG genotype. No other variants were significantly associated with sorafenib toxicity after Bonferroni correction.

Conclusion: To our knowledge, this is the first reported study of a genetic basis of sorafenib toxicity. rs917881 is a common intronic variant in EGFR. RAF kinase, a critical component of the EGFR signaling pathway, is a known target of sorafenib. Patients with the rs917881 A allele treated with sorafenib may be at an increased risk for diarrhea as a result of decreased EGFR expression potentiated by sorafenib-induced inhibition of the RAF/MEK/Erk pathway, which regulates chloride secretion on colonic epithelial cells (Keely SJ et al. J Biol Chem. 1998;273(42):27111-7). Replication analyses in additional patient cohorts and functional studies are ongoing.

Poster Title: Retrospective analysis of the effect of liposomal bupivacaine on postsurgical pain scores and opioid use at a community women's hospital

Primary Author: Jenna Bartlett, University of North Carolina Eshelman School of Pharmacy, North Carolina; **Email:** jenna_wood@unc.edu

Additional Author (s):
Deanna Malone
Julie Cline
Jennifer Mendenhall

Purpose: Postsurgical patients commonly receive a pain regimen containing an opioid. Although opioids are effective, they pose concerns for patients and healthcare providers, including those related to adverse events and their high potential for misuse and diversion. Liposomal bupivacaine is injected into a surgical site to produce postsurgical analgesia. Compared to standard bupivacaine, liposomal bupivacaine is designed to extend the time of pain control and therefore possibly reduce the need for opioids. The purpose of this study was to determine whether liposomal bupivacaine was associated with a decrease in postsurgical pain scores and opioid use at a community women's hospital.

Methods: The institutional review board approved this retrospective chart review. A search of the community women's hospital electronic medical record system was used to identify all female patients that underwent surgery from 11/1/2015 to 3/31/2016 and received injections of liposomal bupivacaine into the surgical site as part of their postsurgical pain control regimen. Each case was age- and surgery-matched 1:1 to control surgical patients that did not receive liposomal bupivacaine. The data collected from each patient's medical chart included: whether or not the patient had an active prescription for an opioid on admission, daily median pain scores during admission (pain scores ranged from 0 to 10, with a score of 10 signifying the worst pain), daily total opioid use during admission (calculated in oral morphine equivalents), length of hospital stay following the surgery, and whether or not the patient received an opioid prescription at discharge. Primary analyses included median pain scores and total daily opioid use at 0 to 24 hours, 25 to 48 hours, and 49 to 72 hours after surgery in patients receiving liposomal bupivacaine versus control. Secondary analyses included length of hospital stay after

surgery and the percentage of patients receiving an opioid prescription at discharge versus control. A subgroup analysis looked at the same outcomes for patients undergoing cesarean section or hysterectomy.

Results: A total of 98 women undergoing surgery at a community women's hospital were matched to 98 controls. Patients were an average age of 36 years old. A total of 52 cesarean section patients, 27 hysterectomy patients, and 19 miscellaneous surgery patients were included in both the treatment and control groups. The median postsurgical pain scores were 3 versus 3 at 0 to 24 hours, 4 versus 3 at 25 to 48 hours, and 4 versus 3.75 at 49 to 75 hours for patients given liposomal bupivacaine versus control. The median total postsurgical opioid use in oral morphine equivalents were 30 versus 24.8 mg at 0 to 24 hours, 22.5 versus 22.5 mg at 25 to 48 hours, and 11.3 versus 15 mg at 49 to 72 hours for patients given liposomal bupivacaine versus control. The length of hospital stay was an average of 61 versus 66 hours for cesarean patients, and 44.6 versus 42 hours for hysterectomy patients given liposomal bupivacaine versus control. At discharge, 94 percent versus 88 percent of patients given liposomal bupivacaine versus control were given an opioid prescription.

Conclusion: Liposomal bupivicaine was not associated with a decrease in postsurgical median pain scores and total daily opioid use in women undergoing surgery at a community women's hospital. When cesarean section or hysterectomy patients were analyzed separately, the data still did not produce any clinical difference in outcome between the treatment and control groups. These results do not support the use of liposomal bupivacaine in women's surgeries for postsurgical pain control to reduce the need for opioids. However, prospective studies are needed to confirm these results and rule out the potential for bias in this retrospective review.

Poster Title: Assessment of pharmacist-driven diabetes care in severely uncontrolled populations

Primary Author: Sheri Balogun, University of North Carolina Eshelman School of Pharmacy, North Carolina; **Email:** sheri_balogun@unc.edu

Additional Author (s):
Patrick Gregory
Kelsey Melloy

Purpose: Many people with type 2 diabetes struggle with disease control and can benefit from additional interventions to help them manage their care burden. Some patients with diabetes have been referred to ambulatory care pharmacists, who can help manage medications, counsel on lifestyle modifications, and resolve medication access issues. Several published studies show that pharmacist-directed care has a significant positive impact on patients' hemoglobin A1c and other disease markers. The purpose of this study was to characterize the impact of an ambulatory care pharmacist on severely uncontrolled diabetes patients at select primary care clinics within the WakeMed Health and Hospitals network.

Methods: WakeMed's institutional review board approved this single-center, retrospective chart review. Data was collected from patients seen at 5 WakeMed primary care practice sites between January 1, 2014 and September 1, 2016. Patients were included if they were 18 years of age or older, had type 2 diabetes, had an A1c greater than or equal to 9 percent up to 3 months before the time of their first pharmacy visit, and had at least two pharmacy visits within the specified time frame. Primary outcomes included changes from baseline A1c and BMI. Secondary outcomes included change in rate of optimal statin use, change in rate of optimal angiotensin converting enzyme inhibitor (ACEi) or angiotensin II receptor blocker (ARB) use, and change in rate of optimal aspirin use.

Results: Fifty-one patients were included in the study. The average starting A1c was 10.9 percent before pharmacy intervention and 8.5 after pharmacy intervention. Forty-three percent of patients had met the general WakeMed A1c goal of less than 8 percent. The average BMI was 35.8 before pharmacy intervention and 35.9 after pharmacy intervention. Forty-three

patients were diagnosed with hypertension. Of those 43 patients, 83.7 percent were correctly prescribed an ACEi or ARB before pharmacy intervention and 83.7 percent were correctly prescribed an ACEi or ARB after pharmacy intervention. Of the 7 patients who were not on an ACEi or ARB after pharmacy intervention, 85.7 percent had a documented reason for no therapy. Forty-eight patients were 40 years or older and met the requirement for statin therapy. Of those 48 patients, 75 percent were on statin therapy before pharmacy intervention and 83.3 percent were on statin therapy after pharmacy intervention. Of the 8 patients who were not on a statin, 37.5 percent had a documented reason against using statin therapy. Fifty percent of patients with an ASCVD 10-year risk score greater than 10 were on aspirin before pharmacy intervention and sixty-four percent after pharmacy intervention.

Conclusion: Pharmacist intervention is linked to a decline in A1c values over time. Patient BMI remained unchanged. Pharmacist intervention increased the likelihood of identification of patients who would benefit from taking a statin or aspirin, but had no effect on ACEi or ARB usage rates in this population.

Poster Title: Use of an interprofessional student team to address quality improvement measures in a primary care practice

Primary Author: Kaitlin Rzasa, University of North Carolina Eshelman School of Pharmacy, North Carolina; **Email:** rzasa@unc.edu

Additional Author (s):
Amanda Gorman
Leah Herity
Stephanie Jean

Purpose: This project was intended to analyze the needs of a primary care practice office in North Carolina. Faculty members worked closely with the practice to identify specific Quality Improvement (QI) needs based on benchmark data. The practice had been consistently below benchmark data (thirty-five percent) for HMG-CoA reductase inhibitor (or statin) and aspirin prescribing patterns for patients with diabetes, and aimed to increase their goal to sixty-five percent compliance. Based on this data, an interprofessional team of students conducted a needs assessment to identify interventions to address this practice gap.

Methods: The interprofessional team consisted of students from a range of disciplines including medicine, pharmacy, nursing, public health, and dietetics. The team began by conducting a needs assessment on site at the primary care practice. This involved shadowing various professionals (physicians, physician assistants, registered nurses, a registered dietitian, and front office staff) in the clinic to gain an understanding of workflow and potential areas for improvement. A needs assessment, using the Ottawa Decision Making Framework, was also completed through interviews with the healthcare professionals in the primary care office. Following the needs assessment, the student team presented a series of tailored interventions to the primary care practice for implementation. Interventions were based on the characteristics of the population, the population served, and the identified barriers to increasing use of statins and aspirin in this population. Interventions were designed and implemented over a period of 2 months, and outcomes measured.

Results: There were a number of areas of opportunity discovered within the clinic setting. The four selected for addressing were provider education, support staff education, patient education, and utilization of electronic medical records (EMR). Provider education was targeted toward doctors and physician assistants and involved reviewing new American Diabetes Association 2016 guidelines, detailing aspects of the metrics that the clinic was supposed to meet, introducing new educational materials for patients, and proposing a new system of analyzing patient records to see who should be targeted. Support staff education focused on nurses and medical assistants and addressed basic information about statins and aspirin and how to identify patients who may need them, and the best way to document this information in the medical record. The third intervention was patient education, in which posters and flyers were developed to inform patients about these medications, and to dispel myths or preconceptions that patients may have. The final intervention was development of a new filter reporting system in the EMR that more easily allowed providers and staff to identify patients with diabetes who are not on aspirin or a statin. After one month of implementation, statin and aspirin use amongst diabetic patients increased nine percent.

Conclusion: The formation of a team involving students from various health-related disciplines fostered the generation of a multifaceted plan to address the needs of a primary care practice. The use of multidisciplinary student teams may be an effective approach to identifying and implementing quality improvement interventions in other healthcare settings as well.

Poster Title: Administration adherence rate of ordered pharmacologic venous thromboembolism prophylaxis

Primary Author: Hannah Mierzwa, University of North Carolina Eshelman School of Pharmacy, North Carolina; **Email:** mierzwa@email.unc.edu

Additional Author (s):
Khushboo Patel
Megan Clarke
Andrew Stivers

Purpose: Venous thromboembolism (VTE), including deep vein thrombosis (DVT) and pulmonary embolism (PE), are known causes of morbidity and mortality among hospitalized patients. VTE deaths are preventable with appropriate administration of thromboprophylaxis, however numerous studies have shown high rates of non-administration among hospitalized patients. The purpose of this study was to retrospectively quantify the administration adherence rate of pharmacologic VTE prophylaxis doses ordered at UNC Medical Center and categorize reasons for non-administration

Methods: This retrospective, institutional review board approved study reviewed electronic health record data for patients admitted to UNC Medical Center from May 1, 2016 - July 31, 2016. Patients were included if they had an order for prophylactic doses of unfractionated heparin, enoxparin, or fondaparinux during the study period. Patients were excluded if they were less than 18 years of age, less than 50kg, or receiving medications listed above for other indications. The primary outcome of this study was to quantify administration adherence of ordered VTE prophylaxis doses and categorize reasons for non-administration. Patient demographic information and medication administration documentation were collected to determine administration adherence and identify documented reasons for non-administration. Identification of barriers for non-administration of VTE prophylaxis will guide targeted quality improvement efforts to increase administration adherence rates at our institution.

Results: A total of 58,498 VTE prophylaxis doses for 4,410 patients were included. Overall, 11,578 of ordered doses were not administered, which represented a non-administration rate of 19.8%. Heparin doses made up the majority of ordered VTE prophylaxis (76.6%), followed by enoxaparin (21.9%), and fondaparinux (0.39%). The most common reason for non-administration was patient refusal (41.9%). Of note, it was found that 20% of the patients represented 70.6% of the overall non-administered doses. Among the total prophylaxis doses ordered, 28,646 (48.9%) were for patients admitted to medicine floors, which accounted for the majority of non-administered doses, with an overall non-administration rate of 22.5%. In comparison, the surgical floors were comprised of 29,130 (49.7%) ordered VTE prophylaxis doses, with slightly lower rates of non-administration (19.2%).

Conclusion: Analysis of ordered VTE prophylaxis doses was proven helpful in quantifying administration adherence rate and identifying barriers of non-administration across our institution.

Poster Title: Review of MyCarolinas Tracker application in diabetes care management

Primary Author: Jamie Rembert, Wingate University School of Pharmacy, North Carolina; **Email:** ja.rembert@wingate.edu

Additional Author (s):
Paige Carson
Lillie Mottox
Jennifer Hicks

Purpose: Technology utilization for the management of chronic disease states, such as diabetes, has increased significantly over recent years. MyCarolinas Tracker is an application that allows patients to input their blood glucose readings which gives providers real-time access to evaluate therapy. This application was designed to decrease the amount of time taken out of patient's and physician's work day by allowing physicians to have a preliminary plan ready before contacting the patient. The primary objective of this study is to evaluate MyCarolinas Tracker technology in providing real-time patient measurements to Care Management pharmacist providers and the associated patient outcomes.

Methods: This Carolinas HealthCare System Institutional Review Board approved quality assurance analysis is designed to review information obtained from MyCarolinas Tracker and evaluate if its use leads to improved patient care outcomes. Data was gathered via the MyCarolinas Tracker application which allows providers to view their patient population using the application, along with patient specifics entered by patients or synced through their technology devices. Cerner was used to acquire patient demographics, specific diabetes related outcomes, and observe patient and provider communication. This data was collected and de-identified using RedCap, then complied to express the benefits and limitations to using MyCarolinas Tracker application within care management programs.

Results: The majority of patients studied were non-Hispanic Caucasian females with a variety of ages (25-63). 11 patients were evaluated for diabetes related outcomes. Hemoglobin A1c was shown to decrease in 6 patients, increase in 2 patients, and 3 patients are still pending follow up A1c results. The majority of patients interacted with their pharmacist provider every 1-2

weeks at the beginning of a 3-month evaluation and an average of every 3-4 weeks by the end of the 3 months. Most of the pharmacist's interventions occurred within the first month of interaction. Opinions from pharmacist providers and patients were gathered and evaluated with varying results.

Conclusion: The use of MyCarolinas Tracker was found to produce beneficial results in managing patients' diabetes. These results correlate with improved diabetes specific laboratory values as well as increased patient motivation. The use of MyCarolinas Tracker is most beneficial in younger populations who frequently use technology, have the means to afford advanced technology, and have motivation to control their disease states.

Poster Title: Implementation and evaluation of patient education related to mosquito-transmitted illnesses by pharmacy students in a developing country.

Primary Author: Cheryl Gentry, Wingate University School of Pharmacy, North Carolina; **Email:** ch.gentry@wingate.edu

Additional Author (s):
Katherine Smart
Sviatlana Drevila
Shawn Taylor

Purpose: To determine current knowledge of rural Honduran citizens in regards to mosquito-transmitted illnesses (chickungunya, zika, and dengue), educate about their prevention and treatment, and evaluate the benefit of the education provided.

Methods: Research took place during a week long medical mission in Honduras. Participants included patients 18 years and older. Research consisted of a questionnaire administered pre- and post-education pertaining to prevention and treatment of mosquito-transmitted illnesses. Interpreters were utilized for questionnaire administration and education.

Results: Thirty-seven participants received education and completed both pre and post questionnaires. Prior to education, the majority of participants knew about the ability of mosquitoes to transmit diseases (97%) and identified one appropriate method to prevent mosquito presence (89%). Approximately half of the participants reported receiving prior mosquito-related education. Ten of the participants reported previous diagnosis with one of the mosquito-transmitted diseases (27%). Following education, all participants answered that mosquitoes can transmit illnesses and most (97%) identified appropriate methods to prevent mosquitos from being near. In addition, the majority of patients (73%) correctly listed all four steps of treatment if a mosquito-transmitted illness is suspected. Regression studies revealed no significant models. No correlation was identified with regards to post-survey responses and demographic factors, age, level of education or frequency of mosquito bites.

Conclusion: Based on the results, members of the community seen during the medical mission had prior knowledge regarding diseases mosquitoes can transmit, how to prevent them, and what to do if such an illness is suspected. Given previous education, most participants correctly answered pre-education questions. In addition, the majority of patients were able to correctly answer post-education questions, which likely reflects the education previously received and the education we provided.

Poster Title: Retrospective review of stress ulcer prophylaxis utilization in post-surgical units

Primary Author: Nicole Free, Wingate University School of Pharmacy, North Carolina; **Email:** ni.free@wingate.edu

Additional Author (s):
Ashley Ford
Becky Szymanski

Purpose: The purpose of this study is to assess the current prescribing practices for stress ulcer prophylaxis (SUP) in post-surgical patients and to evaluate the discontinuation of SUP therapy in patients without risk factors. The results of this study will help identify prescribing practice areas that may need improvement. This could also provide cost-saving strategies by identifying the incidence of SUP use without risk factors in the inpatient setting and non-warranted continuation of medications in the outpatient setting. This information may be used to develop guidelines on SUP use in non-intensive care unit patients at Carolinas Healthcare System Northeast.

Methods: This Institutional Review Board-approved study is a retrospective review with data collection taking place from November 1, 2015 to November 30, 2015. 288 charts of patients admitted to a post-surgical care unit of Carolinas Healthcare System Northeast were reviewed during the study period. Patients were included if they were 18 years or older and admitted to a post-surgical care unit during the study period at Carolinas Healthcare System Northeast with an order for a proton pump inhibitor (PPI) or histamine-2 receptor antagonist (H2RA). Patients were excluded if they were pregnant or in the intensive care unit at any point during the hospital admission. The primary objective was the percentage of post-surgical patients at Carolinas Healthcare System Northeast prescribed SUP without an indication. Secondary objectives included the choice of agent, duplication of therapy, elective versus emergent surgery, origin of order, time between nothing by mouth (NPO) and PPI or H2RA medication order, duration of therapy, and the percentage of post-surgical patients continued on a PPI or H2RA at hospital discharge without an indication. Descriptive statistics were used to evaluate the data.

Results: Of the 288 patient charts reviewed, 142 patients (49.3 percent) were found to have risk factors driving the appropriate use of SUP. Of these patients, 62 percent were prescribed PPIs and 38 percent were prescribed H2RAs. The remaining 146 patients did not have an indication for the use of SUP. 17.4 percent of the orders for SUP were found to be a duplication of therapy. The use of appropriate SUP therapy was found more often in emergent surgeries versus elective surgeries (62.5 percent versus 43.9 percent, respectively). SUP ordered via a physician order set was prescribed without risk factors more often than individually generated orders (67.9 percent versus 17.3 percent, respectively). Time between NPO and the SUP medication order was found to be 0.08 days for patients with risk factors for the development of stress ulcers versus 0.12 days for those without. Average duration of therapy was found to be 4.01 days for patients with risk factors for the development of stress ulcers versus 4.53 days for those without. There were 5 patients (1.74 percent) who were continued on SUP without an indication at discharge.

Conclusion: There is a high amount of SUP being administered without an indication among post-surgical units. SUP prescribing was more appropriate with emergent versus elective surgeries. A larger proportion of orders originated from physician order sets and were more often found to be ordered for patients without risk factors for SUP. There was a small number of patients continued on a PPI or H2RA without an indication at hospital discharge. This data will be shared with the surgical department in order to improve the appropriate use of SUP.

Poster Title: Reduction of low-density lipoprotein cholesterol in patients with atherosclerotic cardiovascular disease or familial hyperlipidemia: a retrospective analysis of PCSK9 inhibitors and other lipid lowering therapies

Primary Author: Ginger Pedersen, Wingate University School of Pharmacy, North Carolina; **Email:** gi.pedersen@wingate.edu

Additional Author (s):
Susan Crawford
Robert Ashworth

Purpose: The recent approval of proprotein convertase subtilisin kexin type 9 inhibitors (PCSK9i) could create a paradigm shift, changing the management of hyperlipidemia, particularly in the statin-intolerant population. The purpose of this study was to compare the efficacy of PCSK9i versus other lipid lowering therapies in the reduction of low-density lipoprotein cholesterol (LDL-C) in patients with atherosclerotic cardiovascular disease (ASCVD) or familial hyperlipidemia (FH).

Methods: This retrospective, non-randomized, single-site cohort study was conducted via electronic chart review, in patients 18 years and older, with clinical ASCVD or FH requiring additional LDL-C lowering. All patients were referred to the clinical pharmacist practitioner (CPP) at a large cardiology clinic for PCSK9i evaluation between October 2015 and June 2016. Patients not seen by the CPP or referred for reasons other than hyperlipidemia management were excluded. Office visits were scheduled with the CPP to conduct patient interviews, review lipid panels, and collect medication histories to ensure guideline-directed medical therapy had been implemented or considered prior to initiation of PCSK9i therapy. Patients were prescribed PCSK9i if they met the FDA labeled indications, were currently on a statin, or were statin-intolerant and on ezetimibe or other lipid lowering therapy (LLT). Patients not meeting these criteria were rechallenged with statins or prescribed other LLT. Lipid panels were collected at baseline and repeated in 1-6 months to evaluate reductions in LDL-C. Considerations for additional lipid lowering therapies were made for patients not at goal. The primary endpoint was the percentage of patients with ASCVD or FH that achieved an LDL goal < 70mg/dL.

Additional lipid parameters and adverse effects were reported and evaluated. All data was analyzed using descriptive statistics and independent t-tests as appropriate.

Results: Of the 85 patients screened, 57 met inclusion criteria (age 68 ± 8.4 years; baseline LDL-C 157 ± 43.3mg/dL). Of these, 35 patients (61%) were initiated on PCSK9i while 22 (39%) were started on other LLT. 3 patients in the PCSK9i group and 8 patients in the other LLT group discontinued therapy prior to obtaining results and were not included in the primary outcome analysis. Of the 46 patients included, 22 (47.8%) achieved an LDL goal of < 70mg/dL, with the majority of patients belonging to the PCSK9i group (n=20, 90.9%). The mean LDL-C reduction overall was 51.5% ± 23.7 with 62.1% ± 15.4 in the PCSK9i arm and 26.4% ± 21.1 in the other LLT arm (p < 0.05). Mean LDL-C at follow-up was 58mg/dL ± 25.3 for the PCSK9i group and 105mg/dL ± 28.7 for other LLT group. The mean percent reductions in total cholesterol for the PCSK9i group and the other LLT group were 42.38% ± 14.63 and 19.23% ± 12.79, respectively. Myalgias, the most common adverse event, were reported by 4 patients in each treatment group. Overall, patients in the PCSK9i arm experienced a greater number of adverse events; however discontinuation rates were greater in the other LLT arm.

Conclusion: This study served as a quality improvement measure, analyzing efficacy and safety while streamlining the initiation process of PCSK9i in a large cardiology practice. Dramatic reductions in LDL-C were seen in the PCSK9i group, with a very low discontinuation rate. The patients in the other LLT group who achieved LDL-C goal were rechallenged on statins. Statins still remain the cornerstone of therapy, but PCSK9i offer a viable alternative to LDL-C reduction, however, studies are needed to establish mortality benefit of PCSK9i.

Poster Title: Assessment of vancomycin administration location in a children's hospital

Primary Author: Brenda Simiyu, Wingate University School of Pharmacy, North Carolina; **Email:** br.simiyu@wingate.edu

Purpose: Vancomycin remains one of the most frequently utilized antibiotics. As an intravenously administered agent, vascular access needs to be established prior to its administration. As a vesicant drug with a pH below 5, some clinical guiding bodies recommend it should be administered through a central line, as a means to minimize complications. In clinical practice, however, vancomycin is often administered through a peripheral line. The purpose of this project was to determine whether peripheral line administration of vancomycin is associated with a higher incidence of complications in a pediatric patient population.

Methods: This study was a retrospective chart review of electronic medical records of vancomycin orders for pediatric patients between January 2014 and May 2015. Vancomycin orders were excluded if the medication was not administered, if the medication was not administered intravenously, or if data was missing related to the order. Data collected included the type of vascular access, infusion time in minutes, dose in milligrams per kilogram, infiltration score or phlebitis, administration of diphenhydramine, and, central line indication, if noted. Categorical endpoints were evaluated using the Chi-square test and two-sample t-tests were used for analysis of continuous data. P values of less than 0.05 were considered as statistically significant.

Results: A total of 339 vancomycin orders were included in the retrospective review. Forty two percent of orders were administered via central line with 58 percent administered via a peripheral line. Documented reasons for use of a central line included the need for reliable access, anticipated long-term antibiotic therapy, presence of permanent central access on admission, and administration of multiple medications and antibiotics. In total, 19 complications were noted, including infiltration, clotting, and Red Man's syndrome. While a higher number of complications occurred in peripherally administered infusions, no statistically significant difference was noted between line placement and adverse events (p=0.062). Diphenhydramine was administered with 12 percent of the infusions. A statistically significant

difference was not found between the two groups for diphenhydramine use (p=0.828). The mean infusion time was lower in administrations via peripheral access (72.55 plus/minus 29.13 minutes. vs. 77.23 plus/minus 30.48 minutes; p=0.136) with the majority of orders being infused over 60 minutes. There was no statistically significant difference in the number of extended infusion times (p=0.057) between the two groups. A statistically significant difference was noted in the mean milligram per kilogram dose of peripherally placed lines (17.97 plus/minus 4.3 mg/kg vs. 19.62 plus/minus 5.27 mg/kg; p=0.002).

Conclusion: Administration of vancomycin via peripheral venous accesses was not associated with a significantly higher incidence of complications compared to central venous access. Given the small sample size of this retrospective review, further studies are needed to further explicate these findings.

Poster Title: Medication use evaluation of parenteral ketorolac in hospitalized patients

Primary Author: Legacy Marsolek, Wingate University School of Pharmacy, North Carolina;
Email: le.marsolek@wingate.edu

Additional Author (s):
Lauren Downing
Rebecca Szymanski

Purpose: The purpose of this study is to assess prescribing patterns and incidence of adverse drug reactions of parenteral ketorolac in the acute care setting. Information obtained may be used to improve current ketorolac prescribing through the development of tools for improved clinical decision support for providers and pharmacists.

Methods: This Institutional Review Board approved retrospective study was conducted by the use of electronic chart review in adults, ages 18 and older, admitted to Carolina HealthCare System Northeast (CHS NE) who were prescribed parenteral ketorolac during January 2016 to May 2016. 150 patient charts were randomly selected for review, assuming 100 patients received at least one dose of ketorolac. Patients were excluded if ketorolac was prescribed in the outpatient or procedural setting. One time dose orders were also excluded. The primary endpoint was the incidence of parenteral ketorolac prescribed to a patient with a contraindication, as defined by the prescribing information. The secondary endpoint was the incidence and types of adverse drug reactions following ketorolac exposure. Demographic data collected included age at admission, length of hospital stay, sex, ethnicity, weight, serum creatinine, and creatinine clearance. Therapy regimen data collected included dose of ketorolac, number of doses received, how many days ketorolac was administered over, if ketorolac was prescribed as needed or scheduled, whether or not ketorolac was prescribed using a power plan, and if the patient had any contraindication to ketorolac. Safety monitoring data included incidence of the following: increase in serum creatinine as defined by the Acute Kidney Injury Network criteria, gastrointestinal bleed, non-gastrointestinal bleed, peptic ulcers, cardiovascular events, and hypersensitivity reactions. All data was analyzed using descriptive statistics.

Results: Of the 150 patient charts reviewed, 23 patients were excluded based on predefined inclusion and exclusion criteria. Of the 127 remaining patients, 32 (25.1%) had at least one contraindication to receiving parenteral ketorolac. In total, there were 42 known contraindications. The most prevalent contraindication was concomitant use of ketorolac with aspirin or other NSAIDs (14 patients, 33.3%), followed by administration of ketorolac in patients at a high risk for bleed (12 patients, 28.6%). Of the 127 patient included in the analysis, 116 received at least one dose of ketorolac. Of the patients that received at least one dose, 8 (6.9%) had a documented adverse drug reaction. The most common adverse reaction was the development of an acute kidney injury during or within 48 hours of the administration of ketorolac. However, the majority of these patients were on other medications known to effect renal function. Of the 8 patients that experienced an adverse event, 5 had a contraindication to ketorolac administration.

Conclusion: This medication-use evaluation demonstrates that CHS NE has processes in place to ensure the appropriate dose and duration of ketorolac. Opportunity exists to improve the screening of package insert contraindications prior to administration of ketorolac. The drug information alerts provided during the ordering process, do not optimally screen for all of the contraindications, such as high risk for bleeding and potential risk of AKI. This information will be used to create tools for providers and pharmacists to enhance the safe prescribing of ketorolac at CHS NE.

Submission Type: Evaluative Study

Session-Board Number: 3-286

Poster Title: Evaluating the safety and efficacy of the standardized urine alkalinization process in acute leukemia and Burkitt's lymphoma patients receiving high dose methotrexate

Primary Author: Laura Bowers, Wingate University School of Pharmacy, North Carolina; **Email:** la.bowers@wingate.edu

Additional Author (s):
Maho Hibino
Marie Cavalier

Purpose: High-dose methotrexate (HD MTX) is associated with toxicities such as renal dysfunction, myelosuppression, and mucositis in patients with impaired MTX clearance. Adjunct treatment with aggressive hydration and urine alkalinization, with a goal urine pH of 7 or greater, can increase MTX solubility and aid in MTX clearance. The acute leukemia and Burkitt's lymphoma urine alkalinization protocols at our institution were recently standardized to decrease confusion for staff and to update these protocols in BEACON. This study aims to evaluate the safety and efficacy of the standardized urine alkalinization process in acute leukemia and Burkitt's lymphoma patients receiving HD MTX.

Methods: This is a single-center retrospective chart review study. We reviewed the available electronic medical records (EMR) of patients who have received one of the following chemotherapy regimens: CALGB10102 – Module C; HyperCVAD – Part B; CODOX-M; CALGB10002 – Course 3, 5, 7; CALGB10701 – Course 4 (CNS prophylaxis). The study included acute leukemia and Burkitt's lymphoma patients who received MTX as part of one of the previously mentioned regimens from December 1, 2015 to September 14, 2016 at Wake Forest Baptist Medical Center (WFBMC). Patients less than 18 years old and those with a CrCl less than or equal to 30 mL/minute were excluded. The primary objective of this study was to assess the time to MTX clearance. The secondary objectives included safety of the standardized urine alkalinization process (renal function and alkalinization-induced toxicities), time to achieve goal urine pH, time to discharge, and compliance with obtaining the goal pH prior to MTX infusion. Results were analyzed using descriptive statistics.

Results: The study included 26 patients, 13 acute lymphoblastic leukemia (ALL) patients in the post-standardization and 13 ALL patients in the pre-standardization group. The post-standardization and pre-standardization group had an average age of 53.69 years and 45.08 years, and 77 percent and 46 percent were male, respectively. The median time to MTX clearance was 48 hours (IQR 24 – 72) for both groups. There were no cases of renal dysfunction. Fluid overload was slightly more common in the post-standardization group occurring in 15 percent of patients, compared to 8 percent of the pre-standardization group. There were no cases of elevated bicarbonate. Two patients in each group were excluded from the urine pH endpoints due to missing urine pH data prior to MTX infusion. All but one patient in the pre-standardization group had a goal urine pH of 6. The median time to achieve goal urine pH was 4.22 hours (IQR 3.38 hours – 6.17 hours) versus 3.83 hours (IQR 2.57 hours – 4.32 hours) in the post-standardization and pre-standardization groups, respectively. The goal urine pH was achieved in 91 percent and 100 percent of the post-standardization and pre-standardization groups, respectively. The median time to discharge was 96 hours in both groups.

Conclusion: MTX clearance remained adequate following implementation of a standardized urine alkalinization protocol without negatively impacting time to goal urine pH or time to discharge. Most patients in both groups achieved a urine pH of 7 or greater regardless of their goal, occurring in 91 percent and 73 percent of the post-standardization and pre-standardization groups, respectively. Alkalinization related toxicities were rare in both groups. These findings are limited due to the small sample size. The standardized urine alkalinization protocol minimizes staff confusion and prevents MTX administration errors. These findings will promote future standardization of other HD MTX regimens.

Poster Title: Effects of chronic opioid use on chronic obstructive pulmonary disease (COPD) exacerbations

Primary Author: Melissa Janis, Wingate University School of Pharmacy, North Carolina; **Email:** me.janis@wingate.edu

Additional Author (s):
Taylor Morrisette
Monica White
Treavor Riley

Purpose: Chronic obstructive pulmonary disease (COPD) is a progressive lung disease characterized by chronic obstruction of pulmonary air flow and increasing breathlessness that is not fully reversible with treatment. Older adults with COPD are more likely to experience chronic musculoskeletal pain, insomnia symptoms, and refractory dyspnea. A recent study of patients with advanced COPD evaluated patients' perception of the addition of an opioid to optimize conventional therapy for the treatment of these problems. Although patient perception was positive, limited data exists on the effects chronic opioid use has on hospital readmission rates and length of stay for COPD exacerbations.

Methods: This was a single-center, retrospective cohort study approved by the Institutional Review Board at the tertiary acute-care center where the data were collected. We identified 750 patients who were admitted with a primary diagnosis of COPD exacerbation (International Classification of Diseases, Ninth and Tenth Revisions, [ICD-9] codes: 491.21, 491.22 and [ICD-10] codes: J44.0, J44.1). Patients were included in the analysis if they were at least 18 years of age and had a complete medical record. Readmissions were characterized as 30-day and 90-day readmissions. If a patient had a readmission within 30 days of hospital discharge, they were counted as having a 30-day readmission and a 90-day readmission. Patients were placed into groups of 0 chronic opioids, 1 chronic opioid, and 2 or more chronic opioids. Baseline patient characteristics included age, gender, ethnicity, number of cardinal symptoms at time of admission, home oxygen use, and chronic medical conditions. Baseline characteristics between groups regarding demographics and comorbidities were compared using a chi-square or Fisher's exact test for categorical data and a Student's t-test for continuous measures.

Readmission rates and hospital length of stay were compared using a Fisher's exact test and Student's t-test, respectively.

Results: Of the 750 patients identified, 736 met inclusion criteria. Of these, 433 patients were on 0 chronic opioids, 233 were on 1 chronic opioid, and 70 were on 2 or more chronic opioids. Readmission rates at 30-days were significantly higher in the 2 or more opioid group compared to the 0 opioid group (14.3 percent versus 4.6 percent, P equals 0.004). When comparing the 2 or more opioid group to 1 or less opioid group, there were higher 30-day readmissions seen in the 2 opioid group (14.3 percent versus 5.6 percent, P equals 0.009). Readmission rates at 90 days were higher in the 2 or more opioid group compared to the 0 opioid group (22.9 percent versus 12 percent, P equals 0.022) and the composite of the 1 and 0 opioid groups (22.9 percent versus 13.7 percent, P equals 0.04). There was no difference in the average length of stay between groups (3.32 days, 3.37 days, and 3.78 days for groups 0, 1, and 2, respectively). There were no differences in readmission rates at 30 or 90 days when comparing the 0 to 1 or 1 to 2 opioid groups.

Conclusion: Patients treated with 2 or more chronic opioids admitted to the hospital for a COPD exacerbation are 2.5 to 3 times more likely to be readmitted to the hospital within 30 and 90 days, respectively compared to those receiving 1 or less opioid chronically. Chronic opioid use did not affect the average length of hospital stay.

Poster Title: Assessing the value of pharmacists within a care management team model through use of a medication-related problem intervention tracking tool (MrPITT)

Primary Author: Jacqueline Luu, Wingate University School of Pharmacy, North Carolina; **Email:** j.a.luu@wingate.edu

Additional Author (s):
Tyler Billings
Paige Carson
Nick Wilkins

Purpose: Pharmacist integration into a care management team is a novel approach to help high-risk patients maximize their medications, improve their disease state, and reduce the use of acute healthcare resources. As pharmacists extend their abilities to new practice areas, it is essential to demonstrate their impact on patient care within those settings. A Medication-Related Problem Intervention Tracking Tool (MrPITT) was created for pharmacist use to identify and resolve medication-related problems (MRPs) for patients managed by the care team. The study aimed to assess the value of pharmacists within a multidisciplinary care management team using the interventions recorded in MrPITT.

Methods: This quality assurance analysis was a 3-month, retrospective, and observational study approved by the local Institutional Review Board to assess the value of pharmacists based on interventions recorded in the MrPITT. The program enrolled adults with uncontrolled diabetes or patients with complex chronic conditions and 1 or more acute care utilizations within the past year. Patients were referred to a care management team facilitated by clinical pharmacists, nurses, and non-clinical health advocates. Each patient enrolled received comprehensive medication therapy management from the pharmacist at baseline and via telephone weekly for a minimum of 3 months. MRPs were assessed as part of routine clinical care and pharmacist interventions were reported via the MrPITT. Pharmacists implemented medication recommendations in patients with diabetes per a physician agreement protocol and notified providers of recommendations concerning other disease states. The primary endpoint was the prevalence of specific MRPs in 3 months, based on pharmacist interventions documented in the MrPITT. Exploratory endpoints included the frequency of acute care

utilizations 12 months prior to and while actively enrolled, change in baseline hemoglobin A1c, body mass index, low-density lipoprotein, systolic blood pressure, and diastolic blood pressure after 3 months of enrollment.

Results: The MrPITT recorded an average of 707 MRPs per month during 3 months of data collection. The MrPITT interventions revealed pharmacists identified approximately 1 MRP (on average) per patient. Suboptimal doses (48 percent) and undertreatment (35 percent) were the most commonly identified MRPs. The majority (80 percent) of patient interactions were conducted by clinical pharmacists in a non-face-to-face interaction via telephone. Practicing within a physician agreement protocol, clinical pharmacists implemented 76 percent of the MRP recommendations, half of which were dose adjustments. Of pharmacist recommendations made to a physician, less than 1 percent were not accepted. Patients managed by the care team experienced overall improvements in clinical markers of health, as evidence by changes in hemoglobin A1c, body mass index, low-density lipoprotein, and blood pressure.

Conclusion: Pharmacists function as effective physician extenders to identify and resolve MRPs within a care management team. The MrPITT adequately captures MRPs and is useful for recording what medication interventions pharmacists perform. Within population health, a more robust tool integrating pertinent physical and lab findings may better associate medication-related interventions with patient outcomes.

Poster Title: Assessment of a pharmacist-managed warfarin service in pediatric cardiology patients

Primary Author: Carrie Tilton, Wingate University School of Pharmacy, North Carolina; **Email:** ca.tilton@wingate.edu

Additional Author (s):
Mary Subramanian
Lauren Wyatt
Elizabeth Woods
Derek Williams

Purpose: Pharmacist-led anticoagulation management has previously been shown efficacious in adult warfarin patients; however, pharmacist-led warfarin management in the pediatric setting has not been studied to date. This project was designed to compare the efficacy of a pharmacist-managed warfarin service to a physician-managed warfarin service (usual care) in an outpatient pediatric population. The goal of this project was to demonstrate non-inferiority of pharmacist-managed to physician-managed warfarin therapy.

Methods: This is a descriptive report detailing pediatric cardiology patients managed on warfarin therapy at Wake Forest Baptist Health Brenner Children's Hospital Pediatric Cardiology Clinic. Fourteen patients with an international normalized ratio (INR) goal determined by a cardiologist were included. Prior to the transition to a pharmacist-led service in September 2014, cardiologists managed the majority of the included patients' anticoagulation. For the physician-managed group, INR values were recorded from March 1, 2013 to August 31, 2014. Following a washout period from September 1, 2014 to December 31, 2014, INR values were obtained for the pharmacist-managed group from January 1, 2015 to June 30, 2016. Patients were included in each analysis if they were followed for more than 3 months. An established collaborative practice agreement allowed for pharmacist-led warfarin management. Dose adjustments and monitoring were guided by an approved protocol. The number of INR measurements, percentage of INR values in therapeutic range (traditional method), percentage of time in therapeutic range (%TTR; Rosendaal method), and reported adverse effects were obtained.

Results: The average number of INR tests was lower in the usual care group compared to the pharmacist-managed group (17.9 tests compared to 33.8 tests). The percentage of time in therapeutic range using the Rosendaal method was higher in the pharmacist-managed group (52.3% versus 47.6%). The percentage of values in therapeutic range using the traditional method was also higher in the pharmacist-managed group compared to usual care (41.1% versus 30.8%). A similar rate of minor adverse effects such as epistaxis, minor bruising, gum bleeding, and delayed cessation of bleeding after lacerations was reported in both groups. In terms of major adverse effects, there was one report of active bleeding requiring vitamin K in the physician-managed group. In the pharmacist-managed group, there was one episode of thrombosis and one episode of infarction reported.

Conclusion: Pharmacist-managed warfarin anticoagulation was non-inferior to usual care in the pediatric outpatient setting in terms of the percentage of time in therapeutic range and the percentage of values in therapeutic range. Usual care demonstrated a decreased frequency of INR testing. Adverse effects were similar in the pharmacist-managed and physician-managed warfarin groups. These results emphasize the value of clinical services provided by pharmacists and expand the correlation of positive outcomes with pharmacist-managed warfarin therapy to the pediatric population.

Poster Title: Psychotropic medications and their effect on chronic obstructive pulmonary disease exacerbations

Primary Author: Monica White, Wingate University School of Pharmacy, North Carolina; **Email:** mo.white@wingate.edu

Additional Author (s):
Melissa Janis
Taylor Morrisette
Treavor Riley

Purpose: Acetylcholine is involved in the autonomic regulation of the airways, resulting in bronchoconstriction and inflammation. In addition, serotonin has been shown to inhibit cell membrane acetylcholinesterase activity. A recent study concluded there may be a clinically significant link between acetylcholinesterase inhibitor (AChEI) use and exacerbations of chronic obstructive pulmonary disease (COPD). The study, however did not evaluate the need for hospitalization in that patient population. The primary purpose of this study was to determine the effect of chronic psychotropic medication use (AChEI, and serotonergic antidepressants) on hospital length of stay and readmissions for COPD exacerbations.

Methods: This was a single center, retrospective cohort study approved by the Institutional Review Board at the tertiary acute-care center where the data were collected. We identified 750 patients who were admitted with a primary diagnosis of COPD exacerbation (International Classification of Diseases, Ninth Revision, Clinical Modification [ICD-9-CM] code 491.21, and 491.22, ICD-10 code j44.0 and j44.1). Patients were included in the analysis if they were 18 years of age or older, and had a complete medical record. Readmissions were characterized as 90-day readmissions. Patients were placed into groups of chronic acetylcholinesterase inhibitor (AChEI) use, serotonergic antidepressant use, combination therapy (receiving both an AChEI and a serotonergic antidepressant), or neither psychotropic medication. Baseline patient characteristics included age, gender, ethnicity, psychiatric history, other chronic medical conditions, and chronic use of inhaled anticholinergics. Baseline characteristics between groups regarding demographics and comorbidities were compared using a chi-square or Fisher exact

test for categorical data and a Student t test for continuous measures. Readmission rates and hospital length of stay were compared using a Fisher exact test and student t test respectively.

Results: Of the 750 patients identified, 736 met inclusion criteria. Of these, 6 patients were on chronic AChEI alone, 275 were on serotonergic antidepressants alone, 15 were on combination therapy (both AChEI and serotonergic antidepressant), and 440 were on neither psychotropic medication. There were no statistically significant differences in 90-day readmission rates between groups. The average length of hospital stay was 5.67 days, 3.37 days, 4.27 days, and 3.3 days respectively. There was a significantly longer hospital length of stay in patients receiving AChEI alone compared to those on neither psychotropic medication (5.67 days versus 3.3 days, P equals 0.036). When comparing all patients receiving AChEI (alone and in combination) to those receiving neither psychotropic medication, there was a significantly longer hospital length of stay (4.67 days versus 3.3 days respectively, P equals 0.02). In addition, when comparing patients receiving an AChEI (alone and in combination) to those not receiving an AChEI (serotonergic group plus neither) the hospital length of stay was 4.67 days and 3.35 days respectively (P equals 0.03). There was no difference seen when comparing the serotonergic antidepressant group to those receiving neither psychotropic medication.

Conclusion: There is no difference seen in 90-day readmission rates for COPD exacerbation in patients on chronic AChEI, serotonergic antidepressants, or neither psychotropic medication. Hospital length of stay was significantly longer in all groups receiving an AChEI compared to groups not receiving an AChEI. Serotonergic antidepressants had no effect on hospital length of stay.

Poster Title: Effect of fluoroquinolone use versus other antibiotics on hospital readmissions and length of stay for chronic obstructive pulmonary disease (COPD) exacerbations

Primary Author: Taylor Morrisette, Wingate University School of Pharmacy, North Carolina; **Email:** ta.morrisette@wingate.edu

Additional Author (s):
Monica White
Melissa Janis
Treavor Riley

Purpose: Antibiotic use in patients with chronic obstructive pulmonary disease (COPD) has been reported to be as high as 79 percent. Approximately 60 percent of these patients receive fluoroquinolones. In July 2016, the Food and Drug Administration issued a safety announcement recommending limitations in fluoroquinolone use for acute bacterial exacerbations of chronic bronchitis when other therapies are available. The primary objective of this study was to determine if there was a difference in hospital 90-day readmission rates and length of stay for COPD exacerbations in patients who received fluoroquinolone, macrolide, or tetracycline antibiotics.

Methods: This was a single-center, retrospective cohort study involving 750 patients hospitalized from January 1, 2012 to December 31, 2015, with a primary diagnosis of COPD exacerbation (International Classification of Diseases, Ninth and Tenth Revisions, [ICD-9] codes: 491.21, 491.22 and [ICD-10] codes: J44.0, J44.1). Patients were included in the evaluation if they were at least 18 years of age or older and had a complete medical record. Patients were assigned to groups based on the antibiotic or combination of antibiotics received (fluoroquinolone, macrolide, tetracycline, or no/other antibiotics). Patients were excluded if they received all three of the study antibiotics. Background characteristics collected include age, gender, ethnicity, number of cardinal symptoms at time of admission, history of noxious exposure, home oxygen use, and history of heart failure or obstructive sleep apnea. All continuous data were analyzed using a Student's t-test. Categorical data were analyzed using either a chi-squared or Fisher's exact test. This study was approved by the Institutional Review Board at the tertiary acute-care center where the data were collected.

Results: Of the 750 patients identified, exclusion occurred in 14 patients for having an incomplete medical record and 3 patients for receiving a fluoroquinolone, macrolide, and tetracycline antibiotic combination. Thus, 733 patients met inclusion criteria. Of these patients, 424 were treated with fluoroquinolone, 60 were treated with macrolide, and 116 were treated with tetracycline antibiotic monotherapy. In addition, 16 patients received combination therapy with fluoroquinolone plus macrolide, 37 received fluoroquinolone plus tetracycline, 6 received macrolide plus tetracycline, and 74 were categorized as no/other antibiotics. There were no statistically significant differences in baseline characteristics, with the exception of higher home oxygen use in the fluoroquinolone plus tetracycline group (p-value equals 0.025). When comparing the monotherapy groups, 90-day readmission rates were 14.4 percent for fluoroquinolones, 15 percent for macrolides, and 20.2 percent for tetracyclines (p-value not significant). Average length of stay was 3.36 days, 3.62 days, and 3.13 days, respectively (p-value not significant). When comparing combination therapy, 90-day readmission rates were 12.5 percent for the fluoroquinolone plus macrolide group, 13.5 percent for the fluoroquinolone plus tetracycline group, and no readmissions in the macrolide plus tetracycline group (0/6). There were also no differences seen in average length of stay between the combination therapy groups.

Conclusion: When comparing fluoroquinolone use to other commonly used antibiotics in patients admitted to the hospital with a COPD exacerbation, there is no difference in hospital 90-day readmission rates or length of stay. These results support the recent Food and Drug Administration safety update, suggesting macrolides and tetracyclines may be valid alternatives when antibiotics are needed, allowing institutions to reserve fluoroquinolones for when no alternative is available.

Poster Title: Cost Benefit of LAI Antipsychotics in an Acute Hospital Setting

Primary Author: Gkeemia Gibson, Wingate University School of Pharmacy, North Carolina;
Email: ke.gibson@wingate.edu

Additional Author (s):
Nicholas Fritz
Minal Patel
Kristine Pariyadath

Purpose: Long-acting injectable (LAI) antipsychotics have been introduced in efforts to improve medication compliance among those patients with schizophrenia6. To date, conflicting data exists regarding the clinical benefit of LAIs8,9. These agents are routinely more expensive than oral therapy, but have the potential to reduce long-term costs to the healthcare systems and patients8,10. One study of a pharmacy-managed LAI clinic estimated an annual cost savings of $37,00011. The purpose of this study is to determine if transitioning patients to LAI therapy is associated with reduced institutional costs at Wake Forest Baptist Health (WFBH); a teaching hospital without a dedicated psychiatric unit.

Methods: This retrospective study reviewed patients who received a long-acting injectable antipsychotic (LAI) during an inpatient admission at an academic medical center between July 2015 and December 2015. Patients were included if they were at least 18 years old, had a diagnosis of schizophrenia, schizoaffective disorder, or schizophreniform disorder, and received a LAI during admission. The index hospitalization was the first hospitalization during the study period in which the patient received a LAI. Patients were excluded if they received electroconvulsive therapy or LAI within the past year. Data was collected by retrospective chart review. The primary outcome was the percentage increase in medication acquisition cost for LAIs compared with an oral antipsychotic during each admission within the study period. Secondary outcomes included days of hospitalization covered by the LAI, total antipsychotic medication costs during admission, and per day antipsychotic medication costs during admission.

Results: This study gathered results from a total of 16 patients. Patients were most commonly started on Invega Sustenna (paliperidone); other LAIs included Abilify Maintena (aripiprazole), Risperdal Consta (risperidone) and haloperidol decanoate. On average, the institutional acquisition cost of LAIs were 1188% more expensive than oral antipsychotic therapy. The mean number of days covered by LAI per hospitalization was 7.15 (median 6 days).

Conclusion: LAI therapy is significantly more costly than oral therapy. Institutions have the potential to reduce both purchasing and reimbursement costs by redirecting LAI therapy management to an outpatient setting.

Poster Title: Disposition of Patients Receiving Long-term Daptomycin Therapy

Primary Author: Irene Smith, Wingate University School of Pharmacy, North Carolina; **Email:** ly.ishimwe@wingate.edu

Purpose: Discharge planning is one of the key factors related to the quality of inpatient care and unnecessary hospital readmission. Determining the most appropriate inpatient setting of care for ongoing treatment such as long-term intravenous antibiotics, involves determining the patients' needs and corresponding their needs with the capabilities of potential sites of care. Hospitals caring for patients with long-term intravenous antibiotics such as daptomycin face formidable financial barriers. The aim of this study is to determine if patients required prolonged admissions to receive daptomycin and identify why the patients were unable to be discharged to home or a long-term care facility.

Methods: A retrospective chart review was performed to assess patients receiving long-term daptomycin therapy in inpatient setting. A list of patients names whose medication profile included daptomycin was generated from March 2016 – August 2016. The data collected included the indication, duration therapy, hospital length of stay and the discharge disposition in addition to the source payer. Data was analyzed descriptively.

Results: A total of 78 patients were included in the data analysis of this study. The indications included osteomyelitis 30% (n = 24), prosthetic joint infection 11% (n=9), endocarditis 10% (n=8), abscess/wound 10% (n=8), UTI 7.5% (n= 6), cellulitis 5% (n=4) and 2.5% (n=2) intraabdominal infections. The mean treatment duration was 5 weeks. Out of the 79 total patients, (n =2) remained hospitalized to finish the total treatment course. Both of these patients were intravenous drug users with a total treatment course of 6 weeks. Also, one patient's discharge was delayed due the lack of health care facilities within his insurance network. 64% (n= 51) were successfully discharged to either home with home health services or other health care facilities to complete their daptomycin treatment course..

Conclusion: The study demonstrate that 51/78 patients requiring long-term daptomycin therapy were successfully discharged to home and other healthcare facilities with the exception of 2 Intravenous drug users, though one patient did experience a delayed discharge due to the lack of insurance coverage. Though only three patients in six months remained hospitalized to receive daptomycin, this represent a significant cost due to the medication cost. Our next steps are to investigate solutions that would allow these patients to receive long term daptomycin therapy in a more appropriate setting, while preserving the quality of their care.

Poster Title: Implementation of a pharmacist driven hepatitis C treatment program for uninsured patients in a free clinic

Primary Author: Jacob Gibson, Wingate University School of Pharmacy, North Carolina; **Email:** ja.gibson@wingate.edu

Additional Author (s):
Glenn Herrington
Jennifer Buxton

Purpose: The U.S. Centers for Disease Control and Prevention estimates that there are between 2.7 and 3.9 million people in the United States infected with chronic hepatitis C and over 150,000 of those people are North Carolinians. There have been advances in hepatitis C medications; however, high cost is a major barrier for patients when it comes to receiving treatment. This project's purpose is to outline how a pharmacist-run hepatitis C treatment program, that utilizes prescription assistance programs, can identify, enroll and provide treatment to patients who have no insurance and are unable to pay for the necessary medication.

Methods: A stepwise approach was taken to identify, evaluate and treat patients. First, the pharmacist coordinated with the physician to identify patients within the clinic who were diagnosed with Hepatitis C. Once these patients were identified, the physician evaluated the patients and then referred them to the pharmacist. The pharmacist then reviewed the patients' medical records to determine what labs were needed to help select the proper therapy. The patients were then contacted by phone by the pharmacist to gauge treatment interest and schedule an appointment. At the appointment the pharmacist gave the patient orders for the labs they still needed and once that lab work was completed and reviewed, the pharmacist and patient worked together to choose the best treatment option using the AASLD and IDSA Recommendations for Testing, Managing, and Treating Hepatitis C. At the meeting the pharmacist explained the benefits and risks of treatment and the importance of medication adherence and after the meeting was complete the pharmacist filled out paperwork for the prescription assistance program. Four to six weeks after the paperwork was submitted the medication arrived at the pharmacy free of charge and the medication was then dispensed on a

monthly basis to the patient. Weekly phone calls were made to assess adherence and to monitor for any adverse effects. Follow-up labs were ordered and evaluated to assess efficacy.

Results: The program has identified eighteen patients thus far. Six patients have either started treatment or have been approved for a prescription assistance program. Five patients are in the process of getting treated and seven were not candidates for treatment for various reasons. The program continues to identify and serve patients within its community.

Conclusion: The pharmacist-run hepatitis C treatment program successfully identifies, enrolls and provides treatment to patients who are eligible.

Poster Title: Use of antimicrobial prophylaxis for the duration of a drain following spinal surgery: Does it impact infection rates?

Primary Author: Kelly Fuhrmann, Wingate University School of Pharmacy, North Carolina; **Email:** ke.fuhrmann@wingate.edu

Additional Author (s):
Jordan Richmond
Haley Gibbs
Kristin Rebo
Jerry Rebo

Purpose: Postoperative drains are widely used following spinal surgery to prevent accumulation of fluid in and around the spinal cord. The use of drains is commonly believed to increase the risk of postoperative infections. Despite lack of supporting evidence, prophylactic antibiotic therapy is often continued for the duration these drains are in place. Given the lack of supporting data and rising healthcare costs associated with Clostridium difficile infections, this practice should be re-evaluated. The purpose of this study was to determine whether antimicrobial prophylaxis for the duration of a drain following spinal surgery impacts surgical site infection and Clostridium difficile rates.

Methods: The institutional review board approved this retrospective cohort study. Electronic medical records were reviewed for adults presenting to Wake Forest Baptist Medical Center for spinal surgery with drain placement from July 1, 2014 to June 30, 2015. One hundred and thirty-four men and women aged 18 and older who underwent spinal surgery and received drain placement following the surgery were included in the study. Patients who received antibiotics within 72 hours prior to spinal surgery were excluded. Variables collected for each patient included age, weight, height, gender, antibiotic and duration of therapy, reason for surgery, duration of surgery, location of surgery, duration of drain, chronic steroid use, presence of diabetes, smoking status, and date of infection (if one occurred). A Fisher's exact test was used for categorical data, and a Wilcoxon rank sum was used for continuous data to compare the proportion of patients in each group. The primary outcome measure was rate of surgical site infections within 30 days following surgery.

Results: One hundred and thirty-four patients were included in this study. Of those, one hundred and thirty patients received prophylactic antibiotics, while four did not. For baseline characteristics, no statistically significant differences were found between the groups for age (p=0.48), weight (p=0.18), duration of drains (p=0.54), gender (p=0.62), obesity (p=0.12), chronic steroid use (p=1), diabetes (p=1), or smoking (p=0.32). A statistically significant difference was observed between the two groups for duration of procedure with a mean duration of 238 minutes (+/- 96) in the antibiotic group versus mean duration of 150 minutes (+/- 53) in the no antibiotic group (p=0.04). This suggests a major difference in the level of difficulty of procedure between the two groups. For the primary outcome, no statistically significant difference was observed between the two groups for surgical site infections. Of the one hundred and thirty patients that received prophylactic antibiotics, 8.46% developed a surgical site infection, while 0% of the four patients that did not receive antibiotics developed an infection (p=1). Two patients included in this study developed Clostridium difficile infections within 30 days of their procedure, both of which received prophylactic antibiotics for the duration of their drains.

Conclusion: Due to limited number of patients in the control group and major confounding factor of procedure duration, no definitive conclusions can be made from this study. Reducing unnecessary antibiotic use may be beneficial to reduce the rates of Clostridium difficile infection, reduce costs, and protect against antimicrobial resistance, but in order to allow for more meaningful results to be obtained, further studies should be conducted with a larger and more similar control group to the treatment group.

Poster Title: Utilization of non-high-density lipoprotein cholesterol and apolipoprotein B monitoring in patients at an increased risk for atherosclerotic cardiovascular disease

Primary Author: James Agtuca, Wingate University School of Pharmacy, North Carolina; **Email:** jamesagtuca@snpha.org

Additional Author (s):
Tiffany Tweed

Purpose: The importance of monitoring non-high-density lipoprotein cholesterol (non-HDL-C) and apolipoprotein B (apo-B) is inadequately delineated in the 2013 American College of Cardiology/American Heart Association Guideline on the Treatment of Blood Cholesterol to Reduce Atherosclerotic Cardiovascular Risk in Adults (2013 ACC/AHA). Their usefulness, however, includes indicating the cholesterol content of all atherogenic lipoproteins (i.e., low-density, very-low-density, and intermediate-density lipoproteins), as well as retaining accurate capability when predicting atherosclerotic cardiovascular disease (ASCVD) events. The purpose of this descriptive report was to determine if monitoring non-HDL-C and apo-B in patients at an increased risk for ASCVD can improve therapeutic outcomes.

Methods: A literature search conducted in PubMed, utilizing "hypercholesterolemia" and "monitoring" terms, limited to 2013 forward, English language, and humans, yielded 63 articles. There were 25 relevant articles involving patients with either mismanaged or resistant dyslipidemia. The following groups were related to clinical worsening secondary to nonattainment of commonly employed treatment goals: cardiovascular disease, type 2 diabetes mellitus (T2DM), familial hypercholesterolemia (FH), and metabolic syndrome. Targets of therapy included atherogenic cholesterol [i.e., non-HDL-C and low-density lipoprotein cholesterol (LDL-C)], apo-B, low-density lipoprotein particle (LDL-P), and triglyceride (TG) levels as defined per the 2015 National Lipid Association Recommendations for Patient-Centered Management of Dyslipidemia (2015 NLA).

Results: Treatment of dyslipidemia was previously guided by targeting LDL-C goals. Yet, evidence from randomized controlled trials indicates this method does not reduce ASCVD risk. In explaining this discrepancy, clinicians have found that normal LDL-C levels paired with elevated non-HDL-C levels identify dyslipidemic subpopulations with elevated levels of apo-B, LDL-P, and low-density lipoproteins of especially pathologic morphology. Current guidelines do not emphasize utilization of comprehensive lipid panel monitoring; however, this literature review identified patient groups who would benefit from non-HDL-C and apo-B monitoring. These include patients with FH, ASCVD, heart transplant, unmanaged T2DM, stage 3 or 4 chronic kidney disease (CKD), elevated serum TGs, fasting glucose, inflammatory markers and/or oxidative stress levels, and elevated non-HDL, apo-B and/or microparticles, e.g., LDL-P. Additionally, those at risk for stroke or who are unresponsive to statins and/or on proprotein convertase subtilisin/kexin type 9 (PCSK9) inhibitor or plasmapheresis/low-density apolipoprotein apheresis therapy would benefit from non-HDL-C and apo-B monitoring. Utilization of these lipid parameters provides stronger ASCVD risk correlation because non-HDL-C is representative of every type of cholesterol with atherogenic potential and apo-B, which serves as the main lipid transporter of all atherogenic subparticles, is indicative of true atherogenic particle count.

Conclusion: Providing evidence-based care is a mainstay of modern healthcare. Nevertheless, particular clinical scenarios merit dependence on professional judgment. While past LDL-C targets have been used almost exclusively in substantiating heart disease and stroke risk, evidence points toward implementation of non-HDL-C and apo-B monitoring, considering their comprehensiveness, accuracy, predictive capability, and relative feasibility, despite their current underutilization due to lack of practitioner knowledge and availability/cost, respectively. And even though apo-B directly indicates atherogenic particle count, its limited accessibility and increased expense preclude widespread use. Therefore, non-HDL-C monitoring may gain prominence as it remains less expensive, more standardized, and globally available.

Poster Title: Evaluation of optimization and cost analysis for automated dispensing cabinets in a comprehensive cancer center

Primary Author: Jared Frye, Wingate University School of Pharmacy, North Carolina; **Email:** ja.frye@wingate.edu

Additional Author (s):
Carrie Tilton
Andre Harvin

Purpose: Automated dispensing cabinets (ADCs) have impacted health care institutions since the 1980's. ADCs provide many benefits to patient care including accessibility secondary to the decentralized model, relief of pharmacists' time spent checking, accountability through documentation, billing efficiency, and improved accuracy. Various optimization strategies exist, however determining the goals and objectives of each individual institution can greatly impact the preferred strategy. This study describes how Wake Forest Baptist Medical Center optimized the use of ADCs in a specific area in an academic teaching hospital. The objective of this initiative was to demonstrate improved efficiency of restocking and decreased cost.

Methods: Seventeen automatic dispensing cabinets were included in this analysis involving the Comprehensive Cancer Center at Wake Forest Baptist Medical Center. These cabinets serve a diverse patient population including oncology, bone marrow transplant (BMT), and intensive care units. ADCs utilization was evaluated from March 1, 2016 through April 30, 2016 with data available from the ADCs server and institution electronic medical record. An optimization algorithm was established based on guidelines determined within the department. Changes to the ADCs included minimum and maximum level adjustments, bin allocation, the addition of medications in high demand, and removal of uncommonly used medications. Various measures including count days, low days, zero days, and cost were analyzed to determine efficiency and financial benefit. The cabinets were reconfigured over a six-week period. A predetermined two-month washout period was incorporated from May 1, 2016 to June 30, 2016. A post-analysis from July 1, 2016 to August 30, 2016 was completed in order to determine the effectiveness of the implemented optimization algorithm. Two months after implementation, a cost-benefit

analysis was conducted to determine the financial impact associated with the modifications conducted.

Results: After implementing the ADCs algorithm to the seventeen cabinets, increased efficiency was indicated by a decrease in count days, low days, and zero days. The average count day decreased from 10.9 to 9.8 (10.21 percent-change). Similarly, the median change decreased from 4.8 to 3.6 (22.92 percent-change). The average low days decreased from 1.29 to 0.26 (80.23 percent-change). The average zero days were reduced from 0.12 to 0.022 (81.03 percent-change). Prior to implementation there were a total of 1012 utilized bins, which accounted for 52,964 dollars worth of various medications. After implementation, there were 883 utilized bins indicating a 13 percent decrease. Lastly, the cost decreased to 47,108 dollars which represents a 11.06 percent decrease.

Conclusion: Wake Forest Baptist Medical Center noticed a significant increase in efficiency and decrease in cost in the Comprehensive Cancer Center after implementing the ADCs algorithm to seventeen ADCs.

Poster Title: Esmolol medication use evaluation in the emergency department setting

Primary Author: Maegan Wells, Wingate University School of Pharmacy, North Carolina; **Email:** ma.wells@wingate.edu

Additional Author (s):
Sara Shields
Rachel Holland
Laura Zane

Purpose: Beta-blockers are commonly used in emergency settings. Intravenous esmolol has a quick onset and a short duration of action, making it ideal for rapid lowering of heart rate and/or blood pressure in emergency situations. For example, esmolol is the drug of choice in aortic dissection, and may be used in atrial fibrillation and thyrotoxicosis. Alternative agents are more suitable for less-critical states, such as hypertensive urgencies. The goal of this medication use evaluation is to determine the appropriateness of esmolol use in the emergency department setting with regard to guideline-recommended indication, dose, and cost-effectiveness (approximate wholesale acquisition cost $260/premix-bag).

Methods: A retrospective study of esmolol utilization from September 2015 through September 2016 at Wake Forest Baptist Medical Center was conducted. Electronic health record reporting functionality was employed to identify adult patients treated with esmolol in the emergency department setting. For inclusion, patients were required to have received at least one dose of esmolol while in the emergency department, either a bolus injection, continuous infusion, or both. A total of 144 esmolol doses were identified with 41 patients meeting inclusion criteria of esmolol administration. Data points collected for each patient receiving esmolol included the indication and dosing strategy. Descriptive analyses were utilized to illustrate appropriate medication use.

Results: Esmolol was administered to a total of 41 patients in the emergency department for the following indications: aortic dissection or aneurysm (19 patients; 46.3%), atrial fibrillation (18 patients; 43.9%), thyrotoxicosis (3 patients; 7.3%), and descending aortitis (1 patient; 2.4%). While 39 patients (95.1%) received a continuous esmolol infusion, 2 patients (4.9%) received an

esmolol bolus only. The average bolus dose was 455.88 mcg/kg, and infusions were ordered as titratable to achieve patient-specific heart rate and blood pressure parameters. The maximum recommended infusion rate of 300 mcg/kg/min was not exceeded in any patient. Based on the retrospective utilization data, the approximate annual cost to the medical center was $10,660.

Conclusion: All patients receiving intravenous esmolol in the emergency department setting were found to have a guideline-recommended indication for administration. In addition, bolus and infusion rate dosing was deemed appropriate for all patients and indications. Based on low annual order volumes and appropriate utilization, esmolol use is considered cost effective in the Emergency Department of Wake Forest Baptist Medical Center. Further investigation of place in therapy and patient outcomes is warranted to determine if medical center guideline optimization is needed.

Jai Patel

Purpose: Tacrolimus is commonly used to mitigate the risk of graft-versus-host disease (GVHD) in allogeneic HSCT patients. High interpatient variability in tacrolimus concentrations exist, which may be attributed to pharmacogenetics and clinical factors. In fact, the Clinical Pharmacogenetics Implementation Consortium (CPIC) recommends increasing tacrolimus dose by 1.5-2 times in CYP3A5 normal and intermediate metabolizers; however, these recommendations were based on studies conducted in solid organ transplant patients. We aim to investigate the interpatient variability in tacrolimus steady-state concentrations and impact on clinical outcomes in allogeneic HSCT patients, and determine if the CPIC dosing recommendations can be applied to this patient population.

Methods: Buccal swabs for DNA extraction and genotyping were collected on patients admitted for an allogeneic HSCT and who provided consent to the study. All patients initiated intravenous tacrolimus 0.03 mg/kg/day on day +5 post-transplant. Tacrolimus levels were drawn every two days (+/- 1) after starting therapy. Steady-state was expected to be reached by the fourth day after starting tacrolimus (i.e. second tacrolimus level). Subsequent dosing was based on therapeutic drug monitoring targeting a therapeutic range of 5-15 ng/mL. A systematic retrospective chart review was completed on patients receiving an allogeneic HSCT from 07/03/14 - 09/20/16 at the Levine Cancer Institute's Bone Marrow Transplant Unit. Plasma concentrations and drug-related adverse events (AEs), including tremors, rash, renal toxicity and headaches, were collected from day +5 to +35, and rates of acute grade II-IV GVHD

(aGVHD) were collected from day +5 to day +150. Descriptive analyses were used to describe tacrolimus levels, and unpaired students t-tests were used to compare steady-state tacrolimus levels between Caucasians and African Americans, between patients who did and did not experience aGVHD, and between patients who did and did not experience tacrolimus-related AEs. All patients are currently undergoing genotyping using a custom next-generation sequencing Ion AmpliSeq™ PGx Panel (Life Technologies) to interrogate single nucleotide polymorphisms (SNPs) in CYP3A5 (*3, *6, *7), CYP3A4 (*1B, *22) and ABCB1 (3435C>T, 1236C>T, 2677A>T) (data not shown).

Results: Of 47 patients analyzed, 74% were male, mean age was 51 (25-77) years, 66% were Caucasian and 30% were African American. Approximately 56% of patients had either acute or chronic myeloid leukemia, while the remaining had other forms of leukemia, lymphoma or myelodysplastic syndromes. Preparative regimens included primarily fludarabine/cyclophosphamide/total body irradiation (81%) or busulfan/cyclophosphamide (15%). The mean tacrolimus steady-state concentration at day 4 ± 1 was 14.1 ± 4.6 ng/mL (< 2.0-21.5). Approximately 6%, 47%, and 47% of patients were below, within and above the target therapeutic range at steady-state. The mean steady-state level in Caucasians and Africans Americans was 14.9 ± 3.7 and 12.9 ± 5.1 ng/mL (p=0.072), respectively. The average steady-state level during the first week in patients that experienced (n=13, 27.7%) and did not experience aGVHD was 9.2 ± 3.5 and 12.0 ± 3.2 ng/mL (p=0.012), respectively. Of patients who did not experience aGVHD, 29% had an average tacrolimus level >12 ng/mL over the first month versus 17% of patients who did experience aGVHD. About 19% (n=9) of patients experienced drug-related AEs, and the mean tacrolimus level at AE was 13.7 ± 4.5 versus 9.5 ± 2.0 ng/mL (p < 0.0001) in patients who did not experience drug-related AEs.

Conclusion: High interpatient variability in initial tacrolimus steady-state concentrations was observed. Nearly half of all patients were supra-therapeutic and 6% were sub-therapeutic at initial steady-state concentrations. Given that CPIC only addresses those who are sub-therapeutic, these dosing recommendations may not be applicable for our HSCT population. The disparity observed in tacrolimus concentrations between Caucasians and African Americans further supports a genetic implication. Importantly, we identified a significant association between tacrolimus concentration and rates of grade II-IV aGVHD and incidence of AEs. Genotyping results may further elucidate the role and importance of pharmacogenetics on tacrolimus concentrations in allogeneic HSCT patients.

Poster Title: Evaluation of pharmacy services on blood pressure control and adherence to antihypertensive medications in patients with diabetes and uncontrolled hypertension

Primary Author: Marci Wood, Albany College of Pharmacy and Health Sciences, Vermont; **Email:** marci.wood@acphs.edu

Additional Author (s):
Michael Biddle

Purpose: Patients with hypertension are at risk of adherence issues due to a lack of presentation of specific signs and symptoms of this disease state. Non-adherence is of particular concern in patients taking multiple chronic medications, such as patients with hypertension and another comorbid condition. Cardiovascular disease is a major cause of morbidity and mortality in patients with diabetes, and hypertension is a common comorbid condition in this patient population. This project aimed to identify patients with diabetes and uncontrolled hypertension at risk for non-adherence and measure the impact of a pharmacist-led intervention with the goal of improving adherence.

Methods: Patients at a small, rural family medicine clinic in Vermont with an ICD-9 Diagnosis code of 250* (Diabetes Mellitus) and most recent blood pressure greater than 140/90 mmHg were identified using an EMR report for this quality improvement project. This blood pressure cutoff was utilized to categorize patients as having uncontrolled hypertension because it is the goal used by the American Diabetes Association. After exclusion criteria, a total of 50 patients were assessed for adherence at baseline. Assessment of adherence was performed at baseline and after three months using both medication refill data and through direct patient contact to compare these methods. Medication possession ratios (MPRs) were calculated using SureScripts data or refill history from the patient's pharmacy. Patients were contacted via phone or while in the clinic to assess adherence using the Morisky Medication Adherence Scale 8-question survey (MMAS-8), a validated questionnaire specifically studied and used in patients with hypertension. Identification of potential adherence barriers allowed for the pharmacy team to make interventions with the goal of improving adherence. Blood pressure measurements at 3 months were collected to quantify changes from baseline. MPRs and the

MMAS-8 questionnaire were utilized at the 3-month follow-up to assess the impact of the adherence discussion and pharmacy-led intervention.

Results: Patients who were contacted for adherence assessment had a lower average systolic and diastolic blood pressure at 3 months follow-up compared to baseline. Average systolic blood pressure was 151 mmHg at baseline, and 144 mmHg at follow-up; average diastolic blood pressure was 84 mmHg at baseline, and 78 mmHg at follow-up (n equals 32; p equals 0.02, p equals 0.004 respectively). At baseline, 89 percent of patients (n equals 47) were considered to be highly adherent to antihypertensive medication regimen based on MPR calculations compared to 43 percent (n equals 39) when adherence was assessed with the MMAS-8 questionnaire. Three months following the initial contact to assess adherence, average MPR increased from 94.2 percent at baseline to 98.1 percent (n equals 20, p equals 0.05). For patients who had adherence assessed at the 3 month follow up period with the MMAS-8 questionnaire, the number of patients classified as being highly adherent increased from 33 percent to 41 percent (n equals 12).

Conclusion: A discussion of medication adherence resulted in a lower number of patients classified as highly or moderately adherent to their prescribed antihypertensive medication regimen than when adherence was based on a medication possession ratio calculation. The pharmacy team-led intervention was associated with improved blood pressure measurements at 3-month follow up. These findings support the importance of discussing adherence to medication therapy in patients with diabetes and uncontrolled hypertension with use of the MMAS-8 questionnaire as a tool to uncover potential adherence barriers.

Poster Title: Medication use evaluation of anticoagulants for venous thromboembolism in the emergency department

Primary Author: Elizabeth Canterbury, Marshall University School of Pharmacy, West Virginia; **Email:** canterburye@marshall.edu

Additional Author (s):
Scott Perry

Purpose: As outlined in the 2016 Antithrombotic Therapy for VTE Disease: CHEST Guideline and Expert Panel Report, many patients who present with venous thromboembolism do not require admission to the hospital. The purpose of this retrospective medication use evaluation was to identify the number of patients with venous thromboembolism who were admitted to the hospital unnecessarily and/or received suboptimal therapy.

Methods: This evaluation qualified as exempt from review by the Institutional Review Board as it was retrospective and all patient information was de-identified. Electronic medical records from patients who received anticoagulation in the emergency department between January 2016 and May 2016 for the indication of deep vein thrombosis or pulmonary embolism were evaluated. Data collected included anticoagulant used, anticoagulant dose, type of venous thromboembolism, ordering provider, and disposition. These data points were evaluated for appropriateness based on guidelines from the American College of Chest Physicians, clinical judgement, and any extenuating circumstances such as the presence of a hypercoagulability syndrome. Each patient's scenario was recorded as either appropriately admitted, appropriately discharged, inappropriately admitted, or inappropriately discharged. Each scenario was also separately recorded as receiving either appropriate therapy or inappropriate therapy. This information was used to develop a venous thromboembolism treatment decision tree to assist emergency department clinicians with the decision making process.

Results: During the five-month period analyzed, sixty-three patients were diagnosed with deep vein thrombosis. Of those, eleven were admitted inappropriately, thirty-seven were admitted appropriately, fifteen were discharged appropriately, and zero inappropriate discharges occurred. Forty-seven patients received appropriate therapy while sixteen patients received

inappropriate therapy. Documentation in patient charts revealed common themes of failure to follow-up when patients were given an injection of low molecular weight heparin in the emergency department and instructed to return the next day for ultrasound, physician discomfort with the idea of discharging patients with an active venous thromboembolism, and a tendency to contact the patient's primary care provider to ask the primary care provider's preferred course of treatment. Often, primary care providers instructed emergency department physicians to admit the patient until the primary care provider could personally evaluate the patient the following day. The most frequent inappropriate admission resulted from admitting the patient, starting a heparin drip, and discharging the patient on an oral direct factor Xa inhibitor the following day.

Conclusion: Results from this medication use evaluation reflect the need for increased awareness regarding the recommendations made by the 2016 Antithrombotic Therapy for VTE Disease: CHEST Guideline and Expert Panel Report. An emergency department venous thromboembolism treatment decision tree which includes considerations for admission versus discharge as well as patient-specific considerations for selecting the most appropriate therapy could assist with this process. Institution-specific factors such as cost of anticoagulants, physician preferences, and availability of manufacturer coupon cards should be incorporated into the decision tree.

Poster Title: Review of discharge prescriptions to treat uncomplicated urinary tract infection from a hospital emergency department in order to assess appropriate duration of therapy for antibiotics

Primary Author: Catherine Higgins, Marshall University School of Pharmacy, West Virginia;
Email: higgins0124@gmail.com

Additional Author (s):
Scott Perry

Purpose: Uncomplicated urinary tract infection (cystitis) is one of the most commonly treated ailments in emergency departments. Inappropriate antibiotic therapy can result in development of resistant bacteria or increased risk of side effects for patients. This study sought to analyze discharge prescriptions for patients treated for uncomplicated UTIs between January and August of 2016 in an urban hospital emergency department. Antibiotic dose, frequency, duration of therapy, and culture sensitivity were compared to current uncomplicated cystitis treatment guidelines. The findings of this study could aid in improvement of proper antimicrobial stewardship practices within the emergency department setting.

Methods: This study was a retrospective chart review between January –August 2016. A urine culture and sensitivity report generated by the microbiology department was reviewed daily for patients with urine cultured from the emergency department. The patient's discharge summary was assessed to gather the antibiotic drug, dose, frequency, and duration prescribed. Sensitivity of the cultured bacteria to the antibiotic prescribed was recorded. The number of times each antibiotic was prescribed was quantified, as well as the number of times a dose, frequency, and duration was used. The rate of culture sensitivities to antibiotics prescribed was calculated. The severity was determined through review of clinical notes. Uncomplicated infections included non-pregnant females with no known urological abnormalities or uncontrolled comorbidities. Patients were excluded if they were male, experienced systemic effects of infection, had pyelonephritis or urinary obstruction, such as kidney stones or bladder abnormalities, were immunocompromised, had renal failure, had an indwelling catheter, asymptomatic bacteriuria, or were pregnant. This data was recorded and stored in a

computerized spreadsheet on a hospital computer where only investigators could access the data. This study was approved by the institutional review board.

The primary endpoint in this study includes appropriateness of antibiotic drug, dose, frequency, and duration prescribed at discharge based on guidelines for treatment of uncomplicated cystitis. The secondary endpoint evaluated was sensitivity of the urine culture to the antibiotic chosen.

Results: 156 discharge prescriptions to treat uncomplicated UTI were written between January-August 2016 in the ED. Of these, 23 sulfamethoxazole-trimethoprim, 31 ciprofloxacin, 71 cephalexin, 24 nitrofurantoin, 1 amoxicillin, 1 amoxicillin-clavulanate, 1 cefdinir, 1 doxycycline, and 3 levofloxacin were prescribed. Bactrim DS twice daily durations ranged from 3-10 days with a resistance rate of 17.4%. Ciprofloxacin 500 mg twice daily durations ranged from 3-12 days, while ciprofloxacin 500 four times daily was written for once with a duration of 10 days. Ciprofloxacin showed a resistance rate of 13.9%. Cephalexin was written for 250 mg twice daily, 250 mg three times daily, 500 mg twice daily, 500 mg three times daily, and 500 mg four times daily; all durations of therapy ranged from 5-10 days. The cephalexin resistance rate was 12.7%. Nitrofurantoin 100 mg twice daily durations ranged from 5-14 days with a resistance rate of 25%. Amoxicillin-clavulanate 875-125 mg twice daily for 14 days was not effective. Cultures were sensitive to both cefdinir 300 mg twice daily and doxycycline 100 mg twice daily for 10 days. Levofloxacin 500 mg daily for 10 days was prescribed twice and levofloxacin 750 mg daily for 7 days was prescribed once; all cultures were sensitive.

Conclusion: Guidelines for treatment of uncomplicated UTI recommend a sulfamethoxazole-trimethoprim therapy duration of 3 days, nitrofurantoin for 5 days, cephalexin for 7-14 days, ciprofloxacin or levofloxacin for 3 days, and amoxicillin-clavulanate for 3-7 days. Amoxicillin, doxycycline, and cefdinir are not currently recommended. Most treatment durations observed on discharge prescriptions from the ED for uncomplicated UTI are several days longer than the recommendations, putting patients at risk of side effects and unnecessary pill burden. With a 12.7% resistance, cephalexin is the most effective antibiotic to treat uncomplicated UTI in this ED.

Poster Title: Are there gender related differences in infants born with neonatal abstinence syndrome in Cabell County, West Virginia

Primary Author: Taylor Mills, Marshall University School of Pharmacy, West Virginia; **Email:** mills162@marshall.edu

Additional Author (s):
Tyler Flaugher
Randall Johnson
Carson Terwilliger
Shekher Mohan

Purpose: Neonatal abstinence syndrome (NAS) is a group of problems experienced as a result of withdrawal from substances used or abused by a mother during her pregnancy. Cabell County, West Virginia has the worst opioid drug use per capita in the United States. At Cabell Huntington Hospital, 10.3 percent of babies have been exposed to drugs or alcohol while the national average is 0.5 percent. This study is to determine whether there are differences between male and female neonates born at Cabell Huntington Hospital in treatment of NAS, Finnegan scores, and birth sizes.

Methods: A retrospective cohort study was performed in which maternal and infant data were collected for 26 male and 36 female infants born at Cabell Huntington Hospital (CHH) between January 01 and December 31, 2015. The Cerner Millennium system used at CHH did not easily allow for the extraction of patient data. Therefore, a survey was built using Qualtric's Survey Software to collect and analyze data. Collected data included admission, discharge assessments, mother demographics, self-reported substance abuse, NAS Finnegan scores, methadone dosing's, and urinary and umbilical cord drug screens. Also reviewed were History and Physical reports, nursing and social work progress notes, and general charts for pertinent information. A survey was designed allowing for standardized data collection methods, a built-in system of data validation. All data was analyzed using Microsoft Excel and GraphPad® Prism. All infants born after 28 weeks gestation, diagnosed with NAS and received methadone were included in this study. If infants did not meet the preceding criteria, lacked a completed worksheet containing the mother's demographic information, including information about the

mother's substance use, or were transferred out of CHH or discharged before 168 hours post-birth they were excluded. The Marshall University, Institutional Review Board (IRB) committee approved this study.

Results: Of the 62 infants included in this study, 26 (42 percent) were female and 36 (58 percent) were male. Male infants had a higher average Finnegan score compared to females (8.20 vs 7.78) and experienced more severe tremors (2.16 vs 1.90). Males were started on methadone approximately 8 hours before females (53.72 vs 61.85 hours after birth). Also male infants were treated for NAS longer (32.39 vs 27.62 days) at a higher average dose (1.3 vs 1.01 mg/kg). Male infants also received more doses of methadone within the first 168 hours of birth compared to females (27.09 vs 22.96 doses).

Conclusion: These data indicate that male infants suffer from more severe withdrawal syndrome. The more severe withdrawal calls for a more intense methadone regimen. Therefore, male infants receive methadone sooner, longer, and more doses.

Poster Title: Is there differences in Finnegans scores between buprenorphine and polydrug exposed infants born with neonatal abstinence syndrome in Cabell County, West Virginia?

Primary Author: Randall Johnson, Marshall University School of Pharmacy, West Virginia; **Email:** johnson655@marshall.edu

Additional Author (s):
Tyler Flaugher
Taylor Mills
Carson Terwilliger
Shekher Mohan

Purpose: Clinical diagnosis of neonates suffering from opioid withdrawal is known as neonatal abstinence syndrome (NAS). The Finnegan scoring system is used to assess the severity of NAS. Cabell County, West Virginia is the epicenter for opioid abuse in the US per capita; 103:1000 babies born at Cabell Huntington Hospital (CHH) are born with NAS (national average is 5:1000). The objective of this study is to determine the differences in Finnegans scores between infants exposed to buprenorphine compared to polydrugs (i.e. cannabinoids, cocaine, heroine) and how that could be used improve treatment protocols and outcomes of this vulnerable population.

Methods: Data was obtained from patient charts at Cabell Huntington Hospital (CHH) in Huntington, WV. Using the secure Cerner Millennium patient data system information was collected (2015-2014) using a survey built through Qualtrics Survey Software, provided by Marshall University. Data collected included admission/discharge assessments, the mother's demographic information and admitted substance abuse, NAS Finnegan score's, methadone dosing, urinary and umbilical cord drug screens. History and physical reports, nursing and social work progress notes, and the general charts were also reviewed for pertinent information. A survey design was utilized to standardize data collection methods. This provided a built-in system of data validation and efficient data analysis using Microsoft Excel and Graphpad(R) Prism. Inclusion criteria was: birth at CHH between January 1 and December 31, 2015; born after 28 weeks gestation; and diagnosed with NAS and/or received methadone as treatment for NAS. Exclusion criteria was: not meeting the preceding criteria, lacked information regarding

the mother's demographic information and admitted substance use, or were transferred out of CHH or discharged before 168 hours post-birth. The Marshall Univ., Institutional Review Board (IRB) committee approved this study.

Results: Of 62 infants in this study, 31 (54 percent) were infants born to polydrug-using mothers and 26 (46 percent) infants were identified as being born to mothers who were taking only buprenorphine. Of the mothers in the polyabuse group, 19 (59 percent) used Subutex, 10 (31 percent) used Suboxone and 11 (34 percent) used heroin. Additionally, 12 (37 percent) infants were born to mothers that tested positive for hydrocodone, codeine, or oxycodone and 4 (13 percent) used gabapentin or benzodiazepines. There was an 18 percent difference in mean methadone received (1.36 mg/kg vs.1.15 mg/kg) between polyabuse and buprenorphine groups, suggesting that patients in the polyabuse group required more intense methadone therapy. Infants of polydrug-using mothers had higher mean Finnegan Score values (8.31 vs. 7.65), higher tremor scores (1.93 vs. 1.72). The polydrug exposed infants also had a greater occurrence of hyperactive moro reflex (55.8 percent vs 39.0 percent), myoclonic jerking (4.1 percent vs 2.2 percent), sleep disturbances (20.5 percent vs 16.6 percent), and diarrhea (19.8 percent vs. 14.0 percent). The buprenorphine group had higher rates of excessive high pitched crying (5.1 percent vs. 7.2 percent), fever (23.2 percent vs 26.5 percent), and vomiting (4.6 percent vs. 5.4 percent).

Conclusion: This data suggests that differences in NAS score among the two drug use groups may be caused by differences in symptom presentation related to the specific substances involved. Further extensive data are currently being collected to determine if recommendations to develop an independent protocol to treatment NAS infants that have been exposed to multiple drugs compared to a single drug should be utilized to improve patient outcomes.

Poster Title: Mood disturbances induced by hepatitis therapy: a case report

Primary Author: Tyler Clay, Marshall University School of Pharmacy, West Virginia; **Email:** clay114@marshall.edu

Additional Author (s):
Ashley Brown

Purpose: This case report describes mood disturbances concurrent with hepatitis C treatment in two middle aged males with psychiatric illnesses. The first patient is a 41-year-old male with a 16-year psychiatric history significant for bipolar disorder, recurrent major depression, and substance abuse disorder, including opioid dependence. Other medical history includes gastroesophageal reflux disease, hypertension, and hepatitis C with abnormal liver function tests. Prior to ledipasvir/sofosbuvir therapy the patient had attempted interferon therapy, but was unable to complete treatment due to unknown side effects. The patient had been psychologically stable for the preceding three years. Ledipasvir/sofosbuvir therapy was initiated for treatment of hepatitis C in addition to the patient's ongoing therapy (suboxone, gabapentin, quetiapine, dexlansoprazole, and hydrochlorothiazide). Approximately 6 weeks after initiation of ledipasvir/sofosbuvir treatment, the patient began to report uncharacteristic symptoms of anger and aggression along with documented outbursts seen in group substance abuse therapy. The second patient is a 57-year-old male with a psychiatric history significant for opioid dependence. Comorbid conditions include benign prostatic hyperplasia, hypothyroidism, and allergic rhinitis. Prior to sofosbuvir treatment the patient had no comorbid psychiatric conditions. Sofosbuvir therapy was initiated for treatment of hepatitis C in addition to the patient's ongoing therapy (suboxone, gabapentin, clonidine, levothyroxine, tamsulosin, and loratadine.) Four weeks after initiation of sofosbuvir treatment the patient began to report weakness, tiredness, decreased appetite, nausea, and depressed mood. Patient symptoms escalated coinciding with significant weight loss and he was initiated on escitalopram therapy for dysthymia. The patient reported escitalopram therapy had a mild impact but continued to experience trouble sleeping and a general lack of motivation. Both patients reported side effects continued to persist throughout hepatitis treatment, and for 12 and 15 weeks following completion of treatment respectively. After the completion of therapy, the patients reported a return to baseline mental status, and have remained at baseline for a minimum of nine months.

These cases demonstrate that mood disturbances are one of many factors that should be monitored in patients being initiated on ledipasvir/sofosbuvir or sofosbuvir therapy.

Poster Title: Implications of overfill in commercially premixed intravenous admixtures used in pediatric medication preparation

Primary Author: Amber Tippens, Marshall University School of Pharmacy, West Virginia; **Email:** tippens1@marshall.edu

Additional Author (s):
Elizabeth Canterbury
Nicole Rockich-Winston
Brian Train
Leesa Prunty

Purpose: The antibiotic admixtures used for neonatal and pediatric patients generally require dilution and manipulation due to the lack of commercially available premixed, ready-to-use intravenous (IV) formulations due to weight based doses used in this population. Standard dose adult IV premixed bags are currently available for certain medications, but concerns for potential overfill with resulting concentration difference, particularly for small doses, has limited this practice. The purpose of this study was to evaluate the stated concentrations against the standards for two commercially available antibiotic premixed products, cefazolin and levofloxacin, in order to assess the effect of overfill in these products.

Methods: Standards and samples were analyzed using reversed-phase chromatography with a Shimadzu C-18 column (3 micrometers, 50 x 4.6 mm) and a 50:50 mixture of acetonitrile and phosphate buffer (pH 6) mobile phase on a Shimadzu LC20AT/SPD-M10A high-pressured liquid chromatography (HPLC) instrument. Detection wavelengths for cefazolin and levofloxacin were 260 and 280 nm, respectively. Standard curves were created from five dilutions, from 0.33 to 33 mg/mL for cefazolin and 2.5 to 500 mg/mL for levofloxacin. Similarly, two commercially available premixed intravenous admixtures, cefazolin sodium 1 g/50 mL in dextrose (B. Braun Medical, DUPLEX) and levofloxacin 250 mg/50 mL in dextrose (Claris Lifesciences) were sampled in triplicate. Samples were diluted to create five analysis concentrations from 0.2 to 20 mg/mL for cefazolin and from 2.5 mg/mL to 500 mg/mL for levofloxacin. Retention times and area under the curve (AUC) were recorded for standards and samples intended for analyses.

Independent samples t-tests evaluated the AUC for the samples against standard curves. An alpha level of 0.05 was used to assess statistical significance.

Results: The cefazolin sodium Duplex system samples were, on average, 0.9 plus or minus 0.11 percent lower for each of the five sampled concentrations but did not demonstrate statistical significant differences (p=0.64). Retention times for cefazolin standards and samples were consistent at 0.65 plus or minus 0.05 minutes. Similarly, the levofloxacin premixed admixture samples averaged 0.78 plus or minus 0.18 percent lower for each concentration but did not demonstrate statistical significant differences (p=0.89). Retention times for levofloxacin were constant at 0.74 plus or minus 0.07 minutes.

Conclusion: The results suggest that drawing doses from premixed, standard dose IV admixture products to the recommended pediatric dosage according to the stated drug concentration on the bag will result in appropriate pediatric concentrations even with the manufacturer overfill. In addition, this evidence suggests that hospitals should feel comfortable using these products as an additional measure to potentially reduce compounding errors in pediatric IV medication preparation.

Poster Title: Evaluation of a pharmacy-driven neonatal aminoglycoside dosing protocol: before and after

Primary Author: Omar Ahmed, Marshall University, School of Pharmacy, West Virginia; **Email:** ahmed13@marshall.edu

Additional Author (s):
Justin Simpkins
Colleen Heffner
Leesa Prunty

Purpose: Aminoglycoside antibiotics have limited tissue distribution, are dependent on renal elimination, and have a narrow therapeutic index. Ensuring the selection of appropriate dosing regimens, alongside the observance of therapeutic serum levels are needed to establish safe and effective treatment. This is especially the case in the neonatal population. The primary objective of the study was to compare the number of supratherapeutic trough values for aminoglycosides following implementation of a pharmacy-driven neonatal aminoglycoside dosing protocol.

Methods: The institutional review board approved this retrospective cohort study. Patient's date of birth, height, weight, gestational age, aminoglycoside dose, levels, dates and times of levels drawn were recorded. All neonates treated with aminoglycosides admitted to the Neonatal Intensive Care Unit (NICU), Neonatal Therapeutic Unit (NTU), or the Newborn Nursery from December 2012 to May 2013 (pre-protocol), and September 2015 to February 2016 (post-protocol) were included. Patients with Cystic Fibrosis were excluded. Prior to the protocol, Neofax, 5mg/kg/dose every 24 hours, and/or prescriber preference were used for dosing. The protocol established is based on patient's corrected gestational age, renal function and indication. After protocol implementation, neonates of corrected gestational age (cGA) 29 weeks or younger received 5 mg/kg every 48 hours. Additionally, neonates of cGA 30–34 weeks, and 35 weeks or older, received 4 mg/kg and 5 mg/kg every 24 hours respectively. Data was analyzed to establish if safety parameters improved after protocol implementation.

Results: Overall there were 162 infants included in the pre-protocol group and 278 infants in the post-protocol group. There were 33 trough values (20 percent) versus 84 trough values (30 percent) drawn in the pre- and post- protocol groups respectively. Among infants with trough levels in the post-protocol group, 7 infants were treated with gentamicin doses which did not follow the protocol, and 3 of these trough values were greater than 2 mcg/ml (42.8 percent). Comparing the trough values of pre-protocol dosing strategies with infants treated using the protocol, of the infants less than 30 weeks cGA, 27 percent (n=3) pre-protocol versus 0 percent (n=0) per-protocol trough levels were greater than 2 mcg/ml. In the infants between 30-34 weeks cGA, neither group had any reported trough values greater than 2 mcg/ml. In infants with cGA 35 weeks or older, 13 percent (n=2) versus 6 percent (n=3) pre-protocol compared with per-protocol dosed infants had trough values above goal.

Conclusion: After the implementation of a pharmacy-driven neonatal aminoglycoside dosing protocol, a higher overall percentage of trough values were within the goal range. Infants less than 30 weeks cGA, and 35 weeks or greater cGA, had a higher percentage of troughs within the goal range in the protocol group compared with the pre-protocol findings. Further study is warranted to assess nephrotoxicity and ototoxicity outcomes and appropriateness of current trough goal value.

Poster Title: Influenza and pneumonia vaccination requirements, and infection rates in nursing homes and assisted living facilities in West Virginia.

Primary Author: Melissa Buse, University of Charleston School of Pharmacy, West Virginia; **Email:** melissabuse@ucwv.edu

Additional Author (s):
Alice Gahbauer
Jamie Bennett
Michelle Herdman

Purpose: In 2014, West Virginia reported 19.6 deaths per 100,000 people due to influenza and pneumonia, but in adults ≥ 65 years only 69.8 percent and 67.7 percent received the annual flu and pneumonia vaccines, respectively. According to the Centers for Disease Control and Prevention, vaccination is the best way to prevent contraction of illness with a vaccination rate of >90 percent in high-risk individuals, such as ≥ 65 years, being necessary. This study is looking to determine if a correlation exists between influenza and pneumonia vaccine requirements and infection rates in nursing homes and assisted living facilities in West Virginia.

Methods: The institutional review board approved this evaluative study with data collected via paper survey. Surveys were mailed through United States Postal Service to nursing homes and assisted living facilities in West Virginia that qualified through pre-determined inclusion criteria. Envelopes and informational letters were personalized with the name of the director of nursing or equivalent at each facility. A second round of surveys were generically addressed and sent to the facilities that did not respond to the personalized packet. Facilities who returned the survey were entered into a drawing to win supplies for their activities department, such as books and board games. A pilot survey was sent to 20 facilities in Kanawha County, West Virginia. In a continuation of the study, surveys were sent to qualifying facilities in the 54 remaining counties of West Virginia. Survey questions asked the number of facility residents, age of residents, vaccination requirements and recommendations for residents and employees, and documentation of influenza and pneumonia cases from 2013 to 2016. The surveys did not consist of any personal information of the survey taker or facility residents. All participating facilities were de-identified for data analysis and publication. Descriptive statistics will

determine if vaccine requirements and offering vaccines onsite appear to decrease infection rates among facility residents and employees.

Results: The pilot survey of Kanawha County resulted in a 50 percent response rate, with 7 facilities reporting >80 percent of their residents over the age of 65. Of the 10 facilities, 50 percent state vaccines are required of the residents, but influenza and pneumococcal vaccines are not included in those requirements. Ninety percent of the facilities said they require a medical history intake form prior to the residents moving in, with only 60 percent inquiring about vaccine history on this form. Eighty percent stated they recommend the annual influenza vaccine to its residents, but only 60 percent of facilities offer the vaccine on site. Sixty percent of facilities recommend the pneumococcal vaccine, but only 50 percent offer the vaccine on site. The data from the remaining 54 counties are still being collected.

Conclusion: The lack of influenza and pneumococcal vaccine recommendations and requirements in nursing homes and assisted living facilities included in the pilot study show there is a deficit in the number of residents ≥ 65 years of age receiving the vaccines appropriately. An increase in vaccinations is needed in these facilities to reach the >90 percent vaccination rate necessary for immunity in this high-risk age group. It is postulated that the remaining counties will offer similar results, indicating room for improvement in influenza and pneumococcal vaccination processes in nursing homes and assisted living facilities throughout West Virginia.

Poster Title: Drug shortages: Beating the odds

Primary Author: Kaitlyn Farley, West Virginia University, West Virginia; **Email:** kfarley3@mix.wvu.edu

Additional Author (s):
Alyssa Ruberto
David Cecere
Daniel O'Neil

Purpose: Over the past decade, the United States has experienced a fluctuating number of drug shortages. There are many explanations for these shortages, which include, but are not limited to, manufacturing decisions, the inability to obtain necessary materials, and varying supply and demand. Hospitals must have plans in place to quantify and mitigate the drug shortages that will inevitably occur. These strategies may differ based on hospital size, formulary size, typical number of shortages experienced at the location, or other hospital specific variables.

Methods: West Virginia University (WVU) Medicine's flagship hospital, Ruby Memorial Hospital, uses numerous strategies to mitigate drug shortages. Weekly, in-person meetings are held twice weekly. The initial meeting is held with the inventory team, while the second meeting consists of all the key stakeholders. These meetings help bring the staff up-to-date and assist in the discussion of ideas to help keep care optimal during drug shortages. A weekly online newsletter and tracking spreadsheet are continuously maintained to outline and update the plan for drug shortages. The tracking spreadsheet includes the product, manufacturer, tentative shortage release dates, comments surrounding the shortage, a list of alternative drugs being used, and a color categorization. This color categorization includes red (on hand supply is less than the 30 day estimated usage), yellow (on hand supply is equal to the 30 day estimated usage), and green (on hand supply will last at least two months or that the shortage has a plan). Lastly, manufacturer relationships are also used to help mitigate drug shortages by enabling additional amounts of drug to be acquired. In addition, medications that are on shortage are clearly labeled in the pharmacy to make all staff aware there is a shortage and to help prevent these drugs from being loaned out. Ruby Memorial has one person dedicated to drug shortages that coordinates drug shortage plans and drug supplies.

Results: By using weekly data from shortage meetings, we compared the number of shortages at Ruby Memorial Hospital in 2015 to 2016. We did this for the first two quarters of 2015 and the first two quarters of 2016. Upon comparison, the number of shortages on the final day of quarter one in 2016 was nearly the same as quarter one in 2015. However, the number of shortages on the final day of quarter two in 2016 is about 40 percent of the number from quarter two in 2015. The decrease in the amount of active shortages at Ruby Memorial Hospital can be attributed to various factors. Within the 12 months between quarter two of 2015 and quarter two of 2016, the pharmacy department implemented the various methods listed above. We believe this attributed mainly to the decrease in active shortages because there was only a slight change in national data. Data via the University of Utah Drug Information Service showed a decrease from 219 active shortages to 191 nationwide. This shows only a 13 percent decrease compared to Ruby Memorial Hospital's nearly 40 percent decrease.

Conclusion: While data suggest drug shortages have improved across the country, the burden continues to be an issue for health-systems. WVU Medicine's flagship hospital, Ruby Memorial Hospital, has implemented numerous strategies to relieve the pressure drug shortages place on patient care. Over the past two years, Ruby Memorial Hospital has implemented twice weekly meetings, a weekly online newsletter, a color-coded tracking sheet, improved manufacturer relations, and full-time equivalent (FTE) support. These strategies have greatly improved the volume and inconvenience of drug shortages.

Poster Title: Duration of antibiotic treatment in community-acquired pneumonia in the outpatient setting

Primary Author: Andrew Harmon, West Virginia University, West Virginia; **Email:** aharmon2@mix.wvu.edu

Additional Author (s):
Jonathan Kline

Purpose: Recent updates to IDSA guidelines have continued to encourage a shorter course of antibiotic therapy. The current community-acquired pneumonia (CAP) guidelines recommend a minimum of five days of antibiotics for patients who respond to treatment. The purpose of this project was to assess the overall treatment patients diagnosed with CAP in an outpatient setting are receiving.

Methods: Adults 18 years of age or older who had a CAP diagnosis within the years of 2015 to 2016 were identified. Exclusion criteria included diagnoses classified as health-care associated pneumonia (hospitalized for 2 or more consecutive days in the last 90 days), more than 24 hours hospitalized for CAP treatment, and any patient who received at least one dose of IV antibiotic in the ED. The EMR was abstracted for the following data: patient's demographics, comorbidities, recent antibiotic use, and antibiotic use for current episode. The primary outcome of this project was the average days of antibiotics prescribed for CAP. Secondary outcomes included appropriate antibiotic based off the IDSA guidelines, imaging to confirm diagnosis, and a recurrent diagnosis of CAP within 30 days of completing treatment.

Results: 100 patients treated for CAP were studied. 71 of these patients underwent imaging and 48 patients had positive results on chest imaging. Of the 23 patients whose imaging was negative, 1 patient had antibiotics stopped. The average days of antibiotics prescribed was 8.3 days. The most prevalent antibiotics prescribed were Doxycycline (n=62) and Azithromycin (n=23) as monotherapy. 48 percent received the appropriate medication based off of the IDSA guidelines. Most patients with a comorbidity received inappropriate antibiotics. 16 percent had recurrence of pneumonia in 30 days after stopping treatment. 10 of these 16 patients were not prescribed the appropriate antibiotic on first diagnosis.

Conclusion: Overall, treatment exceeded the recommended days. The findings of this project also identify issues imaging patients to confirm a pneumonia diagnosis. Most of the time, the treatment plan did not change even with negative imaging. The findings of this project strengthen the argument that antibiotic stewardship is still in need of great improvement.

Poster Title: Ceftriaxone utilization before and after a change in community-acquired pneumonia recommended regimen at an academic medical center

Primary Author: Kristina Stemple, West Virginia University School of Pharmacy, West Virginia; **Email:** kstempl1@mix.wvu.edu

Additional Author (s):
Lisa Keller

Purpose: Our large academic medical center has recently implemented hospital-wide efforts to reduce the use of third-generation cephalosporins. One of these efforts was a change in the recommended community-acquired pneumonia (CAP) empiric regimen from ceftriaxone plus doxycycline to ampicillin-sulbactam plus doxycycline, which was communicated by an alert in the electronic medical record. The primary objective of this study was to compare the ceftriaxone Days of Therapy (DOT) per 1000 Patient Days before and after the change in our recommended CAP regimen. Secondary objectives were to evaluate the indications for ceftriaxone use, if therapy was empiric or culture driven, and microbiological data.

Methods: This was an IRB-approved retrospective review of electronic medical records of all hospitalized patients who were prescribed ceftriaxone during March 2015 and March 2016. Patients who received one dose of ceftriaxone in the Emergency Department and then discharged were excluded from this study. Electronic medical records were reviewed for age, gender, length of stay, ordering service, indication for ceftriaxone use, location of first administration (Emergency Department or inpatient), days of therapy, empiric or culture driven therapy, and microbiological data. Descriptive statistics were utilized to describe data collected. Ceftriaxone DOT per 1000 patient days was used to evaluate the difference in utilization before and after the change in our recommended CAP regimen.

Results: The total number of patients meeting inclusion criteria in the March 2015 and March 2016 groups were 247 and 208, respectively. The overall ceftriaxone utilization rate was 53 DOT per 1000 patient days in March 2015 and 43 DOT per 1000 patient days in March 2016. The use of ceftriaxone for patients specifically with pneumonia decreased from 17 DOT per 1000 patient days to 7 DOT per 1000 patient days. The overall utilization rate for ceftriaxone specifically for

urinary tract infections decreased from 20 DOT per 1000 patient days to 16 DOT per 1000 patient days. The top two indications for ceftriaxone use in both groups were urinary tract infections (41% March 2015 and 40% in March 2016) and pneumonia (29% in March 2015 and 27% in March 2016). 94% of the ceftriaxone use was empirically driven in the March 2015 group and 97% in the March 2016 group. Of the ceftriaxone use that was culture driven, Escherichia coli was the most common pathogen targeted in microbiological data for both groups. 16% of patients in March 2015 and 13% of patients in March 2016 received their first dose of ceftriaxone in the Emergency Department.

Conclusion: After the implementation of the change in our recommended regimen for CAP, there was a reduction in overall ceftriaxone DOT per 1000 patient days. In addition, there was a decrease in the disease-specific DOT per 1000 patient days for pneumonia and urinary tract infections, the two most common indications observed. This study has demonstrated that electronic medical records may be used as a form of communication to implement therapeutic changes and impact antibiotic utilization rates.

Session-Board Number: 3-312

Poster Title: Ertapenem use before and after the implementation of a Best Practice Advisory (BPA) de-escalation reminder for meropenem

Primary Author: Jennifer Burdock, West Virginia University School of Pharmacy, West Virginia; **Email:** jburdock@mix.wvu.edu

Additional Author (s):
Lisa Keller

Purpose: Our institution recently implemented a Best Practice Advisory (BPA) de-escalation alert for patients receiving 72 hours of broad-spectrum antimicrobials that cover Pseudomonas aeruginosa, including meropenem. This alert prompts providers that enter the electronic medical record to consider de-escalating therapy if Pseudomonas aeruginosa has not been isolated. For meropenem, the alert-recommended de-escalation antibiotic is ertapenem. The primary objective of this study was to determine ertapenem indications for use before and after implementation of the BPA de-escalation reminder. Secondary objectives included comparing ertapenem days of therapy per 1000 patient days and frequency of de-escalation therapy from meropenem to ertapenem.

Methods: This was an Institutional Review Board-approved retrospective chart review of electronic medical records. Patients receiving at least 1 dose of ertapenem between July 2014-December 2014 (pre-BPA implementation) and July 2015-December 2015 (post-BPA implementation) were included and evaluated for the following: age, gender, indication for use, Days of Therapy for ertapenem, length of hospital stay, location of first dose administration, Infectious Diseases consult, and initial ordering service.

Results: The total number of patients meeting inclusion criteria was 414 in the pre-BPA group and 531 in the post-BPA group. The most common indications for ertapenem use in both groups were intra-abdominal infections (pre-BPA 25%, post-BPA 30%), pneumonia (pre-BPA 24%, post-BPA 18%), and surgical prophylaxis (pre-BPA 18%, post-BPA 18%). Ertapenem Days of Therapy per 1000 patient days were 22 in the pre-BPA group and 28 in the post-BPA group. Seventy-four patients (18%) in the pre-BPA group were de-escalated from meropenem and 71 patients (13%) in the post-BPA group were de-escalated from meropenem.

Conclusion: The most common ertapenem indications for use were intra-abdominal infections, pneumonia, and surgical prophylaxis. The rate of overall ertapenem use increased in the post-BPA implementation timeframe, however, the rate of those de-escalated from meropenem therapy decreased.

Poster Title: Readmission Rates Due to Adverse Drug Reactions Associated with Inappropriate Antipsychotic Continuation upon Discharge from the ICU

Primary Author: Sara Mantick, West Virginia University School of Pharmacy, West Virginia; **Email:** smantick@mix.wvu.edu

Additional Author (s):
Jay Martello

Purpose: Continuation of antipsychotics post intensive care unit (ICU) admission could increase the chance of harm and unnecessary adverse drug reactions to patients in whom these medications are not required. Few studies describe outcomes in patients continuing antipsychotics on an outpatient status after discharge from the ICU. The primary objective of this study was to determine whether patients discharged from the ICU on antipsychotic therapy without an identified indication for extended treatment experienced adverse events related to therapy that resulted in hospital readmission.

Methods: This was an Institutional Review Board-approved retrospective chart review of electronic medical records. Patients ≥ 18 were included from 2012 - 2016 if they were admitted to the ICU at anytime during their index admission and received an antipsychotic while in the ICU. Patients who had a documented indication for antipsychotic therapy or who were receiving them prior to admission were excluded. Additional reasons for exclusion included treatment for alcohol or benzodiazepine withdrawal. Data collected for analysis of potential antipsychotic-related readmissions included serum creatinine, electrocardiogram results, and CNS changes from baseline. The primary outcome was 90 readmission rates from the index admission. The secondary outcome was the number of these patients continued on antipsychotic therapy after discharge.

Results: A total of 432 patients were identified by inclusion and exclusion criteria for analysis of the primary outcome. Of these patients, 94 (22%) were identified as having continued antipsychotic therapy as outpatients. A total of 39 patients (9%) were readmitted within 90 days of index admission. Of these, 9 (23%) had potential antipsychotic-related adverse effects reported on admission.

Conclusion: Nearly a quarter of patients who spent time in the ICU and received an antipsychotic during their index hospitalization were continued on antipsychotics after discharge. While a small number of patients had readmissions potentially related to antipsychotic adverse effects (2% of the total population), this studied identified a potential significant medication reconciliation issue that needs to be addressed.

Poster Title: Management of positive tracheal aspirate cultures in neonates at an academic medical center

Primary Author: Emily Stewart, West Virginia University School of Pharmacy, West Virginia; **Email:** estewar5@mix.wvu.edu

Additional Author (s):
Courtney Sweet
Lisa Keller

Purpose: Antibiotics are often overused, which can cause bacterial resistance. One example of this overuse is treatment of positive tracheal aspirate(TA) cultures in neonates. TA cultures are poor indicators of infection because they are not specific or sensitive. This study will show us how positive TAs are being managed in neonates at our institution. The primary objective of this study is to see how often antibiotics are prescribed to neonates with positive TAs. Secondary objectives include evaluation of oxygen requirement for the neonates in the 72-hour period prior to culture, presence of tracheostomy tube, and whether other positive cultures were present.

Methods: This study was an Institutional Review Board-approved retrospective chart review of electronic medical records. Patients admitted to the neonatal unit between January 2012 and December 2015 who had a positive tracheal aspirate culture were evaluated for the following: age, gender, tracheal aspirate culture bacteria, antibiotics, empiric or targeted antibiotic therapy, route and duration of therapy, length of admission, days from admission of patient to when cultures were drawn, number of white blood cells in the culture, oxygen requirement, and what other cultures were drawn on the same day and bacteria. Descriptive statistics were utilized to analyze the collected data.

Results: The total number of patients meeting inclusion criteria was 69 with a total of 180 positive tracheal aspirate cultures. The median gestational age was 27 weeks. The median time to positive tracheal aspirate from admission was 27 days. 53% of all positive cultures received empiric antibiotics; 23% of all positive cultures received targeted antibiotics. The mean duration of treatment with antibiotics was 13 days. Of the positive tracheal aspirate cultures treated

with empiric antibiotics, approximately 14% had other positive cultures present (e.g. – blood, wound). The mean duration of treatment with antibiotics was 13 days. 66% of the patients had a less than 10% change in oxygen requirement from 72 hours prior to culture draw. Only 12% of patients had a greater than 20% change in oxygen requirement. 13% of patients had a tracheostomy tube present at the time of culture.

Conclusion: Over the 3-year study period, over half of the positive tracheal aspirate cultures were treated with empiric antibiotics. The majority of these cultures were isolated positive cultures, with no identified organisms in blood or other areas. Most patients did not have a significant change in their oxygen requirement from 72 hours prior to culture draw and did not have a tracheostomy tube present.

Poster Title: Correlation between documentation of screening for diabetic retinopathy and whether diabetic patients met goal Hemoglobin A1c

Primary Author: Jessica Fiant, West Virginia University School of Pharmacy, West Virginia; **Email:** jfiant@mix.wvu.edu

Additional Author (s):
Jonathan Kline

Purpose: Keeping up with diabetic patients and ensuring they receive recommended screenings for long-term complications, and managing their diabetes is a challenging task. The purpose of this study was to determine if there was a correlation between providers documenting screenings for diabetic retinopathy in their diabetic patients, and if the patients were at goal hemoglobin A1c. The rate of patients receiving diabetes management education at the clinic from an ambulatory care pharmacist that had documentation of screening was also evaluated.

Methods: A registry of all diabetic patients at a family medicine clinic in Harpers Ferry, West Virginia through January 1st, 2015 was identified. The registry included 1213 patients. Exclusion criteria included patients without documentation of ever being seen at the clinic, patients with gestational diabetes, and those with newborn diabetes. A retrospective chart review was conducted to find documentation of screening for diabetic retinopathy. Upon finding documentation, a hemoglobin A1c was recorded that was on or closest to the date of documentation. Other data collected included date of screening, history of diabetes management education at the clinic, method of screening, and prescribing of diabetes medications. The primary outcome was to evaluate a correlation between patients who had documentation of screening, and their diabetes control as defined by hemoglobin A1c less than or equal to 7.0%. The secondary outcomes were the rate of documentation of screening in patients receiving diabetes management education at the clinic, and the screening result, if obtainable.

Results: In the past eight years, 75% of the cohort had documentation of at least one screening. Of these 890 patients, 49.8% were at goal A1c, therefore there was no correlation. Of those with a screening, 70% had screening results documented. In total, 15.6% of these patients had evidence of diabetic retinopathy in varying presentations. . Only 18.2% of the cohort received diabetes management education, however 90.2% of these patients received a screening.

Conclusion: Although there was no correlation between documentation of screening and diabetes control, the results demonstrated the important role of the ambulatory care pharmacist providing diabetes management education in the clinic setting. Improving diabetic retinopathy screening rates in patients can lead to earlier treatment if needed, resulting in better long-term quality of life for diabetic patients.

Poster Title: Evaluating safety of continuous labetalol infusions at a large academic tertiary care hospital

Primary Author: Nicholas Sandoval, West Virginia University School of Pharmacy, West Virginia; **Email:** nsandov1@mix.wvu.edu

Additional Author (s):
Jeffrey Garavaglia

Purpose: Continuous labetalol (Cl) infusions are often used to urgently treat severe hypertension resistant to boluses of intravenous (IV) labetalol or other IV antihypertensive agents. Current FDA approved labeling suggests starting a Cl infusion at 2 milligrams per minute (mg/min), titrated per physician discretion, and continued until adequate blood pressure response is achieved. Few reports exist on the safety of exceeding 300 mg of a Cl infusion during a 24-hour period. The purpose of this study was to assess the safety of current practices at our institution with regards to adhering to the manufacturer's suggested maximum dose of 300 mg.

Methods: The West Virginia University institutional review board approved this retrospective drug-utilization evaluation. Women and men aged 18-90 were included in the study if they received a continuous infusion of IV labetalol for at least 2 hours. Patients concurrently receiving continuous IV infusions of propofol or dexmedetomidine were excluded from the study. A retrospective chart review from June 2014 to June 2016 was completed. The primary outcome measure was to assess the number of patients that exceeded the suggested max dose of 300 mg. Secondary outcome measures included percentage of patients that experienced significant hypotension or bradycardia and treatment of the adverse events. Significant hypotension was defined as a systolic blood pressure of less than 90 and/or a diastolic blood pressure of less than 60 while bradycardia was defined as a heart rate less than 50 beats per minute lasting longer than 2 hours.

Results: A total of 118 patients' charts were reviewed and 48 patients met the inclusion criteria. Sixty patients were excluded from the analysis because they did not meet the 2-hour infusion requirement and another 10 patients were excluded because they were concurrently receiving continuous infusions of IV propofol or dexmedetomidine. More than half (58.3% n = 28) of the patients received greater than the recommended maximum dose of 300 mg. Patients that exceeded the 300 mg dose on average received 913 mg per 24 hours (range of 302 mg to 2100 mg). No patients experienced significant bradycardia. Nearly 20% (n = 9) of patients experienced significant hypotension while on the continuous infusion. Of the patients that experienced significant hypotension, nearly 45% (n = 4) received greater than the recommended dose of 300 mg. All labetalol infusions administered to patients that experienced significant hypotension were discontinued and 33.3% (n = 3) of these patients received bolus infusions of normal saline to treat hypotension.

Conclusion: While continuous intravenous labetalol infusions can be used safely to treat severe hypertension in the acute setting, monitoring of the cumulative administered dose is essential. Education regarding the appropriate use and recommended maximum daily dose of CI infusions at our institution is warranted. Furthermore, adding alerts in the electronic medical record that warn the prescriber of the recommended cumulative dose of 300 mg of the CI infusion may help prevent adverse drug events in the future.

Poster Title: Vitamin K as a reversal agent for warfarin at Jefferson Medical Center

Primary Author: Kyle Sukanick, West Virginia University School of Pharmacy, West Virginia;
Email: ksukanic@mix.wvu.edu

Additional Author (s):
Jonathan Kline

Purpose: Warfarin dosing poses an obstacle for health care practitioners in trying to keep up with patients diet, medications, and changing lifestyle. A change in any one of these factors can alter patients INR and increase their risk of bleeding. The use of Vitamin K can be used to decrease patient's INR, but it poses the risk of altering the stability of Warfarin dosing going forward. The purpose of this study was to evaluate how well Jefferson Medical Center was using Vitamin K as a reversal agent in accordance with the CHEST guidelines.

Methods: This was a retrospective, chart-review analysis of patients who received vitamin K at Jefferson Medical Center in the past two years. Exclusion criteria were newborns receiving a Vitamin K injection. Baseline patient characteristics were collected and included age, gender, weekly warfarin dose, and the three previous INR levels, if applicable. When evaluating the use of Vitamin K, evaluation was based on dose, route, patients current INR, emergent bleeding, and timing of follow up of INR. Data was analyzed using descriptive statistics.

Results: In total, 115 people were included in the study. The average weekly warfarin dose 31.1mg and the average INR that triggered Vitamin K therapy was 8.82. Only 37.4% of people had an active bleed upon administration of warfarin. The average follow up INR time was 25.91 hours. The preferred method of administration was oral; followed by intravenous, intramuscular, and subcutaneous. In total, 60.9% of Vitamin K administration met the correct INR, route, dose, and bleeding status per the CHEST guideline. Factoring in follow-up INR time, the appropriateness drops to 12.3%.

Conclusion: Use of Vitamin K, as a reversal agent, is being over utilized at Jefferson Medical Center. The clinical significance of this impacts the patient's warfarin stability long-term for outpatient doctors and ambulatory care pharmacist trying to stabilize a patient's warfarin dose.

Poster Title: Interpretation of urinalyses at Jefferson Medical Center

Primary Author: Zachary LaDuke, West Virginia University School of Pharmacy, West Virginia;
Email: zladuke@mix.wvu.edu

Additional Author (s):
Jonathan Kline

Purpose: It is widely accepted that the first step in diagnosing a urinary tract infection (UTI) is to order a urinalysis. The urinalyses may not always be interpreted correctly. The purpose of this study was to determine if the urinalyses being ordered in the emergency department at Jefferson Medical Center were being interpreted correctly, based on a predetermined set of criteria.

Methods: Patient data was collected from past emergency department visits over a period of seven days. Patients were included if they received a urinalysis test and were over the age of 18. Patients were excluded if they were pregnant or had recurrent UTI's, defined as three or more UTI's in the last year. Each urinalysis was determined to be "positive" or "negative" based on a predetermined set of criteria. These criteria included UTI-associated symptoms and the amount of leukocyte esterase, nitrites, and white blood cells in the urine. Each patient chart was also examined to see if there was a positive or negative urine culture associated with the urinalysis, and also whether the patient had been treated or not.

Results: Out of 100 patients that were included in the study, it was found that 28 patients were treated for UTI. Eleven (39.3%) of those patients had urinalyses that met our previously stated "positive" criteria. Eighty-six patients had urinalyses that were considered "negative" and 5 (5.8%) produced positive cultures. Of the 14 remaining urinalyses that were considered "positive", 5 (35.7%) produced a positive culture. Out of 19 patients who received a urinalysis without presenting with UTI-associated symptoms, only 3 (15.7%) had positive cultures.

Conclusion: Less than half of the patients who were treated for a UTI were treated based on a "positive" urinalysis as determined by the specific criteria. This clearly shows that we are not following, what has been determined from previous studies to be, good predictors of a positive urinalysis and furthermore an accurate UTI diagnosis. This study can be used to make an argument for setting a predetermined criteria for all urinalyses ordered on patients who present with UTI-associated symptoms.

Submission Category: Oncology

Submission Type: Evaluative Study

Session-Board Number: 3-319

Poster Title: Rate of hospital admissions in patients receiving oral chemotherapy at a large academic medical center

Primary Author: Valerie Elder, West Virginia University School of Pharmacy, West Virginia; **Email:** velder1@mix.wvu.edu

Additional Author (s):
Christina Hoban

Purpose: Chemotherapy administration is a complex process with significant potential for complications and toxicity. Oral chemotherapy agents are becoming increasingly more common, with estimates suggesting that they comprise approximately 25 percent of all new antineoplastic agents in development. The American Society of Clinical Oncology has set forth safety and quality standards, known as the Quality Oncology Practice Initiative, for the assessment, monitoring, and improvement of oncology practice. The objective of this study was to provide a benchmark to evaluate the rates of hospital admissions in ambulatory patients receiving oral chemotherapy and to assess compliance with the Quality Oncology Practice Initiative guidelines.

Methods: The institutional review board approved this retrospective chart review. This study included men and women age 18 and older with a prescription for an oral chemotherapy agent written from January 1, 2014 to December 31, 2014. Patients who began the medication prior to January 1, 2014, were enrolled in a clinical trial, or were being treated for a non-oncology diagnosis were excluded. Descriptive statistics were used to analyze the data collected during the chart review. The primary outcome measure was to evaluate the rate of hospital admissions in these patients within 30, 60, and 90 days of initiating an oral chemotherapy agent. Secondary outcome measures included rate of documentation of dose, schedule, a lab and toxicity monitoring plan, a follow up plan, and medication education during the visit the prescription was written as well as the rate of documentation of prescription start date, symptom and toxicity assessment, and medication adherence at the following visit.

Results: One hundred and eighty-nine men and women age 18 and older with a prescription for an oral chemotherapy agent written in 2014 were enrolled in the study. The admission rates 30, 60, and 90 days after initiating oral chemotherapy were 28/189 (15 percent), 30/189 (16 percent) and 11/189 (6 percent), respectively. A higher percentage of patients were admitted within the first two months of therapy than in the third month. On the day of the initial prescription, 72 percent of the patients had documentation of dose, 65 percent had documentation of schedule, 53 percent had documentation of a lab and toxicity monitoring plan, 79 percent had documentation of a follow-up plan, and 54 percent had documentation of medication education. During the follow up visit, 66 percent of patients had documentation of the prescription start date, 79 percent had documentation of symptom and toxicity assessment, and 16 percent had documentation of assessment of medication adherence. Goal of treatment was documented 19 percent of the time.

Conclusion: Without any formal intervention, the rates of hospital admission in patients receiving oral chemotherapy ranged from 6 to 16 percent within the first 90 days of treatment. Many of the secondary endpoints require improvement to meet current guidelines. These results indicate the need for formal monitoring practices to enhance patient outcomes and safety and that these interventions may be most important within the first two months of oral chemotherapy use. While oral chemotherapy treatment was not evaluated as the cause for admission, it can be hypothesized that advancement in monitoring and documentation practices will reduce hospital admissions in these patients.

Poster Title: Retrospective analysis of dexamethasone utilization and outcomes in preterm infants experiencing moderate or severe respiratory distress syndrome

Additional Author (s):
Courtney Sweet

Purpose: Respiratory distress syndrome (RDS) is a precursor of bronchopulmonary dysplasia (BPD), a disease consisting of pulmonary fibrosis, inflammation, edema, and destruction of alveoli. Controversy surrounds the use of dexamethasone to treat RDS and/or prevent BPD, as this practice has been associated with adverse neurodevelopmental outcomes. Therefore, the purpose of this study is to retrospectively assess the usage and short- and long-term effects of dexamethasone therapy in preterm infants experiencing moderate or severe RDS in order to better understand the utilization and outcomes at a large academic medical center.

Methods: This retrospective, observational study was approved by the institutional review board. Subjects included were patients in the neonatal intensive care unit who received at least one dose of dexamethasone for the treatment of moderate or severe respiratory distress syndrome at WVU Medicine between 2009 and 2015. Patients were excluded if dexamethasone was administered at 0.25 mg/kg once or for three doses for facilitation of extubation. A total of thirty patients were included in the study. Collected demographic data includes gestational age at birth, birth weight, sex, BPD diagnosis, history of surfactant and prenatal steroid use, and maternal diagnoses. Data collected regarding dexamethasone therapy includes age at initiation, initial dosing, average daily doses, number of titrations, average days per titration, total exposures, and overall duration of therapy. Courses of therapy will be considered separate if ten or more days elapse between doses of dexamethasone. To determine the outcomes of therapy, collected data will include details of ventilation, growth velocity, and neurodevelopmental delay. Descriptive statistics will be used to analyze the data.

Results: Thirty patients met inclusion criteria. Two-thirds of patients were males, and 90 percent of patients had severe BPD. Mean gestational age at birth and birth weight were 26 2/3 weeks and 0.88 kg. A mean of 2.54 surfactant doses were received. Dexamethasone was initiated at a mean postnatal age of 6 1/7 weeks and a median dose of 0.2 mg/kg/day for a median duration of 10 days. Eleven patients received a second course of therapy. For the first course, 19 patients (63.3 percent) were supported with high frequency oscillatory ventilation (HFOV) on initiation day and 3 (10 percent) and 2 (6.9 percent) patients were on HFOV on the last day of therapy and one-week post-dexamethasone, respectively. Growth velocity (GV) was 13.3 g/kg/day the week prior to initial treatment but fell to 0.89 g/kg/day during treatment. The week following therapy, GV was 14.3 g/kg/day. Thirteen patients (43.3 percent) were confirmed to have neurodevelopmental delay at a mean age of 19.8 months. Six patients were without delays, while the developmental status of 11 patients was undetermined.

Conclusion: Dexamethasone effectively aids in weaning infants with RDS from HFOV to other forms of ventilation while only temporarily restricting growth velocity. However, the possibility of long-term neurodevelopmental delays warrants careful utilization of dexamethasone in this population. Overall, more research is necessary to determine whether dexamethasone may also assist in further stepdown ventilation support and to assess the details of long-term deleterious outcomes.

Poster Title: Comparative analysis of students' and clinicians' evaluations of interprofessional collaborative practice simulations

Primary Author: Brynn Johnson, West Virginia University School of Pharmacy, West Virginia; **Email:** bjohnso6@mix.wvu.edu

Additional Author (s):
Catessa Howard
Racheal Sween
Jon Wietholter
Aletha Rowlands

Purpose: Interprofessional education (IPE) plays an important role in training health professionals in both the classroom and clinical practice. Students frequently participate in interprofessional education scenarios including standardized-patient simulations. Through curriculum-based interprofessional education, faculty and practicing clinicians are continually assessing students. Although frequently assessed, students often do not have the opportunity to assess interprofessional education and interprofessional collaborative practice (IPCP). Furthermore, clinicians and students rarely discuss their perceptions of interprofessional collaborative practice with one another. The purpose of this study was to analyze the difference between students' assessments of interprofessional collaborative practice versus practicing clinicians' assessments of interprofessional collaborative practice.

Methods: The institutional review board approved this investigative study. Sixty-two nurses employed by West Virginia University (WVU) Medicine were enrolled in an interprofessional education program consisting of a standardized patient simulation sponsored by a Health Resources and Services Administration (HRSA Grant NO: UD7HP28543) through the WVU School of Nursing. Following preliminary nursing assessment, a physician and a pharmacist joined to provide patient care. The simulations were recorded and later reviewed by the research team. Three students (two pharmacy and one nurse practitioner) and three clinicians (one pharmacist, one physician, and one nurse) were assigned to evaluate the simulation videos with each video being reviewed by three individuals, including at least one clinician and one student. The encounter was evaluated using a modified version of the Interprofessional

Socialization and Valuing Scale (ISVS) with 24 selected questions assessing partnership, cooperation, coordination, and shared-decision making. Each question was scored as "Never," "Rarely," "Occasionally," "Most of the time," or "Always." For comparative purposes, answers were converted to a numerical value between 1 and 5 (Never = 1, Always = 5). Student evaluations were compared to clinician evaluations for the videos as a whole, for each individual video, and for each individual question.

Results: Student evaluations were compared to clinician evaluations and differences greater than 10% were considered significant and less likely due to chance. The average overall score for all videos was 3.64 for clinicians and 3.57 for students, which did not exceed the pre-defined threshold of 10%. However, a difference greater than 10% between student and clinician evaluations was observed for 21/37 videos. Student ratings were lower than clinician ratings in 13 videos and clinicians' ratings were lower in 8 videos. When comparing the average score for each individual question a difference greater than 10% was observed for 8 questions. Student ratings were lower than clinician for 6 questions and clinician ratings were lower than students' for 2 questions. The largest difference between clinician and student evaluations was observed for the question "Team members considered alternative approaches to achieve shared goals," with an average clinician score of 3.59 and an average student score of 2.47.

Conclusion: Overall, evaluations of the videos were consistently different between clinicians and students, with the majority of student ratings being lower than clinicians'. The difference observed in clinicians' and students' evaluation of interprofessional collaborative practice may be due to students receiving a substantial amount of curriculum-based interprofessional education and having a thorough understanding of how it should work when done effectively. It is possible upcoming practitioners place a higher priority on interprofessional collaborative practice when caring for patients, making them more likely to assign lower ratings when using standardized scales to evaluate others completing an interprofessional collaborative practice experience.

Poster Title: Assessment of prophylactic antibiotics for surgical site infections in elective colorectal surgeries after adoption of hospital-wide surgical site infection prevention bundle

Primary Author: Yasmine Zeid, West Virginia University School of Pharmacy, West Virginia;
Email: yazeid@mix.wvu.edu

Additional Author (s):
Shelley Porter

Purpose: Post-operative surgical site infections are a common problem associated with elective colorectal surgeries. Guidelines recommend redosing prophylactic antibiotics if surgery exceeds two half-lives of the drug. Antibiotics were not being redosed at our facility during these surgeries, and a rise in surgical site infections was observed. A new antibiotic bundle consisting of ceftriaxone and metronidazole was adopted to minimize the incidence of infections since these antibiotics do not require redosing. The purpose of this study was to determine the rate of surgical site infections and the appropriateness of antibiotics administered for elective colorectal surgeries after adoption of this bundle.

Methods: The institutional review board approved this single-center, retrospective chart review of elective colorectal surgeries. Men and women were enrolled if they were 21 years or older and undergoing elective colorectal surgery. Patients undergoing emergent surgery and those who were pregnant were excluded. A surgical site infection prevention antibiotic bundle consisting of ceftriaxone 2 g and metronidazole 500 mg was adopted on March 2, 2016. Data was collected between March 3, 2016 and August 31, 2016. Antibiotics administered pre-operatively were assessed for appropriate selection, dose, and timing based on our facility's antibiogram and guideline recommendations. Pre-operative antibiotics also were assessed to determine if the newly adopted antibiotic bundle was used. Data was collected to determine the incidence of post-operative surgical site infections, causative organisms of infection, length of stay, 30-day readmission, and demographic information. The primary endpoints of this study were the rate of post-operative surgical site infections and the appropriateness of pre-operative antibiotic regimens.

Results: Fifty-five patients were identified as having undergone a colorectal procedure, and 9 were excluded for undergoing emergent surgery or for being younger than 21 years of age. The incidence of surgical site infections after adoption of the ceftriaxone and metronidazole bundle was 8.7 percent versus 22.6 percent before adoption of the bundle. The frequency of the ceftriaxone and metronidazole bundle being used was 78.3 percent. The incidence of no antibiotics being documented or antibiotics other than a combination of ceftriaxone and metronidazole being used was 21.7 percent. Of those patients with a surgical site infection, only 25 percent were identified as having received appropriate pre-operative antibiotics. Prior to the adoption of the antibiotic bundle, between January 1, 2014 and July 31, 2015, 16.5 percent of patients received appropriate pre-operative antibiotics. After adoption of the bundle, between March 2, 2016 and August 31, 2016, 93.4 percent of patients received appropriate pre-operative antibiotics.

Conclusion: Adoption of the ceftriaxone and metronidazole bundle eliminated the need for redosing during elective colorectal surgeries. Adoption of the bundle also appeared to reduce the incidence of surgical site infections secondary to elective colorectal surgery. Compliance with the appropriate selection of pre-operative antibiotics was improved. More long-term data collection is needed to determine whether or not adoption of the ceftriaxone and metronidazole bundle is sustainable and can maintain a reduction in post-operative surgical site infections.

Poster Title: Evaluation of the centralized production of intracameral moxifloxacin for cataract surgery and its impact on cost reduction

Primary Author: Alexander Radish, Concordia University Wisconsin, Wisconsin; **Email:** alexander.radish@cuw.edu

Additional Author (s):
Chad Smith
Ann Parks
Anne LaDisa

Purpose: There is extensive evidence-based literature supporting the use of intracameral (IC) moxifloxacin as a new method for preventing postoperative endopthalmitis after cataract surgery. The Aurora Pharmacy Packaging Center (APPC) has started a new process for aseptically drawing up IC moxifloxacin for three ophthalmic surgeons. The purpose of this study was to evaluate APPC's centralized IC moxifloxacin production for quality assurance and quantify reduction in costs.

Methods: APPC's compounding procedure of IC moxifloxacin was evaluated using United States Pharmacopeia (USP) Convention 797 guidelines and compared with evidence based literature. Patients who received IC moxifloxacin intraoperatively from one of three ophthalmologists during cataract surgery performed during the first 7 months of APPC IC moxifloxacin production were identified using electronic health records. After patients were identified, cost savings were calculated by reviewing costs associated with drug and production supplies used by APPC.

Results: APPC's current process was validated as compliant with USP 797's sterile compounding guidelines, including specific guidelines for ophthalmic medications. USP 797 validation criteria included proper sterile technique, equipment, room sterility and pressure, beyond use dating, and storage. Before APPC's current process of preparing IC moxifloxacin, 1 vial of moxifloxacin was used per surgery and cost 140 dollars. Since implementing centralized production of moxifloxacin, 1 vial of moxifloxacin produced 9 IC injections and reduced cost to 20 dollars per surgery. The cost savings to the organization was 120 dollars per case. There were 459 cataract

surgeries among the 3 ophthalmologists during the study time resulting in a savings of over 55,000 dollars and a projected annual savings of over 100,000 dollars due to the new centralized production of IC moxifloxacin.

Conclusion: APPCs compounding procedure was found to be compliant with industry quality standards with significant cost savings. This study may impact hospital administrators to consider use of centralized moxifloxacin production to provide quality care at a reduced cost.

Poster Title: Pharmacist Initiated Culture Follow-up in the Emergency Department Reduces Time to Treatment Optimization

Primary Author: Elizabeth Pegelow, Concordia University Wisconsin, Wisconsin; **Email:** elizabeth.pegelow@cuw.edu

Additional Author (s):
Jessica Cowell
Ryan Feldman
Matthew Stanton
Cathyyen Dang

Purpose: Urinary tract infections (UTI) and sexually transmitted infections (STI) are frequently encountered medical conditions in the emergency department (ED). Antimicrobial therapy prescribed for treatment is empiric due to the delay between obtaining a culture and growth of an organism to direct definitive therapy. A culture review and call-back process is paramount to ensuring appropriate therapy and preventing complications of inadequately treated infections for patients not requiring hospital admission. This project investigates if pharmacist driven culture follow-up in the ED results in a reduction in time from final culture results to patient contact, when compared to the previous nurse driven process.

Methods: This retrospective pre- and post-intervention analysis occurred in a 40 bed ED that has 70,000 annual visits and is part of a 550 bed academic medical center. All patients with cultures drawn in the ED for UTI or STI in whom a change in therapy was indicated after final cultures resulted were included. Pre-intervention, all cultures were reviewed by the third-shift charge nurse and forwarded to the designated advanced practice provider (APP). Pharmacist involvement was obtained at the discretion of the APP. Post-intervention, all cultures were first reviewed by an ED pharmacist who then forwarded results as well as treatment recommendations to the designated APP. Data was collected via electronic health record (EHR) from September 15, 2015 to February 15, 2016 for the pre-pharmacist intervention group and April 1, 2016 to September 30, 2016 for the post-intervention group. A short workflow adjustment period was allowed between data sets. The primary outcome measured was time from final culture result to patient contact by the APP documented in the EHR. Secondary

outcomes included prevalence of treatment failure defined as patient return to the ED within 72 hours for the same medical problem, 30 day admission for related conditions (UTI, pyelonephritis, urosepsis), and percentage of accepted pharmacist recommendations. Statistical analysis was completed with Mann-Whitney U test.

Results: A total of 240 patients were included; 143 patients were in the pre-intervention group and 97 patients were in the post-intervention group. There were 103 patients in the pre-UTI group, 79 patients in the post-UTI group, 40 patients in the pre-STI group, and 18 patients in the post-STI group. In the overall study population, patient ages ranged from 18 to 98 years old, 80% female, 12.5% pregnant, 13.75% catheter related infections. In the post-intervention group, patients were contacted a median of 19.83 hours earlier than in the pre-intervention group (CI 95%, 17.15-22.5; p < 0.001). Post-intervention, median contact time for patients with a UTI was 15.06 hours earlier (CI 95%, 8.35-19.03; p < 0.001) and the median contact time for patients with an STI was 47.31 hours earlier (CI 95%, 29.1-67.41; p < 0.001) than the pre-intervention group. Post-intervention, fewer patients returned to the ED within 72hrs for the same medical problem (1 post- vs. 7 pre-), fewer patients were admitted for related conditions within 30days (3 post- vs. 6 pre-), and more recommendations were appropriately documented (87.4% post- vs. 60.9% pre-).

Conclusion: Pharmacist initiated culture review in the ED culture-call back process reduces time from final culture results to initiation of optimal antibiotic treatment. This intervention holds promise for reducing subsequent ED visits, hospitalizations, unnecessary healthcare utilization, and healthcare costs. Routine pharmacist involvement in the culture review process appears to have great value.

Poster Title: Pharmacist led medication history pilot in a pediatric hospital: Evaluation of barriers

Primary Author: Kayla Phillips, Concordia University Wisconsin - School of Pharmacy, Wisconsin; **Email:** kayla.phillips@cuw.edu

Additional Author (s):
Julie Teske
Sheila Frieder
Steven Linden
Susan Wheeler

Purpose: Improvement in medication reconciliation has been on the forefront of changes in hospital practice in recent years. With nurses and other staff demonstrating varying practices for medication reconciliation, it is important to standardize a process to ensure best patient care. Studies have shown when an accurate medication history is obtained the potential for medication errors during the admission and post discharge subsequently decreases. Pharmacist involvement in medication history processes could potentially reduce medication related errors. This project was designed to create a process and identify barriers which prevent pharmacists from obtaining medication histories in a high risk patient population: pediatrics.

Methods: A goal of the pharmacy team at HSHS St. Vincent Children's Hospital has been to increase pharmacist involvement in patient care to prevent medication errors. Pharmacist led medication reconciliation has been identified as one area of opportunity to accomplish this goal. A pharmacy student in collaboration with the hospital pediatric service, clinical colleagues, and pharmacy staff created a protocol for pharmacy involvement in obtaining medication histories within the newly designated children's hospital. The protocol includes a process of how to contact the pharmacy for a medication history, specifically outlines the information that should be obtained during each encounter, and designates where to document the information. Corrections based on the patient and family interview were made to the medication list in the electronic medical record. All pharmacist interventions were also tracked on a data sheet. Within a six week period, a limited number of medication histories were completed by pharmacy. Limitations to obtaining medication histories were identified and

process improvements were made throughout the trial in an attempt to overcome barriers encountered.

Results: A total of twelve medication histories were obtained during the six week period. The pharmacy student was not contacted for any histories within the first two weeks of the pilot. Due to inadequate referrals from the nursing staff the process was re-evaluated, barriers were assessed, and changes to the process were made. Opportunities identified included the pharmacy student attending morning huddles on the pediatric floor, reminding nursing daily to contact the pharmacy with any new admissions, and monitoring for new admissions throughout the day. With the changes made, nine medication histories were obtained during the following two weeks. Lastly, within the last two weeks of the pilot only three medication histories were obtained. Barriers were again reassessed with pharmacy and nursing staff to identify changes that would need to be made in order to expand and sustain this pharmacy service within the children's hospital. As a team we identified that the biggest hurdles for pharmacy completion of admission histories are due to the nursing workflow and availability of pharmacy staff at the time of admissions.

Conclusion: Medication reconciliation completed by pharmacy staff has proven to be best practice. Continuing barriers preventing implementation are lack of pharmacy notification when there is an admission and having inadequate staff available to complete the histories. Solutions to these barriers include: improvements in nursing workflow during admission, automatic consult to pharmacy when admissions occur, and having trained pharmacy staff available during all shifts. These improvements may aid in a higher success rate of obtaining medication histories and reaching the pharmacy's goal to prevent medication errors.

Poster Title: A national survey evaluating pharmacist completion of daily bedside patient evaluations.

Primary Author: Karina Sundar, Concordia University Wisconsin - School of Pharmacy, Wisconsin; **Email:** karina.sundar@cuw.edu

Additional Author (s):
Kayla Phillips
Ann Biesboer

Purpose: The level of pharmacist participation in direct patient interaction is often dependent on the institute of practice. With advancement of the profession, pharmacists have become more involved in medical teams and direct patient care. Previous studies have shown that by increasing pharmacist participation in multidisciplinary rounds, preventable adverse drug events were decreased by as much as 78 percent. However, no data is available discussing the impact of the pharmacist seeing and communicating with patients daily in the inpatient setting. The purpose of this study was to determine pharmacists' current practice and viewpoints regarding pharmacists performing daily bedside patient evaluations.

Methods: An electronic survey was distributed to the American College of Clinical Pharmacy's (ACCP) critical care Practice and Research Network (PRN) list serve, a national database of self-identified critical care practitioners. The survey evaluated pharmacist demographics, completion of daily bedside patient evaluations (DBPEs), factors influencing and prohibiting DBPEs, and overall pharmacist opinion of the value of DBPEs. We defined DBPEs as physically entering each patient's room to observe and/or communicate with the patient in order to better understand how the patient is responding to therapy.

Results: A total of 122 pharmacists responded to the survey. Of these responses, the majority of pharmacists, 69 percent, indicated that most of their time was spent in a critical care unit. 85 percent of respondents participated in daily rounds as a part of their current practice and 89 percent of the respondents completed DBPEs on at least one patient on a daily basis. According to 68 percent of respondents, the main factor that influenced completion of DBPEs by pharmacists was having the principle being instilled early in their career. The primary factors

that influenced pharmacists not to complete DBPEs were time constraints and patient load, 84 percent and 68 percent, respectively. The majority of DBPEs, 84 percent, were completed during patient care rounds with an interdisciplinary team. 65 percent of pharmacists stated that they either agree or strongly agree with the statement that DBPEs are an important part of inpatient pharmacy practice for high acuity or critical care patients.

Conclusion: The survey data obtained from the ACCP critical care PRN list serve demonstrated that the majority of critical care pharmacists believe that the completion of DBPEs by inpatient pharmacists is an important part of practice. However, it is not always plausible due to common barriers to pharmacy practice such as time limitations and the number of patients that they are overseeing. By instilling this critical aspect of pharmacy practice early in a young pharmacist's career, critical care pharmacists may find ways to prioritize DBPEs above other less important aspects of practice.

Poster Title: Using various extemporaneous pharmaceutical compounding procedures, equipment and quality assurance techniques to enhance CUW SOP student knowledge of emulsions as a pharmaceutical dosage form

Primary Author: Christine Johnson, Concordia University Wisconsin School of Pharmacy, Wisconsin; **Email:** christine.johnson@cuw.edu

Additional Author (s):
Nancy Stoehr

Purpose: Pharmacists are the only profession trained in extemporaneous compounding of pharmaceutical products. Without compounding pharmacists, patients who need specialty medications would not be able to receive proper treatment. The required curriculum of the Concordia University Wisconsin School of Pharmacy (CUW SOP) program provides first year pharmacy students the opportunity for exposure to and practice with non-sterile extemporaneous pharmaceutical compounding. One week during the semester, the students practice compounding an emulsion dosage form. As this is an inherently unstable preparation, stability awareness and quality assurance is of particular concern.

Methods: Objective: To demonstrate the degree to which first year CUW SOP students enhance their knowledge and appreciation for the emulsion dosage form with regard to stability and equipment utilized.
Methods: First year CUW SOP students compared four different types of emulsions: a manufactured emulsion, an emulsion compounded with mortar and pestle, an emulsion compounded with a handheld homogenizer, and an improperly compounded emulsion. Prior to an emulsion compounding lab, the students completed a survey demonstrating their knowledge of the various emulsion compounding techniques and concepts. The students also described and drew anticipated results of microscopic evaluation of these four emulsions. The survey and drawings of microscopic evaluations of the emulsions were repeated after the emulsion compounding experience. During the emulsion compounding lab, each student prepared an emulsion using a mortar and pestle. Students worked as a team to also prepare an emulsion using a handheld homogenizer. Emulsions were visualized under a microscope for differences and signs of instability.

Results: Results were gathered and analyzed using the answers the students record in their pre- and post-lab surveys, as well as their drawing of anticipated and resulted microscopic images. The results were similar to our expected results. Those results were that students will know that the technique involving the handheld homogenizer will prepare a more stable product however; the degree to which it forms a stable product was underestimated prior to lab. After lab they had an advanced appreciation for the equipment utilized as well as the instability and delicacy of preparation of the emulsion dosage form. The globules of the emulsion prepared with a handheld homogenizer were much smaller than the globules in the emulsions prepared with a mortar and pestle as visualized under the microscope.

Conclusion: After completion of this lab the students demonstrated advanced knowledge in compounding extemporaneous emulsion pharmaceutical dosage forms. Prior to lab the students expected the handheld homogenizer to make a more stable emulsion. However, after comparing the responses from the post-lab knowledge assessment to the pre-lab one, it was apparent that they left the lab with a deeper comprehension about extemporaneously compounded emulsions than before lab. Without the knowledge students gain in this course they would not be able to appropriately serve patients requiring compounded emulsion dosage forms. This confirms how important non-sterile compounding courses are to pharmacy school curriculums.

Poster Title: I AM FULL: A mnemonic for pharmacists to ensure optimal monitoring and safety of Total Parenteral Nutrition

Primary Author: Christopher Bohl, Concordia University Wisconsin School of Pharmacy, Wisconsin; **Email:** chris.bohl@cuw.edu

Additional Author (s):
Ann Parks

Purpose: Total parenteral nutrition (TPN) involves the intravenous delivery of nutrients to patients who cannot tolerate food enterally. Due to the inherent complexity and limited use of TPN, the monitoring parameters for these patients can be cumbersome for pharmacists to properly implement, resulting in possible safety issues. Checklists have been recommended to improve the safety and efficacy of complicated healthcare interventions. In this study, a guideline-derived mnemonic was developed and implemented to systematically and safely manage TPN therapy. Pharmacist feedback was gathered to investigate the safety and efficiency of TPN monitoring via the use of this novel mnemonic.

Methods: The institutional review board approved this survey-based study, which used the mnemonic, I AM FULL, to standardize TPN monitoring. This tool was developed through the review of guidelines and peer-reviewed journal articles. The mnemonic combines seven essential components of TPN use and monitoring: Indications, Allergies, Macro/Micro nutrients, Fluid, Underlying comorbidities, Labs, and Line type. Pharmacists are encouraged to use the mnemonic for initiation and daily monitoring of TPN. The mnemonic was piloted via a group of 46 pharmacists from Aurora St. Luke's Milwaukee, WI. Prior to implementation of the mnemonic, pharmacists were educated on how to use the tool at a department meeting, during which a PowerPoint was presented and pocket reference cards were distributed. The effectiveness of this mnemonic was assessed through pre- and post-implementation surveys. The pre-implementation survey, consisting of six questions, was distributed as a paper copy at the time of training. The post-implementation survey, consisting of seven questions, was completed via surveymonkey two weeks after the mnemonic education. Descriptive analysis was conducted to measure the quality of the mnemonic, ease of use, time for monitoring, and confidence in safety and efficacy.

Results: Forty-six pre-implementation and nineteen post-implementation surveys were returned and analyzed. The pre-implementation survey demonstrated 26% percent of pharmacists monitor TPN daily, 50% weekly to monthly, and 24% greater than monthly. Additionally, 98% of responders felt a mnemonic would improve safety and efficacy of TPN monitoring. The post-implementation survey showed 100% of pharmacists felt that the mnemonic provided a methodical process to monitor TPN, and 94% of pharmacists were satisfied or very satisfied with the mnemonic. With 1-10 minutes considered the ideal time frame for efficient TPN monitoring, the pre-implementation survey showed 80% of responders taking between 1-10 minutes to monitor a TPN. In contrast, the post-implementation showed an improvement in the percentage of pharmacists achieving this ideal, with 94% of surveyed pharmacists taking between 1-10 minutes for TPN monitoring. Furthermore, comparison of the pre- and post-implementation surveys revealed a marked increase in the percentage of pharmacists confident in their ability to safely monitor the use of TPN. The pre-implementation survey showed that 59% of pharmacists were confident or very confident in the safety and efficacy their own monitoring process. However, following implementation of the mnemonic I AM FULL, 88% of pharmacists were confident or very confident in the monitoring process.

Conclusion: TPN is a high alert medication requiring special attention by pharmacists. A mnemonic providing a systematic monitoring process may increase pharmacist's confidence in TPN monitoring and improve safety and efficacy of TPN use. Evaluation of pre- and post-implementation surveys revealed a desire for a systematic TPN monitoring tool, as well as a positive perception of the mnemonic I AM FULL. The majority of pharmacists felt the mnemonic improved their confidence and safety in monitoring TPN, and the average time for monitoring was slightly decreased following implementation of the mnemonic. The survey was limited by the low number of post-implementation responders.

Poster Title: Iron sucrose administration and risk of hypersensitivity in an outpatient setting

Primary Author: Amanda Baumann, Concordia University Wisconsin School of Pharmacy, Wisconsin; **Email:** amanda.baumann@cuw.edu

Additional Author (s):
Shannon Werner

Purpose: Intravenous (IV) iron sucrose is used for the treatment of iron deficiency anemia (IDA) from many causes. Compared to first generation IV iron preparations, iron sucrose has a lower incidence of hypersensitivity reaction. Labeling recommends iron sucrose doses less than or equal to 200 mg be administered IV by slow injection or infusion. This medication use evaluation was completed to describe the incidence of iron sucrose-associated hypersensitivity and adverse drug reactions (ADRs) following implementation of an outpatient administration guideline recommending IV injection for administration of iron sucrose doses less than or equal to 200 mg.

Methods: This retrospective chart review included outpatients from two hospital-based infusion clinics (oncology and non-oncology) who received a dose of iron sucrose 200 mg between August 1, 2013 and April 30, 2014 and August 1, 2015 and April 30, 2016. The different time periods were selected to account for modifications made to the outpatient administration guidelines in April 2014 that recommended IV injection for administration of iron sucrose doses less than or equal to 200 mg. Patients with any indication for iron sucrose were included. The following data points were collected for each patient: demographic information, indication for iron sucrose, number of iron sucrose doses and type of administration (IV injection or infusion), past allergy or intolerance to any IV iron product, baseline hemoglobin and iron indices, and details regarding any hypersensitivity or ADR (type, timing, intervention, outcome). Hypersensitivity was defined as any undesirable immune response (Immunoglobulin E (IgE) mediated or non-IgE mediated) resulting from free iron in circulation. Signs or symptoms included dizziness, hypotension, nausea, vomiting, and diarrhea. An ADR was defined as phlebitis, gastrointestinal (GI)/nausea/diarrhea, lethargy, dizziness, and other ADRs. The primary descriptive outcome was difference in hypersensitivity or ADR when iron sucrose 200 mg was administered as an IV injection or infusion.

Results: Of the 148 pre- and 87 post-guideline modification patients who received iron sucrose 200 mg, a random sampling of 26 patients was evaluated from each time period. There were no apparent differences in baseline characteristics between groups, with the exception of ferritin level. The most common indication for iron sucrose was IDA due to chronic blood loss. Of the total 226 doses of iron sucrose, there were no hypersensitivity reactions. ADRs were noted in 3.5 percent of IV injection and 3.1 percent of infusion administrations. After a total of 105 doses of iron sucrose in the pre-guideline modification group and 121 doses in the post-guideline modification group, nine and six ADRs, respectively, were documented. The most common ADRs were GI/nausea/diarrhea, dizziness, and other ADRs (headache and myalgia/arthralgia). There were no drug-related deaths, serious adverse events, or ADR-related discontinuation of therapy. Sixty percent of reactions, in both pre- and post-guideline modification groups, were delayed reactions. Onset of reaction occurred after the second infusion and after the first infusion in the pre- and post-guideline modification group, respectively.

Conclusion: In the present population, administration of iron sucrose 200 mg as IV injection is safe, resulting in no incidents of hypersensitivity and demonstrating a similar rate of ADR when compared to infusion. IV injection administration is a convenient option in the outpatient setting and may increase patient satisfaction, increase nurse efficiency and optimize chair time.

Poster Title: Comparison of doctorate of pharmacy dual degrees and pharmacy residencies utilizing economic data

Primary Author: Michael Cottonaro, Concordia University Wisconsin School of Pharmacy, Wisconsin; **Email:** michael.cottonaro@cuw.edu

Additional Author (s):
Christian Albano
Dean Arneson
Robert Burlage

Purpose: Creating ways to become more competitive without increasing financial burden is a synergistic goal between the pharmacy profession and students. Two ways in which students may achieve this goal are pharmacy residencies and dual or joint degrees. Opportunity costs of completing a post graduate year one (PGY1) pharmacy residency were compared to the direct costs of different dual/joint degrees, including Masters of Business Administration (MBA), Public Health (MPH), and various Sciences (MS) with a doctorate of pharmacy. The results of this research will be useful in guiding the profession and pharmacy students in their continuing education.

Methods: Approval from the Institutional Review Board was not necessary prior to completing this research due to primary data being obtained through open source databases. Data was obtained from pertinent nation databases such as ASPH, AACP, and other organizations as well as from an extensive online review involving pharmacy, pharmacy residencies, and Master's Degree programs throughout the United States. Dual/joint degree programs included any Doctorate of Pharmacy combined with a Masters program with any credit overlap between programs that was acknowledged via American Association of Colleges of Pharmacy (AACP) "Dual-Degree Programs Anticipated for 2015-2016." Pharmacy residency programs included PGY1 programs with information available from the American Society of Health-System Pharmacists (ASHP). Arkansas, California, South Carolina, and Wisconsin have been evaluated because they provide an adequate sample size, minimize regional difference, and include a range of average pharmacists' salaries. Our economic model compared dual/joint degrees to residencies via a calculation of mean hours per week at mean pharmacist salary, plus total extra

tuition, needed to match mean residency salary. California and Citidel of South Carolina are the exceptions to this model due to both degrees being awarded simultaneously.

Results: While completing a dual/joint degree, 17-23 hours per week at average pharmacist salary is what would be required in order to match a PGY1 residency salary in all circumstances but California and Citadel. More specifically, in Arkansas, 17-23 hours per week is required. In South Carolina, 18-23 hours per week is required, not including Citadel. In Wisconsin, 18-23 hours per week is required. These values all take tuition and duration of the respective dual/joint degree programs into account. California could not be included in this calculation because all programs require both degrees to be rewarded simultaneously which forces the student to postpone working as a pharmacist. Duration of doctorate of pharmacy dual degrees in California also range from no extra time to one extra year required. This forces a direct comparison of financial costs between PGY1 residencies and dual/joint degrees. This cost ranged from $54,375 less cost to $129,805 more cost when choosing a dual/joint degree over a PGY1 residency. This situation is also seen with regards to Citadel as their program requires no additional time than the doctorate in pharmacy which leads to the dual degree program being $43,004-$29,468 less costly than a PGY1 residency.

Conclusion: Dual/joint degree and residency programs both vary, but the immediate costs of each are very similar. With regards to the 10 dual/joint degree programs that the "hours per week" could not be calculated, half of the programs had less costs than the residencies in the respective state. With regards to the 5 dual/joint degrees that the "hours per week" could be calculated, they ranged from 17-23 "hours per week." This amount of time commitment is very reasonable for a student. Lastly, there are many factors to consider when choosing post doctorate of pharmacy opportunities in order to become more competitive.

Poster Title: Evaluation of patients receiving lung transplant with additional dose of basiliximab post-operatively due to excessive blood loss

Primary Author: Robert Wolf, Concordia University Wisconsin School of Pharmacy, Wisconsin; **Email:** robert.wolf@cuw.edu

Additional Author (s):
William Peppard
Danielle Mabrey
Jared Longlais
Elizabeth Pegelow

Purpose: Successful lung transplantation is dependent upon adequate immunosuppression. Currently, most lung transplants use immunosuppressing induction agents, including polyclonal antibodies or interleukin-2 receptor antagonists. Basiliximab is a monoclonal antibody that antagonizes interleukin-2 receptors on T-lymphocytes. Surgeons at our institution are concerned that patients may not be maintaining optimal immunosuppression due to loss of basiliximab secondary to perioperative blood loss. As such, patients have received an additional dose of basiliximab to account for drug loss based largely on surgeon discretion. The primary goal of this study is to determine patient characteristics and outcomes associated with higher dosing of basiliximab.

Methods: Froedtert Hospital is a 550 bed academic medical center and level one trauma center located in Milwaukee, Wisconsin; completing approximately 15 lung transplants per year. A retrospective analysis of patients admitted to Froedtert Hospital who had a lung transplant from June 2015 through July 2016 was completed. Inclusion criteria included adult lung transplant recipients admitted to Froedtert Hospital who had basiliximab administered for induction immunosuppressive therapy. Patients less than 18 years of age, receiving a re-transplant or multi-organ transplant were excluded. Patients were classified into two groups: traditional dosing of basiliximab (defined as 20mg intravenously (IV) on the day of transplantation and a single dose of 20mg IV on post-operative day four) and higher dosing of basiliximab (defined as 20mg IV on the day of transplantation and two post-operative doses of basiliximab). The primary objective of this study was to compare the number of infections

within 90 days of transplant between the standard dosing group of basiliximab to the group who received an additional dose. Infection was further defined as the use of antibiotics within 90 days after the transplant procedure, excluding prophylactic antibiotic use. Secondary objectives included length of hospital stay, length of intensive care unit (ICU) stay, in-hospital mortality, length of surgery, and estimated intraoperative blood loss.

Results: A total of 10 double-lung transplant patients were analyzed, four of whom received a higher dose of basiliximab and six a traditional dose. Three of the four patients in the higher dose basiliximab group developed an infection postoperatively, compared to all six in the traditional dose group. Secondary outcome results showed the median ICU length of stay in the higher dose group was 14.1 days (mean SD = 13.1 plus/minus 4.7 days) and 5.4 (mean SD = 29.6 plus/minus 31.8 days) in the traditional dose group. Median estimated intra-operative blood loss in the higher dose group was 1700ml (mean SD = 1952.5 plus/minus 1055 mL) compared to 450mL (mean SD = 916.67 plus/minus 842.4 mL) in the traditional dose group. Length of hospital stay and in-hospital mortality rate were unable to be assessed at the time of this analysis as two patients had not yet discharged from the hospital.

Conclusion: The primary outcome of this study demonstrated overall no difference in 90-day post-operative infection rates between patients receiving an additional dose of basiliximab compared to those receiving traditional dosing. Results showed that patients receiving an additional dose of basiliximab had more intra-operative blood loss than those in the traditional dosing group, and, interestingly, a shorter ICU length of stay. Based on these results, it appears that an additional dose of basiliximab in patients with a proportionally greater amount of blood loss is safe. However, further investigation with a larger patient sample size is necessary to draw conclusions.

Poster Title: Appropriate initial empiric therapy in the surgical intensive care unit for methicillin-resistant Staphylococcus aureus (MRSA) pneumonia and non-MRSA pneumonia

Primary Author: Hannah Turner, University of Wisconsin - Madison, Wisconsin; **Email:** turnertot92@gmail.com

Additional Author (s):
Spencer Laehn
William Peppard
Angela Huang
Thomas Carver

Purpose: The Infectious Disease Society of America (IDSA) 2016 hospital acquired pneumonia (HAP) guidelines state to initiate MRSA pneumonia therapy when the hospital local antibiogram has greater than ten to twenty percent of Staph aureus isolates that are methicillin resistant The surgical population at Froedtert Medical Lutheran Hospital (FMLH) historically has a MRSA rate of _____ percent. The goal of this evaluation was to determine if appropriate initial empiric therapy was achieved and what changes could be made to the initial empiric therapy.

Methods: A retrospective analysis of trauma patients in FMLH's surgical intensive care unit was completed by a pharmacy student and resident. A list of patients with laboratory confirmed MRSA HAP and confirmed non-MRSA bacterial HAP between July 1, 2007 - January 17, 2016 was analyzed. The MRSA HAP and non-MRSA HAP arms are reused from a previous data set. Both arms were collected differently from one another. The MRSA HAP arm was all the incidents of MRSA HAP from July 1, 2007 - January 17, 2016. The non-MRSA HAP arm utilized a random number generator to randomly pick non-MRSA HAP patients within the time period of July 1, 2007 - January 17, 2016. An excel spread sheet with specific criteria was made by the resident to help identify risk factors associated with MRSA PNA and appropriate empiric antibiotic coverage some criteria includes, but not limited to: organisms cultured, date of culture, empiric antibiotics used, appropriate empiric coverage for sensitives, final antibiotic used for de-escalation, age, gender, in the past 90 days from when culture drawn greater than 2 days in a nursing home or long term facility, chest tubes prior to culture and date of

placement. Patients who were under 18 years of age, pregnant, had cystic fibrosis, had chronic tracheotomies, or had cultured organisms deemed to be colonization alone were excluded.

Results: The top bugs seen in the FMLH surgical intensive care unit for non-MRSA HAP were MSSA, H influenza beta lactamase positive and negative, and E Coli. For the 55 patients analyzed for non-MRSA HAP, 49 percent of patients had a multi-organism infection. As for the MRSA HAP, 40 percent of the total 27 patients analyzed had a multi-organism infection. The top bugs seen in a MRSA HAP multi-organism infection were Psedomonas aeruginosa, Enterobacter cloacae, Proteus mirabilis, and H influenza beta lactamase positive. For those with non-MRSA HAP 92.7 percent of patients were started on appropriate total empiric coverage while for the MRSA HAP 92.6 percent of patients were started on appropriate total empiric coverage.

Conclusion: If patients in the non-MRSA HAP arm were empirically started on monotherapy Cefepime or Zosyn then 98.2 percent, and 98.2 percent of patients respectively would be appropriately covered. This would mean that five and a half percent more patients would be appropriately covered if on Cefepime or Zosyn monotherapy for initial empiric therapy. As for the MRSA arm, these patients received 92.6 percent of appropriate initial total empiric coverage. If the initial therapy was changed to monotherapy Ceftriaxone, Cefepime, or Zosyn then the MRSA patients would be inadequately covered by 70.4 percent, 59.3 percent and 59.3 percent respectively.

Poster Title: Pharmacokinetics of psilocybin in normal, healthy adults

Primary Author: Alexandra Ribaudo, University of Wisconsin - Madison School of Pharmacy, Wisconsin; **Email:** aribaudo@wisc.edu

Additional Author (s):
Randall Brown
Christopher Nicholas
Daniel Muller
Paul Hutson

Purpose: Psilocybin is a naturally occurring tryptamine known for its hallucinogenic effects. Although it was classified as a Schedule I drug in 1970, emerging research has found that psilocybin may be useful for the treatment of anxiety and depression associated with advanced cancer and substance abuse disorders. Collaboration among multiple universities is seeking to develop psilocybin into an FDA approved drug. The goal of this project was to characterize the safety and pharmacokinetics (PK) of escalating oral doses of psilocybin in a population of healthy adults.

Methods: After obtaining regulatory approvals, twelve healthy adults with prior hallucinogenic experience were recruited from the southern Wisconsin area. Subjects were screened for psychiatric illness and other excluding factors. Eligible subjects received six to eight hours of preparatory counseling and trust-building with two trained guides prior to their eight hour treatment session. Oral psilocybin doses were administered at least four weeks apart at 0.3, 0.45, and 0.60 mg/kg. Venous blood samples were collected at the following times: pre-dose, 15, 30, 45, 60, 90, 120 min, 3, 4, 6, 8, 12, 18, 24 hours. Urine was collected over 24 hours after each dose. Subjects were kept in the UW Clinical Research Unit overnight for blood sampling and received debriefing with their study guides the following day. Ascorbic acid was added to plasma and urine to stabilize the active metabolite, psilocin. Psilocybin and psilocin concentrations in the plasma and urine were analyzed by Covance Laboratories (Madison, WI). Population PK modeling was performed using a nonlinear mixed effect modeling program (NONMEM) with exploration for significant covariates predicting clearance and volume of

distribution. The final model was selected based upon minimization of the objective function and visual inspection of residual and VPC plots.

Results: Thirteen subjects were recruited to the study. Blood samples could not be obtained from one subject after the first dose was administered and the subject was replaced. Two of the twelve evaluable subjects were women, and the median age was 43 years (range 24 to 61). One subject was removed from the study after the first dose due to white-coat hypertension, and another subject declined the third dose due to scheduling difficulties. All doses of psilocybin were well-tolerated. Mild, temporary elevations of blood pressure and heart rate were common, as were mild headaches that responded well to acetaminophen. No serious adverse events occurred. Psilocin PK could be accurately described using a modified one-compartment model with linear absorption and a bidirectional compartment for the formation of psilocin glucuronide, the major metabolite. No parent psilocybin was detectable in any urine or plasma sample. Renal clearance accounted for less than 4% of the elimination of psilocin. Weight was not found to be a significant covariate for clearance or volume of distribution. The following parameters were identified (mean [SE%]): clearance (CL/F) of 164 L/hr [23.2%], volume of distribution (V/F) of 298 L [20.2%], and absorption rate constant (ka) 0.367 hr-1 [9.3%].

Conclusion: When administered in an appropriate environment with adequate preparation, even high doses of psilocybin are well-tolerated. The resulting concentration vs. time data were best fit by a one compartment model with reversible formation of the glucuronide metabolite. None of the tested demographic or laboratory covariates were found to have a significant impact on the model. Dose modification of psilocybin for renal dysfunction does not appear to be necessary.

Session-Board Number: 3-334

Poster Title: Updating a pneumonia decision support tool based on the 2016 hospital-acquired and ventilator-associated pneumonia clinical practice guidelines

Primary Author: Irene Chung, University of Wisconsin - Madison School of Pharmacy, Wisconsin; **Email:** iwchung@wisc.edu

Additional Author (s):
Susanne Barnett
Paul Lata
Russell Hynek

Purpose: The Infectious Diseases Society of America and the American Thoracic Society released new guidelines this year on the treatment of hospital-acquired pneumonia (HAP) and ventilator-associated pneumonia (VAP). This necessitated a comparison of the hospital's current pneumonia decision support tool and the 2016 guidelines to identify and remedy discrepancies to ensure appropriate and optimal use of antibiotics.

Methods: The "Management of Adults With Hospital-acquired and Ventilator-associated Pneumonia: 2016 Clinical Practice Guidelines by the Infectious Diseases Society of America and the American Thoracic Society" was analyzed. Differences between the recommendations from the guidelines and the hospital's pneumonia decision support tool were identified. Interpretation of the guidelines and identified inconsistencies were discussed with pharmacists and physicians. Hospital antibiogram and methicillin-resistant Staphylococcus aureus (MRSA) rates were used to develop facility-specific recommendations. A presentation was created highlighting proposed updates to the pneumonia decision support tool to facilitate discussion at the antimicrobial stewardship meeting and feedback was recorded. Mock-up of the updated decision support tool to be created and presented for further discussion and eventual review for approval by the antimicrobial stewardship committee.

Results: Discrepancies identified included changes in recommended use of lab markers, therapy, and duration. One key change from the existing pneumonia decision support tool from the 2016 guidelines was the delineation of patients that required double versus single pseudomonas coverage based on risk factors. Qualitative feedback from the antimicrobial

stewardship committee on the proposed recommendations was also obtained. Sample of feedback included commentary on reinforcing seven day duration of treatment and removing the restricted drug consult for meropenem if ordered through the decision support tool.

Conclusion: Update of the existing decision support tool for HAP and VAP was necessary given discordances from the 2016 guidelines. Review of hospital antibiogram and MRSA rates is vital to ensure recommendations are tailored to the practice site.

Poster Title: Antimicrobial stewardship and Clostridium difficile infection: evaluation of fluoroquinolone restriction adherence and clinical outcomes associated with alternative antibiotics

Primary Author: Shelby Tjugum, University of Wisconsin - Madison School of Pharmacy, Wisconsin; **Email:** stjugum@wisc.edu

Additional Author (s):
Margaret Jorgenson
Jeffrey Fish
Lucas Schulz

Purpose: Clostridium difficile infection (CDI) occurs due to a multitude of factors and significantly affects patient and hospital outcomes. One contributing factor to CDI development is the administration of fluoroquinolones. In response to high CDI rates, our institution restricted fluoroquinolone antibiotic use on units deemed to be of highest risk of poor outcomes from CDI; the solid organ transplant and medical/surgical intensive care units. The objective of this project was to measure compliance with a unit based fluoroquinolone restriction policy while assessing drug-class restriction safety and efficacy.

Methods: A multi-disciplinary workgroup was formed and created unit-specific, indication based tables listing empiric and step-down fluoroquinolone interchanges. These tables served as the backbone of the institutional restriction policy. The policy was displayed electronically at the time of order entry and clinical pharmacists upheld compliance with the policy during order verification. Use of fluoroquinolones required preauthorization by an infectious disease physician or pharmacist. Prospective tracking of all patients receiving treatment courses of antimicrobials occurred on the target units from July 5, 2016 to August 5, 2016. Indications for antimicrobials were collected via chart review and were considered policy compliant if selection was consistent with the interchange tables. The primary outcome was policy compliance. Secondary outcomes were rate of acute kidney injury (AKI) and efficacy of antimicrobial interchange. Acute kidney injury, as defined by the 2012 Kidney Disease Improving Global Outcomes guidelines, was collected and reported overall and for the subgroup of aminoglycoside-based treatment courses. Additional risk factors for nephrotoxicity were

collected for all patients who developed AKI. Efficacy was measured by treatment success, defined as lack of readmission for the same infection within one month, and mortality rate. The rate of hospital-acquired CDI, defined as the diagnosis of CDI more than 48 hours after admission, was also collected during the study time period.

Results: One hundred and twenty-four patients received 138 treatment courses and were included. Composite compliance was 75.4 percent with the fluoroquinolone restriction policy (79.7 percent and 71.6 percent on the transplant and intensive care units, respectively). The most common scenario resulting in policy violation was avoidance of aminoglycoside use. Acute kidney injury developed in 15.2 percent of courses overall. A total of seven treatment courses included an aminoglycoside; two of these resulted in AKI. When specifically reviewed, the patients undergoing these treatment courses had multiple risk factors for AKI development including age, co-morbid conditions, sepsis, and concurrent nephrotoxic medications. Overall treatment was successful in 95.6 percent of courses. Mortality rate during the study period was 8.1 percent. Hospital-acquired CDI during the study period was 0.72 percent.

Conclusion: Fluoroquinolone restriction and use of alternative antibiotic therapies on high-risk units was successful, safe, and effective. Overall compliance with the restriction policy was satisfactory, but adherence can be increased further by revising the unit-specific tables to include missing indications. One month after the implementation of the pilot, the rates of hospital-acquired CDI within the institution are continuing to trend downwards.

Poster Title: Discharge delay root causes and controlled substance prescribing satisfaction at an academic medical center

Primary Author: Erika Bauer, University of Wisconsin - Madison School of Pharmacy, Wisconsin; **Email:** eebauer@wisc.edu

Additional Author (s):
David Hager

Purpose: Hospitals functioning near capacity risk their ability to admit patients through transfers or between units, leading to treatment delays. UW Health formed a capacity management group to address this problem, with discharges prior to noon as the primary metric. Currently, 20.4 percent of discharges meet this metric, 4.6 percentage points below the goal. Pharmacists previously reported dissatisfaction and delays resulting from the controlled substance prescribing process; however, other barriers could be identified with workflow analysis. The purpose of this project was to assess the root causes of discharge delays at an academic medical center.

Methods: All inpatient pharmacists were trained to create intervention documentation in the electronic health record whenever patient education was completed after noon during a predefined fourteen-day period, from May 16 through June 1, 2016. Discharge delay root causes previously identified were available for selection, including: awaiting controlled substance prescription signature, awaiting provider medication reconciliation/changes/clarifications, medical factor, post-discharge factors, pharmacist workload, and discharge medication orders not complete by noon. Interventions were done at the patient level and tied to demographic and discharge time information.
An intervention report then complied the time of completed discharge medication orders, discharge education, and actual discharge for all discharged inpatients during the time period. Patients without pharmacist documented education, and duplicate entries were excluded. When documentation was not completed, the subtype was assigned as "discharge medication orders not complete by noon", or "unknown".
An online survey of medical resident perceptions of controlled substance prescription signing was created and then distributed to second through fourth year residents by the director of

graduate medical education. Questions included: respondent's demographic information (post-graduate year, department, DEA registration); estimation of interruptions and discharge delays with current system; satisfaction; perception of impact of expanding provider registration; priority of morning discharges; and a free text comment field.

Results: During the two-week period, 1600 inpatient discharges were reported with 24 percent discharged before noon. In cases where patients were discharged after noon, discharge medication education was completed at or after noon 72 percent of the time. Discharge medication orders not completed by noon, accounted for the primary cause in 50 percent of discharge delays. Additional reasons included patient factors (9.2 percent), medical factors (6.6 percent), pharmacist workload (4.5 percent), controlled substance prescription signing (4.1 percent), amongst others.
The medical resident perceptions survey had 51 respondents, with the most common programs being surgery, medicine, and anesthesiology. They reported disagreeing (slightly to strongly) with controlled substance signing satisfaction 75 percent of the time. Ninety-six percent agreed that expanding medical resident controlled substance signing would reduce discharge delays.

Conclusion: Although a small percentage of primary causes attributed to discharge delays, controlled substance prescription signing is an issue identified by both pharmacy and medical residents causing needless delays in patient discharges. A majority of discharge delays resulted from pharmacists not receiving timely discharge medication orders. This strongly supported a separate project. A limitation of this workflow analysis is that root causes of discharge delays are dependent on medication orders. With this root cause addressed, additional downstream causes may be identified. Expansion of resident controlled substance prescribing may improve discharge workflow, and improve pharmacist and physician satisfaction.

Session-Board Number: 3-337

Poster Title: Use of adjunct beta-lactams to prevent the in vitro development of daptomycin resistance in vancomycin-resistant enterococci

Primary Author: Megan Burley, University of Wisconsin - Madison School of Pharmacy, Wisconsin; **Email:** mburley@wisc.edu

Additional Author (s):
Warren Rose
Xuting Zheng

Purpose: Daptomycin (DAP) is a critical component in the treatment of vancomycin-resistant enterococci (VRE) infections. Development of DAP resistance (DAP-R) within the course of DAP treatment in previously DAP susceptible VRE poses a significant clinical challenge. Prevention of DAP-R is necessary to salvage DAP effectiveness as antibiotic treatment options for VRE are limited. The purpose of this study was to determine if adjunct use of beta-lactams added to DAP prevents the long-term, in vitro development of DAP-R in VRE.

Methods: Two DAP susceptible VRE strains isolated from patients known to develop DAP-R within the course of DAP treatment were examined in a 28-day in vitro serial passage. Minimum inhibitory concentrations (MICs) for VRE isolates (2267 and 8019) were determined by broth microdilution for DAP and the following beta-lactams: ampicillin, ceftriaxone, ampicillin plus ceftriaxone and ertapenem. Isolates were grown in triplicate and exposed to increasing concentrations of DAP with or without static concentrations of ampicillin, ampicillin plus ceftriaxone, ceftriaxone or ertapenem. Starting concentrations of DAP were based on 25% the initial DAP MIC and sub-inhibitory concentrations of beta-lactams were based on the free serum concentration average for each beta-lactam. Cultures were shaken overnight at 37°C at 160 rpm. Cultures showing growth at 24-hours were diluted 1:100 in fresh broth with increasing DAP concentrations while maintaining the same beta-lactam concentration. DAP concentrations were steadily increased until overnight growth was observed using the following increments: 0.25 mg/L until growth at 1.0 mg/L, 0.5 mg/L until growth at 5 mg/L, 1 mg/L until growth at 15 mg/L and finally, 5 mg/L until the end of the experiment. Serial passages were performed over a 28-day period and DAP MICs were obtained on days 0, 7, 14, 21 and 28.

Results: Exposure to different beta-lactams produced variant effects on DAP MICs throughout the 28-day experiment. In both VRE strains, the addition of ampicillin and ampicillin plus ceftriaxone to DAP tended to produce lower DAP MICs as compared to DAP alone over a 28-day period. In strain 2267, DAP plus ceftriaxone had a lower DAP MIC compared to DAP alone; however, in strain 8019, the MIC for DAP plus ceftriaxone was higher compared to DAP alone. Interestingly, ertapenem hastened the rate of DAP MIC increase compared to DAP alone in both strains. Despite the lower DAP MICs with these combinations compared to DAP alone, all MIC values obtained at the end of the 28-day experiment were considered non-susceptible (DAP MIC > 4 mg/L) and not clinically significant.

Conclusion: Use of adjunct a beta-lactam added to DAP did not prevent the long-term development of resistance in a 28-day in vitro serial passage. Although ampicillin and ampicillin plus ceftriaxone tended to result in lower MIC values for both VRE strains, MIC values at the end of day 28 were not within the DAP susceptibility range as tested in the clinic. Combination therapy with DAP plus beta-lactams appears to have distinct effects for synergy and resistance prevention. Further in vitro experiments using different antibiotics is warranted to salvage DAP utility.

Poster Title: Vasopressin in the intensive care unit (ICU): An initial evaluation of a usage reduction initiative

Primary Author: Alexander Kellogg, University of Wisconsin - Madison, School of Pharmacy, Wisconsin; **Email:** akellogg2@wisc.edu

Additional Author (s):
Ryan Draheim
Matt Willenborg
Jeff Fish

Purpose: The cost of vasopressin has increased from less than three dollars to greater than 100 dollars per vial in the past two years. The previously recommended rate of administration for vasopressin at UW Health – University Hospital was 0.04 units/minute. The Surviving Sepsis Campaign dosage recommendation was cited as justification for a rate decrease to 0.03 units/minute. Physician leaders also recommended reserving vasopressin for patients who were receiving an escalating dose of norepinephrine. The purpose of this study was to determine the effects of the recommended changes in vasopressin administration on clinical outcomes.

Methods: This study was a single center retrospective analysis. The first fifty patients identified from a random number generator who received vasopressin at a rate of 0.04 units/minute in the ICU between January 2015 and June 2016 and did not meet exclusion criteria were the control group. The first fifteen patients to receive vasopressin at a rate of 0.03 units/minute from January 2015 to September 2016 and did not meet exclusion criteria served as the intervention group. Exclusion criteria were an ICU length-of-stay (LOS) of less than 24 hours or missing ICU LOS data. The primary endpoints were patient mortality and the standardized mortality ratio (SMR). The SMR was calculated using the overall group mortality divided by the median predicted mortality based on APACHE IV scores. Secondary endpoints included ICU LOS and the ratio between actual and predicted ICU LOS based on APACHE IV scores. Fisher's exact test was used to compare mortality, and the Mann-Whitney U test was used to compare ICU LOS.

Results: The median baseline APACHE IV score was 117 for the control group, and 130 for the intervention group. The control group was 54 percent (27/50) male versus 47 percent (7/17) in the intervention. The median age in both groups was 62 years. Median weight was 80.0 kg for the control versus 76.8 kg for the intervention. The actual mortality was 52 percent (26/50) in the control group vs 60 percent (9/15) in the intervention group (p equals 0.77). The median predicted ICU mortality for the control group was 43.1 percent and for the intervention group was 58.2 percent. The SMR for the control group was 1.21 versus 1.03 for the intervention group. The median length-of-stay in the ICU was 4.9 days in the control group vs 7.0 days in the intervention group (p equals 0.93). The ICU LOS ratio was 0.56 for the control vs 0.74 for the intervention.

Conclusion: Reducing vasopressin usage did not significantly affect mortality or ICU LOS. There appears to be a clinically significant change in ICU LOS, though both groups reported a lower LOS than predicted. SMR was lower for the intervention group, but both groups were high compared to predicted mortality based on median APACHE IV scores. This initial analysis is auspicious of vasopressin usage reduction at UW Health-University Hospital. The actual mortality in both groups and the actual difference in ICU LOS favoring the control group warrants further analysis with a larger group of patients to evaluate the effect on clinical outcomes.

Poster Title: Pediatric enoxaparin treatment: impact of a pharmacist dosing, titration and monitoring delegation protocol

Primary Author: Eric Chmielewski, University of Wisconsin - School of Pharmacy, Wisconsin; **Email:** echmielewski@uwhealth.org

Additional Author (s):
Nicole Lubcke
Sarah Emanuele
Heather Jones
Anne Rose

Purpose: Treatment dosing of enoxaparin in pediatric patients is based on actual body weight with the goal to achieve a therapeutic anti-Xa level 4-6 hours post dose. An internal review identified variable practices with monitoring the anti-Xa and a dosing strategy that failed to produce therapeutic anti-Xa levels in a reasonable time. A modified age-based dosing scheme for enoxaparin was developed and incorporated into a delegation protocol allowing pharmacists to dose adjust and monitor enoxaparin. The purpose of this study was to evaluate the new dosing strategy and protocol by examining the impact on time to therapeutic anti-Xa level.

Methods: A retrospective chart review of patients receiving enoxaparin in treatment doses was conducted following implementation of the delegation protocol from March 2016 to July 2016. Results were compared with those of a previous internal medication use evaluation conducted prior to the implementation of the delegation protocol from September 2011 to November 2015. Patients ≤18 years old who received enoxaparin for treatment of thrombosis and had anti-Xa monitoring while inpatient were included. Patients were excluded if they received prophylactic enoxaparin doses, did not have anti-Xa levels drawn, or had orders for enoxaparin that were never administered. The primary outcome was time to first therapeutic anti-Xa level.

Results: A total of 98 patients met the inclusion criteria during the study time periods. Seventy-eight patients were included pre-protocol and 20 patients were included post-protocol implementation. Mean time to therapeutic anti-Xa level was 69.8 hours pre-protocol and 12.3 hours post-protocol (p < 0.001). Patients who achieved a therapeutic anti-Xa after the first dose of enoxaparin was 2 (2.5%) pre-protocol compared to 11 (55%) post protocol (p < 0.001). Pharmacists intervened on initial ordered doses of enoxaparin on 25% of orders post-protocol.

Conclusion: A modified age-based enoxaparin dosing strategy and implementation of a pharmacist-led enoxaparin dosing and monitoring delegation protocol decreased time to therapeutic anticoagulation in pediatric patients being treated for thrombosis.

Poster Title: Diabetes education and wellness program for patients suffering from mental illness: Quality improvement through pharmacy intervention

Primary Author: Bryan Haugen, University of Wisconsin Madison, Wisconsin; **Email:** bhaugen2@wisc.edu

Purpose: People suffering from a mental illness are at an increased risk to develop diabetes. Risk factors for diabetes including, poor diet, physical inactivity, poor self-care and lack of access to care are often also associated with behavioral illnesses. Journey Health and Wellness sought to improve the quality of care of its diabetic clients by developing an education and wellness program with pharmacist intervention. The program was developed to increase disease state knowledge, assess and overcome barriers participants face from living with diabetes and mental illness, and improve the quality of diabetes care participants receive.

Methods: The education and wellness program was developed and organized by a committee that consisted of a pharmacy intern and two registered nurses. The program consisted of four, one hour, weekly sessions. Each session focused on a different topic of diabetes care, general pathology, diet and physical activity, medication management and coping with diabetes and mental health. Each session included weekly goal setting and review, education and a discussion utilizing the health belief model and motivational interviewing. Medication profile review was conducted to ensure adequate therapy. Patients were recruited to be included in the program if they were over the age of 18 years old, had a diagnosis of diabetes as well as a diagnosis for a mental health disorder and received care by Journey Health and Wellness providers. Baseline demographic and quality of care data was collected during session one. Additional measures included a perceived barriers survey and pre- and post-session medication knowledge survey. Evaluation for quality improvement was completed through administration of a survey using a 10-point likert scale as well as subjective observation by the program's committee.

Results: Seven patients completed the four-week program. All participants suffered from type two diabetes, with mental health diagnoses ranging from generalized anxiety disorder to schizophrenia. Baseline data resulted in participants rating their perceived quality of care from

providers as an average of 5.6 out of 10. All patients rated their diet and physical activity habits as poor and rated that their mental health negatively impacts their self-care as an average of 6.7 on the 10-point scale. The barriers that participants most commonly perceived were the feelings of being overwhelmed when attempting to eat healthy and a dislike for taking medications. Motivational interviewing techniques were positively used to provide patients with strategies to overcome common barriers. Medication knowledge survey showed an improvement in anti-psychotic medication knowledge. At the end of the fourth session 71% had made changes to their diet and 28% had made changes in their physical activity routines. There was also a 100% improvement in knowledge regarding diabetes pathogenesis and antidiabetic medications. Finally, the overall number of perceived barriers decreased following session four.

Conclusion: Participants were provided education and support in order to improve the quality of care they were receiving and improve the participant's self-care. Medication management and providing strategies to overcome mental health barriers was an integral part that resulted in an improvement of how the participants perceived their care. Patients also benefited from the use of weekly goal setting, the health belief model and motivational interviewing to change lifestyle habits. Pharmacists play an important role in managing chronic disease states and are able to provide a unique point of view to improve the quality of care mentally ill patients receive.

Poster Title: Granulocyte colony-stimulating factor utilization post-autologous hematopoietic stem cell transplant in multiple myeloma patients: does one size fit all?

Primary Author: Emily Jackson, University of Wisconsin Madison School of Pharmacy, Wisconsin; **Email:** erjackson@wisc.edu

Additional Author (s):
Jason Jared
Jennifer Piccolo
Mary Mably
Natalie Callander

Purpose: Use of granulocyte colony-stimulating factor (GCSF) after autologous hematopoietic stem cell transplant (HSCT) is recommended by the American Society of Clinical Oncology for all patients to reduce the duration of severe neutropenia. Currently at UW Health, standard operating procedure is to not utilize GCSF post-transplant in multiple myeloma patients, however, it is occasionally administered after autologous HSCT based on patient specific risk factors. The purpose of this project was to evaluate a single institution's experience with GCSF after autologous HSCT in myeloma patients.

Methods: Retrospective chart reviews were conducted on patients 18 years and older with multiple myeloma that underwent autologous HSCT at UW Health from January 2015 to May 2016. Data was collected on demographics, length of stay post-transplant, doses of GCSF given, time to engraftment, Eastern Cooperative Oncology Group (ECOG) performance status, and intravenous antibiotic use and duration.

Results: In total, 100 patients were reviewed. Five were excluded from analysis due to death and 44 were excluded from primary analysis due to discharge prior to engraftment. Of the 56 patients included, 25 received one or more doses of GCSF with an average of 5.7 doses per patient. The average age for the GCSF group was 64.6 years versus 63.7 years for the non-GCSF group, and the median ECOG performance score for each group was 1. The average time to engraftment for the GCSF group was 12.6 days compared to 14.3 days for the non-GCSF group. Average inpatient length of stay post-transplant for the GCSF group was 17.6 days versus 16.6

days for the non-GCSF group. The average duration of intravenous antibiotics administered was 5.2 days in the GCSF group compared to 5.5 days in the non-GCSF group. A subgroup analysis of patients 65 years and older showed that the average time to engraftment for the GCSF group was 12.2 days compared to 14.5 days in the non-GCSF group. The average length of stay post-transplant for the GCSF group was 17.9 days versus 16.3 days in the non-GCSF group. The median ECOG performance score for each group was 1.

Conclusion: Although GCSF decreased time to engraftment, administration did not appear to be correlated with decreased length of stay post-transplant and duration of intravenous antibiotics remained similar between the two groups.

Poster Title: Hemolysis and anticoagulation in mechanical circulatory devices: a comparison of heparin and bivalirudin

Primary Author: Lauren Brownell, University of Wisconsin School of Pharmacy, Wisconsin;
Email: lrahn@wisc.edu

Additional Author (s):
Jennifer Lai
Anne Rose

Purpose: Treatment of hemolysis and suspected pump thrombosis in patients with mechanical circulatory devices (MCD) traditionally includes intravenous unfractionated heparin (UFH). Direct thrombin inhibitors, such as bivalirudin, may also be considered as a treatment option; however, little evidence is available to support their use in this patient population. At the University of Wisconsin Hospital in Madison, heparin or bivalirudin may be used to treat patients with suspected pump thrombosis based on laboratory indicators of hemolysis. The purpose of this study was to retrospectively compare the efficacy of heparin versus bivalirudin in treating hemolysis.

Methods: Adult MCD patients with episodes of hemolysis, occurring between July 2011 and June 2016, were identified for retrospective chart review as part of a quality improvement project. Hemolysis was defined as a lactate dehydrogenase (LDH) level greater than three times the upper limit of normal. Patients were evaluated for anticoagulation treatment with heparin, bivalirudin, or both. Data was extracted from the electronic health record and included: patient demographics, LDH level at time of anticoagulation, anticoagulants used, dose of anticoagulation, anticoagulation monitoring parameters, time spent within therapeutic range, duration of anticoagulation therapy, time to LDH normalization, antiplatelet therapies administered, incidence of infections, incidence of abnormal heart rhythms, and bleeding events. The primary outcome was resolution of hemolysis as indicated by normalization of LDH levels.

Results: Twenty-one unique hemolysis events occurring in fifteen MCD patients were evaluated. Of the 21 events, 20 were initially treated with UFH, eight were switched from initial treatment with UFH to treatment with bivalirudin, and one was treated with bivalirudin only. The average LDH level at UFH initiation was 1359 U/L (range 344 to 4637). In the events where treatment was switched from UFH to bivalirudin, the average LDH level at bivalirudin initiation was 1580 U/L (range 663 to 2414). In the event treated with bivalirudin only, the LDH level at bivalirudin initiation was 1838 U/L. LDH normalization occurred in six (30%) of the 20 events treated with UFH and five (62.5%) of the eight events switched from UFH to bivalirudin. LDH normalization did not occur during the event treated with bivalirudin only.

Conclusion: Both heparin and bivalirudin showed resolution of hemolysis in MCD patients, with bivalirudin showing a trend towards being more effective, although the study was not powered to show significance. Further investigations are needed to determine which agent is more effective in the treatment of pump thrombosis and hemolysis.

Poster Title: Barriers to annual influenza vaccination in heart failure and cardiac transplant patients

Primary Author: Briana Frolov, University of Wisconsin, Madison, Wisconsin; **Email:** frolov@wisc.edu

Additional Author (s):
Besa Jonuzi
Jared Mills
Kassandra Fabbri
Orly Vardeny

Purpose: Patients with heart failure and/or cardiac transplant are at an increased risk of influenza infection and subsequent influenza-associated morbidity and mortality. In heart failure and/or cardiac transplant patients, receiving an annual influenza vaccination is safe and effectiveand reduces cardiac-associated or influenza-associated hospitalizations and overall mortality. The percent of patients with cardiovascular conditions receiving annual influenza vaccinations is underwhelming. Several barriers to influenza vaccination have been reported in patients without non-high risk conditions, but there are limited data on barriers in heart failure and/or heart transplant patients.

Methods: Individuals adults over the age of 18 diagnosed with heart failure and/or recipients of a cardiac transplant and followed at the University of Wisconsin – Madison Advanced Heart Disease Clinic were invited to participate. During routine clinic appointments consenting patients were asked to complete a questionnaire on attitudes and beliefs towards the influenza vaccine. In addition to baseline characteristics, participants were surveyed on adherence to annual influenza vaccination and barriers to annual influenza vaccination, which were assessed on a likert scale. The primary objective was to describe adoption of and barriers to annual influenza vaccination among this high risk population. The secondary objective was to explore potential predictors of annual vaccination in this study sample. All participants provided written informed consent in accordance with established guidelines for the protection of human subjects.

Results: Participants (N=31) were more commonly white (93.5%), male (77.4%), and over 60 years of age (58.1%). When asked if their pharmacy provided vaccinations, 64.5% stated their pharmacy did with 22.6% stating they didn't know. Majority of patients (74.2%), regardless of belief concerning the effectiveness of the vaccine and having personal beliefs against the vaccine, received the influenza vaccine within the past year. A small minority of patients (9.7%) stated they had a previous reaction to the vaccine. Barriers prevalent during this survey included access to vaccination, perceived lack of benefit to vaccination, and low appreciation of the health risks associated with influenza infection. Among patients who stated they have not been vaccinated for over one year, the most commonly reported barrier was the belief that the influenza vaccine caused influenza infection. Barriers such as perception of infection from the vaccine, lack of knowledge regarding potential benefits from vaccination, and not enough information from health care providers were common for patients who do not believe the influenza vaccine is effective, with 37.5% stating that their health care provider does not offer information about the influenza vaccine.

Conclusion: Although there are many barriers to influenza vaccination among heart failure and/or cardiac transplant patients, common themes included perception of infection from the vaccine, lack of appreciation for potential benefits to vaccination, and not enough information from health care providers. These barriers may be mitigated with education from health care providers on the increased risk of influenza infection in this population and further explanation of why influenza vaccination is necessary.

Poster Title: Statin use in adults with diabetes: a gap analysis of EQuIPP versus health system data from 14 community pharmacies

Primary Author: Tyler Prickette, University of Wisconsin, School of Pharmacy, Wisconsin; **Email:** prickette@wisc.edu

Additional Author (s):
Katherine Hartkopf
Joseph Cesarz

Purpose: The Affordable Care Act shifted health care models to define, measure, and reward quality. The Centers for Medicare & Medicaid Services (CMS) implemented a five-star quality rating system for Medicare prescription drug plans including medication-use quality metrics extending to community pharmacies. The Electronic Quality Improvement Platform for Plans and Pharmacies (EQuIPP) is an information management platform pharmacies use to evaluate performance on quality metrics. Information comes from insurers enrolled in the program, so there are plans not captured. This study compared compliance rates for one quality measure in EQuIPP versus that across 14 community pharmacies in a health-system.

Methods: Dispensing data for patients between the ages of 40-75 filling any anti-diabetes medication from December 2015 through May 2016 was collected from the 14 UW Health community pharmacies. Patients were included if they had two fills of any anti-diabetes medication during the observation period. Patients meeting criteria were assessed for a single statin fill during the time period to determine statin use. Data collected included age, earliest fill of statin or anti-diabetes medication if no statin filled, prescription insurance, and specific pharmacy location. Statin use was also evaluated by prescription insurance. Data for the same metric was available through EQuIPP and was collected into a single report to be compared to the health-system data.

Results: According to EQuIPP, 71 percent of patients across all UW Health community pharmacies on any anti-diabetic medication also filled a statin medication. In the health-system specific analysis, 703 of 1153 patients (61 percent) had a statin filled during the observation period. The average age of the patients was 58.2 years old. Store 3 had the best percentage of

statin use at 78.5 percent (n equals 107). Conversely, store 13 had the worst percentage at 35.7 percent (n equals 14). Store 1 had the second lowest percentage at 44 percent (n equals 145). The largest insurer of patients included in this evaluation had 66.2 percent statin use (n equals 225).

Conclusion: There was a ten percent lower report of statin use in patients age 40-75 on any anti-diabetic medication when comparing EQuIPP reports and the entire health-system data. Available tools that provide community pharmacies visibility on CMS five-star measure performance have limitations such as providing feedback on only a portion the patient population. Regardless, UW Health community pharmacies are not performing on this metric. Processes are underway to prepare and implement a targeted intervention with the intent of improving compliance with this measure across the UW Health community pharmacies. Post-implementation data will be collected.

Poster Title: Development and evaluation of potential impact of an anti-factor Xa guideline for unfractionated heparin

Primary Author: Catherine Kuecker, University of Wisconsin-Madison, Wisconsin; **Email:** katie.kuecker@wisc.edu

Additional Author (s):
Melissa Heim
Carla Staresinic

Purpose: Monitoring unfractionated heparin (UFH) with anti-factor Xa (anti-Xa) results in shorter time to achieve therapeutic anticoagulation and higher number of individuals able to achieve therapeutic anticoagulation compared to monitoring with activated partial thromboplastin time (aPTT). Due to the growing need for anti-Xa monitoring and provider requests, an UFH guideline monitored with anti-Xa was developed. Due to cost of anti-Xa (15 times aPTT cost) and limited accessibility (send-out lab), criteria for monitoring with anti-Xa was determined. Additionally, the current institution-specific UFH guideline monitored with aPTT was evaluated to determine patients per year that would be transitioned to monitoring with anti-Xa.

Methods: To develop the institution-specific UFH guideline monitored with anti-Xa, an extensive literature review was completed. A draft guideline for low/medium intensity (goal anti-Xa 0.1-0.3 units/ml) and high intensity (goal anti-Xa 0.3-0.7 units/ml) was developed based on the current UFH guideline monitored with aPTT and literature review. The guideline was reviewed and approved by the Anticoagulation Committee, and Pharmacy and Therapeutics Committee. To evaluate the impact of the draft guideline, a report was generated for all patients admitted to the William S. Middleton Veterans Hospital who received UFH from March 13, 2015 to March 13, 2016. Patients who received UFH for less than 24 hours were excluded. A random sample of patients was selected for retrospective chart review and baseline international normalized ratio (INR) and aPTT, indication for heparin infusion, and whether the patient achieved goal therapeutic aPTT range after three consecutive heparin adjustments were documented.

Results: Criteria for anti-Xa monitoring included 1) patients with elevated baseline aPTT greater than 40 seconds (with INR less than 2.0, if on warfarin), 2) failure to achieve therapeutic aPTT range with three consecutive UFH adjustments in active thrombosis, 3) heparin resistance, and 4) select indications (eg- LVAD). The retrospective chart review was IRB exempt. Total UFH instances administered were 270 and a random sample of 80 instances was selected. An elevated baseline aPTT was documented in 7/80 (9%) patients. However, 2/7 (29%) patients with elevated baseline aPTT had an INR greater than 2.0. This would result in 5/80 (6.25%) patients in the sample and 17 patients per year to be transitioned to anti-Xa monitoring. The majority of patients sampled were receiving UFH for non-active thrombosis indications (55/80, 69%), while 25/80 (31%) patients were receiving UFH for active thrombosis. After three consecutive heparin adjustments, 9/25 (36%) patients receiving UFH for active thrombosis were not within therapeutic goal aPTT range. This would result in 9/80 (11.25%) patients in the sample and 30 patients per year to be transitioned to monitoring with anti-Xa. Overall, an anticipated 47/270 (17%) patients per year could be expected to utilize anti-Xa monitoring. Heparin resistance was not evaluated.

Conclusion: An UFH guideline monitored with anti-Xa for select populations was developed and approved by institutional committees. Overall, approximately 17% of patients requiring UFH can be estimated to be transitioned from aPTT to anti-Xa monitoring.

Poster Title: Vancomycin prophylaxis for prevention of Clostridium difficile recurrence in renal transplant patients

Primary Author: Lindsey Splinter, University of Wisconsin-Madison, Wisconsin; **Email:** lsplinter@wisc.edu

Additional Author (s):
Jillian Descourouez
Glen Leverson
Jeannina Smith
Margaret Jorgenson

Purpose: The prevalence of Clostridium difficile infection (CDI) in solid organ transplant (SOT) recipients is higher than in the average hospitalized patient due to multiple risk factors. Clinical data supporting secondary prophylaxis of CDI with oral vancomycin is limited. The primary objective of this study was to describe the use of prophylactic vancomycin for prevention of recurrent CDI in renal transplant recipients (RTX) on broad-spectrum antibiotic (BSA) therapy.

Methods: This was a retrospective review of adult RTX patients receiving oral vancomycin prophylaxis, 125 mg twice daily, during a unit specific CDI outbreak window from 1/1/2013–12/31/2015. Data collection included patient demographics, transplant specific demographics, date of primary CDI and treatment, concomitant BSAs received during prophylaxis and their associated CDI risk as defined in previous literature, indication for BSAs, concomitant acid suppression therapy proceeding and during BSA therapy, probiotic therapy proceeding and during BSA therapy, and CDI breakthrough; defined as confirmed CDI recurrence after greater than or equal to 48 hours of oral vancomycin prophylactic therapy.

Results: Ten renal transplant recipients met study inclusion criteria; sixty percent (n equals 6) were female, eighty percent (n equals 8) were recipients of their primary transplant patients. The average age at transplant was 63 years plus or minus 14.9 years. The majority of patients developed their primary CDI greater than or equal to one year post-transplant (70 percent, n equals 7). Only thirty percent (n equals 3) developed their primary infection within the first year post-transplant, all occurred within the first three months. There was only one case of NAP1+

associated CDI. The primary case of CDI was treated with oral vancomycin in the majority of cases (80 percent, n equals 8), one patient received combination therapy with metronidazole and oral vancomycin. The mean associated CDI risk hazard ratio of BSA received concomitantly during oral vancomycin prophylaxis was 3.4. Eighty percent (n equals 8) of patients were receiving acid suppression therapy prior to and throughout admission. Forty percent (n equals 4) were using a probiotic prior to admission. There were no documented cases of CDI breakthrough while on oral vancomycin prophylaxis. Duration of oral prophylactic vancomycin ranged from 2-47 days.

Conclusion: In a small case series of renal transplant patients during a unit specific CDI outbreak, oral vancomycin prophylaxis appeared to be successful in CDI prevention. Further research is necessary to investigate this potential CDI reduction strategy.

Poster Title: Potential Cost Savings From a Stepwise Daptomycin Dosing Regimen in Patients With Renal Insufficiency

Primary Author: Andrew Cannon, University of Wisconsin-Madison School of Pharmacy, Wisconsin; **Email:** arcannon@wisc.edu

Additional Author (s):
Annette Drobac
Steve Ebert

Purpose: Daptomycin is a concentration-dependent antibiotic with a key pharmacokinetic/pharmacodynamic measure of area-under-the-curve (AUC)/minimum inhibitory concentration (MIC). According to manufacturer labeling, the daptomycin dosing interval should be changed from daily to every 48 hours in patients with a creatinine clearance < 30 mL/min. However, pharmacokinetic data in the labeling shows the AUC of daptomycin increases in a stepwise fashion as kidney function declines below 80 mL/min. This study utilizes published pharmacokinetics of daptomycin in patients with varying degrees of renal dysfunction to devise an alternate dosing regimen using a gradual dose reduction scheme and analyzes the cost savings.

Methods: We obtained retrospective data records from patients treated with daptomycin at UnityPoint Health-Meriter Hospital from January 1st, 2016 to August 31st, 2016. Patients were included if they received a dose of daptomycin within this time period in the hospital or clinic setting. Patients were excluded if their creatinine clearance was < 30 mL/min (Cockcroft-Gault) since daptomycin doses were already adjusted, or if their creatinine clearance was >80 mL/min since no dose adjustment was indicated. An alternate daptomycin dose was calculated based on the patient's renal function; mild impairment (50-80 mL/min) to receive 83% of the normal daily dose and moderate impairment (30-50 mL/min) to receive 66% of the normal daily dose. These percent reductions in dose were calculated based on the ratio of the published daptomycin AUC in patients with normal renal function to those with impaired renal function. Doses calculated by the new method were compared with doses actually received. A cost of $420 for each 500 mg vial of daptomycin was used to calculate potential cost savings.

Results: Over the eight month trial period, 23 patients who had received 222 doses of daptomycin were identified as eligible for the alternate dosing method. Use of the stepwise approach would have resulted in a cost savings of $14,000 in this eight month period, projected to $21,000 in savings per year. This dose reduction would not be expected to reduce the efficacy of daptomycin and may in fact reduce side effects.

Conclusion: A new daptomycin dosing regimen based on stepwise creatinine clearance adjustments for patients with a creatinine clearance of 30-80 mL/min appears reasonable in patients with renal dysfunction and can reduce the cost of daptomycin use in healthcare systems. Pharmacokinetic data released by the manufacturer support this method. Post-implementation studies should be completed to ensure adequate efficacy in treating serious skin and soft tissue infections and bacteremia with this new dose adjustment method.

Submission Type: Evaluative Study

Session-Board Number: 3-348

Poster Title: Patient satisfaction after six months of an extended interval of INR follow-up protocol

Primary Author: Hayley Tatro, University of Wisconsin-Madison School of Pharmacy, Wisconsin; **Email:** htatro@wisc.edu

Additional Author (s):
Catherine Kuecker
Andrea Porter
Amanda Margolis

Purpose: The feasibility, safety, and patient satisfaction of an extended International Normalized Ratio (INR) follow-up interval up to 12 weeks is currently being evaluated through an ongoing prospective cohort study at the William S. Middleton Memorial Veterans Hospital. To assess patient satisfaction, the Duke Anticoagulation Satisfaction Scale (DASS), a validated 25-item scale addressing positive and negative aspects of anticoagulation, is being used. The purpose of this project was to determine the relationship between patient satisfaction regarding anticoagulation therapy and the extended INR follow-up interval six months into the cohort.

Methods: The DASS was distributed to all study participants at enrollment and six months after enrollment. The DASS is a seven-point Likert scale ranging from "not at all" to "very much." Patients completed the survey in person or it was mailed to them. If the mailed surveys were not returned in a timely manner, patients were contacted via telephone and the survey was sent again. The analysis was conducted on participants who completed both the enrollment and six month DASS surveys. Statistical significance for the difference in each question was calculated using the Wilcoxon Signed Rank test using a significance level of 0.05. This project was approved by the University of Wisconsin – Madison Health Sciences Institutional Review Board and by the William S. Middleton Memorial Veterans Hospital Research and Development Committee.

Results: A total of 47 patients completed the DASS survey at enrollment and six months. Of the 25 questions, six demonstrated a statistically significant difference. Of these six questions, only one showed an improvement in quality of life (impact of bleeding or bruising limits ability to work for pay: -0.34, p=0.04). The other five questions demonstrated a decrease in quality of life (affect on daily life: 0.11, p=0.02; inconvenience of anti-clot treatment: 0.32, p=0.02; time burden: 0.42, p=0.049; negative impact on life: 0.59, p=0.03; difficulty with anti-clot management: 0.59, p=0.0013).

Conclusion: Patient satisfaction did not increase after six months of involvement in a protocol to extend the INR follow-up interval. However, the items with statistically significant changes were less than a 0.6 difference on a seven-point scale and therefore, may not be clinically significant. Possible explanations for the results include decreased patient comfort due to decreased feedback from fewer INR results and less frequent provider interaction. Further research is needed to identify specific patient characteristics that could correlate to higher patient satisfaction with an extended interval of INR follow-up.

Poster Title: Evaluation of local versus send-out trizole antifungal serum drug concentration monitoring in a large academic institution: A retrospective analysis

Primary Author: Anh Van, University of Wisconsin-Madison School of Pharmacy, Wisconsin; **Email:** avan@wisc.edu

Additional Author (s):
Erin McCreary
Lucas Schulz
David Andes

Purpose: Serum drug concentration (SDC) is used as a tool to guide accurate dosing, appropriate toxicity monitoring, and optimal therapy selection for triazole antifungals. SDC is frequently completed as a 'send-out' test. This limited availability extends the time between sample collection and laboratory results for antifungal SDC. The purpose of this project was to evaluate the effect of performing local triazole SDC monitoring on antifungal drug costs and patient clinical outcomes, and determine the need for development of specialized in-house laboratory with antifungal drug assay availability.

Methods: Patients who received triazole antifungal (itraconazole, posaconazole, or voriconazole) therapies between 8/2013 and 8/2015 were included. Patients without SDC were excluded. Data collection included demographic information, indication requiring antifungal therapy, location of SDC processing (local or send-out), time to notification of SDC result, number of antifungal dose adjustments, number of days of overlapping antifungal therapies, days to goal SDC, antifungal drug utilization, hospital length of stay, intensive care unit length of stay, and mortality. The average wholesale price as of September 2016 was used to calculate cost savings. The primary outcome was aggregate antifungal drug costs, including the cost of monitoring. Secondary outcomes included hospital length of stay, intensive care unit length of stay, and mortality.

Results: Of the 135 included patients, antifungal SDCs were available in 74 patients, with 30 patients on treatment therapies and 44 patients on prophylaxis therapies. The median turn-around-time for lab results was 53.5 (range 25-254) hours for send-out testing and 11 (range 3-36) hours for local testing. Local testing reduced the cost of overlapping, -azole-alternative therapy by $3098 and $587 for treatment and prophylaxis, respectively. There was a statistically significant difference in the mean hospital length of stay 10.3 days (s = 7.2 days) vs. 21.4 days (s = 13.9 days) (p=0.03), intensive care unit length of stay 1.7 (s = 2.9 days) vs. 3 days (s = 4.7 days) (p=0.45), and the rate of mortality 14% vs. 30% (RR=0.48; p=NS) between in-house and send-out group within treatment group.

Conclusion: Local SDC monitoring of triazole antifungal medications results in faster turn-around- times, lower antifungal drug costs and may improve patient clinical outcomes for patients receiving treatment courses at our institution. Patients receiving triazoles for prophylaxis indications do not see improved outcomes. Further study is warranted to evaluate the contribution of send-out testing policies and sources to the improvement in patient care at other institutions.

Poster Title: High-dose mycophenolate following pancreas transplantation: evaluation of a hospital protocol

Primary Author: Nathan Menninga, University of Wisconsin-Madison School of Pharmacy, Wisconsin; **Email:** nate.menninga@wisc.edu

Additional Author (s):
Shelby Tjugum
Margaret Jorgenson
Jillian Fose
Robert Redfield

Purpose: Mycophenolate is an antiproliferative agent that is a mainstay of maintenance immunosuppression following solid organ transplant. Pancreas allografts (PTX) are thought to convey increased immunologic risk over renal transplants, and may require aggressive maintenance immunosuppression to prevent rejection. Per our institutional protocol, PTX recipients are initiated on intensified dosing of mycophenolate, defined as 2160 mg per day of mycophenolate sodium (MYF) or 3000 mg per day of mycophenolate mofetil (MMF) immediately post-transplant. The purpose of this study was to evaluate compliance with the protocol and determine the etiology of protocol violation.

Methods: A retrospective review of electronic medical records of adults who underwent PTX transplantation at UW Hospital from January 1, 2011 through July 1, 2015 was conducted. Subjects were included if they were discharged from their transplant encounter with an immunosuppression regimen containing mycophenolate. Baseline demographic data were collected for all patients. The mycophenolate dose on discharge along with all dose reductions that occurred within the first year following transplantation were recorded. When available, the indication for the reduction was noted. The percentages of subjects who required a dose reduction from intensified therapy, as well as the corresponding indication for the reduction, were calculated to determine common indications for protocol deviation.

Results: A total of 197 PTX transplants occurred during the study period. Four of these PTX recipients were not discharged on mycophenolate and were excluded from the analysis. Of note, 5 PTX recipients were transplanted twice during the study period with each transplant counted as a separate opportunity for protocol compliance. The majority of patients (n equals 113, 59 percent) were discharged on mycophenolate intensified dosing per our institutional protocol. Within 30 days of transplantation, 33 percent (n equals 37) required a dose reduction. An additional 34 percent (n equals 38) required a dose reduction within 3 months. The most common indications for dose reduction were diarrhea (n equals 41, 40 percent) and neutropenia (n equals 16, 16 percent). The most common discharge regimen that deviated from institutional protocol was a total daily dose of 1440 mg of MYF or 2000 mg of MMF (n equals 70, 36 percent). In comparison with protocol regimens, only 5 percent (n equals 4) of patients discharged on non-protocol mycophenolate required a dose reduction within 30 days and an additional 28 percent (n equals 22) of these patient required a dose reduction within 3 months.

Conclusion: Our study indicates historical compliance with an institutional protocol of intensified dose maintenance mycophenolate following PTX is not high. Of the patients who received protocol dosing upon discharge, a majority required dose reductions within 3 months as a result of adverse events. These findings suggest that intensified dosing of mycophenolate is not well tolerated after PTX in our patient population. A review of outcomes should be conducted to determine if the potential benefits of this protocol outweigh risks associated with poor tolerance.

Session-Board Number: 3-351

Poster Title: Evaluation of multi-dose tamper evident packaging at an academic medical center

Primary Author: Taryn Hinners, university of wisconsin-madison school of pharmacy, Wisconsin; **Email:** thinners@wisc.edu

Purpose: The FDA only has requirements for prescription drug packaging sufficient to protect stability of the drug, not tamper resistance. ISMP Quarterly Action Agenda identified a situation where a used oxymetazoline was restocked and almost administered to a second patient until the doctor noticed there was blood on the nozzle. The purpose of this project was to identify types of packaging for non-injectable, multi-dose medications and assess whether they comply with OTC tamper resistance standards. Secondly, to develop recommendations for optimization of packaging and dispensing of non-injectable, multi-dose medications.

Methods: ● Performed a literature search of tamper evident packaging best practices for non-injectable, multi-dose products
● Evaluated non-injectable, multi-dose medications dispensed in an inpatient pharmacy and categorized the type of tamper evidence packaging
● Assessed compliance with best practice standards for tamper evidence
● Developed recommendations to improve non-injectable multi-dose medication tamper evident packaging practices

Results: A total of 252 non-injectable, multi-dose products were evaluated for tamper evident packaging. The fraction of non-injectable, multi-dose medications for which packaging aligned with OTC tamper resistance standards was 140/252 (56%). The fraction of non-injectable, multi-dose medications that are packaged in a manufacturer box was 159/252 (63%). Of these medications that were packaged in a box, 52 (21%) had the box sealed shut, serving as the visible form of tamper evident packaging.

Conclusion: A majority (56%) of non-injectable, multi-dose medications dispensed from the UW Health inpatient pharmacy aligned with tamper resistance best practices. Yet, there is opportunity to improve packaging and dispensing of non-injectable, multi-dose medications to ensure tamper evident packaging due to inconsistencies of manufacturing packaging.
The following recommendations were developed:

Removal of products from manufacturer boxes for dispensing.

Standardization of tamper evident seals for multi-dose items in which the manufacturer supplied product doesn't comply with best practices.

Purchase products based on optimal tamper evident packaging.

Educate pharmacy staff about evaluating tamper evident packing during medication dispensing and returns to the pharmacy.

Poster Title: Pharmacist-driven multidisciplinary order set intervention to streamline organ donor medication orders in an academic level one trauma/surgical intensive care unit.

Primary Author: Benjamin Heikkinen, University of Wisconsin-Madison School of Pharmacy, Wisconsin; **Email:** bheikkinen@wisc.edu

Additional Author (s):
Spencer Laehn
Lindsey Dailey
Sarah Paul
William Peppard

Purpose: Successful organ donation depends on the proper management of cardiovascular, endocrine, and hemodynamic management, to optimize the condition of the organ(s). A delay in supportive medication turnaround time was noted by the Wisconsin Donor Network (WDN) coordinators and hospital nursing staff. Manual medication order entry and "non-stat" priority dispense processing were noted to be contributing factors. To address this delay, a multidisciplinary quality improvement effort was undertaken, in collaboration with the WDN, to simplify how donor medications were ordered, verified, distributed, and administered. The objective of this study was to streamline the medication use process and improve medication turnaround time.

Methods: This was a single-center, quasi-experimental, retrospective chart review of organ donor medication orders at Froedtert Hospital. All patients who had WDN orders initiated and subsequent WDN medications administered were included. The pre-intervention data was collected from September 1, 2014 – February 28, 2015, while the post-intervention data was collected from August 1, 2015 – September 13, 2016. The intervention included the implementation of an organ donation medication order set. Froedtert hospital standard stock formulations and distribution processes were matched with the products included in the order set. The WDN along with nursing staff were encouraged to communicate with pharmacists regarding upcoming WDN orders to increase vigilance and improve time to order verification. Finally, the order set was ordered as "stat" which electronically flags pharmacy and nursing staff in real time. The primary outcome was the average turnaround time (defined as the total

time from medication order to administration) for all medications studied within the pre-intervention versus post-intervention groups. The secondary outcome was the total turnaround time for each individual medication in the pre-intervention versus post-intervention groups. Medications that were analyzed included: hydrocortisone, methylprednisolone, insulin, levothyroxine bolus, and levothyroxine continuous infusion.

Results: A total of 15 patients representing 65 orders were identified pre-intervention and 13 patients representing 64 orders were identified post-intervention. The intervention was utilized in all post-intervention medication orders. The average turnaround time for all medications was significantly longer in the pre-intervention group compared to the post-intervention group, 105.8 vs. 85.3 minutes, p < 0.007. When each medication was analyzed individually, only the turnaround time for levothyroxine continuous infusion showed a statistical improvement between pre- and post-intervention groups (106.4 vs. 78.4, p < 0.029). The other medications included in this analysis were: hydrocortisone (110.7 vs. 92.3, p=0.208), methylprednisolone (122.4 vs. 86, p=0.157), insulin (86.3 vs. 82.2, p=0.801), and levothyroxine bolus (103.1 vs. 87.2, p=0.220).

Conclusion: The use of the organ donation order set intervention significantly shortened mean medication turnaround time and has improved customer service to patients, nurses, and WDN coordinators.

Poster Title: Risk of venous thromboembolism after lung transplant before and after implementation of the Lung Allocation Score

Primary Author: Katherine Rolling, University of Wisconsin-Madison School of Pharmacy, Wisconsin; **Email:** kebrodsky@wisc.edu

Additional Author (s):
Mary Hayney
Rebecca Felkner

Purpose: Venous thromboembolism (VTE) is a significant cause of morbidity and mortality following surgery, and the incidence following lung transplantation is particularly high. On May 4, 2005 the United Network of Organ Sharing (UNOS) switched from time-on-list prioritization to the new Lung Allocation Score (LAS) for lung allocation. The LAS was developed to allocate lungs to those with both the most urgent need as well as those predicted to have the best outcomes after transplant. The purpose of this study was to describe the incidence of VTE within the first year of transplant before and after the implementation of the LAS.

Methods: Manual chart review was performed on patients receiving primary lung transplant at University of Wisconsin Hospital from January 1, 2000 to May 31, 2014 with data collected through July 31, 2014. Data collected included established VTE risk factors at time of transplant as well as at the time of VTE, as applicable. Clinical information regarding primary transplant and VTE events was also collected. This study received approval by the University of Wisconsin institutional review board.
This material is the result of work supported with resources and the use of facilities at the William S. Middleton Memorial Veterans Hospital, Madison, WI. The contents do not represent views of the Department of Veterans Affairs or the United States Government.

Results: Four hundred thirty-eight patients were included in the study. Among patients who had a VTE in the first year, those transplanted after LAS implementation had higher BMI (26.5 plus or minus 5.0 vs. 22.1 plus or minus 3.1; p equals 0.03); all other demographics between groups were comparable. The overall incidence of VTE following lung transplant during the study period was 19.4 percent. The incidence of VTE in the first year and the first 90 days post-

transplant was 14.3 percent and 10.5 percent, respectively. There was a increased risk of VTE in the first year for those transplanted post-LAS implementation (OR 3.61; 95 percent CI, 1.67 to 7.80; p equals 0.001) as well as an increased risk of VTE in the first 90 days after surgery post-LAS (OR 3.35; 95 percent CI 1.38 to 8.09; p equals 0.005). Overall, risk of VTE was higher in the first 90 days versus days 91 to 365 (OR 2.59; 95 percent CI 1.46 to 4.60; p equals 0.001). While overall presence of VTE did not affect survival (p equals 0.6), there was decreased survival among patients who had their VTE in the first year versus patients who did not (p less than 0.0001).

Conclusion: After the implementation of the LAS by UNOS, University of Wisconsin Hospital has seen an increased incidence of VTE in the first year after lung transplantation. This may be associated with the prioritization of sicker patients on the waiting list. The increased risk of VTE in the first year after transplant and accompanying increase in mortality may warrant increasing the length of post-surgical prophylaxis to cover a greater period of the increased risk. The highest incidence of VTE occurred in the first 90 days, which may represent a more manageable period for prophylaxis than the entire first year.

Submission Category: Pediatrics

Submission Type: Descriptive Report

Session-Board Number: 5a-001

Poster Title: Assessing pediatric medication use experiences and patient counseling in community pharmacies: perspectives of children

Primary Author: Mara Rubin, University of Pittsburgh School of Pharmacy, Pennsylvania; **Email:** mfr18@pitt.edu

Additional Author (s):
Amanda Brothers
Olufunmilola Abraham

Purpose: There has been a substantial increase of children diagnosed with chronic conditions, with over 6 million children in the United States requiring management with medications. Children with chronic conditions have a higher risk of improper administration, dosing errors, and nonadherence. To improve adherence, disease-management, and health outcomes, pediatric patients need to be directly educated about the safe and effective use of medicines. This study aimed to explore the perspectives of children regarding: (1) pediatric patients' knowledge and medication use experiences for chronic conditions; (2) how they want to learn about medicines; and (3) perceptions of community pharmacist-provided counseling.

Methods: Patients were recruited from three community pharmacies; one located in rural Western North Carolina, and two located in an urban region of Western Pennsylvania. Semi-structured interviews (n=20) were conducted with children aged 7 to 17 years of age taking a medication for at least one chronic illness such as asthma, diabetes, depression and attention deficit hyperactivity disorder. Informed consent was obtained from all participants before the interview was initiated. The Institutional Review Boards of the University of Pittsburgh and the University of North Carolina approved this qualitative study. Data was collected from July 2015 to December 2015. The interview guide was developed and piloted to elicit children's perspectives of their knowledge and medication use experiences, facilitators of patient counseling, and perceptions of community pharmacists. Interviews were face-to-face for Pennsylvania participants and via telephone for North Carolina participants. Interviews lasted approximately 20 minutes, were audio-recorded, and professionally transcribed. Transcripts were reviewed for accuracy and a codebook was developed for data analysis. NVivo 10: QSR International data analysis program was used for assessing content and thematic analysis to

identify relevant codes and themes. In order to increase inter-rater reliability, four researchers met to review all codes, their definitions, and refine the codebook. Inter-rate reliability was acceptable (kappa=0.79). Coding discrepancies were discussed and resolved by the research team.

Results: All participants were non-Hispanic White and most were female (60%), aged aged 12 to 14 (45%) and in the ninth grade or above (50%). Six themes emerged from participant responses: (1) child's knowledge, self-management, and medication use experiences; (2) essential medication information and sources; (3) child's frequent absence from the pharmacy; (4) patient counseling needs and recommendations; (5) use of interactive technologies to facilitate learning about medicines; and (6) perceptions of pharmacists. Children were confident in their ability to self-manage their medications without parental supervision, but also stated they had occasional difficulty in remembering to take their medicines. Most children expressed that they are comfortable and receptive to pharmacists educating them about their medications, particularly how medications affect the human body, how they were manufactured, and related research studies. Children reported that their absence during medication pick-up at community pharmacies was a barrier to receiving counseling by pharmacists. Even if the children said they were present in the pharmacy, they were often elsewhere in the store while their parents picked up the prescription and interacted with pharmacy staff. Children recommended the use of interactive and educational technologies such as TV kiosks and tablets to facilitate pediatric counseling.

Conclusion: Findings suggest that children are frequently not present at pharmacies during prescription pickup; however, children are comfortable and open to pediatric medication counseling by pharmacists. Direct pediatric medication counseling by pharmacists in community pharmacies can improve pharmacy practice by creating accessible clinical-based medication services in the community for children. Educational interventions incorporating interactive technologies need to be developed to facilitate clinical pediatric medication counseling in the community. Further research is warranted to examine the effects of interactive technology use by pharmacists to increase pediatric medication counseling and improve children's knowledge and safe use of their medicines.

Poster Title: Evaluating the utility of the "STOPP" criteria as a tool for clinicians working in transitions of care in elderly patients.

Primary Author: Jonathan Worley, Campbell University College of Pharmacy & Health Sciences, North Carolina; **Email:** jlworley1219@email.campbell.edu

Additional Author (s):
Nita Johnston

Purpose: The healthcare system, as it stands, offers countless opportunities in which miscommunication, lack of understanding, and a lack of resources can lead to sub-optimal care for the patient. One such area is the period of transition that occurs following the discharge from inpatient care. This study is intended to evaluate the utility of the STOPP (Screening Tool of Older Persons' potentially inappropriate Prescriptions) portion of the STOPP and START (Screening Tool to Alert doctors to Right Treatment) criteria in the determination if discharge medications for the elderly are appropriate.

Methods: This retrospective/prospective study focused strictly on the STOPP criteria for cardiovascular and CNS drugs. This project was initiated and completed during an introductory hospital rotation in June, 2016, with limitations placed to ensure completion of the project: only STOPP criteria was utilized for each patient and only cardiovascular and CNS "STOPP" medications were analyzed.
Retrospectively, the hospital's electronic health record software was utilized to generate a list of 25 discharged patients, greater than or equal to 65 years old in the month of May, 2016. This was done to establish a baseline of the patient population. Each patient's admission and discharge medication list was evaluated using specific aspects of the "STOPP" criteria. Prospectively, patient's marked for discharge that were greater than or equal to 65 years old were analyzed in the same manner on a daily basis until a similar sample size was reached. For both sections of the study, "STOPP" criteria was used to determine the total number of potentially inappropriate medications. The percentage of patients in the prospective sample being discharged with "STOPP" medications was assessed. The percentage of patients being discharged on "STOPP" medications in the retrospective portion was then compared to the

percentage of patients in the prospective portion following interventions and recommendations made to the discharging physician.

Results: Retrospective data reveals a total of 12, out of 25, patients with "STOPP" medications listed on their profile at discharge. Fifteen (15) medications meeting "STOPP" criteria were found ordered for these 12 patients at discharge; fourteen (14) "STOPP" medications were listed on their pre-admission inpatient profile. A total of 12 interventions would have been possible in this patient population with 48% of patients being discharged on "STOPP" medications.

Prospectively, a total of 11, out of 22, patients were identified with "STOPP" medications on their profile at discharge. A total of 14 "STOPP" medications were found ordered for these patients at discharge and 12 "STOPP" meds at inpatient admission. We identified 11 interventions that were possible, and, of these 11 possibilities, 5 interventions were made. The remaining 6 possible interventions were categorized as "Intervention not needed/recommended". Before interventions were made, 50% of patients in this sample were being discharged on "STOPP" medications; this percentage decreased to 36.36% after interventions.

Conclusion: Using "STOPP" criteria to prospectively analyze discharge medications by the pharmacist led to a reduced number of patients discharged on "STOPP" medications. Additionally, the retrospective data showed similar intervention possibilities. Note, the "START/STOPP" criteria is not intended to replace clinical judgement and sound decision making. Contrastingly, "START/STOPP" criteria is designed to provide a reference and/or starting point in evaluating the suitability of elderly patient's medications, which this study supports. However, further research utilizing the full "START/STOPP" criteria is needed to determine if this should be routine monitoring by clinical pharmacist at transitions of care.

Poster Title: Medication use evaluation of aztreonam in a community hospital

Primary Author: Dania Lopez, University of Arizona College of Pharmacy, Arizona; **Email:** dlopez@pharmacy.arizona.edu

Additional Author (s):
Dana Bowers

Purpose: Self-reported penicillin allergies play a major role in antibiotic selection. Approximately five percent of the general population of hospitalized patients report a penicillin allergy. In patients with a penicillin allergy, aztreonam is an alternative broad spectrum antibiotic for suspected and/or confirmed Gram-negative infections. Using alternative antibiotics such as aztreonam for non-IgE mediated penicillin allergy has been linked to unfavorable clinical outcomes. The purpose of this study was to evaluate the utilization of aztreonam in a community hospital.

Methods: This was a single center, retrospective medication use evaluation of all patients, aged 18 years or older who received at least one dose of aztreonam from January 1-March 31, 2016 at Kingman Regional Medical Center in Kingman, Arizona. Patients who received multiple course of aztreonam were included only once. The data were obtained from electronic medical records and included: age, gender, duration of treatment, documented penicillin allergy, type of allergic reaction, dose, duration, receipt of other beta-lactams and microbiological data. The primary endpoint was to evaluate the utilization of aztreonam. Data were analyzed and reported as descriptive statistics.

Results: A total of 42 patients received aztreonam during the study period. Sixty-four percent of patients were female and the median age was 64 years. Fifty-two percent of aztreonam use was for the treatment of pneumonia. The mean duration of treatment was 1.3 days (standard deviation of 1.5 days). Thirty-six patients reported a penicillin allergy. Out of these patients, a total of 19 (53 percent) reported an "unknown" reaction to penicillin. Three patients (8 percent) reported an IgE mediated reaction to penicillin (anaphylaxis). Most of the patients who reported a penicillin allergy either received a beta-lactam antibiotic during a previous hospital admission (16 patients, 44 percent) or during or after the study period (14 patients, 39

percent). Two patients who reported anaphylaxis to penicillin were safely administered other beta-lactams after documentation of penicillin allergy.

Conclusion: Most people who received aztreonam had non-IgE mediated reactions to penicillin and received other beta-lactams prior to and/or after aztreonam. This represents an opportunity for better assessment of penicillin allergy to ensure appropriate utilization of aztreonam. Criteria will be established to help guide aztreonam prescribing for patients with true, IgE mediated penicillin allergy.

Poster Title: Impact of student pharmacist-led motivational interviewing on antibiotic adherence in an ambulatory care outpatient pharmacy setting

Primary Author: Katherine Yang, University of Michigan College of Pharmacy, Michigan; **Email:** katyang@med.umich.edu

Additional Author (s):
Heba Sobh
Miranda Rippin
Dawn Hall
Steven Duda

Purpose: Antibiotic resistance is a growing concern worldwide, which is perpetuated by the inappropriate use of antibiotics. Inappropriate antibiotic uses include antibiotic non-adherence as well as incorrect drug choice, dose, or duration. To combat resistance, techniques to improve antibiotic adherence, such as motivational interviewing (MI), have potential to aid antimicrobial stewardship efforts in the outpatient setting. The purpose of this study was to assess the impact of a student pharmacist-led MI on antibiotic adherence rates in outpatients who were prescribed an oral antibiotic.

Methods: The institutional review board approved this prospective, cohort study. Patients at least 18 years old who were prescribed an oral antibiotic for at least three days in duration were included from June through July 2016. Patients unable to speak English, on concurrent use of antibiotics for another etiology, without electronic health record documentation, lost to follow-up, or switched off the antibiotic were excluded. A student pharmacist trained in motivational interviewing (MI) conducted the counseling sessions from Monday to Friday between 8:00am – 4:30pm. Patients without a MI were the comparator group. Data collection included demographics, antibiotic therapy, duration, and disease state. All patients were offered a follow-up phone call on the anticipated antibiotic completion date, which included systematic assessment of adherence and satisfaction. During the calls, four survey questions were asked to both groups to evaluate adherence and five survey questions were asked to assess patient satisfaction for the MI group. The primary outcome was adherence rate defined as completion of antibiotic on the anticipated completion date, assuming the first dose was

taken the day the medication was obtained. Secondary outcomes included patient satisfaction to the MI and evaluation of prescribing patterns and appropriateness.

Results: We enrolled 176 patients who were prescribed an oral antibiotic for at least 3 days. Of the 176 patients, 55 were identified as motivational interviewed (MI), while 121 had no MI. Adherence rate to antibiotic regimens was 87% (46/55) in the MI group, while the control group had an adherence rate of 57% (69/121); ($p < 0.01$). Satisfaction for the MI was assessed on a 5 point scale, with 1 being very unsatisfied and 5 being very satisfied. 3.6% rated the MI as a 3, 1.8% as a 4 and 94.5% as a 5. The mean satisfaction rate for the MI was 98% (4.9/5; SD=0.39). Prescribing patterns were analyzed in those who were diagnosed with bronchitis and streptococcal pharyngitis. According to institutional bronchitis guidelines, 82% (14/17) of medications were unecessary and 41% (7/17) had the incorrect therapy duration ($p < 0.05$). Additionally, according to pharyngitis guidelines, 84% (16/19) of medications were unnecessary and 6% (1/19) had the incorrect therapy duration ($p < 0.01$).

Conclusion: Use of motivational interviewing in patients who were prescribed an oral antibiotic for at least 3 days improved adherence rates and was associated with high satisfaction rates. Further studies would be needed to validate the impact of student pharmacist-led interviewing on antibiotic adherence and subsequent patient outcomes. In addition, evaluation of antibiotic prescribing patterns identified several important areas for outpatient antimicrobial stewardship intervention.

Submission Category: Ambulatory Care

Submission Type: Descriptive Report

Session-Board Number: 5a-005

Poster Title: Role of pharmacy students and residents in smoking cessation intervention at a safety net clinic in Skid Row, Los Angeles

Primary Author: Hoang Ly, University of Southern California School of Pharmacy, California; **Email:** hoangly@usc.edu

Additional Author (s):
Miranda Wong
Lauren Eng
Christie Vo
Danielle Stutzman

Purpose: The Center for Community Health (CCH) is an urban safety net clinic located in the heart of downtown Los Angeles that serves patients with a variety of chronic illnesses, a significant proportion with co-occurring mental illness and substance use disorders. Safety net clinic providers describe barriers to offering smoking cessation interventions such as lack of time, perceived lack of patient readiness to change, and inadequate provider and patient resources. In 2011, student pharmacists from the University of Southern California (USC) School of Pharmacy launched a smoking cessation program at CCH in an effort to reduce barriers to smoking cessation interventions.

Methods: Several changes were instituted to the USC School of Pharmacy smoking cessation program during the 2015-2016 academic year. First, student pharmacists were required to attend a training session at the beginning of each semester on counseling points for weight and stress management, behavioral modifications, motivational interviewing, and nicotine replacement therapy (NRT) to improve quality of patient counseling. While NRT was previously the main focus, strategies to avoid a slip, how to deal with cravings through the DEADS (delay, escape, avoid, distract, substitute) strategy, and setting SMART (specific, measurable, attainable/achievable, relevant, timely) goals were incorporated to help participants deal with triggers or cravings. Furthermore, a monthly check-in session through summer was initiated to ensure continuity of care. The role of resident pharmacists expanded to include more extensive discussion with students and under a newly developed collaborative practice agreement, the

resident pharmacist prescribed nicotine gum, lozenges, and patches. Funds for nicotine patches were donated by USC Graduate Student Government.

Results: Since late 2015, the smoking cessation program has had 13 participants. Because of the nature of the population, many have been lost in follow-up. To date, 3 participants have been smoke free for at least 1 month. The presentation on healthcare related topics, NRT counseling, cessation management strategies, motivational interviewing, and writing SOAP notes reinforced learning from the classroom. Participants benefited from learning about their disease state and how it relates to smoking, having a social support group, one-on-one counseling, and pharmacist access. With the combination of all these services there was an increase in the success of the participants and check-in sessions ensure they remain smoke-free for life.

Conclusion: Since 2011, the USC School of Pharmacy has offered pharmacological tools and social support to a vulnerable population in the heart of downtown Los Angeles in an attempt to reduce barriers to smoking cessation interventions. Changes made in the 2015-2016 academic year allowed all individuals involved in this program to benefit: student pharmacists can apply their knowledge in a clinical setting, patients are provided the appropriate resources to quit smoking, and resident pharmacists can precept students and utilize their clinical expertise.

Submission Type: Descriptive Report

Session-Board Number: 5a-006

Poster Title: Design and implementation of antibiotic lock therapies for the treatment of catheter-related bloodstream infections.

Primary Author: Hayden Ingram, Pacific University, Oregon; **Email:** ingr1485@pacificu.edu

Additional Author (s):
Tyler Larson

Purpose: Antibiotic lock therapy is an important method for sterilizing a catheter lumen in patients with confirmed blood stream infections in order to salvage the long-term catheter. A lack of a current protocol with recipes to guide antibiotic lock therapy as well as a concern for patient safety due to potential exposure to heparin in lock solutions was identified. This project was designed to identify a variety of antibiotic lock recipes from current literature with low amounts of heparin and then create computerized physician order entry sets for these recipes.

Methods: A review of literature was conducted to identify recipes for antibiotic locks and create a protocol to guide which antibiotic solution to use for different organisms (i.e. cefazolin lock for MSSA) and how much heparin was needed for stability of the antibiotic lock. Each antibiotic lock was added to the computerized physician order entry, allowing providers to choose from the variety of recipes constructed in this project. Charge codes were assigned for each recipe and were based off the most expensive drugs costs and the pharmacy's flat compounding fee. Recipes were built to print on labels in the pharmacy with specific instructions for pharmacy staff on how to create the solution along with any specific precautions.

Results: A total of 24 articles were reviewed and 16 antimicrobial lock recipes, 10 for non-hemodialysis catheters and 6 for hemodialysis catheters, were added to computerized physician order entry sets, nearly tripling options for providers. Assessment of the literature was used to guide the creation of a protocol with recommendations for 8 different microbiological culture results. On average the amount of heparin in the lock solution decreased significantly. Only 1 of the 10 non-hemodialysis catheter recipes contains any heparin; at a concentration of 100 units/mL. Also the protocol limited the amount volume of antibiotic lock solution from 5mL to 3mL and included an optional IV consult to determine an

appropriate volume to administer to a patient. Considering the approximate volume of a catheter to be around 2.5mL, the decrease in volume and concentration of heparin in solutions for non-hemodialysis catheters represents a potential decrease heparin exposure of 12,500-25,000 units (if line was inappropriately flushed) to 0-300 units.

Conclusion: Literature is available to guide the creation of both antibiotic lock protocols and lock solutions that contain lower amounts of heparin than presented in current Infectious Disease Society of America (IDSA) guidelines. The expansion of antibiotic lock recipes allows physicians to choose from a larger variety of antibiotics and minimized unnecessary exposure to concentrated heparin solutions.

Poster Title: Methylnaltrexone bromide utilization in trauma patients

Primary Author: Aaron Coon, Roseman University of Health Sciences, Utah; **Email:** acoon@student.roseman.edu

Additional Author (s):
Paul Wohlt

Purpose: Methylnaltrexone Bromide is a subcutaneously-administered peripherally-acting mu-opioid receptor antagonist. The FDA approved the use of methylnaltrexone for the treatment of opioid induced constipation in patients with chronic non-cancer pain in September 2014. At Intermountain Medical Center, methylnaltrexone is on formulary with a restriction to only use in patients that have failed laxative therapy. The purpose of this medication use evaluation was to determine if methylnaltrexone was being used appropriately in trauma patients, specifically if patients had tried and failed laxative therapy as instructed by the bowel protocol, and to analyze the most cost effective treatment.

Methods: All trauma patients at Intermountain Medical Center, age 18 and above, who received methylnaltrexone from February 1st, 2016 to June 1st, 2016 were reviewed, totaling 42 patients. Every patient in the sample had previously been treated with opioids, and had tried at least 1 laxative. Patients with a colostomy were excluded from the study. Data were collected for each patient documenting bowel protocol compliance, length of stay, length of time patients were going without a bowel movement, length of time between methylnaltrexone dose and bowel movement, other gastrointestinal agents given at the same time, and if loose stools were present. Cost of methylnaltrexone, and alternative gastrointestinal agents were collected, analyzed and compared.

Results: Methylnaltrexone was effective with the majority of patients having a bowel movement within an average of 0.8 days. Intermountain Health Care's formulary restricts the use of methylnaltrexone to patients who have failed laxative therapy; however the bowel protocol was followed only in 8 of the 42 patients (19%). The average length of time that patients went without a bowel movement was 4.2 days. 88% of patients remained in patient for at least one day after their dose. Thirty seven patients were not discharged for at least one day

after receiving their dose of methylnaltrexone, 23 remained for at least 2 days afterwards, and 16 remained for at least 3 days, giving many of these patients the opportunity to try cheaper alternative agents prior to the use of methylnaltrexone. The manufacturer recommends holding laxatives for at least 3 days after a dose methylnaltrexone is given. This was not the case for most of the patients in this review, 38 out of 42 were still using other gastrointestinal agents within the 3 days. Ten of these patients had loose stools for at least 2 days after receiving their dose of methylnaltrexone.

Conclusion: Allowing methylnaltrexone to be used for patients that have tried laxative therapy for at least 3 days, and are being kept in the hospital for the sole reason that they have not had a bowel movement could save the patient $2,327.96 per day, a total saving of $97,774.32 for the 42 patients during the 4 month period. This was not the case for the majority of patients in the evaluation. Moving forward all alternative agents should be attempted for patients not meeting the above criteria to make sure that we are not giving our patients unneeded and costly medications.

Submission Type: Descriptive Report

Session-Board Number: 5a-008

Poster Title: Reduction in missing medications by education intervention

Primary Author: Sena Avila, University of Arizona College of Pharmacy, Arizona; **Email:** avila@pharmacy.arizona.edu

Additional Author (s):
Mark DiGiacomo
Danielle Rhine
Bryan Edwards

Purpose: Missing medications can lead to duplication of work, delays in workflow, and most importantly, it can delay the administration of medications. Inpatient delays in medication administration can lead to increases in both recovery time and length of hospital admission. The purpose of this study was to assess the effects of educating pharmacy and nursing staff at a Veterans Affairs Health Care System on the number of missing medication requests, and to determine whether the total number of missing medication requests would decrease.

Methods: Baseline data were collected eight days prior to an education intervention. Education sessions were provided to both pharmacy and nursing staff. Due to limited time, only one ward was selected for intervention. Nursing staff on that ward received two education sessions to cover all shifts worked in a twenty-four hour period. Weekend staff who were unable to attend the education session received an email which included the education materials. Nurses were educated on proper procurement, storage, and return of tubes and medications. Additionally, nurses were provided handouts and an email that contained information on the workflow in the pharmacy.
The pharmacy staff was asked to tube medications to patient wards every 30 minutes, send expensive, short dated, patient owned medications before administration time, package out of stock items immediately or ask the pharmacist to change orders, and send all medications, including the emergency department medications, immediately. Pharmacists were advised to verify orders as soon as possible and identify when it was necessary to send a first dose. Post intervention data were collected for eight days following intervention. Additionally, the Bar Code Medication Administration (BCMA) Committee had a meeting prior to the intervention, in which missing medication problems were discussed. To assess whether the BCMA meeting had

an effect on the number of missing medication requests, data were collected post BCMA meeting as well.

Results: There were 137 total missing medication requests during the pre-intervention week. Both 0900 and 2100 administration times had the most missing medication requests along with medications that were scheduled to be administered now, as needed, or once. Furthermore, data showed that some nurses had higher missing medication requests than others. The average time to order verification by a pharmacist was 20 minutes. Post-BCMA meeting, there were 98 total missing medication requests (28 percent reduction). Post-intervention data showed a further reduction to 68 total missing medication requests, which was a 50 percent reduction from baseline. Both 0900 and 2100 continued to have the most missing medication requests; however, there was a 55 percent reduction at 0900 and a 42 percent reduction at 2100. Post intervention average time to order verification by a pharmacist decreased to 16 minutes (20 percent reduction).

Conclusion: The education intervention resulted in a 50 percent total reduction in the number of missing medication requests and a 20 percent improvement in the average time to order verification by a pharmacist. In conclusion, education has an impact on reducing missing medication requests.

Poster Title: Post- Transplant Monitoring by Community Pharmacists May Increase Early Detection of Complications in Renal Transplant Recipients: A Medicare Claims Analysis

Primary Author: Molli Gremillion, University of Louisiana at Monroe College of Pharamacy, Louisiana; **Email:** mgrem315@gmail.com

Purpose: Kidney transplantation is associated with lifelong immunosuppressive treatment, which may cause the recipient to develop further immunologic and endocrine disorders. Several co-morbid disease states, like diabetes, can arise during the post-transplant period and may go undetected due to infrequent screening protocols. The purpose of this study is to determine if community pharmacist monitoring would be a suitable solution to undetected co-morbidities that may occur following a patient's first year post-transplant.

Methods: Tacrolimus and mycophenolate Medicare claims from 2013 were analyzed to determine the average number of claims kidney transplant recipient made for each drug.

Results: Transplant recipients in their second or third year post-transplant and who were over the age of 65 were 5.24 (+/-0.24) times more likely to visit a pharmacy to pick up their medication than they were to visit an outpatient clinic for a transplant follow-up. Patients in their second or third year post- transplant and under the age of 65 were 4.70 (+/-0.0071) times more likely to visit a pharmacy to pick up their medication than an outpatient clinic.

Conclusion: For patients in their second or third year post-transplant, community pharmacist monitoring may be a suitable addition to clinical based transplant pharmacist monitoring for co-morbid disease states.

Submission Type: Evaluative Study

Session-Board Number: 5a-010

Poster Title: Retrospective Medication Use Evaluation of Naloxone at the Wilmington VA Medical Center

Primary Author: Kayla Garzio, Philadelphia College of Pharmacy, Pennsylvania; **Email:** kgarzio@mail.usciences.edu

Additional Author (s):
Heather Murphy

Purpose: The purpose of this retrospective medication use evaluation was to evaluate naloxone distribution at the Wilmington VA Medical Center.

Methods: All intramuscular and intranasal naloxone prescriptions were reviewed from March 31, 2016 to June 30, 2016. The list included patient name, prescriber name, and location. Data collection included risk factors identified on CPRS note template versus problem list, as well as occurrence of opioid overdose. The charts were reviewed to ensure the requesting provider accurately completed the note template.

Results: There were sixty-four naloxone prescriptions dispensed during the evaluated time period. Of the sixty-four charts reviewed, four requests were not appropriately filled out where the risk factor selected did not correspond with a diagnosis on the patient's problem list. The most common risk factors identified included high opioid dose (31%), current or history of substance use disorder (25%), and opioid use with comorbid mental health disorder (23%). There were four successful overdose reversals reported.

Conclusion: There was approximately a 6% error rate in selecting the correct risk factors for opioid overdose, thus suggesting the template is easy to use and straight forward for providers. Provider education over time increased awareness thus increasing prescriptions in previously lacking locations. Patient education occurs at the time naloxone is ordered by the physician, pharmacist, or nursing staff and is of utmost importance for overdose recognition and correct management.

Poster Title: Comparison of Hepatitis C Medication FDA Indications and Guideline Recommendations vs. Sustained virologic response (SVR) rates in patients with Genotype 2 and 3

Primary Author: Leigh Cervino, University of Maryland School of Pharmacy, Maryland; **Email:** lcervino@umaryland.edu

Additional Author (s):
Lauren Hynicka

Purpose: To compare package labeling and guideline recommendations to sustained virologic response rates in primary literature in order to determine differences in various reference recommendations for the treatment of patients with chronic viral Hepatitis C infected with genotype 2 and 3.

Methods: Using the AASLD/IDSA guideline recommendations pre and post velpatasvir/sofosbuvir approval, package labeling was reviewed for each medication recommended by the guidelines in the treatment of patients infected with genotype 2 and 3 for FDA approval. The medications reviewed included velpatasvir/sofosbuvir, sofosbuvir plus ribavirin, and sofosbuvir plus daclatasvir for genotype 2 and 3 infected patients. In addition, the AASLD/IDSA guideline recommendations and the strength of the guideline recommendations were compared to the values of sustained virologic response after 12 weeks (SVR-12) .

Results: With the approval of velpatasvir/sofosbuvir came significant changes to the AASLD/IDSA guideline recommendations for the treatment of patients infected with genotype 2 and 3 Hepatitis C. Most notably was the creation of a do not use list which included sofosbuvir plus ribavirin regimens. FDA approved treatment for patients with genotype 2 include velpatasvir/sofosbuvir and sofosbuvir. AASLD/IDSA guidelines recommend use of either velpatasvir/sofosbuvir or sofosbuvir plus daclatasvir in the treatment of this patient population. Daclatasvir is not FDA approved for use in patients infected with genotype 2. Sustained virologic response rates in the treatment of patients infected with genotype 2 are 99-100%, 86-94%, and 89-100% with velpatasvir/sofosbuvir, sofosbuvir plus ribavirin and sofosbuvir plus daclatasvir, respectively. FDA approved treatment options for patients infected with genotype 3 include

velpatasvir/sofosbuvir and sofosbuvir and daclatasvir. AASLD/IDSA guidelines recommend use of either velpatasvir/sofosbuvir or sofosbuvir plus daclatasvir in the treatment of these patients. Sustained virologic response rates in the treatment of patients infected with genotype 3 are 93%, 82-92%, and 58-86% with velpatasvir/sofosbuvir, sofosbuvir plus ribavirin and sofosbuvir plus daclatasvir, respectively.

Conclusion: Many clinicians rely on package labeling and guidelines to make treatment decisions, particularly in the rapidly evolving field of chronic viral Hepatitis C. Based on the available literature it may be important for clinicians to note the sources of information and their relevance to clinical practice. Through a more thorough evaluation of primary literature clinicians may be able to better determine which sources should be used when making effective treatment decisions.

Poster Title: Gene expression changes in induced Pluripotent Stem Cells (iPSC) derived cardiomyocytes following doxorubicin exposure

Primary Author: Javon Prophet, Texas Southern University College of Pharmacy and Health Sciences, Texas; **Email:** jdprophet44@yahoo.com

Additional Author (s):
Michelle Hildebrandt
Monica Reyes

Purpose: The use of anthracyclines, such as doxorubicin, in cancer treatment regimens is often associated with progressive and irreversible damage to the heart leading to heart failure. This is particularly a concern for the childhood cancer survivor population, who commonly are treated with anthracycline-based chemotherapy regimens. Although there is a cumulative dose limit of 450mg/m2 to 550mg/m2 for patients receiving doxorubicin, identification of biomarkers leading to anthracycline-induced cardiotoxicity is better understood at the cellular level. induced Pluripotent Stem Cells (iPSC) derived cardiomyocytes is used to display the physiology of the human heart following exposure to anthracyclines, and elucidate the underlying mechanisms.

Methods: In this study, previously generated RNAseq data from iPSC-derived cardiomyocytes following various time- and dose-dependent exposure to doxorubicin were analyzed with a focus on 65 genes in the p53 pathway and 38 genes in doxorubicin's pharmacodynamics/pharmacokinetic (PK/PD) pathway. An analysis was conducted using the GenePattern software to identify differences in gene expression compared to controls for each time point on days 0, 7, 12 at dosages of 50nM, 150nM, and 450nM, and the significant genes were extracted (p less than 0.05).

Results: From the p53 pathway 26 of 65 genes were found to have significant changes in gene expression (p less than 0.05), while 6 of 38 genes were significant in doxorubicin's PK/PD pathway (p less than 0.05). David, a functional enrichment analysis tool revealed that the p53 pathway has a decrease in expression of genes involved with the cell cycle (CDK1, CCNB1, CCNB2, CDK2, CCEN2), an increase in expression of genes involved with apoptosis (BAX, IGF1),

DNA repair and DNA damage prevention (GADD45A, SESN1, SESN2). In the PK/PD pathway, genes involved with mitochondrial function (CYBA) showed a decrease in expression. The functional enrichment analysis suspects CYBA to be a gene directly involved with doxorubicin induced cardiotoxicity.

Conclusion: We can infer that the doxorubicin treatment of cardiomyocytes results in changes in the cell cycle, DNA repair process, apoptosis, and mitochondrial dysfunction. These observed expression changes in gene profiles from the p53 and PK/PD pathways, help to further understand the mechanisms involved leading to doxorubicin-induced cardiotoxicity in the childhood cancer survivor population.

Submission Type: Evaluative Study

Session-Board Number: 5a-013

Poster Title: The pharmacist's role in medical marijuana counseling: Patient and pharmacist perspective

Primary Author: Nicole Kim, UCSD Skaggs School of Pharmacy and Pharmaceutical Sciences, California; **Email:** nicoleyk7@gmail.com

Additional Author (s):
Yasmine Anouty
Tiffany Cheng
Jenny Dong
Amelia Weidling

Purpose: Current evidence regarding the use of medical marijuana from the patients' perspective is lacking. Despite the controversy around therapeutic benefits, pharmacists as drug experts might be able to counsel users who feel inadequately informed on medical marijuana and increase safe usage of the medication as well as improved adherence to their therapeutic regimen. The study purposes are to evaluate whether medical marijuana users believe the pharmacist has a role in the education of its usage, and conversely, to gauge pharmacists' perspectives towards the use of medical marijuana and their ability to educate about its use.

Methods: The institutional review board approved the two online surveys that were distributed and completed through an online survey tool. Subjects for the patient perspective survey were recruited from local medical marijuana advocacy group chapters. Subjects for the pharmacist perspective survey were recruited from the pharmacy school volunteer faculty. All participants provided informed consent. The surveys asked about issues such as the patient's want of pharmacist counseling, the difference in effects before and after using medical marijuana, the factors affecting a pharmacist's comfort level in counseling, and the type of education on medical marijuana that the pharmacist has received. For the patient survey, a total of 53 responses were recorded and evaluated by chi-square tests. For the pharmacist survey, a total of 37 responses were recorded and evaluated by Fisher's exact test and by a case-control odds ratio test.

Results: There was no correlation between patient's duration (in years) of medical marijuana use and interest in pharmacist intervention. There was no correlation between patient's experience of medical marijuana side effects and interest in pharmacist intervention. There was no correlation between patient's usage of other medications for the same indication as medical marijuana and interest in pharmacist intervention. There was a significant difference in a pharmacist's confidence to counsel on medical marijuana between pharmacists who have received some type of education (whether it be in pharmacy school or continuing education) on medical marijuana and those who received none. Those who were confident to counsel were 6.1 times more likely to have received education.

Conclusion: No trends have been determined in patient-specific factors and interest in pharmacist intervention for medical marijuana use. Education about medical marijuana is associated with a pharmacist's comfort level in counseling on the medication. Future directions might question patients on perceived barriers to seeking pharmacist intervention, including social factors and popular opinion. Increased exposure to medical marijuana education as part of professional training could position pharmacists to counsel users who feel inadequately informed on medical marijuana and promote safe usage of the medication alone and in polypharmacy.

Submission Type: Descriptive Report

Session-Board Number: 5a-014

Poster Title: Impact of a didactic and an experiential public health course on the knowledge and use of public health information by pharmacy students

Primary Author: Catherine Duong, Midwestern University - Glendale, Arizona; **Email:** cduong22@midwestern.edu

Additional Author (s):
Rebekah Jackowski
Lynn Patton
Kathleen Fairman

Purpose: Previous research at two different colleges of pharmacy studied pharmacy students' attitudes and/or perceptions of public health, but they did not evaluate the pharmacy students on their knowledge and application of public health. The goal of this study is to assess pharmacy students' knowledge and application of public health information prior to a didactic course in public health, after completion of the didactic course, and again after completion of service learning.

Methods: One pre-course survey and two post-course surveys were given to first-year pharmacy students to assess changes in their knowledge and application of public health after completing a didactic public health course and after an experiential public health course. The pre-survey was given to the students as they started the program in June 2015. The first post-survey was given to the students after completion of a didactic public health course at the end of Summer Term in August 2015. The second post-survey was given after the completion of an experiential public health course at the end of either Fall Term in December 2015 or Winter Term in February 2016, depending on which quarter the students completed their experiential public health course. Participants were asked to provide a unique identifier according to a formula in order to match the surveys upon analysis. The knowledge questions were multiple-choice and included who should get the annual flu vaccine, what the most common youth psychiatric disorder is, and what diseases are affected by periodontitis. The application questions were open-ended and included defining public health and stating a community pharmacist's role in public health. An application question asked if the student referred anyone to any of the listed or other public health services.

Results: Of 216 unduplicated survey records, 72 (33%) were unable to be matched. Only 6 respondents had 3 matching surveys. Although only 6 first-year pharmacy students had 3 matching surveys, we were able to assess the pharmacy students' knowledge and application of public health information as a group. Based upon the data that we have, the cohort's knowledge increased from pre- to post-didactic and experiential. The percentage referring to a public health resource also increased. Many understood that public health's focus is beyond just the individual's health. Moreover, many recognized that community pharmacists are accessible and resourceful health professionals who can contribute to public health through preventive and supportive measures such as promoting and administering vaccines or referring patients to resources.

Conclusion: Students demonstrated increased knowledge of public health and the ability to apply their knowledge to patients after completion of both a didactic course and an experiential course in public health.

Poster Title: Efficacy of topical lidocaine 5% patch for post-thoracotomy and sternotomy pain in cardiothoracic intensive care unit adult patients

Primary Author: Michael Liu, University of Saint Joseph School of Pharmacy, Connecticut;
Email: vu.mvan@gmail.com

Additional Author (s):
Ayse Hursid
Van Vu
Mabel Wai
James Nunez

Purpose: Significant perioperative pain related to the surgery, respiratory care, and mobilization remains prevalent in CTICU patients. Post-thoracotomy somatic and neuropathic pain from cardiac surgery is more common than other persistent incisional pain. Although the effectiveness of local infiltrative anesthetic agents and oral neuropathic agents have been published, there is only 1 study to date that evaluated the use of topical 5% lidocaine patch. Potential advantages of lidocaine patch include avoidance of systemic toxicities and excellent safety profile. This project was designed to evaluate the efficacy of lidocaine 5% patch for post-thoracotomy or sternotomy pain in cardiothoracic ICU adults.

Methods: We conducted a retrospective cohort, single-center study in the CTICU from Jan 1st,2015–December 31 st , 2015. Primary outcome is mean numeric pain ratings (0-10) for sternum and thoracotomy sites, 12 hours after 1 st patch is placed based on the drug's time to maximum peak concentration. Secondary outcomes include total opioid administered converted to morphine IV equivalence, CTICU and hospital length of stay (LOS), and total dose of other opioid analgesics (e.g.,tramadol) and non-opioids. Nominal and continuous data were analyzed with chi-square text of independence and two sample t test, respectively. Analysis was performed with Microsoft Excel Tool Pak 2015.

Results: Both the lidocaine and control groups had similar baseline characteristics (p>0.05 for all variables, if applicable). There was no statistically significant difference between both the lidocaine and control groups in mean numeric pain ratings for sternum and thoracotomy sites

(2.0 vs 1.9, respectively; p=0.58). No statistically significant differences were detected between both the lidocaine and control groups for mean CTICU LOS, and hospital LOS (mean CTICU LOS were 3.06 vs. 3.11, respectively; p=0.86. Mean hospital LOS were 8.26 vs. 7.61, respectively; p=0.47). No difference in total dose of other opioid analgesics and non-opioids was found (p>0.05 for all variables).

Conclusion: Lidocaine 5% patches did not reduce acute post-operative post-thoracotomy and sternotomy pain, LOS, or reduction in the need of total dose of opioids or non-opioids in the CTICU adult patients.

Submission Category: General Clinical Practice

Submission Type: Descriptive Report

Session-Board Number: 5a-016

Poster Title: Evaluating the implementation of interprofessional education in top pharmacy school curriculums in the United States

Primary Author: Carolyn Zhu, Ernest Mario School of Pharmacy, Rutgers University, New Jersey; **Email:** carolynxzhu@gmail.com

Additional Author (s):
Melissa Coward
Michael Toscani
Donna Feudo
Carol Goldin

Purpose: Healthcare practice has become an increasingly collaborative and multidisciplinary field, and it has become essential for healthcare professionals to communicate effectively with other practitioners to optimize patient care. Pharmacy schools are starting to implement interprofessional education (IPE) into their curriculums to better prepare students to serve on these collaborative healthcare teams. The purpose of this study was to explore publically available information relating to the structure and integration methods of IPE into nationally top-ranked pharmacy curriculums, summarize the IPE core competencies and assessment standards in these schools, and gauge overall student perceptions after program completion.

Methods: Our study involved an extensive website search and evaluation of IPE programs at the top thirty pharmacy schools in the United States (as ranked by U.S. News in 2016) and a literature review of articles analyzing specific IPE experiences. We collected data on overall IPE program structure, timing of incorporation into the pharmacy curriculum, therapeutic areas covered in each session, types of healthcare students included in the program (pharmacy, medical, nursing, etc.), and achievement of core competencies and assessment standards. From the literature review that incorporated evaluation of multiple IPE programs, we gathered information on student experiences and perceptions of their programs, limitations and barriers to IPE, and student views on the impact of IPE participation on their own future clinical performances and overall delivery of patient care.

Results: Fifteen of the top thirty pharmacy schools we evaluated using publically available data (50%) currently have formal IPE programs in place. The majority of these programs integrate IPE early in the curriculum, usually during the first professional year. Medical, nursing, and pharmacy students are most commonly involved; however, universities that are associated with other healthcare programs may also incorporate physician assistant, physical therapy, dentistry, and social work students. While the specific therapeutic areas covered by each program differ, the main topics covered include ethical discussions, simulated patient cases of common disease states such as diabetes, COPD, and cardiovascular disease, and community health issues such as opioid overdose. Core competencies and assessment standards for each program are generally very consistent across programs: the schools aim to have students become more knowledgeable about roles and responsibilities of all practitioners, effectively delegate tasks based on students' academic backgrounds, and apply their clinical knowledge. Based on our literature search, we found that participating students had positive experiences with IPE programs and often felt these sessions confirmed their career choices. However, cost, administrative support, levels of student preparation, and resistance to change were cited as frequent barriers to IPE.

Conclusion: Following the recently released Accreditation Council for Pharmacy Education (ACPE) Standards 2016 requiring students to demonstrate competency in interprofessional teams, we anticipate a strategic integration of IPE into pharmacy schools' curriculums nationwide in the next few years. Medical and nursing students' curriculums have also mandated interprofessional programs to prepare students to function collaboratively. We believe that long-term development of IPE programs will ultimately optimize patient care, increase positive health outcomes, validate the value of pharmacists on healthcare teams, and encourage more frequent and discussion-based collaborations among healthcare professionals. The value of these programs should be studied systematically and communicated broadly.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Evaluative Study

Session-Board Number: 5a-017

Poster Title: Evaluation of a prescriber-driven prior authorization adjudication process at the Durham Veterans Affairs Medical Center (DVAMC)

Primary Author: Alana Ferrari, The UNC Eshelman School of Pharmacy, North Carolina; **Email:** ferraria@unc.edu

Additional Author (s):
Anna Jackson
Janine Bailey
Mohamed Hashem

Purpose: The purpose of this study was to evaluate the effectiveness of a provider-driven prior authorization process. To ensure safe and timely processing of formulary restricted testosterone replacement therapy (TRT) and naloxone kit orders, medication use evaluation templates (MUETs) were developed. MUETs, which are completed by providers, are electronic forms that contain monitoring and safety parameters. By completing this form, providers self-adjudicate the orders and determine the appropriateness of the medication. MUETs for TRT and naloxone kits were implemented in 2015 at the DVAMC and are assessed for effectiveness through this post-hoc analysis.

Methods: To perform this post-hoc analysis, a retrospective chart review was conducted from the VA Computerized Patient Record System (CPRS). Veterans were included for initial selection if they had a TRT or naloxone kit prescription filled between 1/1/2016 and 6/1/2016 at the DVAMC. A total of 577 veterans for TRT and 55 veterans for naloxone were identified from the VA Corporate Data Warehouse. Veterans were de-identified and a total of 138 veterans were randomly selected as a convenience sample for TRT analysis and 53 veterans for naloxone were used for analysis. Two veterans were excluded from naloxone kit selection as their prescriptions were not dispensed. Additionally, veterans were excluded from analysis if a completed order MUET was not found in their medical charts. Of the 53 remaining naloxone prescriptions, six order MUETs were missing from veteran progress notes and only 50/138 of the veterans selected for TRT MUET evaluation had an order MUET located within their progress notes. The primary endpoint assessed the occurrence of accurately completed MUETs by reconciling MUET responses with documentation in veteran charts. Additionally, secondary endpoints for TRT

MUET analysis involved assessing the accuracy of completed individual sections in the TRT MUET including indication/symptoms, required baseline labs, and provider-initiated discussion concerning clinical warnings/precautions or contraindications to TRT.

Results: The primary endpoint was reached in 35/50 of the TRT MUETs and 39/47 of the naloxone rescue kit MUETs. Of the 50 TRT MUETs analyzed, 42 contained symptoms listed in the appropriate subsection while nearly all of the veterans had symptoms of testosterone deficiency located in their progress notes. Additionally, 49/50 veterans had indications for TRT listed in both their MUETs as well as their progress notes. After progress note review, only 4/50 veterans prescribed TRT had contraindications to therapy and 100% of these veterans were being closely followed by a provider and had a documented risk/benefit discussion in their medical records. Of the completed MUETs, baseline testosterone levels were found in 45/50; hematocrit levels in 48/50; PSA levels in 46/50; and liver function tests were found within 44/50.

Conclusion: Overall, most providers who completed MUETs were adherent to the process and provided accurate information. Additionally, providers who switched veterans to non-formulary TRT formulations documented consideration of formulary intramuscular TRT. This demonstrates that formulary compliance is also facilitated by using the provider-driven templates. These MUETs provide a reliable process for the prescribing of formulary restricted therapies with uncomplicated criteria without extensive pharmacist review.

Poster Title: Evaluation of herbal and nonprescription medication supplement usage in elderly patients

Primary Author: Candice Bautista, Massachusetts College of Pharmacy and Health Sciences University, Massachusetts; **Email:** candicejbautista@gmail.com

Additional Author (s):
Michael Steinberg

Purpose: Both patients and providers frequently overlook herbals and other nonprescription medications when creating medication lists. This can lead to various unexplained drug interactions or adverse effects, especially in the elderly population due to polypharmacy. The purpose of this study was to analyze supplement usage in the elderly population, their rationale for usage, whether drug interactions occurred and if they disclosed their nonprescription medication usage to their physicians or pharmacies. A secondary focus was to determine why some patients decided not to take nonprescription medications.

Methods: The institutional review board of MCPHS University approved this survey-based study. Elderly patients (greater than or equal to 65 years old) admitted to select care areas of Milford Regional Medical Center were given a survey to determine herbal and nonprescription medication usage. Pharmacy interns assisted patients in the completion of the surveys. Survey questions gathered information regarding whether or not patients ever used nonprescription medication supplements, the names of the supplements as well as the rationale for taking each. Questions also included whether patients disclosed this information to their physician or pharmacy, as well as where they usually purchase these supplements and approximately how much they spent each month on supplements. If patients did not take supplements, or previously used to and stopped, they were asked as to why. A comprehensive medication list of prescription medication was also obtained for each patient completing a survey. The lists of supplements and medications were then entered into Lexicomp (Lexicomp, Inc: Wolters Kluwer Clinical Drug Information; Hudson, OH) to determine any drug interactions.

Results: Of the 128 patients surveyed, 78 patients currently took supplements, 48 patients did not take supplements, and 2 patients used to take supplements but stopped. A vast majority of supplements being taken were vitamins (61 percent). The second largest group was herbal supplements (27.7 percent). Most supplements were recommended by a health care provider (74.2 percent) but many patients were recommended supplements by a friend or family member, heard about it on television, or did their own research (25.7 percent). For overall efficacy, patients were split between deciding their supplements worked as expected (47.9 percent) or unsure if their supplement was working (46.0 percent). Almost all patients told their physician about supplement usage (94.6 percent), however, fewer patients told their pharmacy (60.0 percent). Several patients did not know to disclose that information to their pharmacy (30.8 percent). A majority of supplements were bought from a pharmacy (72.9 percent) but many supplements were bought from supermarkets, online, or other venues where counseling could not be obtained (30.5 percent). Most patients spent less than 30 dollars a month on supplements (67.2 percent). When analyzing drug interactions, only four patients had significant drug interactions and only one patient had a Category X interaction.

Conclusion: Despite the fear of drug interactions of supplements with long medication lists in the elderly, there does not seem to be many drug interactions in the group studied. Patients tend to disclose their supplement usage with their physician which can prevent these errors from occurring. Many of these supplements are being recommended by health care providers but many patients are also being recommended supplements by friends, family, or the media.

Submission Type: Descriptive Report

Session-Board Number: 5a-019

Poster Title: Evaluating compliance to a platinum agent hypersensitivity reaction classification and management algorithm at a large academic medical center

Primary Author: Rutvik Joshi, The Ohio State University College of Pharmacy, Ohio; **Email:** joshi.209@osu.edu

Additional Author (s):
Ambar Khan
Michael Berger
Joe Melucci

Purpose: Platinum agents (carboplatin, cisplatin, and oxaliplatin) are capable of causing unpredictable hypersensitivity reaction during any stage of cancer treatment. Definitive treatment recommendations and evidence based literature in management of patients with the hypersensitivity reaction is lacking. Our institution formulated and adopted a detailed policy to classify and manage all platinum related hypersensitivity reaction. This policy was implemented in June 2014. The purpose of this project was to evaluate compliance to the formulated algorithm and to determine opportunities for improvement in compliance to the policy.

Methods: Data from the event reporting system were used to identify patients with a hypersensitivity reaction event to platinum agents from November 2014 to March 2016. Four main categories were evaluated by chart review including: appropriate documentation of the HSR event in the electronic medical record, future desensitization (shortened, standard and prolonged) plan for subsequent chemotherapy cycles, characterization of intensity of hypersensitivity reaction, (mild, moderate-low, moderate-standard and severe) and documentation of the hypersensitivity reaction in the allergy list. Each healthcare professional has a specific responsibility of documentation within the hypersensitivity reaction algorithm. The role of the provider (advanced practice provider or attending physician) is to enter the hypersensitivity reaction event in the problem list, whereas, the responsibility of the registered nurse is to document the event timeline in the progress note. The policy also requires the provider to document the desensitization plan for future cycle(s) in the problem list. According to the policy, all platinum agents' hypersensitivity reaction intensity should be classified and documented. Finally, the policy instructs the nursing staff to document platinum agent in the

allergy list. Through retrospective analysis of patient charts, we identified documentation strengths and weaknesses. These results were presented to pharmacy and therapeutics committee for discussion.

Results: Seventy-three platinum related hypersensitivity reactions were reported from November 2014 to March 2016. Twenty-five hypersensitivity reaction events were randomly selected from four outpatient infusion sites. Twenty-one hypersensitivity reactions were entered in the problem list. Of the four hypersensitivity reactions not added to the problem list, one was undocumented and the other three were documented in the progress note. The event timeline for each patient's hypersensitivity reaction was documented appropriately in the progress notes. The future desensitization plan was entered in the problem list for 13 patients and elsewhere in the chart for two patients. Treatment plan discontinuation, patient death, infusion rate and premedication modification, or completion of the chemotherapy cycles led to a lack of documentation for the remaining 10 patients. The distribution of mild, moderate-low, moderate-standard, and severe intensity were 7, 10, 5 and 3 respectively. Of the three severe hypersensitivity reactions, one received successful subsequent platinum infusion with a prolonged desensitization, whereas the platinum agent was discontinued permanently for the other two patients. The platinum agent was entered in the allergy list for 17 patients. The remaining eight patients had either a mild or moderate-low reaction, therefore the reaction was not added to the allergy list.

Conclusion: Conducting a retrospective audit of the policy was helpful in identifying areas for improvement with respect to compliance to the hypersensitivity reaction policy. It was evident that providers are diligent in entering hypersensitivity reaction in patient's problem list. However, they have room for improvement in future desensitization plan documentation. Nursing staff is thoroughly documenting hypersensitivity reactions in progress notes but they also have room for improvement in updating allergy list for mild and moderate-low intensity hypersensitivity reaction.

Poster Title: Prazosin administration for the treatment of nightmares in psychiatric patients

Primary Author: Mark Maas, University of Kansas School of Pharmacy, Kansas; **Email:** mark@maasfamily.org

Additional Author (s):
Brittany Melton
Karen Moeller
Amad Din

Purpose: The United States Food and Drug Administration currently indicates prazosin, an alpha-adrenergic antagonist, for the treatment of hypertension. Recently, studies have found that prazosin is beneficial for the treatment of post-traumatic stress disorder (PTSD) and is most commonly used off-label for PTSD nightmares. With the growing use of prazosin for PTSD nightmares, we have seen an increasing trend in prazosin's use for non-PTSD nightmares in clinical settings. This study aimed to evaluate the safety and efficacy of prazosin when it is used to treat nightmares while considering diagnoses and concurrent medications.

Methods: This study was approved by the University of Kansas Medical Center's institutional review board. Potential patients were identified through Healthcare Enterprise Repository for Ontological Narration (HERON), a searchable clinical database of patient records. Adults (18 years of age or older) who experienced at least one psychiatric admission within the last 5 years and had taken prazosin at least once were included in the study. Patients were excluded if they were subsequently found to have not received prazosin or received prazosin for hypertension. Patient charts and medication administration records were reviewed to gather pertinent information, including demographics, histories of substance abuse, current diagnoses (namely post-traumatic stress disorder, other psychiatric disorders, personality disorders, or disorders that impair sleep), documented cause of trauma (if applicable), documented efficacy of prazosin, documented side effects of prazosin, and concurrent medications that effect sleep. Patient chart review was conducted by one researcher while another randomly reviewed five percent of charts to ensure consistency and accuracy. Statistics were assessed using SPSS version 22, and included descriptive statistics for patient demographics and prazosin use.

Results: Of the 80 patients initially identified, only 64 met the inclusion criteria. Prazosin doses ranged from between 1 to 6 mg, with 2 mg being the average. Of these individuals, 48.4 percent were male and 75.0 percent were Caucasian, with a mean age of 39.8 years. Most patients suffered from a substance abuse disorder, most commonly alcohol (37.5 percent), cannabis (40.6 percent), or stimulants (40.6 percent). The majority of patients (81.3 percent) had a diagnosis of post-traumatic stress disorder, while 31.3 percent of patients had diagnosed major depressive disorder, and 26.6 percent of patients had diagnosed anxiety. Some patients (12.5 percent) had an additional diagnosis for a medical condition that affected sleep, such as sleep apnea. There was clinical documentation of at least partial effectiveness for 65.6 percent of patients who received prazosin. The remaining 34.4 percent of patients either did not have documented comments on effectiveness or the physician reported prazosin to be ineffective. Of the patients who did not have a PTSD diagnosis, 57.1 percent of patients had documentation of effectiveness. Only 6.4 percent of patients had documented adverse reactions to prazosin. Most psychiatric patients (92.2 percent) were on at least one additional medication that affected sleep.

Conclusion: Prazosin was frequently documented of reducing nightmares during psychiatric admissions. The low rate of adverse reactions indicates that prazosin, at the very least, may serve as a safe and effective new approach to treating nightmares for psychiatric patients. However, the cessation or reduction of nightmares for patients during psychiatric visits could be attributed to other medications or treatments conducted during their hospital stay. A more widespread, prospective study would better establish prazosin as an applicable treatment for psychiatric patient nightmares nationwide.

Poster Title: Evaluation of Counseling Prevalence and Effectiveness on Metered-dose Inhaler Technique

Primary Author: Victoria Paradiso, Presbyterian College School of Pharmacy, South Carolina; **Email:** vgcottle@presby.edu

Additional Author (s):
Megan Slimmer
Darien Campbell
Kayce Shealy
Tiffaney Threatt

Purpose: Guidelines suggest healthcare providers assess inhaler technique by having participants demonstrate use of their inhaler. However, there is little guidance on the best assessment method. The aims of this study were: (1) assess the incidence and extent of counseling provided to participants who use a metered-dose inhaler, (2) determine the prevalence of metered-dose inhaler misuse in adults, and (3) determine if any associations exist between the counseling method and the participant's ability to properly use a metered-dose inhaler.

Methods: Adult participants who had a current or previous history of metered-dose inhaler use were recruited from retail pharmacies and physician offices in Laurens County, SC. Exclusion criteria included the use of a metered-dose inhaler spacer, non-English speaking, or a current acute respiratory illness. Participants completed a survey regarding inhaler use and previous counseling, a subjective checklist assessment by demonstrating use of a metered-dose inhaler, and an objective assessment by using the Vitalograph Aerosol Inhalation Monitor. Descriptive statistics were used to analyze demographic information. Fisher's exact tests were used to analyze nominal data. All analyses were completed in 2010 Microsoft Excel or SAS 9.4.

Results: One hundred participants were enrolled in the study, and 99 participants completed all steps. Participants were mostly white females, with an average age of 53 years. The most common methods of counseling received were verbal communication (55%) and demonstration (47%); however, approximately 25% of participants never received counseling on their inhaler.

Of 100 participants, ninety four percent were found to have insufficient metered dose inhaler technique. No association between the method of counseling and successful metered dose inhaler technique with the Vitalograph Aerosol Inhalation Monitor was identified (p=0.313). Participants were less likely to correctly use the Vitalograph Aerosol Inhalation Monitor if they missed more than 3 steps in the subjective assessment. (p=0.032).

Conclusion: No counseling method evaluated achieved optimal results. A participants' ability to follow a checklist may be indicative of proper metered dose inhaler technique.

Poster Title: Performing Gap Analysis to assure compliance of the new USP Chapter Standards for Sterile Compounding and safe handling of Hazardous Drugs in Specialty Infusion

Primary Author: Corey Medler, The University of Tennessee Health Science Center College of Pharmacy, Tennessee; **Email:** cjmedler@gmail.com

Additional Author (s):
Fred Choy
Mitra Gavgani

Purpose: The purpose of this project is to ensure that our specialty infusion pharmacy is compliant with the standards and guidelines of the new United States Pharmacopeia (USP) < 800> Chapter as well as to continue to provide world class safety for not only patients, but also the employees (pharmacy staff, nursing, warehouse and delivery staff, etc.).

Methods: The project was broken down into four parts. The first step was to identify a detailed gap analysis tool that could be customized to include all 18 sections of the USP < 800> Chapter. The tool was modified to meet the practice setting of this specialty infusion pharmacy. Areas that were examined included: an introduction list of hazardous drugs, type of exposure, personal handling, facilities/engineering controls, environmental quality/control, personal protective equipment (PPE), communication, personnel training, receiving, labeling, package, transport and disposal, dispensing, compounding, administration, deactivating, decontaminating, cleaning and disinfecting, spill control, documentation/ standard operating procedures (SOPs), and medical surveillance. Each section had various components that were marked as "Met," "Not met," or "Not Applicable," which identified areas in need of improvements. The second step was locating SOPs and required forms (acknowledgement and training) to ensure that they were up-to-date to include content specifying hazardous drug compounding. The third step was inspecting facilities and employee processes, specifically storage, handling, biological safety cabinets, clean room, administration, and PPE utilized by employees. The last step was to develop an action plan for improvements based upon the results of the survey with target dates to make specific completions prior to July 1st, 2018.

Results: This gap analysis resulted in an overall compliance score of 71.6 percent (106/148). This included 106 components in the "Met" category, 42 components in the "Not Met" category and 43 components in the "Not Applicable" category. Not applicable was indicated for procedures, clean room layout and equipment standards that are not yet required as they are new components in USP < 800> Chapter. Sections with the lowest compliance were PPE at 63.3 percent, SOPs at 52.6 percent, medical surveillance (not required) at 18.8 percent and environmental quality and control (not required) at 0 percent. The PPE score reflected changes in use of goggles, respirator, and wearing two pairs of gloves. SOPs score was low due to a lack in specification for hazardous drugs. Medical surveillance and environmental quality/control are currently not required, but rather just recommendations. Moving forward, the areas that need improvement are separate storage and refrigeration for hazardous drugs (hazardous drugs need to be stored together and refrigerated antineoplastic drugs need to be placed in a dedicated refrigerator in a negative pressure room with a minimum of 12 air changes per hour), use of goggles, integration of Closed-System Drug-Transfer Device (CSTD) and proper PPEs when handling hazardous drugs.

Conclusion: Overall, this preliminary internal gap analysis helped to identify areas within the specialty infusion department that required adjustments in order to become compliant with the new USP < 800> Chapter. These results were used to develop a detailed action plan to be finished by the end of December 2017 to allow extra time for any additional training and delays before the official USP < 800> July 1st, 2018 launch date. To review and validate our findings, an external USP < 800> expert will conduct an independent gap analysis prior to finalizing the action plan.

Poster Title: Evaluation of a year-long pharmacy mentorship program: A quality improvement initiative

Primary Author: Shaziya Barkat, Midwestern University Chicago College of Pharmacy, Illinois;
Email: sbarkat14@midwestern.edu

Additional Author (s):
Avani Patel
Margaret Lee
Jane Lee
Jessica Peng

Purpose: Mentorship, defined as a mutual professional relationship between at least two individuals that is typically long-term, has largely been correlated with positive outcomes including professional and personal growth and higher proficiency. Evaluating a mentorship program for areas of development can help both interested mentors and mentees gain the most out of their experience. The purpose of this study is to identify the benefits and challenges that mentors and mentees experienced when participating in the Mentorship Program and to determine areas of improvement to develop a successful mentoring relationship.

Methods: A survey was administered to evaluate the quality of the program based on the subjects' overall satisfaction. Subjects were first-year, second-year, and third-year student pharmacists at the Midwestern University Chicago College of Pharmacy and needed to be members of the MWU ICHP Mentorship Program. Subjects completed a survey that was aimed towards their satisfaction and professional improvements as well as the Mentorship Program's quality and efficacy in the matching process. The survey was anonymous, which was indicated on the cover sheet, and included 16 questions for mentors and 15 questions for mentees. The mentees documented their individual mentorship meetings per quarter, through which we tracked the number of times they had met and determined how beneficial the program was at providing guidance.

Results: 33 mentors and 36 mentees participated in the survey. Categories including satisfaction, quality, improvements, and effectiveness were analyzed. Both the mentors and mentees strongly agreed to recommend this program to others at 69.7 percent and 71.4 percent, respectively. Additionally, mentors and mentees found themselves to be more confident networking as a result of participating in the program with 46.9 percent and 57.1 percent, respectively. An analysis for quality and effectiveness was conducted separately for mentors and mentees. Overall, mentors agreed (53.1 percent) that the program prepared them to be a mentor and strongly agreed (56.2 percent) that it helped them build their leadership skills. As for the mentees, 51.4 percent strongly agreed that the program helped them with their academics and 50 percent agreed that it helped them gain information on career opportunities.

Conclusion: Overall, the mentors and mentees were satisfied; mentees felt more confident networking due to this program and mentors developed in their leadership skills. Based on the feedback and results, improvements such as organizing training workshops to set clearer expectations for mentors and mentees and providing more social events will be implemented into the program.

Session-Board Number: 5a-024

Poster Title: PPROM care process model change

Primary Author: Bailee Binks, Roseman University, Utah; **Email:** baileebinks@gmail.com

Additional Author (s):
Alisa Thomas

Purpose: Demonstrate the clinical relevance of updating a current care process model for premature rupture of membranes (PPROM) to include azithromycin as the preferred agent vs. erythromycin. Antibiotics in the setting of PPROM has shown to decrease fetal complications and prolong latency. The American College of Obstetrics and Gynecology recommends treating with ampicillin plus erythromycin then 5 days of oral antibiotics. There is a nationwide erythromycin shortage necessitating the question of whether or not azithromycin could be used in its place. Azithromycin also provides better tolerability, a favorable pharmacokinetics profile, less drug-drug interactions, and significant cost savings.

Methods: A management pharmacist and a pharmacy student wrote a proposed update to the PPROM care process model. This was presented to pharmacy management as well as the OB development committee. The presentation included cost savings benefit, a literature review, current guidelines, examples of other facilities using azithromycin in their protocols, side effect comparison, pharmacokinetic data, interactions, and pregnancy category.

Results: The system wide ob development group accepted our proposal and many physicians will begin utilizing azithromycin instead of erythromycin. Azithromycin is now included on the standard order set for PPROM.The average savings per year based on past delivery per year average and 3% estimated incidence of PPROM is $315,000 reduction in cost billed to patient and a $51,000 reduction in total medication cost.

Conclusion: This Care Process Model update increases visibility of pharmacists' roles in cost savings and patient outcomes.

Poster Title: Identifying the impact of BOOST teaching on readmissions at a community hospital

Primary Author: Tyler Tinkham, University of Utah, Utah; **Email:** tyler.tinkham@gmail.com

Additional Author (s):
Bailee Binks

Purpose: After being discharged from the hospital, up to 20 percent of Medicare patients are readmitted within 30 days. In 2011, there were approximately 3.3 million readmissions in the United States, resulting in 41.3 billion dollars of unnecessary patient charges. Intermountain Healthcare hospitals began implementing a discharge counseling program entitlted BOOST teaching (Better Outcomes for Older Adults by Optimizing Safe Transitions) to identify high risk groups in an attempt to decrease readmission rates in these populations. Riverton Hospital is an Intermountain community hospital with 97 beds. Current BOOST teaching efforts focus on patients in the medical/surgical and intensive care units.

Methods: Patients who qualify for BOOST are identified daily, according to the following 6 criteria: Poly-pharmacy (> 10 prescribed medications), New Anticoagulant, Uncontrolled Diabetes , New Antiplatelet, High Risk Heart Failure Medications, and New Antiarrhythmic Medications. A pharmacist or pharmacy intern will counsel these patients before discharge focusing on simplifying the medication regimen, intervening on duplications of therapy, reviewing drug interactions, and explaining medication indications and appropriate administration techniques.

Results: Of the 155 patients who were identified as BOOST during the study period, 64 were taught by a pharmacist or pharmacy intern. A total of 29 BOOST patients were readmitted to the hospital within 60 days (25 of them within 30 days), leading to an 18.5 percent readmission rater in this specific population. Pharmacists and Pharmacy Interns spent an average of 8.07 minutes preparing to teach each patient, and 14.27 minutes actually teaching the patients.

Conclusion: As cost control and payment models focusing on outcomes become more mainstream for health care systems, pharmacists can participate in improving patient outcomes and decreasing financial burden by empowering and educating patients regarding their

medications. In the future, Riverton Hospital will track readmission rates to determine if BOOST teaching is a significant component of reducing readmissions. Currently, readmission rates of patients who received BOOST teaching are similar to the national average among Medicare patients (20 percent). These preliminary data will be used to track improvement within this hospital as BOOST teaching continues.

Session-Board Number: 5a-026

Poster Title: Expansion of a pharmacy technician based medication reconciliation program to the emergency department: A pilot program

Primary Author: Curtis Lee, University of Southern California School of Pharmacy, CALIFORNIA; **Email:** curtiscl@usc.edu

Additional Author (s):
Laura Ota
Herman Ing
Chris Sakanoi
Brande Ribillia

Purpose: Obtaining and completing an accurate medication history upon hospital admission is necessary for patient safety. Studies have demonstrated that pharmacy technicians can accurately complete medication reconciliation when compared to pharmacists and other health care practitioners. Medication reconciliation prior to inpatient admission can improve appropriate drug therapy and possibly minimize drug related adverse events. A pilot program to expand pharmacy technician driven medication reconciliation to start in the emergency department prior to admission will improve workflow and time to completing an accurate medication history. This initiative will provide the health care team with the most updated and accurate patient medication list.

Methods: A pharmacy technician driven medication reconciliation program was initiated in March 2013 and expanded hospital-wide in October 2015, completing medication reconciliation in approximately 77% of all patients admitted to the hospital. Medication reconciliation is currently completed 50% by the Emergency Department pharmacist and 50% by pharmacy technicians. Pharmacy technicians prioritize medication reconciliation by interviewing patients admitted to the hospital on the prior day. A pharmacy intern pilot program was designed to expand the pharmacy technician service area to initiate patient interviews in the Emergency Department soon after hospital admission orders. The pharmacy intern worked with the Emergency Department pharmacist to learn department specific workflow, triage, and the Emergency Department navigator in the electronic medical record. All medication history information was discussed and reviewed by the Emergency Department pharmacist for

accuracy. Data was collected on the time of admission to medication reconciliation and types of discrepancies reconciled. To support the expansion of pharmacy technician medication reconciliation to start in the Emergency Department, a comprehensive training manual, medication competency, and training checklist was developed to train medication reconciliation pharmacy technicians on the expanded role in the Emergency Department environment.

Results: Data was collected retrospectively for a three-week period, including patients admitted to the hospital through the Emergency Department during the hours of the pilot program. Patients admitted from a long term care facility or who were recently admitted within the past month, were excluded. Ninety-four patients were analyzed and 80 patients met inclusion criteria. New patients admitted were captured through Trigger Sheets (15%), ED Track-board (40%), and Manual Lookup (45%). Over the pilot program, 77.6% of patients had at least one medication discrepancy on the home medication list with each of these patients averaging 3.92 medication discrepancies. In addition, 59.2% had changed or discontinued therapy, 30.6 % had missing or incomplete information, 24.5% had omitted therapy, and 14.3% had duplicate therapy. The pilot program completed medication reconciliation within an average of 2.26 hours following hospital admission versus the Emergency Department Pharmacist within 1.9 hours. Compared to current procedures (outside of the pilot program), 73 patients admitted during the same time period took an average of 25 hours to complete medication reconciliation from the time of admission orders.

Conclusion: Expanding the pharmacy technician driven medication reconciliation program to start in the Emergency Department improved the time from admission to medication reconciliation from 25 hours to 2.26 hours, similar to that of the Emergency Department Pharmacist (1.9 hours). Supplemental material was developed to introduce the pharmacy technician to the Emergency Department environment and workflow. Upon full implementation, the expansion of pharmacy technician workflow is expected to reduce the Emergency Department Pharmacist medication reconciliation related workload to allow focus on other clinically based initiatives while also providing cost-savings to the hospital.

Submission Type: Evaluative Study

Session-Board Number: 5a-027

Poster Title: Impact of Meds to Beds program on servicing patients with prior authorization or additional medication education needs

Primary Author: Joy Shi, UCSD Skaggs School of Pharmacy and Pharmaceutical Sciences, California; **Email:** jxshi@ucsd.edu

Additional Author (s):
Diana Schultz
Theresa Knoetze

Purpose: Meds to Beds, a complimentary bedside delivery service for discharge medications that includes pharmacist counseling, exists to address gaps in transitions of care. Medications requiring prior authorization and medications classified by the Institute for Safe Medication Practices (ISMP) as high-alert pose unique problems at discharge. These medications can lead to unintentional non-adherence, where resource limitations such as access or sufficient counseling prevent patients from following treatment recommendation. The purpose of this study was to evaluate the impact of Meds to Beds on addressing medication access and adherence issues specifically associated with these problematic discharge medications.

Methods: The Institutional Review Board approved this prospective study. The list of problematic discharge medications to be analyzed was first determined. The list of discharge medications often requiring prior authorization (PA med list) was generated via analysis of outpatient pharmacy's daily sales from January 1, 2016 – June 30, 2016. The list of high alert medications often dispensed at discharge (HA med list) was provided by the Medication Safety Pharmacist. Following the generation of these lists, existing manufacturers' free-trial cards for medications on the PA med list were collected, and personal reference cards containing a list of the available cards were created and distributed to case managers, social workers, and diabetes nurse educators. Counseling guides were created or compiled from ISMP and the health district's resources for medications on the HA med list.
From August 8, 2016 – September 2, 2016 (intervention period), eligible patients discharged on a medication from the PA med list or HA med list were informed via telephone of the free-trial cards or pharmacy counseling resources available to them respectively, and then offered the Meds to Beds service. Prescription capture rates, which served as a surrogate marker for

medication access, were compared between the intervention period and July 11, 2016 – August 5, 2016 (pre-intervention period).

Results: For medications often requiring prior authorization, the prescription capture rate rose from 22.3 percent during the pre-intervention period to 33.8 percent during the intervention period. While increased, the association between informing patients about free trial card information and increased prescription capture rates was not significant (p equals 0.096). For medications classified as high alert, the prescription capture rate rose from 26.2 percent during the pre-intervention period to 50.0 percent during the intervention period. There is a statistically significant association between informing patients about counseling services available for high alert medications and increased prescription capture rates (p equals 0.005). The odds of accepting the Meds to Beds service were 2.82 times higher among patients informed of the counseling resources available to them than among patients uninformed (95 percent CI equals 1.27-6.35). Patient sex, length of stay, and time between ordering the discharge prescription and patient discharge were not confounding factors (adjusted OR equals 2.81, 2.88, 2.62 respectively) on prescription capture rates.

Conclusion: Meds to Beds can be used to address discharge complications related to problematic discharge prescriptions. Informing patients about counseling services available for high alert medications significantly increased the prescription capture rate. Although there was a non-significant increase in the prescription capture rate for medications often requiring prior authorization, the distribution of financial reference cards to varying healthcare professionals promotes future increases in filling these prescriptions. The streamlined Meds to Beds workflow process may prove useful in sustaining high prescription capture rates.

Submission Category: Clinical Services Management

Submission Type: Evaluative Study

Session-Board Number: 5a-028

Poster Title: Assessing pharmacist competency for administrating anticoagulation clinic in a community hospital

Primary Author: Kevin Machi, University of Saint Joseph's School of Pharmacy, CONNECTICUT; **Email:** kmachi@usj.edu

Purpose: The purpose of this clinical management project was to assure that pharmacists in charge of anticoagulation clinic were competent in the information and confident in managing a patients internationalized normalized ratio. For the most part, pharmacists with anticoagulation competency should be in charge adjusting the patient's anticoagulation dose appropriately. They should also be responsible for clinical documentation of the critical aspects in the patient medical record for communication among health care practitioners. It is vital that the pharmacists first show that they are competent with the information of warfarin and familiar with the guidelines on dosing the drug appropriately.

Methods: I have constructed a 1 to 2-day course for registered pharmacists. It was open to those who are interested in the clinical management of patients on anticoagulant therapy, and/or who are looking to expand their practice to involve patient management of outpatient anticoagulation therapy. The program I constructed was broken down into two parts, day one was fixated on pathophysiology of thromboembolic disorders, and the pharmacology of anticoagulation agents. Day 2 was fixated on patient education and program administrative procedures. At the completion of the 2-day traineeship there was an assessment that required a 100% as a passing grade for the course. A certificate of completion will be awarded upon successful completion of the traineeship.

Results: There were 10 pharmacists that took the anticoagulation competency assessment and 9 out of the 10 received a passing grade of 100%. The individual that did not pass had another review session focusing on the areas that he/she answered incorrectly and reassessed the competency assessment. The pharmacist director felt that the examinations were vital in refreshing the minds of pharmacists in anticoagulation treatment. The pharmacists whom took the assessment provided feedback of the 2- day course and felt that the examination was informative, relevant with the most recent updated guidelines, and provided confidence in their anticoagulant therapeutic dosing for patients.

Conclusion: Overall the competency assessment proved to be vital in determining the proficiency of pharmacists and reassurance that patients were being managed and treated on anticoagulation medications properly. The assessment continues to be incorporated in the hospitals guidelines for a pharmacist to become a member of the anticoagulation clinic team. I have also shown the competency assessment to other hospitals where I have received feedback of their interest in incorporating a similar modified assessment to fit there needs.

Submission Type: Evaluative Study

Session-Board Number: 5a-029

Poster Title: Impact of bumetanide to torsemide conversion in veterans with heart failure

Primary Author: Sirena Louie, University of California, San Diego Skaggs School of Pharmacy and Pharmaceutical Sciences, California; **Email:** solouie@ucsd.edu

Additional Author (s):
Wooseob Kim
Felix Yam

Purpose: The three most common loop diuretics, furosemide, bumetanide, and torsemide, are effective in treating the hallmark symptoms of heart failure, peripheral edema, fatigue, and shortness of breath. While previous studies compared the effectiveness of furosemide to either bumetanide or torsemide, no studies have evaluated the comparative effectiveness between bumetanide and torsemide. The purpose of this study is to evaluate the impact of converting heart failure patients on stable oral doses of bumetanide to equipotent oral doses of torsemide.

Methods: The institutional review board approved this single center, retrospective, observational cohort study of 72 veterans with heart failure who were converted from stable doses of bumetanide to equipotent doses of torsemide. All patients prescribed bumetanide with less than a three-month supply remaining during the bumetanide drug shortage in March 2014 were converted to equipotent doses of torsemide. Patient data were collected to determine torsemide failures and outcomes in the 12 months after diuretic conversion. Torsemide failures were defined as discontinuation with in one year and/or torsemide dosage adjustments within the first three months of conversion. Hospital admissions and emergency department visits for heart failure were compared 12 months before and after diuretic conversion. Additional data were collected to explore potential risk factors associated with torsemide failure.

Results: Sixty-eight patients met inclusion criteria and were included in the analysis. The majority of patients was male and had heart failure with preserved ejection fraction. Fifty-seven percent of patients had severe chronic kidney disease (stage III or greater). At the end of one year, 16 (24%) of patients discontinued torsemide and were converted to another loop diuretic.

Six (9%) patients required a dosage adjustment within the first three months following the diuretic conversion. Overall, 22 (32%) of patients met our definition for torsemide failure at the end of the first year. After two years, the overall torsemide failure rate increased to 28 (41%). There were no statistical differences in the proportion of patients hospitalized or presenting to the ED for worsening heart failure one year prior to diuretic conversion compared to one year after diuretic conversion (45% vs. 29%; p=0.52). Additional univariate analysis did not identify any patient characteristics that were significantly associated with torsemide failure.

Conclusion: Findings from this study demonstrate a relatively high discontinuation rate of torsemide when converted from bumetanide. Individual patient factors may explain differences in clinical efficacy between torsemide and bumetanide. Despite high torsemide discontinuation rates, we did not observe any statistically significant differences in hospitalizations or ED visits before and after bumetanide to torsemide conversion. Larger studies are needed to evaluate the clinical significance of these data.

Poster Title: Retrospective review of twice daily vancomycin in place of every 12 hour vancomycin

Primary Author: Karalynne Thacker, Roseman University, Utah; **Email:** kthacker@student.roseman.edu

Additional Author (s):
Bailee Binks
Simon Pence

Purpose: Vancomycin is an important antibiotic for treating gram positive organisms that are resistant to beta-lactams including MRSA. Patients admitted to the hospital typically receive vancomycin every 12 hours if given twice daily. One out of every 1000 patients in the United States receives outpatient antibiotic therapy every year. Due to dosing convenience, hours of operations, and patient adherence the infusion services at Utah Valley often give patients vancomycin outside of the 12 hour range. This study aims to determine if variation from a strict 12 hour schedule effects patient outcomes or therapeutic drug monitoring.

Methods: Patients who received vancomycin twice daily between July 1, 2014 to July 1, 2016 were included in this analysis. All included patients that received vancomycin were assessed for age, gender, diagnosis, length, trough levels, outcomes, and adverse drug reactions. These data were compared to average outcomes from patients receiving vancomycin every 12 hours.

Results: 69 patients were treated with vancomycin at Utah Valley Infusion Services. 31 of these patients are excluded from this study because they did not receive vancomycin twice daily. Of the 38 patients who received vancomycin twice daily only one was readmitted to the hospital within 90 days. The average trough concentration was 15.07mcg/ml. The highest trough concentration was 22mcg/ml and the lowest trough concentration was 6.5mcg/ml. 32 patients were diagnosed with cellulitus, 2 with endocarditis, 2 with osteomyelitis, 1 with UTI, 1 infected joint, and 1 with parotitis.

Conclusion: Twice daily vancomycin dosing seems to be a viable alternative in an outpatient setting compared to every 12 hour dosing. This flexibility is beneficial to patients and saves outpatient clinics the cost of extending hours.

Submission Type: Evaluative Study

Session-Board Number: 5a-031

Poster Title: Impact of drug library changes and staff education on infusion pump dose error reduction software compliance

Primary Author: Annie Hu, UC San Diego Skaggs School of Pharmacy and Pharmaceutical Sciences, California; **Email:** anh100@ucsd.edu

Additional Author (s):
Diana Schultz

Purpose: According to a study from 2003, up to 35 percent of medication errors resulting in significant harm were a result of infusion device problems. Smart infusion pumps mitigate the risk of infusion errors with dose error reduction software (DERS). Programming the infusion devices outside of the DERS has been identified as the cause of many infusion errors. Compliance in properly using DERS is paramount to infusion safety. The purpose of this study was to determine if making targeted drug library changes and educating staff on proper use of Guardrails, a type of DERS, would improve compliance.

Methods: This quality improvement study looked at the compliance rate of Guardrails usage before and after drug library changes and staff education on the Guardrails software. Approval from the UC San Diego Investigational Review Board and the Palomar Health Investigational Review Committee was obtained. Infusion data that was transmitted wirelessly from the infusion pumps to Knowledge Portal, a web-based information portal, were analyzed by an interdisciplinary team composed of a student pharmacist, clinical pharmacist, and clinical nurse specialist to determine appropriate modifications to the drug library of the smart pump as well as the Guardrails compliance rates, which was calculated as the percentage of total infusions using Guardrails versus basic infusions. The interventions occurred over the period of July 2016 to August 2016. The pre- and post-intervention compliance rates were analyzed with Stata statistical software, with a p-value of 0.05 determining statistical significance.

Results: Pre-intervention Guardrails compliance was at 83.9 percent and post-intervention Guardrail compliance was at 86.2 percent, resulting in a 2.3 percent increase. A chi-square test showed a significant increase (p less than 0.05) between Guardrails compliance before and

after the drug library update and staff education (chi-square equals 74.6, df equals 1, p equals 0.00).

Conclusion: Pharmacy and nursing oversight in the analysis of infusion data allowed for targeted updates to the drug library and appropriate staff education to be carried out, thus bringing compliance closer to the medical center's goal of having 90 percent infusions run under Guardrails software. Continued reevaluation of the drug library and modifications to meet the practical needs of therapy may be useful in maintaining a high compliance of utilizing dose error reduction software such as Guardrails.

Poster Title: Use of a medication adherence tool in a multicultural and multilingual ambulatory population

Primary Author: Waleed Alshehri, MCPHS University, Massachusetts; **Email:** phwaleed@gmail.com

Additional Author (s):
Mimi Mukherjee

Purpose: Medication adherence is one of the cornerstones of a successful pharmacotherapeutic plan. Non-adherence to medications can cause disease progression and further complications that increase health care costs. The cause of non-adherence is important to identify in order to find a solution. This pilot project was conducted to determine if the Medication Access and Adherence Tool (MAAT) is effective in identifying possible medication adherence issues and their cause in an indigent, multicultural and multilingual ambulatory care population.

Methods: This pilot project was approved by the university and clinic research committee. Informed consent was obtained from all participating patients. On 6 clinic days, all patients over 18 years old with appointments to see the clinical pharmacist were asked if they were willing to answer five questions about their medication adherence. The five questions were about the patients' perceived need for medications to treat their health problems, ability to take the medications every day as prescribed, frequency of missing doses, ability to pay for the medications, and perception regarding medication adverse effects. According to patients' preference, the questionnaire, and informed consent were provided in one of three languages: Portuguese, Spanish, and English. In addition to the questionnaire, demographic data on gender, age, language, and number of daily medications were also documented.

Results: A total of 14 patients participated in the pilot study. Seven percent of the patients were somewhat sure they needed medications to treat their health problems, and fourteen percent were not sure at all. Fifty percent found it somewhat difficult to pay for their medications, and 14 percent found it very difficult. Fourteen percent reported somewhat often experiencing adverse effects from their medications, and 7 percent were very often

experiencing adverse effects. More females than males were very sure that they needed their medications for health problems; however, the difference between males and females was not statistically significant (p equals 0.538). More patients greater than age 40 said they had difficulty paying for medications but the difference was not statistically significant (p equals 0.3). Of note, 92 percent of the reported patients felt they could take their medications as prescribed, but this high percentage may be because patients were being followed by a clinical pharmacist.

Conclusion: The medication access and adherence tool (MAAT) was found to be helpful in identifying reasons for medication non-adherence in an indigent multicultural and multilingual population of ambulatory care patients.

Poster Title: Incidence of oropharyngeal candidiasis in renal transplant patients receiving immunosuppresion

Primary Author: Rita Parsiani, Pacific University School of Pharmacy, Oregon; **Email:** nass5191@pacificu.edu

Additional Author (s):
Ali Olyaei

Purpose: Oropharyngeal candidiasis remains to be one of the major causes of complications following kidney transplantation. Oropharyngeal candidiasis is an opportunistic infection most observed in patients with a compromised immune system. The overall incidence differs according to prophylaxis and type of induction therapy given in transplant recipients. The objective of this retrospective analysis was to investigate the prevalence of risk factors and the incidence of oropharyngeal candidiasis in renal transplant recipients within 3 months after transplantation.

Methods: The institutional board review (IRB) approved this single-center cross sectional study. It was completed at Oregon Health and Science University in Portland, Oregon. A retrospective chart review of 517 consecutive renal transplant patients (298 males, 219 females, mean age: 47 [18-77]) was conducted between the dates of January 1st, 2010 and July 13th, 2015. Patients who were included had a clinical diagnosis and prescription for the treatment of oropharyngeal candidiasis within three months post-transplant. Patients were excluded if they received clotrimazole troches for increasing tacrolimus levels, deceased within 30 days of receiving renal allograft, undergoing re-transplantation, lost to follow up (minimum of 3 months), severe, uncontrolled diarrhea or evidence of malabsorption and pregnant patients. The primary outcome was the incidence and time to infection of oropharyngeal candidiasis within 3 months after transplant. The secondary outcomes investigated comorbidities, gender, race, renal disease, type of donor and type of induction immunosuppressant.

Results: Five hundred and seventeen kidney transplant patients were evaluated for the development of oropharyngeal candidiasis. The majority of the patients evaluated were male (57.6%) and white (72.1%). Diabetes mellitus was the most common cause of kidney failure (24.4%). A total of 71 patients (13.7%) developed oropharyngeal candidiasis and were treated with Nystatin while 446 patients (86.3%) did not have any evidence of candidiasis requiring treatment. The median time to oropharyngeal candidiasis was 34 days [5-71 days]. Patients showed a higher propensity to developing oropharyngeal thrush with the following characteristics male gender, Black or Hispanic race, diabetes, hemodialysis, increased episodes of rejection, deceased donor allograft recipient and thymoglobulin induction.

Conclusion: Approximately 13% of the renal transplant recipients experienced oropharyngeal candidiasis and received appropriately treatment. Further research is needed to understand and monitor the prevalence of this infection. This would assist in establishing a protocol to reduce the burden of fungal diseases. Risk factors should be taken into account when determining a patient's risk for developing oropharyngeal candidiasis and other potential invasive fungal diseases after transplant. Patients with higher susceptibility of developing oral candidiasis should be considered for prophylactic therapy especially in the first 30 days after transplantation.

Poster Title: Evaluation of varenicline as a smoking cessation aid in a medically underserved population

Primary Author: Amanda Lehmann, University of Maryland Eastern Shore School of Pharmacy and Health Professions, Maryland; **Email:** arlehmann@umes.edu

Additional Author (s):
Javaria Alvia
Yen Dang

Purpose: Approximately fifteen percent of the population in Maryland smoke cigarettes, making it rank the fourth highest among the states for prevalence of tobacco consumption. Smoking rates are even higher on the Eastern Shore of Maryland where one in four adults are cigarette smokers. Varenicline is a first-line Food and Drug Administration approved smoking cessation aid for patients achieving tobacco abstinence. This study aimed to evaluate the usage of varenicline as a smoking cessation aid in a medically under-served population in Maryland.

Methods: A retrospective analysis was conducted on three federally qualified health system clinics managing patients for tobacco dependence. Patients were included if they were cigarette smokers eighteen years of age or older, used varenicline for at least one month, and were titrated to recommended dosage formation of varenicline after seven days. Patients who used chewing tobacco, smokeless tobacco, hookah, and electronic cigarettes were excluded. The primary endpoint was the change in cigarette consumption in packs per day at one month. Secondary endpoints included the change in packs per day at three months and the number of patients achieving 50 percent reduction or abstinence from cigarettes at one month and three months. Subgroup analyses were conducted to analyze the effects varenicline on patient specific factors including race, duration of smoking, number of clinic visits, education level, and mental health status. Statistical analysis was performed using Wilcoxon signed rank test to analyze continuous nonparametric data. McNemar's Chi Squared test was used to analyze nonparametric categorical data. All P values were two-sided and the alpha was set at 0.05. Last observation carried forward was used to account for missing data.

Results: Of the one hundred sixty patients screened, only sixty patients were included in the primary analysis due to loss to follow-up or an insufficient duration of varenicline treatment. For the primary endpoint, patients using varenicline at the end of one month smoked 0.25 ± 0.09 packs per day compared to 0.5 ± 0.076 packs per day at baseline (P < 0.05). At three months, the median consumption was 0 ± 0.066 packs per day (P < 0.05). Only two patients (0.3 percent) taking varenicline experienced nausea or vomiting. No other significant side effects were reported. The results for the subgroup analysis showed that race (P = 0.43), education level (P = 0.69), mental health status (P = 0.93), quantity of smoking (P = 0.49), number of clinic visits (P = 0.48), and duration of smoking (P = 0.93) did not differ in the efficacy of varenicline at one month compared to baseline.

Conclusion: Varenicline was efficacious in reducing cigarette consumption with minimal side effects in a medically underserved population. Patients with mental disorders, limited education level, and a long duration of smoking did not differ in efficacy outcomes on varenicline. The high number of patients lost to follow up in the study reflects the need for providers to address smoking cessation status at every visit to enhance medical access and prevent further tobacco-related complications.

Poster Title: Bridging the Vaccination Gap: the disparity between real and ideal adult immunization rates

Primary Author: Kelley Lu, The University of Texas at Austin College of Pharmacy, Texas; **Email:** kelleylu@utexas.edu

Additional Author (s):
Christina Maher

Purpose: A healthcare provider's recommendation is a primary factor in patients receiving and staying up-to-date on vaccinations. The purpose of this study is to examine institution protocol and current knowledge status of adult vaccinations. We will be evaluating pneumococcal vaccinations in the adult and high-risk populations to gauge healthcare provider awareness of adult vaccination recommendations. This project will educate providers on the pneumococcal vaccinations available and the CDC's Advisory Committee on Immunization Practices recommendations for pneumococcal vaccination in adults. The goal of educating healthcare providers about this vaccination gap is to increase immunization rates to reduce the incidence of vaccine-preventable disease.

Methods: The study employs a cross sectional, non-experimental design. The survey assesses 1) healthcare provider's patient demographics 2) hospital protocols regarding adult vaccinations 3) knowledge regarding pneumococcal vaccination recommendations. The survey will be distributed to practicing healthcare providers employed by either institution affiliated hospital prior to large-scale distribution of the survey. The finalized electronic Qualtrics survey will be sent out through national organizations (e.g. American Society of Health- System Pharmacists, American Pharmacists Association, American Medical Association). The survey will be preceded by an informational cover letter describing the anonymity of the participants, and that the purpose of this study is to assess knowledge of adult immunizations in clinical settings. Respondents will be given 2 weeks to complete the electronic survey, after which data collection will close for analysis. The closing page of the survey will thank participants for their responses and also provide educational information on the Advisory Committee on Immunization Practices (ACIP) recommendations for pneumococcal vaccination, and links to updated adult immunization guidelines.

Results: Of the 48 healthcare providers who took the survey, representing 12 different states, 89.6% (43) serviced an adult population of 18 years or older. Of the 43 healthcare providers serving adults, 41.9% (18) practiced primarily in the hospital setting, 39.5% (17) practiced primarily in the community setting, and the remaining 18.6% (8) practiced in another setting not classified within hospital or community. The providers were then asked whether clinicians at their institution routinely ask patients about their immunization history. Only 69.8% (30) individuals responded "Yes" to routinely asking patients about immunization history. When asked about a protocol for giving adult pneumococcal vaccinations at their institution, 65.1% (28) providers responded "Yes". 16.3% (7) responded "No" and 18.6% (8) did not know if their institutions had a protocol utilized for pneumococcal vaccination. 51.2% (22) healthcare providers correctly identified the ACIP recommendations for pneumococcal vaccinations in adults, and 41.9% (18) healthcare providers correctly identified the ACIP recommendations for the vaccine-naive high-risk adult population.

Conclusion: Adult patients rely on their healthcare professionals to have a basic knowledge of immunization practices. This survey was helpful in identifying the lack of protocols for pneumococcal vaccinations, as well as knowledge gaps of healthcare providers regarding adult pneumococcal vaccination recommendations. Through providing the correct ACIP recommendations to providers after the survey, the survey helped to close this knowledge gap in providers. This survey also helped to raise awareness regarding pneumococcal vaccination practices in healthcare providers.

Session-Board Number: 5a-036

Poster Title: Marine Pharmacology and Pharmaceuticals Pipeline in 2016

Primary Author: Michelle Nguyen, Midwestern University Chicago College of Pharmacy, Illinois;
Email: mnguyen43@midwestern.edu

Additional Author (s):
Dom Dop Nguyen
Alejandro Mayer

Purpose: Over fifty percent of marketed drugs are extracted from natural sources or produced synthetically from natural products, and a percentage of those FDA-approved medications are derived from marine compounds and have made an impact in our field. These marine-derived medications are widely known and have helped many patients, especially those with cancer. The marine pharmaceutical pipeline has attracted a multitude of people to the website from across the world, and hopefully inspired or aided those with an interest in marine compounds.

Methods: Various databases were utilized to research and analyze new data and approvals of medications derived from marine compounds, which are mostly used for cancer, pain, and hypertriglyceridemia. The databases employed were PubMed, MARINELIT, a database for marine natural products literature at http://pubs.rsc.org/marinlit/, and clinical trials databases which included https://clinicaltrials.gov/, as well as a Chinese and European clinical trials database. As changes in trials, drug development phases I, II, and II, and FDA-approval occurs, the information on the clinical marine pharmaceutical pipeline webpage was regularly updated.

Results: The status of the marine pharmacology and pharmaceutical pipelines was assessed in mid 2016. In early 2014, the clinical marine pharmaceutical pipeline (Mayer et al. TIPS 31:255-265, 2010) consisted of 10 marine-derived compounds in clinical development. Included in the clinical marine pharmaceutical pipeline were three monoclonal antibodies conjugated to monomethyl auristatin E, a synthetic analog of the marine compound dolastatin, which were in either Phase I, Phase II or Phase III clinical trials. However, in September 2016, the clinical marine pharmaceutical pipeline consists of 13 marine-derived compounds and 16 auristatin-containing antibody drug conjugates in different phases (FDA-approved and Phases I, II, and III) of clinical development. The most recent information on the clinical marine pharmaceutical

pipeline is available to the public at large at
http://marinepharmacology.midwestern.edu/clinPipeline.htm.

Conclusion: There are six FDA-approved marine-derived drugs in the US market, while one is no longer available. The drugs cytarabine (Cytosar-U®, Depocyt®, FDA-approved 1969), eribulin mesylate (Halaven®, FDA-approved 2010), brentuximab vedotin (Adcetris®, FDA-approved 2011) and trabectedin (Yondelis®, FDA-approved 2015) are for cancer, ziconotide (Prialt®, FDA-approved 2004) for pain, and omega-3-acid ethyl esters (Lovaza®, FDA-approved 2004) for hypertriglyceridemia. The drug that is no longer available is vidarabine (Vira-A®, FDA-approved 1976), an antiviral. Thus in September 2016, the marine clinical pharmaceutical pipeline continues to be very active.

Poster Title: A pharmacist-led hospital discharge follow-up clinic in a primary care health center

Primary Author: Sarah Fischer, University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Colorado; **Email:** sarah.n.fischer@ucdenver.edu

Additional Author (s):
Sarah Anderson
Joel Marrs
Rebecca Hanratty

Purpose: Hospitals' readmission rates are a quality metric subject to public reporting and potential financial penalty. A pharmacist-led hospital discharge clinic embedded in a primary care clinic (Gipson Eastside Family Health Center) was created to improve the timeliness of post-discharge follow up and reduce 30-day readmission rates. It was hypothesized that 30-day readmission rates for patients seen in the Eastside Hospital Discharge Clinic (EHDC) would be lower than the baseline readmission rate.

Methods: Established patients discharged between October 1, 2014 and September 30, 2015 were called within 2 business days of discharge and invited to schedule an EHDC appointment with a pharmacist. Eligible patients included any patient discharged from the study hospital. Medication reconciliation and education were the primary foci of the EDHC appointment. A supervising physician reviewed and cosigned each appointment encounter and participated in the appointment if necessary. The primary outcome measure was patient readmission rate to the study hospital only. Secondary outcome measures included time between hospitalization and EDHC appointment and characterization of pharmacist interventions within the EDHC appointment.

Results: A total of 187 patients were identified as eligible for an EHDC appointment and 23 (11%) were enrolled. Patients in the study cohort had a mean age of 61.5 years, 65.2% were male, and 56.5% were African American. Common reasons for initial hospitalization were cardiac- (N=10) or diabetes-related (N=5). The mean length of stay was 2.8 days, time between hospitalization and EHDC appointment was 6.8 days and time between EHDC and PCP appointments was 7.6 days. All patients received at least one pharmacist-led intervention:

medication reconciliation (78.3%), patient education (65.2%), and medication adherence counseling (43.5%). There was a 17.4% 30-day readmission rate. Of the remaining 164 patients who did not attend a follow-up appointment with a pharmacist, 32.3% were re-admitted to the hospital within 30 days of initial hospitalization. The mean length of stay for these patients was 3.3 days and time between initial hospitalization and readmission was 11.8 days. Major reasons for not scheduling an EHDC appointment were that the patient declined the offer to have an appointment with a pharmacist and the inability to reach the patient due to no answer or non-working telephone number.

Conclusion: Patients who attended an EDHC appointment were readmitted at nearly half the rate of those who did not. However, the small sample size and high-risk population likely confounded the results. Not all patients received all components of the EHDC appointment because the appointment was individualized based on each patients' needs. The feasibility of implementing a pharmacist-led hospital discharge service that fits the transitional care management services model has the potential to improve patient care.

Poster Title: Atypical Presentation of Coccidioidomycosis

Primary Author: Wendy Lin, The Ohio State University, Ohio; **Email:** lin.1207@osu.edu

Additional Author (s):
Joseph Gastaldo
Katherine Fitz

Purpose: Coccidioidomycosis, most commonly known as "valley fever", is a fungal infection caused by the spores of the Coccidioides species. Most prevalent in the southwestern United States and Central America, Coccidioides may lead to respiratory infections when inhaled. In endemic regions, Coccidioides is estimated to affect approximately 30 to 60% of the population. Following exposure, a majority of patients may be asymptomatic or may experience mild flu-like symptoms; however, one to two percent of the infected population may experience dissemination of spores to the skin, bones, and joints with delayed presentation of symptoms up to several months after initial exposure. Complications from disseminated infection may range from skin inflammation and lesions to meningitis. We report a case of a 48 year-old black male with history of total knee arthroplasty and subsequent recurrent infections of his prosthetic knee. Intraoperative cultures revealed Coccidioides species. Though rare, Coccidioidomycosis infection of the bone and joints is associated with high mortality rates if not appropriately diagnosed and treated

Poster Title: From training wheels to two wheels in half the time: A pharmacy intern training program

Primary Author: Charlotte Wagner, University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Colorado; **Email:** charlotte.wagner@ucdenver.edu

Additional Author (s):
Ferras Bashqoy
Jennifer Hamner

Purpose: At Children's Hospital Colorado (CHCO) pharmacy, we were challenged to train several interns in a short period of time in addition to training other pharmacy staff. Our goal was to create a pharmacy intern training program that prepares trainees to the same level of skill in a shorter period of time. We set to reduce training days for interns by 50 percent.

Methods: A program was created that included didactic as well as hands-on training. It started with a 3-day operational orientation that included topics that were suggested by current pharmacy staff. This orientation was lead by a senior pharmacy intern. Then, trainees spent time hands-on-training for 8 hours a day with an overlap for 4 hours with a dedicated intern trainer. The dedicated intern trainer did not have staffing responsibilities and could focus their attention fully on the trainee. Finally, trainees would take a competency to ensure their ability to independently staff shifts required of them. Training days were measured retrospectively by looking at pharmacy department schedules after the new program (2015-2016) and comparing them to the standard technician training plan that was historically used prior to the implementation of this new program. Days spent training in our Central pharmacy and IV clean room were quantified and used as a comparator as these shifts are required training for all new technicians and interns at CHCO. Training shifts outside of central pharmacy or the IV clean room, interns who were not trained following this new training program, and interns who had previously been technicians at CHCO were excluded. In addition, we surveyed all trainees before and after going through the program to determine if their perceived comfort level with hospital pharmacy was improved.

Results: Eight interns were trained in the 2015 summer break from school and three interns were trained in the 2016 summer break from school using this new training program. Intern training days in the Central Pharmacy were reduced from 10 days per employee in the past to an average of 7 days per intern, a reduction in training days of 30 percent. Intern training days in the IV room were reduced from 15 days per employee in the past to an average of 10.7 days per intern, a reduction in training days by 28.6 percent. On average, the perceived comfort level of the trainee to work in the IV room was improved 3.8 points out of 10 and confidence of the trainee to work in the Central pharmacy was improved 2.27 points out of 10 after going through the program.

Conclusion: CHCO new pharmacy interns trained an average of 17.7 days per intern compared to 25 days in the past. After this program, the trainees were able to independently staff in central pharmacy and IV room. In addition, the trainees overall felt more comfortable with the material they were learning. The key to the success is a trainer free from staffing duties to focus on the trainee. This can be easily accomplished with interns during their summer break. In addition, continuous quality improvement is essential to ensure the program continues to meet the needs of the trainee and the pharmacy department.

Submission Type: Case Report

Session-Board Number: 5a-041

Poster Title: Differential diagnostic considerations for psychotic and substance-induced disorders

Primary Author: Oanh Pham, The Univerisity of Oklahoma College of Pharmacy, OKLAHOMA; **Email:** opham1@ouhsc.edu

Additional Author (s):
Ondria Gleason
Nancy Brahm

Purpose: Diagnostic criteria for schizophrenia spectrum and other psychotic disorders, substance/medication-induced psychotic disorders, and substance-related disorders (with a separate category for phencyclidine) have features that make presentations similar. These include delusions, hallucinations, and changes in cognition. Diagnostic criteria for schizophrenia also include delusions, hallucinations, as well as disorganized speech and behaviors. Schizoaffective disorder includes specific mood disorder criteria. In the case of substance/medication-induced psychotic disorders, the literature reports that during acute intoxication with a synthetic cannabinoid, psychotic-like symptoms are often present, and acute effects usually last from 30-120 minutes, but the symptoms can last until the next day. Reported symptoms of psychosis are delusional thoughts, hallucinations, disorganized and/or paranoid thought processes, euphoria, anxiety, and suicidal thought. The presentation of phencyclidine, or a similar compound, is different, however. One difference in individuals who use phencyclidine is the duration of effects. While the primary effects may last several hours, these effects generally extend 8 days or longer and in what have been termed 'vulnerable individuals.' Symptoms may last for weeks and precipitate a persistent psychotic episode resembling schizophrenia. When first discovered, the neurobiological changes associated with chronic, intermittent low dose phencyclidine use resembled those seen in persons with a diagnosis of schizophrenia. Given the similarities in the presentation of these disorders, use of nonpharmacological and pharmacologic resources aid in the differential diagnostic workup.
An actively psychotic 31-year-old African-American male was involuntarily admitted into an inpatient facility. Psychiatric history was positive for schizoaffective disorder and cannabis use. Baseline functioning included intermittent auditory hallucinations. For this admission, psychotic exacerbation secondary to substance abuse was suspected. The patient had been maintained

as an outpatient with both a long-acting antipsychotic (optimized) and an oral antipsychotic (low dose). In the inpatient setting, both nonpharmacological interventions (seclusion, limited stimulation, time) were used as well as pharmacological interventions to help stabilize the patient. Full inpatient treatment and assessment information were not available for review. Following more than 21 days of inpatient treatment, the patient is still actively psychotic as evidenced by bizarre statements and art works and verbalization of the intent for self-harm. The patient continues on inpatient status with residential care as a placement consideration. Literature retrieval was accessed through OVID, Google Scholar, MEDLINE, and PubMed (1965-September 2016). Research into the relationship between synthetic cannabinoids and psychosis, phencyclidine use and psychosis/schizophrenia, and differential diagnostic measures were reviewed. Included in the review were pathophysiology and treatment options. Identifying a suspected substance is challenging. Problems clinicians may encounter include limited familiarity with or no information on the substance(s) used, the inability of standard urine drug screening products to detect all synthetic compounds (given the variability of product formulations and potency), and the lack of a detectable metabolite. Psychotic symptoms may exceed the anticipated duration of action if a substance is suspected. Based on these factors, patient assessment may be limited to the evaluation of laboratory results and imaging diagnostic screening available in the individual facility and clinical presentation.

Poster Title: Meds to beds pharmacy program to improve patient outcome through an interactive survey post discharge.

Primary Author: Mark Sarlo, West Virginia University, West Virginia; **Email:** mwsarlo@mix.wvu.edu

Additional Author (s):
Emily Stewart
Larry Calamine
Krista Dupont
Logan Sanders

Purpose: At WVU Medicine a discharge program was implemented in 2012 to aid in giving the patient a seamless transition of care at time of discharge. The use of an outpatient pharmacy to fill patient's prescriptions prior to discharge has shown to improve patient outcomes and potentially plays a beneficial role in reducing readmissions. A three month study was conducted through follow-up telephone encounters to survey patients using the discharge pharmacy to assess the patients' outcomes and the patients experience with our discharge program.

Methods: In an effort to improve on the patient's outcome and reduce re-admissions after discharge, the Medical Center Pharmacy (MCP) at West Virginia University Hospital has implemented a post discharge program. Patients were selected post discharge past 30 days and based on several disease states were targeted for high readmission by CMS (Centers of Medicare and Medicaid services). These patients were contacted via telephone and asked a 7 question survey to gain more knowledge of the patients experience in relation to the program. Questions included: if the patient know about the service prior to admission, how were they informed of the service, how friendly the staff was, how timely the service was , if counseling was given, and if the patient was readmitted to the hospital 30-90 days after discharge.

Results: Since the launch of the program four years ago, the service has been offered to over 40,000 discharge patients. The capture rate has reached as high as 50% in electing to use the service with an average of around 30%. The role of the discharge pharmacist in the continual care of the patient has also shown an impact on patient compliance and understanding of their

medication. Over 700 patients were attempted to be contacted with over 300 being reached over a 90 day time frame. 95% of medications reached the patient within a timely manner and over 90% of patients received counseling at time of discharge. Readmission data reached over 20% on selected disease states .

Conclusion: Implementation of the discharge program has made a significant impact on the continual care of the patient prior to discharge. Prescriptions filled during the patient's discharge have showed improved compliance and a reduction in readmission. Readmission data reached over 20% on selected disease states showing the need for targeting these disease states with amended services, such as MTM (Medical therapy Management), Medication reconciliation and increased discharge counseling with post discharge follow-up encounters.

Poster Title: Patient satisfaction with medication therapy management services across a large integrated care delivery system

Primary Author: Michelle Mages, Drake University, Iowa; **Email:** michelle.mages@drake.edu

Additional Author (s):
Laura Odell

Purpose: This project was designed to assess the level of patient satisfaction with pharmacist provided comprehensive medication reviews across specialty and primary care sites in a large integrated care delivery system. Results provided insight on patient perceptions of clinical ambulatory care pharmacists and revealed areas of strength and potential areas of improvement for comprehensive medication reviews.

Methods: A satisfaction survey was distributed to patients receiving comprehensive medication reviews at 20 clinics within an integrated care delivery system from May through July of 2016. This study did not meet criteria for institutional review board review. The survey tool was tested and validated in a previous study by the Health-systems Alliance for Integrated Medication Management. Surveys were provided to patients by either desk staff at the time of check in for the pharmacist appointment or by the pharmacist at the start of the pharmacist appointment. Patients received a paper survey along with a postage paid envelope. Surveys were returned by mail to a central location for data collection. Responses were compiled and statistics were performed using Microsoft EXCEL. The brief survey includes thirteen questions, three of which assess demographics. The remaining ten questions are value-based and incorporate three conceptual areas of care provided by the clinical ambulatory care pharmacist, including specific medication-related needs, pharmacist performance, and overall satisfaction. Nine questions ask patients to give an evaluation of their experience on a 4-point scale (strongly agree, agree, disagree, strongly disagree). The last question allows patients to express overall satisfaction with care and service on a 5-point Likert scale (excellent to poor). Lastly, patients could freely write in any comments or concerns in an open text box.

Results: Surveys were distributed to 606 patients and 288 surveys were completed and returned. Incomplete surveys were included for completed questions only. The overall response rate was 48 percent. Seventy percent of returned surveys were from primary care clinic sites. Thirty percent were from specialty clinic sites including cardiology, transplant, pharmacogenomics, and dialysis. Forty-nine percent of respondents were male and 51 percent were female. When examining age, 61 percent of respondents were 65 years of age or older, 30 percent were 45 to 64 years old and 8 percent were 25 to 44 years old. Patients responded positively to value-based questions. Over 90 percent of patients strongly agreed or agreed to positive statements about care and services for seven of the nine value-based questions. Two questions regarding pharmacist helping the patient understand the best way to take medications and finding ways to take medications more easily resulted with 81 percent and 89 percent of patients strongly agreeing or agreeing. When asked about overall satisfaction, 95 percent of patients rated their care as very good or excellent. Responses were consistent across sites with the lowest overall satisfaction being 83 percent and the highest being 100 percent at eleven of the twenty sites.

Conclusion: Patients are highly satisfied with comprehensive medication reviews provided by clinical ambulatory care pharmacists in specialty and primary care settings of an integrated care delivery system, spanning across multiple geographic regions. Consistently, across all sites, 95 percent of patients rated overall satisfaction with quality of care and services received from the clinical pharmacist as excellent or very good. Patient satisfaction surveys can be effectively implemented in ambulatory care pharmacy settings to assess patient perceptions of pharmacists. Results can be used to determine patient satisfaction with care and services provided by the pharmacist and reveal potential areas of improvement.

Poster Title: Evaluation of vancomycin-associated nephrotoxic event rates in obese patient populations.

Primary Author: Vahid Sula, Roseman University of Health Sciences, Nevada; **Email:** vsula@student.roseman.edu

Additional Author (s):
Shih Bia
Lisa Krautstrunk
Ragini Bhakta

Purpose: Based on established recommendations, vancomycin is dosed at 15 to 20 milligrams per kilogram every 8 to 12 hours of actual body weight. With more complicated infections, guidelines recommend doses to obtain even higher trough levels than what was once targeted. As doses increase the concern for nephrotoxicity also increases. Obese and morbidly obese patients, requiring higher doses, are then especially at risk. In this analysis, we evaluated obese patients on vancomycin and reported vancomycin doses, troughs levels, and additional nephrotoxic risk factors to determine if there was a link with increased nephrotoxicity in this population.

Methods: This single-centered, multiple campuses, IRB approved, study retrospectively evaluated patients given vancomycin at St. Rose health system between January and September 2014. Patients with a body mass index (BMI) greater than or equal to 30 kilograms per meters squared were evaluated. Patients were excluded if they were less than 18 years old, pregnant, or had a BMI less than 30 kilograms per meters squared. Exclusion criteria also included patients with less than two vancomycin doses administered or having no recorded vancomycin troughs. BMI was further sub-divided into three categories; BMI ranging from 30 to 34, 35 to 39, and greater than or equal to 40. All patients had the following data collected; BMI, vancomycin dose, frequency, trough, indication, renal function, pertinent lab values, concomitant antibiotics, other nephrotoxic agents, ICU admission, and relevant patient demographics. Data collection was then synthesized through an Excel sheet. Beyond assessing acute kidney injury through tracking serum creatinine to identify a nephrotoxic event no clinical

judgment was used; we only reported what was specifically stated by the nephrologist consultations.

Results: 1000 patients were at or above the BMI classification of obesity. Of these patients, 566 patients were also excluded for having less than two vancomycin doses administered or having no recorded vancomycin troughs. The remaining 434 patients were recorded; with 194 females and 240 males, an average patient age of 65 years old, and an average BMI of approximately 37 kilograms per meters squared. 72 out of the 434 patients, or 16.5 percent, were confirmed to have experienced a nephrotoxic event. Of the 72 events, 37 were attributed solely to "factor X" in reference to a multitude of other potential causes of nephrotoxicity as reported primarily by nephrologists such as contrast-induced nephrotoxicity, nephrotoxicity due to diuretics, administration of antibiotics suspected of nephrotoxicity (aminoglycosides or cefepime for example). 28 other events were attributed to both "factor X" and vancomycin. Conversely, only 7 events were attributed to vancomycin exclusively.

Conclusion: Our analysis primarily reveals a synergistic association with vancomycin and nephrotoxicity when in the presence of other nephrotoxic events. Directly and solely attributing vancomycin to increased nephrotoxicity was not a substantial finding in this study. This study provides further insight into clinical considerations regarding the use of vancomycin in obesity.

Poster Title: Evaluation of plasma-derived C1 esterase inhibitor use and patient outcomes throughout an academic health system

Primary Author: Elizabeth Kramer, Ohio Northern University Raabe College of Pharmacy, Ohio; **Email:** e-kramer.2@onu.edu

Additional Author (s):
Mandy Leonard
Thomas Achey

Purpose: Hereditary angioedema (HAE) and angiotensin converting enzyme inhibitor (ACEI)-induced angioedema are serious conditions that require medical attention. There are several drugs available to help with acute episodes of HAE, some of which have evidence for additional efficacy in ACEI-induced angioedema. In 2009, C1 esterase inhibitor (C1INH) was added to the institutional formulary restricted to Allergy and Immunology for HAE. In January 2016, its use was expanded to the health system for management of HAE and ACEI-induced angioedema.

Methods: Patients were included if they had a medication order for C1 esterase inhibitors during the period of January 1, 2015 to May 31, 2016. The primary objective was to assess adherence to the health system formulary restriction criteria. The secondary objectives were to evaluate the indication, if it was being used for prophylaxis or treatment, dose, frequency and patient outcomes (defined as time to symptom relief and time to complete resolution of angioedema). This retrospective chart review was submitted to the institutional review board and given exemption status.

Results: There was a total of 11 orders (n=7 patients) for C1INH during the evaluation period. For patient demographics, six patients were female and one patient was male; the age range was 33 to 69 years and five patients were managed at the institution's academic medical center, one patient at an in-state community hospital and one at an out-of-state community hospital. For indication, three patients were administered C1INH for prophylaxis of HAE prior to high risk procedure(s) and four patients were administered C1INH for the treatment of angioedema (n=2 with HAE exacerbations, n=1 for ACEI-induced angioedema, and n=1 for idiopathic angioedema). For the primary objective, 9/11 (82%) of C1INH orders met formulary

restriction criteria. Treatment doses of C1INH ranged from 5.5 units/kg to 40 units/kg. Of the patients managed for an angioedema exacerbation, time to symptom relief was approximately 1 hour (n=2), and time to complete resolution was a mean of 16 hours (n=3). Only one patient required an intervention beyond first-line medications.

Conclusion: The formulary restriction criteria were followed and were determined to be adequate for this medication. Despite nearly all patients obtaining symptom relief, there was a wide range of doses administered. With the conflicting evidence currently available for doses for these conditions, it may be helpful to establish a dosing protocol for the management of HAE and ACEI-induced angioedema.

Poster Title: Resveratrol induces suicide gene therapy vector of early growth response-1 and growth-arrest DNA damage inducible 45 alpha in nonsmall cell lung carcinoma cell line

Primary Author: Deepka Bhatia, Bernard J. Dunn School of Pharmacy - Shenandoah University, Virginia; **Email:** mle14@su.edu

Additional Author (s):
Michael Le
Carlette Cavenaugh
Patrick Kakeu

Purpose: Purpose: GADD45a gene is a key regulator in G2/M cell cycle transition and apoptosis. In lung cancer such as non-small cell lung carcinoma, the expression of this gene was found to be minimal. Therefore, we hypothesized that exogenous supply of GADD45a can result in increased inhibition of these lung cancer cells. The purpose therefore was to create a novel suicide gene therapy vector of growth arrest DNA damage alpha gene (GADD45a) by combining inducible promoter of early growth response-1 (Egr-1) that is upregulated by non-toxic doses of resveratrol to achieve growth arrest and apoptosis in NSCLC.

Methods: Methods: GADD45a open reading frame (ORF) was PCR amplified from GADD45a cDNA (Origene, MD) using specific primers:
F-5'-GGGCGAATTCGGATCCGCCACCATGACTTTGGAGGAATTCTCG-3';
R-5'-TTGGAATTCGCGGCCGCTCACCGTTCAGGGAGATTAAT-3'; and cloned into pTarget vector (Promega, WI). In addition, further manipulation of this vector was carried out by inserting 460 bp of early growth response-1 (Egr-1) promoter upstream of start site using specific primers:
E460F-5'- ATGGCTCGACAGATCTGCTTGGAACCAGGGAGGAG;
E460R-5'-TCAACGGGGCGGGCGATCGCGGCCTCTATTTGAAGGGTCTGG
to create a switch that is inducible in response to tested dose of resveratrol. The cloned vector was then transfected in A549 lung cancer cells and its expression, cell viability of cancer cells and the rate of apoptosis were measured.

Results: Results: Egr-1 mRNA and protein expressions were quantified by PCR and western blot techniques and showed dose dependent induction after the resveratrol treatment. Egr-1 mRNA was peaked at 2 h that was further confirmed by Fluorescence in situ hybridization (FISH) assay. Furthermore, overexpression of resveratrol induced GADD45α protein through our gene therapy vector delayed the cancer progression and increased cellular apoptosis. The data from cell viability assay and flow cytometric analysis suggested resveratrol alone had marginal suppression in cell growth and negligible induction in apoptosis, but resveratrol plus gene therapy vector exhibited less than 50% cell viability and approximately 20% higher apoptosis as opposed to control. Transfection with gene therapy vector but without resveratrol treatment did not significantly affect cell growth or apoptosis in these cells.

Conclusion: Conclusion: Present study confirmed the potential of Egr-1 promoter as an inducible switch upon resveratrol exposure and was able to selectively control therapeutic gene expression (GADD45a) in the tumor. Furthermore, use of resveratrol as an inducible drug being nontoxic and protective to normal cells offer advantage to highly toxic chemotherapy drugs that is currently used in immune compromised cancer patients. In addition, this therapy may work synergistically with traditional lung cancer treatment and could possibly help in lowering doses of radiotherapy and chemotherapy.

Submission Category: Cardiology/ Anticoagulation

Submission Type: Case Report

Session-Board Number: 5a-047

Poster Title: Evaluating efficacy, safety, and tolerability of proprotein convertase subtilisin/kexin type 9 (PCSK9) inhibitors in a large multi-centered outpatient cardiac group

Primary Author: Reena Sail, Midwestern University,-College of Pharmacy, Glendale, Arizona; **Email:** rsail89@midwestern.edu

Additional Author (s):
Sydney Smith
Sophia Bonnin
Desislava Stoyanova

Purpose: Purpose: This case series examines the use of proprotein convertase subtilisin/kexin type 9 (PCSK9) inhibitors, a novel class of cholesterol-lowering agents, in patients at a large multi-centered outpatient cardiology practice. The case series focuses on the specific indication for use of PCSK9 inhibitors, efficacy outcomes within six months after initiation, and occurrence of any adverse drug events.

Methods: A review of the Cardiac Solutions electronic medical record (EMR) was performed to identify all patients who had received an order for PCSK9 inhibitor therapy from September 2015 to August 2016. Inclusion criteria included adults (aged 18 years or older) who had an order for a PCSK9 inhibitor. A chart review was performed to gather patient information including age, race, gender, lipid panels before and within six months after PCSK9 inhibitor initiation, history of cholesterol lowering medications, whether the patient had been concurrently treated with a statin medication, any documented intolerances to statin medications, the indication for PCSK9 inhibitor use, and any adverse reactions reported to the therapy. Patients who did not have a lipid panel drawn before or within six months after initiating PCSK9 inhibitor therapy were excluded, as well as those who never initiated therapy. In patients who met the inclusion criteria, pre- and post-PCSK9 inhibitor lipid panels were compared to assess efficacy of therapy.

Results: A total of sixteen patients were identified from the EMR as receiving an order for a PCSK9 inhibitor. Of the sixteen, four patients were never initiated due to lack of insurance coverage or inability to afford the medication. Three patients did not have documented lipid panels pre-PCSK9 inhibitor therapy, so their data was excluded. One patient discontinued therapy after only one dose because she developed a facial rash that resolved within 2-3 days.

A total of eight patients were evaluated for efficacy. The average age was 62 years, 62 percent of patients were female, all patients were Caucasian, 62 percent of patients had clinical atherosclerotic cardiovascular disease, and only 25 percent of patients were receiving concomitant statin therapy. Additionally, two patients in the secondary prevention group and one patient in the primary prevention group had a diagnosis of familial hypercholesterolemia. Total cholesterol (TC) and low-density lipoprotein (LDL) cholesterol were statistically significantly lower after initiation of PCSK9 inhibitor therapy [TC 249 mg/dL vs. 162 mg/dL, LDL 147 mg/dL compared to 67 mg/dL]. Triglycerides and high-density lipoprotein cholesterol both showed nonsignificant decreases.

Conclusion: PCSK9 inhibitors seem to be safe and effective, demonstrating an average LDL reduction of 54 percent within a small sample of patients who have elevated LDL levels despite maximally tolerated statin therapy, including patients who were statin-intolerant. Cost is one of the biggest barriers to initiating PCSK9 inhibitor therapy. Although these agents show significant LDL-lowering, more longitudinal research should be done to evaluate the efficacy of these agents in reducing morbidity and mortality.

Poster Title: Eliminating unnecessary wastage of high-use or high-cost drugs: A cost-savings model

Primary Author: Blake Bennie, Lipscomb University College of Pharmacy, Tennessee; **Email:** bennieba@mail.lipscomb.edu

Additional Author (s):
Rhett Hogan

Purpose: As total U.S. drug expenditure has increased 29% in the last two years ('13-'15), many institutions have had to look for creative ways to control spending. Pharmacists are commonly charged with using their clinical knowledge to identify appropriate opportunities to achieve savings.
The two primary targets for cost-saving initiatives are high-cost and high-use drug products. For example, vasopressin, once commercially available at less than $10 per vial, it is now only available as brand-name at $138 per vial. Whereas, glycopyrrolate, available as a 1 ml and 5 ml vial, is widely used by most anesthesia groups.

Methods: For vasopressin, we identified that our 100 units / 100 mL bag was creating waste and medication safety issues. The primary driver for both was that a 100 unit bag expired in 24 hours but contained around 72 hours of drug based on the most common physiologic dose. We found that a 40 units / 40 mL bag would be more appropriate. Using purchase data and the number of bags compounded over the last four quarters, we calculated a historical total spend per quarter. We then projected a theoretical spend per quarter, had we been using our new bag size. The difference in our historical and projected spend was our projected savings.
For glycopyrrolate, we identified the average dose administered by anesthesia and determined that a 5 ml vial would yield a significant amount of waste on almost every patient. Using purchase data, we totaled the amount spent on 5 ml vials per quarter. Using the average dose administered, we projected how many 1 ml vials we would have used instead and what we would have spent acquiring them. The difference in our total amounts spent was our projected savings.

Results: We projected a potential savings of $312,266 for our vasopressin drip change, and a potential savings of $140,803 for our glycopyrrolate vial exchange. While the data and dollar amounts reflected were calculated using the published average wholesale price of both brand-name vasopressin and glycopyrrolate, the result is still a substantial and significant cost savings amount.

Conclusion: Our analysis and subsequent implementation allowed our institution to achieve a significant cost savings. We believe targeting high cost and high use drugs might yield similar results elsewhere and therefore recommend other facilities replicate our process. While this analysis was focused on two medications that we selected, we would contend that there is abundant opportunity for achieving cost savings with other drugs and in health systems of all sizes.

Poster Title: Demographic characteristics predicting thirty day readmissions among patients referred to a hospital's pharmacotherapy service

Primary Author: Gabriel Arguinchona, Washington State University College of Pharmacy, Washington; **Email:** gabriel.arguinchona@wsu.edu

Additional Author (s):
Jennifer Taylor

Purpose: Medication therapy management and pharmacotherapy services, provided by trained pharmacists, are consistently proven to be beneficial to patients, with respect to reducing preventable hospital readmissions. Realizing clinical and financial resources are not always available to provide this service to every patient, efficient identification of patients presenting a high risk for readmission is required. The intent of this study was to determine how differences in patient gender, age, length of hospital stay, and amount of home medications, affect readmission risk within thirty days of discharge.

Methods: Qualification for exemption was determined by the institutional review board for this retrospective study of de-identified patient data, collected over a 6-month time period. Inclusion criteria included patients referred to the service, but declined a pharmacotherapy consultation (n equals 185). Readmission rates among males (n equals 85) and females (n equals 100) was discovered, allowing for comparisons of collected variables between separate genders. The numerical categories were divided into separate value ranges. Patient age was categorized by patients younger than 45 years, patients aged 45 to 54, 55 to 64, 65 to 74, 75 to 84, and patients aged 85 and older. Patient's home medication lists were evaluated by the total number of prescription and over-the-counter medications present at discharge. Patients were sorted by medication lists containing fewer than 10 medications, 10 to 15 medications, 16 to 20 medications, and more than 20 medications. Length of stay was sorted by patients admitted for fewer than 3 days, 3 to 4 days, 5 to 6 days, and more than 6 days. The three numerical categories were evaluated for the entire patient population, and separate genders, allowing for identification of trends between males and females.

Results: Readmission rate of all patients was 19.5 percent. Readmission rate of females and males was 21.0 percent (risk ratio equals 1.1, 95 percent CI equals 0.7 to 1.7, P equals 0.75) and 17.6 percent (risk ratio 0.9, 95 percent CI equals 0.5 to 1.6, P equals 0.72), respectively. No patterns among readmission rates between age groups were discovered. Readmission rates of patients with medication lists containing 16 to 20 medications was 23.4 percent (risk ratio equals 1.2, 95 percent CI equals 0.7 to 2.2, P equals 0.54) and those containing more than 20 medications was 31.8 percent (risk ratio equals 1.6, 95 percent CI equals 0.9 to 3.2, P equals 0.16). Readmission rates based on a length of stay, when separated between genders, produced reciprocating trends. Readmission rates of males admitted fewer than 3 days was 25.0 percent (risk ratio 1.3, 95 percent CI equals 0.7 to 2.4, P equals 0.44). Females staying 5 to 6 days and staying over 6 days had readmission rates of 28.1 percent (risk ratio equals 1.4, 95 percent CI equals 0.8 to 2.7, P equals 0.24) and 33.3 percent (relative risk equals 1.7, 95 percent CI equals 0.7 to 4.0, P equals 0.21), respectively.

Conclusion: Unfortunately, the small sample size of patients produced p-values rendering no significant conclusions about readmission. Differing trends discovered among male and female patients, based on the amount of time spent in the hospital during their initial admission, will require more time and a larger sample to confirm these suspicions. Producing any useful data for predicting patient readmission trends will require a long-term, multi-year study, throughout the entire hospital. Clear understanding of the aforementioned variables, and their role in readmissions, will provide means for development of tools identifying high-risk individuals, creating avenues for pharmacists to help increase patient safety.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Descriptive Report

Session-Board Number: 5a-050

Poster Title: Utilizing search engine analytics to identify popular curiosity and regional distribution of medication inquiries

Primary Author: Stella Kyaw-Soe, Ernest Mario School of Pharmacy, Rutgers University, New Jersey; **Email:** stk65@scarletmail.rutgers.edu

Additional Author (s):
Priyal Soni
Yangmin Chen
Vatche Demirjian
Evelyn Hermes-DeSantis

Purpose: Google Trends is a publicly accessible tool that captures relative data on the volume, geographic location, and common related queries of Internet searches over time compared to total search volume. This study identifies the 2015 top-selling brand medications in the U.S. and the inquiries related to these agents most frequently searched for on Google. Healthcare professionals may be able to use Google Trends data to identify the educational needs by categorizing the information requests.

Methods: The 2015 top 20 global brand medications by dollar amount were identified using IMS Health. Google Trends was utilized to examine the regional distribution of searches of those medications in the U.S. Data obtained was limited to web searches made from January 1, 2015 to December 31, 2015. For each medication, states were ranked by most Google searches related to that agent and the top 3 states were identified. In addition to regional distribution, top related queries in regards to each medication were also recorded. The related queries reflect user's secondary searches following the initial medication inquiry. Only the 3 most popular related queries for each medication were used. After data collection, the frequency of state's appearance in the top 3 rank lists was calculated to determine whether a pattern in regional distribution existed. Next, the top related queries were categorized into the following: side effects, indication, generic, similar/alternative medication, cost or dosage/administration related searches. Frequency was calculated for each of these categories.

Results: The top 20 selling drugs identified were: Abilify, Advair Diskus, Avastin, Copaxone, Crestor, Enbrel, Harvoni, Herceptin, Humira, Januvia, Lantus Solostar, Lyrica, Neulasta, Nexium, Novolog, Remicade, Rituxan, Sovaldi, Spiriva, and Xarelto. States with the highest ranking of medication searches to total Google searches in that state were West Virginia (20 percent), Connecticut (18.3 percent) and Pennsylvania (10 percent). Only 21 states appeared in the top 3 rank listing with the majority of them being located on the east coast of the U.S. The common related queries that most frequently appeared in the secondary searches were side effects (25 percent), similar/alternative medications (18.3 percent), and cost (13.3 percent). Other categories included indication, generic, and dosage/administration. It is interesting to note that some of the related queries were for products in the same or similar class that may have been guided by the paid sponsored results in Google.

Conclusion: Google Trends may be a helpful aid for healthcare professionals in population-based care. Recognizing the limitations of the data is important since the information is relative to the total number of Google searches in that state. Identifying the areas of highest and lowest relative inquiry and relevant Google searches of medications may help tailor educational endeavors. Results show that overall consumers of information, both patients and healthcare providers, are concerned with understanding the possible side effects and cost-reducing methods. Google Trends may be a useful surveillance tool to monitor future patterns in healthcare informational inquiries.

Submission Type: Evaluative Study

Session-Board Number: 5a-051

Poster Title: Clinical characteristics and changes, not captured by the Hendrich II Fall Risk Assessment, observed in patients who experienced in-hospital falls

Primary Author: Kathleen Sullivan, Massachusetts College of Pharmacy and Health Sciences University - Worcester, Massachusetts; **Email:** ksull1@stu.mcphs.edu

Additional Author (s):
Ruchi Singh
Kevin Nguyen
Hao Nguyen
Abir Kanaan

Purpose: Institutions use assessment tools to identify patients who are at risk of falls during hospitalization. At our institution, the Hendrich II Fall Risk Assessment tool is utilized upon admission, and the assessment is repeated every eight hours until discharge. Patients are then placed on fall precaution interventions according to their perceived risk. Since this tool may not capture all factors that predispose patients to falls, we sought to identify additional clinical characteristics that are not captured by the Hendrich II score in an attempt to improve patient safety.

Methods: A retrospective review was performed on 102 patients who experienced falls during their hospital stay between November 2015 and April 2016. Data collected included patient demographics, admission diagnosis, home and hospital medications, blood pressure, and electrolyte values (sodium and potassium). Past medical history was documented for each patient, and focused on disease states that may contribute to increased fall risk, such as neurological, cardiovascular, and musculoskeletal conditions, diabetes and alcohol and/or drug abuse. Electrolytes and Hendrich II scores were repeated at the time of the fall, and blood pressure measurements were gathered before and after the fall occurred.
The use of universal fall precautions, such as non-skid footwear, securing a patient bed in a low wheel locked position with raised side rails, and placing the phone and call light within reach, are required for all inpatients regardless of Hendrich II Score. However, patients with Hendrich II scores of 5 or greater are deemed "high risk" for falls and required additional fall precautions. These include yellow wristbands and slip-resistant socks, and a yellow sign placed in the

patient's room alerting the staff to the increased falls risk. Patients with a Hendrich II score less than 5 can be placed on additional fall interventions if a staff member believes extra precautions are necessary.

Results: The 102 patients represented 103 falls. The average age was 63.5 years, 50.5 percent were men, with an average of 6 fall-risk diseases recorded per person. The most common were cardiovascular (30.6 percent) and neurological (23.8 percent) conditions. Blood pressure (BP) was measured pre-fall in 100 patients (average 130/73 mmHg), and post-fall in 97 patients (average 128/73 mmHg).
Sodium and potassium levels were reported in 98 patients on admission and 93 at the time of fall. At time of fall, 14 percent and 15 percent of patients had abnormal sodium and potassium levels, respectively, a decrease from 22.5 percent and 16 percent.
Between admission and the inpatient falls, 47 patients had 5 or more total medication changes; of which 21 patients had at least 10 changes. The number of medications increased by 38.4 percent after admission, (average 9.2 home medications compared to 12.8 inpatient per person). Overall, the use of antihypertensives decreased 40.9 percent from the time of admission until falls, however, adrenergic blocker use increased by 3.7 percent. Of the 102 patients, 55 had at least 1 BP medication change, while 29 patients had 2 or more changes.

Conclusion: Clinical characteristics of patients, such as preexisting cardiovascular and neurologic conditions, the number of medications administered, and inpatient medication changes, especially those effecting blood pressure, may be considered to identify patients at increased risk of falls. Electrolytes, as well as BP did not seem to affect the fall risk; however, these characteristics need to be explored further since the time of measurement did not occur consistently at the time of fall.

Poster Title: Completing an assessment of risk for hazardous drugs in preparation for United States Pharmacopeia chapter 800 (USP 800) implementation for a health-system outpatient pharmacy setting

Primary Author: James Steigerwalt, Wilkes University Nesbitt School of Pharmacy, Pennsylvania; **Email:** james.steigerwalt@wilkes.edu

Additional Author (s):
Kumaran Ramakrishnan
Krista Decker

Purpose: United States Pharmacopeia chapter 800 (USP 800) outlines new handling requirements for hazardous drugs in healthcare settings, and will require many procedural changes for pharmacies to become compliant. Certain dosage forms of hazardous drugs can be handled through containment strategies alternate to those outlined in USP 800 if deemed to have a low risk of exposure by the pharmacy. The purpose of this project was to complete an assessment of risk for all hazardous drugs dispensed to determine which can be handled through containment strategies alternate to those outlined in USP 800 for a health-system outpatient pharmacy setting.

Methods: Each dosage form of every hazardous drug currently dispensed by the Johns Hopkins Outpatient Pharmacies was identified using the National Institute of Occupational Safety and Health's (NIOSH) List of Antineoplastic and Other Hazardous Drugs in Healthcare Settings. An assessment of risk was completed for each dosage form of each hazardous drug based on the requirements outlined in USP 800. Information collected included the drug name, dosage form, type of hazard, drug packaging, manipulation during product dispensing, and risk of exposure. Criteria were created to differentiate the risk of exposure for healthcare workers into three levels of risk: low, moderate, or high risk of exposure. Hazardous drugs were then assigned to these levels of risk for exposure based on a scoring system. This scoring system differentiated exposure risk based on the specific dosage form, drug packaging, and manipulation of the hazardous drug. Medications that scored higher on the scoring system were assigned a higher level of risk. Each completed assessment of risk was then documented to help direct implementation of USP 800 in the outpatient pharmacy setting.

Results: 251 individual hazardous drugs and dosage forms were identified as being dispensed by the Johns Hopkins Outpatient Pharmacies. Further classified into the type of hazardous drug (as defined by the NIOSH List of Antineoplastic and Other Hazardous Drugs in Healthcare Settings), 87 were antineoplastic drugs, 84 were non-antineoplastic, and 80 were considered to be of reproductive risk only. After completing an assessment of risk for each dosage form of each hazardous drug, 177 hazardous drugs were determined to exhibit a low risk of exposure, 55 as a moderate risk of exposure, and 19 as a high risk of exposure. Dosage forms commonly assigned a low risk of exposure included film-coated oral tablets, oral capsules, final dosage forms that only require product labeling, and unit-dose packaged products. Moderate risk of exposure drugs included oral solutions, oral suspensions, and dust forming oral tablets. High risk of exposure drugs were exclusively compounded products involving manipulation of an original dosage form (such as pulverizing tablets or opening capsules).

Conclusion: After completing an assessment of risk for all hazardous drugs dispensed in the Johns Hopkins Outpatient Pharmacies, it was identified that the majority (71%) of hazardous drugs dispensed have a low risk of exposure to pharmacy staff. Therefore, the majority of hazardous drugs in the outpatient pharmacies can likely be handled through containment strategies alternate to those outlined in USP 800. This project helped to clearly identify which drugs are considered hazardous and their relative risk of exposure. The completed assessment of risk document can be used as a guiding document throughout the future phases of USP 800 implementation.

Submission Category: General Clinical Practice

Submission Type: Evaluative Study

Session-Board Number: 5a-053

Poster Title: Spacing Practice Improves Retention in the Self-paced Learning of Brand/Generics

Primary Author: James Terenyi, The UNC Eshelman School of Pharmacy, North Carolina; **Email:** jterenyi@unc.edu

Additional Author (s):
Heidi Anksorus
Adam Persky

Purpose: Learning brand/generic equivalencies is a central task for future pharmacists. Some students will attempt to learn material all in one sitting (a Massed Schedule) whereas other students will study over time (a Spaced Schedule). In addition, some students will study and re-study and not practice retrieving information. The purpose of this study was to experimentally test the impact on learning brand/generic drug information when various schedules of retrieval practice were employed in a self-paced course.

Methods: Students (n=151) completed weekly quizzes during the semester on the-brand/generic for 100 commonly prescribed drugs. Each student completed part of the drug list on a schedule of equal, expanding, or contracting spacing, or just one practice (massed) or study only in a counterbalanced design. The primary outcome was performance on a 50-question, fill-in-the-blank assessment 6 weeks after the course concluded.

Results: On measures of long-term retention, the contracting spacing schedule led to superior retention (67.2%) compared to the massed practice (50.1%, p < 0.001) and study only condition (45.6%)(p < 0.001) but not significantly different than expanding practice (58.3%, p=0.229) or equal practice (58.7%, p=0.283). The study only condition resulted in lower retention compared to all conditions except massed practice. Overall performance decreased by almost 50% (final exam 95%, long-term retention 55%) over a 6-week period.

Conclusion: Students were able to retrieve a large fraction of name-brand/generic conversions after 6 weeks of not studying or practicing. A contracting spacing schedule was the best schedule of practice. Follow-up studies are needed to determine which schedules will show superiority over longer retention periods.

Poster Title: Evaluation of errors and waste with a technology-assisted workflow system at a tertiary care hospital

Primary Author: Karly Dancsecs, Duquesne University Mylan School of Pharmacy, Pennsylvania; **Email:** dancsecsk@duq.edu

Additional Author (s):
Nellie Jafari
Laura Mark

Purpose: Technology-assisted workflow (TAWF) systems were developed for use in the intravenous (IV) room to improve patient safety. They minimize the amount of medication errors by creating checkpoints at each stage of IV preparation. Through the use of barcode scanning technology, TAWF systems intercept errors before the pharmacist verifies the final drug product. The technology also prioritizes the production of doses based on administration due time allowing for increased efficiency and reduction in waste volume. This project was designed to evaluate the frequency of errors and waste at a tertiary care hospital using a TAWF system.

Methods: The project evaluated products made in the IV room from November 1st, 2015 to November 30th, 2015. All IV products were included in the analysis except for products that were bypassed through the TAWF system, such as chemotherapy, epidurals, blood products, and total parenteral nutrition (TPN). The primary endpoint was the number of errors in IV product preparation intercepted by the TAWF. The secondary endpoints were types of errors made, number of IV bags wasted, and the cost associated with the waste. Two error reports were generated using the TAWF. The first error report showed the errors that were intercepted through barcode scanning. The second error report documented the errors that were caught during the pharmacist final verification. The errors were classified and the frequency of each error type was calculated. An automated report was generated of all wasted products and grouped based upon drug classification. The cost of waste for each drug category was calculated.

Results: The institution prepared 34,284 doses during the survey period. Two hundred sixty-seven (0.8%) total errors were documented in the automated reports. Barcode scanning technology intercepted 237 (89%) of the errors. One hundred sixty-one (68%) of the intercepted errors were due to a wrong drug or diluent selected. Thirty (11%) of the errors were documented during the pharmacist final verification. The most common type of error during pharmacist final verification was wrong drug concentration. The hospital wasted 441 drug products, which resulted in a cost of $16,669 for the month. The top five drug classes resulting in the most cost were immunosuppressants, vasopressors, anti-hypertensives, and antibiotics. Antibiotics were the most wasted products at the institution, making up 41% of the waste. The most common antibiotic wasted was cefazolin.

Conclusion: TAWF systems improve safety in health care settings through barcode scanning. They also provide benefit to pharmacy departments through documentation of IV errors and waste for ongoing quality assurance evaluations. Although the technology reduces the number of errors, pharmacist judgement is still needed since all errors were not intercepted by the TAWF before reaching the pharmacist. This evaluation identified future projects that need to be implemented, such reducing antibiotic waste, preventing the wrong drug or diluent from being selected to prepare an IV, and optimizing the TAWF system to intercept more errors.

Poster Title: Decontamination for disruptive dirt: HPV vs UVC decontamination in the hospital pharmacy setting

Primary Author: Brooke Kohls, Ohio Northern University, Ohio; **Email:** b-kohls@onu.edu

Additional Author (s):
Denise Rodriguez
Obi Ofoche
Polly Trexler
Florin Kuhn

Purpose: IV contaminants put patients at risk for serious infections, yet contamination of pharmacy sterile compounding areas remains an issue in many institutions. A wide variety of cleaning products, procedures and schedules are employed in this setting; however, exceeding counts of microorganisms and organisms of concern are found in biannual ISO area certifications. Not only does required re-certification after an action level finding place a financial burden on pharmacies, but also fines and suspension of operations may follow. The purpose of this study was to evaluate the efficacy of decontamination methods not currently used in the hospital pharmacy setting.

Methods: Two pilot studies were devised, one using hydrogen peroxide vapor technology (HPV) and another using UVC devices. For the duration of each pilot study, environmental control staff (EVC) and pharmacy staff documented daily cleaning on wall logs, and additionally pharmacy staff audited the activity of EVC to ensure consistency. B&V Sampling was contracted for the collection of samples for both studies. On day one of each two week study, B&V took a full set of surface and air samples in the two rooms designated most historically troublesome in The Johns Hopkins Central Pharmacy. These rooms included the hazardous cleanroom and patient specific anteroom. Sampling was followed by the EVC terminal cleaning (most thorough decontamination in current cleaning schedule), followed by the respective study decontamination process, with full sets of B&V samples after each step. On day 7, full sets of B&V samples were again obtained. On day 14, EVC terminal cleaning was completed for a second time with B&V samples before and after. The surface and air samples obtained were

used to evaluate the immediate decontamination effects of the EVC terminal cleaning, each study decontamination process (HPV and UVC), and the effects on bacterial load over time.

Results: Beginning with the HPV pilot study, many organisms of concern were detected, with only one action level finding due to an exceeded count; therefore, numbers of colony forming units (CFUs) of organisms of concern were compared. Interestingly in the anteroom, zero CFUs were detected before day one EVC terminal cleaning and 8 CFUs mold/yeast after terminal cleaning (2 Pseudomonas spp., 4 Alternaria spp., 1 Neisseria spp., 1 Rhodotorula spp.). Day one HPV decontamination brought the count down to 2 CFU mold (2 Alternaria spp.). Levels remained relatively constant through day seven and day fourteen until after the second EVC terminal cleaning, increasing to 19 CFUs coagulase positive staphylococci (CPS). A similar trend appeared in the anteroom during the UVC pilot, with zero CFUs before EVC terminal cleaning, 4 gram negative rods (GNR) after terminal cleaning (2 Pantoea spp., 2 Acinetobacter spp.), and 2 GNRs after UVC decontamination (2 Pectobacterium spp.). The trend was different in the cleanroom, with EVC terminal cleaning generally not affecting the CFU count (one single CFU increase and one single CFU decrease incidents), HPV completely decontaminating the room to zero CFUs, and UVC also not largely affecting the CFU count.

Conclusion: While both studied decontamination processes appeared to decrease room contamination overall, the difference in trends between the anteroom and cleanroom was alarming. In particular, the rise in organisms of concern after EVC terminal cleaning in the anteroom alone and not the cleanroom indicated that there were likely other factors at play. Following an evaluation of facilities, it was determined that the location of the anteroom was a contributing factor to its consistent contamination – especially post-EVC terminal cleaning. After proposed facility alterations, future studies will be required to confirm the effects of facilities and efficacy of HPV and UVC decontamination.

Poster Title: Evaluation of daptomycin utilization in a community hospital

Primary Author: Elizabeth D'Andrea, Washington State University College of Pharmacy, Washington; **Email:** elizabeth.dandrea@wsu.edu

Additional Author (s):
Dana Bowers

Purpose: Ensuring the appropriate use of antimicrobials is the cornerstone of an antimicrobial stewardship program. These programs can help guide appropriate use of high-cost antimicrobials, such as daptomycin. Daptomycin is approved for several indications for Gram-positive organisms including complicated skin and soft tissue infections (cSSTIs), as well as, bacteremia and right-sided infective endocarditis (IE) from methicillin susceptible Staphylococcus aureus (MSSA) or methicillin-resistant S. aureus (MRSA). The role of the stewardship team is to routinely evaluate the use of antimicrobials and ensure they are being prescribed appropriately. The purpose of this study was to evaluate the utilization of daptomycin.

Methods: This was a single center, retrospective medication use evaluation. Data were collected using electronic medical records for all patients who received daptomycin from January 1st, 2015 through March 30th, 2016 at Kingman Regional Medical Center (KRMC) in Kingman, Arizona. All patients who received at least one dose of daptomycin were included in the study. Patients that were readmitted within or after a 30-day period of initial daptomycin treatment and received daptomycin were considered a new course. Pertinent data were collected including: demographic data, indication for use, medical diagnoses, dose, duration, frequency, creatinine phosphokinase levels (CPK), previous or subsequent vancomycin therapy, microbiological data and 30-day readmission. The primary outcome of this study was to assess the utilization of daptomycin at KRMC. The secondary outcome was 30-day all-cause readmission rates. Data were analyzed and presented as descriptive statistics.

Results: There were a total of 71 daptomycin courses during the study period (53 inpatient and 32 outpatient courses). Thirty-eight percent of patients were female with a median age of 62. The most common indication was SSTIs (87 percent, n=46). The doses administered ranged

from approximately 4 milligram (mg)/kilogram (kg) to 8 mg/kg, rounded using a standardized pharmacy dosing protocol. The median therapy duration for inpatient courses was 5 days (25-75 IQR 2.5-8) while it was 15.5 days (25-75 IQR 7-23) for outpatients. Twenty-three courses (43 percent) received vancomycin treatment prior to daptomycin. Five patients had vancomycin discontinued due to renal function decline. Six patients reported a vancomycin allergy. Twenty-six courses (49 percent) had positive microbiological cultures, and of these, 20 (77 percent) had Gram-positive organisms. Sixteen courses had discrepancies between ordering indication and the medical diagnoses. Fourteen courses had a discrepancy between the dose given and the medical diagnoses. Osteomyelitis was confirmed in fourteen patients but only 6 of these patients received recommended doses of 6 or 8 mg/kg. The number of courses discharged on daptomycin from the hospital was 19 and 34 received their full course while in the hospital. Nineteen courses (36 percent) were readmitted within 30 days.

Conclusion: Opportunities for improving daptomycin use were identified through this study. The current daptomycin dosing protocol will be updated to include an indication for osteomyelitis. Following current guidelines, vancomycin should be used first line in Gram-positive SSTIs, MRSA bacteremia and right-sided IE. Criteria for daptomycin use will be established to help guide appropriate use to include: true vancomycin allergy, vancomycin failure, confirmed vancomycin resistant infection and outpatient use for patient compliance.

Submission Category: Ambulatory Care

Submission Type: Evaluative Study

Session-Board Number: 5a-057

Poster Title: Effect of discharge medication delivery and counseling on hospital readmission

Primary Author: Jeannette Bernay, University of Washington School of Pharmacy, Washington;
Email: bernayj@uw.edu

Additional Author (s):
Laurel Brown
Hung Troung
Craig Pederson
Adam Ricceri

Purpose: Appropriate counseling about medications and their use are an important part of the patient discharge process and important for smooth transition of care. It has been argued that this education can reduce medication non-adherence, reduce adverse events, reduce medication errors and reduce re-hospitalizations. The purpose of this study was to develop an interdisciplinary procedure to provide this service, identify obstacles to long-term implementation, and determine if re-admissions within 30 days were reduced in patients receiving discharge medication delivery and counseling by a pharmacy intern.

Methods: One floor was selected to participate in this limited, three-week trial. In coordination with the nursing staff, patients with the potential to discharge to home were identified each day. Patients being discharged to a Skilled Nursing Facility were excluded. The program coordinator met with each patient to explain the program and give them the opportunity to opt-in. If he or she provided informed consent to participate in the program, all information required to process the prescription was collected, including prescription insurance information. The hospital outpatient pharmacy, medical intern, resident, and attending were informed of the patient's participation. Patient information and discharge prescriptions were sent electronically and/or delivered to the pharmacy. These prescriptions were processed using the current Standard Process. Upon completion of the order, the program coordinator delivered the medications and counseled the patient at his or her beside. Patients were also given a survey to rate the program.

Results: For the primary outcome, 1 of 11 patients (9%) in the treatment group were readmitted to the hospital within 30 days, and 4 of 22 patients (18%) not receiving treatment were readmitted (p = 0.62).

Of the patients eligible for participation, 58 percent signed up for the program. Differences between the group that received discharge medication delivery and counseling (n = 11) and the group that did not (n = 22) were not significant. Categories examined were sex, ethnicity, age, weight, number of discharge medications, number of home medications, hospital stays within the previous 30 days, and hospital re-admittance within the subsequent 30 days. The only statistically significant finding was mean length of stay of 11 days for those who opted-in to the program, compared to 4 days for those who did not (p = 0.038).

Every patient gave the program the maximum rating, finding the service very valuable and helpful. It also received high reviews from medical staff and pharmacists.

Conclusion: Patients who received bedside delivery of discharge medications were less likely to be re-admitted to the hospital within 30 days. Although this finding is not statistically significant, it is clinically significant. One limitation of this study is the small sample size. The program was well-received by patients and healthcare providers. Improvement opportunities include consistent staffing, coordinator availability, timely discharge medication reconciliation, delivery hours, storage of delivered medications and payment method. This trial demonstrated that a discharge medication delivery and counseling program can contribute to the reduction of re-admissions and provide a positive patient experience.

Submission Category: Infectious Diseases

Submission Type: Descriptive Report

Session-Board Number: 5a-058

Poster Title: Use of Antiviral Agents for Chronic Hepatitis B Virus Infection in Pregnant Women: Review of Clinical Evidence

Primary Author: Samantha Stockmann, Pacific University, College of Health Professions, School of Pharmacy, Oregon; **Email:** stoc7299@pacificu.edu

Additional Author (s):
Katherine Gazlay
Marina Kawaguchi-Suzuki

Purpose: The purpose of this systematic literature review is to assess the safety and efficacy of antiviral therapy in pregnant women chronically infected with hepatitis B virus (HBV) and to collect data on cesarean section rates, mother to child vertical transmission rates, and rates of any teratogenicity with the use of antiviral therapy.

Methods: For this systematic review, two databases, PubMed and Web of Science, were used. Two investigators independently screened articles found by these databases, using predetermined inclusion and exclusion criteria. The inclusion criteria for the screening were: 1) studies among pregnant women with chronic HBV infection, 2) studies which measured at least one outcome of interest listed below, and 3) studies specifying the antiviral treatment pregnant women received. Studies among women who had coinfection with human immunodeficiency virus were included. The exclusion criteria were: case reports, abstracts, animal or in vitro studies, non-English literature, studies with investigational drug use, studies in infants born to HBsAg positive fathers and HBsAg negative mothers, and studies in women of childbearing age who were not pregnant. The outcomes of interest included: 1) HBV DNA levels and HBsAg and HBeAg titer levels in pregnant women, 2) cesarean section rates, 3) premature delivery rates, 4) mother to child HBV transmission rates, and 5) the teratogenicity of antiviral therapy in infants.

Results: With PubMed and Web of Science, 272 and 71 articles were found respectively. After screening, 35 studies were included in this literature review. The most common antiviral agent studied in pregnant women was lamivudine, followed by telbivudine and tenofovir. In studies investigating maternal outcomes, 13 (37.1%) studies reported that post-treatment HBV DNA levels were significantly lower in mothers who received an antiviral agent, compared to those

who did not receive any antiviral treatment. Six (17.1%) studies reported cesarean section rates were not significantly different between mothers taking antiviral therapy and those who did not. Twelve (34.3%) studies reported infants receiving immunoprophylaxis as recommended by the AASLD and WHO/CDC. Regarding infant safety, premature deliveries were reported in 21 (60%) studies and observed with the use of tenofovir, telbivudine, and lamivudine, as well as in control groups. Among these 21 studies, 9 (25.7%) studies reported premature birth rates were not significantly associated with antiviral use. No teratogenicity was reported in any of the studies included in this review. Twenty-two (62.9%) studies investigated mother to child transmission rates with two studies of note reporting significantly higher HBV vertical transmission rates in control groups, compared to treatment groups.

Conclusion: Based on this systematic literature review, the use of tenofovir, lamivudine, or telbivudine may be supported for pregnant women with chronic HBV infection, which aligns with the recent AASLD guideline recommendations. However, current evidence for the use of antiviral agents, aside from these antivirals, to treat chronic HBV infections in pregnant women is limited. No significantly higher rates of premature delivery or teratogenicity were reported in the current evidence we reviewed. However, clear documentation is lacking on other adverse drug reactions for infants born to mothers taking antiviral therapy for chronic HBV infections.

Poster Title: Descriptive analysis of the relationship between midpoint evaluation scores and final grades for advanced pharmacy practice experience year student pharmacists

Primary Author: Michelle Sebok, University of Maryland Eastern Shore School of Pharmacy and Health Professions, Maryland (MD); **Email:** msebok@umes.edu

Additional Author (s):
Brandon Green

Purpose: Advanced pharmacy practice experiences (APPEs) are on-site training courses. These courses makeup the final year of doctorate of pharmacy programs. While all APPEs require a final course score, midpoint evaluations are optional and limited research is available on the predictive qualities midpoint evaluations have on final scores. The purpose of this study was to analyze the relationship between midpoint scores and final scores.

Methods: . To observe a relationship between the potential impact midpoint evaluations may have on final outcomes of APPE scores, a cohort of APPE grades of University of Maryland Eastern Shore School of Pharmacy and Health Professions student pharmacists was collected and analyzed to determine if there were statistical differences between final scores of students who received a midpoint evaluation during the course and those who did not (these students only received a final score). T-tests were used to compare final grades, with the presence of midpoint grades being the variable. The data was further categorized and analyzed to account for variance in scores. A secondary analysis was done to determine the strength of the predictive quality of midpoint scores on final scores. These analysis were done using paired t-tests, correlation, and regression models.

Results: The results indicated a statistically significant difference in final scores between courses that included and did not include midpoint evaluations, with those who received a midpoint evaluation scoring higher than those who did not. The mean final score for all APPEs with midpoint scores was 4.34, and the mean final score for all APPEs without midpoint scores was 4.16, with a difference of 0.179, and $P < 0.01$. The secondary evaluation exhibited a significant relationship between midpoint and final grades. The mean increase in score from the midpoint evaluation to the final evaluation was 0.461 ($P < 0.0001$, R-squared 50.96%).

Conclusion: While a difference of 0.179 doesn't seem very large, it could mean the difference between passing, failing, or receiving honors in a course. Limitations to this study included the narrow subject pool, a need for more comprehensive course information, and inherent variability across preceptor grading. Future studies should include more inclusive data in order to come to a comprehensive conclusion that midpoint evaluations have a significant impact on final grades for APPEs. From the data collected and strength of significance, we would recommend to continue to encourage midpoint evaluations for pharmacy APPE students.

Submission Type: Evaluative Study

Session-Board Number: 5a-060

Poster Title: Vancomycin pharmacokinetic parameters in patients with traumatic brain injury

Primary Author: Nicholas Nelson, University of North Carolina Eshelman School of Pharmacy, North Carolina; **Email:** nnelson2@email.unc.edu

Additional Author (s):
Kathryn Morbitzer
Denise Rhoney

Purpose: Traumatic brain injury (TBI) is a devastating injury with high disability and mortality rates. These patients are at an increased risk for many medical complications, especially infection, which significantly impact overall patient outcomes. Case reports have been published demonstrating alterations in vancomycin pharmacokinetic (PK) parameters in TBI patients that have resulted in sub-therapeutic antibiotic concentrations, but data assessing this phenomenon is scarce. The primary objective of this study is to evaluate the PK parameters of vancomycin in TBI patients in a larger patient population to determine if further research in this area is warranted.

Methods: The institutional review board approved this single-center, retrospective cohort study of adult patients at least 18 years of age with TBI who received vancomycin and had at least one reported steady-state vancomycin serum level from April 2014 to December 2015. Patients who were pregnant, had serum creatinine greater than 1.4 mg/dL, received renal replacement therapy during admission, had a history of nephrectomy, or had a BMI less than 18 kg/m2 were excluded from the study. Chart reviews were performed for baseline characteristics of age, gender, height, weight, classification of TBI, suspected infection source, Glasgow Coma Scale (GCS) score, Sequential Organ Failure Assessment (SOFA) score, serum creatinine, and comorbidities. Patient characteristics at the time of vancomycin serum trough concentration were collected including serum creatinine and GSC score, as well as fluid balance and the type of vasopressor given (if any) 48 hours prior to serum trough concentration. Data for vancomycin dosing regimens were collected for vancomycin dose, dosing frequency, days from injury to trough concentration, and serum trough concentration(s). Predicted PK parameters based on population data were compared with calculated PK parameters based on

serum trough concentrations at steady state. The difference was assessed using a two-sample Wilcoxon rank-sum test where P less than 0.05 was considered statistically significant.

Results: Of 34 identified patients meeting inclusion criteria, chart reviews were performed for 32 patients. The patients were primarily male (72%) with a median age of 36 years (IQR, 24.5-52), GCS of 7 (IQR, 5-10) and baseline creatinine clearance (CrCl) of 116 mL/min (IQR, 96-130.5). Most patients were treated for suspected respiratory infection (53%) using a dosing regimen of 17 mg/kg (IQR, 13-19) every 8 hours. Patients had an estimated volume of distribution of 54.81 L (IQR, 48.8-63.98) and a median CrCl of 167 mL/min (IQR, 128-198) when serum trough concentrations were taken. There was no significant difference between estimated and calculated elimination rate constant (0.14 inverse hour (IQR, 0.11-0.17) vs. 0.13 inverse hour (IQR, 0.12-0.15); P equals 0.7371). There was also no significant difference in predicted and measured trough concentrations (10.4 mcg/mL (IQR, 7.09-15.0) vs. 11.5 mcg/mL (IQR, 7.8-13.7); P equals 0.7986).

Conclusion: Patients with TBI were administered typical doses of vancomycin (15-20 mg/kg) on a frequent basis (every 8 hours) but still did not achieve adequate therapeutic concentrations. It should be noted that these patients also exhibited increased creatinine clearance. This alteration may be contributing to the sub-therapeutic trough levels obtained for these patients. The results of this study support the need for further research to be conducted evaluating vancomycin dosing methods and pharmacokinetic parameters in patients with TBI.

Submission Type: Evaluative Study

Session-Board Number: 5a-061

Poster Title: Use of ceftaroline in osteomyelitis patients with complicated methicillin resistant Staphylococcus aureus (CO-MRSA)

Primary Author: Karineh Lalikian, Pacific University School of Pharmacy, Oregon; **Email:** lali0198@pacificu.edu

Additional Author (s):
Rita Parsiani
Rodney Turner

Purpose: Vancomycin is the standard therapy for methicillin-resistant Staphylococcus aureus (MRSA) infections. However, incidences of strains with high minimum inhibitory concentrations are increasing, requiring alternative therapy when vancomycin therapy fails. Ceftaroline has in vitro activity against MRSA and is Food and Drug Administration approved for the treatment of acute bacterial skin and soft tissue infections and community acquired pneumonia. While single cases have reported ceftaroline use for osteomyelitis, larger studies and case series are not available to guide clinical decision. The purpose of this study is to evaluate the efficacy and safety of ceftaroline in patients with osteomyelitis due to MRSA.

Methods: A retrospective chart review was conducted of patients admitted between April 2011 through March 2016 at a five hospital system. Patients 18 years and older were included if they had a diagnosis of osteomyelitis, and at least one positive culture for MRSA. The primary outcome is clinical cure, defined as completion of 6 to 8 weeks of ceftaroline therapy or a minimum course of 7 days with a switch to oral antibiotic therapy to complete the duration of therapy. Secondary outcomes include adverse reactions associated with ceftaroline, length of hospital stay. Failure is defined as a switch to an alternative intravenous agent, death due to infectious cause, or readmission within 6 months after treatment completion. Demographics and clinical characteristics will be compared in those achieving and not achieving clinical cure by Wilcoxon rank-sum test for continuous variables and the Fisher's exact test for nominal variables. This study was approved by the Legacy Health institutional review board.

Results: Fourteen patients met the inclusion criteria, including 8 males and 6 females with a median age of 56 years [ranging from 36-93]. Thirteen of the 14 patients had multiple, significant comorbidities. The median length of hospital stay was 21 days [ranging from 5-75] with a median duration of ceftaroline of 15 days [ranging from 4-70). All patients received prior antimicrobial therapy with a median time to switch to ceftaroline of 12 days [ranging from 2-159]. Six of the 14 patients (43%) achieved clinical cure. Three patients completed a total of 6 weeks of ceftaroline therapy, with 2 (67%) achieving clinical cure. Patients with vertebral osteomyelitis (57%) had a greater length of stay, longer ceftaroline treatment, and lower cure rates (38% vs. 50%) than those with non-vertebral osteomyelitis. Higher vancomycin MIC's were also associated with lower ceftaroline cure rates (P=0.12). Four (29%) patients died but only 1 death was considered infection-related. Two patients experienced adverse reactions leading to the discontinuation of ceftaroline (transaminitis, pruritic rash).

Conclusion: Ceftaroline is currently being used in patients with complicated MRSA infections. It is a reasonable alternative for patients failing other therapies and may improve outcomes in those who complete the full duration of therapy. However, further trials are warranted in order to confirm clinical outcomes in patients with MRSA osteomyelitis.

Submission Type: Descriptive Report

Session-Board Number: 5a-062

Poster Title: Clinical pharmacist identification of adverse drug events (ADEs) in a transitional care management program

Primary Author: Karly Powell, The University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Colorado; **Email:** karly.powell@ucdenver.edu

Additional Author (s):
Danielle Rhyne
Sunny Linnebur
Joseph Vande Griend

Purpose: Preventing medication-related readmissions is critical. Studies have shown that 30% of hospital discharges have at least one medication discrepancy and 20% of patients experience an adverse event within three weeks. Clinical pharmacists have specialized training to implement interventions during the transition from hospital to home. The overall goal of this poster is to illustrate the role of clinical pharmacists in identifying adverse drug events in a transitional care management service at a geriatric clinic.

Methods: A transitional care management program was developed and implemented at the University of Colorado Seniors Clinic. Clinical pharmacists within the clinic called patients to complete medication reconciliation after discharge from the hospital. Adverse drug events were identified via telephone outreach to the patients. Adverse drug events were defined as any adverse outcome of patient injury caused by medication use. The telephone calls, including descriptions of adverse drug events and recommendations, were documented within the electronic medical record and sent to the patient's provider for review. After the provider received notification of medication related issues, the provider was able to collaborate with the clinical pharmacist or follow up with the patient during an office visit to assess the adverse drug event. This project analyzed adverse drug events in senior's clinic patients discharged from the University of Colorado Hospital from August 2014 through October 2015.

Results: After 14 months, clinical pharmacists completed medication reconciliation on 369 patients. There were a total of 39 adverse drug events in 35 patients that were identified and documented by the clinical pharmacists. Of the 35 patients, 3 were readmitted within 30 days of discharge. There were 26 (66.7%) adverse drug events caused by medications known to cause adverse events in older adults over the age of 65.

Conclusion: Clinical pharmacists are vital members of the health care team. Clinical pharmacists' role in identifying adverse drug events during the transitional care management service at the University of Colorado Seniors Clinic benefited both patients and providers. Early identification and resolution of adverse drug events is one way for pharmacists to prevent future hospital readmissions.

Poster Title: Anti-Xa assay interference among patients transitioning from an oral selective factor Xa inhibitor to unfractionated heparin

Primary Author: Kelsey Haller, University of Pittsburgh School of Pharmacy, Pennsylvania; **Email:** keh131@pitt.edu

Additional Author (s):
Brian Keaton
James Coons

Purpose: Laboratory monitoring is essential when managing patients requiring unfractionated heparin (UFH), particularly when transitioning from other anticoagulants. At some institutions, the anti-Xa assay has replaced activated partial thromboplastin time (aPTT) as a measure of UFH activity. While anti-Xa lab monitoring has its advantages, recent use of a selective factor Xa inhibitor has been observed to falsely elevate anti-Xa concentrations in our patient population. Therefore, appropriate management of UFH in these patients presents a clinical challenge. The purpose of this project was to describe the impact of oral selective anti-Xa inhibitors on anti-Xa concentrations and to determine an appropriate management strategy.

Methods: This was a retrospective analysis of patients admitted to the University of Pittsburgh Medical Center (UPMC) Presbyterian Hospital. The project was approved by the UPMC Quality Improvement Board. Patients with supratherapeutic anti-Xa concentrations that received intravenous UFH and were prescribed either apixaban or rivaroxaban prior to admission were included. Patients admitted after March 2015 were targeted to coincide with the implementation of institutional anti-Xa monitoring for UFH. Data collection included: demographics (age, sex, race), co-morbid conditions (such as renal and hepatic function) and other anticoagulant use. Descriptive statistics were used to characterize the study results.

Results: This quality improvement initiative will describe the effects of oral selective factor Xa inhibitors on anti-Xa concentrations in patients that require UFH during their hospitalization at UPMC Presbyterian Hospital.

Conclusion: The results of this project will inform appropriate therapeutic decisions about how to monitor UFH in patients that recently received an oral selective Xa inhibitor.

Session-Board Number: 5a-064

Poster Title: Effect of educational background on perceptions of teaching preparedness

Primary Author: Kathryn Ray, Campbell University College of Pharmacy and Health Sciences, North Carolina; **Email:** koray0603@email.campbell.edu

Additional Author (s):
Wesley Rich
Timothy Bloom

Purpose: Pharmacy faculty come from diverse educational backgrounds in terms of terminal degree and post-graduate training. They are a mix of PharmDs and PhDs, and faculty members with a PharmD represent an additional mix of clinical and non-clinical faculty. Most or all PhD programs have a required teaching component while few PharmD programs include teaching experience as a graduation requirement. We surveyed faculty at one college of pharmacy to see if differences in educational background have an impact on self-perception of teaching ability and need for further development.

Methods: Faculty at Campbell University College of Pharmacy & Health Sciences, a teaching-intensive institution, were surveyed for educational background, teaching experience, and self-perceptions of teaching ability using an online questionnaire approved by the Institutional Review Board. The questionnaire was designed after reviewing a previous publication, with permission of the author. A link to the questionnaire was sent to 55 faculty members in the Pharmacy Practice and Pharmaceutical Sciences departments. Faculty were eligible to participate if they held a terminal degree regardless of whether they taught in the Doctor of Pharmacy Program. The first portion of the questionnaire collected demographic information while the second portion asked about teaching experience prior to joining the faculty and included Likert-type questions on confidence in areas related to teaching. A reminder email was sent to all non-responders one week after the initial participation request was sent. A final reminder to complete the survey was sent two weeks after the initial contact. At the end of the three-week survey period, 31 faculty members had fully completed the survey, resulting in a 56.3% return rate. The data were analyzed using SPSS for frequency and descriptive statistics. The responses of faculty with prior teaching experience and those without were compared by t-test with significance determined at $p < 0.05$.

Results: Almost 68% of respondents had a PharmD while nearly 46% had a PhD. The majority of respondents (67.7%) were in the Pharmacy Practice department and the median range of time as a faculty member was 7-10 years. Half of faculty members taught students while they were in graduate or pharmacy school; the most common format involved providing lab instruction. After becoming faculty members, those with prior teaching experience did not feel as strongly that they needed faculty development in a variety of teaching areas including developing course objectives, writing exam questions and analyzing exam performance. However, a significant difference based on previous teaching experience was seen only with providing an effective lecture (p=0.038). Both groups placed high importance on developing their teaching methods as their career progresses. This was supported by 76% of respondents saying that they often or always attend teaching-related sessions at their professional meetings.

Conclusion: Teaching experience prior to becoming a faculty member had little impact on self-perceived need for development in multiple areas related to teaching. PhD and PharmD-educated faculty equally and strongly agree they need to improve their teaching ability and frequently take advantage of opportunities to do so. The faculty surveyed also felt supported by their department in pursuing professional development aimed at teaching.

Session-Board Number: 5a-065

Poster Title: Predicting Vancomycin AUC24 Based on Plasma Concentrations: A Simulated Evaluation

Primary Author: Ryan Wong, Auburn University Harrison School of Pharmacy, Alabama; **Email:** rzw0031@auburn.edu

Additional Author (s):
Emily Tsaio
William Ravis

Purpose: For vancomycin (VAN), the relationship between the AUC over 24 hr (AUC24) to the MIC for bacteria has been found to be a predictor of efficacy. Due to the multi-compartment features of VAN, routine plasma concentrations monitoring may not accurately permit estimates of AUC24's. The study investigated the usefulness of several proposed and new methods for estimating AUC24 from limited plasma concentration sampling.

Methods: A VAN population pharmacokinetic model was selected from the literature and used to predict VAN plasma concentrations for subject with 100%, 50%, 25% and 5% renal function on days 1, 3, and 7. There were 50 subjects in each renal function group and simulations were based on a loading dose followed by maintenance dose given at a time interval adjusted for renal function. Values of AUC24 were determined by a method suggested by Bauer (Method B), based on a 1-compartment model (Method C), as well as single point relationships. Sampling times utilized in the calculation included time 0 and post-dose times of either 1.5, 2, and 3 hr, and at the trough. Concentration values at the dosing interval midpoint (Cmid) and minimum (Cmin) were also estimated.

Results: The accuracy of AUC24 predictions varied among the methods, the points selected, and was also affected by renal function group. For all subjects, by the B and C methods, AUC24 was overestimated more when the post-dose sampling time was 1.5 hr ($20.6\pm11.2\%$ and $20.8\pm8.7\%$) as compared with 2 hr ($10.8\pm7.9\%$ and $13.1\pm6.6\%$) and 3 hr ($2.7\pm10.1\%$ and $7.0\pm7.2\%$) times. Method B appeared slightly better than method C depending on renal function group and sampling times. For the B and C methods, AUC24 prediction errors were significantly less for the normal renal function group compared to groups with 0.5, 0.25, and

0.05 fractions of renal function. Equations were determined to predict AUC24 based upon Cmid and Cmin and these AUC24 estimates were better than Methods B and C with % errors of 0.3±5.9% and 0.6+10.1%, respectively.

Conclusion: After 3-7 days of VAN dosing, values of Cmid or Cmin may be useful in accessing AUC24 and appear to be a better approach than methods utilizing 3 sampling times. These approaches need to be evaluated with different population parameters and also compared to Bayesian predictions.

Poster Title: Implementation of a diabetes collaborative drug therapy management (CDTM) agreement: Changes in hemoglobin A1c one year later

Primary Author: Navneet Kaur, Pacific University Oregon School Of Pharmacy, Oregon; **Email:** kaur4442@pacificu.edu

Additional Author (s):
Sarah White
DeAnna Rhoden

Purpose: To assess the impact of pharmacist management of chronic diabetes in an outpatient setting. This project was designed to evaluate the outcomes of the Collaborative Drug Therapy Management (CDTM) agreement with practitioners by assessing changes in hemoglobin A1c values one year later after implementation.

Methods: This IRB approved retrospective observational study was performed via electronic chart review on patients referred by physicians to receive chronic management of their diabetes with a pharmacist at a primary care office. Patients A1c values before the referral and after management of their diabetes with the clinical pharmacist were compared. The inclusion and exclusion criteria listed in the CDTM agreement was used to enroll patients. Patients had to be receiving regular medical care at the clinic and be diagnosed with diabetes mellitus type 1 or 2. "High risk" patients were enrolled in this study as stated in the CDTM agreement. Patients were considered "high risk" if they met one of the following: HbA1C greater than or equal to 9%, HbA1C greater than or equal to 8% plus established coronary artery disease, peripheral artery disease, history of stroke, new insulin-dependent diagnosis, significant hypoglycemia/hyperglycemia, uncontrolled hypertension, or atherosclerotic cardiovascular disease risk greater than or equal to 7.5% and need for statin intensification. Patients were dismissed from the service if they failed to show up for three consecutive office and/or phone visits, if they no longer wanted to receive the service, or if the provider/pharmacist felt this service was no longer appropriate for them. The primary objective was measurement of glycemic control defined as having an HbA1C value less than seven percent as stated in the CDTM agreement.

Results: Of the 78 patients referred over by physicians to the service, 44 patients were excluded in the study. Of the 44 patients excluded, 19 patients were not "high risk" and 25 patients' physicians were not part of the CDTM agreement. Nine patients were lost to follow-up during the study. Of the total 25 patients included in the study, 12 (48%) patients attained hemoglobin A1c goal of less than or equal to 7% and 16 (61.5%) patients achieved at least 1% or more reduction in their A1c. Average absolute change in A1c was 1.972%. Changes in A1c values varied from 0.4% to 7.5%.

Conclusion: This study demonstrated that implementation of the Collaborative Drug Therapy Management (CDTM) agreement has had a positive impact on patient's hemoglobin A1c values within a year. It can be concluded that chronic diabetes management by clinical pharmacists in an outpatient setting can be a beneficial option for patients whose A1c values cannot be maintained at 7 percent or lower by their primary care physician.

Submission Type: Descriptive Report

Session-Board Number: 5a-067

Poster Title: Comparing the presence of family members to nurse's time spent performing delirium prevention activities in the medical intensive care unit

Primary Author: Jillian Grapsy, University of Pittsburgh, Pennsylvania; **Email:** jig29@pitt.edu

Additional Author (s):
Nicolette Diehl
Lauren Albert
Caroline Beck
Olivia Marchionda

Purpose: The purpose of this study is to investigate the impact of family presence on the nurse's time spent on conducting non-pharmacologic delirium prevention activities in a medical intensive care (MICU). We hypothesized that family presence will decrease the amount of time that the nurse spent on conducting delirium prevention activities due to the increased activity in the patients' rooms.

Methods: This was a time and motion study that included nurses working in the MICU at the University of Pittsburgh Medical Center, Presbyterian Hospital. Eighteen nurses, who were caring for thirty-five patients, were observed by student pharmacists for a total of 71.77 nonconsecutive hours. Observations occurred for four hour time blocks from 8:00 AM to 12:00 PM, 12:00 PM to 4:00 PM, or 3:00 PM to 7:00 PM. Of the eighteen nurses observed, seventeen were responsible for caring for two patients. During observation, the nurse's actions were timed and recorded with a focus on those activities used in delirium prevention. Data were summarized by median and ranges due to non-normal distributions. The Mann Whitney-U Test was used to compare the groups of nurses that did and did not have a family member present. We considered a p-value of ≤ 0.05 to be statistically significant.

Results: The median (range) for total time that nurses spent performing non-pharmacologic delirium prevention activities was 0.95 minutes (0-18.32) per patient out of the four hours block. Family members were present for 20 of the 35 patients that the observed nurses cared for during the four hour block. The median (range) time that a family member was present during the four hour time period observed was 0.33 hours (0-2.2 hours). The median time that

nurses spent conducting delirium prevention activities changed with respect to the presence of a family member. The median (range) time spent performing delirium prevention activities was 0.813 minutes (0-18.32 minutes) when a family member was present compared to 1.06 minutes (0-12.50 minutes) when a family member was not. There was not a statistically significant difference between the time that nurses spent conducting non-pharmacologic delirium prevention activities if family members were or were not present (p = 0.50).

Conclusion: There is no causal relationship between the presence of family and the nurses' time spent performing delirium prevention in the MICU and any difference is due to chance. The data suggests that nurses provide all patients with the same level of delirium prevention care and the presence of family does not lessen the need for delirium prevention methods to be utilized. This data shows the importance of educating nurses on practicing delirium prevention activities regardless of the presence of family members and further studies can be conducted to determine barriers to nurses delivering delirium prevention in the MICU.

Poster Title: Pharmacist prophylactic probiotic prescribing: impact of a delegation protocol on Clostridium difficile rates in an academic medical center

Primary Author: Nikita Shah, University of Wisconsin - Madison School of Pharmacy, Wisconsin; **Email:** nikita.shah@wisc.edu

Additional Author (s):
Eric Chmielewski
Lucas Schulz
Marc-Oliver Wright
Nasia Safdar

Purpose: Clostridium difficile infection (CDI) is a concern for many hospitals. Antibiotic exposure is an important risk factor for CDI and, often, a necessary treatment modality. Therefore, unique prevention strategies are being investigated, including probiotic administration. In order to increase probiotic utilization in patients receiving broad spectrum antibiotics, a delegation protocol allowing pharmacists to order probiotics for these patients was implemented. This study aims to determine compliance with probiotic ordering and the safety and efficacy of probiotics given during the index hospitalization for primary CDI prevention.

Methods: A pre/post retrospective review of patients receiving broad-spectrum antibiotics was conducted on the family medicine, general medicine, and hospitalist services for a total of two months. Data was collected using the electronic medical record. Inclusion criteria consisted of patients starting high-risk antibiotics for treatment of suspected infection. Patients who had active pancreatitis, gastrointestinal perforation, Crohn's disease, recent post-pyloric gastrointestinal surgery, were receiving exogenous immunosuppression, or who had CDI within 90 days were excluded. The primary outcome was compliance to delegation protocol, specifically, prescribing probiotics to qualifying patients within 24 hours of antibiotic administration. Secondary outcomes included receipt of probiotics after exposure to high-risk antibiotics greater than 24 hours but during the hospitalization and cases of CDI within 14 days of antibiotic administration.

Results: During two months, 253 patients met inclusion criteria. One-hundred and six patients were excluded, most often for pancreatitis. Pharmacists prescribed probiotics within 24 hours of starting high risk antibiotics in 93 of 147 (63.3%) of eligible patients. Probiotics were initiated during the hospitalization in 121 of 147 (82.3%) of patients. Zero patients receiving probiotics within 24 hours of high-risk antibiotic initiation developed CDI compared to two of 30 (0.07%) patients receiving probiotics after 24 hours (P = 0.0529). Unfortunately, probiotic delegation protocol implementation failed to change the ward CDI rate, 7.15 vs. 7.5/10,000 patient days, and a rate ratio of 0.95; 95% CI: 0.347, 2.43 (p=1.00) There were no complications, i.e. bacteremias, throughout the study period duration related to probiotic administration.

Conclusion: Overall, pharmacists demonstrate good compliance to implementing the probiotic delegation protocol and may be valuable in prevention of CDI. Still, it is unclear the impact of the protocol on CDI rate.

Poster Title: Contraception and teratogen registry analysis (CONTRA)

Primary Author: Vivian Cheng, University of North Carolina Eshelman School of Pharmacy, North Carolina; **Email:** vivian_cheng@unc.edu

Additional Author (s):
Mackenzie Farrar
Courtenay Wilson
Rebecca Grandy

Purpose: More than half of all pregnancies are unintended, yet recent studies have shown that family planning is not being discussed between the majority of women and their primary care providers. These discussions should include contraception options, teratogenic medication use, control of chronic conditions, and appropriate folic acid supplementation. Pharmacists can play a critical role in optimizing medication use prior to conception, counseling on contraception, and proactively identifying women in need of preventive reproductive health care. However, standardizing family planning documentation in electronic medical records (EMR) is crucial for pharmacists and other providers to identify potential pharmacotherapy interventions.

Methods: This retrospective chart review examined the effectiveness of using a registry and phone intervention by student pharmacists on women at risk for adverse outcomes with an unintended pregnancy. The EMR of a large academic family medicine practice was screened for females between ages 14-55 taking at least one teratogenic medication from this pre-specified list: angiotensin-converting enzyme inhibitors, angiotensin II receptor blockers, statins, valproic acid, lithium, paroxetine, methotrexate, and warfarin. Exclusion criteria included current pregnancy, age under 18 years old, or lack of an office visit in the last three years. In total, 182 patients met inclusion criteria. Student pharmacists reviewed patient charts for the type of teratogenic medication, contraception use, smoking status, and folic acid or multivitamin use. A new Family Planning tab was created in the EMR to standardize contraception documentation for all patients. Student pharmacists called patients without contraception documentation using an approved script to discuss family planning and updated their charts accordingly. Patients were encouraged to contact their primary care physician (PCP) for further family planning and to utilize free multivitamins provided by the clinic. The primary outcome was the

number of women using contraception while on a teratogen. Secondary outcomes included the percentages of incorrectly documented teratogen use, incorrect records of lack of contraception use, patients that followed up with their PCP, and patients using multivitamins with folic acid.

Results: Of the 182 included patients, 131 patients (71.9%) were using contraception while taking a teratogen. Thirty patients (16.5%) had ambiguous teratogen documentation but could not be reached by phone to verify their medication history. Forty-four patients (24.2%) were successfully contacted by student pharmacists to verify their contraception or teratogen use. Seven patients (3.8%) were no longer taking the teratogen originally documented in their chart. Thirteen patients (7.1%), originally missing contraception documentation, were found to actually be using contraception, and their charts were appropriately updated. Two patients (1.1%) that were not using contraception expressed interest in scheduling an appointment with their PCP to further discuss family planning. However, three months after the phone intervention, neither had scheduled an appointment with their PCP. One patient (0.5%) was not using contraception and was unwilling to follow-up with her PCP about family planning. Additionally, 55 (30.2%) women were taking multivitamins with folic acid. Ten patients (5.5%) were found to have transferred care and were thus excluded from the study.

Conclusion: This chart review and phone intervention led by student pharmacists demonstrated the lack of consistent, accurate contraception and teratogen documentation. This could lead to missed opportunities for a discussion of teratogenic medication use during childbearing age. Our study showed the need for a centralized location to record a patient's method of contraception in the EMR so providers can better evaluate medication use. Furthermore, less than one-third of our patients were taking multivitamins with folic acid, so it is evident that the promotion and education of the importance of folic acid supplementation must be expanded at this practice.

Poster Title: Physician-Pharmacist Collaborative Management: Narrowing The Socioeconomic Blood Pressure Gap

Primary Author: Maxwell Anderegg, University of Iowa College of Pharmacy, Iowa; **Email:** maxwell-anderegg@uiowa.edu

Additional Author (s):
Tyler Gums
Barry Carter

Purpose: Race, income, education, and insurance status are significant predictors of blood pressure control. Individuals with lower education or income have higher rates of uncontrolled hypertension. Uninsured (self-pay) individuals suffered from a higher rate of uncontrolled hypertension compared to those publicly and privately insured. Team-based care has been proven to improve hypertension control, but there is little information whether this model can reduce the gap in health care disparities. The purpose of this study was to evaluate whether pharmacist intervention could reduce health care disparities by improving blood pressure in high-risk racial and socioeconomic subjects compared to the control group.

Methods: This study was a prospective, cluster-randomized, multicenter clinical trial involving 32 medical offices from 15 U.S. states. The network of medical offices was selected to include a high percentage of minority patients. Offices were stratified based on structure of pharmacy services provided and percentage of minority patients. Offices were then randomized to one of three study arms after they were stratified: usual blood pressure care, a 9-month intervention, or a 24-month intervention. Both intervention arms were designed to be identical for the first 9 months so the a priori analysis plan was to combine the two at 9 months and compare to usual care for the main study outcomes. A clinical pharmacist was embedded within each medical office and made recommendations to physicians and patients. The analyses in minority subjects were pre-specified secondary analyses but all other comparisons were secondary, post-hoc analyses. The 9-month visit was completed by 539 patients, 345 received the intervention and 194 were in the control group. The primary outcome of interest in the current analysis was the difference in mean systolic blood pressure reduction between control and intervention study arms in groups with various racial and socioeconomic differences at the 9-month time period.

Results: Following the intervention, mean systolic blood pressure was 7.3 mm Hg (95%CI= 2.4, 12.3) lower in subjects from racial minority groups who received the intervention compared to the control group (p=0.0042). Subjects with < 12 years of education in the intervention group had a systolic blood pressure 8.1 mm Hg (95% CI=3.2, 13.1) lower than the control group with lower education (p=0.0001). There was a significantly greater reduction in systolic BP in the intervention group patients making < $25,000 than the control group patients making < $25,000 (7.3 mm Hg, 95% CI= 2.0, 12.6, p=0.008). The control group receiving Free and None/Self-Pay insurance had the smallest reduction in systolic BP by the 9-month endpoint. The intervention group achieved a systolic BP 13.1 mm Hg lower (95% CI=5.8, 20.4) than the control group in patients without insurance (p=0.0004).

Conclusion: This study demonstrated that pharmacist intervention reduced health care disparities in blood pressure in at-risk socioeconomic populations. We found that intervention groups at high-risk for health care disparities had a significantly larger reduction in blood pressure than the same high-risk control groups. Our findings suggest that a pharmacist intervention in primary care clinics can successfully reduce health care disparities for those at risk based on racial and socioeconomic characteristics.

Poster Title: Characteristics of Bicalutamide-Induced Neuroendocrine Differentiation of Prostate Cancer Cells in vitro

Primary Author: Vu Nguyen, University of Maryland Eastern Shore School of Pharmacy, Maryland; **Email:** vnguyen@umes.edu

Additional Author (s):
Miguel Martin-Caraballo
Yoon Kwon

Purpose: Therapies designed to reduce androgen production and/or receptor activation have proven to be effective in reducing the growth of prostate cancers. However, sustained treatment with antiandrogen therapies can result in androgen-independent growth, which leads to increased mortality. The switch of prostate cancer to an androgen-refractory state is associated with neuroendocrine differentiation (NED) of cancer cells. We hypothesize that NED is accompanied by significant changes in the Ca2+ homeostasis of prostate cancer cells. We investigated the effect of the androgen receptor blocker, biculatamide, in promoting NED of cancer cells and whether it was accompanied by increased T-type Ca2+ channel expression.

Methods: Lymph node-derived prostate LNCaP cells were used as a model of prostate cancer cells that undergo NED. LNCaP cells were treated with biculatamide (Casodex®, 10-20 µM) for 4-10 days. Cells were also cultured in an androgen-depleted media to simulate the effect of anti-androgen therapies. Changes in the T-type Ca2+ channel subunit Cav3.2 expression and several differentiation markers were assessed by western blot and real-time PCR analysis. Measurements of dendritic length and number of primary branches was use to determined morphological changes in prostate cancer cells undergoing NED.

Results: The treatment of LNCaP cells with bicalutamide for 4-10 days resulted in significant morphological differentiations as evidenced by the development of long dendrite-like processes and increased branching. Bicalutamide treatment of LNCaP cells also evoked a significant increase in the expression of neuron-specific enolase, a marker of prostate cancer cells undergoing NED. Bicalutamide-evoked NED of LNCaP cells resulted in a significant increase in the protein expression of the T-type Ca2+ channel subunit Cav3.2. There were no changes in

the levels of Cav3.2 mRNA, suggesting that bicalutamide regulates T-type Ca2+ channel subunit expression by a posttranscriptional mechanism.

Conclusion: These results demonstrated that the bicalutamide treatment of prostate cancer cells leads to NED and increased expression of T-type Ca2+ channels. Thus, it appears that T-type Ca2+ channels could be a possible target for future therapeutic strategies against prostate cancers refractory to anti-androgen therapies. Future work will investigate the role of T-type Ca2+ channels in promoting the NED of prostate cancer cells.

Session-Board Number: 5a-072

Poster Title: Quantitative Analysis of Electronic Prescribing Quality Related-Incidents

Primary Author: Ahmad Alamer, University of Arizona, Arizona; **Email:** aalamer@email.arizona.edu

Additional Author (s):
Ana Hincapie
Julie Sears
Terri Warholak

Purpose: To analyze quality related events and errors related to e-prescribing that affect community pharmacist and patients and to develop best practice recommendations for improving patient safety. The aims were to: 1) examine the frequency, type, and contributing factors of e-prescribing quality events reported to the Pharmacy Quality Commitment (PQC) System and the Pharmacy and Provider prescribing Experience Reporting Portal (PEER) Portal; and 2) determine the potential impact of Surescripts e-prescribing "ideal prescription" guidelines adoption in preventing e-prescribing quality problems and errors.

Methods: This was a retrospective analysis of - extracted e-prescribing related events reported to PQC and PEER Portal between January 2011 and January 2015. For aim 1, descriptive statistics were calculated for variables of interest from each data source, PQC and PEER portal, independently. In addition, a combined PQC and Peer Portal dataset was created to estimate frequencies and percentages for variables that were collected using similar taxonomies in both reporting portals. Variables summarized for the combined sample included: event type (i.e., incorrect drug, strength, directions, quantity, or patient) and whether or not the event reached the patient. For aim 2, a random sample of the combined PQC and PEER dataset was analyzed by determining the proportion of e-prescription events that would be considered preventable if the prescriptions were compliant with the elements of the "ideal e-prescribing order."

Results: A total of 589 events were reported to the PEER Portal from 2010 to 2015. Patient directions problems were the most frequent type of incidents (n=210) of which 10% (n=21) reached the patients. Quantity selection (n=158) and drug selection (n=96) were the next most frequently reported events, 20% of which reached the patient. Similarly, the most frequent

event type reported to the PQC system was incorrect directions (23.3%, n=128) followed by incorrect prescriber (17 %), incorrect drug (15%) and incorrect strength (12%) from a sample of 550 reports. For aim 2, 429 of 1,139 events were analyzed and classified as preventable or not preventable. Three strategies were identified as potential error prevention strategies for over two thirds of the quality related issues. These were: 1) use of standardized drug descriptions; 2) use of valid prescription quantities; and 3) maintenance of accurate prescriber and pharmacy information in the Surescripts directory.

Conclusion: Most of the events were resolved before reaching the patient. However, a large number of events required intervention of the e-prescribing staff, which may contribute to a considerable cost burden for the pharmacies. Software developers and vendors have the potential to greatly impact the number of e-prescribing related incidents by adopting three strategies in their systems: 1) use of standardized drug descriptions; 2) use of appropriate prescription quantities; and 3) maintenance of up-to-date prescriber and pharmacy information in the Surescripts directory. Adopting these standards may aid in reducing errors, creating better health outcomes, increased safety, and better patient relationships.

Session-Board Number: 5a-073

Poster Title: Provider compliance with an electronic Risk Evaluation and Mitigation Strategy (REMS) for Belatacept

Primary Author: Lisa Grossman, Columbia University College of Physicians and Surgeons, New York; **Email:** lvg2104@cumc.columbia.edu

Additional Author (s):
Hojjat Salmasian
Demetra Tsapepas

Purpose: The Food and Drug Administration mandates Risk Evaluation and Mitigation Strategies (REMS) for drugs with known serious risks, to ensure the benefits outweigh the risks. Belatacept, licensed in 2011 for maintenance immunosuppression after kidney transplant, confers an increased risk of post-transplant lymphoproliferative disorder (PTLD) and progressive multifocal leukoencephalopathy (PML) in EBV seronegative patients. To ensure compliance with the Belatacept REMS program, our institution created a previously described customized order entry item in the CPOE system, with a required pre-infusion checklist. Herein, we describe provider compliance with the pre-infusion checklist. In a secondary analysis, we examine in-hospital uses of Belatacept.

Methods: Researchers queried the electronic health record (EHR) database of NewYork-Presbyterian / Columbia University Medical Center for de-identified data dated after order entry item and pre-infusion checklist implementation. Data obtained included Belatacept order entries, Belatacept medical administration record entries, relevant labs and ICD codes for all patients receiving Belatacept, and all pre-infusion checklists. An independent researcher verified data accuracy using manual review. We conducted the descriptive analysis with R statistical package.

Results: 73.9% of all Belatacept infusions had a pre-infusion checklist completed any time prior to infusion, but only 54.3% had a checklist completed within 24 hours prior to infusion. If the provider completed a pre-infusion checklist, the provider checked all six items 95.4% of the time. The provider type completing the checklist constituted primarily nurses (89%). Providers

used Belatacept for both initial and conversion immunosuppression dosing (at 10mg/kg) followed by maintenance immunosuppression (at 5 mg/kg).

Conclusion: Our analysis indicates less than ideal compliance with a pre-infusion checklist for Belatacept. Whether providers complete the checklist's specified actions but do not fill out the checklist, or whether providers do not complete the checklist's actions, remains unclear. However, the degree of non-compliance highlights the need for additional strategies and monitoring to ensure proper implementation of REMS programs.

Poster Title: Dental students' perceptions of the role of pharmacists in the practice of dentistry

Primary Author: Sandra Avelar, Roseman University of Health Science College of Pharmacy, Utah; **Email:** savelar@student.roseman.edu

Additional Author (s):
Michael Curcio
Vijay Kale

Purpose: A focus on interprofessional education has recently become a common theme in health sciences curricular standards. This study aims to identify the attitudes and perceptions of dental students regarding the role of pharmacists in the practice of dentistry.

Methods: Following IRB approval, students enrolled at Roseman University of Health Science College of Dental Medicine were given the opportunity to complete a 19-question paper survey. Participation in the study was voluntarily. Surveys were handed to participants individually and completed in person. To be included in our study, participants were required to be English-speaking students currently enrolled in the Roseman University of Health Science College of Dental Medicine. Dental students younger than 18 years of age were excluded from our study.

Results: A total of 132 dental students completed the questionnaire. Students in their first year of dental school (59) represented 44.7% of respondents. About half of respondents, (68, 51.52%) had less than one year of experience in oral healthcare. A small majority of respondents (69, 52%) had a friend or family member who works in the field of pharmacy, and these respondents were more likely to rate their knowledge of the field of pharmacy as greater than 'moderate' (24.6% vs. 12.7%). Nearly half (62, 46.97%) of respondents were aware that pharmacy students must earn a doctorate degree before becoming a pharmacist; 43 (32.58%) erroneously believed that becoming a pharmacist required only a bachelor's degree. One-hundred-four (79.39%) respondents agreed that pharmacists play an important role in the practice of dentistry, with 23 (17.56%) strongly agreeing. One-hundred-five (79.54%) agreed that pharmacists can help improve therapeutic outcomes for dental patients. Sixty (45.80%) of respondents agreed that they would trust a pharmacist to counsel patients on oral hygiene

products, but only 34 (25.95%) agreed that they would trust a pharmacist to counsel patients on oral hygiene behaviors. Finally, a large majority (78, 82.44%) agreed that patients would benefit from more collaboration between dentists and pharmacists.

Conclusion: Overall, dental students in this single-centered, cross-sectional study see value in interprofessional collaboration between dentists and pharmacists. Our investigation identified some gaps in knowledge and trust among dental students with respect to pharmacists. This exploration of the current perceptions of future dentists about the incorporation of pharmacists in their field of practice can serve as a gauge of the current state of interprofessional education between students of pharmacy and dentistry.

Poster Title: Evaluation of controlled substance drip discrepancies in the Pediatric Intensive Care Unit one-year post implementation of electronic documentation and wasting

Primary Author: Shelby Newton, Harrison School of Pharmacy, AL; **Email:** esn0001@auburn.edu

Additional Author (s):
Sarah Hancock
Brenda Denson
Mary Claire Estess

Purpose: Prior to May of 2015, Children's of Alabama used a Controlled Substance Transaction Form to document the use of controlled substance drips. Requirements for each form included documentation of the time of administration of each drip as well as any waste, which required a witness signature. Administration of each drip was also documented in the electronic medication administration record (eMAR). In May of 2015 the process of documentation of controlled substances switched from the traditional transaction form to an electronic format. The aim of this project was to evaluate the effectiveness of an electronic documentation and wasting system one-year post-implementation.

Methods: Beginning May of 2015 nurses in the PICU at Children's of Alabama used a new process for the use of controlled substance drips. While they were still required to document the administration of each drip in the eMAR, they now recorded the waste in an automated dispensing machine (ADM) instead of on the controlled substance transaction form. Education was provided to the nurses prior to the implementation of the new process. Six weeks of data from 12 months post-implementation was pulled from both the eMAR and the ADM and was further evaluated for discrepancies. The data from May of 2016 was then was compared to data collected from the first six weeks following the new procedure.

Results: In 2015, six weeks after the change in the documentation system, there were 537 total drips dispensed with 19 discrepancies (3.54 percent). This was a 0.48 percent increase in the number of discrepancies found compared to 3.06 percent calculated six weeks prior to the implementation. While the percentage of discrepancies due to lack of eMAR documentation did improve, this percentage was not statistically significant. From 5/1/2016 to 6/11/2016 there were 366 drips dispensed to the PICU with 4 discrepancies (1.09 percent) found (p=0.029). Three of the four (75 percent) discrepancies were due to lack of documentation in the eMAR. The one-year post-implementation data shows a statistically significant decrease in the number of discrepancies.

Conclusion: One-year post implementation of electronic documentation and wasting of controlled substance drips at Children's of Alabama showed a significant decrease in the number of discrepancies found. There were 171 less drips delivered to the PICU during the six-week time frame beginning May 1, 2016 compared to the six weeks post-implementation in May of 2015. While there was a 2.45 percent decrease in the number of discrepancies found, there does still seem to be some issues concerning documentation in the eMAR.

Poster Title: Do direct-acting oral anticoagulants provide good value for the money? A budgetary model of Medicaid beneficiaries with nonvalvular atrial fibrillation.

Primary Author: Courtney Kruse, Midwestern University, College of Pharmacy, Arizona; **Email:** ckruse94@midwestern.edu

Additional Author (s):
Kathleen Fairman
Lindsay Davis
David Sclar

Purpose: State Medicaid programs have encountered challenges with increasing prescription drug costs due to price inflation and the introduction of new medications. Decision analytic models are often utilized to facilitate budgetary analyses and formulary decisions about new medications. However, many published models cannot be applied to Medicaid programs due to long time horizons or assumed populations (commercially insured). The purpose of this study was to provide budgetary estimates from a Medicaid, payer perspective for direct-acting oral anticoagulants (DOACs) versus warfarin in nonvalvular atrial fibrillation (NVAF) using number needed to treat, an easily calculated measure of treatment impact.

Methods: A budgetary impact analysis utilized (a) Medicaid cost data and (b) efficacy outcomes from the following pivotal clinical trials: Randomized Evaluation of Long-Term Anticoagulation, (RE-LY 2009), Apixaban for Reduction in Stroke and Other Thromboembolic Events in Atrial Fibrillation, (ARISTOTLE 2011), and Rivaroxaban Once Daily Oral Direct Factor Xa Inhibition Compared with Vitamin K Antagonism for Prevention of Stroke and Embolism Trial, (ROCKET 2011). Medicaid drug utilization files were used from 2009 to the second quarter of 2015 to estimate total oral anticoagulant reimbursement accounting for rebates at generic/brand statutory minimum (13%/23%) and assumed maximum 13%/50%) to produce an average rebate of 40%. Drug cost per patient per year (PPPY) was calculated as cost per claim (summed cost divided by summed claims) times 12, assuming 30-day supplies. To address 60-and 90-day supplies, a sensitivity analysis was performed. For each national drug code (NDC) and quarter, the number of milligrams dispensed was calculated (as strength multiplied by quantity). These values were converted to months of treatment based on assumed average daily dosages in

milligrams: 10 (apixiban), 300 (dabigatran), 20 (rivaroxaban), and 5 (warfarin). NNT values were calculated from the trial reports and applied to a hypothetical population of 500,000 Medicaid enrollees with NVAF to estimate avoided medical events under two DOAC market share scenarios: 2015 actual and 50% increase. Costs were adjusted for inflation.

Results: Medicaid costs for oral anticoagulants increased consistently with DOAC market share. From 2009 to 2015, inflation and rebated adjusted cost per claim increase by 173-279% depending on the rebate amount (maximum and minimum). For all but two outcomes, intracranial hemorrhage and hemorrhagic stroke, the DOAC versus warfarin comparison was nonsignificant in at least one trial. For the primary outcome, stroke or systemic embolism, NNT values were: 167 (RE-LY), 303 (ARISTOTLE), and no significant difference (ROCKET, non-inferior but not superior). For intracranial hemorrhage, the NNT values ranged from 213-500. For gastrointestinal hemorrhage, warfarin was superior in two trials, and one trial found no difference. Thus, DOACs prevented 36 ischemic strokes, 111 systemic embolisms, and 280 intracranial hemorrhages and caused 794 gastrointestinal hemorrhages in a cohort of 500,000 people with 21% using DOACs. These changes in medical events resulted in an estimated reduction in medical costs of $8.5 to 9.4 million, which was (3-5%) of added drug costs. After accounting for medical events and reduced monitoring, total cost increased by $129.2-$232.2 million ($258-$464 PPPY), depending on rebates.

Conclusion: The use of DOACs in NVAF was associated with increased Medicaid costs with small cost reductions due to medical event avoidance. There was a substantial net cost to the Medicaid program five years after the initial launch of DOACs. Through the use of a model based on NNT values, such analyses can inform state Medicaid programs of drug value, aid in formulary decisions, and indicate the need for rebate negotiations with manufacturers in the future.

Submission Type: Evaluative Study

Session-Board Number: 5a-077

Poster Title: Leveraging the benzathine penicillin G shortage: evaluating historical prescribing patterns in a community non-teaching hospital emergency department and identifying cost savings

Primary Author: Danielle Cenin, Ohio Northern University Raabe College of Pharmacy, Ohio; **Email:** d-cenin@onu.edu

Additional Author (s):
Brett Rodgers
Matthew Hoover

Purpose: In June 2016, the Centers for Disease Control and Prevention recommended reserving benzathine penicillin G for patients with syphilis, due to a shortage of the medication. The recommendation advised using alternative therapies for other infections. Prescribing restrictions were placed on benzathine penicillin G at the institution to reserve supplies for syphilis. Adherence to the restriction halted use of the medication. Due to this observation, the investigators sought to evaluate and categorize pre-shortage indications of benzathine penicillin G and determine if cost savings may have occurred if the restriction and use of alternative therapies was applied to historic use.

Methods: Following guidelines of the Institutional Review Board, this evaluation was categorized as a quality assessment and improvement activity. Data for benzathine penicillin G doses used at the study institution's emergency department from June 2015 through June 2016 was evaluated. Investigators collected the following information: dose, number of syringes used per dose, discharge diagnosis, and patient age. All doses administered were included in the evaluation and cost savings analysis. Doses were excluded from the cost savings analysis if used for a sexually transmitted disease related indication. Doses were categorized to the following indications: sexually transmitted disease related indication or non-sexually-transmitted disease related indication. Doses administered for non-sexually-transmitted disease related indications were converted to an alternative therapy, amoxicillin capsules or liquid. Investigators took a conservative approach and converted patients less than 18 years of age to liquid therapy and patients greater than or equal to 18 years of age to capsules. One benzathine penicillin G injection offers complete therapy and cost savings were calculated based on complete therapy

with amoxicillin. The cost for a dose of benzathine penicillin G varies based on syringe size used. Total cost of therapy with benzathine penicillin G was calculated based on the number of syringes used. Total therapy for liquid and capsule amoxicillin was estimated to be 1.8% and 1.2% of the average cost of a dose of benzathine penicillin G.

Results: Over the evaluation timeframe, there were 249 doses of benzathine penicillin G administered in the study institution's emergency department. Of these doses, only 2% (5 doses) were administered for a sexually transmitted disease related indication. Of the 244 doses administered for non-sexually-transmitted disease related indications, 97 doses were administered to patients less than 18 years old and 147 doses were for patients greater than or equal to 18 years old. Actual cost for benzathine penicillin G for non-sexually-transmitted disease related indications was estimated to be tens of thousands of dollars. Converting all of these patients to amoxicillin therapy would have cost approximately 1.5% of the actual cost of benzathine penicillin G therapy. Based on the historic use during the timeframe evaluated, a cost savings of 98.4% of the total cost of benzathine penicillin G therapy would occur if amoxicillin was used in place of benzathine penicillin G for these non-sexually-transmitted disease related indications.

Conclusion: Applying the Centers for Disease Control recommended restrictions to historical benzathine penicillin G use identified cost savings opportunities. Benefits of benzathine penicillin G use include therapy completion with a one-time injection, bypassing non-adherence to oral therapy. Limitations to this evaluation include the inability to account for non-adherence and complications of non-adherence. Additionally, patients may not be able to obtain total therapy at discharge. The investigators conclude that converting patients to amoxicillin therapy, instead of benzathine penicillin G for non-sexually-transmitted disease related indications, may result in cost savings and that discharge delivery services offered to patients may result in addressing non-adherence.

Submission Type: Evaluative Study

Session-Board Number: 5a-078

Poster Title: Optimizing Verification Workflow for Improved Medication Safety in the Outpatient Pharmacy Environment

Primary Author: Austin Green, The University of Texas at Austin, College of Pharmacy, Texas; **Email:** austinlgreen@utexas.edu

Additional Author (s):
Rakeshkumar Patel
Samuel Houmes

Purpose: In the outpatient pharmacy setting, medication safety remains at the forefront of the pharmacist's focus. From an initial data analysis, 39 percent of medication errors in the pharmacy were initiated from the point of verification. This disproportionate amount of errors for one phase of the pharmacy workflow can cause major adverse events for patients and allow for Health Insurance Portability and Accountability Act (HIPAA) breaches to occur. To reduce the number of verification to will call medication errors, a key contributor to the overall number of verification-based errors, the verification to will call workflow procedure was restructured.

Methods: All medication errors used in this study were self-reported through a system called Hopkins Emergency Response Organization (HERO). HERO reports were collected from December 1, 2015 through July 19, 2016 and a total of 66 medication errors were reported through this system for the former verification workflow. Of those 66, the 26 verification-based errors were determined by finding the first position where an error was made in accordance with the Standard Operating Procedures. The data presented in the study for the current verification workflow are preliminary and represent HERO reports from July 25, 2016 through August 12, 2016. The data were normalized per prescription volume and a chi-squared analysis was run to test the data for statistical significance.

Results: Preliminary analysis of the new workflow HERO reports over a three-week period show that while the numerical verification to will call error rate had decreased, there was not a statistically significant difference between the old and new workflow (p=0.64) as per the chi-squared analysis. This difference results from the lack of longitudinal research, as chi-squared

tests are only reliable measures of statistical significance if all involved data points have a numerical value greater than or equal to five. In this data, there was only one verification to will call error made. However, after final data collection, there should be enough data points to show statistically significant comparative data.

Conclusion: While the change in verification to will call procedure does place slightly more responsibility on the verification pharmacist, this change is believed to help prevent medication errors based on perfunctory numerical analysis of the number of verification to will call-based errors per prescription volume before and after implementation of the new workflow procedure. After six additional months, data should be analyzed once more for final comparative analysis, which can yield more definitive results as to the utility of this workflow implementation.

Poster Title: Description of industry curriculum within accredited United States colleges of pharmacy

Primary Author: Marine Schmitt, Oregon State University & Oregon Health and Science University, Oregon; **Email:** schmittmarine23@gmail.com

Additional Author (s):
Rosemary Boshar
Sean Harrison
Jerry Silverman

Purpose: To increase awareness of pharmacy students and stakeholders for the need to enhance access and increase the variety of pharmaceutical industry courses within colleges of pharmacy to meet the growing student demand for industry practice.

Methods: A list of all currently accredited U.S. schools of pharmacy was gathered from the Accreditation Council for Pharmacy Education's (ACPE) website. School-specific curriculum information was collected using student handbooks and course catalogues listed on college of pharmacy websites. Courses were added if they included the word "industry" in their course title or description. Any course providing knowledge or information on a specific area of industry was included, specifically those within the areas of: health economics, clinical science/development, marketing, regulatory affairs (including the FDA), drug information, and pharmaceutical research/development. After manual data collection, a standardized email was sent to deans of their respective schools of pharmacy inquiring about specific industry courses/events, their credit-hour qualification, and a brief summary. This information was added to the database in aggregate. This is the first of a continuing effort by IPhO to monitor and report upon the curricular inclusions of industry pharmacy practice courses.

Results: It was determined that 40.7% of pharmacy schools offer at least one elective course that meets the entry criteria related to the pharmaceutical industry and/or includes a discipline, such as clinical research or pharmacogenomics that is relevant to the pharmaceutical industry. The majority of these elective courses were in disciplines, such as health economics (26%), preclinical research (18%), or clinical development (17%). The highest percentage (52%) of

pharmacy schools offering industry courses are located along the east coast of the U.S., while the lowest percentage (14%) are located in the Pacific Northwest. Only 13% of the elective courses identified and reported upon in this research provided syllabi topics describing the various aspects of pharmaceutical commercialization from drug development and regulatory approval to marketing and sales strategies through life-cycle management.

Conclusion: Pharmacy students have minimal opportunity to explore the biotech and pharmaceutical industry, as less than half of colleges offer relevant courses. When industry courses are offered, they explore a very narrow commercial function or discipline. Unfortunately, a narrow scope of the pharmaceutical and biotech industry does not provide students with an understanding and appreciation of the functional relationships, responsibilities, and collaborations that industry pharmacy practice provides. This knowledge is essential for those students applying for post-graduate industry fellowship programs and entry-level industry positions, as the competitiveness for securing these positions continues to increase.

Poster Title: Pharmacist and physician perspectives on medication dose adjustments in obese patients

Primary Author: Carolyn Lathrope, Roseman University of Health Sciences, Utah (UT); **Email:** clathrope@student.roseman.edu

Additional Author (s):
Tharit Manoi
Danielle Nguyen
Ashley Robison
Glenn Windmiller

Purpose: The medical community has well established guidelines for health care providers to make dose adjustments in the following areas: pediatrics, geriatrics, renal and hepatic impairment. Such dose adjustments are easily found on tertiary resources; however there are no specific guidelines for dose adjustments in obese patients. This study was designed to determine where pharmacists and physicians obtain medication dose adjustment information for obese patients and to determine which providers are currently making these adjustments.

Methods: A survey was created containing ten questions related to medication dose adjustments in obese patients. This survey was distributed to pharmacists and physicians licensed and practicing in the state of Utah. The survey was structured to capture information in several key areas: current acknowledgement of the need to adjust medication doses in obese patients, employment protocols for medication dose adjustments, and current medications identified as needing a dose adjustment in obese populations (medication class, indication, and pharmacokinetics). The survey was open for participants to access from Sept 2nd 2016-Sept 29th 2016. The survey instrument was validated through content validity and face validity. Survey questions were developed through background literature and our study objectives. Face validity was established through a survey instrument reviewed by three groups: pharmacists, residents, and pharmacy students. Physicians and pharmacists working in bariatric surgery and/or weight loss clinics and physicians and pharmacists working in pediatrics were excluded from this survey.

Results: Seventy five pharmacists and thirty three physicians accessed the survey. Fifty eight pharmacist surveys were completed with enough information for statistical analysis. Twenty six physician surveys were completed with enough information for statistical analysis. Physicians who completed the survey worked in a clinic or a hospital. Pharmacists who completed the survey reported employment in clinics, hospitals or retail pharmacies. Physicians reported fifty percent of their institutions had protocols for dose adjustments in obese patients. Fifty two percent of pharmacists surveyed indicated their employers offered protocol for dose adjustments in obese patients. The majority of physicians and pharmacists identified that they learned about dose adjustments in obese patients during residency. The majority of physicians and pharmacists indicated they collaborated with other health care workers twenty five percent of the time. Pharmacists indicated they considered dose adjustments in obese patients fifty percent of the time. Physicians indicated they thought about dose adjustments in obese patients seventy five percent of the time. Physicians also indicated that they referred or consulted with a pharmacists seventy five percent of the time for medication dose adjustments in obese patients. Common medications that were listed as needing dose adjustments are vancomycin, enoxaparin, insulin and other antibiotics.

Conclusion: This survey was helpful in identifying if employers of physicians and pharmacists currently have protocols for medication dose adjustments in obese patients, which medications are commonly adjusted, and which health care providers are actively considering medication dose adjustments in obese populations.

Submission Category: Quality Assurance/ Medication Safety

Poster Title: Nursing perception of discharge medication delivery before and after the implementation of a decentralized pharmacy technician

Primary Author: Christopher Bell, The University of Utah College of Pharmacy, Utah; **Email:** chris.bell@pharm.utah.edu

Additional Author (s):
Joey Wilkinson
Anne Tran
Paul Wohlt
Mike Akagi

Purpose: Patient medication adherence is a key initiative at Intermountain Medical Center. Ensuring that patients leave the hospital with their discharge medications in hand may improve adherence. A medication bedside delivery program was developed to facilitate adherence. Nursing frustration with the hospitals initial model catalyzed a quality improvement initiative to expedite delivery of medications. A decentralized pharmacy technician may help improve efficiency and success of this program and improve nurses' perception of it. A goal was set to gain a better understanding of nurses' perception of this program and its efficiency before and after the implementation of a decentralized pharmacy technician.

Methods: A 14-question, internal, web based survey was emailed to all nurses on the surgical trauma and surgical transplant floors at Intermountain Medical Center. 14 days after the initial invitation, nurses were sent an email reminder to complete the survey. The survey was closed after 30 days. The survey was administered before and 11 months after the implementation of a decentralized outpatient pharmacy technician stationed on the respective floors. The results of the two surveys were compared and analyzed. Additionally, following the implementation of a decentralized pharmacy technician, data involving the time it takes for medications to be delivered to patients following discharge orders was collected and analyzed.

Results: 52 out of 75 nurses completed the pre technician survey and 41 out of 82 nurses completed the post technician survey. The pre survey found that 5.8 percent of nurses had a very poor overall opinion of the medication bedside delivery program, 26.9 percent had a poor opinion of it, 23.1 percent had a neutral opinion of it, 9.6 percent had a good opinion of it, and 5.8 percent had a very good opinion of it. The post survey found that zero percent of nurses had a very poor or poor overall opinion of the program, 14.6 percent had a neutral opinion of it, 61 percent had a good opinion of it, and 12.2 percent had a very good opinion of it. Additionally, the post survey found that 65.9 percent of nurses believe discharge medications should be delivered within 30-60 minutes after placement of discharge orders and 24.4 percent of nurses believe this should occur within 61-90 minutes. Data collected following the implementation of the decentralized technician found that 31.5 percent of medication deliveries occurred within 30-60 minutes after placement of discharge orders, 37.5 percent occurred within 61-90 minutes, and 26.7 percent occurred after 90 minutes.

Conclusion: The addition of a decentralized pharmacy technician has demonstrated the benefit of this position to the medication bedside delivery program. The streamlining of the delivery process has given nurses a more favorable impression of the program. Additionally, with efficient delivery of medication, this may allow for additional time to provide medication education, which also benefits patient adherence. The results of this survey show that the utilization of a decentralized pharmacy technician to facilitate bedside delivery was a positive quality improvement. It should be noted that nursing expectations of a reasonable delivery time show there is still room for improvement.

Submission Type: Descriptive Report

Session-Board Number: 5a-082

Poster Title: Pharmacy impact on preventing adverse drug events during hospital admissions by building the best possible medication history for patients on hemodialysis

Primary Author: Rebecca DeMuro, University of New England College of Pharmacy, Maine;
Email: rdemuro@une.edu

Additional Author (s):
Nancy Nystrom
Linh Dang
Leslie Ochs

Purpose: Patients on hemodialysis often have numerous co-morbidities and multiple providers that result in polypharmacy and challenging medication management. The goal of this quality improvement project is to show how pharmacy staff can improve the accuracy of home medication lists and prevent potential adverse drug events for these complex patients during a hospital admission.

Methods: A pharmacy team comprising of two pharmacists, three pharmacy technicians, and two pharmacy students set out to perform medication histories on hemodialysis patients that were admitted through the emergency department. Data were collected from April 15, 2015 through July 15, 2016 for medication histories performed by the pharmacy team during weekday service hours between 7:00 am- 4:30 pm. A Best Possible Medication History (BPMH) was generated through patient, family member or caregiver interviews and included confirmation of medication fill data from pharmacies, electronic health information databases, dialysis centers, and health care providers. For patients admitted off hours, medication errors were identified upon reconciliation of the completed BPMH with the admission orders and communicated to providers for correction. Changes made to the home medication list were tracked and categorized by pharmacological classes.

Results: During this project, a total of 100 hemodialysis patients medication histories were performed by the pharmacy team. Original home medication lists or prior to admission (PTA) lists were compared to the BPMH completed by the pharmacy, summarizing the number and types of medication changes. For the 100 patients reviewed, a total of 1645 medications were on the PTA lists. Of this total, 46% of the medication changes made to the original PTA medication lists were categorized as removals, additions, or changes based on missing strength, dose, or frequency. The medication changes were further categorized by drug classes and summarized as removals/additions/changes. Dialysis administered medications were the most common class of medications added to the PTA lists. These medications included erythropoietin-stimulating agents (ESAs), injectable iron, oral or injectable vitamin D analogues and heparin. Other dialysis-associated medication classes such as antihypertensives, diuretics, hyperparathyroid-regulators and phosphate binders accounted for many of the changes made to the PTA medication lists.

Conclusion: Pharmacy involvement in generating the best possible medication histories for hemodialysis patients proves to be beneficial for both the patient and the hospital by improving the accuracy of the PTA medication lists and preventing medication errors from occurring during hospital admission. Pharmacists, pharmacy technicians and student pharmacists have the knowledge and experience to provide a more detailed and thorough approach to assure medications were correctly entered on the patient's home medication list and further assisted in the reconciliation of medication errors made during the admission.

Submission Type: Descriptive Report

Session-Board Number: 5a-083

Poster Title: Establishing an institutional time to de-escalation in pediatric patients with Staphylococcus aureus and Enterobacteriaceae infections

Primary Author: Merrion Buckley, University of Tennessee Health Science Center, Tennessee; **Email:** mbuckle5@uthsc.edu

Additional Author (s):
Delia Carias
William Greene
Josh Wolf
Randall Hayden

Purpose: Antimicrobial de-escalation is a key component of stewardship programs and clearly supported in national guidelines. Appropriate de-escalation of empiric antimicrobial therapy when microbiological results become available correlates with improved patient outcomes and decreased medical costs. This study aimed to examine the time to de-escalation of empiric antibiotic therapy to definitive pathogen directed therapy at a pediatric cancer hospital.

Methods: Laboratory Information Systems in conjunction with the antimicrobial stewardship program at our 68 bed pediatric hospital developed an automated email to notify pharmacists when susceptibilities had been resulted on positive blood cultures. Between June 2013 and April 2015, 614 emails were sent to the clinical pharmacists working directly with each care team, so that these individuals might take appropriate steps toward de-escalation. These alerts were retrospectively reviewed. De-escalation was defined as either eliminating one empiric antibiotic when combination therapy was used or changing to an agent with narrower activity spectrum.

Results: Of the 614 positive blood cultures, 141 unique bloodstream infections were identified. The most common bacteria identified were Staphylococcus aureus (14) and those belonging to the family Enterobacteriaceae (39). All patients with S. aureus (9 susceptible to methicillin and 5 resistant to methicillin) were initially started on vancomycin, and all were appropriately de-escalated when susceptibilities became available (9/9 stopped vancomycin and 5/5 stopped

concomitant cephalosporins). The mean time to de-escalation for S. aureus was 9.6 hours (2 – 31).

Enterobacteriaceae infections were divided into those susceptible to cephalosporins (31) and those resistant (7). Of the 31 susceptible to cephalosporins, 13 were empirically treated with a cephalosporin plus an aminoglycoside and 10 were de-escalated to cephalosporin monotherapy. Eighteen of the 31 were empirically started on a carbapenem and all were either de-escalated to a cephalosporin (15) or carbapenem without an aminoglycoside (3). The mean time to de-escalation for Enterobacteriaceae susceptible to cephalosporins was 12.3 hours (1-51). In all cases, treatment of Enterobacteriaceae identified as resistant to cephalosporins was appropriately changed based on susceptibilities within 5 hours of result availability (mean 2.1 hours, 1 – 5 hours). Overall mean time to pathogen-directed therapy for both S. aureus and Enterobacteriaceae was 10 hours.

Conclusion: Prompt notification of antimicrobial susceptibility results enables rapid modification of antimicrobial therapy. Further development and evaluation of computer-based decision support tools in the area of antimicrobial stewardship is warranted.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Evaluative Study

Session-Board Number: 5a-084

Poster Title: Evaluation of medication administration of solid dosage forms via enteral feeding tubes in a community teaching hospital

Primary Author: Irene Yang, Ernest Mario School of Pharmacy, Rutgers University, New Jersey; **Email:** irene.yang94@gmail.com

Additional Author (s):
Kristina Rosus
Jennifer Wright
Charlene Blubaugh

Purpose: The improper administration of medication via an enteral feeding tube can lead to numerous patient-safety concerns while increasing healthcare costs. Concerns include varied medication efficacy, altered medication absorption, and tube clogging, which may require tube replacement. Solid dosage forms (tablets or capsules) given via enteral tubes have been identified as potential sources of preventable medication errors. The primary objective was to characterize the inappropriate administration of solid dosage forms through enteral feeding tubes. The secondary objective was to identify barriers in the electronic health record (EHR) contributing to the inappropriate ordering and subsequent administration of medications via enteral feeding tubes.

Methods: Adult patients with enteral tube feed orders were included in this retrospective chart review between June 8 and July 15, 2016. Patients were excluded if nursing staff administered medications via the oral route. Orders for tablets and capsules were identified via the medication administration record (MAR). Appropriateness was evaluated based upon available evidence for administration of the medication via the patient specific enteral tube. In addition, the EHR was utilized to review accuracy of ordered administration route and whether the correct route was available for providers to select when ordering this medication. Nursing administration comments were also assessed for accuracy, specifically whether medications that should not be crushed were identified as such. The use of pancreatic enzyme and sodium bicarbonate was used to identify a clogged tube needing additional steps beyond flushing with water to open. Descriptive statistics were utilized to evaluate the results. The institutional

review board (IRB) categorized this review as a quality assurance/quality improvement activity exempt from IRB oversight.

Results: A total of 35 patients and 116 administered medications were included in this review. Incorrect medication administration via an enteral feeding tube was found to have occurred five times in four patients. These medications were duloxetine, omeprazole, aspirin/extended-release dipyridamole, and enteric coated aspirin. Of the 116 administered medications these five medications had no literature supporting administration via enteral tube. In addition, four occurrences were found where nursing administration comments failed to identify medications that should not be crushed. These were potassium chloride extended-release, ergocalciferol, and omeprazole in two separate instances. The majority of medications (89%) were ordered through the incorrect route, with providers selecting oral as the most common inappropriate choice. All non-crushable medications were found to be orderable through feeding tube routes within the computerized physician order entry (CPOE). Of the 35 patients, two patients were given pancreatic enzymes and sodium bicarbonate, signifying a clogged tube that could not be cleared via standard measures of flushing with water. One of these two patients was given duloxetine while the other did not receive any medications that should not be administered via enteral feeding tube.

Conclusion: Administration of solid dosage form medications via enteral feeding tubes presents several opportunities for preventable medication errors that may lead to patient harm. Of the 35 patients reviewed, four were found to have been given medications via enteral feeding tubes that should not be crushed, raising concerns of varied medication efficacy, altered medication absorption, and tube clogging. These findings revealed the need for improvements in the technological systems, including an evaluation of available routes of drug administration in the CPOE. Resources for all healthcare providers are also needed to help decrease medications errors and improve patient safety.

Submission Category: Pain Management

Submission Type: Descriptive Report

Session-Board Number: 5a-085

Poster Title: Role of pharmacy students in an opioid safety population health initiative

Primary Author: Tasha Farnaam, Thomas J. Long School of Pharmacy and Health Sciences, California; **Email:** t_farnaam@u.pacific.edu

Additional Author (s):
Sian Carr-Lopez
Allen Shek
Lorrie Strohecker
Cynthia Valle-Oseguera

Purpose: The chronic use of opioid pain medication presents serious risks, including overdose and opioid use disorder. In 2016, the US Department of Health and Human Services Centers for Disease Control and Prevention (CDC) published a guideline for prescribing opioids for chronic pain. Pharmacists play an important role in managing the population prescribed chronic opioid therapy. As such, it is advantageous to teach pharmacy students strategies to improve clinical outcomes for this population with chronic pain.

Methods: A collaboration between Veterans Affairs (VA) Northern California Health Care System (NCHCS) and University of the Pacific (UOP) was established in September of 2015. The focus was building a population health program whereby pharmacy students, under the direct supervision of VA clinical pharmacists, would provide population health services for Veterans within NCHCS. An introductory pharmacy practice experience elective course was developed and approved by the faculty at UOP; ten students were admitted into the course in August of 2016. Students were granted remote access privileges to the VA computerized patient record system (CPRS). The population health experiences were conducted by students and VA preceptors at UOP. A decision to focus initially on the VA opioid safety initiative was made. Learning activities included reviewing the CDC guidelines, performing state prescription drug monitoring to identify aberrant behavior, interpreting urine drug tests, documenting progress notes in CPRS, and communicating alarming findings to other health care professionals including a pain clinical pharmacy specialist or the patients' providers. Students were taught how to use a clinical dashboard to identify patients within the population of chronic opioid users who had upcoming medical appointments such that the results of screening could be

available for the appointment. Students completed a baseline assessment during the first day of the course regarding their experience and competence performing population health activities.

Results: Strategic members of the VA healthcare team included the pain clinical pharmacy technician, the pain clinical pharmacy specialist, the population health clinical pharmacy specialist and the primary care physician. The pain clinical pharmacy technician was instrumental in teaching strategic methods to identify aberrant behaviors using the state prescription drug monitoring program and teaching students the process to document progress notes into CPRS. The pain clinical pharmacy specialist was the most common VA team member added as a co-signer on students' progress notes. The baseline assessment of ten pharmacy students revealed that two had previous experience using a clinical dashboard to conduct population health activities, one had experience performing population health activities for the population prescribed chronic opioid therapy and one had experience interpreting the results from the state prescription drug monitoring program. VA is examining other high-risk populations and ranking next steps for pharmacy student-initiated population health endeavors.

Conclusion: Introductory pharmacy practice experiences can be developed to enable students to cultivate skills in managing populations at risk for adverse clinical outcomes. This includes populations taking high-risk medications such as chronic opioids, anticoagulants or oral chemotherapy; high-risk populations based on behaviors such as use of tobacco products or those requiring pre-exposure prophylaxis for HIV; and the population in transitions of care requiring medication reconciliation and education. Health systems such as VA are motivated to implement strategies to address the needs of high-risk populations.

Submission Type: Descriptive Report

Session-Board Number: 5a-086

Poster Title: PREVENT-OD: A pilot survey

Primary Author: Michael Hoang, Massachusetts College of Pharmacy & Health Sciences University - Worcester, Massachusetts; **Email:** emailmikehoang@gmail.com

Additional Author (s):
Alyssa Bowling
Anthony Villanova
Thomas Clark
Aimee Dietle

Purpose: In Massachusetts (MA), over 1500 fatalities may be attributed to opioids with an estimated rate of 24.6 deaths per 100,000 residents in the past year. Compare that with the rate of deaths due to motor vehicle crashes at 4.9 deaths per 100,000 residents within the same time period. The hypothesis of this study is that at discharge post-overdose (OD), patients have limited access to resources and that pharmacists can be viable in providing access to this care. This study aimed to identify barriers to implementing OD prevention services and to assess the feasibility of utilizing pharmacists to deliver these services.

Methods: Pharmacy directors within MA from 33 different hospital systems were contacted on August 29, 2016 to distribute the online survey titled Pharmacist REmedied ViEws in Needing to Treat OverDoses (PREVENT-OD). This anonymous survey and study design was approved by a local IRB and exempted from informed consent given minimal risk to participants. Additionally, a link to the survey was posted on a Massachusetts Pharmacists Association forum. Eligible survey participants consisted of hospital pharmacists currently practicing in MA that had some familiarity with their respective emergency department protocols. Participants were ineligible if they were pharmacists who did not practice in MA and/or if they had no familiarity with their hospital's ED services. Survey questions asked if each institution offered counseling and/or reversal agents (i.e. intranasal naloxone) at the point of discharge and rated pharmacists' perceived opinions on proposed ideas to increase access to OD prevention resources. The survey was closed on September 16, 2016.

Results: Overall, 15 unique responses were collected: 14 met inclusion criteria with 1 response exluded for not being from a pharmacist practicing in MA. 78.6 percent of eligible respondents indicated that their institution provides counseling at point of discharge for OD patients. Of those, 72.7 percent feel it's been effective in reducing opioid-related deaths. The most commonly cited barrier to implementing counseling services was time and staffing (90.9 percent). Despite a large amount of EDs offering counseling, relatively few, 28.6 percent, reported offering intranasal naloxone kits. For those successfully implementing providing nalxone, 100 percent feel this was effective in preventing deaths with the most common barrier being a lack of standardized protocols (75 percent). Participants were asked to rank feasibility of several proposals to increase access to preventive strategies on a scale of 1-5, with 1 being very easy and 5 being the most difficult. The mean reported implementation difficulty of each proposal was as follows: supply each patient with naloxone kits, 2.5; provide counseling by pharmacy staff, 3.0; provide counseling by nursing staff, 3.6; provide counseling by patient's PCP, 3.5; and offer naloxone kit/counseling to a spouse, partner, family member, or emergency contact in the care of the patient, 2.3.

Conclusion: Results show a large gap between the number of hospitals that offer counseling and those offering naloxone. However, all responses agree that naloxone is effective at reducing deaths. Of the three counseling resources provided (primary care provider, nursing, pharmacy), implementing pharmacy counseling services was easiest to implement. Furthermore, pharmacists feel it would be relatively easy to implement providing naloxone to high risk patients. The best treatment is often prevention, and this may offer some insights as a starting point to the next course of action.

Poster Title: A review of student pharmacist discharge medication reconciliation program at a level 1 trauma, academic medical center

Primary Author: Farah Raheem, University of Arizona, Arizona; **Email:** raheem@pharmacy.arizona.edu

Additional Author (s):
Supranee Soontornprueksa
Kelvin Tran
Christopher Hagen
Bernadette Cornelison

Purpose: This quality improvement project focused on chart reviews to evaluate the effectiveness of student pharmacists performing discharge medication reconciliation. The purpose of this project is to analyze frequency and type of discrepancies found by the student pharmacists after the completion of the medication reconciliation at a level 1 trauma, academic medical center. The primary objective was to measure the effectiveness of student pharmacist-based medication reconciliation at discharge by collecting the frequency of medication related discrepancies. The secondary objective was to measure how student pharmacist-based medication reconciliation can improve medication related errors and characterize the types of discrepancies found.

Methods: Data was collected by performing a chart review of medical records from May 2015 to March 2016. Inclusion criteria were all patients greater than or equal to 18 years of age who were admitted to the adult medicine units and who have had a discharge medication reconciliation completed by student pharmacists. All patients who did not fit the inclusion criteria were excluded. Collected data included age, number of medications, number of discrepancies, types of discrepancies, severity level, and amount of time per review. The data was analyzed using descriptive statistics.

Results: A total of three patients were documented to have received discharge medication reconciliation between May 2015 and March 2016. The average discrepancy per patient was found to be 0.67 percent. The time spent per student to provide discharge medication reconciliation was 1 to 15 minutes for 2 data points and 31 to 60 minutes for 1 data point.

Conclusion: The average discrepancies were low compared to findings in other studies. There were no data available to analyze the severity and types of discrepancies. The current system at the facility does not require discharge medication reconciliation. Also, the facility does not enforce documentations in the electronic records. Additionally, patients may be discharged without alerting the pharmacy department. To increase efficiency of medication reconciliation and documentation at the facility, the pharmacy department should utilize graduate interns or students pharmacists who are not in their advanced pharmacy practice experience.

Poster Title: Development of a simple, rapid, accurate, and precise method for measuring vancomycin concentrations in rat pup kidneys using high-performance liquid chromatography (HPLC) with UV detection

Primary Author: Jack Chang, Midwestern University- Chicago College of Pharmacy, Illinois; **Email:** chang.jack624@gmail.com

Additional Author (s):
Harshwardhan Jain
Brooke Griffin
Marc Scheetz
Medha Joshi

Purpose: The purpose of this research was to develop a simple, rapid, accurate, and precise method for measuring vancomycin concentrations in rat-pup kidney tissue homogenate (KTH) using high- performance liquid chromatography (HPLC). We aimed to extrapolate on previously developed assays for determination of vancomycin in rat plasma, for determination of vancomycin in rat- pup KTH.

Methods: Sprague-Dawley rat-pup kidneys were prepared for HPLC sampling by ultrasonic homogenization. Kidneys were weighed and water was added in a 1:3 ratio. Next, the mixture was homogenized for 3-5 minutes. Stock solutions of vancomycin hydrochloride (VHCl) and caffeine (CA) were prepared at concentrations of 1.5 mg/mL and 1 mg/mL respectively, in a mixture of methanol:water (1:1). Caffeine was used as the internal standard owing to its stability in formic acid. VHCl was added to rat KTH (40 microliters) to obtain concentrations of 15, 30, 45, 60 and 75 mcg/mL. CA was added to obtain a concentration of 10 mcg/mL. Samples were transferred to Phree phospholipid removal tubes (Phenomenex, Torrance, CA), mixed with 240 microliters of 1-percent formic acid in methanol and centrifuged at 6600 g for 15 minutes (Sorvall, Thermo-Scientific). The eluent was filtered through 0.2 micron syringe filters and analyzed using HPLC. A calibration curve was prepared in vancomycin-spiked rat-pup KTH with 6 replicated concentrations from 15-75 mcg/mL. An Agilent 1260 series HPLC system was used to analyze spiked rat KTH. A Kinetex Biphenyl analytical column (2.6 micrometers, 100 A, 50 x 3 mm. Phenomenex, Torrance, CA) was used with a preceding UHPLC guard column. A

gradient method was used to separate the analyte and mobile phase flow rate was 0.5 mL/min. Eluents were analyzed at wavelengths of 198, 220, 230 and 240 nm.

Results: For the blank rat- pup KTH samples, the wavelength 198 nm displayed the highest lambda max. Retention times of VHCl and CA in plasma were 4.32 and 5.22 min, respectively. No significant interfering peaks from endogenous substances in the blank rat KTH were observed at the retention time of the analyte or the internal standard, respectively. The mean regression equation for nominal vancomycin concentrations (i.e. "x") to integrated area ratios (i.e. "y") in spiked KTH was found to be: y = 0.0057x - 0.038 (R-squared value = 0.9996). Intra-day assay precision (percent-RSD) was found to range between 0.35 and 3.58 percent. Inter-day assay precision (percent-RSD) ranged from 0.40 to 1.72 percent. Corresponding accuracy always exceeded 96-percent. The highest percentage recovery was 91.2-percent. Percentage recovery remained constant in the samples both upon immediate HPLC and with HPLC 24 hours after KTH was spiked with vancomycin. The lower limit of quantification (LLOQ) for VHCl using this method was found to be 2.996 mcg/mL.

Conclusion: In conclusion, the described method was found to be efficient, accurate and precise for measuring vancomycin concentrations in rat- pup kidney tissue homogenate using HPLC. Our method will be useful for future translational studies of vancomycin pharmacokinetics in rats.

Poster Title: Audit of Antimicrobial Stewardship Interventions at a Pediatric Hospital Using Documentation in the Medical Record

Primary Author: Rachel James, The Ohio State University College of Pharmacy, Ohio; **Email:** rij9204@gmail.com

Additional Author (s):
Mark Doles
Jessica Tansmore

Purpose: In response to increasing rates of antimicrobial resistance worldwide, the Centers for Disease Control and Prevention and Infectious Diseases Society of America have recommended that all inpatient healthcare settings institute antimicrobial stewardship programs (ASP) to ensure patients receive proper therapy while slowing development of antibiotic resistance. The ASP at Nationwide Children's Hospital is comprised of a pharmacist and a physician champion and was implemented in January of 2015 to review hospital-wide usage of linezolid and meropenem. This study was designed to determine acceptance rates of recommendations made by the ASP regarding antibiotic regimens for admitted patients at Nationwide Children's Hospital.

Methods: This retrospective chart audit was found to be exempt from IRB review. All patients with an ASP intervention between February and May 2016 were included in the study. Interventions are documented as a "smart" note in the medical record, and all interventions are automatically compiled into a monthly report that lists patient information and type of intervention. Patients were excluded if the documented note could not be found or if information was incomplete. Each note was examined for the types of recommendations made ("continue current antimicrobials" vs. "other"), and whether each recommendation for a change in therapy was accepted within a time period of 48 hours. Other variables measured included the service to which the patient was admitted, incidence of prior consultation with Infectious Disease (ID), ASP medication, ASP treatment indication, note author, and justification for recommendation. The primary outcome measure was the rate of acceptance of "other" recommendations made by the ASP pharmacist. The secondary outcomes were overall compliance with ASP guidelines (rate of "continue" plus "accepted" recommendations),

acceptance of ASP recommendations with prior ID consult at the time of recommendation, and acceptance rate in the services utilizing ASP drugs the most (determined post-hoc).

Results: Sixty-nine patients had a total of 122 notes and 139 separate recommendations from the ASP pharmacist in the medical record. Ninety-one (65%) of these recommendations were made for linezolid and forty-eight (35%) were made for meropenem. Vancomycin monitoring had not yet begun during the period of interest. Ninety-six (69%) of the recommendations were "continue". Of the 43 "other" recommendations, twenty-six (60%) were accepted by the medical team, giving a total overall compliance rate of 88%. Reasons for non-acceptance were largely undocumented in the medical record. The most common "other" recommendations were as follows: "alternate agent based on culture/lab data" (44%), "consult with ID" (23%), and "dose optimization" (12%). Eleven patients had received an ID consult prior to the publication of the ASP pharmacist's recommendations, and only 3 (27%) of the recommendations were subsequently accepted by the medical team. Based on number of recommendations made, the top 3 services utilizing ASP targeted antibiotics were Non-Neonatal Intensive Care (Pediatric and Cardiothoracic), Pulmonary, and Nephrology; rates of compliance on these services were 84%, 91%, and 90% respectively.

Conclusion: The overall ASP compliance rate for our program is 88%, similar to those reported elsewhere in the literature. Notably, our ASP has also been successful in meeting all goals of reducing unnecessary antimicrobial use thus far. The use of "smart" documentation in the medical record appears to be a novel and effective method to capture ASP interventions. The program could benefit from increased resources and continued provider education on the goals of ASP recommendations. Future studies should explore the impact of ASP compliance rates on cost and clinical outcomes, as well as the impact of the ASP on vancomycin usage.

Submission Type: Evaluative Study

Session-Board Number: 5a-090

Poster Title: Effects of mandatory and standardized initial pharmacist consultation on INR testing compliance and therapeutically in-range INR draw frequency in atrial fibrillation patients on warfarin

Primary Author: Lauren Sanders, University of Arizona College of Pharmacy, Arizona; **Email:** laurensanders@pharmacy.arizona.edu

Additional Author (s):
John Sellers
Matthew Bertsch

Purpose: The purpose of this study was to evaluate the efficacy of a mandatory, pharmacist-led, educational intervention implemented at two Sun Life Family Health Center (SLFHC) pharmacy locations in Casa Grande and Eloy, Arizona upon atrial fibrillation patient compliance with INR (International Normalized Ratio) draws, recommended to be re-drawn every 30 days, and the number of therapeutically in-range INRs (range of 2.0-3.0). This intervention furthermore aimed to improve patient understanding of factors influencing INR and the importance of maintaining an in-range INR, due to the negative effects of having an out of range INR (i.e. too little or too much anticoagulation).

Methods: A mandatory, educational intervention, utilizing both direct pharmacist-patient consultation (in person or via telephone) and a patient education pamphlet, was implemented for atrial fibrillation patients at two SLFHC pharmacy locations in Casa Grande and Eloy, Arizona. The pharmacist-led consultation was a brief, initial/annual consultation to verify dosage and how the patient is taking the medication warfarin. Pharmacists conducting the consultations were provided with a checklist of counseling points to ensure added uniformity across the patient population. Measured nominal data included patient compliance with frequency of INR draws (every 30 days) and frequency of therapeutically in-range INRs (2.0-3.0 for atrial fibrillation patients). Data collection began on November 18, 2015. The educational intervention was implemented on February 7, 2016. Data collection concluded on April 7, 2016. Pretest data was collected via the Electronic Health Record kept by Sun Life Family Health Center. All data were collected, de-identified, and provided for analysis by the preceptor, Matthew Bertsch, PharmD, who is the director of pharmacy for SLFHC. The size of the sample

was 23 atrial fibrillation patients. A total of 83 INR draws were included in the pre-data. A total of 57 INR draws were included in the post data. Data were obtained through the use of purposive sampling. A chi-square test with an alpha level of 0.05 was calculated in order to compare pre and post-intervention outcomes.

Results: For baseline, pre-intervention results, 13 of the 23 atrial fibrillation patients (56.52%) demonstrated compliance in obtaining INR draws every 30 days, and 36 out of 83 INR draws (43.47%) were found to be therapeutically in-range. After the implementation of the intervention, 15 out of 23 atrial fibrillation patients (65.22%) demonstrated compliance in obtaining INR draws every 30 days, which was an 8.5% numerical increase (p=0.76) from baseline. 28 out of 57 INR draws (49.12%) were found to be therapeutically in-range, which was a 5.75% numerical increase (p=0.62) from baseline. Utilizing Chi-Square to analyze patient compliance for pre and post-results yielded a Yates' p-value of 0.76. Analyzing in-range INRs for pre and post-results yielded a Yates' p-value of 0.62.

Conclusion: Low baseline data values and marginal increase post-intervention demonstrated the need for intervention in INR monitoring and highlighted the potential positive impact of pharmacist-led patient education upon therapeutic outcomes. While the effect of the intervention was deemed inconclusive, as results were not statistically significant, this could have been partially due to project limitations. Despite this, a standardized approach to patient consultation on warfarin was established and provided insight into current patient compliance and in-range INR draws. An extended period of data collection would be warranted to sufficiently determine correlation, as well as the potential positive impact in the future.

Poster Title: Japanese pharmacy students' perceptions of medication adherence

Primary Author: Victor Loi, University of the Pacific, California; **Email:** v_loi@u.pacific.edu

Additional Author (s):
Sari Nakagawa
Nancy Nguyen

Purpose: Limited studies have shown that healthcare professional students studying in the U.S. who participated in medication adherence exercises have developed greater empathy and appreciation for their patients regarding the difficulty of achieving optimal medication adherence. However, it is unknown if a similar experience occurs among Japanese pharmacy students. This presentation describes the survey results completed by pharmacy students who participated in a medication adherence exercise at Kobe Gakuin University, Department of Pharmaceutical Sciences in Kobe, Japan.

Methods: A four-week elective course, consisting of 8 lectures and discussions, was provided by an American Clinical Professor of Pharmacy Practice for the Japanese pharmacy students at Kobe Gakuin University. All students enrolled in the elective course participated in a medication adherence exercise. The purpose was to expose students to the potential complexities of medication adherence with HIV therapy. Students were randomly assigned to take, as the patient, one of three simulated medication regimens. Each simulated regimen consisted of small round candies which represented three separate daily medications commonly used in HIV treatment. Each student was instructed to follow their assigned regimen (e.g. proper schedule and instructions on how to take the medication) to the best of their abilities for six consecutive days. At the end of the exercise, students discussed their experience with the class and course instructor. Following the discussion, students completed a 17-question survey regarding their experience with the medication adherence exercise. Survey questions assessed the students' adherence rates and perceptions in regards to medication adherence and barriers to adherence.

Results: A total of 29 students, mostly first and second year pharmacy students (in a six-year pharmacy program), completed both the adherence exercise and the survey. Before beginning the medication adherence exercise, 58.6% of the students agreed or strongly agreed that "it will be easy for patients to take medications." In comparison, 6.8% of students agreed or strongly agreed with this statement after completing the exercise. Nearly 80% of students rated their "prescribed" medication regimen as somewhat complex, complex, or very complex. At the completion of the exercise, 58.6% of students reported less than optimal (less than 95%) medication adherence. Among these students, the most common medication-related reasons for doses missed included inconvenient timing of doses (24.1%) and difficulty swallowing medications (20.7%). The most common patient-related reasons for missed doses included forgetfulness (27.6%) and other priorities/too busy (27.6%). All students agreed or strongly agreed that the exercise was valuable in "understanding a patient's perspective with taking medications." As a result of this exercise, 34.4% of students agreed or strongly agreed that they "will be able to provide patients with counseling and advice on how to achieve optimal medication adherence."

Conclusion: Prior to the activity, a majority of Japanese pharmacy students who participated in the medication adherence exercise believed that taking medications would be easy. However, more than half of the students experienced difficulty achieving optimal medication adherence. The students found the exercise valuable in understanding a patient's perspective with taking medications. The results of the survey suggest that a medication adherence exercise may benefit Japanese pharmacy students in understanding the issues patients may face adhering to their prescribed medications.

Poster Title: Changing the landscape of pharmacy compounding- Development of an extemporaneous orodispersible film preparation using the unit-dose method

Primary Author: Wen Chin Foo, Department of Pharmacy, Faculty of Science, National University of Singapore., Outside the US: Singapore; **Email:** wenchin.foo@u.nus.edu

Additional Author (s):
Yuet Mei Khong
Rajeev Gokhale
Sui Yung Chan

Purpose: The paradigm shift from oral liquid medicines to innovative solid dosage forms (iSDF) for pediatric patients was catalyzed by changes in global pediatric regulations in the last decade which have placed emphasis on the development of age-appropriate formulations. iSDF are a departure from traditional solid dosage forms (tablets or capsules) to more easily-swallowed, pediatric-friendly solid dosage forms such as orodispersible or chewable formulations. Our study aimed to develop a formulation and method for the compounding of an extemporaneous orodispersible film (ODF) preparation in the pharmacy setting.

Methods: Ondansetron hydrochloride dihydrate which is a Biopharmaceutical Classification System (BCS) Class I/III drug was used as the model drug. Its high solubility negates any potential bioavailability issues common with extemporaneous preparations thus making it an appropriate drug for pharmacy compounding. Hydroxypropyl methylcellulose (HPMC) was selected as the film-forming polymer and glycerol as the plasticizer in consideration of their relative safety in children. A casting solution was prepared by dissolving all formulation components in water and ODFs were subsequently prepared using the solvent-casting process. To overcome issues of poor content uniformity and dose variations associated with the conventional method of casting a master film and cutting individual film units to size, we developed the unit-dose method which effectively circumvents these problems. This method involves casting each film unit onto individual wells confined by circular bank structures. An ideal ODF should be thin, easy to handle without breaking and disintegrate rapidly in the buccal cavity before being swallowed with saliva. To optimize the formulation, we studied the effect of various critical formulation parameters (polymer concentration, drug concentration and volume

of casting solution) on the ease of preparation and critical quality attributes of the product: film thickness, mechanical properties and disintegration time. A two-level, full-factorial experimental design with three factors was employed. The ODFs were also characterized with respect to moisture content, drug crystallinity and in vitro dissolution.

Results: All ODFs prepared with the unit-dose method demonstrated excellent drug content uniformity with acceptance values (AV) of 0.38 - 4.95 which met U.S. Pharmacopeia requirements of AV less than 15. Casting solutions of higher HPMC concentration were preferred because they foamed less easily and require shorter drying times. Physical evaluation of the ODFs showed that they were smooth in texture, strong and flexible thus indicating good patient acceptability. ODFs with drug loads less than 16 percent formed amorphous solid dispersions but drug recrystallization was observed at a high drug load of 32 percent. Low HPMC concentration and low volume of casting solution yielded thin but strong and flexible ODFs with the shortest disintegration time (less than 11 sec). In vitro dissolution tests indicated a degree of taste-masking attributed to the basic nature of ondansetron (pKa 7.4). At pH 6.8 (buccal cavity simulation: phosphate buffer solution; 50mL; USP Apparatus II), less than 42 percent of drug was dissolved at 15 mins for ODFs with a high drug content of 12.8mg ondansetron. At pH 1.1 (gastric environment simulation: 0.1N hydrochloric acid; 500mL; USP Apparatus I), all ODFs achieved more than 95 percent drug dissolution within 30 minutes.

Conclusion: We present a simple, inexpensive method and easy-to-prepare formulation for the compounding of an extemporaneous ODF preparation as an alternative to conventional oral syrups/suspensions. An ODF formulation containing a water-soluble drug, ondansetron hydrochloride at clinically relevant strengths was developed. ODFs prepared fulfilled the requirements for clinical efficacy and safety with regards to drug content uniformity, in vitro dissolution and safety of excipients. The best formulation was selected based on product performance in terms of good mechanical properties and disintegration time. This formulation can be used as a basis for the development of extemporaneous ODFs for other suitable drugs.

Session-Board Number: 5a-093

Poster Title: Antimicrobial utilization and potential drug-drug interactions in nursing homes in Singapore

Primary Author: Aysu Selcuk, National University of Singapore, Singapore; **Email:** a0135969@u.nus.edu

Additional Author (s):
Christine B Teng
Sui Yung Chan
Kai Zhen Yap

Purpose: Inappropriate antimicrobial use is an important problem in nursing homes where more than half of the residents were prescribed at least one course of antimicrobial in a year. Antimicrobial use data have been reported in many countries to assess its prevalence, utilization and appropriateness. The objective of this study is to determine antimicrobial usage prevalence and utilization in Singapore nursing homes as well as to describe the risk of significant drug-drug interactions with addition of antimicrobials to residents' medication regimens.

Methods: This retrospective study was conducted by using data from four nursing homes in Singapore. All medications used by residents in December 2008 were reviewed. Residents were eligible if they stayed in the nursing home during the study period. WHO ATC/DDD index was used to determine antimicrobial utilization rate. Only use of systemic antimicrobials was included in the study. Drug-drug interactions were detected by using online drug interaction checker program. The prevalence of systemic antimicrobial use, antimicrobial utilization, and drug-drug interactions with the addition of antimicrobials to the residents' medication regimens were analyzed.

Results: During the one-month period, 712 residents were eligible for the study of which 70 (9.8 percent) used at least one antimicrobial during their nursing home stay. The antimicrobial utilization rates were 28.3 DDD (defined daily doses) per 1000 resident days and 24.8 DOT (days of therapy) per 1000 resident days. Clinically significant drug-drug interactions were present in more than half of the residents (41 out of 70) and 15 out of 41 involved an antimicrobial agent.

The most commonly prescribed antimicrobials were amoxicillin-clavulanate, ciprofloxacin and doxycycline, respectively. Respiratory infections were the most common reason for the antimicrobial use in the nursing homes studied.

Conclusion: This study is the first that describes the utilization of antimicrobials in Singapore nursing homes. The utilization rate in our nursing homes is comparable to other developed countries. Prescription of antimicrobials resulted in a high incidence of significant drug-drug interactions. Further studies to assess the appropriateness of antimicrobial use in the nursing homes are needed.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Descriptive Report

Session-Board Number: 5a-094

Poster Title: Utilization of the University of North Carolina Hospitals' Drug Information Center across a multi-hospital health system

Primary Author: Katherine Summers, University of North Carolina Eshelman School of Pharmacy, North Carolina; **Email:** kate_summers@unc.edu

Additional Author (s):
Jennifer Cruz

Purpose: Drug Information Centers play a valuable role in providing support to physicians, pharmacists, nurses, and other healthcare providers. The University of North Carolina Hospitals' (UNCH) Drug Information Center (DIC) recently expanded its services to support 10 affiliate hospitals in its health system. After expansion, it was anticipated that request volume would increase and that common types of questions encountered might change as a result of more institutions utilizing DIC services. The purpose of this project was to compare the volume of DIC inquiries 1 year before and after the expansion date, and to evaluate the change in types of requests.

Methods: UNCH is a public, academic medical center with over 800 beds. The affiliates are community hospitals averaging 268 beds (range 25 to 660). The UNCH DIC offers support for classic drug information requests and also shares preexisting institution-specific documents, such as policies and formulary reviews. The UNCH DIC is supported by 2 pharmacists, 1 student intern, and 18-20 learners throughout the year rotating each month (1st year residents, 2nd year residents, and 4th year pharmacy students). The UNCH DIC uses a cloud-based electronic database to log many aspects of each question received, including (but not limited to): affiliation of the requestor, classification of the request, and time spent researching and answering the question. The DIC designates request types into 1 of 16 standardized categories. The UNCH DIC officially expanded it services to the health-system level on August 5, 2015. In order to compare how question volume, support time, and common request categories changed after the expansion date to affiliate hospitals, data were compared for 1 year preceding and 1 year following the expansion date (August 5, 2014 – August 4, 2015 versus August 5, 2015 – August 4, 2016). The total number of questions, documented time, and

question category each year were compared, as well as the most common categories of requests for UNCH versus its affiliates.

Results: The total number of requests was 339 in the year preceding the expansion date and 506 the year following the expansion date (monthly average, 28.1 vs. 41.8), though question volume and total time spent answering requests varied by month. The total amount of time spent responding to questions per year was 286.9 hours before the expansion and 478.1 hours after the expansion (monthly average, 23.8 vs. 38.8). Before expansion, the 3 most common categories of requests were more traditional drug information-type questions and comprised 42% of all requests received. These included adverse reactions/allergies (14%), drug compatibility/stability (14%), and dosing/administration (14%). After expansion, the 3 most common categories comprised 35% of all requests received and included dosing/administration (13%), adverse reactions/allergies (11%), and medication use policies/guidelines (11%). Differences between UNCH and affiliate request types post-expansion were also examined. The 3 most common categories received from UNCH were drug compatibility/stability (14%), dosing/administration (14%), and formulation/pharmaceutics (12%). The 3 most common categories received from hospital affiliates were medication use policy/guidelines (37%), formulary (management, restrictions, and preauthorization) (14%), and dosing/administration (13%). All affiliate hospitals utilized the UNCH DIC post-expansion, with the number of requests ranging from 2 to 32.

Conclusion: DICs can be a valuable resource for a health system as a whole. After expansion to affiliate hospitals, the annual number of requests increased by 49% and the amount of research/response time increased by 67%. More institution-specific information was sought rather than traditional drug information questions, as 2 categories encompassed over half of affiliates' inquiries: institutional policies/guidelines or formulary status/restrictions. This growth trend may continue over time as knowledge spreads about the services offered and/or other hospitals join the health system. If growth continues, the UNCH DIC may need to consider increasing support staff in the future.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Evaluative Study

Session-Board Number: 5a-095

Poster Title: Analysis of electronic prescribing quality related-incidents: Look alike sound alike medications

Primary Author: Julie Sears, University of Cincinnati James L. Winkle College of Pharmacy, Ohio; **Email:** searsjl@mail.uc.edu

Additional Author (s):
Ana Hincapie
Ahmad Alamer
Semin Goins
Terri Warholak

Purpose: Electronic prescribing requires a set of standards to maintain consistency from the provider entry system to the desired pharmacy network. These guidelines commonly coexist with recommendations created by organizations to decrease the occurrence of errors and increase patient safety. The objectives of this study were to 1) identify error-prone medications for electronic prescribing; 2) compare current national and international guidelines for electronic display of medication information, and assess their scope in preventing look alike sound alike (LASA) errors in the electronic setting. By comparing the guidelines and recommendations, a comprehensive set of standards may be created to further reduce errors.

Methods: This was a retrospective cross-sectional analysis of e-prescribing quality related events reported to two national web-based error reporting systems. Reports from 2011 to 2015 were reviewed to identify incidents related to LASA medications. The compilation of LASA pairs was compared to the existing LASA list provided in the Institute for Safe Medication Practices (ISMP) guidelines for possible inclusion of commonly confused drug names. Guidelines that addressed the electronic display of medication information were searched in various databases of peer and non-peer reviewed literature. The information used for the comparison was directly extracted from the publications of these guidelines. The comparison focused on the content of the recommendations for patient information, pharmacy information, medication names, abbreviations, numbers/units of measure, and information display. The project was exempted from IRB approval.

Results: Of the 1,139 events reviewed for incidents related to e-prescribing, 177 events were identified to have occurred as a result of incorrect drug selection. There were 87 potential LASA drug pairs, and only six pairs were found to be currently in the ISMP LASA list. Four guidelines were found: 2 from the United States (Surescripts and ISMP), 1 from Australia, and 1 from the United Kingdom. The comparative analysis revealed similar recommendations for medication names with the exception of Surescripts and the ISMP, which include additional recommendations for utilizing the standardized medication names only and the inclusion of medications suffixes for the generic and brand name within the input field. All systems address the same concerns for standardization of approved abbreviations and formatting of numerical/units of measure. Similarities in recommendations include using approved numerical formatting, the elimination of trailing zeros, and the inclusion of leading zeros. The greatest amount of variance occurs within information display. All guidelines identify the importance of avoiding word truncation within fields, but Surescripts includes more descriptive recommendations for the e-prescription components. All guidelines acknowledge the importance of using national tall man lettering in medication names to reduce LASA errors with the exception of the Surescripts.

Conclusion: The combination of the recommendations from each system can create a more secure e-prescription and eliminate many of the preventable errors which are occurring during the electronic prescribing process. Utilization of tall man lettering and the addition of new pairings of LASA medications to the ISMP list would assist in safer medication practices. Electronic prescribing errors, which are commonly resolved prior to reaching the patient, increase overall costs to the providers and pharmacies and increase patient wait times due to the need for provider/pharmacist contact for prescription clarifications.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Descriptive Report

Session-Board Number: 5a-096

Poster Title: Standardization of a medication reconciliation workflow in an adherence packaging home delivery program

Primary Author: Cassandra Hacker, Ohio Northern University, Ohio; **Email:** c-hacker@onu.edu

Additional Author (s):
J. Deal
Thomas Achey

Purpose: The goal of adherence packaging is to improve health outcomes and safety by facilitating patients' abilities to take medications as prescribed. This is accomplished by removing the burden of procurement and organization of medications, as well as having the medications verified by a dispensing pharmacist. A vital component of the program is the initial phone interview and medication reconciliation. A standardized format for conducting a medication reconciliation ensures the most reliable information is gathered from the patient and/or their caregiver(s). Our purpose was to standardize the medication reconciliation phone interview process to facilitate a more streamlined workflow.

Methods: A standardized medication reconciliation phone interview was created as a document and incorporated into the Cleveland Clinic Health System electronic medical record (EMR) system in the format of a fill-in medication review. This was created separately from the current inpatient medication reconciliation form, as such tasks in the outpatient setting are completed over-the-phone with additional variables to be addressed (e.g. shipping information, source reliability, and barriers to adherence). Additionally, a training presentation was created for conducting a medication reconciliation phone interview and documenting such encounters within the EMR. The content is written at a level ideal for technical personnel, pharmacy students, and interns. A corresponding training checklist was created to verify competency prior to trainees completing patient interviews. Having a standardized medication reconciliation tool to use comprehensively across the home delivery program will help prevent respective errors including, but not limited to: patients not receiving necessary medications, adverse drug events, drug-drug interactions, duplications in therapy, and medication use without an indication. Many of these discrepancies occur at transitions in care; thus, the transition to the

adherence packaging program requires a standardized and efficient guide to obtain the most accurate information from the patient and/or caregiver(s) in the initial on-boarding encounter.

Results: The method for use in the day-to-day workflow is described below. A pharmacist or technician trained in the standardized phone interview method will obtain a list of patients to call to conduct initial medication reconciliations or follow-up calls for subsequent monthly shipments. The interviewer will preview the patient using the EMR to obtain necessary background information prior to conducting the call. With the currently documented information available within the EMR for comparison, the interviewer will use the medication review documentation within the EMR to guide the course of the interview, with prompts to fill in information from the patient and/or caregiver(s). Logistics information is collected at this time to allow for the first medication shipment. Upon completing the interview, any discrepancies will be reconciled with the respective prescribers in order to maximize patient adherence. The first medication shipment is sent and the patient will receive a follow-up call at day 21 in the fill cycle. At this point, an abbreviated medication reconciliation is completed to discuss any new medication changes or barriers to adherence. Discrepancies are again reconciled before the next medication shipment.

Conclusion: Standardization and incorporation of a medication reconciliation tool within an adherence packaging home delivery program provides a streamlined workflow and improved quality of patient care by ensuring access to the most up-to-date patient information.

Poster Title: Does inhibition of Cyclin Dependent Kinase 8 prevent resistance to trastuzumab in HER2 positive breast cancer?

Primary Author: Chuck Hennes, South Carolina College of Pharmacy, South Carolina; **Email:** chennes@email.sc.edu

Additional Author (s):
Martina McDermott
Eugenia Broude

Purpose: Resistance to targeted therapies is a significant problem for breast cancer and our lab recently showed that CDK8 is over expressed in breast cancer and associated with worse relapse free survival for breast cancer patients. Combination of CDK8 inhibitors with HER2 targeted therapies suggests that dual inhibition not only potentiates targeted therapies but can also slow the emergence of resistance to tyrosine kinase inhibitors such as Lapatinib. Here we tested a combination therapy of HER2 targeting monoclonal antibody, Trastuzumab (Herceptin), with a CDK8 inhibitor for overcoming resistance to Trastuzumab.

Methods: 14 T12.5 flasks were seeded with 150,000 SKBR3 cells and 14 T12.5 flasks of BT474 cells were seeded with 250k in each flask with a total of 3 ml of media per flask. We then split the flasks up into the following 4 groups: Control, Senexin B, Trastuzumab, and a combination of Trastuzumab + Senexin B. Drug-containing media was replenished every 3-4 days and cells were split when needed. The cells were treated twice a week until the control cells become confluent and there was an obvious treatment effect in the Trastuzumab alone group. At this point the first set of flasks were fixed and stained. This process was repeated for 3-months. At the end of the 3-month period the newly emerged "resistant" cells were allowed to grow in a P150 Petri dish to expand cell numbers for further testing whether inhibition of CDK8 prevents resistance to Trastuzumab. Once enough resistant cells were available they were seeded into 96-well plates for the MTT cell growth assays, a colorimetric assay for assessing cell growth, in duplicates to determine if they were resistant to either drug.

Results: The cells were treated for one week and were then stained with crystal violet. At approximately four weeks both Trastuzumab and SNXB caused a decrease in cell numbers. Similarly, the combination treatment had an even greater decrease in cell numbers than each of the monotherapies. Trastuzumab treated BT474 cells were actively growing and were less sensitive to Trastuzumab. Importantly, the BT474 cells did not grow under the combination treatment suggesting that the combination was very effective at preventing the emergence of resistance in these cells. However, in the SKBR3 cells despite an initial response to the combination treatment it was not effective at preventing the emergence of resistance and the cells grew back after approximately 5 weeks of treatment. This suggests that further study is required to determine whether this is a cell line specific effect.

Conclusion: Combination therapy of Senexin B and Trastuzumab showed a promising effect of prevention of resistance in the BT474 cells, but did not have the same effect in the SKBR3 breast cancer cells. This study suggests that further testing of the effects of Trastuzumab and Senexin B in HER2 positive breast cancer could yield promising results in the prevention of resistance.

Poster Title: Evaluating the impact of a pharmacist-run diabetes needs assessment service on inpatient diabetes education rates and hospital length of stay

Primary Author: Allyn Walkama, Northeast Ohio Medical University College of Pharmacy, Ohio; **Email:** awalkama@neomed.edu

Additional Author (s):
Laura Nice
John Moorman

Purpose: It is estimated that the overall length of stay is as high as 5 days for patients with diabetes and multiple co-morbid conditions. The Diabetes Management Team at Cleveland Clinic Akron General was established with the goal of decreasing the 30-day hospital readmission rate and hospital length of stay. We identified that diabetes education was occurring late in the hospital stay, which may have been resulting in increased length of stay. Our goal was to evaluate the impact of a diabetes needs assessment service on hospital length of stay for patients with diabetes.

Methods: The diabetes assessment service involves a PGY1 pharmacy resident who performs daily assessments on patients with diabetes who are admitted to the hospital. Patients with the following criteria were identified and assessed: on a medication for treatment of diabetes, admitted to hospital (OB/maternity areas), and either a hemoglobin A1c greater than 9 percent in past 10 days or a blood glucose greater than 300 mg/dL in the past 5 days. We completed a retrospective analysis of consecutive hospital admissions where criteria was met for screening between January 2015 and May 2016. Data collected included: admission date, discharge date, date patient assessed, inclusion and exclusion reason, date seen by education and/or endocrinology (and the date each was ordered), discharge disposition, and reason for hospital admission (ICD and DRG codes). The primary objective was to determine the impact of the service on hospital length of stay. We also intended to assess the reach of the service, the appropriateness of diabetes education referrals and the impact of the service on length of stay in the subgroup of patients discharged to home. Fisher's exact test was used to compare nominal data, and Student's t-test was used to compare continuous data.

Results: Between January 2015 and May 2016, there were a total of 2179 hospital admissions who met criteria for assessment. Of those, 1641 admissions were assessed by a pharmacy resident (75.2 percent reach). Patients met criteria for assessment within 1.67 days of admission, and were seen by a pharmacy resident within 0.5 days of being identified. Diabetes education was initiated by a pharmacy resident during 13.8 percent of the admissions where an assessment was performed. For admissions where a pharmacist did not assess the patient, diabetes education was ordered in 9.4 percent of the admissions (p-value for comparison equals 0.007). For all participants, there was a non-significant increase in length of stay for admissions where the patient was assessed by a pharmacy resident who ordered diabetes education as opposed to those not assessed (5.02 versus 4.78 days, respectively; p-value equals 0.619). However, for the subgroup of patients who were discharged home, there was a significant increase in length of stay for patients seen by a pharmacy resident who ordered diabetes education versus those not assessed (4.49 versus 3.41, respectively; p-value less than 0.001).

Conclusion: The diabetes assessment service assessed about 75 percent of patients identified, and did so early in the hospital stay (about 2 days after admission). We saw an increased length of stay in patients who had diabetes education ordered by the service if being discharged home. Diabetes education was provided within 3 days of admission, and many of the patients in the control group were missed due to being discharged early. Therefore, we feel that it is unlikely that the service itself increased length of stay, and may instead be related to other comorbidities.

Poster Title: Pharmacy Communication Barriers and Impact on Patient Health Outcomes, Medication Adherance, and Safety- A Review of the Literature

Primary Author: Sahiba Bedi, Roseman University of Health Sciences, Utah; **Email:** sbedi@student.roseman.edu

Additional Author (s):
John Tran
Taylor Allen
Nakisa Mirrafie
Erin Johanson

Purpose: The purpose of this study was to collect and analyze peer-reviewed journal articles related to the subject of communication barriers in the field of pharmacy, specifically identifying communication barriers between pharmacists and patients and their impact on patient care. The focus of the search was on the impact that pharmacists had on the overall health outcomes of patients, medication adherence, and safety.

Methods: A literature review was conducted using PudMed Database. Peer-reviewed articles that expanded over the past 20 years were identified using search terms "pharmacy + communication + barriers, adherence, education, counseling, language." Both national and international literature was reviewed. The data was analyzed to identify the barriers that limit thorough communication between patients and pharmacists, different tools that are used by pharmacy staff to meet the needs of patients with communication challenges, the negative impacts of the lack of communication between patients and pharmacists, as well their views on how to improve the communication in the field of pharmacy.

Results: Of the search completed, 26 total articles were chosen for relevance to the topic. 15 articles found the biggest hindrances to the communications between pharmacists and patients were "Language Barriers" and "Education." 10 articles suggested that "Cultural Differences" in regards to background and socioeconomical status as a contributing factor. The biggest negative impact found was that patients lack of knowledge in the side effects of medications, which lead to non-compliance and pharmacist workflow demands and time constraints.

Currently the most common tool used to address communication barriers in the pharmacy is using interpreter services. 6 articles suggested ideas on improving communications is to have on-going education for the patients over multiple visits to the pharmacy. 3 articles discussed implementing Spanish courses in the Doctor of Pharmacy curriculum to encourage graduating competent well diverse pharmacists.

Conclusion: Evaluating barriers in communication is very important to improving patient health outcomes. Better connection between pharmacists and patients can be made by providing interpreting services and material in different languages. Continuing patient education and follow up methods were also said to be a way to improve patient/pharmacist communication. Pharmacies and pharmacists being able to provide appropriate communication and education services to their patients is key to improving patient adherence and patient satisfaction overall. Future studies are planned to survey community pharmacists and preceptors to identify communication barriers and methods to address those with patients.

Poster Title: Retrospective review of prescribing practices seen in a pediatric cohort diagnosed with bronchiolitis

Primary Author: Angela Kaitschuck, The University College of Pharmacy, Arizona; **Email:** kaitschuck@pharmacy.arizona.edu

Additional Author (s):
Metrejean Christina
Kimberly Sassenrath
Rijan Shrestha
Kara Snyder

Purpose: The American Academy of Pediatrics (AAP) recommends that no medication and only supportive care supplemental oxygen be used in the treatment of bronchiolitis. This project was conducted to identify the frequencies of prescribed medications in the treatment of pediatric patients with bronchiolitis at Banner University Medical Center-Tucson (BUMC-T) and compare these prescribing practices to a national study.

Methods: The project was a retrospective chart review that analyzed all pediatric patients (ages 21 and under) in 2015 with the international classification of disease (ICD)-9 diagnosis codes for bronchiolitis (466.11 and 466.19) at BUMC-T. Exclusion criteria included patient readmissions within the study period for the same diagnosis, missing bronchiolitis diagnosis in the electronic health record (EHR), and patient unreconciled identities via EHR. Patient EHRs were reviewed and data were collected including: age of patient at admission, sex, length of stay, readmissions for same reason within 30 days, and medications given to patient. Respiratory medications given during the hospital stay were categorized into 4 classes: bronchodilators, steroids, oxygen, or none, and each category was further analyzed for specific type of mediation to determine the extent to which prescribers were authorizing medications against guidelines. All information was then compared to a national study that also analyzed prescribing practices against bronchiolitis guidelines.

Results: Out of the 163 patients analyzed in the study, 49.7 percent of patients were given a bronchodilator and/or a corticosteroid (against guidelines) versus 58 percent nationally. At BUMC-T, a total of 164 therapies were initiated against guidelines in 81 patients. The majority of medications given were bronchodilators (69.5 percent) with albuterol (43.3 percent) being prescribed the most. Corticosteroids were used in 12.2 percent of therapies (compared to national average of 16.3 percent) and hypertonic saline in 18.3 percent of therapies.

Conclusion: While BUMC-T physicians are prescribing less than the national average of 58 percent, 49.7 percent of the institute's pediatric patients with bronchiolitis were still prescribed medications against the guidelines. With current guidelines stating no medications should be given, improvement in BUMC-T's prescribing practices for pediatric patients diagnosed with bronchiolitis should be considered.

Poster Title: Investigation of factors associated with influenza vaccination uptake in rural Columbus County, NC

Primary Author: Amber Hooks, Campbell University College of Pharmacy and Health Sciences, North Carolina; **Email:** arhooks0402@email.campbell.edu

Additional Author (s):
Hillary Best
Ashley Rankin
Peter Ahiawodzi

Purpose: Influenza vaccines are either met with acceptance or rejection. Rural pharmacies are exposed to patients in both categories. It is important to find out who does not vaccinate based on demographics as well as reasons for not vaccinating. The purpose of this study was to find out which demographics are less likely to vaccinate in a rural healthcare setting, which can help rural pharmacists target methods and approaches to increase influenza vaccine uptake in these populations.

Methods: The study involves 100 patients, 18 years or older, who consented to and completed surveys that were distributed upon their visit to one of the three Walgreens Pharmacy locations in Columbus County, NC between June 1 and July 31, 2016. Information collected included age, sex, race, marital status, education, distance to doctor, distance to Walgreens, and their influenza vaccine uptake status within the past year. Logistic regression was used to analyze associations between the various factors and vaccine uptake in the past year. All analyses were performed using SPSS software, version 22 (IBM SPSS Statistics for Macintosh, Armonk, NY) at alpha level 0.05. This research project was approved by an institutional review board of Campbell University and Walgreens corporation.

Results: The results indicated that patients less than or equal to 35 years old and patients 36-50 years old are 2.07 and 2.52 times more likely, respectively, to not get vaccinated when compared with patients over age 50. Patients with a high school education or less were 1.87 times more likely to not get vaccinated compared to those with more than a high school education. We also found that males were 1.96 times more likely to not get vaccinated when

compared to women. The study also indicated that patients who live fifteen minutes or less from their doctor's office were 2.33 times more likely to get vaccinated compared to those patients with over a fifteen minute drive. Also, patients less than a five minute drive from Walgreens were 1.64 times more likely to get vaccinated compared to those patients who live over 15 minutes from a Walgreens.

Conclusion: In conclusion, patients younger than 50 years old, males, and those with education only up to high school level were less likely to vaccinate. It was also noted that nearness to a doctor's office or Walgreens Pharmacy had influence on patients' influenza vaccine uptake. This information is important to rural public health and pharmacy practice as it provides the necessary data of which populations should be targeted for education to increase influenza vaccine uptake.

Poster Title: Piloting Medication Histories in the C.S. Mott Children's Hospital Post-Anesthesia Care Unit (PACU)

Primary Author: Nathan Lake, University of Michigan, Michigan; **Email:** laken@med.umich.edu

Additional Author (s):
Humaira Nawer
Deborah Wagner
Elizabeth Lopes
Kristen Schaeffler

Purpose: Medication errors are the third leading cause of death in the US. Surgical patients are at high risk due to postoperative medications and unintended alteration of regular regimens. Many mistakes are preventable through medication history and reconciliation. Accurate medication history and reconciliation at all care transitions is part of the Joint Commission's patient safety goals, and studies demonstrate that histories performed by trained pharmacy personnel are more accurate than histories performed by other professionals. In this project, we aimed to develop an efficient process for performing histories on PACU patients for early identification of discrepancies between home and inpatient medications.

Methods: Medication history and reconciliation forms were designed based on literature review of validated forms used at other institutions. Patients were tracked using a PACU "Status Board" in the electronic medical record portal, MiChart. Included patients were inpatient or surgical admits with an age of greater than two and less than eighteen years of age. Excluded patients were patients who were admitted to an intensive care unit from the PACU, patients undergoing a cardiac procedures, and patients with surgery end times beyond 1500. Interviews were conducted with the patient's parent(s)/guardian(s) while the patient was in Phase 1 recovery, after Status Board indicated, "family paged." Parents/guardians were asked about their child's prescription medication history, over-the-counter medication use, as well as allergy information and adherence. Information that was collected from parents was compared to what was on the patient's electronic medical record. Once a discrepancy was identified, the results were recorded and documented as a pharmacy note in the patient's medical record. Inpatient pharmacists then had access to the note at the time of order verification and could

page doctors regarding discrepancies found. Data was collected regarding the interview types, patient age and surgery type, medication categories, and error classifications.

Results: Families and nursing were generally receptive to pharmacy presence within the PACU. Over the course of twenty-two days (ranging from June to July 2016), seventy-five medication histories were performed. This covered 44.6 percent of all eligible surgical cases within the project period. The average age of patients was 9.6 years and the average time per interview was 9.5 minutes. A total of seventy-four discrepancies were found. The most common type of discrepancy was omission of medications, with the most common medication categories with errors being vitamins/herbals/supplements, allergy medications, and gastrointestinal medications. Using the error classification system developed by the National Coordinating Council for Medication Error Reporting and Prevention (NCC MERP), the most common error category was category C, meaning and error occurred that reached the patient but did not cause harm.

Conclusion: The workflow designed in this pilot project was successful in assessing the frequency and type of discrepancies in medication lists in surgical patients when transitioning from the PACU to the general care unit. It was found that vitamins, herbals, and supplements had the most discrepancies. The most common type of discrepancy was omission of medications. This project paves the way for a permanent pharmacy presence within the PACU for performing and documenting medication histories.

Poster Title: Proton pump inhibitors' post marketing adverse reactions and possible link to Alzheimer's disease development

Primary Author: Tigran Makunts, University of California San Diego Skaggs School of Pharmacy and Pharmaceutical Sciences, California; **Email:** tmakunts@ucsd.edu

Additional Author (s):
Isaac Cohen
Rabia Atayee
Ruben Abagyan

Purpose: Proton pump inhibitors (PPIs) are the leading therapeutic agent for gastro-esophageal disease, dyspepsia, peptic ulcer, acid reflux and other upper gastrointestinal disorders. PPI use is positively associated with an increased risk of community-acquired pneumonia (CAP) and osteoporosis development both in men and women. PPI use came into question after recent studies found an association between PPI use and risk of Alzheimer's dementia in elderly patients. The goal of this study was to perform a deeper analysis of PPI post marketing patient data and look for possible links between PPI use and development of CAP, osteoporosis and dementia.

Methods: FAERS (FDA Adverse Event Reporting System) and AERS (Adverse Event Reporting System, pre-2012 version) databases from 2002 to 2016 were combined and matched by case numbers into a master file. Over 8.1 million unique records were compiled. UNIX tools were used to search and isolate reports with the patients on the drug of interest. There were 5403 reports where PPIs were the only class of medication used. Same method was performed for patients on histamine-2 receptor antagonists (H2RAs) for comparison cohort with same drug indication. There were 1494 reports where H2RAs were the only class of medication used. ADR frequencies over 1.5 percent were analyzed. Odds ratios, log odds ratios (LogOR) and 95 percent confidence intervals were calculated. LogOR was used when comparing PPI ADRs to H2RA ADRs. Frequency analysis was used to assess ADRs where Odds ratios analysis was not possible due to zero reports in H2RA cohort.

Results: Patients on FAERS who only took PPIs had significantly lower reports of urticaria (LogOR -0.58, LogOR error 0.15), dizziness (LogOR -0.34, LogOR error 0.16), and dyspnea (LogOR-0.76, LogOR error 0.13), when compared to patients who only took H2RAs. Patients on FAERS who only took PPIs had a significantly higher frequency of reports of anxiety (LogOR 1.27, LogOR error 0.42), acute renal failure (LogOR 1.36, LogOR error 0.42), tubulointerstitial nephritis (LogOR 1.04, LogOR error 0.33), and gastro-esophageal reflux disease (LogOR 0.96, LogOR error 0.21), when compared to patients who only took H2RAs. Hypomagnesemia (3.56 percent), hypocalcemia (2.37 percent), subacute cutaneous lupus (1.93 percent), hypokalemia (0.85 percent), skin exfoliation (0.79 percent), and cutaneous lupus (0.73 percent) were present only in the PPI ADR reports.

Conclusion: PPI patients had adverse reactions that were absent in the H2RA group. PPI patient reports had a high frequency of hypomagnesemia and hypocalcemia. Magnesium plasma and cerebra-spinal fluid levels are lowered in Alzheimer's and other neurodegenerative disease patients. Decrease in magnesium and calcium levels is a possible risk factor in dementia development. Lowered magnesium and calcium levels are a major risk factor for osteoporosis development. The appearance of lupus which is an autoimmune disorder can possibly be linked to CAP prevalence in PPI users. Impaired immunity makes patients susceptible to infection.

Submission Type: Evaluative Study

Session-Board Number: 5a-104

Poster Title: Retrospective analysis of postsurgical outcomes following infiltration with liposomal bupivacaine with or without bupivacaine HCl in patients undergoing unilateral total knee arthroplasty

Primary Author: Sara Catherine Pearson, University of Louisiana at Monroe School of Pharmacy, Louisiana; **Email:** pearsosc@warhawks.ulm.edu

Additional Author (s):
Drayton Daily
Mark Dodson
Adam Pate

Purpose: Methods for controlling post-surgical pain are mostly centered on opioid analgesics. These drugs, however, are associated with side effects such as nausea, vomiting, constipation and carry the risk for abuse and addiction. Liposomal bupivacaine is a non-opioid analgesic that provides analgesia at the surgical site for up to 72 hours after injection. The objectives of this retrospective study were to assess the postsurgical outcomes including length of stay, discharge disposition, and narcotic consumption in patients who underwent unilateral TKA and received general anesthesia, liposomal bupivacaine, or coadministration of liposomal bupivacaine with 0.5% bupivacaine HCl.

Methods: In this IRB approved retrospective study, data was collected on 348 unilateral TKA patients who were operated on by a single-surgeon at a single surgical site from January 2013 through July 2015. Anesthesia and nerve blocks were administered to each patient according to the attending anesthesiologist's clinical judgement. In addition to nerve blocks and anesthesia, patients either received an intraoperative injection of 20 ml of liposomal bupivacaine + 40 ml of normal or an intraoperative injection of 20 ml of liposomal bupivacaine + 30 ml of bupivacaine HCl + 40 ml of normal saline. Patients who underwent a TKA from January 2013-December 2013 did not receive any formulation of bupivacaine in addition to standard anesthesia and nerve blocks. Patients received any oral or IV pain medications deemed appropriate by the physician for controlling post-operative pain. Post-operative opioid use was recorded both as the number of pills and as morphine milligram equivalents (MME) dispensed to the patient within 90 days pre- and post-operatively. Data was collected from electronic medical records (EMR) and the

Louisiana Prescription Monitoring Program (LAPMP). This data was organized in an Excel spreadsheet on a password protected device and then analyzed for statistical significance.

Results: In 348 consecutive patients, the mean (SD) length of stay was 2.2 (0.9) days in the general anesthesia group, 1.8 (0.8) days in the liposomal bupivacaine group (P < 0.0001 vs the general anesthesia group), and 1.4 (0.7) days in the liposomal bupivacaine + 0.5% bupivacaine HCl group (P < 0.0001 vs each of the other treatment groups). It was found that there were no significant differences between groups in postsurgical narcotic consumption in patients who were not taking opioids before their surgery. However, in patients who were taking opioid painkillers within the 90 days leading up to surgery, it was shown that there was a significant reduction in number of narcotic pills dispensed to patients who received the combination of liposomal bupivacaine + bupivacaine HCl (p=0.038211). On average, patients in the liposomal bupivacaine + 0.5% bupivacaine HCl group had significantly fewer prescription fills, after the original post-operative prescription, compared with the liposomal bupivacaine group (1.3 [SD 1.2] vs 1.8 [SD 1.7]; P < 0.05) and the general anesthesia group (vs 2.2 [SD 1.8]; P < 0.001).

Conclusion: In this retrospective study, about twice as many patients who received liposomal bupivacaine combined with 0.5% bupivacaine HCl were discharged within 24 hours after surgery compared with the other two treatment groups, and earlier discharge was not associated with higher opioid use. Additionally, patients in this group who had been taking opioids within 90 days prior to surgery showed a reduction is post-operative opioid use. The use of liposomal bupivacaine in combination with 0.5% bupivacaine may decrease opioid consumption of unilateral total knee patients after surgery and could potentially decrease potential for opioid abuse.

Poster Title: Cure with ledipasvir/sofosbuvir for chronic hepatitis C virus in an individual with gastric bypass surgery

Primary Author: Sara Valanejad, Campbell University College of Pharmacy & Health Sciences, North Carolina; **Email:** smvalanejad0221@email.campbell.edu

Additional Author (s):
Steven Johnson
Amanda Teachey
Sarah Griffin

Purpose: The impact of gastric bypass on the pharmacokinetics of various medications has been reported, specifically, in regard to reduction in oral medication absorption. The duodenum is completely bypassed which decreases the effective surface area for drug absorption. In addition, gastric pH is increased in this patient population, which can affect the absorption of pH-dependent drugs such as ledipasvir. As seen in pharmacokinetic studies, gastric pH affects the absorption of ledipasvir. Therefore, proton pump inhibitor (PPI) use raises concern with concomitant administration of ledipasvir/sofosbuvir (LDV/SOF). Presently, no data exists for the treatment of chronic hepatitis C virus (HCV) with LDV/SOF in an individual with a history of gastric bypass surgery. We report a single case of a patient who was cured of chronic HCV with LDV/SOF after 8 weeks of treatment, who had a past medical history significant for gastric bypass. The patient underwent elective Roux-en-Y gastrojejunostomy bariatric surgery roughly 3 years prior to initiation of LDV/SOF treatment. Baseline workup of the patient included: HCV treatment-naïve, HCV RNA viral load of 438,890, HCV genotype 1a, and fibrosis score of F1 (by FibroScan) and F1-F2 (by FibroSure). Concomitant medications included none with significant drug-drug interactions, with the exception of pantoprazole. Pantoprazole low dose (20 mg daily) was only used alongside treatment with LDV/SOF during the final week of therapy due to worsening gastroesophageal reflux disease. Throughout treatment, the patient tolerated LDV/SOF well while only experiencing a minor headache. No missed doses were reported. Follow-up HCV RNA viral loads were undetectable at weeks 3 and 7 of treatment. Lastly, a viral load was collected 16 weeks after completing full treatment, indicating sustained virological response. Based on this individual case, LDV/SOF may be an option in the treatment of HCV in patients post-gastric bypass surgery, although further research is warranted.

Poster Title: Evaluating the need for antibiotic stewardship services on evening, night and weekend shifts in a large academic medical center.

Primary Author: Tracelyn Freeman, University of Michigan College of Pharmacy, Michigan; **Email:** tracelyn@med.umich.edu

Additional Author (s):
Gregory Eschenauer
Twisha Patel
Jerod Nagel

Purpose: IDSA stewardship guidelines recommend prospective audit with feedback as the cornerstone for promoting appropriate antibiotic utilization. However, many stewardship programs are not resourced to implement this strategy during evenings, nights and weekends, and there is minimal data evaluating the incidence of inappropriate antibiotic use during these off hours. The objective of this study is to determine whether antibiotic prescribing may be improved with expansion of stewardship services to such periods.

Methods: The University of Michigan Hospital (UMHS) mandates prior authorization of 16 restricted antibiotics prior to dispensing 7-days per week between the hours of 0700-2300 via an approval pager. A member of the stewardship team (pharmacist or physician) covers the pager Mon-Fri during the day (0700- 1530) and an ID fellow or non-stewardship ID physician covers the pager on evenings (1530- 2300) and weekends (0700- 2300 Sat-Sun). No approval is required during nights (2300- 0700). Additionally, a stewardship pharmacist reviews a list of all patients receiving restricted antibiotics Mon-Fri, but this service does not occur on weekends. This retrospective single center cohort study included orders for restricted antibiotics in adult patients in May 2016. Orders for restricted antifungals per UMHS transplant or hematology prophylaxis protocols were excluded. The incidence of initial appropriate antibiotic therapy was compared during the day to evening, night, and weekend shifts. Additionally, the time to discontinuation/de-escalation of inappropriate restricted antibiotic use was compared in the different time periods, as were the effects of the "blackout" periods on the efficacy of a 72-hour "timeout" period wherein appropriate empiric therapy is reviewed for potential de-escalation.

Results: A total of 118 patients received a restricted antibiotic; 91 were included in the analysis and 27 were excluded. The rate of initial appropriate prescribing was 75/91 (82.4%) for all patients. The rate of appropriate prescribing was numerically higher for orders placed on the day shift versus evening/night shifts (82.4% vs. 75%, p=0.164), as well as for weekday versus weekend orders (87.5% vs. 66.7%, p=0.170). All 16 inappropriate antibiotics were stopped (n=4) or de-escalated (n=11), and there was no significant difference in time to discontinuation or de-escalation for orders started on day versus evening/night shifts (62.4 vs. 67.4 hours, p=0.860) or weekday versus weekend orders (52.3 vs. 75.3hr, p=0.415).

Modifications were made for 23/75 (30.7%) patients receiving initial appropriate empiric antibiotic therapy; 10 antibiotic orders were discontinued and 13 were de-escalated. The mean time to modification was 57.2 hours. The time to modification was significantly quicker if the 72-hour timeout period occurred during the weekday versus weekend (41.4 vs. 132 hours, p=0.001).

Conclusion: The rate of initially appropriate antibiotic prescribing was numerically higher when a member of the stewardship team covered the pager compared to evening/night shifts when there was no coverage or an ID fellow or non-stewardship ID attending covered the pager. Additionally, the time to discontinuation or de-escalation of initially appropriate antibiotic therapy was significantly quicker if the 72-hour timeout review occurred during the week when the stewardship team pharmacist reviewed patients compared to the weekend when no stewardship services are offered. This evaluation suggests antibiotic prescribing may be improved with expansion of current stewardship services to off hours.

Poster Title: Developing a new tool to streamline the medication review process in fall assessment for community-dwelling older patients in Central Valley, California

Primary Author: Cuihong Leung, California Health Sciences University, California; **Email:** leung262@chsu.org

Additional Author (s):
Christopher Foley
Patty Havard
Taher Hegab
Peggy Trueblood

Purpose: Numerous medications may contribute to fall risk significantly in community-dwelling older patients. Medication review is an important component listed in the CDC's Algorithm for Fall Risk Assessment. The pharmacy students from California Health Science University (CHSU) have been collaborating with physical therapy, nursing and kinesiology students from California State University, Fresno through the Senior Awareness and Fall Education (SAFE) program since June of 2015. The goal of this project is to develop a new comprehensive approach to help guide pharmacy students with varying levels of drug knowledge to review patients' medication lists and assess patients' fall risks.

Methods: A comprehensive literature review was performed using PubMed. Articles included the American Geriatrics Society 2015 Updated Beers Criteria, START/STOPP criteria, Medication Interventions for Fall Prevention in the Older Adult by Cooper J. from JAPhA, Management of Falls in Older Persons: A Prescription for Prevention by Moncada L. from AAFP, etc. Major prescription medication classes were identified as "Fall Risk Increasing Drugs (FRIDs)" including antidiabetic agents, cardiovascular agents, benzodiazepines, hypnotics, antipsychotics, antidepressants, anticonvulsants, analgesics, anticholinergics, and antiemetics. An organizational tool (PDF document) was then created to categorize all the medications based on drug classes in tables. The tables included both generic and brand names of the medications, subclasses, fall-related side effects, suggested patient interview questions and patient education instructions. The pharmacy students used this tool during the Senior Awareness and Fall Education (SAFE) program to assess each patient's fall risk. Patient education materials

were then generated based on the patient's medication classes. All students involved in the SAFE screening events were asked to fill out a post-activity survey for quality assurance. The survey's data was used to analyze the effectiveness and efficiency of the new fall assessment approach.

Results: There was a total of nineteen students who participated in the SAFE screening in September 2016. Eighteen of the nineteen students completed the post-activity survey. There were five (27.78%) pharmacy-year-1 students, five (27.78%) pharmacy-year-2 students and eight (44.44%) pharmacy-year-3 students who attended the screening. Eight students (44.44%) were first-time participants while ten students (55.55%) participated in at least one other SAFE screening previously. Among the eighteen students, fourteen students (77.77%) ranked the SAFE screening FRIDs tables as "very helpful" or "extremely helpful" and four (22.22%) ranked the tool as "somewhat helpful". When the survey asked "how efficient using the SAFE screening FRIDs tables were in looking up patient's medications", eleven students (61.11%) ranked the tool as "very efficient" or "extremely efficient", five students (27.78%) ranked the tool as "somewhat efficient", and two students (11.11%) ranked the tool as "slightly efficient". When the survey asked "how useful the SAFE screening FRIDs tables were in generating patient-specific interview questions", fourteen students (77.78%) ranked the tool as "very useful" or "extremely useful", three students (16.67%) ranked the tool as "somewhat useful", and one student (5.56%) ranked the tool as "slightly useful". Other questions yielded similar results.

Conclusion: Medication review is an important component of fall risk assessment. Pharmacists play a key role in assessing community-dwelling older patients for fall risks. By using a search function on the downloaded PDF table, students can quickly identify FRIDs in patient's medications, pinpoint fall-related medication side effects, provide medication therapy modification recommendations to patient care providers, and convey the necessary patient education counseling points. Based on initial survey results, the tool that was designed and modified for SAFE screening appears to be efficient and useful in guiding the pharmacy students with varying levels of drug knowledge.

Poster Title: Evaluating the feasibility of maintaining a patient database for nine outpatient clinics

Primary Author: Rachel Lumish, University of Maryland School of Pharmacy, Maryland; **Email:** rachel.lumish@umaryland.edu

Additional Author (s):
Martin Bishop
Meghan Swarthout

Purpose: Pharmacists can improve chronic disease state management in the ambulatory care setting. Previous studies have measured pharmacist-led improvement in chronic disease control in individual clinics, but there is limited data on assessing ongoing clinical outcomes in multiple clinic sites. This project was designed to demonstrate the feasibility of creating and maintaining a database of patient outcomes in nine primary care clinics with an embedded pharmacist at a large academic health system.

Methods: To compile the patient database, reports were created in the electronic medical record (EMR) to extract patient demographic visit information for completed pharmacist appointments from July 2015 through June 2016. The patient level data in the report included medical record number (MRN), patient name, ZIP code, referral reason, payer (including ACO beneficiary status), and appointment diagnosis. The report also contained visit information, including visit date, clinic location, and pharmacist provider. Manual chart reviews were then performed for each patient to record markers of disease control, including blood pressure, hemoglobin A1c, and weight. The status of the patient was denoted as active, inactive, discharged, referred, or deceased.

Results: A total of 908 patients were seen by pharmacists at 1,847 visits during fiscal year 2016. Approximately 5 minutes was dedicated to each manual chart review over a period of 4 months.

Conclusion: Although examining outcomes data from nine outpatient clinics will provide valuable support for the role of pharmacists in chronic disease management, a more sustainable method of data collection is essential. This method of database compilation is limited by the extensive time required to maintain the dataset, making it unfeasible to collect data in real time. Automating the collection of visit data from the EMR would allow for continual assessment of disease control in pharmacist-managed patients. We are currently working with EMR programmers to develop an automated data extraction method for real time monitoring of clinic visits and patient outcomes.

Poster Title: Implementation of new student leadership positions to increase committee participation in an American Society of Health-system Pharmacists state affiliate

Primary Author: Kiri Golleher, Pacific University School of Pharmacy, Oregon; **Email:** goll5679@pacificu.edu

Additional Author (s):
Aron Beugli
Kristine Marcus
Ryan Gibbard

Purpose: Student involvement in professional pharmacy organizations is an important component of professional development. Motivation and awareness of opportunities in our state affiliate were limited at our School of Pharmacy. Student leadership recognized student-based gaps in representation and conveyance of information between the student chapter and state affiliate councils. Six new leadership positions were designed to address the need for sustainable student participation within key affiliate committees; expanded student representation at the state level; and creation of leadership opportunities external to the school. Secondary needs included increased communication between the student chapter and state-affiliate and opportunities to expand student body engagement.

Methods: A student holding the elected leadership position of the Oregon Society of Health-system Pharmacists (OSHP) Student Chapter President assessed current student participation in state affiliate committees. After identification of opportunity, student leadership drafted a proposal for the creation of six leadership positions on three major state affiliate committees. Job descriptions defining responsibilities, roles, terms of service, and reporting structure were drafted. The proposal was submitted to the organization faculty advisor, Assistant Dean of Student Affairs, and President of Oregon Society of Health-system Pharmacists. After receiving support, these positions were offered to the student body through an application and interview panel selection in the fall—three positions for second-year students and three positions for first-year students. Selected students were expected to attend monthly council meetings off campus and quarterly student organization meetings for a two-year staggered term. The current student chapter president was expected to initially communicate with the state affiliate

council chairs and attend the first monthly council meeting to facilitate introductions for each of the councils where students were seated. Student representatives were expected to record relevant information, seek opportunities for wider student involvement, and represent Pacific University School of Pharmacy Student Chapter interests. Additionally, these six positions were encouraged to volunteer and attend Oregon Society of Health-System Pharmacists conferences.

Results: Prior to implementation in August, one student participated at the Oregon Society of Health-system Pharmacists board meeting, and zero students participated in the three major councils—Educational Affairs, Organizational Affairs, and Professional Affairs. Five applications were received for the three second-year positions and seven applications were received for the first-year positions. After placement of students and conclusion of the school year in May, one student had continued to participate in the Oregon Society of Health-system Pharmacists board meeting, and six students participated in the three major councils. One student was additionally placed on the Industrial Relations sub-committee due to continued expressed interest in both leadership and professional service after the committee selection period was closed. Secondary measures of success included a threefold increase in the number of volunteer opportunities for the general student body at the Annual Seminar between 2015 and 2016. All new leaders attended monthly committee meetings when held, and were added to corresponding mailing lists. Information gathered was conveyed to student leadership at official quarterly meetings increasing the number of reports received from zero to twenty-one reports, not including unofficial conversations, emails, or impromptu student meetings.

Conclusion: By creating a leadership structure that encompassed both school leadership and connected external professional service, both areas of need were addressed. Overall student body awareness of health-system professional service increased and the six new leaders identified additional areas for students to volunteer which expanded student presence and engagement within the professional organization. Correlating information demonstrated greater student attendance at conferences hosted by the state affiliate compared to the year prior to implementation. Student participation was well received by the professional organization, formally acknowledged, and other state pharmacy school student chapters were requested to institute a similar structure.

Poster Title: Evaluating prevalence and types of clinical pharmacy interventions in an HIV ambulatory care setting

Primary Author: Austin Hinkel, University of Houston College of Pharmacy, Texas; **Email:** ajhinkel@uh.edu

Additional Author (s):
Shutian Ju
Rustin Crutchley
Alexa Vyain
Joseph Gathe

Purpose: Previous studies have shown positive treatment outcomes when including an HIV clinical pharmacist as an integral part of the interdisciplinary healthcare team in the care of HIV infected patients. This role is becoming more important with an aging HIV population impacted by an increased prevalence of both comorbidities and polypharmacy. The objective of this study is to evaluate the prevalence and types of interventions made by the HIV clinical pharmacy team in an ambulatory care setting.

Methods: This study received IRB approval from the University of Houston. Our retrospective cohort analysis included 435 HIV patients from Therapeutic Concepts who were seen by the pharmacy team (comprising students, residents and an HIV clinical pharmacist) from July 2014 to September 2015. For each patient encounter, the pharmacy team identified problems and documented associated interventions using a standardized problem and intervention checklist. Acceptability of all interventions by the physician and physician assistant from the pharmacy team was recorded. The clinical pharmacy intervention types were comprehensive including optimization of antiretroviral (ARV) therapy, adherence assessment, managing drug-drug interactions (DDIs), medication reconciliation, and treatment optimization of a diverse range of common comorbidities such as depression, diabetes, dyslipidemia and hypertension. Results of these study findings were evaluated using descriptive statistics.

Results: Among the 435 patients who were included in the analysis, a total of 1359 interventions were made, averaging 3.1 interventions per patient. As a whole, 1295/1359 (95.3%) interventions were accepted by the physician and physician assistant at Therapeutic Concepts. Among the 1295 interventions accepted, 167 (12.9%) were focused on optimization of ARV therapy, 131 (10.1%) on adherence counseling (i.e. suboptimal adherence noted during clinic encounter), 141 (10.9%) on management of clinically relevant DDIs also including drug-food, drug-disease and drug-herbal/over the counter (OTC) interactions, 386 (29.8%) on medication reconciliation, 21 (1.6%) on referrals, 29 (2.2%) addressing miscellaneous physician consultation and drug information requests, 188 (14.5%) addressing miscellaneous patient consultation and drug information requests, and 232 (17.9%) interventions on treatment optimization of various comorbidities. Among the interventions for comorbidities, the most representative interventions (>5%) were hypertension (15.1%), pain (11.2%), diabetes (10.8%), dyslipidemia (9.9%), miscellaneous infections excluding opportunistic infections (8.2%), and depression (6.7%).

Conclusion: Numerous interventions were executed by the pharmacy team. Most common interventions (>10%) made included optimization of ARV therapy, adherence counseling for non-adherent patients, management of DDIs, medication reconciliation, patient drug information requests, and optimization of different comorbidities. There was a high acceptability rate (>95%) by the physician and physician assistant regarding pharmacy interventions. This study suggests that the pharmacy team can play a critically important role in improving overall treatment outcomes for an aging HIV-infected population with multiple comorbidities and polypharmacy. Future follow-up studies are planned to evaluate the impact of pharmacy interventions on both HIV and comorbidity treatment outcomes.

Poster Title: Evaluation of the frequency of the determinates of HLA-B*15:02 in a Mexican population compared with a Caucasian population

Primary Author: Jasmine Bryant, Shenandoah University - Bernard J Dunn School of Pharmacy, Virginia; **Email:** jbryant13@su.edu

Additional Author (s):
Su Ngo
Robbie Kidd

Purpose: Carbamazepine has been associated with cutaneous adverse drug reactions such as Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN) in patients with the HLA-B*15:02 haplotype. HLA-B*1502 has been studied prominently in broad areas across Asia and has been found almost exclusively in the Han Chinese population. There is a lack of data on HLA-B*15:02 frequency in Hispanic populations within the United States. Due to the gap of clinical information regarding the proper evaluation of Hispanics in this regard, we cannot assume that the same association will not occur in this Hispanic population.

Methods: The Shenandoah University Institutional Review Board approved this cross-sectional study prior to its commencement. The Hispanic and Caucasian DNA samples came from existing databases. The DNA samples were analyzed for rs3909184 and rs2744682 on an Applied Biosystems Quantstudio 6 Flex with TaqMan Drug Metabolism Genotyping Assays under conditions specified by the manufacturer. Genotype and variant allele frequencies comparisons were done in SPSS v24 using Pearson Chi Square test and Fisher's exact test where appropriate. A $p < 0.05$ was considered to be statistically significant.

Results: A total of 188 Mexican and 179 Caucasian samples were analyzed. The frequency of the rs3909184 variant allele was 3.8% in the Mexican American samples and 5.2% in Caucasian samples (p=0.336). The rs3909184 genotype frequencies did not differ significantly (p=0.394). The frequency of the rs2844682 variant allele was 17.6% in the Mexican American samples and 13.2% in Caucasian samples (p=0.097). The rs2844682 genotype frequencies did not differ significantly either (p=0.111). Based on the combination of these two genetic variations, the

HLA*B 15:02 haplotype could be present in three (1.6%) Mexican American sample and one (0.006%) Caucasian sample, but this was not significantly different (p=0.328).

Conclusion: Based on results of this study, there were no significant differences in the frequency between the two genetic variations studied or the possible presence of the HLA*B 15:02 haplotype between Mexican American and Caucasians. Although there was a slight trend that the rs2844682 variant allele may occur at a higher frequency in the Mexican American population. A limitation of this study is that we could not determine if the genetic variations were in phase to confirm the presence or absence of the HLA*B 15:02 haplotype. Further evaluation needs to be performed with Sequence Specific Oligonucleotide Probe Hybridization Polymerase Chain Reaction.

Poster Title: Exploring potential predictors of intrinsic resistance to multi-targeted tyrosine kinase inhibitors in patients with solid tumors

Primary Author: Michael Carulli, University of South Florida College of Pharmacy, Florida; **Email:** mcarulli@health.usf.edu

Additional Author (s):
Christine Walko
Howard McLeod
Nancy Gillis

Purpose: Tyrosine kinase inhibitors (TKIs) are commonly prescribed antineoplastics used to treat a variety of cancer types. Unfortunately, approximately 15-25 percent of patients will not respond to treatment, which poses a significant burden considering the high potential for side effects and cost of these medications. This study explores the demographics and clinical factors of patients treated with multi-targeted TKIs in the context of whether they derived benefit or were resistant to treatment. We conducted a retrospective cohort study to investigate potential predictive factors of response in patients prescribed multi-targeted TKIs (i.e., axitinib, cabozantinib, pazopanib, regorafenib, sorafenib, sunitinib, or vandetanib).

Methods: Patients were identified from Moffitt Cancer Center's Total Cancer Care cohort with the inclusion criteria that they received a multi-targeted TKI and were diagnosed with a solid tumor. We performed chart reviews of electronic medical records to confirm diagnosis, TKI administration, and duration of treatment. Patient response to TKI was determined using imaging scans before TKI initiation and at first imaging follow-up, incorporating tumor size changes and radiologists' and oncologists' impressions to classify individuals as either a "responder" or "non-responder (resistant)". Patients with complete response, partial response, mixed response, or stable disease were classified as "responders", while patients who had progressive disease at first imaging follow-up were classified as "non-responders"; patients who discontinued treatment early due to side effects were excluded. Data was organized using Microsoft Excel, and demographic information, including age at diagnosis, sex, race, ethnicity, diagnosis, and multi-targeted TKI received was summarized. Each demographic and clinical category was evaluated to determine the rate of resistance based on the number of patients

who were non-responders divided by the total number of patients, in that category, who received the drug. We calculated the average, median, and range of treatment duration stratified by response, medication, and diagnosis. The primary objective of this study was to identify demographic or clinical variables that may be associated with resistance to multi-targeted TKIs.

Results: A total of 262 solid tumor patients who were prescribed multi-targeted TKIs were included in this study. The majority of patients were white (94 percent), non-Hispanic (92 percent), and the median age was 56 years old (range 21-88). The most common diagnosis in our cohort was renal cell carcinoma (RCC, 52 percent), followed by sarcoma (20 percent), and less than 10 percent for all other tumor types. Half of the patients received sunitinib, followed by sorafenib (28 percent). A total of 77 patients were excluded from further analyses due to unknown response. The overall resistance rate in our cohort was 21 percent, consistent with that observed in phase III clinical trials of these medications. Responders remained on treatment significantly longer than non-responders (median duration 11.0 mo vs. 3.6 mo, p less than 0.001). Patients aged 60-69 had a higher rate of resistance than expected (30 percent), as did patients who received pazopanib (35 percent). Tumor types with higher resistance rates than expected included melanoma (43 percent), pancreatic neuroendocrine (36 percent) and sarcoma (28 percent), among others. Overall, patients who received axitinib remained on therapy the longest (median 11.7 mo, range 9.6-20.7 mo).

Conclusion: Multi-targeted TKIs are highly effective therapies for a wide range of tumor types; however, according to phase III clinical trials, approximately 15-25 percent of patients do not respond. We conducted a retrospective cohort study to identify demographic and clinical factors that may be predictive of response to these agents. Results from our study suggest that demographic and clinical factors, including but not limited to, sex, age, and diagnosis, may influence likelihood of response to multi-targeted TKIs. Future studies will explore the utility of genetics to better predict resistance to these widely-prescribed medications.

Poster Title: Evaluating and reducing missing medication messages at a large community teaching hospital

Primary Author: Mallory O'Connor, The Ohio State University, Ohio; **Email:** oconnor.246@osu.edu

Additional Author (s):
Josh Soppe
Girish Dighe
Bob Hammond
Michael Bandy

Purpose: There is no doubt that advances in technology have made medication prescribing and verification easier and safer. Electronic health record (EHR) programs have more tools than ever that allow pharmacy, nursing, and physicians to communicate more easily. However, inefficient use of these tools can lead to a loss of productivity, operational failures, and patient safety issues. The objective of this study is to evaluate the incidence of missing medication messages and implement interventions that will reduce missing medications, and thus missing medication messages, within the institution.

Methods: An institutional review board exempt, descriptive, observational analysis was performed on all missing medication messages at Riverside Methodist Hospital (RMH). RMH has a hybrid model pharmacy (approximately 60:40) split between automatic dispensing cabinets and centralized dispensing. A new EHR with two-way electronic messaging capabilities was launched within the institution in May 2015. New reporting capabilities allowed for tracking of electronic message categorization, medication message description, message processing turnaround time, associated hospital unit, and overall content of the message. Measurable outcomes were dependent on proper medication message categorization which became a limitation. In September 2015, medication messages were categorized into the following groups: a) adjust time b) need new bag c) missing medication d) other. Many missing medication requests were for medications perceived to be missing (e.g. medication was delivered to wrong location so nurse could not administer it). Interventions were implemented to reduce these false requests. Pharmacy staff education was performed on five points

commonly identified to precipitate a missing medication request in order to prevent missing medications. The primary outcome measured was total missing medication messages over total medications dispensed in the hospital.

Results: Missing medication message counts decreased substantially. Immediately after EHR implementation, integrated two-way messaging allowed for communication of medication issues between nursing and pharmacy. Numerous types of messages were sent with no way of tracking them at first. With the eventual installation of message categories to the EHR, the messages of each type could accurately be tracked, allowing for data collection specifically on missing medication messages. Message tracking noted that particular medications experienced a high rate of missing medication messages. Pharmacy operations then relocated those particular medications from the central pharmacy to automated dispensing cabinets, which resulted in a 15.37% decrease in missing medication messages. Pharmacy operations noticed that some missing medication messages were sent as a result of pharmacy staff failing to place and locate medications per protocol. A department wide education session included guides and assessment on proper protocol which was followed by a 10.04% decrease in missing medication messages. Utilizing the features of EHR and performing operational adjustments have resulted in a decrease in the amount of missing medication messages.

Conclusion: Interventions made at RMH reduced the volume of missing medication messages sent to the pharmacy. Secondary to reducing the number of missing medication messages, these interventions also decreased the amount of missing or late medication administrations. Additionally, the interventions helped increase efficiency by decreasing the amount of time spent investigating and re-dispensing missing medications. Nursing is highly involved in medication administration operations. The next step is to intervene at the nursing level to improve medication delivery to patients.

Poster Title: Effect of contaminated blood culture results on antimicrobial therapy in hospital setting

Primary Author: Nga Nguyen, University of Maryland Eastern Shore, School of Pharmacy and Health Professions, Maryland; **Email:** nhnguyen@umes.edu

Additional Author (s):
Julia Brocato
Michael Miller

Purpose: In the emergency department at Peninsula Regional Medical Center (PRMC) blood cultures are drawn by technicians rather than nurses or phlebotomists, resulting in an increase in contaminated samples. Contaminated cultures may result in therapeutic decisions that are not optimal for the patients. This may prolong the hospital stay, increase antibiotic use and resistance, and lead to possible adverse reactions and increased health care costs. The purpose of this study is to evaluate how false positive blood culture results affect antibiotic selection and the impact on length of hospital stay. The study will also investigate prescriber specialties in selecting antimicrobial therapy.

Methods: This retrospective study was conducted at PRMC in Salisbury, Maryland and was approved by the institutional review board. A list of patients with contaminated blood cultures was obtained from the microbiology department. The blood samples were drawn in the emergency department between July 2015 and July 2016. Blood cultures were considered contaminated if they grew coagulase-negative staphylococci, Corynebacterium species, Bacillus species other than Bacillus anthracis, Propionibacterium acnes, Micrococcus species, viridans group streptococci, enterococci, and Clostridium perfringens. Patients were excluded if they had clinical signs of bacteremia (prolonged temperature above 38 degrees Celsius, hypotension with systolic blood pressure less than 90mmHg, leukocytosis or neutropenia with a left shift differential, or disseminated intravascular coagulopathy) plus one of the following: long term IV catheter, immunocompromised with a central line, peritoneal dialysis, hemodialysis, or extensive postsurgical infection with coagulase-negative staphylococci. Also, patients were not included if they were not admitted to the hospital or if they were started on antibiotics deemed consistent with diagnosis on admission. Patient charts were reviewed to determine

appropriateness of antibiotic therapy using current therapy guidelines. Duration of hospital stay was recorded for patients receiving inappropriate treatment and compared to a control group. The control group was chosen randomly and consisted of patients with similar diagnoses over the same time period with double negative blood cultures. Chi-squared test was performed for nominal data.

Results: The total number of cases with contaminated blood cultures was 172 initially, but 127 cases were excluded by the criteria and appropriate therapy. The number of patients included in the analysis was 90 with 45 patients in the inappropriate treatment group and 45 patients in the control group. The average age of the inappropriate treatment group was 69 years, and 60 percent were male. For the control group, the average age was 70 years, and 53 percent of patients were male. There was a statistically significant difference between the length of hospital stay for patients with false positive blood cultures and those with true negative blood cultures (p equals 0.0114). The range for length of hospital stay in the inappropriate treatment group was 39 to 571 hours, compared 17 to 376 hours in the control group. The average length of stay between the two groups were 149 hours and 94 hours, respectively. Among the 23 prescribers that selected antibiotics for false positive blood cultures, 57 percent were hospitalists, 22 percent were internists, 9 percent were physician assistants, and 4 percent for each were specialists in family medicine, pulmonary medicine, and geriatric-internal medicine.

Conclusion: Contaminants in blood cultures can cause unnecessary antibiotic treatment and prolong hospital stays. Therefore, it is important to identify the common pathogens that mostly cause contaminants in blood culture to select the appropriate therapy and avoid other costs.

Poster Title: Comparative Pharmacodynamics of Imipenem and Imipenem-Relebactam Against Wild-type and Resistant Populations of P. aeruginosa and Non-Proteeae Enterobacteriaceae

Primary Author: Joshua Knight, South Carolina College of Pharmacy - MUSC campus, South Carolina; **Email:** knightjo@musc.edu

Additional Author (s):
Roger White

Purpose: A beta-lactamase inhibitor combination, imipenem (IMI)/relebactam (REL), is currently in Phase 3 (P3) clinical trials. Monte Carlo analysis (MCA) was used to assess the potential impact of imipenem (IMI)/relebactam (REL) compared to IMI alone against wild-type (WT) and imipenem-resistant (R) P. aeruginosa (PA) and non-proteeae Enterobacteriaceae (NPE).

Methods: Single-compartment pharmacokinetic parameters, current MIC distributions, and clinical pharmacodynamics (PD) targets from peer-reviewed literature were used to perform a 10,000 subject Monte Carlo simulation. A range of CrCl distributions from our institution, ranging from 10-120ml/min, were used to simulate individual clearances. The pharmacodynamic goals analyzed were 20%, 40%, and 60% free time above the MIC. The initial dose used for both IMI and IMI-REL was 500mg q6h. The analysis assed two methods of dealing with decreased renal function: the current package IMI insert renal adjustment guidelines and the P3 dosing for IMI-REL recommended by Merck. The effects of two volumes of distribution (0.24L/kg to represent healthy volunteers and 0.31L/kg to represent critically ill patients) and the effect of infusion time (0.5 hours or 3 hours) were also examined. The above parameters were used to perform MCA on wild-type and resistant subpopulations of Pseudomonas aeruginosa and non-proteeae Enterobacteriaceae.

Results: Target attainment (TA%) was ≥90% for IMI-REL for all PD targets and organisms except for T>MIC ≥60% for resistant Pseudomonas aeruginosa (81 to 89%). With IMI, TA% was ≥90% only for wild type Non-proteeae Enterobacteriaceae at all targets. TA% for IMI-REL was 35-50% greater than that of IMI alone. TA% was similar for normal and critically ill patient volumes (≤11% difference). Differences in TA% due to the length of the infusion were minimal; however,

with resistant populations, TA% was often slightly higher with the 0.5 hr. infusion at T>MIC≥20% and slightly lower at T>MIC≥60%. TA% for IMI was slightly higher with P3 IMI/REL dosing.

Conclusion: The addition of relebactam restored imipenem's activity against the resistant organisms evaluated. Imipenem alone still has sufficient activity against non-proteeae Enterobacteriaceae, but appeared ineffective against the other organisms studied. Given imipenem's short half-life and short dosing interval, the effects of increased patient volume had a negligible effect on target attainment. However, the proposed phase 3 dosing for IMI-REL appears superior to the current imipenem package insert adjustment for renal dysfunction as it improved target attainment at all PD targets.

Poster Title: Medication use evaluation: Identifying older adults on antidepressant therapy and the incidence of hyponatremia.

Primary Author: Emily Gray, Pacific University School of Pharmacy, Oregon; **Email:** gray8798@pacificu.edu

Additional Author (s):
Bridget Bradley
Brandon Nuziale
Danielle Backus

Purpose: The 2015 American Geriatrics Society Beers Criteria contains a list of potentially inappropriate medications (PIM) that pose an added health risk to older adults. Included in this list are the following antidepressants; selective serotonin reuptake inhibitors (SSRIs), serotonin-norepinephrine reuptake inhibitors (SNRIs), and bupropion. One of the reasons they are on the Beers Criteria is because they may cause or exacerbate the syndrome of inappropriate antidiuretic hormone secretion (SIADH) or hyponatremia. This retrospective study identified patients on these therapies and determined incidence of hyponatremia with the goal of optimizing safe antidepressant prescribing within our clinic.

Methods: The institutional review board approved this retrospective medication use evaluation. Patients were identified within the electronic medical record (EMR) if they were greater than or equal to 65 years of age and taking an SSRI, SNRI, or bupropion. The population included in this evaluation included patients at least 65 years of age who were prescribed SSRI/SNRI, or bupropion therapy for at least 6 months. Additionally they must have had sodium levels drawn prior to therapy initiation and at any point after therapy initiation. The following data was collected from patient chart review: patient's date of birth, primary care physicians, antidepressant and dose of current antidepressant, dates of antidepressant use, and sodium levels. Age at pre-sodium draw and average post-sodium levels were calculated. Patients whose sodium levels were shown to be less than 135mg/dL were further evaluated for concurrent disease states or medications which may contribute to hyponatremia.

Results: Based on preliminary data collection, 103 patients were identified as at least 65 years of age and prescribed the aforementioned antidepressants. Of those, 46 patients fit the inclusion criteria and were evaluated for incidence of hyponatremia. Of the identified 46 patients, three patients were found to have average post- therapy sodium levels below 135mg/dL. Of the three hyponatremic patients, one was noted to have documented history of hyponatremic lab values before initiation of SSRI therapy. Medications prescribed for these patients include bupropion, fluoxetine, and citalopram.

Conclusion: Preliminary results showed a prevalence of hyponatremia of 6.5% in the study population. These results may indicate a place for improved provider education on the dangers of antidepressant use in the presence of hyponatremia. After further evaluation, there may also be opportunity to create a clinic specific protocol outlining appropriate monitoring for geriatric patients on those antidepressants and recommendations if hyponatremia is noted. All but one patient in the 103 screened patients had appropriate monitoring of sodium levels. There was also no documented antidepressant medication changes based on abnormal sodium readings.

Poster Title: Utilization of a CYP2C19 genotype-guided antiplatelet treatment algorithm over time in patients undergoing percutaneous coronary intervention

Primary Author: Alexandra Cervantes, University of North Carolina Eshelman School of Pharmacy, Chapel Hill, North Carolina; **Email:** aebarber@email.unc.edu

Additional Author (s):
Vindhya Sriramoju
Nicholas Varunock
George Stouffer
Craig Lee

Purpose: Dual anti-platelet therapy (DAPT) with aspirin and a P2Y12 inhibitor is the standard of care for patients undergoing percutaneous coronary intervention (PCI). Clopidogrel, a prodrug, requires CYP2C19 metabolism to form its active metabolite. Individuals that carry one or two CYP2C19 loss-of-function (LOF) alleles are at increased risk for adverse cardiovascular outcomes. To circumvent this risk, our institution implemented an algorithm that optimizes DAPT by integrating CYP2C19 genotype and clinical factors to guide P2Y12 inhibitor selection in high-risk patients undergoing PCI. In this study, we evaluated use of the treatment algorithm over 18 months following implementation in a real-world clinical practice.

Methods: This single-center, retrospective cohort study included all 903 patients receiving PCI with coronary stent placement between July 2012 and December 2013. Patient demographics, PCI indication, CYP2C19 genotype, cardiovascular history, antiplatelet therapy, and anticoagulant therapy were obtained from the electronic medical record at index PCI. To observe initial P2Y12 inhibitor selection and changes in treatment, antiplatelet therapy was recorded at admission, discharge, and three follow-up visits up to one year after coronary stent placement. Final maintenance therapy was defined as the P2Y12 inhibitor prescribed to the patient after index PCI and CYP2C19 genotyping at the last follow-up visit. Evaluation of algorithm sustainability in clinical practice was guided by assessment of genotype availability at the time of the index PCI and final P2Y12 inhibitor maintenance therapy selection in CYP2C19 LOF allele carriers. Temporal trends in algorithm utilization were evaluated using descriptive

statistics to compare completion of genotype testing (yes versus no), final maintenance P2Y12 inhibitor therapy (clopidogrel versus either prasugrel or ticagrelor), and changes in anti-platelet therapy from clopidogrel to prasugrel/ticagrelor in LOF carriers (yes versus no) over time. Comparisons of these endpoints were made across three 6-month intervals of time (July-Dec 2012, Jan-Jun 2013, July-Dec 2013) by chi-square. A P-value less than 0.05 was considered statistically significant.

Results: The study population were on average 63 years old, 66.2 percent male, 20.5 percent African American, and 49.6 percent presented for PCI with an acute coronary syndrome. Clopidogrel was more commonly selected as the final maintenance therapy (71.1 percent) compared to prasugrel/ticagrelor (29.9%). A CYP2C19 genotype was obtained in 636 (70.4 percent) patients; of these, 191 (30 percent) carried 1 or 2 LOF alleles. Prasugrel/ticagrelor was prescribed in 136 of 191 (71.2 percent) LOF carriers, and 101 of 445 (22.7 percent) patients without a LOF allele. CYP2C19 genotyping testing frequency at the time of index PCI significantly declined over time from 80.6 percent (Jul-Dec 2012) to 54.9 percent (Jan-Jun 2013) and 56.4 percent (Jul-Dec 2013) (P less than 0.001). There was also a significant decrease in use of prasugrel/ticagrelor as the final maintenance therapy in LOF carriers (83.1 to 76.4 to 53.8 percent, respectively, P less than 0.001), which was accompanied by less frequent switching from clopidogrel to prasugrel/ticagrelor in LOF carriers over time (P equals 0.025). No significant difference in use of prasugrel/ticagrelor as the final maintenance therapy was observed over time in those without a LOF allele (21.3 to 19.9 to 27.4 percent, respectively, P equals 0.289).

Conclusion: Overall, CYP2C19 genotype testing frequency in patients undergoing PCI and conversion to prasugrel/ticagrelor in LOF carriers was high over 18 months following implementation a genotype-guided treatment algorithm. However, sustained use of the algorithm in practice appeared to decrease over time, as indicated by a decrease in CYP2C19 genotype testing frequency and a decrease in prasugrel/ticagrelor use in LOF carriers. These results suggest that P2Y12 inhibitor selection is complex in real-world clinical practice and influenced by multiple factors. Ongoing analyses seek to identify predictors of genotype testing and therapy selection in order to better characterize obstacles that influence algorithm sustainability.

Poster Title: Comparing weight perception and actual weight in pharmacy students throughout their didactic pharmacy school career

Primary Author: Kelsey Dearman, University of Louisiana at Monroe School of Pharmacy, Louisiana; **Email:** dearmakm@warhawks.ulm.edu

Additional Author (s):
Stephanie Barre
Maddie Kirkwood
Adam Pate

Purpose: As of 2016, Louisiana is at the forefront of the obesity epidemic, with the highest adult obesity rate at 36.2%. High obesity rates may skew individuals' perceptions of what a "normal weight" is. As the most accessible healthcare providers, pharmacists have the opportunity to educate and motivate patients regarding their weight and health. Currently most pharmacy graduates are likely unprepared to fulfill this role. The purpose of this study was to evaluate pharmacy students' perception of weight, intentions regarding weight, and overall health as they progressed through pharmacy school.

Methods: Consenting class of 2016 students completed an Institutional Review Board approved health and wellness survey during the fall semester of the first (P1), second (P2), and third (P3) professional years. Out of seventy-three students surveyed in the first year, fifty-eight students (79% response rate) completed the survey all three years. Students were asked to describe their current weight (underweight, normal, overweight, and obese), define their intentions regarding weight, and describe their current health as poor, intermediate, or ideal in addition to recording actual weight and height.

Results: Fifty-eight pharmacy students completed the survey throughout their didactic pharmacy education. There was a statistically positive change (p=0.03), using repeated measures analysis of variance, in description of current weight. Intentions regarding weight, body mass index (BMI), and perception of overall health status as these students progressed through pharmacy school did not change significantly (p>0.05). In their first year of pharmacy school, the majority (50%-75%) of students in each BMI classification of underweight, normal,

overweight, and obese believed their current weight was "normal". In contrast, during their second and third years, these students' perceptions of their weight more accurately reflected their true BMI classification (p=0.03). With respect to intentions regarding weight, half of underweight first year students wanted to lose weight, as compared to underweight students in their second and third year who reported wanting to gain weight. Of first year overweight and obese students, 35% and 50% respectively, perceived their overall health status to be ideal. This percentage decreased among these particular students during their second and third year of pharmacy school.

Conclusion: The pharmacy school curriculum may play a positive role in shaping pharmacy students' perceptions of weight, intentions regarding weight, and overall health status. Although there was a significant change in pharmacy students' ability to perceive weight, this study identifies that there is a need to better equip students to modify their own weight and lifestyle. By incorporating this into the curriculum, students may be better prepared to influence positive weight change in their patients and enhance patient education and outcomes.

Poster Title: Oritavancin for the treatment of recurrent cellulitis

Primary Author: Laura Higgins, Rutgers, The State University of New Jersey

Ernest Mario School of Pharmacy, New Jersey; **Email:** laura.higgins118@gmail.com

Additional Author (s):
Shreya Joshi
Michelina Hesse
Shimeng Liu
Joseph Reilly

Purpose: Oritavancin is a lipoglycopeptide antibiotic used for the treatment of acute bacterial skin and skin structure infections (ABSSSIs) caused by gram-positive microorganisms. In clinical trials, oritavancin was shown to be non-inferior to vancomycin in treating ABSSSIs. Due to its long half-life, oritavancin can be administered as a single intravenous (IV) infusion in the emergency department (ED) or an outpatient setting. This single-dose therapy can be utilized to prevent hospital admissions or expedite early discharges in select patients. However, healthcare institutions may be hesitant to use oritavancin seeing its high drug acquisition cost and not consider its impact on the overall healthcare costs. This case illustrates the clinical and economic benefits of using oritavancin in a patient with recurrent cellulitis. A 33 years old, homeless female with a history of IV drug abuse (IVDA) presented to the ED with cellulitis of her left arm. The patient had presented to our institution with ABSSSIs in the past, which included 4 ED visits and 2 admissions involving 11 hospitalized days over the last 13 months. Her last ED encounter was for the same cellulitis on her left arm one month prior to this presentation. She was admittedly noncompliant with oral antibiotics and had left a previous hospital admission against medical advice without completing her full course of IV vancomycin. Prior antibiotics given for cellulitis included cephalexin, clindamycin, doxycycline, sulfamethoxazole-trimethoprim, cefazolin, and IV vancomycin.
On presentation in the ED, the patient had a fever of 100.1 degrees Fahrenheit, but was hemodynamically stable and her laboratory values were unremarkable. No cultures were obtained and she was not deemed a candidate for oral antibiotics due to noncompliance and social issues. The patient was given a 1,200 mg dose of oritavancin for this cellulitis episode and discharged from the ED without hospital admission. Other antibiotics she received during this

visit included one dose of oral azithromycin and one dose of intramuscular ceftriaxone for suspected pelvic inflammatory disease. There were no documented adverse reactions to oritavancin. After the treatment with oritavancin, the patient did not present to our institution for 7 months. She later presented to the ED for cellulitis of a lower extremity and her previous left arm infection had resolved. A financial analysis for this patient with Medicaid insurance revealed significant losses for her diagnosis related group (DRG) 603. The cost for 11 days of hospital stay at our institution, not inclusive of any other costs, exceeds 24,000 dollars. A total of only 9,914 dollars were received as payment for her DRG including the five separate instances when she presented to our hospital with cellulitis. The overall hospital charges for this patient exceeded 100,000 dollars prior to oritavancin administration. This case demonstrates that oritavancin can be an effective and financially beneficial treatment option for ABSSSIs in select patients by decreasing the long-term healthcare costs associated with preventable hospital admissions and readmissions. Further studies are needed to evaluate the full financial benefit of using oritavancin exploring drug reimbursement and potential cost avoidance.

Poster Title: Pharmacist impact on medication use and prevention of adverse events in patients enrolled in home-based primary care in the El Paso Veterans Affairs healthcare system

Primary Author: Sedona Mann, University of Arizona College of Pharmacy, Arizona; **Email:** mann@pharmacy.arizona.edu

Additional Author (s):
Michelle Topping
Amista Salcido

Purpose: Pharmacists are an under-represented discipline in the Home Based Primary Care (HBPC) team when conducting home visits with patients. Traditionally, medication changes were determined solely through the online electronic visit conducted by the pharmacist. This study looks at the impact of the Veterans Affairs Clinical Pharmacy Specialist (CPS), who has prescribing authority and monitors medication use. The pharmacist conducts an online electronic (e-visit) on all newly enrolled patients in the El Paso, TX area and then follows up with a visit in the patient's home. In the patient's home, the pharmacist directly reviews and reconciles prescription and over-the-counter medication use.

Methods: This study used a visit checklist created by the clinical pharmacy specialist for consistency in reporting all possible interventions. Some of the items included reviewing the patient's active problems, drug allergies, medications (including medical supplies), refills, fill history, medication expirations, vitals, assessment/plan which includes any added, deleted, held, or changed medications. The initial checklist reviewed patient's age, sex, race/ethnicity, number of medications, number of disease states, reason for visit, and intervention that was needed during the visit. Interventions included discontinuing medications, medications not on the patient's medication list, over-the-counter medications, expired medications, how the patient is taking his/her medications, how he/she actually takes it, and how he/she organizes their medications. All demographic information was collected for each patient and recorded in their visit checklist. A two-tailed t-test was conducted on the electronic event and home visit interventions. A one-sample t-test was conducted on the home visit data to determine significance in the increase of total interventions conducted, when the home visit was added to

the electronic visit. A P-value was set to 0.05, and a Bonferroni Correction was used to correct for the multiple comparisons of the post hoc tests.

Results: A total of 222 interventions were completed during the electronic visit for the 29 patients and an additional 346 interventions were completed during the home-visits. All patients received an electronic visit followed by a home visit. Medication problems found could have resulted in an adverse event or hospitalization. The home visit was significant for added intervention (mean of 3.5862 [SD plus or minus 2.810], P less than 0.00001) compared to the electronic visit (mean of 0.6897 [SD plus or minus 0.660], P less than 0.00001). The deleted intervention was significant for the home visit (mean of 1.5517 [SD plus or minus 3.356], P less than 0.0007) compared to the electronic visit (mean of 1.5517 [SD plus or minus 1.682], P less than 0.0007). The electronic visit was significant in the other category (mean of 1.03 [SD plus or minus 0.186], P less than 0.00001) compared to home visit (mean of 0.1034 [SD plus or minus 0.310], P less than 0.00001). Overall, the home visit was significant (mean of 11.9310 [SD plus or minus 4.847], P less than 0.0001) over the electronic visit (mean of 7.6552 [SD plus or minus 3.384], P less than 0.001).

Conclusion: Prior to this project, evidence showing the importance of the clinical pharmacy specialist making home visits was undocumented. During home visits, the pharmacist found many interventions that were missed in the electronic visit. For example, deleting duplicate medications not identified during the electronic visit or adding (non-Veterans Affairs prescribed) medications the patient was taking but not listed on their medication list. The results show that the representation of clinical pharmacy specialist in the interdisciplinary team is beneficial to the patient's health, with an increase in: added, changed, and deleted interventions with home visits versus electronic visits.

Poster Title: Quality improvement of diabetic care of adult and pediatric patients on insulin pumps at a tertiary care center

Primary Author: Jared Tate, University of Arizona College of Pharmacy, Arizona; **Email:** tate@pharmacy.arizona.edu

Additional Author (s):
Kendall Day
Nathaniel Oman
Marie Maloney

Purpose: Current literature suggests that the most common errors in diabetic care in a hospital setting include: patients receiving the wrong insulin; receiving the wrong dose; receiving insulin at the incorrect time; and inadequate carbohydrate adjustment. At a local tertiary care center, differences exist between insulin protocols in the pediatric and adult units for pump-using insulin-dependent diabetics. This was identified as an area of interest for improving medication safety and appropriate use of a high-risk medication like insulin. The purpose of this project was to assess protocol adherence and compare quality of diabetic care in the adult and pediatric units.

Methods: Data were retrospectively collected for 50 patients (25 adult and 25 pediatric) admitted to the hospital between January 1, 2014 and January 1, 2016. Patients were identified by an order for rapid acting insulin (lispro, aspart, or glulisine). Information collected from the patients' electronic health record included both biometric markers and protocol adherence by providers. Biometric information collected included: initial blood glucose reading and average blood glucose in the first 24 hours, blood glucose readings for the remainder of their hospital stay, and incidence of hypoglycemia (defined as a single blood sugar reading of less than 70mg/dL). Information collected to assess adherence to hospital protocol included: documentation of site assessment, orders and documentation for correction ratios, basal rates, and carbohydrate adjustment. If the patient was admitted for either hyperglycemia or diabetic ketoacidosis, data collection started once the patient was taken off IV insulin and began using pump. When appropriate, data between adult and pediatric units was compared using a Student's t-test.

Results: Site assessment was documented for 14 patients in the pediatric unit versus 2 patients in the adult unit. In the pediatric unit, appropriate ordering of basal rates, correction dosing, and nutritional dosing took place in 100%, 100%, and 96% of cases respectively and was appropriately documented in 100%, 96%, and 96% of cases respectively. In the adult unit, appropriate ordering of basal rates, correction dosing, and nutritional dosing took place in 76%, 64%, and 52% of cases respectively and was appropriately documented in 72%, 56%, and 24% of cases respectively. A total of 14 hypoglycemic events were documented among 7 adult patients and a total of 9 hypoglycemic events were documented among 6 pediatric patients. The average blood glucose reading for the entire length of stay was 185.1 mg/dL (standard deviation equals 50.6) for the adult unit and 183.5 mg/dL (standard deviation equals 56.4) (p equals 0.457) for the pediatric unit.

Conclusion: Adherence to hospital protocol in documenting site assessment is higher in the pediatric unit than the adult unit. Numbers of appropriate orders and documentations for basal rates, correction doses, and carbohydrate adjustment were higher in the pediatric setting than the adult setting. Numbers of patients experiencing hypoglycemia were similar between the adult and pediatric units, but numbers of individual incidents of hypoglycemia were higher in the adult unit. There was no significant difference between the adult and pediatric units for average blood glucose during the entire length of stay, within the first 24 hours, or after the first 24 hours.

Poster Title: Tolerance of intravenous iron dextran at a single academic facility

Primary Author: Emily Shor, St. Louis College of Pharmacy, Missouri; **Email:** emily.shor@stlcop.edu

Additional Author (s):
Alyssa Thompson
Eli Deal
Nathan Martin

Purpose: Intravenous low-molecular weight iron dextran is indicated for patients with iron deficiency who are unable to take oral iron or experience insufficient efficacy with oral replacement. Adverse effects have been reported, including anaphylaxis and death. Much of the reported clinical experience with this product is derived from use in patients undergoing dialysis. The primary purpose of this study was to determine the proportion of patients experiencing adverse reactions in a wide range of patients and to categorize the types of reactions experienced. The second purpose was to provide insight into the potential factors that contribute to reactions to iron dextran.

Methods: This is a retrospective study evaluating patients receiving intravenous iron dextran hospitalized at a single academic medical center between July 1, 2014 and July 31, 2015. Baseline demographics, concurrent steroid use, premedications, date/time of test dose and infusion, dose of infusion, reactions to test dose and/or infusion, and allergies were collected. The primary outcome was the proportion of patients experiencing adverse reactions. Anaphylaxis was characterized by sudden onset of respiratory difficulty, such as respiratory distress, and/or cardiovascular collapse. Cardiovascular reactions included hypertension, hypotension, chest pain/tightness, tachycardia, and/or flushing. Dermatologic reactions included pruritus. Gastrointestinal reactions included nausea and/or vomiting. Musculoskeletal reactions included myalgia, backache, and/or local phlebitis. Neurologic reactions included headache, chills, and/or dizziness. Respiratory reactions included shortness of breath. Patients were segregated based on presence of adverse reaction, and differences in baseline characteristics were assessed.

Results: Final analysis included 406 patients. Reactions to the test dose or infusion were reported in 11 (11/406=2.7%) and 21 patients (21/406=5.2%) respectively. Reported reactions were cardiovascular (13/406=3.2%), musculoskeletal/soft tissue (8/406=2%), gastrointestinal (6/406=1.5%), neurological (6/406=1.5%), dermatologic (2/406=0.5%), and/or respiratory (3/406=0.7%) in nature and treatable with diphenhydramine, acetaminophen, oxycodone, ondansetron, methylprednisolone, metoprolol, famotidine, and/or epinephrine. Respiratory distress was noted in two patients (2/406=0.5%). Of the patients experiencing a reaction from the test dose, 4 patients received an infusion dose. Of these, 2 patients (2/4=50%) experienced a reaction. Premedications, including methylprednisolone (10/406=2.5%), diphenhydramine (7/406=1.7%), and acetaminophen (2/406=0.5%) were administered to a total of 17 patients (17/406=4.2%), and adverse reactions were reported in 3 of these patients (3/17=17.6%). Use of daily steroids, including prednisone (202/406=49.8%), dexamethasone (1/406=0.2%), methylprednisolone (1/406=0.2%), or hydrocortisone (1/406=0.2%), was reported in a total of 205 patients (205/406=50.5%) with 16 patients (16/205=7.8%) experiencing an adverse reaction. Overall, the patients who experienced reactions to iron dextran were younger (49.8 years v. 55.8 years), and a greater proportion were male (59.4% v. 52.9%) and Caucasian (62.5% v. 58.3%). Patients experiencing reactions also reported fewer allergies with 71.9% reporting 0 or 1 allergy compared to 66.6% of those not experiencing reaction.

Conclusion: Although adverse reactions occurred, life-threatening reactions were rarely reported in this population. The low incidence of anaphylaxis supports that iron dextran is a safe option for treating iron deficiency. Daily steroid use may be associated with decreased incidence of adverse reactions. Increased incidence of adverse reactions may be correlated with younger, male, and Caucasian patients. This study indicates that an increased number of reported allergies does not correlate with an increased risk of adverse reactions.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Evaluative Study

Session-Board Number: 5a-123

Poster Title: Increasing smart pump compliance in a tertiary teaching hospital

Primary Author: Jennifer Panic, The University of Arizona College of Pharmacy, Arizona; **Email:** panic@pharmacy.arizona.edu

Additional Author (s):
Simbarashe Zvavamwe
David Djane
Sarah Elmer
Se Choi

Purpose: The Alaris smart pump is a computerized device used to infuse intravenous (IV) medications. Smart pumps have two modes, Guardrails or basic infusion. Guardrails is a software program that sets hard and soft limits for rates and volumes for a library of medications, thereby preventing medication administration errors. The medication safety committee at the Banner University Medical Center - South (BUMCS) identified low compliance with using Guardrails as a serious problem. The problem was approached by identifying the reasons why compliance was low, and then conducting training sessions for nurses to change attitudes and practices surrounding smart pumps and Guardrails.

Methods: Data was collected from the Continuous Quality Improvement (CQI) reporter in Guardrails at BUMCS for September 2015. The overall compliance was 83 percent using Guardrails, vs. 17 percent using basic infusion. The medication safety committee determined that the target compliance rate was 90 percent or higher. Next, a survey was created and administered to discover nurses' attitudes and practices towards using the software. The survey was administered using paper copies given to 81 total nurses in several units, including the intensive care unit (ICU), the emergency department (ED), and the medical/surgical unit, by pharmacy students in person during work hours at the hospital. Survey results were summarized in order to create a targeted, site-specific training session for nurses on several units at BUMCS. The training, which was given at eight different nursing staff meetings around the hospital in January, included real examples of how using Guardrails has helped nurses avoid medication administration errors, a discussion of the current compliance rate and the goal compliance rate, technical instruction on how to find various medications within Guardrails,

and hands-on practice with actual smart pump units. A total of 77 nurses were educated at these training sessions. Finally, compliance data was collected for March 2016 from the Guardrails CQI reporter, and the September 2015 rate vs. March 2016 were compared using chi-square.

Results: The survey results from January showed that the majority of nurses surveyed (42 percent of 81 nurses) received lecture-based training about smart pumps without a hands-on component. Sixty six percent of nurses felt that their training was adequate. Forty eight of 81 nurses surveyed said that their top reason to not use Guardrails was because the drug was not in the library. Nurses' survey results from January 2016 revealed that many nurses (20 of 81) were not using Guardrails to infuse IV fluids including electrolytes, lactated ringers solution, fluids and fluid boluses.

Our intervention focused on teaching the nurses on how to find drugs in the system and most importantly be able to navigate through the Alaris smart pump's different fluids with ease. In September of 2015, 83 percent of the 15,120 total infusions were administered using Guardrails, while 17 percent were done using the basic infusion function. In March 2016, during the post-intervention time period, 90 percent of the 8,432 total infusions were completed using Guardrails and 10 percent with basic infusion. The 7 percent increase in compliance was statistically significant (p is less than 0.001).

Conclusion: Guardrails can protect the patient and the hospital from IV medication administration errors. The better compliance there is, the more protection Guardrails can provide. The data suggests that a site-specific, hands-on educational intervention for nurses can be an effective way to increase compliance with Guardrails. The percent compliance may have increased even more if the training had been provided to all nurses using smart pumps, and also if more than 10 minutes had been allotted for the training sessions. Another important way to increase Guardrails compliance is to ensure that the drug library in Guardrails is constantly updated.

Poster Title: Incidence of hypoglycemia in burn patients: A focus in process improvement

Primary Author: Sean Lloyd, University of Tennessee Health Science Center - College of Pharmacy, Tennessee; **Email:** slloyd3@uthsc.edu

Additional Author (s):
David Hill
William Hickerson

Purpose: Glycemic control in burn patients is difficult due to altered processes and physiological responses to insulin in the body. Recommendations for goal blood glucose have changed over time for intensive care patients, and evidence exists to suggest benefit for a different target in thermal injury. It was previously thought that a more strict intensive insulin therapy improved morbidity and mortality, but it has been shown to increase incidence of hypoglycemia and mortality. This study was conducted in a single southeastern United States burn center to assess the incidence and outcomes of hypoglycemia during continuous insulin infusions (CII).

Methods: This study was a retrospective, single center, electronic chart review conducted with institutional review board approval. All patients admitted to the burn unit between January 1, 2013 and October 31, 2014, who received a continuous insulin infusion (CII) were included. Patients with incomplete data or who received less than 24 hours of CII were excluded. Data was collected using the institution's electronic medical record system. SigmaPlot 11.2 was used for data analysis. Univariate analysis was used to compare patients with and without hypoglycemia. Independent variables with a p less than or equal to 0.1 were included in a multivariable logistic regression. During regression modeling, p less than 0.05 was considered significant. Nominal data were analyzed by Fisher's exact test. Continuous variables were compared using either Mann-Whitney U test or t-test, depending on normal distribution. Shapiro-Wilk test was used to test for normal distribution. Analysis of variance was utilized to compare glucose variability between scales.

Results: During the study period 38 patients met inclusion criteria with 6 being excluded. The average patient was a 52-year-old Caucasian male, weighing 95 kg with a 33 percent TBSA burn, and an APACHE II score of 20. Hypoglycemia was present for 87 of 6540 hours of CII therapy (1.1 percent). Two thirds experienced a serum glucose less than 70 mg/dL and half less than 60 mg/dL. The most common assessed reasons for the hypoglycemic episodes were protocol violations and glucose variability. Patients with hypoglycemia (less than 60 mg/dL) were older, had a history of diabetes, lower albumin and serum creatinine, longer CII duration and length of stay, and lower average carbohydrate intake. After multivariable logistic regression, only history of diabetes remained a statistically significant risk factor with an odds ratio of 15.4 (95 percent CI: 2.5, 95.1). Four different CII scales were prescribed. A modified scale for renal failure (Scale 1) reduced the amount of renal failure patients experiencing hypoglycemia from 91 percent to 62 percent. All scales had high glucose variability as assessed by hours per day within goal range. Scales 0 and 3 had lower rates of hypoglycemia, but also lower time within the goal range.

Conclusion: The overall rates of hypoglycemia, blood glucose variability, and protocol violations raise concerns about the scales in use during the time period of the study. Education to increase protocol adherence is unlikely to achieve adequate control, as evidenced by the high percentage of patients with large drops in glucose in absence of protocol violations. The amount of different scales in use with varying protocols likely contributed to protocol violations. Our data together with nursing feedback and updated glucose targets demonstrate the need to create and consolidate usage to a single scale in attempts to improve glycemic control.

Purpose: Heart failure currently affects 5.1 million people in the United States alone and accounts for a large amount of hospital readmissions every year. The Center for Medicare and Medicaid Services penalizes hospitals for 30-day readmissions, costing hospitals thousands of dollars every year. The overall purpose of this retrospective, quality improvement project was to determine the frequency of 30-day readmissions for congestive heart failure at Banner University Medical Center South and compare the costs of these readmissions to the projected costs of opening a clinic.

Methods: Information regarding 30-day readmissions for congestive heart failure patients over a 6-month period was gathered using the Banner University Medical Center South electronic health record database. Using these numbers, we extrapolated to a 12-month period and found an estimated annual cost of 30-day readmissions using cost information acquired from the hospital's finance department. We then estimated the costs of opening and running a heart failure clinic where patients may go during an acute exacerbation. We used a conservative estimate that the clinic could prevent roughly 30% of the current 30-day readmissions at Banner University Medical Center South and calculated how much money this reduction in readmissions could potentially save. A flow chart comparing the costs of readmissions to the projected costs of a congestive heart failure clinic was completed.

Results: Between April 2015 and September 2015, 10 of 43 patients at Banner University Medical Center South were readmitted within 30 days due to congestive heart failure exacerbation, with one patient being readmitted twice (number equals 11). The average length of stay per patient was 3 days, at 2,100 dollars per day (6,300 dollars per patient per 3 day stay) according to the hospital's finance department. Through the extrapolation of our patient data to a 12-month period, it was found that readmissions cost the hospital approximately 138,600 dollars per year. Using a conservative estimate that the clinic could prevent roughly 30 percent of readmissions, it was found that the number of readmissions could be reduced by 6.6, which was rounded to 7 people. The cost of 7 readmissions would be 44,100 dollars, which was used as the reduction in cost due to the potential heart failure clinic. We then subtracted the estimated cost of the clinic, which was 12,456 dollars, from the estimated savings of preventing 7 readmissions. This gave an overall savings of 31,644 dollars.

Conclusion: The most cost effective option for Banner University Medical Center South is to have patients visit a congestive heart failure clinic to receive care and counseling instead of being readmitted for every acute exacerbation. By preventing roughly 30 percent of readmissions (7 people), an estimated 31,644 dollars in hospital costs could be saved yearly. While this estimate appears marginal, an expansion of the clinic across multiple facilities may result in an increase in savings. Additionally, the clinic carries the ability to improve health and social outcomes for heart failure patients. Limitations include limited patient data and time frame.

Poster Title: Antibiotic prescriptions on discharge from hospital to long-term care

Primary Author: Bo Park, Oregon State University/Oregon Health & Science University, Oregon;
Email: parbo@ohsu.edu

Additional Author (s):
Brie Noble
David Bearden
Christopher Crnich
Jon Furuno

Purpose: The Centers for Medicare and Medicaid Services (CMS) recently proposed to require long-term care facilities (LTCFs) to develop antibiotic stewardship programs. The prevalence of antibiotic prescribing on discharge from acute care to LTCFs will clearly impact these processes; however this has not previously been well-described. In this study, we aimed to quantify the frequency and characteristics of patients prescribed antibiotics on discharge from acute care to LTCFs. We hypothesized that patients with evidence of an infection or receiving antibiotics on the index admission would be more likely to be prescribed antibiotics on discharge compared to patients without these exposures.

Methods: This was a retrospective cohort study examining the frequency of antibiotic prescriptions among adult (age ≥ 18 years old) inpatients discharged from Oregon Health and & Science University (OHSU) Hospital to a LTCF between February 1, 2012 and January 31, 2015. Prior to study commencement, the OHSU Institutional Review Board approved this study and granted a waiver of informed consent. We utilized discharge disposition data from the OHSU Department of Care Management and demographic, diagnosis, laboratory, and pharmacy data from a repository of patients' electronic health records. Our primary outcome of interest was receiving an outpatient prescription for systemic antibiotics on discharge to a LTCF. Our primary exposures of interest were evidence of bacterial infections or receiving antibiotics on the index hospital admission. Evidence of a bacterial infection was defined as having both a positive clinical culture for a bacterial organism AND an International Classification of Diseases, version 9 (ICD-9) diagnosis code for a bacterial infection. Descriptive statistics including means, standard deviations (SD), medians, and interquartile ranges (IQR) were calculated. Odds ratios

(ORs) and 95% confidence intervals (CIs) were used to quantify the relationship between our exposures and outcomes of interest.

Results: There were 4,457 adult discharges to LTCFs during the study period. Mean (SD) age was 68.7 (14.3) years and 49.6% were male. Median (IQR) inpatient length of stay was 7 (4-12) days. Approximately 28.6% of patients had an outpatient antibiotic prescription on discharge of which 25.7% had >1 antibiotic prescription. The most frequently prescribed antibiotics were fluoroquinolones (17.8%), cephalosporins (17.6%), and penicillins (15.3%). Among patients who had an outpatient antibiotic prescription on discharge, 52.3% had evidence of an infection and 96.5% received antibiotics on the index admission . Patients with evidence of a bacterial infection on the index admission were significantly more likely to receive an outpatient antibiotic prescription on discharge to LTCFs (OR = 9.9, 95% CI = 8.4 to 11.6). Similarly, patients who received antibiotics during the index admission were significantly more likely to receive an outpatient antibiotic prescription on discharge to LTCFs (OR = 16.7, 95% CI = 12.3 to 22.7). Approximately 39% of patients discharged to LTCFs were readmitted to the hospital within 30 days of discharge.

Conclusion: These data suggest that a large proportion of patients discharged from acute care to LTCFs receive outpatient prescriptions for antibiotics. In addition, although receiving a prescription for antibiotic on discharge to LTCFs was associated with evidence of an infection on the index hospital stay, only 52% of patients who received an antibiotic prescription had evidence of an infection. These results may have important implications for the proposed CMS antibiotic stewardship requirements in LTCFs. Our future studies will aim to better understand how this high prevalence of antibiotic prescribing on discharge affects antibiotic prescribing and resident outcomes following LTCF admission.

Poster Title: Texting and educating on lifestyle therapy: a pilot study in a Spanish-speaking population in North Carolina

Primary Author: Ina Liu, Eshelman School of Pharmacy at University of North Carolina, Chapel Hill, North Carolina; **Email:** ina_liu@unc.edu

Additional Author (s):
Madison Jones
Sarah Anderson
Catherine Feng
Frank Tillman

Purpose: Access to mobile phones is becoming commonplace as technology becomes widespread for Americans. This study evaluated the effectiveness of using cellular communication as a means of enhancing health outcomes in a community outreach program connected with a Spanish language mass in a Catholic church in North Carolina. Patients received biweekly text messages containing cardiovascular lifestyle modification recommendations. The primary objective of this study was to determine if a text messaging program impacted participants' blood pressure and confidence in managing their health. Interest in continuing the program beyond the study was a secondary outcome.

Methods: Participants for this Institutional Review Board-approved prospective cohort study were recruited via weekly announcements in a Spanish language mass during a six-week period. Inclusion criteria were age 18 years or older, owning a mobile phone with unlimited text messages, and informed consent. Participants completed a 7-item, investigator-developed survey. Survey items included age, gender, cardiovascular-related medical conditions, preference for English or Spanish messages, difficulty understanding medical conditions (1-5 scale, with 1 indicating never and 5 indicating always), needing help reading prescriptions (1-5 scale, with 1 indicating never and 5 indicating always), and confidence in managing health (1-10 scale, with 10 indicating most confident). Investigators performed blood pressure assessment for each participant. Participants received two messages per week focused on personalized cardiovascular lifestyle modifications for 20 weeks. At study conclusion, participants completed a 6-item follow-up survey including 3 prior questions regarding difficulty understanding medical

conditions, help reading prescriptions, and confidence in managing health, plus 3 new questions regarding frequency of reading text messages (1-3 scale, with 1 indicating never and 3 indicating always), helpfulness of text messages (1-10 scale, with 1 indicating not helpful and 10 indicating very helpful), and interest in continuing to receive messages. Post-intervention blood pressures were performed by investigators. Survey questions with scaled responses were assessed with the Siegel-Tukey test. Blood pressure readings were assessed using Wilcoxon signed ranks test.

Results: In total, 33 persons enrolled; 1 person withdrew. Of the 32 participants, 31 persons received Spanish-language messages. Baseline survey was completed by 32 participants; 21 (43 percent) were female with an average age of 48 years. Self-reported cardiovascular risk factors included 8 (25 percent) with type 2 diabetes, 7 (22 percent) with hypertension, and 9 (28 percent) with hyperlipidemia. Follow-up survey was completed by 7 persons (25 persons were lost to follow-up). Median rated difficulty understanding medical conditions remained 2 pre- and post-intervention (5 indicating always). Median baseline score of needing assistance reading prescriptions was 2 and increased to 3 post-intervention (5 indicating always). Median score in confidence managing health remained 7 pre- and post-intervention (10 indicating most confident). Average baseline systolic blood pressure was 131 mmHg, which decreased to 118 mmHg (mean difference -13 mmHg, p equals 0.06). Average baseline diastolic blood pressure was 79 mmHg, which decreased to 78 mmHg (mean difference -1 mmHg, p equals 1). Median score in how often messages were read was 3 (3 being always). Median score in helpfulness of the messages was 9 (10 indicating very helpful). A total of 6 persons (86 percent) expressed desire to continue receiving text messages.

Conclusion: This pilot study notes the positive benefits of implementing a texting intervention designed to improve blood pressure control and confidence in managing health in a Spanish-speaking population in North Carolina. Although there were no differences in confidence measured pre- and post-intervention, participants ranked the messages 9/10 in terms of helpfulness. For a population in which 22 percent of individuals have hypertension, a decrease in systolic blood pressure from a pre-hypertensive to a normal range exemplifies the potential benefits of text messages that reinforce lifestyle changes.

Poster Title: Sustainability of an antimicrobial stewardship program (ASP) to reduce antibiotic prescribing in children admitted to the hospital for asthma

Primary Author: Jimmy Seo, St. John's College of Pharmacy and Health Sciences, New York; **Email:** jimmyseo734@gmail.com

Additional Author (s):
Gladys El-Chaar

Purpose: Antibiotics are generally not recommended during an asthma exacerbation; however, they continue to be prescribed in children. When antibiotic use is not indicated, unjustified use may lead to antimicrobial resistance, adverse reactions, and increased health care costs. The American Academy of Pediatrics (AAP) set a benchmark for unjustified antibiotic prescribing at 6.6 percent. In 2015/2016, we implemented an antibiotic stewardship program at our institution to change prescribing behaviors. The program reduced unjustified antibiotic prescribing from 8.7 to 4.9 percent. The purpose of this study was to observe whether our ASP was able to sustain this reduction in antibiotic prescribing.

Methods: This study was exempt from Institutional Review Board approval. This was a concurrent chart review of antibiotic use in pediatric patients admitted for asthma at our institution. Included were children 6 months to 19 years who were admitted for an asthma exacerbation. Patients with any underlying diseases such as muscular dystrophy, cerebral palsy, or complement deficiency were excluded from the study. Data collection included patient demographics, length of hospital stay, 7-day readmission rates, maximum temperature at home and during the first 24 hours of admission, prior antibiotic or steroid use within 7 days of admission, culture results, complete blood count and differential, lactate levels, and antibiotic prescribed, including name, dose, frequency, route of administration, number of doses, and diagnosis for use. Antibiotics were justified if used for: 1) Empiric antibiotic therapy for a high suspicion for infection, such as elevated neutrophil, band or white blood cells counts along with fever, or an elevated lactate level or 2) the treatment of a documented infection, including pneumonia or other infections. Data were analyzed for the unjustified rate of antibiotic use and the rate of 7-day readmission.

Results: From February to September 2016, we enrolled 47 pediatric patients in this study. Ages ranged from 10 months to 19 years (mean = 6.2 years, CI: 5.9-7.4), and 64 percent were male. One patient was excluded due to cerebral palsy. The average length of stay was 3.6 days (CI: 2.9-4.3). In 21 patients, after being admitted for asthma exacerbation, sepsis was ruled out and in 3 children urinary tract infections were ruled out. Ten patients received antibiotics (21.3 percent) and of those, 3 were unjustified (6.4 percent). Of the antibiotics prescribed, 7 children received ceftriaxone, 3 azithromycin, 2 amoxicillin, 1 levofloxacin, and 1 tobramycin. There was an average of 1.7 doses administered (CI: 1.3- 2.1) and an average of 3 days (CI: 2.5-3.5) of antibiotic exposure. Nine patients previously received antibiotics within 7 days of admission to the hospital and of those, 5 continued to receive antibiotics after admission (55.6 percent). Of 11 patients who received steroids within 7 days of admission, 1 patient received antibiotics (9.1 percent). One patient was readmitted within 7 days of being discharged home. The patient was originally diagnosed with parainfluenza virus and given azithromycin and cephalexin, but was readmitted with a diagnosis of pneumonia.

Conclusion: Over the course of eight months, our children's medical center continued to be successful in sustaining the reduction in unjustified antibiotic prescribing in children admitted for asthma exacerbations. Our rates of unjustified use continued to fall below the expectations set by the AAP. Long-term effects of sustaining this improvement is expected to help reduce antibiotic resistance and the development of adverse reactions related to antibiotic prescribing in children.

Poster Title: Comparing the time for nursing administration of inhaler treatments vs nebulized treatments in patients with COPD at Rochester General Hospital

Primary Author: Mariah Haley, St. John Fisher College Wegmans School of Pharmacy, New York; **Email:** meh03096@sjfc.edu

Additional Author (s):
Karlie Mahan
Bob Reiss

Purpose: Chronic obstructive pulmonary disease (COPD) exacerbations commonly lead to hospital admissions in the United States. Multi-dose inhalers have up to a month's supply of medication, and at times cost over $200 per inhaler, are frequently ordered then discarded after a 3-4 day admission. The purpose of this Investigational Review Board approved study was to determine if using single-dose nebulized treatments instead of inhalers would negatively impact nursing administration time at Rochester General Hospital (RGH), a 528 bed community hospital. Earlier work suggested the cost savings in using nebulized medications in place of inhalers could save RGH over $450,000 annually.

Methods: In May 2016 RGH Pharmacy Interns collected the time that nurses were directly involved with inhaler administration on one surgical floor and one medical floor. Time was recorded while nurses obtained the inhaler from the floor's automated dispensing machines (ADM), prepared, administered, and documented the treatment. A stopwatch was utilized to collect time during direct involvement, and was paused if the nurse performed other functions unrelated to the administration of the inhaled medications. In June 2016 new orders for inhalers on the same surgical and medical floor were changed to nebulized treatments as approved by the Pharmacy and Therapeutics Committee for this project. Nurses at RGH were already familiar with administering nebulized treatments. A pharmacy resident prepared a compatibility chart that was provided for nurses, indicating which nebulized solutions could be mixed together and inhaled simultaneously. Data was collected during morning administrations for both inhaler and nebulizer therapies. Times were rounded to the nearest minute.

Results: Thirty-one inhaler administrations were observed. All 31 samples came from patients who were prescribed fluticasone-salmeterol or umeclidinium for COPD. The mean time was 4 minutes for administration. Nurses spent time locating the inhaler, which was frequently not stored in the ADM in opposition to hospital policy. There were instances where the inhalers could not be found and replacement inhalers were dispensed. Thirty-six nebulized treatments were observed after the Pharmacy & Therapeutics Committee approved change. Data came from administrations of ipratropium-albuterol, budesonide, and albuterol nebulizer treatments. The mean time was 2 minutes for nurses to obtain, administer, and document the treatments. Nine samples came from administrations where two nebulized medications were mixed and given at the same time. Nebulized medications were consistently stored in the ADMs. Nurses did not stay in the patient's room during treatment unless they were attending to other tasks.

Conclusion: Using nebulized treatments in place of inhalers for admitted patients with COPD did not present a negative impact on the time nurses needed to administer the treatment. Further review of primarily using nebulized treatments for inpatients with COPD can move forward at RGH. In addition to saving time, this represents a cost savings of which a portion could be used to hire Respiratory Therapists to educate patients prior to discharge on the proper use of inhalers at home, along with assuring the proper discharged inhaler is being ordered for the patient's need and insurance coverage.

Poster Title: Trends associated with the Office of Prescription Drug Promotion warning letters for advertising and promotion (2000-2016)

Primary Author: Boning Zhao, Rutgers University, Ernest Mario School of Pharmacy, New Jersey; **Email:** boningzhao95@gmail.com

Additional Author (s):
Sung-Joo Park
Michael Toscani

Purpose: One of the issues with the Office of Prescription Drug Promotions' regulations of pharmaceutical advertising and promotion is the fact that only a small portion of all advertisements and promotions are reviewed. This is especially a concern for direct-to-consumer advertisements where the potential for exposing consumers and patients to misleading information is a risk. We evaluated the trend of Office of Prescription Drug Promotion warning letters to gain insight on the areas of focus from the Office of Prescription Drug Promotion.

Methods: The Office of Prescription Drug Promotion periodically issues warning letters for misleading promotional and advertisement content created by pharmaceutical companies. All the warning letters publicly issued by the Office of Prescription Drug Promotion on their website from 2000 to 2016, totaling 336 warning letters, were reviewed and categorized as relating to either direct-to-consumer or promotional content. Then, the most frequent forms of advertisement and promotion that appeared in the warning letters were identified and defined by percentage, to the total number of warning letters from 2000 to 2016. The most commonly occurring forms of advertisement and promotion were then individually analyzed by yearly frequency to determine any trends.

Results: There are various forms of promotion and advertisement used by pharmaceutical companies. The most common forms of promotion that target healthcare professionals include brochures, sales aids, professional journals, and convention exhibits while the most common forms of advertisements that target consumers and patients include websites, brochures, print advertisements, and television advertisements. From 2000 to 2016, the ratio of warning letters,

related to direct-to-consumer advertising, to the total number of warning letters remained relatively consistent (approximately 50 percent). The total number of warning letters fluctuated without any correlation. The yearly percentage of warning letters related to website advertisement and promotion has an increasing trend. The yearly percentage of warning letters related to print advertisement has a decreasing trend. The number of warning letters related to television advertisements has a decreasing trend. The number of warning letters related to convention exhibits has a decreasing trend. In addition, the number of warning letters related to professional journal promotions has a decreasing trend as well.

Conclusion: Direct-to-consumer advertisements make up approximately 50 percent of all warning letters issued by the Office of Prescription Drug Promotion from 2000 to 2016. The main areas of focus for warning letters include sales aids, websites, print advertisements, television advertisements, and convention exhibits. With the growth of the internet in the past decade, there have been increases in warning letters associated with website advertisements and promotions and decreases in warning letters related to print advertisements, professional journal promotions, convention exhibit promotions, and television advertisements. Additional research is needed to evaluate these changes as they are related to market forces.

Poster Title: Efficacy and safety of various abuse deterrent formulations on the prevention of inappropriate use of oxycodone: a systematic review

Primary Author: Alexander Heinz, Roosevelt University College of Pharmacy, Illinois; **Email:** aheinz@mail.roosevelt.edu

Additional Author (s):
Jerry Cavanagh
Julia Gilbert
Abby Kahaleh

Purpose: Opioid abuse is a major public health issue that has been growing in the past decade throughout the United States. One of the most highly abused opioids is oxycodone. Oxycodone is widely accessible and easily manipulated to increase euphoria. The purpose of this systematic review is to evaluate the efficacy and safety of opioid-deterrent formulations on reducing opioid abuse and identify gaps in current knowledge of the effectiveness of formulations. Specifically, the study compared current abuse deterrent formulations to educate prescribers, pharmacists, and patients about innovative strategies to prevent abuse.

Methods: A systematic review was conducted via randomized controlled trials published in English, performed in North America, conducted within the past 5 years and studied abuse deterrent formulations of oxycodone. Three abuse deterrent formulation categories were analyzed from the studies: opioid antagonist formulations, formulation technology and aversive excipient formulations. The 12 studies included in the systematic review evaluated one or more abuse deterrent formulation categories that were compared to the original oxycodone formulation or a placebo. Subjects included in the studies were either patients that use oxycodone to treat chronic pain or recreational users of oxycodone. Three reviewers conducted the systematic review for quality assurance. The systematic review was conducted through Pubmed, MEDLINE, clinicaltrials.gov, Cochrane Database of Systematic Review, and Cochrane Central Register of Controlled Trials (CENTRAL). A ranking system was utilized in comparing the adverse event profile and efficacy of reducing opioid abuse with 1 indicating the preferred formulation and 3 being the undesired formulation. The ranking was performed individually by 3 reviewers to increase the inter-rater reliability.

Results: The majority of abuse deterrent technology analyzed demonstrated potential to decrease the abuse of opioid analgesics and had similar efficacy results; however, their safety profiles and types of abuse they prevented differed. Aversive excipient formulations with niacin is efficacious in preventing opioid abuse, however, it has a high incidence of adverse effects. Studies showed that 98-100% of patients experienced treatment-emergent adverse effects with aversive excipient formulations. Medications formulated with opioid antagonists such as naloxone or naltrexone have been found to be relatively efficacious in preventing abuse, particularly by non-oral routes such as intravenous injection and intranasal inhalation. These medications have similar safety effects as currently FDA approved opioid analgesics. However, the use of opioid antagonist formulations is limited among patients who have trouble swallowing or requiring the use of a feeding tube for medication administration. Formulation Technology demonstrated efficacy and a significant reduction in opioid abuse, while maintaining a similar adverse event profile to oxycodone alone. Crushed formulation technology products maintained the desired pharmacokinetics thus lowering the likelihood of illicit use by crushing. Consequently, this allowed these medications to be available for patients who have trouble swallowing or require gastric tube for medication administration.

Conclusion: Based on the results of the systematic review, opioid antagonists are efficacious in preventing abuse; however, they are more successful in preventing abuse via non-oral routes such as intravenous or intranasal routes. Formulation technology prevents opioid abuse by oral route and non-oral routes of administration and has a safety profile similar to currently approved opioid analgesics. Aversive excipient formulations demonstrated significant abuse prevention but had adverse events in nearly all patients. Formulation technology demonstrated the best efficacy in reducing opioid abuse potential while maintaining a much lower incidence of adverse effects than aversive excipient and opioid antagonist formulations with oxycodone.

Poster Title: Assessment of medication safety labeling risk factors present on investigational drugs

Primary Author: Maxwell Norris, University of Michigan College of Pharmacy, Michigan; **Email:** maxn@umich.edu

Additional Author (s):
Kimberly Redic
Helen Tamer
Amy Skyles
Erika Price

Purpose: The Food and Drug Administration (FDA) does not currently regulate investigational drug labels, making them highly susceptible to contain Institute for Safe Medication Practices (ISMP)-identified labeling safety risk factors. This study quantified the incidence of ISMP-identified labeling risk factors present on investigational drugs managed by the University of Michigan Health System Research Pharmacy (UMHS-RP). The intent was to validate the presence of risk factors identified by ISMP in 2007 and to determine the need for further guidance from the FDA on investigational drug labeling.

Methods: The UMHS-RP electronic inventory system was used to identify investigational drugs managed by the service at the start of the study. Investigational drugs that were already commercially available, out-of-stock at time of evaluation, or required non-sterile compounding such as over encapsulation were excluded. For drugs with multiple strengths, only one strength was included. Data was collected between June 15th and July 31st of 2016. For each included drug, packaging and labeling were assessed via a data collection form containing the factors identified by ISMP. Broad categories of factors assessed included drug naming conventions; drug labeling, content, and formatting; drug packaging; and expiration dating. For quality assurance, a sample of 20% of data forms were reviewed for accuracy by a second reviewer. For each risk factor, the percent of drugs evaluated that were positive for the factor was calculated. Sub-analysis by study phase, study sponsor, and study design was also completed to identify any notable trends.

Results: At the start of the study, the initial data extract contained 1138 drugs. Of these,158 met criteria for inclusion in the analysis. Over 90% of drug labels contained the drug name, drug strength, and dosage form. The average label font size was 8.8 points, compared to the ISMP-recommended font size of 12 points. Less than 30% of drugs used font size or otherwise differentiated drug name and strength from other label content. Seventy-percent of proprietary names were comprised of letters and numbers only (i.e. not a generic name). Over half (52%) of the protocol identifiers contained look-alike, sound-alike portions that were present with other protocols managed by UMHS-RP. Only about half (54%) of all drug labels contained an expiration date. Most notable trends were related to the phase of the study. Compared to Phase I studies, Phase III studies were more likely to have an expiration date present (33% vs. 86%), protocol number present (42% vs 94%), and additional languages other than English present (31% vs 80%).

Conclusion: Despite recent and increased attention on unsafe labeling practices of investigational drugs, these results show that there still exist significant rates of known labeling risk factors regardless of the study phase, design, or sponsor. Stronger regulations or recommendations must be set in place by the FDA in order to reduce the presence of risk factors on investigational drugs and improve the safety of their use in patients enrolled in clinical trials.

Submission Category: Ambulatory Care

Submission Type: Descriptive Report

Session-Board Number: 5a-133

Poster Title: Assessing patient comprehension of step-by-step proper inhaler use

Primary Author: Demi Bennett, Massachusetts College of Pharmacy and Health Sciences University - Manchester, New Hampshire; **Email:** dbenn1@stu.mcphs.edu

Additional Author (s):
Ruth Manzi
Joshua Desclos
Helen Pervanas

Purpose: Inadequate inhaler use can often lead to exacerbations and increased hospitalization. Education on proper inhaler use is a vital component to promote patient adherence, prevent exacerbations and increase overall quality of life. This study was designed to assess inhaler use and determine whether patients could demonstrate the correct steps to ensure proper administration.

Methods: Student pharmacists enrolled at MCPHS University on a six week ambulatory care Advanced Pharmacy Practice Experiential (APPE) rotation, evaluated patients on how they use their inhaler. Criteria for the study included the following; English-speaking patients, 18 years of age or older, on active inhaler medication listed on the electronic medical record, and informed patient consent. Standardized forms were created for each inhaler citing each step as recommended by the manufacturer. An intake form gathered the following information; diagnosis for inhaler use, name and strength of inhaler, dose/frequency, inhaler duration, who taught inhaler use, compliance, spacer use/cleaning, priming, expiration dates, and whether they performed all steps correctly. Student pharmacists educated patients when improper inhaler use was identified. This study was approved by the MCPHS University Institutional Review Board (IRB).

Results: A total of 14 patients (50% female, 50% male) were assessed regarding their inhaler use. The average patient age was 54 years old, 64.28% were Caucasian and 21.43% were Hispanic. Eighty-two percent were diagnosed with asthma and 18% were diagnosed with COPD. Seventy-six percent of patients were taught how to use an inhaler by a provider (38%) or nurse (38%), while 24% were self-taught. None of the patients reported being educated on how to

use their inhaler by a pharmacist. Based on the overall collected data, 38.19% of patients did not perform all inhaler steps correctly and were diagnosed with asthma; 75% or both asthma and COPD; 25%. The majority of errors; 75% were associated with albuterol inhalers. Of the patients who were prescribed inhalers that required priming, 38.88% of patients performed priming before administration. One hundred percent of the patients who reported priming, performed priming correctly. Thirty three percent of patients regularly checked the expiration date on their inhalers.

Conclusion: This study highlighted areas of concern around proper inhaler use, specifically with rescue inhalers which can have an impact on asthma and COPD, leading to increased exacerbations, doctor visits and hospitalizations. A greater need for patient education is necessary when dispensing inhalers as revealed by the research. Pharmacists are the most accessible providers, are knowledgeable in medication use and are often one of the last health care providers a patient comes in contact with before starting their inhaler. Patient counseling by pharmacists on every new inhaler may help increase adherence and decrease exacerbations.

Poster Title: Neonatal abstinence syndrome prevention behaviors among primary care prescribers, buprenorphine prescribers, and pain management clinic directors

Primary Author: Alexandra Ross, Bill Gatton College of Pharmacy, TENNESSEE; **Email:** schleg@etsu.edu

Additional Author (s):
Anh Dinh
Nicholas Hagemeier
Ivy Click
Jeri Basden

Purpose: Neonatal abstinence syndrome (NAS) is a growing public health concern in the United States, and particularly so in Tennessee. Despite prescribers' acknowledgement of the importance of NAS prevention, very little is known about prescribers' NAS prevention behaviors. The objective of this study was to evaluate opioid prescribers' NAS prevention attitudes, subjective norm beliefs, perceived behavioral control beliefs, and behaviors.

Methods: A survey instrument was developed using Tennessee-specific chronic pain guidelines as a resource for question content and the theory of planned behavior (TPB) as a theoretical framework. The survey instrument assessed how often a prescriber would engage in prevention across 15 distinct behaviors. For each behavior, a total of 12 items measured prescribers' attitudes, subjective norm beliefs, and perceived behavioral control beliefs. TPB items were responded to using a 7-point scale with appropriate response anchors. A random sample of 100 primary care physicians (PCPs), 100 DATA-waivered buprenorphine prescribers (BUP), and 100 pain management clinic directors (PMC) comprised the sampling frame. The survey was administered using the Tailored Design Method and took place between December 2014 and February 2015. Data were analyzed using SPSS version 22.

Results: A total of 41 usable responses were obtained. Primary care prescribers engaged in NAS prevention behaviors less often than buprenorphine prescribers and pain management clinic directors. Given 10 female patients of child bearing age prescribed a prescription opioid for greater than 7 days, PCPs indicated they would discuss the risk of NAS with 5.8 patients (PMC,

8.6 BUP, 7.0), discuss a birth control plan with 5.7 patients (PMC, 7.5 BUP, 8.2), recommend long acting reversible contraception (LARC) to 3.7 patients (PMC, 6.4 BUP, 5.9), direct 3.5 patients (PMC, 5.8 BUP, 4.0) to resources that provide LARC, and give 5.2 patients (PMC, 7.2 BUP, 6.8) a pregnancy test. Significant differences in the extent to which prescribers discuss controlled substance database results with patients (PCP, 5.5; PMC, 9.3; BUP, 7.1; p equals 0.005) and discuss the expectation that patients inform providers if they become pregnant (PCP, 6.8; PMC, 9.3; BUP, 9.9; p equals 0.011) were noted across study cohorts. Perceived importance of behavioral engagement and self-efficacy beliefs toward prevention behaviors were overwhelmingly positive (medians 7 on 7-point scale). The extent to which respondents perceived other prescribers like them to engage in prevention behaviors was generally positive, but varied across behaviors (medians 4-7).

Conclusion: The extent to which prescribers engage in NAS prevention is variable across prevention behaviors. In general, PCPs engaged in NAS prevention behaviors less often than their BUP and PMC colleagues. Low engagement was particularly noted for recommending LARC and directing patients to community resources that provided access to LARC. Pharmacists, especially in community settings, may be able to assist prescribers by checking patient profiles and recommending patients talk to their providers about starting LARC. Moreover, with appropriate contraception prescribing authority and collaborative practice agreements, pharmacists may be able to provide access to LARC and thus prevent NAS.

Poster Title: Medication use evaluation of fluoroquinolones within a rural medical center

Primary Author: Cody McKenzie, Washington State University, Washington; **Email:** cody.mckenzie@wsu.edu

Additional Author (s):
Tram Pham
Kelly Moran

Purpose: Evaluate the appropriateness of fluoroquinolone prescribing within a rural medical center. Recent FDA safety alerts have been issued to caution the use of these antimicrobial agents in uncomplicated urinary tract infections, acute sinusitis, and acute bronchitis because the serious adverse effects associated with these drugs generally outweigh the benefits.

Methods: Retrospective electronic medical chart review was conducted to identify patients who had received fluoroquinolone antibiotics from 1/1/2016 to 6/30/2016. The following data was reviewed: current antibiotic prescription, dose and instructions, patient age, indication, concurrent corticosteroid use, previous antibiotic prescribed within the last 3 months, drug allergies, co-morbidities, renal function, culture and susceptibility results, and recent laboratory parameters used for monitoring purposes. The focused indications included acute sinusitis, acute exacerbation of bronchitis, and uncomplicated urinary tract infection, but also included other indications for which a fluoroquinolone was prescribed. The current IDSA and Sanford Antimicrobial Guidelines were referenced as the most up-to-date recommendations. Descriptive statistics based on the data collected was used to analyze the appropriateness of fluoroquinolone prescriptions.

Results: The study identified 167 patients with prescriptions for a fluoroquinolone antibiotic from January 2016 through June 2016. Fluoroquinolones were found to be empirically prescribed most commonly for UTIs, COPD exacerbation, pneumonia, sinusitis, and bronchitis, respectively. The prevalence of inappropriately prescribed fluoroquinolones was 35 percent based on patients' clinical profiles, diagnoses, and the availability of alternative antibiotic therapies. 109 prescriptions were deemed appropriate while 58 prescriptions were considered

inappropriate. There were no severe adverse effects reported for patients that were prescribed a fluoroquinolone for the three indications stated in the FDA alert.

Conclusion: The results of this evaluation will be presented to the Pharmacy and Therapeutics Committee. Intervention will be provided to prescribers and pharmacists in the form of clinical education to highlight and reinforce the FDA warning against the use of fluoroquinolones as first-line agents for acute sinusitis, acute exacerbations of bronchitis, and uncomplicated urinary tract infections. This intervention is provided due to the potential risk of serious adverse reactions outweighing the benefits. Prescribers and pharmacists will be encouraged to provide consistent patient education to heighten the awareness about the potential disabling side effects of fluoroquinolones.

Poster Title: Outcomes and characteristics of patients with potentially inappropriate classification of Clostridium difficile infection at a community hospital

Primary Author: Jinkyung Keum, Mercer University College of Pharmacy, Georgia; **Email:** jinkyung.keum@live.mercer.edu

Additional Author (s):
Bobby Jacob
Samuel Peasah
Angela Shogbon
Adam Bressler

Purpose: Clostridium difficile infection (CDI) is the most commonly recognized cause of diarrhea in hospitalized patients. The Center for Disease Control and Prevention (CDC) classifies CDI as healthcare facility-onset, community-onset, or community-onset healthcare facility-associated. Delays in stool sample collection or physician laboratory orders may lead to inaccurate patient classifications and potentially adverse clinical and economic implications. The objective of this pilot study was to evaluate the difference in clinical outcomes between patients with definite community onset CDI and those who may have been inappropriately classified as healthcare facility-onset due to delayed stool sample collection or physician orders for Clostridium difficile testing.

Methods: This was a retrospective, observational study of inpatient-adults with a positive stool sample for Clostridium difficile from January 1, 2015 to March 31, 2016 at a community hospital. A patient's CDI was classified as definite community-onset CDI (positive stool sample within 3 days of admission) or healthcare facility-onset (positive stool sample at least 3 days post-admission). The healthcare facility-onset group was further analyzed to identify patients who were symptomatic within 3 days of admission but had a delay in obtaining either a stool sample or physician laboratory order until after 3 days. This group was defined in the study as the possible community onset CDI group. The definite community-onset group was compared to the possible community-onset group with respect to several clinical endpoints. Study endpoints included patient demographics, admission diagnoses, white blood cell counts, serum albumin, serum creatinine, loose stool count, treatments for CDI, duration of therapy,

concurrent antibiotic use, re-admission, and death. Data was analyzed using descriptive statistics utilizing the Statistical Analysis System version 9.3.

Results: A total of 105 patients were identified as having definite community-onset CDI compared to 25 patients who were classified as possible community-onset CDI. All patients in the possible community-onset CDI group had a delayed stool sample collection or a physician order beyond hospital day 3 despite being symptomatic for CDI during the first 3 days of admission. No statistically significant differences were noted between groups with respect to patient demographics, admission diagnoses, or admission laboratories for white count, serum albumin or serum creatinine. In addition, no differences were noted in type of initial CDI treatments or concurrent antibiotic use. However, the possible community-onset group did have a longer total length of hospitalization (10.8 days versus 7.6 days, adjusted P-value 0.0075) and duration of initial CDI treatment (5.5 days versus. 3.5 days, P-value 0.0352). Furthermore, patients in the possible community-onset CDI group were more likely to be discharged on oral vancomycin and less likely to receive oral fidaxomicin (6 percent versus 15 percent, P-value 0.0223). No differences were noted between groups with respect to 30-day readmission, 90-day readmission, or death.

Conclusion: Our findings suggest that patients who receive inappropriate CDI classification due to delayed stool sample collection or physician laboratory ordering, may have longer length of hospitalization and duration of therapy, which represents potentially significant clinical and economic challenges for the health care system. Further research is warranted to confirm these findings in a broader range of health care systems. If confirmed, research regarding interventions to improve accurate CDI classification may be warranted.

Submission Type: Evaluative Study

Session-Board Number: 5a-137

Poster Title: Repurposing raloxifene for use in KRAS-dependent pancreatic adenocarcinoma

Primary Author: Heather TRUE, Pacific University School of Pharmacy, Oregon; **Email:** true5212@pacificu.edu

Additional Author (s):
Adeleke Badejo
Ashim Malhotra

Purpose: We investigated whether the drug raloxifene could be repurposed for the treatment of pancreatic cancer. Treatment is challenging due to 1) lack of target-specific drugs, 2) prohibitive cost of drug development, and 3) chemoresistance. Raloxifene can induce cell death in cancer, and was FDA-approved for breast cancer treatment in postmenopausal women, making its use in pancreatic cancer a therapeutic extension. Since 90 percent of patients have a mutation in the Kristen Rat Sarcoma viral (KRAS) oncogene, our goals were to 1) identify the affected molecular pathways following raloxifene treatment, and 2) compare these changes in KRAS-dependent versus non-KRAS pancreatic cancer.

Methods: To rapidly identify drugs that could have an important impact on the treatment of pancreatic cancer, we sought to re-purpose existing FDA-approved drugs. For this, we screened drugs that could induce apoptosis (cell death) of human pancreatic cancer cells. Raloxifene was identified from this screen since it 1) induced apoptosis of cultured human pancreatic cancer cells; 2) altered either apoptotic or cell survival proteins; and, 3) elicited specificity, by effecting these changes only in the mutant, but not wild-type KRAS pancreatic cancer. We treated human KRAS-mutant, or KRAS wild-type pancreatic cancer cells in culture with increasing doses of raloxifene (0.05 uM, 0.5 uM, 5 uM, and 20 uM) for 3 days. Following treatment, we conducted protein analysis by Western blot to determine changes in protein targets or determine differential protein activation between KRAS mutant or wild-type cells. To verify our results, we ablated the tafazzin gene, a reduction of which was our primary finding in response to raloxifene treatment, and investigated whether raloxifene treatment could cause cell death in the absence of tafazzin. We used the student t-test and ANOVA for statistical analysis; setting p less than 0.01 to reflect high significance. All experiments were repeated a minimum of three separate times.

Results: Raloxifene reduces tafazzin expression in a dose-dependent manner. At physiological dose, there occurs a 50 percent decrease in the tafazzin protein when KRAS-mutant cells are treated with raloxifene, a p value of 0.0136. At the highest dose, there is an 83 percent decrease in tafazzin levels, a p value of 0.0009. These p values suggest that the raloxifene-mediated reduction in tafazzin is significant. Reduction of tafazzin is therapeutically relevant because it compromises the mitochondria, setting up the conditions for killing KRAS-mutant cells. This effect is limited to the KRAS-mutant cells, thus suggesting a targeted effect. Raloxifene causes a threefold increase in the protein level of the pro-apoptotic protein Bim, suggesting that this SERM drug has multiple effects in pancreatic cancer. To test the effect of tafazzin reduction on cellular energy, we measured ATP levels of raloxifene-treated pancreatic cancer cells at different time points. ATP first increases up to one day after treatment and then decreases by 52 percent over the next two days of treatment. This trend is observed across all treatment points. This decrease in ATP induces signalling pathways that can cause cell death.

Conclusion: Our results demonstrate that targeting the mitochondria in mutant KRAS pancreatic cancer is a viable strategy for making these chemoresistant cells susceptible to drug treatment. Specifically, raloxifene targets and suppresses the mitochondrial protein tafazzin, and destabilizes KRAS-dependent pancreatic cancer cells. Our data also provide mechanistic insights by showing a raloxifene-mediated increase in the proapoptotic protein Bim, and an overall reduction of cellular energy, indicating that raloxifene activates multiple signal transduction pathways simultaneously. Importantly, since our study was conducted employing human pancreatic cancer cells, our data illustrate the most plausible pharmacological effects of raloxifene were it used in human pancreatic cancer.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Evaluative Study

Session-Board Number: 5a-138

Poster Title: Impact of pharmacy education on the accuracy of tobacco-use documentation in hospitalized patients

Primary Author: Seth Anderson, University of Arizona College of Pharmacy, Arizona; **Email:** sanderson@pharmacy.arizona.edu

Additional Author (s):
Joseph Murata
Joshua Coulter

Purpose: Having accurate tobacco-use documentation allows healthcare providers to assess readiness for change in those who may want to quit using tobacco products. It allows them to accurately prescribe medication, avoid possible drug interactions, verify appropriate therapy during dispensing, and to monitor other adverse drug events caused by tobacco products or nicotine replacement therapy after administration. The purpose of this project was to determine if pharmacy education provided to nurses would improve the accuracy of tobacco-use documentation on admission to the general medical floor at Northwest Medical Center in Tucson, Arizona.

Methods: All qualifying patients (those admitted within the past three days to the general medical floor, who were physically present, awake, English-speaking, and consented to being interviewed) were interviewed on three separate days in February 2016. Each patient had his or her current and former tobacco-use status as well as quantity of tobacco-use documented based on answers from an interview script. Patient answers were compared to tobacco-use status on the electronic health record. The electronic health record must have the current status, former status, and quantity that match what was obtained from the interview to be considered correct. This data constituted the pre-intervention data. Over the course of one week, pharmacy students instilled the importance of correct tobacco-use documentation to the nurses on the general medical floor at selected nursing huddles, disseminated fliers stressing the importance of correct documentation to the nursing staff, and sent an email reiterating the importance to the clinical nurse leaders and nurse directors to further disseminate to their respective nursing staffs. On three separate days in March, the same methods conducted pre-

intervention were repeated to obtain the post-intervention data. The primary outcome measured was the accuracy of tobacco-use documentation in patient's electronic health record.

Results: Prior to the intervention, 41 out of 62 patients (66.13 percent) had tobacco-use status correctly documented and 21 out of 62 patients (33.87 percent) had incorrect tobacco-use documentation. After the intervention, 52 out of 58 patients (89.66 percent) had tobacco-use status correctly documented and 6 out of 58 patients (10.34 percent) had incorrect tobacco-use documentation. Pharmacy education provided from pharmacy students to nurses showed a statistically significant impact on accurate tobacco-use documentation (P equals 0.002), showing an absolute increase in accuracy of 23.53 percent.

Conclusion: Interprofessional collaboration represents a unique approach to optimizing patient care. Coordinated efforts between pharmacy students and the nursing staff at Northwest Medical Center showed a statistically significant improvement in correctly documenting patient tobacco-use status. Correct documentation of patient tobacco-use status allows healthcare professionals the opportunity to provide tobacco cessation interventions to those patients who are correctly identified as tobacco users. Additionally, potential drug interactions between patients' medications and tobacco can be caught before becoming a problem in those patients. Further research should be done to determine the longevity of these interventions.

Poster Title: Relevance of student involvement in professional organizations, leadership positions, and service to pharmacy postgraduate residency program acceptance - a literature review

Primary Author: Trenna Weathers, Roseman University of Health Sciences College of Pharmacy, Utah; **Email:** tweathers@student.roseman.edu

Additional Author (s):
Erin Johanson
Devan Turner

Purpose: The purpose of the study was to conduct a thorough literature review identifying the extent student involvement in professional organizations, leadership positions, and service correlates to pharmacy postgraduate residency attainment. In addition to extensive effort in academic achievement of a competitive GPA and class rank, pharmacy students are encouraged to spend time in professional organizations, leadership obligations, and service endeavors to increase their chance of obtaining a residency. Participation in these non-didactic activities have not been extensively identified in the literature in regards to importance.

Methods: A thorough review of literature published in the last twenty years regarding pharmacy postgraduate residency programs was conducted using the US National Library of Medicine's PubMed database. Articles selected for inclusion were peer reviewed articles that focused on the characteristics that have been proven to assist pharmacy students as they apply for postgraduate residency programs. Search terms included: "class rank," "GPA," "professional organizations," "leadership positions," "service," as primary terms. Additionally "research," "work experience," and "publications" were utilized for inclusivity. Results from the aforementioned foci were compiled in order to analyze and assess their significance to acceptance into post graduate residency programs. Themes were identified and each peer-reviewed article was assigned to specific categories.

Results: Thirty-five articles were identified as relevant to the study's aims. Twenty-two articles (63%) were published between 2006 and 2015. Twelve articles (34%) pertained to pharmacy, eleven (31%) pertained to medical, and ten (29%) pertained to other healthcare professions. Thirteen articles (37%) cited membership in professional organizations as a contributing factor to residency attainment. Eight articles (23%) cited leadership positions as a contributing factor to residency attainment. Ten articles (29%) cited service as a contributing factor to residency attainment. Thirteen articles (38%) cited test scores as a contributing factor to residency attainment. Twelve articles (34%) cited GPA as a contributing factor to residency attainment. Eleven articles (31%) cited class ranking as a contributing factor to residency attainment. Twelve articles (34%) cited student publications as a contributing factor for residency attainment. Within the twelve articles pertaining to pharmacy five (42%) cited leadership, five (42%) cited service, five (42%) cited GPA as a contributing factor, five (42%) cited class ranking, and 5 (42%) cited student publication as a contributing factor to attaining a pharmacy post graduate residency.

Conclusion: A literature review identified professional organization membership, leadership position, and service as factors for attainment of a pharmacy postgraduate residency. Membership in a professional organization, test scores, and GPA were the most cited for obtaining a postgraduate residency followed by student publications and class ranking. Within the articles pertaining to pharmacy, two of the characteristics of interest, professional organization membership and leadership positions, were among the most prevalent. The significance and level of importance of each characteristic was not clear. Future studies are needed to quantitatively rank the characteristics that contribute to pharmacy residency candidate selection, attainment and successful performance.

Poster Title: Evaluating the Accuracy of Inpatient Electronic Medical Record Penicillin Allergy Fields

Primary Author: Matthew Plakosh, St. John Fisher College, NEW YORK; **Email:** mdp06724@sjfc.edu

Additional Author (s):
Mary Staicu
Allison Ramsey

Purpose: A thorough history is one of the most important components in the clinical evaluation of drug hypersensitivity. Previous studies have detailed the inaccuracy of drug allergy reporting in paper charts, which results in prolonged patient admissions and unnecessary avoidance of first-line medications. The impact of the electronic medical record (EMR) on documentation of patient allergies has not been extensively evaluated. The purpose of this study is to evaluate the accuracy of patients' penicillin allergy reactions documented in the EMR compared to their interview responses.

Methods: Adult inpatients with a documented penicillin allergy were randomly selected and prospectively interviewed using a penicillin allergy history algorithm (PAHA) from February to August 2016. The PAHA assessed and categorized allergic reactions based on the Gell and Coombs classification scheme. The penicillin allergy history obtained from the patient interviews were then compared to the penicillin allergy history documented in the EMR. Patients unable to give informed consent or hospitalized in the intensive care unit were excluded.

Results: A total of 100 patients were enrolled in the study: 68 female, 32 male, with an average age of 64 ± 17 years. When comparing data obtained using the PAHA to the EMR there was a total of 69 discrepancies: 32 patients had an incomplete EMR history, reporting some but not all symptoms; 19 patients reported different symptoms than what was documented in the EMR; 14 patients had no reaction documented; 2 patients had a penicillin allergy of 'family history' without a personal history; 1 patient had an intolerance inappropriately documented as an allergy; 1 patient confirmed a history of a penicillin allergy but had since tolerated penicillin..

Documentation of the penicillin allergy history was poor across all professions, however, advanced practice providers and nurses had the most accurate entries (40%, 32%).

Conclusion: The majority of the reviewed EMR penicillin allergy histories were inconsistent with the patient interview responses. Implementation of a standardized PAHA to thoroughly and accurately obtain a penicillin allergy history could serve to improve EMR allergy history documentation, which may improve patient outcomes.

Submission Type: Descriptive Report

Session-Board Number: 5a-141

Poster Title: Impact of integration between smart infusion pumps and the electronic health record on related key performance indicators.

Primary Author: Anh Ngo, University of Iowa College of Pharmacy, Iowa; **Email:** anh-ngo@uiowa.edu

Additional Author (s):
John Beyer
Trang Dang

Purpose: Programmable infusion pumps have been in use as early as the 1960s, with modern smart infusion pumps becoming available in the early 2000s. Smart infusion pumps introduced unique safety features; however, the electronic health record (EHR) and smart infusion pumps remained on separate systems without any interoperability. Recently, there has been a focus to close the loop between smart pumps and the EHR, often referred to as 'smart pump integration.' This study examines data from the University of Iowa Hospitals and Clinics, a 700+ bed, 200+ clinic tertiary health system which implemented system-wide integration in June of 2015.

Methods: Data were collected from quarterly reports over a range of 21 months from October 1, 2014 to June 30, 2016. Integration of BD (Becton, Dickinson and Company) CareFusion Alaris smart pumps and Epic EHR (electronic health record) occurred from April 2015 to June 2015, with pilots as early as February 2014. Metrics evaluated include: Total Counter Starts; Total Guardrails compliance (adult, pediatric, and neonatology libraries); Top 5 (drug) Overrides; Guardrails Alerts; and Total Good Catches. Within the Guardrail Alerts, subcategories were broken into: Overrides (All Overrides with Risk, High Risk Overrides, and Overrides Completed in less than 2 seconds); Cancelled Infusions; and Reprogrammed Infusions. The Overrides were also analyzed by drug libraries and types of infusions. The drug libraries include: Adult; Adult High Risk; Pediatrics; Pediatrics High Risk; Neonatology; and Neonatology High Risk. The types of infusions are: Bolus Infusions; Continuous Infusions; Fluid Infusion; Intermittent Infusion; and PCA (patient controlled analgesia) Infusion. Total Good Catches were also analyzed by the drug libraries (Adult, Pediatric, and Neonatology) and by error type: Decimal Point Errors; Double Digit Entry Errors; Rate/Dose Errors; and High Rate.

Results: From January 2013 through June 2016, there were over 9.3 million total counter starts. Out of these counter starts, the Guardrails Compliance was 90% (Adult 91%, Pediatric 85%, Neonatology 88%). The most common top 5 override drugs for every quarter in the 6 quarters were (in no specific order): propofol, oxytocin, 3% sodium chloride, nicardipine, and epinephrine. There were a total of 332,563 Guardrail Alerts across the 3.5-year time period. Out of these, an average of 13% were cancelled infusions, with a downward trend (slope of -0.0017 and R-squared = 0.57) and an average of 6% were reprogrammed, with a downward trend (slope of -0.0027 and R-squared = 0.63) after integration. The overall percentage of non-overridden alerts ranged from 16.0% to 28.6% per quarter. The overall percentage of overridden alerts (average 80.1%) ranged from 71.4% to 84.0%. The percentage of high risk overrides ranged from 3.4-4.4%. Out of the five different types of infusions, intermittent infusions consistently had the highest amounts of overrides. The total amount of good catches for the entire period was 2,333 with a downward trend, slope of -12.57 and R-squared value of 0.49 after integration. The most common type of good catch was decimal point errors.

Conclusion: Overall, pump integration increased guardrail compliance, even with an increase in smart infusion pump utilization. This increase in utilization introduced an increase in alerts, which is expected as drug libraries need to be updated as workflow changes and clinical decisions alter. The total amount of alert overrides increased with utilization. The amount of alerts that were not overridden remained relatively static, regardless of how many overrides. The amount of 'good catches' increases with utilization, but decreases after integration. Further data analysis on alerts and overrides can evaluate additional parameters such as patient units, types of medications, and drug library updates.

Session-Board Number: 5a-142

Poster Title: Could statin use lead to new onset diabetes mellitus?

Primary Author: Jason Bowen, Palm Beach Atlantic University, Florida; **Email:** jason_bowen@pba.edu

Additional Author (s):
Jocelyn Freimuth
Paul Petrillo
Winston Johnson

Purpose: In recent years, statins have been shown to have added benefits as treatment or prevention for many common disease states. At the same time, type 2 diabetes mellitus is also on the rise. A review of these studies is needed in order to determine if there is any harmful correlation between statin use and type 2 diabetes mellitus.

Methods: Retrospective cohort studies were completed in different countries investigating the correlation between statin use and type 2 diabetes mellitus. A review of this literature was completed.

Results: In the Wang et al trial, there were 5,754 cases (13.7%) studied from 1997 to 2009 that developed new onset of diabetes mellitus. The Kaplan-Meir curve showed the use of statins increases the risk of onset of diabetes mellitus with a HR: 1.15; 95% CI: 1.08-1.22, and $p < 0.001$. The results of the Ma et al trial showed 1,360 out of 16,027 of patients (8.5%) studied from 2006 to 2009 developed new onset of diabetes mellitus. With the use of pravastatin (HR: 1.34; 95% CI 1.15-1.55; p—0.0001) and atorvastatin (HR: 1.29, 95% CI 1.16-1.44; $p < 0.0001$), there was an increased risk of new onset of diabetes mellitus. Any association for new onset of diabetes mellitus and the use of simvastatin could not be assessed due to the results not being statistically significant. In the Carter et al trial, there was an association of increased cases of new onset of diabetes mellitus for the use of atorvastatin (HR: 1.22; 95% CI: 1.15-1.29), simvastatin (HR: 1.10; 95% CI: 1.04-1.17), and rosuvastatin (HR: 1.18; 95% CI: 1.10-1.26). Fluvastatin and lovastatin could not be assessed due to the results being statistically insignificant.

Conclusion: After reviewing trials, there seems to be some association between statin use and the development of new onset diabetes mellitus. Yet, because all three trials were retrospective studies, a cause-and-effect relationship between statins and new onset of diabetes mellitus is not clear. However, it is note-worthy that no particular statin showed a consistent association for causing new onset diabetes mellitus. In conclusion, it is in the best interest of health care professionals to monitor glucose and HbA1c levels in all patients taking any statin in hopes of decreasing their risks of developing new onset of diabetes mellitus.

Poster Title: Tearing down the walls: barriers to medication access in urban populations and solutions to bridge the gap

Primary Author: Michelle Li, Ernest Mario School of Pharmacy, Rutgers University, New Jersey;
Email: michelle.li0613@gmail.com

Additional Author (s):
Emily Burd
MIchael Toscani
Joseph Fiore
Paul Weber

Purpose: As of the 2010 United States Census, 80.7 percent of the population lived in urban areas. Globally, in 2014, 54 percent of the population lived in urban areas; both figures continue to rise annually. The purpose of this project was to identify healthcare access issues faced by patients in urban centers, present solutions that healthcare professionals of varying disciplines can implement to address these access barriers, and to evaluate current practices in comparison to the solutions created by an expert panel.

Methods: An initial literature search was conducted to attain background knowledge on barriers to medication access in urban centers in the United States and globally. A panel of interdisciplinary experts was assembled, representative of health policy, nursing, pharmacy, and social work. These panelists were interviewed and probed individually and as a group, with the goal of identifying key issues faced by patients in urban populations. Once key issues were identified, the panel provided its experience that included examples of innovative approaches. The concluding portion of the symposium focused on solutions. It also involved audience interaction with the panel to brainstorm ideas regarding bridging the gap between patients and medication access and adherence.
After the conclusion of the symposium, a more detailed literature search was conducted to identify current practices in urban centers in the United States, with special attention paid to the four pillars identified in the event (Uninsured/ Underinsured Patients, Medication Adherence, Coordination of Care, and the Social Determinants of Health). The literature was then compared to the recommendations given by the expert panelists.

Results: The panelists noted that affordable health services for all immigrants are essential to ensure basic human rights and promote preventive healthcare. In addition, they deemed medication adherence as a major problem in urban areas. Research has shown that communication between physicians and patients is key to increasing adherence. In order to improve, the panelists suggested that counseling on medications at multiple points along the healthcare journey will benefit patients.

The panelists cited that walking the patient to the outpatient clinic increases the likelihood of patients returning for follow-up. A study documenting an inner-city, community-based outpatient health center observed that the group visit format maximized healthcare provider productivity and patient learning, and identified flaws in the current system.

Regarding several social determinants of health discussed, the panelists suggested physician office hours in the evenings and weekends. A study in an urgent care clinic confirmed the most common reasons for seeking care in this setting were extended hours, transportation availability, and, most commonly, appointments were not required. These factors held greater weight than the absence of copay, suggesting income is not the strongest influence in patient access to healthcare.

Conclusion: Following the subsequent literature search, it is evident that the four pillars of barriers identified remain prominent issues in today's urban areas. There are many solutions that can be presented that healthcare professionals of varying disciplines can implement to address these access barriers. Discussion by the expert panel and further research both suggest that change must occur not only in financial coverage but also in the infrastructure of primary care.

Poster Title: Evaluation of over the counter medication knowledge and literacy in middle school and high school students

Primary Author: Tessa Kelly, St. John Fisher College Wegmans School of Pharmacy, NY; **Email:** tck04009@sjfc.edu

Additional Author (s):
Kelly Conn
Allison Bosworth
Matthew Zak

Purpose: Over the counter (OTC) medications are commonly utilized by the public, including adolescents, to self-treat many conditions. Unfortunately, these products can be dangerous if not used safely and appropriately. Adolescents between 13 and 19 years old composed 7.32 percent of the human exposure cases reported to U.S. poison control centers in 2014. Among these cases, there were 53 fatalities involving pharmaceuticals. This is an age range where medication use becomes more independent and the education they receive throughout the school curriculum is unknown. This study was designed to evaluate OTC medication knowledge and literacy among middle and high school students.

Methods: We conducted a cross-sectional study that included a two-part survey completed by middle school (MS) and high school (HS) students in a local school district; MS included grades 7 and 8 and HS included grades 9-12. This study was approved by the institutional review board and consent was indicated by voluntary completion of the survey. Students were presented with the option to complete the survey by their teacher during their physical education class. The survey included demographic questions (age, gender, race, ethnicity, grade, etc.) as well as questions about their medication use for chronic illness and where they receive medication information. To assess OTC medication knowledge and literacy, the survey included two subsections: knowledge and interpretation. The knowledge subsection included questions on brand vs. generic (6 questions), side effects (4 questions), indication (3 questions) and combination use of OTC medications (2 questions) and the interpretation subsection (4 questions) included a reference sheet with two drug information labels. The knowledge section of the survey was distributed and completed separately so that the reference sheet with drug

information labels did not influence answers. Data were analyzed using simple descriptive statistics, as well as chi-square and student t-test for comparative statistics.

Results: A total of 309 students completed the survey. Students were predominantly male (61.4 percent), white (81.2 percent), and non-Hispanic (84.3 percent). The mean age was 14 years (sd 1.8, range 11-18); 46.2 percent were in MS and 53.8 percent in HS. Students reported getting medication information from their doctor (73.1 percent), parents (56.6 percent), pharmacist (41.4 percent) and school (21.4 percent). The percentage of students with correct medication knowledge responses were 17.6 (side effects 7.6, brand vs. generic 18.8, and indication 26.4) and correct interpretation responses were 54.7. 63.2 percent of students did not know it is unsafe to take naproxen and ibuprofen at the same time; 65.2 percent did not know it is unsafe to take two products containing acetaminophen at the same time. When asked specifically if active and brand drug names are different, 60.3 percent of students were not aware (MS 73.6 percent vs. HS 48.8 percent, p-value less than 0.001). Most students (68.5 percent) agreed they always talk to an adult before taking any medication (MS 78.6 percent vs. HS 60.5 percent, p-value less than 0.001). Overall, HS students answered more knowledge and interpretation questions correctly compared to MS students (all p-values less than 0.05).

Conclusion: Our study describes the knowledge and literacy levels regarding OTC medications in a large cross-section of middle and high school students. Overall, students were better at the interpretation of drug labels compared to knowledge-based concepts. It is likely that this population needs additional education and counseling regarding the safe and appropriate management of OTC medications. The information learned from this study is an important foundation for future educational programs aimed at proper use of OTC medications in middle and high school students.

Poster Title: Evaluation of factors leading to inpatient falls in patients with low Hendrich II score

Primary Author: Ruchi Singh, Mass College of Pharmacy and health sciences (MCPHS), Worcester, Massachusetts; **Email:** 0212854@my.mcphs.edu

Additional Author (s):
Kathleen Sullivan
Kevin Nguyen
Hao Nguyen
Abir Kanaan

Purpose: The Hendrich II Fall Risk Assessment (HIIFRA) tool is used at our institution for primary prevention of falls. The tool is utilized upon admission and during hospital stay. A HIIFRA score of 5 or more indicates high risk of falls and requires patients to be placed on falls prevention strategies. However, it was observed that some patients with low fall-risk also receive falls prevention strategies, a practice that is driven by clinical judgement. The purpose of this project was to identify factors that drive clinical judgment to place low fall-risk patients on fall prevention strategies.

Methods: A retrospective review was done on 102 patients, representing 103 falls, who experienced falls while hospitalized between November 2015 and April 2016. The data collected comprised of patient age, gender, past medical history, HIIFRA score upon admission and before the fall time, and whether patients were placed on additional fall prevention strategies. The HIIFRA tool focuses on eight independent risk factors: symptomatic depression, altered elimination, dizziness/vertigo, confusion/disorientation/impulsivity, male gender, any administered benzodiazepines or anti-epileptics, as well as a get-up-and-go test to identify any issues with gait or balance. Each factor is assigned a score, and a HIIFRA score of 5 or more indicates a patient is at high-risk of falls. Hospital policy requires that all patients, regardless of fall risk, are placed on universal fall precautions, which include placing the call button and phone within patient reach, and ensuring the patient's bed is secured in a low position with locked wheels. In addition, it is mandatory that high-risk patients are placed on additional fall precautions, which include a yellow wristband and non-slip socks, and a yellow fall precautions sign placed outside the patient's room, to notify staff of the increased fall risk. If a patient was

placed on additional fall precautions despite a low-risk HIIFRA score, the reason for the intervention was documented.

Results: Upon admission, 46.1 percent of the total 102 patients had a HIIFRA score of 5 or more and were initiated on additional fall prevention strategies, 17.6 percent had a score of less than 5 and were not placed on fall precaution strategies, and 4.9 percent of patients had no HIIFRA data available. Of the 50 patients who scored low, 32 patients (64 percent) were placed on additional fall precaution strategies despite their HIIFRA score. This decision was determined using the clinical judgment of the nursing staff. Of the low-risk patients placed on additional fall precautions, 34.4 percent had a history of previous falls, 12.5 percent experienced extreme generalized weakness, 6.25 percent had hematuria and anemia, 6.25 percent had psychiatric conditions (drug/alcohol abuse or suicidal ideation), and 6.25 percent had altered mental status. Other conditions associated with additional fall precautions included recent surgery, alcohol withdrawal, malignancy, septic shock, and seizure disorders. When comparing these findings to the risk factors of the patients who were deemed low-risk for falls and were not placed on falls precautions, the most common reasons for initiating fall precautions in low-risk patients were a history of falls or recent surgery.

Conclusion: Factors that drive the clinical judgment of the nursing staff to place low fall-risk patients on fall prevention interventions include specific clinical conditions, such as a recent surgery or a history of falls. These characteristics, along with other clinical conditions, are not captured in fall-risk assessment tools such as the HIIFRA, and should be evaluated further in order to accurately identify factors that predispose patients to inpatient falls.

Submission Type: Descriptive Report

Session-Board Number: 5a-146

Poster Title: Development and implementation of a pilot pharmacy home care service with second and fourth year pharmacy students in older adults.

Primary Author: Nahed Elias, Notre Dame of Maryland University, Maryland; **Email:** nelias1@live.ndm.edu

Additional Author (s):
Janet Akinduro
Camron Jenkins
Ki Moon
Michaela Palma

Purpose: The purpose of this study is to describe the development and implementation of the pharmacy home care service conducted by pharmacy faculty members, second year, and fourth year pharmacy students to add to the literature on potential roles and impact of pharmacists in providing care to older adults in the home setting and potential impact on pharmacy student learning outcomes. Pharmacy students, under the supervision of a Clinical Pharmacist followed the Pharmacist Patient Care Process to guide patient-centered care and establish the value pharmacists bring to an interprofessional healthcare team.

Methods: A pharmacist and second-year pharmacy students completed twenty-seven home visits conducting medication reconciliation, patient education, and comprehensive medication reviews. Before each visit, the pharmacy team collected pertinent patient information from the patient's medical chart, assessed medication therapy for appropriateness, and identified potential discrepancies to be addressed during the patient interview. After each visit, clinical interventions and recommendations were documented via a SOAP note that was added to the patient's medical chart and shared with the health care team. The pharmacist followed up regarding the recommendations with the CRNP and RN case manager during weekly rounds.

Results: Twenty-one patients were seen in a three-month period, which consisted of 27 patient encounters. Median number of medications reported per patient were 13 (IQR 10-17) and median number of medication discrepancies identified per patient were 3 (IQR 2-4.5). A total of 146 pharmacy interventions were made, which consisted of the following: 50 therapeutic

interventions, 15 drug information, and 81 patient education interventions. A median of 2 (IQR 1-2) therapeutic interventions were made per patient. Therapeutic interventions requiring provider approval had an acceptance rate of 65%. Total median time spent in providing clinical pharmacy services and coordination of care was reported at 3 hours per patient. Based on overall satisfaction survey results, both patients and pharmacy students involved in the home visits reported high satisfaction rates with pharmacy services provided and learning experiences.

Conclusion: Pharmacy students participated in a service learning opportunity in which valuable knowledge and experiences were gained that enhanced didactic learning. Having seen firsthand the daily struggles that older patients and their caregivers face, the students gained a broader perspective and better understanding of the challenges presented when caring for this population.

Poster Title: Antimicrobial stewardship strategies: Assessing the potential impact of antibiotic de-escalation in an inpatient setting, a current state analysis

Primary Author: Jami Wiley, University of Washington School of Pharmacy, Washington; **Email:** jamik@uw.edu

Additional Author (s):
Job Pan
Zahra Kassamali

Purpose: Antimicrobial stewardship is becoming an increasingly important area in medicine and is now a Joint Commission requirement for all hospitals. One facet of antimicrobial stewardship programs (ASP) is an antibiotic time out (ATO). An ATO is a reassessment of antibiotic therapy after 48 hours. Since bacterial cultures usually return data after 48 hours, the ATO represents an opportunity to tailor therapy to positive cultures, and/or de-escalate antibiotics to a less broad spectrum agent. The objective of this investigation was to evaluate the potential impact of antibiotic de-escalation among patients receiving piperacillin/tazobactam (P/T) empirically for the treatment of respiratory tract infection.

Methods: This was a retrospective, current state analysis, conducted at a 303-bed, acute care community hospital within the Seattle metropolitan area of Washington. IRB approval was not sought as this project was determined to be a quality improvement activity as defined by the Department of Health and Human Services Office for Human Research Protections. We included all adults, at least 18 years old, admitted during the month of January 2016 and received P/T for treatment of respiratory tract infection. Among patients whose antibiotics were de-escalated or not de-escalated from P/T, we compared demographic information, results of respiratory microbiology cultures, and severity of illness defined according to intensive care unit (ICU) admission and CURB-65 score. The primary endpoints were survival to discharge and hospital readmission within 30 days. Secondary endpoints included length of stay, occurrence of Clostridium difficile infection (CDI), and clinical stability, defined by 2007 IDSA community-acquired pneumonia guidelines. Descriptive statistics were used to analyze data.

Results: 51 patients were included; median age was 69 years, 57 percent were male, 63 percent were admitted to the ICU. 34 of 51 (67 percent) patients had antibiotic therapy de-escalated prior to discharge and 17 of 51 (33 percent) patients did not. Median length of P/T before de-escalation was 3 days, and median duration of total antibiotic therapy was 8 days, including inpatient and outpatient prescriptions . The de-escalated group had a higher rate of ICU admission (65 percent vs 59 percent), more patients with procalcitonin level obtained (62 percent vs 38 percent), and were younger (69 years vs 72 years) compared to the non-deescalated group . Median CURB-65 score was 2 in both groups. 79 and 65 percent of patients with de-escalated and non-deescalated therapy respectively, survived to discharge. 15 percent and 6 percent of patients in the de-escalated and non-deescalated groups respectively were readmitted to the hospital within 30 days. No patients developed new CDI. At discharge, 62 percent of de-escalated patients and 59 percent of non-de-escalated patients met criteria for clinical stability. 26 patients (51 percent) had respiratory cultures; 9 (35 percent) were positive: 8 bacterial and 1 viral, none had Pseudomonas isolated.

Conclusion: Overall, de-escalating antibiotic therapy was not associated with increased mortality, however, patients did have a higher rate of readmission. The low rate of microbiologically confirmed infection may indicate non-bacterial and/or non-infectious etiologies. More frequent hospital readmission in the de-escalated group warrants further investigation, particularly regarding patients' co-morbidities and underlying pathology. These data support the need for a targeted antibiotic de-escalation strategy to preserve the function of broad spectrum antibiotics. Our study demonstrates ample opportunities for implementation of ASP strategies at our institution.

Submission Type: Descriptive Report

Session-Board Number: 5a-148

Poster Title: Systematic characterization of pediatric elective courses

Primary Author: Anthony Todd, Auburn University Harrison School of Pharmacy, Alabama;
Email: amt0037@auburn.edu

Additional Author (s):
Frances Hoffman
Emily Olivier
Allison Chung
Lea Eiland

Purpose: As of July 2016, there are 135 U.S.-based colleges and schools of pharmacy with accredited professional degree programs and 3 schools with precandidate status. The 2011 ACPE Accreditation Standards indicate that part of the pharmacy school curriculum must include "Pharmacist-Provided Care for Special Populations," including pediatric patients. Although the 2016 ACPE Accreditation Standards make no specific mention of required special populations, it can be inferred that pediatrics would still be a significant component of the didactic pharmacy school curriculum. The purpose of this study was to systematically characterize various pediatric elective courses currently provided at different schools of pharmacy.

Methods: This was a descriptive study to characterize the various pediatric elective courses provided at different U.S. schools of pharmacy. Pediatric course syllabi, teaching methods, and/or special topics were solicited through three organizational listservs in May 2016. Data was collected by reading and evaluating those syllabi and extracting the following pertinent information: course descriptions, number and types of instructors, evaluation processes, credit hours, hours per week, length of course, estimated out-of-class work/time, prerequisites, student composition, required texts, outcomes/objectives, teaching style/format of course, grade composition, assignment types, unique projects of the courses, and presence of satellite campuses. All data was entered into a secured Google Sheets document. Course syllabi were used to develop a list of common topics related to pediatrics.

Results: Twenty-three pediatric course elective syllabi, email descriptions, research reports, and topic overviews representing 16 schools across 10 states from 2011 to 2016 were evaluated. Faculty composition of the courses varied from one coordinator/instructor (n=4, 17.39%) to multiple coordinators/instructors (n=5, 21.74%) of various combinations. Instructors included clinical pharmacists, physicians, pharmacy residents, and other healthcare disciplines. Course credit hours were typically either 2 credits (n=11, 47.83%) or 3 credits (n=5, 21.74 %); however, not every sample evaluated had credit hour information presented. Major topics of discussion included pharmacokinetics (11/15, 73.33%), common pediatric disease states and disease process (11/15, 73.33%), and drug information/literature evaluation (9/15, 60%). Topics not covered as frequently included ethics and legislation (5/15, 33.33%), pediatric psychiatry (5/15, 33.33%), and neonatal intensive care unit (NICU) concepts (2/15, 13.33%). Unique projects observed include mock patient rounds, clinical debates, and on-site experiences.

Conclusion: Each school had widely varied methods of delivering their pediatric elective courses. Through the data collection, commonalities in major topics covered were found, but there are still discrepancies that should be addressed. Future work includes surveying pediatric course coordinators to gain more specific information regarding their programs where data is lacking. The data obtained through this characterization will allow the various U.S. schools of pharmacy to evaluate their own pediatric course electives as part of their ongoing course development to ensure all students have similar topic and disease state exposure to pediatrics.

Poster Title: Leishmania persistance in immunocompromised patients: an in-vitro model of parasite survival

Primary Author: Cody Traweek, Pacific University School of Pharmacy, Oregon; **Email:** traw6677@pacificu.edu

Additional Author (s):
Breanne Embrey
Cannie Tran
Jasmine Perdeh
Sigrid Roberts

Purpose: Leishmaniasis is caused by over 20 species of Leishmania parasites, most prevalently found in tropical climates. In the United States, a growing number of cases have been reported due to increased international travel to endemic areas. Patients are considered cured of the disease when clinical symptoms are resolved, however, Leishmania parasites can persist after therapy cessation suggesting more effective treatments are needed. The purpose of this study was to develop an in vitro model to explore long-term survival and persistence of Leishmania parasites with the ultimate goal to develop better therapeutic strategies.

Methods: Two case reports were analyzed to better understand the relevance of Leishmania persistence in patients. In addition, a model was developed to study Leishmania persistence in the laboratory using gene deletion mutants unable to synthesize polyamines. Long-term survival experiments were performed to assess whether these parasites were able to subsist in a quiescent-like stage. Mutants were incubated in polyamine- free media and survival was assessed by rescue with polyamine- supplemented media. In addition, cell cycle phase arrest of wild type and polyamine- starved parasites was determined to test our hypothesis that quiescent-like parasites arrest in G1/G0 phase of the cell cycle.

Results: Review of the literature revealed that clinically cured patients could develop leishmaniasis years after initial diagnosis. We generated and characterized polyamine pathway mutants as models for quiescence. Parasites that were not capable of synthesizing the polyamines putrescine and spermidine died within two weeks, while the presence of putrescine

alone enabled parasites to survive for up to 6 weeks. Cell cycle analysis was performed and revealed that while wild type parasites showed 47.8% accumulation in G1/G0 phase, quiescent-like cells exhibited 64.1% accumulation in G1/G0 phase.

Conclusion: Leishmania can establish chronic intracellular parasitism and persist lifelong in the host. In immunocompromising conditions the host no longer has the ability to contain the parasite infection leading to reactivation. We established that polyamine pathway gene deletion mutants could serve as model for quiescent parasites. While mutant parasites died in the absence of both polyamines, the presence of putrescine alone resulted in arrest in G1/G0 phase, typical for quiescent cells. This model can be used to explore the cellular reprogramming in parasites that enables persistence and may ultimately aid in the development of future therapeutic strategies for full parasite eradication.

Poster Title: Evaluation and compliance of the prescription drug monitoring programs (PDMPs)

Primary Author: Roubir Moawad, Marshall University school of pharmacy, West Virginia; **Email:** moawad1@marshall.edu

Additional Author (s):
Tyler Flaugher
Raice Stevens
Tenzin Norzin
Shekher Mohan

Purpose: Prescription drug abuse is among the fastest-growing drug problems in the nation. Prescription Drug Monitoring Programs (PDMPs) have been implemented to track controlled substances prescribed by authorized practitioners that is dispensed by pharmacies. PDMPs help providing early warning signs of drug epidemics and detecting drug diversion. The purpose of this study is to evaluate the compliance and opinions of practicing pharmacists on the PDMP in West Virginia and the Tri-State (Kentucky and Ohio) area. The data collected from this project seek to provide recommendations that could be used to help improve compliance and ease the use of the PDMP programs.

Methods: Board certified pharmacists were invited to complete an online survey created in Qualtrics (licensed by Marshall University) to evaluate their current compliance and opinions of the PDMP in their state that is used to track controlled substances prescribed by authorized practitioners and dispensed by pharmacies. Non-practicing pharmacists were excluded from the study. Respondents were asked their gender, age, ethnicity, primary state of practice, years of experience as a pharmacist, current role, how many prescriptions are dispensed daily, whether if they have access to the state PDMP program or not, and questions to assess their opinions, level of compliance and finally any recommendations on how to improve their state PDMP program. All data were collected, recorded, de-identified and analyzed directly onto a secure password protected data sheet built within Qualtrics. Descriptive statistics were used to analyze the results. The project was approved by the IRB prior to the deployment of the survey to collect the data.

Results: All the respondents (66) stated that they have access to their state's PDMP but only 92 percent have access on terminals where they process prescriptions. The results showed that 92 percent indicated that PDMP programs helped them identify issues with control substances prescriptions. The majority of respondents (85 percent) agreed that PDMP helps in the reduction of control substance abuse. Using Likert scale survey items, respondents were asked about the barriers of the program. Most of the respondents (32 percent) stated that the PDMP is inconvenient while only 8 percent said that it was very convenient. The majority of the respondents (82 percent) thought that the program need some to significant improvement in the completeness aspect. Accuracy comes as a close second to be improved. Asking the participants for when to use the program; over 80 percent indicated that they should always check in cases that involve patients with multiple providers in the last 3 months, out of town or unfamiliar prescribers and potential signs of abuse and diversion. The recommendations from the participants almost took the same theme which is to have the system integrate between all states and include updates in real time.

Conclusion: Prescription Drug Monitoring Programs are very valuable tool to help prescribers and pharmacists track control substance use, which in turn assists with the efforts to decrease abuse of control substances. The findings of the study provide evidence to suggest the importance and effectiveness of the PDMPs in preventing drug abuse and verifying prescriptions to differentiate between prescriptions that are prescribed for legitimate medical use. These programs allow patients to fill controlled substance prescriptions for legitimate uses.

Poster Title: Does insurance type alter the pharmacy-based health system resources required to access 17 alpha-hydroxyprogesterone (17OHP), a women's health specialty medication?

Primary Author: Nitya Simon, University of Illinois, Chicago College of Pharmacy, Illinois; **Email:** simon18@uic.edu

Additional Author (s):
Tracy Souvannasing
Rebekah Hanson
Rebecca Stone

Purpose: Specialty medications are those requiring special handling, administration, or monitoring, and are usually high cost. Specialty medications require health system resources to overcome access barriers such as prior authorizations. Delay in access to time-sensitive specialty medications, such as 17 alpha-hydroxyprogesterone (17OHP) for prevention of preterm birth, may be detrimental to patient care. Pharmacists and pharmacy students are pharmacy-based health system resources, and often play a vital role in acquiring specialty medications. This study investigates variance in utilization of pharmacy-based health system resources required among different insurance types to access 17OHP.

Methods: This retrospective cohort evaluation includes patients prescribed brand 17OHP (Makena®) for prevention of preterm labor at the University of Illinois at Chicago between September 1, 2013 and April 1, 2016. Patients were identified by 17OHP administration records. Pharmacist or pharmacy student interventions were documented as standard 17OHP ordering procedure, and included submission of prior authorization(s) and communication with healthcare staff. Primary outcomes include the number of interventions over a therapy course. Secondary outcomes include number of days from ordering to 17OHP initiation. Data was extracted from 17OHP pharmacist ordering records and the electronic medical record using a Redcap standardized data collection sheet. SPSS software was used for descriptive statistics and ANOVA analysis.

Results: A total of 152 patients were evaluated; 63 (41 percent) were insured by traditional Medicaid, 60 (39 percent) were covered under a Medicaid managed care organization (MCO), and 29 (20 percent) had non-Medicaid insurance. There was a difference in the total number of documented interventions between groups (mean 11.7 plus and minus sign 5.0, versus 11.9 plus and minus sign 5.2, versus 14.7 plus and minus sign 4.0, P equals 0.021). No difference was found between the groups in days to 17OHP initiation (mean 15.1 plus and minus sign 14.3, versus 17.0 plus and minus sign 16.6, versus 17.6 plus and minus sign 7.4, P equals 0.677).

Conclusion: The number of pharmacist or pharmacy student interventions is a surrogate marker for the pharmacy-based health system resources required to overcome access barriers associated with 17OHP. Significantly more pharmacy based health system resources were required to access of 17OHP for non-Medicaid insurances compared to traditional Medicaid and MCOs. While non-Medicaid insurance required more interventions to access 17OHP, number of days to initiation remained consistent between the groups.

Submission Category: Infectious Diseases

Submission Type: Evaluative Study

Poster Title: Multi-year evaluation of fidaxomicin use for treatment of Clostridium Difficile Infection at a community hospital

Primary Author: Michelle Vu, Mercer University College of Pharmacy, Georgia; **Email:** michelle.vu@live.mercer.edu

Additional Author (s):
Bobby Jacob
Samuel Peasah
Angela Shogbon
Adam Bressler

Purpose: Clostridium difficile infection (CDI) is one of the most common etiologies of hospital-acquired infection. Current guidelines from the Infectious Disease Society of America and American College of Gastroenterology recommend first-line treatment with metronidazole or oral vancomycin depending on severity of infection. Fidaxomicin was approved for treatment of CDI in 2011 based on studies demonstrating non-inferiority to oral vancomycin. The objective of this study was to evaluate the characteristics and the use of fidaxomicin for treatment of patients with suspected CDI at a community hospital.

Methods: This was a retrospective, observational study of adult patients admitted to a community hospital from November 2011 to June 2015 who received a charge for fidaxomicin 200 mg twice daily. Prescribing of fidaxomicin at the hospital was restricted to the infectious disease and gastroenterology services. Data collected included baseline demographics, admission diagnoses, past medical history, risk factors for CDI, onset of diarrhea, C. difficile laboratory test results, number of stools, white blood cell count, serum albumin, prior treatment regimens for CDI, response to fidaxomicin, and use of concomitant antibiotics, excluding agents to treat CDI. Risk factors for CDI included age, duration of hospital stay, past and current exposure to antimicrobial agents, exposure to chemotherapy, immunosuppression, gastrointestinal surgery, tube feedings, and use of proton pump inhibitors or histamine-2 antagonists. Clinical outcomes evaluated were resolution of diarrhea symptoms as noted by nurse documentation, re-admission at day 90 post-discharge, and recurrence of CDI defined as re-admission to the hospital within 90 days with a diagnosis of CDI. Institutional Review Board

approval was obtained from the study institution and Mercer University. Data collected from our study were analyzed utilizing the Statistical Analysis System (SAS) version 9.4 and summarized using descriptive statistics.

Results: A total of 102 patients were evaluated, including 40 patients who received fidaxomicin as initial therapy and 61 patients who received fidaxomicin after receiving another agent for initial CDI therapy. Risk factors for CDI included prior antibiotic use (80 percent), home use of acid suppressive therapy (52 percent), age greater than 65 years (50 percent), and prior hospitalization in past 90 days (50 percent). Thirty-eight patients were categorized as mild or moderate (37 percent), 24 patients as severe (24 percent), 5 as severe and complicated (5 percent), and 25 patients as recurrent (25 percent). Ten patients were uncategorized due to insufficient lab data (10 percent). The average length of hospital stay was 20 days and average duration of fidaxomicin therapy was 5.4 days. Sixty patients (59 percent) received previous oral metronidazole (26 percent), oral vancomycin (41 percent), or both (8 percent). A total of 41 patients (40 percent) had resolution of diarrhea symptoms during the hospital stay. Forty-four patients (43 percent) were readmitted to the hospital within 90 days of discharge with 8 of these patients having recurrent CDI (8 percent of total).

Conclusion: These findings support a potential role for fidaxomicin in the treatment of patients with CDI admitted to the community hospital. Opportunities for improvement in quality of care exist as evidenced by the relatively low response to therapy compared to clinical trials; however, CDI recurrence was lower than national rates, and all-cause re-admission comparable to national rates. Extensive length of stay may be driven by CDI severity, with the majority categorized as either severe or recurrent. Further research is warranted to study factors that predict positive clinical response to fidaxomicin as initial and alternate therapy for CDI.

Poster Title: Assessing the health care student's perceptions and attitudes of pharmacy and interprofessional education at student-run free clinics

Primary Author: Liza Vo, Midwestern University College of Pharmacy - Glendale, AZ, Arizona; **Email:** lvo96@midwestern.edu

Additional Author (s):
Maduni Hemachandra
Richard Herold
Andy Huynh
Nicole Early

Purpose: One method to improve the healthcare system in the United States it by facilitating collaboration through interdisciplinary teams. This starts with interprofessional education which can range from modules to clinical experience, with the latter shown to be more impactful. While student run free clinics can provide valuable clinical and interdisciplinary experience, there is a lack of a clear distinction of roles within these clinics, particularly for pharmacy students. This study assessed perceptions and attitudes of pharmacy and non-pharmacy students towards interdisciplinary healthcare and the role of pharmacists at student-run clinics after pharmacy roles had been clearly delineated.

Methods: The Institutional Review Board approved this cross-sectional study which was conducted at two homeless shelters in Central Phoenix, Arizona from 2015 to 2016. Midwestern University student volunteers signed an informed consent and completed surveys before and after attending student-run free clinics. At each clinic, pharmacy students were assigned to an interdisciplinary team with students from the following disciplines: osteopathic medicine, physician assistant, dental, and physical therapy. All student volunteers were verbally instructed about their responsibilities for the clinic. Pharmacy students were specifically provided with a comprehensive list of goals to guide them through each patient encounter. Interdisciplinary teams were assigned patients to complete a non-invasive work-up, formulate an assessment, and propose a treatment which was presented to physician and pharmacy preceptors. These specific instructions included acquiring the patient's list of current medications, their allergies and reactions, checking for any disease and drug interactions,

presenting the patient case and assessment to the pharmacy preceptor, and appropriately counseling for medications dispensed. Survey questions utilized a five-point Likert scale to assess the student's attitudes and perception of general interdisciplinary health care and to assess the role of pharmacists in interdisciplinary health care. Pre and post surveys were matched by a unique identifier and compared using Wilcoxon signed-rank and Mann-Whitney U tests.

Results: A total of 141 students were surveyed but 23 students were excluded for incomplete surveys, resulting in a total of 76 non-pharmacy students and 42 pharmacy students with data for analysis. Surveys responses from non-pharmacy disciplines were made up of 67.1 percent of Doctors of Osteopathic Medicine students, 15.8 percent Physician Assistant students, 14.4 percent Occupational Therapy students, and 2.6 percent Nurse Anesthetist students. Baseline opinions regarding the benefits of overall interdisciplinary experiences were more positive with pharmacy students compared to the non-pharmacy students in both the pre and post surveys. Both pharmacy and non-pharmacy students showed statistically significant improvement in opinions regarding the use of interdisciplinary teams to maintain enthusiasm in careers (p equals 0.002 and 0.011 respectively) and to better meet the emotional and financial needs of patients (p equals 0.007 and less than 0.001 respectively). When comparing the perceptions of non-pharmacy students who worked with pharmacy on their team during clinic to those who did not, there was a statistically significant improvement in opinion regarding whether or not having pharmacists or pharmacy students on the team improves the quality of healthcare (p equals 0.024).

Conclusion: Both the use of student run free clinics and delineation of specific roles of each discipline are beneficial in improving attitude and perception towards interdisciplinary teams and also of the role of pharmacists in health care. By improving the attitudes and perceptions, we can promote and facilitate better collaboration in interdisciplinary teams to improve the quality of health care delivery to patients. Additionally, early collaboration in a student's interdisciplinary education can help with promoting the profession of pharmacy to provide more comprehensive, and consistent high-quality care.

Submission Category: Leadership

Submission Type: Descriptive Report

Session-Board Number: 5a-154

Poster Title: Cultivating leaders in pharmacy: a leadership development program for pharmacy students

Primary Author: Cynthia Cheung, Rutgers University Ernest Mario School of Pharmacy, New Jersey; **Email:** cynthiacheung94@gmail.com

Additional Author (s):
Kenneth Hu
Lucio Volino

Purpose: Although participation in pharmacy organizations is common for students, leadership positions tend to be held by more senior students rather than entry level or junior students. In addition, pharmacy students may not be presented with many overall opportunities to formally develop leadership skills throughout pharmacy programs. Our NCPA chapter designed the Leadership Development Program (LDP) which provides participants with structured workshops related to essential leadership skills. The purpose is to expose entry-level and junior students to the various facets of becoming a leader earlier in their pharmacy education while continuing to develop students in executive leadership roles.

Methods: Each fall, NCPA's Professional Affairs coordinator informs potential participants, first pre-professional (PP1), second pre-professional (PP2), and first professional (P1) students, about the LDP program via Facebook and email. The program is promoted at the pharmacy school's involvement fair and during the organization's General Interest Meeting. An application for the program is released to students online. Students may submit their applications over a period of ten calendar days. The application gathers information regarding students' participation interests, their desired learning outcomes from the program, and committee preferences (Legislative Affairs, Business Plan, Public Relations, Fundraising, Professional Affairs, Social, and Patient Care). The committee coordinator serves as a mentor to one or two applicants (mentees). Mentees are invited to the program at the discretion of the Professional Affairs coordinator, who looks for specificity and maturity in applicants' responses. In collaboration with the coordinator, the mentee must draw up an outline for an event that is relevant to the committee. The mentee will be responsible for executing their plan in the spring semester. Formal development of leadership skills occurs through the Professional Affairs

committee's initiatives. The Professional Affairs coordinator designs workshops which target specific leadership skill sets, such as public speaking, networking, CV building, interviewing, and professional dressing. Mentees are required to attend each workshop. The program concludes with a golfing lesson to expose mentees to an active networking skill.

Results: In the 2015-2016 program year, eighteen LDP applications were received from six PP1s, seven PP2s, and five P1s. A total of 12 students (66.7%) were selected as LDP mentees: four PP1s (33.3%), five PP2s (41.7%), and three P1s (25%). Each committee coordinator was assigned two mentees with the exception of the Social and Public Relations committees, which only received one mentee each. Five 2-hour leadership-based workshops were held from November through April, and were led by three post-doctoral fellows and two faculty members. Interactive sessions followed each lesson to allow students the opportunity to practice the skills they learned. These included four public speaking exercises, two-minute rounds of speed-networking between mentees, mentors, and fellows, CV critiques, followed by a five-minute mock interview with two mentors, 20 examples of business appropriate and inappropriate attire, and a golf lesson and practice session at a driving range. Upon completion of the program, participants have expressed that the experience taught them many valuable lessons and improved their overall self-confidence. Many of these students have subsequently served on executive boards and committees in numerous other organizations, including 13 of 22 (59.1%) executive board and committee members of NCPA for 2016-2017.

Conclusion: Students who have participated in the LDP gained experience in public speaking, networking, CV building, interviewing, professional dressing, and golfing. These opportunities may not have been available to them otherwise. Through structured workshops and programs, less experienced PP1, PP2, and P1 students learned and applied skills to enhance their involvement in leadership opportunities while seasoned leaders further developed their leadership and mentoring skills. The LDP model can be utilized by other schools of pharmacy interested in further developing their current and soon to be leaders.

Poster Title: Impact of the addition of a clinic pharmacist on the safety of heart failure and heart transplant patients

Primary Author: Jessica Man, Midwestern University Chicago College of Pharmacy, Illinois; **Email:** jman76@midwestern.edu

Additional Author (s):
Michelle Fine
Nichole Melody
Farah Barada

Purpose: Heart failure and heart transplant medication regimens are complex and put patients at a high risk for readmission after discharge. A multidisciplinary approach is vital in preventing medication errors, lowering hospital re-admission rates, and improving patient outcomes. A pharmacist was added to a cardiology clinic with the aim of improving heart failure and heart transplant patient safety and improving patient's baseline knowledge about their disease state. This study is designed to identify these safety interventions and to serve as a framework for other clinics wishing to initiate a pharmacist for the care of patients with heart failure and heart transplant.

Methods: This was a retrospective observational study that evaluated patients followed in an outpatient cardiology clinic from November 2015 to July 2016. The clinic pharmacist documented encounters with patients in the electronic medical record. Patient encounters were defined as any interaction with the patient, including telephone calls after discharge, office visits alongside an attending physician or advanced practitioner, one on one office visits with the patient and pharmacist for medication therapy management, assistance with access to medications, and clinical questions/consults. Clinic and telephone encounter notes were extracted using the clinic's electronic medical record. The types of patients evaluated by the clinic pharmacist included recently diagnosed, highly symptomatic, and potentially non-compliant heart failure; advanced heart failure with a ventricular assist device; and patients who received a heart transplant. The safety of patients was evaluated by analyzing data on pharmacist documented services including medication reconciliation, disease state and medication education, clinical recommendations, and aid with patient access to medications

including prior authorization, refills, and lower-cost options. Additionally during a transitional care phone call, the pharmacist identified and resolved medication discrepancies after hospital discharge. A medication discrepancy was defined as the patient taking a medication differently from the discharge instructions.

Results: A total of 658 patients were included in the 9 month study, accounting for 1,549 patient encounters, averaging 9 encounters per day. Thirty-seven percent of the encounters were office visits with heart failure patients recently discharged from the hospital or during routine follow up. The breakdown of the remainder of patient encounters conducted by the clinic pharmacist included ventricular assist device clinic visits, 23 percent; transitional care telephone calls to patients after hospital discharge, 17 percent; assistance with access to medications,10 percent; heart transplant evaluations and post transplant office visits, 6 percent; medication therapy management, 5 percent; and clinical questions/consults, 2 percent.

During these 1,549 patient encounters the pharmacist contributed to the safety and education of the patients. The majority of safety interventions included medication reconciliation, which occurred during 1,206 encounters. Pharmacist assistance with access to medications and care occurred 770 times. The pharmacist educated patients on medication and disease management in 518 encounters and made 503 clinical recommendations on guideline directed medical therapy and monitoring. Starting in January 2016, the pharmacist called 260 patients recently discharged from the hospital during a transitional care call. The pharmacist resolved at least one medication discrepancy in 85 patients during the phone calls.

Conclusion: The addition of a pharmacist in a clinic setting resulted in a substantial number of clinical interventions and the resolution of a number of medication discrepancies from discharge. The pharmacist was also able to provide medication therapy management, education, and assistance with access to medications. This is the first observational study of its kind to describe the impact of a clinic pharmacist on the care of patients with heart failure, left ventricular assist device, and heart transplant. This study may serve as a framework for other pharmacists wishing to initiate a cardiology clinic for the safety of this patient population.

Session-Board Number: 5a-156

Poster Title: Impact of sleeve gastrectomy on psychiatric medication use

Primary Author: Kristen Russo, University at Buffalo School of Pharmacy and Pharmaceutical Sciences, New York State; **Email:** kmrusso2@buffalo.edu

Additional Author (s):
Esra Mustafa
Joseph Caruana
Scott Monte

Purpose: Sleeve gastrectomy (SG) is the most common surgical intervention for obesity in the U.S. The SG involves removal of 80 percent of the stomach without manipulation of the intestinal tract. It is thought medications are not significantly altered with SG. Given that about 56 percent of obese subjects presenting for surgery have comorbid psychiatric diagnoses, it is of interest to determine symptom change and medication use after SG. Therefore, the primary objective is to identify patient reported perception of change in anxiety and depression symptoms after SG. The secondary objective is to identify medication use and relationship to symptom change.

Methods: The protocol was approved by the State University of New York at Buffalo Institutional Review Board. Subjects with anxiety or depression diagnoses treated with medication at the time of SG were retrospectively identified from medical records of a bariatric surgery center in Buffalo, NY. Phone outreach to eligible subjects was made by the study investigators to complete a seven-point global impression of change scale that classified symptoms as very much worse, much worse, minimally worse, minimally improved, much improved, very much improved, and those having no change. Symptom improvement was defined as either all reported symptoms improving or at least one symptom improving while the remaining were unchanged. The same criteria were applied for worsening. A mixed profile was established if at least one symptom improved and one worsened. No change required the same profile before and after surgery. Antianxiety and antidepressant medication changes were identified during subject interview and verified by electronic medical records. Medication changes were categorized as no change, discontinued, decreased or increased. Results are presented descriptively as the percentage change from the pre-surgery baseline.

Results: 43 subjects completed telephone survey. 17 diagnosed with anxiety were on benzodiazepine, SSRI or combination therapy. 13 (75 percent) had no change in therapy. 3 (18 percent) decreased use. 1 (6 percent) increased. Symptoms were unchanged in 1 (6 percent), improved in 9 (53 percent), worsened in 2 (12 percent) and mixed in 5 (29 percent). When symptoms improved the same dose was present in 6 of 9 cases (67 percent), dose decreased in 2 (22 percent), and dose increased in 1 (11 percent). The 2 cases of symptom worsening came while on the same dose. 42 subjects diagnosed with depression were on SSRI, SNRI or combination therapy. 30 (70 percent) had no change in therapy while 8 (19 percent) discontinued, 2 (5 percent) decreased, and 1 (2 percent) increased. Symptoms were unchanged in 2 (5 percent), improved in 29 (70 percent), worsened in 3 (6 percent), and mixed in 8 (19 percent). When symptoms were improved the same regimen and dose was present in 21 of 29 cases (72 percent) and discontinued in 6 (14 percent). The 3 cases of worsening included 2 (67 percent) where medication was discontinued and the third a dose increase (33 percent).

Conclusion: Anxiety symptoms improved in over 50 percent of subjects. 75 percent had no therapy change. Symptom improvement came predominantly at same or reduced doses. In 12 percent of cases worsening dose was the same. Depression symptoms improved in 70 percent. 70 percent had no therapy change. Symptom improvement came predominantly on same regimen and doses. In 7 percent of cases worsening medication was discontinued in 66 percent. These data indicate a majority will have symptom improvement while on the same anxiety or depression regimen and implicates benzodiazepines and SSRIs are not likely to have clinically significant pharmacodynamic alteration after SG.

Session-Board Number: 5a-157

Poster Title: Concomitant Opioid and Benzodiazepine Use: A Systematic Review

Primary Author: Kassie Pfluger, University of North Texas System College of Pharmacy, Texas;
Email: kassie.pfluger@my.unthsc.edu

Additional Author (s):
Annesha White
Kimberly Vernachio

Purpose: In opioid users, the concomitant use of a benzodiazepine medication is associated with an increased risk of adverse reactions and overdose due to the synergistic effects on sedation and respiratory depression. The degree to which adverse events and overdoses occur is unclear when assessing patient characteristics, dosage and formulation. This study primarily sought to assess the prevalence of an adverse event or death after concomitantly taking an opioid and benzodiazepine prescription medication and to determine whether there is an impact on the formulation, dosing, or administration of the medication in overdose.

Methods: A review of the literature was performed using the following databases: PubMed, PsycINFO, The Cochrane Library, and Scopus for peer-reviewed journal articles in English to identify studies regarding concomitant benzodiazepine and opioid medication overdose in adolescents and adults for non-cancer pain through August 2016. Relevant publications and their reference lists were reviewed to assess for inclusion criteria based upon relevance and quality. Applicable publications were reviewed and included if outcomes of patients were clearly documented by medication use. Information on the study design, sample characteristics, purpose of study, intervention components, primary outcome, key findings and risk of bias were abstracted for each article and presented in a table. Articles were excluded in the review if concomitant use of benzodiazepine and opioid analgesic use was not clear or intentional suicide was indicated as cause of mortality. Key search terms utilized were: 'opioid analgesic', 'benzodiazepine', 'non-cancer pain', 'substance-related disorders', 'polypharmacy', 'co-prescribing', 'illicit use', and 'overdose'.

Results: Of the 1,098 reviewed articles, 11 were included in this systematic review and are presented in the summary of findings table. Relevant studies assessed morbidity and mortality associated with opioid and benzodiazepine use, incidence of non-prescribed medications or illicit drug use, and descriptive information on patient populations of greatest risk of overdose. Common reasons for not selecting a particular article were due to study design and incomplete information of medications within each class.

Conclusion: The prevalence of opioid and benzodiazepine misuse and abuse has warranted international attention due to the increased overdose risk with concomitant use. More information is needed regarding dosing, formulation, and particular agent for opioids and benzodiazepines. Assessment of mortality risk is lacking when comparing acute versus chronic drug users and abusers. The incidence of overdose increases as potency increases or when an illicit agent is included due to the central nervous system (CNS) depressant effects.

Poster Title: Evaluation of aspirin utilization in a psychiatric facility

Primary Author: Kaitlyn Victor, University at Buffalo School of Pharmacy and Pharmaceutical Sciences, New York; **Email:** kaitlynv@buffalo.edu

Additional Author (s):
Megan Skelly
Kimberly Mulcahy
Tammie Lee Demler
Eileen Trigoboff

Purpose: Aspirin therapy may be indicated in certain adults for the primary prevention of cardiovascular disease (CVD); however, previous studies have shown inappropriate aspirin utilization, by either over or under prescribing for this indication in select samples. Our primary objective was to determine if aspirin utilization for primary prevention of CVD and if prescribing habits in a state psychiatric facility were appropriate, as previous research does not address utilization in this special subpopulation. Further objectives included quantifying the prevalence of drug interactions with aspirin and the number of bleeding events in patients prescribed aspirin.

Methods: Our Institutional Review Board of record, New York State Psychiatric Institute, approved this study. All inpatient medical charts were reviewed for patients ages 50 to 69 years and those prescribed aspirin during their hospitalization at the Buffalo Psychiatric Center between April 1, 2016 through August 31, 2016. Patients were excluded if they were prescribed aspirin for any indication other than primary prevention of CVD (such as secondary prevention of CVD or pain/fever), if they were hospitalized under a criminal procedural law status, or if their medical records had incomplete laboratory information or past medical history. Aspirin eligibility was based on patients' 10-year risk for atherosclerotic cardiovascular disease (ASCVD) score and the 2016 recommendations from the U.S. Preventive Task Force. A drug interaction report was conducted utilizing Clinical Pharmacology database for individuals being prescribed aspirin for primary prevention of CVD. Drug interactions between aspirin and concurrently prescribed pharmacotherapy were then classified based on severity, and past bleeding events were quantified.

Results: Ninety-six patients met the inclusion criteria for the study. Results indicated that 25 patients would benefit from aspirin therapy based on the calculated ASCVD 10-year risk scores; twenty-two (88 percent) of which were not prescribed aspirin. The remaining 71 patients did not meet criteria for aspirin therapy; fourteen (19.7 percent) were taking aspirin regularly without indication. A total of 17 patients were taking aspirin during the selected time period, and all were concurrently prescribed other medications; therefore, the potential for drug interactions was possible for 100 percent of this sample at some level. Of the total 65 interactions discovered, 10.8 percent were major, 87.7 percent were moderate, and 1.5 percent were minor interactions. For those 17 patients on aspirin therapy, there were no gastrointestinal bleeding episodes or hemorrhagic strokes documented.

Conclusion: Aspirin utilization requires individualized treatment and monitoring, especially in a psychiatric population where polypharmacy is often ubiquitous. Underutilization of aspirin was more prevalent in our psychiatric institution than overutilization. Overutilization did not pose a serious risk for those on aspirin therapy in this sample, as there were no major episodes of bleeding. However, future harm from aspirin still exists based on the high number of major and moderate potential drug interactions with aspirin (98.5 percent). The impact of our findings demonstrates that polypharmacy for multiple disease states affects patient safety.

Poster Title: Tissue plasminogen activator (tPA) dosing for catheter occlusion in pediatric patients at a large academic medical center

Primary Author: Erin Barthelmess, West Virginia University School of Pharmacy, West Virginia; **Email:** ebarthel@mix.wvu.edu

Additional Author (s):
Lisa Garavaglia

Purpose: Tissue plasminogen activator (tPA) is a thrombolytic protein involved in the lysis of blood clots. While the adult dose for catheter occlusion has been well established, recommended dosing for pediatric patients < 30kg remains challenging due to dose calculation based on catheter volume. The primary objective of this study was to evaluate a tPA dosing guideline in pediatric patients less than 30kg at West Virginia University Medicine Children's Hospital. The secondary objectives were to determine the number of patients that did not follow the guideline, and to describe these doses as being higher or lower than advised.

Methods: This is an Institutional Review Board approved retrospective study. Electronic medical records were used to generate a report of 36 pediatric patients that received tPA for catheter occlusion in a seven-month time frame. Patients that were less than 30 kg, less than 18 years of age, and received alteplase for the treatment of catheter occlusion were eligible for inclusion. Exclusion criteria included patients that had a venous access device without French size and/or length of insertion recorded. Data collected included age, weight, medical service, dose of alteplase given (in mLs), catheter type and size, and total number of doses of alteplase given. Descriptive statistics were used to determine the primary outcome.

Results: Guidelines for tPA dosing were followed 77.8% (28 out of 36) of the time. Of the 8 patients that the guideline was not followed, 100% of the doses prescribed were higher than guideline recommendations. Of the 28 patients where guidelines were followed, 89.3% (25 out of 28) of tPA doses were considered successful at resolving catheter occlusion after the first dose. Three out of 28 patients (10.7%) required a second dose for catheter occlusion resolution. These guidelines were implemented shortly prior to data collection. There was a decreasing amount of noncompliance to protocol as time elapsed, with 50% (6 out of 12) not following

protocol in the first three months of the study, versus 8.3% (2 out of 24) noncompliance in the last four months.

Conclusion: At West Virginia University Medicine Children's, we were compliant with our new tPA dosing guideline 77.8% of the time. When the guidelines were followed, 89.3% of doses were effective in restoration of access to catheters after the first dose. After implementation, there was incomplete physician and provider buy in due to lack of confidence in the small doses requested by the guidelines. This data suggests that the guideline implementation is becoming more accepted amongst these providers, and the doses of tPA stated by the guideline are effective in treating catheter occlusion.

Poster Title: Evaluating the continued use of stress ulcer prophylaxis medications after pediatric intensive care unit transfer

Primary Author: Adam Reeb, The Ohio State University College of Pharmacy, Ohio; **Email:** reeb.45@osu.edu

Additional Author (s):
Jenny Mason

Purpose: Proton pump inhibitors and H2 receptor antagonists are commonly used in the pediatric intensive care unit (PICU) for stress ulcer prophylaxis. Currently there are no specific pediatric guidelines for stress ulcer prophylaxis indication while in the PICU. These medications are often continued unnecessarily once patients transfer out of the PICU and can even continue at hospital discharge. The purpose of this study was to evaluate the frequency of PICU patients receiving stress ulcer prophylaxis beyond PICU transfer and at hospital discharge. The potential cost burdens to both the hospital and patient were also calculated.

Methods: This was a randomized, retrospective chart review of patients admitted to the Nationwide Children's Hospital PICU from January through April 2016 for stress ulcer prophylaxis who were prescribed either oral or intravenous ranitidine, omeprazole, or pantoprazole. Patients were excluded if one of these medications were a home medication at time of admission. Baseline demographics were collected as well as dates and times for medication discontinuation, PICU transfer, and hospital discharge. Discharge prescription information was also collected. This study underwent the institutional review board and was deemed exempt.

Results: Out of these 138 patient encounters, 35 encounters were excluded due to one of these medications being listed as a home medication at the time of their hospital admission, leaving 103 patient encounters to be evaluated. Indications for those continued on therapy beyond PICU transfer included 66 percent for stress ulcer prophylaxis, 3 percent for gastroesophageal reflux disease, 2 percent for gastritis, 2 percent for emesis, and 27 percent for unknown indications. Furthermore, 24 percent of those continued on therapy were discharged from the hospital with a prescription for a stress-ulcer prophylaxis medication. Therefore, 14 percent of

patients started on stress ulcer prophylaxis during their PICU admission were continued on therapy at hospital discharge. Estimates for potential patient costs for one extra patient-day of unnecessary therapy for an entire year were calculated using a 70 kg patient and initial starting doses. Yearly patient cost for ranitidine therapy would be about 4,600 dollars for oral therapy and 97,000 dollars for intravenous therapy. For oral omeprazole, this would be about 2,700 dollars per year for capsules and 6,400 dollars for liquid. Lastly, Intravenous pantoprazole would be 36,000 dollars per year.

Conclusion: Results showed that a significant amount of patients are transferred out of the PICU on stress ulcer prophylaxis. Unnecessary use of these medications can be associated with increased risk of adverse events, as well as increased cost burdens to both the patient and the hospital. Therefore, it is important that practices and protocols are put in place to decrease the occurrence of the continued use of these medications beyond PICU transfer if not indicated. Further studies could include implementation of a stress ulcer prophylaxis protocol in the PICU, outpatient medication cost, and pharmacist intervention at PICU transfer.

Submission Type: Evaluative Study

Session-Board Number: 5a-161

Poster Title: Factors influencing fourth year pharmacy student pursuit of research

Primary Author: Keri DePatis, Midwestern University Chicago College of Pharmacy, Illinois; **Email:** kdepatis31@midwestern.edu

Additional Author (s):
Milena McLaughlin
Kathleen Vest

Purpose: There are limited studies regarding pharmacy students' perception of and attitudes towards participating in research. Identifying factors that influence students' pursuit of research opportunities and perceived barriers to pursuing these opportunities may help pharmacy faculty successfully guide students to appropriate research experiences. Information is also lacking as to the best time during pharmacy school to introduce research projects to pharmacy students. The purpose of this study was to identify the factors that influence students to pursue research.

Methods: A voluntary paper-based questionnaire regarding factors that influence students to pursue research opportunities (n=15 questions) as well as demographic information (n=10 questions) was distributed to all fourth year pharmacy students during a mandatory class meeting on two occasions. A cover letter included with the survey served as a consent form and assured confidentiality as results were to be reported on the aggregate. Names or identifying information were not collected. Each student received a $5 Starbucks gift card when turning in their survey. This study was approved by the Institutional Review Board at Midwestern University.

Results: One hundred and sixty 4th year pharmacy students completed the survey (80%). The average respondent was female (n=107, 67.3%) 25 years old (IQR 24-27 years), employed (n=115, 72.8%), and entered pharmacy school with a prior degree (n=104, 65.4). Forty-four percent (n=70) pursued a research project while in pharmacy school. Of the 89 students that did not pursue a research project during pharmacy school, a mandatory research class as a part of the curriculum (n=55, 63.2%), participation in a research workshop during the first weeks of pharmacy school (n=45, 51.7%), and faculty contacting students directly to work on a research

project (n=41, 47.1%) would most strongly influence them to complete a research project. Lack of time (n=61, 68.5%), too much coursework (n=36, 40.5%), and unfamiliarity with the research process (n=35, 39.3) were cited as the top three perceived barriers that have prevented these students from pursuing research. Most students agreed that research is very important to pharmacy practice (n=129, 82.2) and that students should be exposed to research early in their pharmacy education (n=81, 50.6%).

Conclusion: Students perceive research as important to pharmacy practice and feel early exposure would positively influence their decision to pursue research in pharmacy school. Mandatory events that expose students to research early on, including a workshop or research class, appear instrumental in positively influencing pharmacy students to pursue research. Future research should evaluate the efficacy of programs and strategies used to promote research participation among pharmacy students.

Submission Category: Pain Management

Submission Type: Descriptive Report

Session-Board Number: 5a-162

Poster Title: Review of intrathecal medications for chronic pain management

Primary Author: Lindsay Hammeren, Roseman University of Health Sciences College of Pharmacy, UTAH; **Email:** lhammeren@student.roseman.edu

Additional Author (s):
Whitney Mortensen
Elizabeth Sebranek Evans

Purpose: Achieving adequate pain control can be challenging for patients with chronic pain due to cancer and other illnesses. For patients who have failed other treatment options, intrathecal (IT) analgesia can be used to manage persistent pain. The aim of this review was to identify and evaluate literature related to the stability, compatibility, safety, and efficacy of compounds used for long-term IT analgesia.

Methods: A literature search was completed to evaluate the stability, compatibility, safety, and efficacy of IT compounds administered via implantable IT pumps. A variety of drug information resources were utilized including reference and text books, compounding and pain organizations, and published articles cataloged on PubMed, Cochrane Database of Systematic Reviews, and Cumulative Index of Nursing and Allied Health Literature (CINAHL). Compounds were only evaluated for safety and efficacy after sufficient data had been found supporting the stability and compatibility of the solution. Articles were excluded if implanted IT pumps were not involved.

Results: After completing the review of stability and compatibility data, there were 10 compounds remaining which were evaluated for safety and efficacy. These compounds were morphine, hydromorphone, bupivacaine, fentanyl, morphine with baclofen, morphine with bupivacaine, hydromorphone with clonidine, hydromorphone with bupivacaine, fentanyl with bupivacaine, and hydromorphone with both bupivacaine and clonidine. A total of 71 studies were included in the review. Stability and compatibility information was obtained from 25 studies, safety and efficacy information was obtained from 45 studies, and 1 study had information in both categories. The 10 IT compounds evaluated for safety and efficacy in this review appeared to be relatively safe and effective, though the overall quality of the available

literature was poor. Side effects reported in the literature were often easily managed or subsided over time. Most compounds appeared to be successful at managing the patients' pain on a long-term basis where other pain management strategies had failed.

Conclusion: While medical disciplines continue to pursue evidence-based practices, the management of pain intrathecally is done primarily based on the clinical opinions and past experiences of practitioners. This is primarily due to the fact that published data in IT chronic pain management are severely lacking, presenting many concerns for the safety of these patients. More stability and compatibility studies need to be done to ensure that compounds being used long-term in IT pumps are stable for that duration of time. Pain management is an art as much as it is a science, but more studies evaluating efficacy and safety are necessary.

Poster Title: Identifying safe and unexpected drugs for depression using inverse-frequency analysis of population scale data

Primary Author: Isaac Cohen, UC San Diego Skaggs School of Pharmacy and Pharmaceutical Sciences, California; **Email:** icohen@ucsd.edu

Additional Author (s):
Tigran Makunts
Rabia Atayee
Ruben Abagyan

Purpose: Ketamine, a drug indicated for anesthesia, has recently been explored for use in treatment resistant depression and pain management. Ketamine's fast onset of action compared to traditional antidepressants has potential therapeutic advantages for patients with acute depressive episodes. Population scale analysis of ketamine patient outcomes and adverse effects was needed to support previous small scale evidence of ketamine's psychiatric pharmacology. The purpose of this study was to assess the efficacy and safety of ketamine therapy, using the FDA Adverse Event Reporting System (FAERS), and to use inverse-frequency analysis (IFA) to identify other drugs with unexpected psychiatric polypharmacology.

Methods: This study utilized the FDA Adverse Event Reporting System's (FAERS) eight million patient records spanning from 2002 to 2016. FAERS is a database intended to support the FDA's post-marketing drug safety surveillance program. Although the database was designed to be used for monitoring of adverse drug reactions (ADRs), FAERS's large size has made other investigations possible. Here we developed inverse-frequency analysis (IFA), a statistical methodology for determining drug efficacy using population scare adverse effect data. IFA uses the log of the odds ratio (LogOR) in order to determine a drug of interest's efficacy for off-label indications. The large scale of FAERS data makes detection of a drug's unintended protective effects possible with high statistical power. In this study 41,337 patients, who were given ketamine in combination with other drugs, were compared with 238,516 patients, who were given any combination of drugs indicated for pain besides ketamine. ADRs with frequencies above 2.5% were reported and odds ratios were calculated comparing the ketamine patient group with the non-ketamine patient control group. Additionally, important entries indicative

of off-label ketamine pharmacology were reported via IFA as LogOR. The FAERS database was searched by IFA for drugs with negative LogOR for ADR entries indicative of psychiatric pharmacology. Three such drugs were found using this method.

Results: Patients who received ketamine in addition to other therapeutics had significantly lower frequency of reports of depression (LogOR -0.67, LogORerror 0.033), pain (LogOR -0.41, LogORerror 0.019), constipation (LogOR -0.17, LORerror 0.033), vomiting (LogOR -0.16, LORerror 0.025), and nausea (LogOR -0.45, LogORerror 0.023) than patients who received any other combination of drugs indicated for pain. Renal side effects were observed to be the most frequent ADR for patients receiving ketamine. 7.93% of ketamine patients had renal failure and 4.83% had acute renal failure. Other drugs were also found to have significant antidepressant psychiatric activity including, diclofenac (LOR -2.21, LogORerror 0.14), Botox (LOR -1.81, LogORerror 0.053), and minocycline (LOR -0.49, LogORerror 0.017).

Conclusion: Ketamine patients had lower rates of depression and pain than patients who received any other combination of drugs for pain. This may be resultant of a decrease in pain which could impact depression associated with pain or ketamine may be directly helping patients with both pain and depression simultaneously. Further, ketamine receiving patients had lower rates of opioid side effects including nausea, vomiting and diarrhea. Ketamine was also observed to have a high frequency of renal side effects and may be contraindicated in patients with renal impairment. Further, drugs such as antibiotics and NSAIDS may have off label psychiatric effects.

Poster Title: NSCLC Stage IV Pharmacotherapy: Comparison of NCCN Guideline recommendations with approved FDA labeling

Primary Author: Sonal Agarwal, Ernest Mario School of Pharmacy, New Jersey; **Email:** sonal.agarwal2611@gmail.com

Additional Author (s):
Rza Abasov

Purpose: Non-small cell lung cancer (NSCLC) is a deadly disease, which accounts for about 85% of all lung cancer. With a 5-year survival rate of 1%, patients with Stage IV NSCLC are in desperate need for the most optimal and effective treatment in order to decrease their mortality. Most guidelines used by clinicians for treatment of this disease may make recommendations about off-label use of chemotherapeutic agents. We conducted this study in order to evaluate how pharmacotherapy recommended by NCCN Guidelines (January 12, 2016) compares to current approved FDA labeling of the drugs recommended.

Methods: We conducted a literature search using Medline and Guideline.gov to find guidelines for Stage IV NSCLC treatment. Different guidelines were reviewed for completeness of their recommendations. NCCN Guidelines was selected because they had the most comprehensive recommendations that would help guide clinical decision making in treatment of Stage IV NSCLC. We compared all pharmacotherapeutic options, including combo and mono therapy, recommendations to FDA approved indications of those drugs. FDA AccessData and drug manufacturer websites were used for searching FDA approved indications. We considered a recommendation to be "matching" with the FDA labeling if the package insert indication matched the NCCN recommendation and drug combinations suggested by NCCN were explicitly stated in a package insert of one of the drugs used in combination. For EGFR-positive and ALK-positive NSCLC, the package insert had to explicitly state those mutations in order for the recommendations to be considered "matching". If the package insert recommended a drug for first-line therapy while the NCCN Guidelines recommended it for subsequent therapy or vice-versa, the recommendation would be considered "non-matching" with the FDA labeling. Cisplatin and Carboplatin were considered non-interchangeable. After data collection, percentages of "matching" recommendations were calculated for the four types of NSCLC:

Large Cell Adenocarcinoma of the Lung, Squamous Cell Carcinoma of the Lung, EGFR-positive NSCLC, and ALK-positive NSCLC.

Results: The total of 24 drugs recommended in the NCCN Guidelines for any category of stage IV NSCLC was evaluated. Out of 24 drugs, 20 (83.3%) were indicated in the FDA approved labeling and 4 did not have any indication for NSCLC. 12 of 15 recommended drugs (80%) had the FDA labeling for Large Cell Adenocarcinoma NSCLC, 10/13 (77%) for Squamous Cell NSCLC, 4/5 (80%) for EGFR-positive NSCLC, and 3/3 (100%) for ALK-positive NSCLC. Only 17 of 37 NCCN Guidelines recommendations (46%) matched the FDA approved right indications for Large Cell Adenocarcinoma NSCLC, 12/33 (43%) for Squamous Cell NSCLC, 4/8 (50%) for EGFR-positive NSCLC, and 4/4 (100%) for ALK-positive NSCLC. Out of the total 82 NCCN Guidelines recommendations only 36 (44%) matched the official FDA approved indications for those drugs.

Conclusion: In conclusion, 83% of the total drugs recommended by the NCCN Guidelines have approved indication for NSCLC and 44% of the total recommendations from NCCN Guidelines are approved for matching indications. Further research is needed to evaluate and quantify the reasons for these differences.

Poster Title: Acanthamoeba Keratitis: Review of pharmacotherapeutic outcomes (25 year case history).

Primary Author: Akshay Patel, Rutgers Ernest Mario School of Pharmacy, New Jersey; **Email:** akshay6594@gmail.com

Additional Author (s):
Lav Patel
Navaneeth Narayanan
Michael Toscani

Purpose: Acanthamoeba Keratitis (AK) is a rare but growing ocular disease caused by improper contact lens hygiene and/or ocular trauma. The purpose of our project was to assess treatments and clinical outcomes of AK by reviewing multiple case-series of the various available treatment options over the past 25 years. Furthermore, to review in vitro studies of novel treatments of AK aimed at decreasing treatment cytopathic effect (CPE) on human corneal epithelial (HCE) cells while increasing CPE on Acanthamoeba trophozoites and cysts.

Methods: A literature review was conducted using Medline to identify and review retrospective case studies dating from 1992-2016. The data was compiled based upon the treatment regimen utilized. The 4 main areas analyzed were: treatment regimen, pre-treatment visual acuity, post-treatment visual acuity, and treatment regimen outcomes leading to the need for surgical intervention. Additional data points analyzed were: prior contact lenses usage and hygiene, medication usage prior to AK diagnosis, and delay in diagnoses. Further, consolidation of early diagnosed groups were analyzed to find overall final visual acuity of patients diagnosed within 1 month.

Results: Nineteen studies were found detailing the treatment of AK. Within the reviewed cases the treatment that was most used was combination topical therapy to treat an AK infection. Duguid et al conducted the largest case study with 105 patients (111 eyes). The treatment with PHMB and Brolene resulted with 79.3 percent of patients with a final visual acuity better than 6/12. In addition, in patients who received the same treatment, 90.8 percent of those diagnosed early (less than 1 month) had a final visual acuity of 6/12 or better as opposed to 65

percent of patients in the late group (greater than 2 months). In vitro studies with cellulose synthesis inhibitors, 2,6-dichlorobenzonitrile (DCB) and isoxaben, showed decreasing PHMB concentration to 0.00125 percent showed no significant CPE on HCE, but addition of 100 mM DCB or 10 mM isoxaben had 23.4 percent or 18.7 percent additional amebicidal effects on Acanthamoeba. In many patients, corticosteroids have been used prior to diagnosis, but there is insufficient evidence showing any links to positive or negative outcomes.

Conclusion: Acanthamoeba Keratitis is a rare ocular infection that can affect all healthy individuals. The CDC conservatively estimates incidence to be one to two cases per million per year. This case-series review has shown that early diagnosis (less than 1 month) of AK has the best post-treatment results in patients in all treatment groups due to the ability of treatments limiting the ability of AK to spread deeper into tissues. The best visual acuity was attained through the combination of a biguanide and propamidine isethionate treatment.

Poster Title: Gold nanoparticles: A medium for antibiotic delivery

Primary Author: Alfredo Traversa, Midwestern University, Illinois; **Email:** atraversa71@midwestern.edu

Additional Author (s):
Marc Scheetz
Andrew Lee
Jim Rhodes
Jia Fang

Purpose: There is an increasing prevalence of multidrug-resistant (MDR) gram negative bacteria including Acinetobacter baumannii, Pseudomonas aeruginosa and Klebsiella pneumonia. Antibiotics linked to gold nanoparticles (AuNP) have different physiochemical, pharmacokinetic, and pharmacodynamic properties that may improve treatment options for these MDR pathogens. We sought to evaluate the distribution of gold nanoparticles when linked to a commercially available antibiotic. For patent reasons, we are not disclosing the antibiotic or methods of linking at this time.

Methods: Male Sprague-Dawley rats (~300g) were dosed intravenously via the lateral tail vein (n=10). The first cohort (n=5) was the "antibiotic-only" control group and the second (n=5) was the antibiotic-AuNP compound. Blood samples were collected via jugular catheter and prepared as serum and plasma. Tissues were harvested at 24-hour post dose. Tissues included liver, kidneys, skeletal muscle, lungs and thymus. Inductively Coupled Plasma-Mass-Spectrometry (ICP-MS) was utilized to measure elemental [Au].

Results: The antibiotic-only group demonstrated that Au/ tissue (g/g) was less than 0.00001 for all tissues. Rats in the AuNP group tolerated the injections well. The second cohort was the negative control, which was just the AuNP. We found much higher concentrations of Au in the tissue samples. The highest concentrations were found in the Kidney (0.0013 g Au/ g Tissue) and Lung (0.00021 g Au/ g Tissue). Preliminary blood data show that the initial Au plasma concentrations increase with time.

Conclusion: Our preliminary data demonstrated that minimal gold is present in rat tissues that are treated with antibiotic only. Rats tolerated the AuNP well and gold is measurable in various tissues. Gold nanoparticles are a viable option for linking antibiotics. Future work will define the pharmacokinetics of all compounds singly and linked.

Poster Title: Efficacy of an extemporaneous formulation of propranolol in Mexican patients with problematic infantile hemangioma

Primary Author: Azucena Luna, Facultad de Ciencias Quimicas e Ingenieria, Baja California; **Email:** azucena.luna@uabc.edu.mx

Additional Author (s):
Saul Castaneda
Esbeydy Garcia Lopez
Jose Luis Sanchez
Hermelinda De la Cruz Duran

Purpose: Infantile hemangiomas (IH) are the most common vascular tumors of childhood, are presented by 10% in children less than one year. Propranolol one β-blocker mainly indicated for hypertension has proven effective in reducing this type of tumors. In Mexico there are no studies that evaluate the efficacy or parameters to guide treatment in patients with IH, neither propranolol formulations appropriate for the pediatric population.
The purpose of this study is evaluated the efficacy of propranolol in Mexican pediatric patients diagnosed with problematic infantile hemangioma, treated with an extemporaneous solution of propranolol.

Methods: An open prospective observational study at the Children's Hospital of the California´s in Mexico was performed in pediatric patients diagnosed with infantile hemangioma, between the ages of 3-12 months. Patients were treated with an oral solution of propranolol prepared for the pharmacist in doses ranging from 0.5-2.5 mg/kg per day. The treatment efficacy was assessed using a visual scale clinical improvement and measurement of hemangioma, safety of propranolol was determined based on the adverse effects reported.

Results: In a period of 24 months 63 patients were treated, 64% female and 36% male. The IH location was mainly in head and neck (57%). The effectiveness was proven in 95% of patients. Treatment had an average duration of 9.6 ± 2.2 months. Children who started therapy before six months of age had a significantly better response and shorter duration of treatment (8.7 months and 10.7 months respectively). The average effective dose was 1.5 mg/kg/day. On six

patients (9%) cases of adverse effects occurred (insomnia, hypertension, diarrhea and dental caries).

Conclusion: Treatment with extemporaneous formulation of propranolol in this group of Mexican pediatric patients, proved to be safe and effective at an average dose of 1.5 mg/kg/day, reducing the problematic infantile hemangioma; with a minimum incidence of adverse effects.

Poster Title: Frontline pharmacist: HIV screening initiative in an urban academia setting

Primary Author: Lauren Aronin, Touro College of Pharmacy NY, New York; **Email:** laronin@student.touro.edu

Additional Author (s):
Kirolous Makarious
Sefa Kploanyi
Maria Sorbera
Evangelina Berrios-Colon

Purpose: Global efforts to combat the Acquired Immunodeficiency Syndrome (AIDS) epidemic have been increasing due to the impending public health threat. Of the more than 1.2 million people in the US living with HIV, 1 in 8 are unaware of their status, greatly increasing the risk of disease progression and transmission. Rapid point-of-care testing (POCT) can aid in filling the current gaps existing in HIV data. Recently, students and faculty at Touro College of Pharmacy (TCOP) in Harlem, NY have launched an initiative to help increase HIV screenings and integrate patients into care.

Methods: Students and faculty from TCOP conducted a health fair on National HIV Testing Day (June 27th, 2016). At this event, a college affiliated non-profit organization performed POCT for HIV and provided counseling and social work services. All individuals had the choice to discuss healthcare and insurance options allowing for an increased transition into care for the Harlem community. In addition to HIV testing, participants were able to take advantage of blood pressure screenings, medication management and smoking cessation counseling performed by pharmacy students under the direct supervision of clinical faculty members. Pre- and post-surveys were conducted to gather data on demographics, social histories, health care beliefs, screening results, transitions into care, and changes the individuals hope to implement due to the event. The primary objective was to identify persons with HIV who remain undiagnosed and link them into care.

Results: A total of 86 patients completed pre-surveys and 37 patients completed post-surveys. The mean age was 51.67 years with 67.44% of patient identifying as African American. Of the total amount of patients tested, 4.65% tested positive, and 11.63% were integrated into care.

Conclusion: Early detection with subsequent transition into care is a crucial step towards ending the AIDS epidemic. It is the role of healthcare practitioners and institutions to aid in improving this public health crisis. Free community screening events are an effective way to diagnose HIV-positive individuals who remain undiagnosed and establish patient-provider relationships.

Poster Title: Physical compatibility of ketamine with selected drugs during simulated Y-site administration

Primary Author: Emilie Bergsma, University of Florida College of Pharmacy, Florida; **Email:** ebergsma@ufl.edu

Additional Author (s):
Michael Veltri
Alice Chong

Purpose: Ketamine is increasingly being studied for its efficacy in many conditions including analgosedation and chronic pain, particularly for use in the settings of the intensive care and oncology units. In addition to its efficacy it is currently both relatively inexpensive and readily available; hence the resurgence in the use of ketamine. However, ketamine compatibility data is lacking. The purpose of this study was to determine the physical compatibility of ketamine via simulated Y-site administration with drugs commonly used in the pediatric population.

Methods: Study drugs and parenteral nutrition (PN) solutions were chosen based on their frequency of use in the pediatric intensive care unit (PICU) and pediatric oncology unit at The Johns Hopkins Hospital. The most concentrated solution used clinically was chosen for each drug. Test drugs were aseptically prepared using the same process, procedures, and diluents used for preparation of those medications administered in clinical practice. Each test drug was added into an empty individual glass sample cell to which an equal volume of ketamine injection solution (10 mg/mL) was added; to create a 1:1 mixing ratio to simulate Y-site administration. Controls were created by adding each test drug alone into an empty sample cell at the same total volume as the ketamine/test drug combination. Physical compatibility of the admixtures was determined by visual and turbidimetric assessments performed immediately, at 1 hour, and at 4 hours after mixing. The final time period of four hours was chosen based on the typical length of administration and/or flow rates of continuous infusions at this institution. Incompatibility was defined as a significant increase in turbidity of greater than or equal to 0.5 Nephelometric Turbidity Units (NTU) of the mixtures compared to the controls. Visual assessment was used to confirm incompatibilities observed based on turbidity measurements.

Results: Fifteen out of 26 test drugs did not have a significant difference in turbidity measurements between control and test solutions and were therefore determined to be compatible with ketamine. The remaining eleven test drugs demonstrated a significant increase in turbidity between control and test solutions. Based on this development of precipitation, these drugs were found to be incompatible with ketamine. Of note, the addition of ketamine to chlorothiazide resulted in immediate crystallization of the solution.

Conclusion: Cisatracurium, famotidine, ketorolac, levetiracetam, methylprednisolone, mycophenolate, norepinephrine, ondansetron, phenylephrine, prochlorperazine, tacrolimus, vasopressin, vecuronium, and both the Aminosyn- and Trophamine-based PN solutions at concentrations equal to or less than the concentrations tested may be co-infused via a single intravenous line and Y-site connection, with ketamine hydrochloride (10 mg/mL or lower concentration), based upon their physical compatibility over a period of four hours examined in this study. Ketamine should not be administered in combination with any of the other tested drugs due to identified physical incompatibility.

Poster Title: Evaluation of liposomal amphotericin B dosing on renal outcomes in a tertiary care hospital

Primary Author: Mary McNulty, University of Tennessee College of Pharmacy, Tennessee;
Email: mmcnult3@uthsc.edu

Additional Author (s):
Julia Shlensky
Chris Finch
Jennifer Twilla

Purpose: Since its introduction in the 1950's, amphotericin B has remained the standard of care for invasive fungal infections. Although considered a standard of care, amphotericin B has been prescribed with caution because of its ability to cause dose and duration dependent nephrotoxicity to patients. Despite improving the dose-dependent safety profile for this drug by using liposomal and lipid formulations, additional hurdles still remain with its use in the obese patient population. The aim of this retrospective study is to review and compare hospital outcomes in obese versus non-obese patients treated with liposomal amphotericin B (LAmB) and the dosing strategy utilized.

Methods: A retrospective chart review of patients admitted to Methodist LeBonheur Healthcare Adult Hospitals between 1-01-2015 through 7-31-2016 with orders for liposomal amphotericin B (LAmB) was conducted. Patients were initially categorized based on their BMI classification of obese (> 30 kg/m2) or non-obese (< 30 kg/m2). Each patient was evaluated to determine dosing weight used for LAmB (ideal body weight, adjusted body weight, or actual body weight). A determination of the state of the patient's kidney function prior to hospitalization was assessed by a review of the patient's medical history and laboratory values documented in their medical record. Inclusion criteria consisted of: > 18 years of age and active orders for LAmB for minimum of 48 hours. Patients were excluded if they had ESRD on hemodialysis/peritoneal dialysis, incomplete data points for patients and/or pregnancy. The primary objective of this study was to determine the incidence of LAmB-induced acute kidney injury (AKI) in obese versus non-obese patients. Additionally, we aimed to stratify AKI

development based on BMI classification and evaluate treatment failure rates in obese versus non-obese patients.

Results: After review, 44 patients were included in the study (32 non-obese group and 12 obese group). The average BMI for the non-obese group was 21.9 kg/m2 with standard deviation equal to 3.6 and a BMI of 39.1 kg/m2 with standard deviation equal to 7.4 in the obese group. In the obese group, the majority of patients were dosed on actual body weight (83 percent). AKI occurred in 41.6 percent of the obese group compared to 15.6 percent of the non-obese group (p equals 0.11). Based on BMI classification AKI occurred in 1 patient in the underweight group, 1 patient in normal weight, 3 patients in overweight, 2 patients in obesity 1 group, 1 patient in obesity 2 group, and 2 patients with extreme obesity. No significant differences were noted in treatment failure between the groups (16.6 percent obese group versus 12.5 percent non-obese group; p equals 0.66).

Conclusion: Our study revealed a non-significant increase in the incidence of LAmB induced AKI in the obese patient population. The study was limited by the small number of obese patients receiving LAmB. Further studies in the obese patient population are warranted to determine if an association with dosing weight and LAmB exists.

Submission Type: Descriptive Report

Session-Board Number: 5a-171

Poster Title: A literature review of the emphasis of adherence in asthma education programs

Primary Author: Amy Hoang, Midwestern University- Chicago College of Pharmacy, Illinois;
Email: ahoang97@midwestern.edu

Additional Author (s):

Purpose: Current asthma guidelines recommend clinicians to assess and encourage medication adherence, yet the non-adherence rate among patients is 30-70% which can lead to increased asthma exacerbations requiring hospitalization and an overall increase in healthcare costs. Though there are various tools to measure drug therapy adherence such as urine/blood tracers, health outcomes, and pill/refill counts; asthma education programs are often more heavily focused on teaching patients proper medication technique and disease state education. An overall emphasis on medication adherence should be implemented in asthma education programs to ensure patients are receiving maximal benefit from their drug therapy.

Methods: A Pubmed search was performed using the mesh terms: asthma education intervention, asthma education program, and asthma inhaler technique. Articles from 2011 to 2015 were evaluated if an asthma education program was applied with patients in the study.

Results: The search criteria produced eleven total articles. Five articles were excluded because they only provided background information. Six studies with varied study designs, patient population, and duration of treatment were assessed to evaluate if an emphasis was placed on medication adherence in the asthma education programs. Overall, asthma education programs lacked emphasis on adherence and it was only a secondary outcome or unaddressed. More focus was placed on inhaler technique and disease state education in asthma education programs.

Conclusion: Asthma education programs focus on inhaler technique, disease pathophysiology, and reviewing the asthma action plan and had limited emphasis on medication adherence. A possible barrier to measuring adherence is the difficulty in attaining patient reports or the time-consuming nature of collecting tracers and performing pill counts. Future studies with asthma education programs should assess measuring adherence using multiple methods to help determine if one adherence marker is better or easier to perform than another.

Poster Title: Epac role as a novel regulator of airway smooth muscle proliferation in asthma

Primary Author: Musaab Gari, Massachusetts College of Pharmacy and Health Science University, Massachusetts; **Email:** garimh@gmail.com

Additional Author (s):
Rana Alsaffar
Alice Gardner

Purpose: Asthma, a chronic inflammatory disorder, alters key structural cells in the airways. Changes to airway smooth muscle (ASM) include increased ASM mass through increased cell proliferation. These changes are a component of airway remodeling and linked to poorer clinical outcomes in asthmatics. Controlling ASM proliferation is the second messenger cyclic adenosine monophosphate (cAMP) with cellular amounts regulated by phosphodiesterase (PDEs) enzymes. The role of cAMP effector, exchange protein directly activated by cAMP (Epac), in ASM proliferation remains to be elucidated. PDE-Epac signaling in ASM cell proliferation will be researched in primary human airway smooth muscle cells (HASMCs) from asthmatic individuals.

Methods: Cell Proliferation Asthmatic HASMCs were grown to 80-85% confluency and growth-arrested for 24h. Serum-starved HASMCs were treated with 5% FBS for 48h in the absence or presence of rolipram (10 μM) or albuterol (2 μM), or the agonist 8-(4-Chlorophenylthio)-2'-O-methyladenosine-3',5'-cyclic monophosphate sodium salt (8-CPT-2Me-cAMP; 100 μM) which activates Epac but not PKA, or CE3F4 (1 μM) which inhibits Epac. DNA synthesis of ASM was measured by 5-bromo-2'-deoxyuridine (BrdU) incorporation.

Results: Increased cAMP levels following Epac activation by 8-CPT-2Me-cAMP significantly decreased cell proliferation greater than PDE4 inhibition in asthmatic ASM (206% and 29%; $P < 0.0001$ and 0.01, respectively). Co-treatment of asthmatic ASM with the Epac agonist, 8-CPT-2Me-cAMP, and albuterol significantly enhanced the anti-mitogenic effect of the β2-agonist (579%; $P < 0.0001$). In the presence of PDE4 inhibition, 8-CPT-2Me-cAMP further enhanced the anti-proliferative effect of albuterol in asthmatic ASM (109%; $P < 0.0001$). Epac inhibition by

CE3F4 reduced the effects of cAMP-elevating agents: albuterol and 8-CPT-2Me-cAMP on asthmatic ASM cell proliferation (21% and 96%; $P < 0.1$ and 0.001, respectively).

Conclusion: The cAMP effector Epac enhanced the anti-proliferative effects of albuterol and PDE4 inhibition in asthmatic cells. These data suggest the contribution of the cAMP effector Epac in regulating the pro-mitogenic state in ASM. Dysregulated cAMP levels in asthmatic ASM is associated with decreased lung function, and poorer clinical outcomes. Thus, Epac and PDE4 may have the therapeutic potential to control airway remodeling in asthma and improve lung function.

Submission Type: Evaluative Study

Session-Board Number: 5a-173

Poster Title: Role of gender in the comparison of successful rate control with intravenous diltiazem and intravenous metoprolol in an emergency department setting

Primary Author: Shannon Jeong, University of Washington, Seattle, Washington; **Email:** sdjeong@uw.edu

Additional Author (s):
Joshua Villarreal

Purpose: Atrial Fibrillation/Flutter is a common admission diagnosis in the emergency department (ED) and both intravenous (IV) metoprolol and IV diltiazem are commonly utilized to acutely treat these patients. However, there continues to be debate between providers as to if a calcium channel blocker or a beta-blocker will be more effective in rate control. The purpose of this study was to examine if gender played a role in successful rate control with either or both agents in order to contribute to effective advancements in the optimization of acute atrial fibrillation/flutter treatment in the ED.

Methods: This study is a retrospective, comparative study conducted in an academic emergency department. Data was gathered over a 6-month period (January 1, 2015 to June 30, 2015) through medical chart review of ED patients treated for atrial fibrillation/flutter. Patients were included into the study if they were treated with IV diltiazem, IV metoprolol, or both in order to rate control heart rate. Exclusion criteria include suspicion of sepsis/pneumonia, pregnancy, mental status change, the dose was not given specifically in the ED, or if the agent was given for indications other than rate control. Data was collected from the IV diltiazem group, IV metoprolol group, and the cross-over group (use of both agents) in order to evaluate the effectiveness of either or both treatments by determining if successful rate control was achieved, which was defined as heart rate less than 110 beats per minute or a decrease in value greater than 20 percent after the dose was given. From there, the role of gender was examined by determining the number of both males and females that were either successful or unsuccessful in achieving rate control within each group. Secondary endpoints of blood pressure before and after the dose were also collected to examine adverse effects.

Results: Of the 126 patients initially included to be screened, 60 patients were excluded due to defined exclusion criteria. A total of 27 patients were included in the IV metoprolol group, 27 patients in the IV diltiazem group, and 12 patients in the crossover group. In the IV diltiazem group, 18 of 27 or 66.7 percent of patients had successful rate control and 9 of 27 or 33.3 percent did not. Of the successful rate control achieved patients, 9 of 15 were females (95 percent CI, 35.21 percent to 84.79 percent, P less than 0.001) and 9 of 12 patients were males (95 percent CI, 50.5 percent to 99.5 percent, P equals 0.0015). This did not change significantly with the IV metoprolol group, in which 14 of 27 or 51.9 percent of patients had successful rate control and 13 of 27 or 48.1 percent did not. Of the successful rate control that was achieved with IV metoprolol, 5 of 9 were females (95 percent CI, 23.03 percent to 87.9 percent, P less than 0.001) and 10 of 18 were males (95 percent CI, 32.54 percent to 78.46 percent, P less than 0.001). The cross-over group also had comparable results.

Conclusion: From the results of this study, either or both IV diltiazem and IV metoprolol were shown to be effective in allowing for successful rate control in the acute treatment of atrial fibrillation/flutter within the ED setting for both genders. However, many limitations of this study suggest that future studies utilizing a stronger data pool are definitely needed to further explore the safety and effectiveness of the two treatment options to see if there is truly a better acute treatment option for the ED setting for both males and females.

Poster Title: Correlations of anticholinergic rating scale lists with driving impairment in older adults

Primary Author: Vivian Dao, Touro University California, California; **Email:** vivian.dao@tu.edu

Additional Author (s):
Shadi Doroudgar
Paul Perry
Hannah Mae Chuang
Kelan Thomas

Purpose: The purpose of this study was to investigate the correlation of three anticholinergic rating scale lists with driving impairment in older adults. The anticholinergic rating scales lists considered were the Carnahan's Anticholinergic Drug Scale (ADS), Rudolph's Anticholinergic Risk Scale (ARS), and Boustanti's Anticholinergic Cognitive Burden (ACB). The study also aimed to identify which anticholinergic rating scale list (ADS, ARS, or ACB) best predicts driving impairment in older adults.

Methods: A prospective, cross-sectional study (N=114) was conducted at Touro University California. Participants were recruited throughout Napa-Solano Counties of California using convenience sampling. Inclusion criteria were: (1) 60 years of age or greater, (2) actively driving on a weekly basis, and (3) willing to bring in all current medication bottles. Exclusion criteria were: (1) color blindness, (2) cataract surgery, (3) deafness or vestibular balance issues, (4) history of brain tumor, (5) diagnosis of severe psychiatric condition or acute psychiatric episode, (6) baseline Standardized Mini-Mental State Examination (SMMSE) < 25, (7) alcohol or caffeine consumption on study day, and (8) on stimulant medications or illicit drugs. The Charlson Comorbidity Index (CCI) was used as a baseline test to control for confounding comorbidities. SMMSE and Rapid Detect Saliva Drug Screen (SDS) 10-panel were also used as preliminary tests to screen for exclusions among participants. STISIM Drive® M100 Driving Simulator (Hawthorne, California) measured driving outcomes such as the standard deviation of lateral position (SDLP, in cm), mean speed, speed exceedances, and car following coherence. A generalized linear model was used to analyze continuous outcomes such as SDLP. A Zero-Inflated Poisson regression analyzed count outcomes that included non-negative integer values

(i.e. speed exceedances, centerline crossings). Comparison of the lowest Akaike Information Criterion (AIC) selected the best fitting model to predict driving impairments.

Results: The ACB and ARS anticholinergic rating scale lists showed correlations with driving impairment. There were statistically significant correlations between the ACB list and the primary outcome, SDLP (p=0.037), which measured the amount of weaving of the car, and secondary outcomes of speed exceedances (p=0.018) and centerline crossings (p=0.003). Additionally, there were statistically significant correlations between the ARS list and mean time across center line (p=0.035) and mean distance across centerline (p=0.029). Both the ARS and ACB lists showed statistical significance in detecting impairments in car following coherence, which was the time taken for a driver to respond to the lead vehicle's speed. Comparison of the lowest AIC value determined that the ACB list was the best fitting model to determine driving impairment with regards to SDLP, car following coherence, speed exceedance, and center line crossings, whereas the ARS model was the best fitting model to determine impairments in mean time across center line and mean distance across centerline.

Conclusion: Overall, the ACB list was the best model used to predict driving impairments due to adverse effects from anticholinergic drugs. Thus, implementation of the ACB list in clinical settings can help practitioners identify medications with high anticholinergic burden risks to reduce adverse effects among patients. These results are the first to compare the correlations of each anticholinergic drug potency rating scale lists and driving impairment using a driving simulator.

Poster Title: Outpatient antimicrobial prescribing for skin and soft tissue infections in the United States: 2000 and 2014

Primary Author: Khine Aye Mya Tun, University of Texas at Austin College of Pharmacy, Texas; **Email:** khine.tun@utexas.edu

Additional Author (s):
James Shurko
Grace Lee

Purpose: Skin and soft tissue infections (SSTIs) present a challenging public health problem in the United States, particularly due to the emergence and rise of community-associated methicillin-resistant Staphylococcus aureus over the past two decades. This change in epidemiology might have profound effects on the antimicrobial management of SSTIs. However, recent trends of antimicrobials prescribed for SSTIs are unknown. The purpose of this study was to characterize the change in antimicrobial prescribing patterns associated with the management of SSTIs in the U.S. from 2000 to 2014.

Methods: This was a cross-sectional analysis of nationally representative data from the Medical Expenditure Panel Surveys (MEPS) in 2000 and 2014. SSTIs were defined by Clinical Classification Software code 197. Therapeutic drug classes were identified by using the National Drug Code directory, generic names, and the Multum Lexicon therapeutic classification database (Cerner Multum, Inc). Population-based prescription rates were defined as the annual number of outpatient antibiotic prescriptions for SSTIs divided by the overall US civilian non-institutionalized population per 10,000 persons. All analyses were adjusted to account for the MEPS complex study design using weights, clustering, and stratification to derive national estimates. SPSS 23.0® (IBM Corp, Armonk, NY, USA) was used for all statistical analyses.

Results: Overall, outpatient antimicrobial prescribing for SSTIs increased from 1.6 million prescriptions in 2000 to 4.2 million in 2014. Population-based antimicrobial prescription rates for SSTIs doubled from 2000 to 2014 (risk ratio 2.23, 95% confidence interval (95% CI) 1.65 to 3.03). The use of beta-lactam antibiotics significantly decreased from 2000 to 2014 (75% vs. 34%; P < 0.0001). In 2014, the most frequently prescribed antibiotics were cephalosporins

(23%), sulfonamides (16%), and macrolides (16%). Prescription rates for antifungal Furthermore, rates of population-based prescribing for non-beta lactam antibiotics substantially increased from 2000 to 2014 for the following antibiotics: 49-fold for sulfamethoxazole-trimethoprim (0.4 per 10,000 persons to 21.4 per 10,000 persons), 33-fold for clindamycin (0.2 per 10,000 persons to 8 per 10,000 persons), 7-fold for macrolides (3 per 10,000 persons to 22 per 10,000 persons), and 6-fold for tetracyclines (2 per 10,000 persons to 12 per 10,000 persons). Prescription rates for antifungal and antiviral agents remained stable.

Conclusion: Antimicrobial prescription rates for SSTIs have drastically increased from 2000 to 2014. There has been a dramatic shift in prescribing non-beta lactam antibiotics, especially sulfamethoxazole-trimethoprim and clindamycin with a decrease in beta-lactam utilization in 2014 compared to 2000.

Poster Title: Student pharmacists' impact on the Visiting Pharmacist In-Home Program novel advanced pharmacy practice experience

Primary Author: Sara Massey, University of Missouri-Kansas City School of Pharmacy, Missouri; **Email:** semf3d@mail.umkc.edu

Additional Author (s):
Jeremy Eutsler
Jason Grace
Christy Mesik
Valerie Ruehter

Purpose: To analyze quality assurance data on the APPE course at the Tria Health practice site in collaboration with the Visiting Nurse Association. The purpose was to deliver contemporary pharmacy practice content, meet course performance competencies, and to determine the number and types of drug related problems along with pharmacy care plan recommendations identified by senior pharmacy students. Additionally, 30-day readmission rates were tabulated.

Methods: A retrospective record review was performed to collect information on the number of drug related problems, the types of drug related problems and the care plan recommendations identified by student pharmacists who conducted home visits with patients referred through the Visiting Pharmacist In-Home Program from the time period of June 2014 through December 2015. Drug related problems and care plan recommendations were then correlated to current financial data to determine the potential impact on cost-savings by the program. Student evaluation data was reviewed to determine if course competencies were met.

Results: Twenty-one senior students, assigned to Tria Health for an advanced pharmacy practice experience rotation from June 2014-December 2015, participated in the Visiting Pharmacist In-Home Program as part of the clinical course experience. Data was collected through a retrospective record review to identify drug related problems including doses too low, doses too high, indications with no drug, drugs with no indication, therapeutic duplications, and drug interactions. Data was also collected to identify pharmacy care plan

recommendations, potential cost-savings associated with the care plan recommendations, and 30-day readmission rates for patients seen in the Visiting Pharmacist In-Home Program. Student pharmacists saw a total of 590 patients from June 2014 through December 2015. There were 4,472 drugs reviewed and a total of 778 drug related problems were identified. The most common drug related problems were compliance and indications with no drug prescribed. The Visiting Pharmacist In-Home Program potentially avoided 747,795 dollars in health care costs to the patients. 30-day readmission rates were evaluated and pharmacists were not proven to be statistically significant in reducing readmission rates. All students met stated course performance competencies.

Conclusion: Overall, the Visiting Pharmacist In-Home Program identified many drug related problems resulting in potentially thousands of dollars saved. By collaborating with Tria Health and the Visiting Nurse Association, student pharmacists were able to successfully provide contemporary patient care services to patients in their home environment, identify drug related problems, impact cost of care, and meet course learning objectives.

Poster Title: Implications of smart phone applications in patient self-management of diabetes

Primary Author: Mark Martinez, Philadelphia College of Osteopathic Medicine - Georgia Campus School of Pharmacy, Georgia; **Email:** markmart@pcom.edu

Additional Author (s):
Harish Parihar
Park Bin
Maison Isaac
Mody Vicky

Purpose: Various smart phone applications have been developed and are available to assist diabetic patients in management of diet, exercise, and blood glucose. A review of all available diabetes related apps in the iOS app store was performed to determine which diabetic app provides the most interactive offering of operations such as monitoring glucose, water, carbohydrates, weight, body mass index, medication, blood pressure levels, reminders/push notifications, food database, charts, exercise management, email, sync between devices, synching data directly to the prescribers, and other miscellaneous functions such as (twitter integration, password protection, retina display, barcode scanner, apple watch functionality, and cloud synching).

Methods: Data was gathered using the iOS app store on an iPad. The search term used was "diabetes" and 1209 results were obtained. Many results obtained were remotely related to diabetes and focused mainly on diet, exercise, emergency services, refill reminders, providing general diabetes information, and other non-therapeutic options. Each app description was reviewed to only include apps that were designed for tracking blood glucose. All data were obtained in one sitting by one person on the same device, because carrying out the search at different times or on different devices (iPhone) disrupts the order of results. Apps that did not have a glucose tracking feature were excluded from the study.

Results: The search resulted in 1209 results, 85 apps were ultimately retained based on the above explained inclusion criteria. All apps were reviewed for average customer ratings, number of reviews, price, and functions. Among all apps surveyed, 18 apps with the highest

number of user ratings were used for in depth analysis. Out of these 18 apps, nine apps also had a medication adherence function in addition to blood glucose monitoring. The analysis revealed that Diabetes logbook by mySugr app was one of the best apps for blood glucose tracking, differentiating itself by introducing fun as a method of increasing adherence.

Conclusion: A large variation was seen in patient ratings of app features. Many patient reviewers desired simplicity of app functions. Glucose tracking and email features potentially helped patients and health-care providers manage the diabetes more efficiently. However, none of the apps provided the ability to synch data directly to the prescribers. Additional features such as graph customization, availability of data backup, and memorization of previous entries were also requested by many users. The use of apps in patient disease management along with patients and health-care providers' involvement in future refinement and app development should be encouraged.

Poster Title: Identifying Common Adverse Drug Reactions (ADRs) and Over-The-Counter (OTC) Options to Manage Patient Health

Primary Author: Daniel Chang, Ernest Mario School of Pharmacy, New Jersey; **Email:** dancha95@gmail.com

Additional Author (s):
Colleen Hickey
Yu Mao
Richard Rzendzian
Michael Toscani

Purpose: Pharmacists are responsible for counseling patients on potential adverse drug reactions (ADRs) to reduce medication discrepancies and improve adherence and outcomes. In particular, pharmacists can help patients manage ADRs by recommending over-the-counter (OTC) products. A study conducted in community pharmacies in US metropolitan areas found that only 43% of patients receive verbal counseling. These results suggest pharmacists are underutilizing opportunities to manage medication therapies. This project seeks to identify the most common ADRs associated with commonly prescribed drugs to pinpoint how pharmacists can further provide value to the patient's overall well-being with appropriate counseling and recommendations.

Methods: In this investigation, the top 200 drugs were compiled using multiple sources to be applied to the U.S. community pharmacy setting. Using MICROMEDEX, each of the drugs was listed with their generic name, brand name, indication, and common adverse effects. The data collected was further evaluated to identify trends and patterns that might help understand common ADRs and potential ways to mitigate associated risks. Available OTC management options for each of the common ADRs were identified using the Mintel Solutions database.

Results: Of the top 200 drugs investigated, 197 associated ADRs were identified. Of those 197 associated ADRs, the top 15 frequently encountered make up greater than 50% of the total prevalence. 10 of the 15 most commonly associated ADRs can be managed with OTC options.

These two findings reveal that 42% of the most common ADRs associated with the top 200 drugs can be managed with OTCs.

Conclusion: The findings of this investigation highlight the importance of pharmacists' education on associated ADRs and OTC management options available. As the landscape of the medical profession continues to change, it is important to ensure that pharmacists are knowledgeable of all aspects of disease state management. Moreover, it is important that patients are provided accurate information and evidence-based recommendations. Further investigation will identify the knowledge gaps of associated ADRs and OTC management options. Armed with this information, pharmacists can continue to add value through medication therapy management services that will help to improve adherence and overall health and well-being.

Session-Board Number: 5a-179

Poster Title: Clinical efficacy and financial impact of pharmacogenetic testing in psychiatric patients

Primary Author: Minsung Choy, Ernest Mario School of Pharmacy, Rutgers University, The State University of New Jersey, New Jersey; **Email:** minsungchoy@gmail.com

Additional Author (s):
Megan Maroney

Purpose: In psychiatric practice, a trial and error method of prescribing is commonly utilized, which consumes four to six weeks to establish appropriate dosing, often fails to achieve full remission and increases the risk of exposure to drug side effects. There is a need for a better approach in ensuring optimal and cost-efficient medication treatment for psychiatric patients, and pharmacogenetic testing is a possible solution. Pharmacogenetics may provide a more personalized and evidence-based intervention. This literature review was conducted to evaluate the clinical efficacy and the financial impacts of pharmacogenetic testing in psychiatric patient populations.

Methods: A Medline search was conducted from 2005 to 2016, using the following medical subject headings: pharmacogenetics, antipsychotic agents, antidepressive agents, medication adherence, and costs. Also, clinical studies on psychiatric pharmacogenetic testing that were available on the websites' of pharmacogenetic companies like Genomind and GeneSight were assessed. Each article was evaluated for relevance and appropriateness to the objective of this study. All articles were analyzed for study design, patient population, adherence, intervention type, clinical outcomes, and costs. Articles that had outcomes that assessed clinical efficacy and cost-effectiveness of pharmacogenetic testing in psychiatric patients were reviewed.

Results: Nine articles were reviewed. Seven studies used GeneSight Pharmacogenetic testing which evaluated three pharmacokinetic (CYP2D6, CYP2C19, CYP1A2) enzymes and two pharmacodynamic (SLC6A4, HTR2A) genes to categorize medications into three groups (red, yellow, and green) based on the degree of gene-drug interaction. Two studies used the Genecept assay which evaluated three pharmacokinetic (CYP2D6, CYP2C19, CYP3A4) enzymes and seven pharmacodynamic (SLC6A4, 5HT2C, DRD2, CACNA1C, ANK3, COMT, MTHFR) genes.

Two articles evaluated the cost-effectiveness and impact on medication adherence of pharmacogenetic testing. Both studies observed an increase in adherence and a decrease in overall costs in patients using pharmacogenetic testing, though one study saw an increase in medication costs. Another study observed an increase in direct and indirect costs in the group without pharmacogenetic testing. Six studies evaluating the clinical efficacy of pharmacogenetic testing in psychiatric patients showed improved clinical outcomes and higher rates of remission as compared to those who were not tested. In studies using the GeneSight Assay, patients on a medication in the red category (highest gene-drug interaction) observed the most benefit when switched to a medication in the green category (lowest gene-drug interaction). However, there was one randomized clinical trial, which is the gold standard for research.

Conclusion: Though there is a limited amount of research on this issue, pharmacogenetic testing has proven to benefit psychiatric patients by improving clinical outcomes and reducing overall cost of treatment, especially in patients with major depressive disorder with a HAMD-17 score of greater than or equal to14 and one or more previously failed treatments. Furthermore, this literature review was utilized to establish a protocol for pharmcogenetic testing in psychiatric patients in an outpatient setting at Mommouth Medical Center in New Jersey. Future research will be done to study clinical outcomes in patients treated at this facility.

Session-Board Number: 5a-180

Poster Title: Student residency aspirations and perspectives of a longitudinal Advanced Pharmacy Practice Experiences academic year at the Cleveland Clinic

Primary Author: Haili Gentry, Roseman University of Health Sciences College of Pharmacy, Utah; **Email:** hgentry@student.roseman.edu

Additional Author (s):
Erin Johanson
Sandra Avelar
Amy Hale

Purpose: The purpose of this study is to 1) describe the unique longitudinal Advanced Pharmacy Practice Experiences (APPE) experience at the Cleveland Clinic and 2) investigate perceptions of pharmacy students from Roseman University of Health Sciences that are attending the Cleveland Clinic for a unique longitudinal 42 week APPE rotation schedule. This is the first type of experience offered to students out-of-state to travel and complete all APPE intern hours for an entire academic year at a large, highly ranked teaching medical institution. The majority of students went to increase their competitiveness for residency opportunities upon graduation.

Methods: The class of 2017 from Roseman University of Health Sciences College of Pharmacy was given the opportunity to apply, interview, and be chosen to complete their APPE rotations at the Cleveland Clinic. The process for students involved submitting an application to faculty and staff at Roseman University, which included a written essay, curriculum vitae, reviews from preceptors during Introductory Pharmacy Practice Experiences (IPPE), and the students had to maintain test scores of 90% on all didactic assessments to be eligible. After the initial application process, selected students were interviewed by a panel including two APPE coordinators, two clinical pharmacists who hold positions on their respective residency committees, and Roseman University's Associate Dean of Academic Affairs. Candidates with the highest scores after interviews were invited to attend the Cleveland Clinic for their final year of pharmacy school.

Results: 35 complete applications were received by the selection committee. An initial review determined who to interview. After 24 interviews were conducted, 10 students were accepted to participate in APPE rotations at Cleveland Clinic from July 2016 to May 2017. The students visited the Cleveland Clinic four months before their rotations began to obtain Pharmacy Intern licenses in Ohio and become familiar with the clinic and submit requests for rotations. They were provided with numerous opportunities for unique rotations, research, networking, community events, and other opportunities they would not have had if they hadn't attended Cleveland Clinic. Students self-reported feeling that they were more motivated and driven to learn and participate in events than they would have been if they had stayed in a smaller hospital system. They were required to communicate with members of the pharmacy team as well as physicians and many other members of the healthcare team, building relationships between pharmacists and other medical providers. Doing this helped them build confidence in clinical situations and helped them develop skills that will be valuable when applying for residency and in the future as clinical pharmacists.

Conclusion: Students report that transitioning from a private College of Pharmacy to a large and highly successful health system for continuation of pharmacy school education has provided a unique and invaluable experience. The opportunity to incorporate the culture of the Cleveland Clinic's pharmacy practice with our APPE rotation learning activities provided the students a learning experience unique to that of their peers. Students reported that the rotation experiences at the Cleveland Clinic provided them with experiences that will make them competitive candidates for residency. Future studies evaluating this unique program, assessing student learning outcomes and post-graduate residency attainment would prove useful.

Poster Title: Connector integrity testing to assess the efficacy of multiple closed system transfer devices

Primary Author: Shawn Streeter, University of North Carolina at Chapel Hill Eshelman School of Pharmacy, North Carolina; **Email:** shawn_streeter@unc.edu

Additional Author (s):
Charlotte Forshay
Stephanie Salch
Stephen Eckel

Purpose: The risks associated with compounding and administration of hazardous drugs is well known. Numerous studies have been published that demonstrate that potential adverse effects can occur when compounding these types of medications. The risk is increased when individuals do not utilize proper protection. The use of closed system transfer devices (CSTDs) has become commonplace in hospitals, and recent United States Pharmacopeia (USP) 800 guidelines require the use of CSTDs for administration. The purpose of this study is to determine the connector integrity of CSTDs when tested with actual drug in a sterile compounding environment.

Methods: A study was conducted to compare the connector integrity of 6 different CSTDs. Each device was tested for leakage following up to 3 membrane connections. 5-fluorouracil vials were fitted with one CSTD vial access device. A 10 mL syringe was connected to the vial and 7 mLs of total volume was withdrawn in a Pull-Push-Pull method to simulate air bubble removal. The vial was inverted upright to re-inject 5 mLs into the vial and then the connectors were disconnected. The syringe was then reconnected to the vial and the remaining 2 mLs of drug was injected into the vial. This process of withdrawing and injecting volume was then repeated. Litmus paper was used to wipe the membrane of the vial and the syringe connector surface. These methods were repeated with the same CSTD two more times. Testing Group 1 contained 5 samples with data from the 2nd and 3rd connection, and Testing Group 2 contained 5 samples with data from the 1st and 3rd connection. A total of 10 samples were tested for each CSTD. A positive and negative control were also utilized for each device.

Results: A total of 10 samples were tested for each of the 6 CSTD types. Each sample had one litmus paper with qualitative data from the syringe and vial connector demonstrating drug leakage. This resulted in a total of 120 measures that assessed for discoloration. When comparing connector mechanisms across the types of devices, double membrane connectors were found to have 62.5 percent less leakage in comparison to valve connectors. Two CSTDs had no documented leakage in any of the manipulations. The CSTD with the most leakage was valve-based with 100 percent leakage overall in Testing Group 1 and 2.

Conclusion: Out of 6 CSTDs, 4 had detectable leakage while 2 had no detectable leakage. Data showed that double membrane-based CSTDs have significantly less leakage in comparison to valve-based CSTDs.

Submission Type: Descriptive Report

Session-Board Number: 5a-182

Poster Title: Identifying pharmacy practice patterns and predictors associated with surface contamination of hazardous drugs in pharmacies: a descriptive summary of five commonly used antineoplastic agents

Primary Author: Stephanie Salch, UNC Eshelman School of Pharmacy, North Carolina; **Email:** ssalch@email.unc.edu

Additional Author (s):
William Zamboni
Stephen Eckel

Purpose: Antineoplastic agents are known to be harmful to both healthy and cancerous cells, and thus are considered hazardous drugs. The new USP Chapter 800 outlines standards to protect health care personnel when handling hazardous drugs. One strategy to minimize exposure to health care employees is to ensure that the environment has minimal contamination of antineoplastic agents on surfaces. USP Chapter 800 recommends that environmental wipe sampling for hazardous drug surface residue be performed routinely to verify containments. This study analyzed 6 years of wipe data collected from over 300 healthcare institutions to understand patterns of hazardous drug surface exposures.

Methods: The surface exposures of docetaxel, paclitaxel, cyclophosphamide, ifosfamide, and 5-fluorouracil were measured in over 300 pharmacies using the ChemoGLO Wipe Kits. A wipe event was defined as each time an institution ordered a wipe study to be performed. There were 799 different wipe events analyzed in this study. At each wipe event, the institution selected the number of drugs and locations tested. The highest contamination result for each drug among the locations tested was used to summarize the surface contamination. The contamination level for each drug was categorized as non-detectable (ND; ≤10 ng/ft2), low (10-100 ng/ft2), medium (100-1,000 ng/ft2), and high (≥1,000 ng/ft2). Surface exposures for each drug were summarized based on the contamination at first and subsequent wipe events, on the locations associated with high contamination, and on the use of a closed system transfer device (CSTD).

Results: On first wipe event, the incidence (median; range) of high, medium, low, and ND exposures of all drugs analyzed was 6% (3-23%), 18% (13-23%), 17% (14-21%), and 56% (40-67%), respectively; whereas, the incidence of drug exposures on subsequent wipe events was 6% (1-12%), 10% (6-20%), 13% (10-17%), and 71% (57-83%), respectively. Furthermore, 67-86% of all high contamination results were found at locations where chemotherapy was prepared (e.g. airfoil in biologic safety cabinet (BSC), floor near BSC, or BSC surfaces). However, 13-32% of high contamination results were found at other locations in the pharmacy (e.g. countertops, floors, misc. items). The incidence of high, medium, low and ND exposures among institutions who were not using a CSTD was 10% (4-26%), 17% (14-25%), 15% (13-25%), and 52% (31-67%), respectively; whereas, the incidence among institutions who did report using a CSTD was 5% (2-15%), 11% (6-21%), 13% (12-16%), and 71% (54-80%), respectively.

Conclusion: A higher incidence of contamination was identified at first wipe event compared to subsequent wipe events, suggesting that monitoring is beneficial in recognizing and correcting practices that lead to surface exposures. Contaminations were still not completely eliminated at subsequent wipe events, which suggest that continued monitoring is required. High levels of contamination were more prevalent in locations where chemotherapy was prepared. A higher incidence of high, medium, and low contamination levels was detected at institutions that did not use a CSTD compared to institutions that did use these devices, although use of a CSTD did not completely remove all exposures.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Descriptive Report

Session-Board Number: 5a-183

Poster Title: Manufacturers, average wholesale prices (AWPs), and characteristics of controlled substances collected at a series of medication take-back events

Primary Author: Peia Lee, Texas Tech University Health Sciences Center, Texas; **Email:** peia.lee@ttuhsc.edu

Additional Author (s):
Jeanie Jaramillo-Stametz

Purpose: Significant quantities of prescription medication remain unused in homes, resulting in an increased risk of poisonings, abuse, and environmental contamination. Moreover, the financial implications associated with accumulated unused medication may significantly impact families and healthcare spending. This study quantifies, categorizes, and identifies the manufacturers of the controlled substances collected at regional community medication disposal programs also known as take-back events. This aids in identifying the largest contributors of unused medication and is important for the development of public health policy and processes designed to address such issues.

Methods: Community medication take-back events were conducted in three cities in the panhandle of Texas during the months of March and April 2016. Local law enforcement provided control and custody of controlled substances throughout the events. In preparation for these events, volunteers were required to attend one and a half hours training session that included information regarding protection of patient confidentiality, a zero tolerance policy for drug diversion, and safety issues. The medication data were recorded by trained event staffs and pharmacy students. Information collected included medication name, strength, original fill quantity, collected quantity, manufacturer/distributor, and expiration date, as available. The term unit was used to describe one pill, tablet, capsule, unit dose, or milliliter. Information was logged into Microsoft Excel spreadsheets. The Red Book Online tool of Truven Health Analytics Micromedex Solutions application was used to assign average wholesale price (AWP) to each item with the specific manufacturer. However, if the specific manufacturer information was neither recorded nor identified, an average of three listed AWPs for a similar product with the same medication and strength was assigned. Medication waste was calculated by dividing the quantity collected by the original fill quantity. Medication categories were excluded if fewer

than ten line items were collected leaving the remaining controlled substances to be included in the results. Descriptive statistics were used to evaluate and report results.

Results: A total of 3,275 pounds of unused controlled and non-controlled medication were collected from 1,256 participants. Controlled substances were reported by weight, as a proportion of the total medication collected and six percent of the collections were controlled drugs. Cost related to reported controlled drugs was $96,822. Ranked by category, benzodiazepines had the greatest cost ($18,692), followed by testosterone, pregabalin, stimulants, and opioids. In addition, hydrocodone-containing products accounted for one-third of the amount collected. The cost of wasted medication was lowest for carisoprodol ($189). When measured in terms of proportion of medication wasted, testosterone had the highest waste at 83%, followed by hydromorphone, atropine/diphenoxylate, pregabalin, and fentanyl. The lowest proportion of medication wasted was carisoprodol at 46%. The top five manufacturers identified, ranked from greatest related to unused drugs cost to least, they were Actavis ($32,589), Valeant, Pfizer, Qualitest, and Mylan. The top five manufacturers ranked from greatest number of units to the least, they were Qualitest, Mylan, Mallinckrodt, Watson, and Amneal. An overall unused medication rate of 64% was calculated.

Conclusion: This study adds to the growing body of evidence related to the overprescribing of controlled substances and provides insight into the negative economic impact as well as the increased risk of abuse and poisoning in family households. Moreover, manufacturer-specific information is revealed, providing further justification for increased manufacturer stewardship efforts at take-back events. Increasing the number of take-back events in the country help to promote consumer awareness of safe medication disposal and reduce drug abuse and poisoning.

Submission Category: General Clinical Practice

Submission Type: Evaluative Study

Session-Board Number: 5a-184

Poster Title: Comparison of plasma vascular endothelial growth factor levels between chronic kidney disease and cardio-renal syndrome patients

Primary Author: Cameron Asgharpour, Bernard J Dunn School of Pharmacy, VIRGINIA; **Email:** casgharp13@su.edu

Additional Author (s):
Michael Auchey
Maryam Moghimi
Shahrzad Movafagh

Purpose: Chronic Cardio-Renal Syndrome (CRS), a condition of coexisting cardiac and renal failure. Evidence shows that hypoxia plays a role in pathogenesis of both renal and cardiac diseases. We are interested in the role of hypoxic signaling in the pathophysiology of CRS. Vascular Endothelial Growth Factor (VEGF) is an angiogenic protein, transcriptionally induced in response to hypoxic signaling. We propose that hypoxic signaling via VEGF is altered in CRS compared to patients with Chronic Kidney Disease (CKD) alone. The objective of this study is to assess transcriptional activity between disease states by quantifying VEGF in CRS vs. CKD patients.

Methods: This study was approved by Shenandoah University Institutional Review Board. All patients were recruited from a participating kidney and hypertension specialists clinic in Manassas, VA. Chronic CRS was defined as diagnosis of chronic heart failure secondary to kidney disease. CKD staging was defined based on National Kidney Foundation's definitions of stage II-V kidney disease. Patients were recruited on predefined inclusion and exclusion criteria. There were 33 patients in the CHF group and 30 CKD. We quantified and compared VEGF protein levels through ELISA on blood plasma samples in both patient populations. Blood samples were centrifuged to extract plasma and stored at -80 degrees Celsius. Samples were thawed to room temperature upon experimentation. We utilized Abcam INC. ELISA kit for human VEGF and colorimetric detection to help quantify protein expression. Protein levels between groups were compared using standard curve analysis of protein expression via

GraphPad Prism. Patient samples were spiked with 0.074 ng/ml per well from a 6 ng/ml stock due to a low plasma values compared to signal detection threshold.

Results: We were able to quantify plasma VEGF values for 7 CHF patients and 12 CKD patients as they fell within range of detection. The mean values for CHF 215 47 were and for CKD 18313 picograms/ml. The p value was at 0.204
between both groups was not found to be statistically different.

Conclusion: VEGF has a narrow threshold of expression and we tried to spike concentrations to account for this.. The spike could have been added to the samples first as opposed to directly in the wells of the plate. We also had to subtract the standard spike as well as some noise from our negative control for all patient absorbance values. In order to obtain normal distribution and to increase significance we should increase patient population to at least n=50 per disease state group. We could have also used fresh patient samples in order to possibly fix the narrow threshold.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Descriptive Report

Session-Board Number: 5a-185

Poster Title: Evaluation of an emergency department admission medication history pilot using pharmacy technicians

Primary Author: Allyssa Webb, University of Florida - St. Petersburg, Florida; **Email:** allyssawebb@ufl.edu

Additional Author (s):
Alexa Conte
Jennifer Caldwell
Vicky Kang
Nicholas Mastromarino

Purpose: Well-trained pharmacy technicians can perform patient interviews, call retail pharmacies, perform database input, and promote communication between healthcare professionals. Use of pharmacy technicians can decrease the additional time that nurses, pharmacists and other healthcare team members would need to obtain an accurate prior to admission (PTA) medication list and work to make sure a correct medication list is available for admission teams. Tampa General Hospital (TGH) sought to evaluate the effectiveness of utilizing pharmacy technicians to obtain medication histories in the emergency department.

Methods: The pharmacy department trained five pharmacy interns to serve as medication history technicians. The interns functioned in the scope of technicians in regards to the level of electronic medical record access and patient interview. The project involved 16 hour coverage of the emergency department for 30 days (7/5/2016 to 8/3/2016) from 07:00-23:00. Interns reviewed the department trackboard and selected patient interviews according to an established workflow. Patient's marked as 'Intent to Admit' were interviewed first, and additional priority was given to patients flagged for more than 20 medications, age over 75 years, long-acting insulin, and/or no medications listed. During patient interviews, the intern inquired about allergies and preferred outpatient pharmacy, as well as collected the following information for each medication: name, dose, route, frequency, and informant. Following the encounter, interns documented corrections, duration of data collection, duration of electronic medical record update, and whether or not a nurse had previously reviewed the list as complete. For data analysis purposes, the medication errors were further classified into the

following categories: omission, addition, duplication, wrong dose, wrong dosage form, and wrong administration instructions. Descriptive statistical analysis was used to evaluate errors.

Results: A total of 903 patients were assessed and 4026 errors were updated on the PTA medication list with an average of 4.46 errors per patient. The data revealed that 67.4 percent of the time a nurse had previously reviewed the medication list prior to the technician. Of the 4026 total errors that were updated, 1645 errors were omissions, 1131 were addition errors, 543 errors involved incorrect administration instructions, 362 errors involved the wrong dose of a medication, 174 errors involved the wrong dosage form of a medication, and 48 errors involved duplications of a medication. Approximately 2 percent of the medication errors were due to high risk medications. The most cited source of information was the patient or a medication list. The average total time per assessment was 21 minutes, with an average of 14 minutes collecting information from sources and 6 minutes updating the record. A total of 322 patients required an update to allergies, with missing reaction as the most common error.

Conclusion: Utilizing pharmacy technicians to conduct admission medication histories in the emergency department reduces the number of medication errors. Corrected prior to admission lists and allergies enhances patient safety by allowing providers to have an enhanced clinical picture when ordering medications inpatient. Implementing positions filled by pharmacy technicians allows for improved accuracy on prior to admission medication lists. Correct lists improves patient satisfaction by decreasing repeat questions concerning medications, allows nurses and other members of the medical team to have time to perform other duties, and increases accuracy of discharge medication reconciliation.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Evaluative Study

Session-Board Number: 5a-186

Poster Title: Impact of transitions of care pharmacist discharge counseling on patient understanding of high-risk medications

Primary Author: Rachelle Roxas, University of California, San Diego Skaggs School of Pharmacy and Pharmaceutical Sciences, California; **Email:** rmroxas@ucsd.edu

Additional Author (s):
Christine Cadiz

Purpose: Multiple institutions have implemented the federally funded Community-based Care Transitions Program (CCTP) to improve quality of care and reduce hospital readmissions in high-risk Medicare patients. Studies have examined the impact of transitions of care (TOC) programs on hospital readmission rates. However, few have analyzed the effects of TOC services on patient medication understanding, which has the long-term potential to reduce preventable readmissions. The purpose of this study is to evaluate the impact of TOC pharmacist discharge counseling on patient understanding of high-risk medications.

Methods: Researchers conducted a prospective pre-post study on eligible CCTP patients referred for pharmacist counseling during the two-month study period. Pharmacists provided medication education counseling and patient-friendly medication schedules using a Medication Action Plan prior to discharge from the hospital. Data were collected for up to five randomly selected high-risk medications, including anticoagulants, anti-diabetics, anti-platelets, anti-hypertensives, asthma or chronic obstructive pulmonary disease treatments, and cardiovascular medications. Data were quantified through an adapted Medication Understanding Questionnaire (MUQ), which was scored after being delivered verbally to patients in the hospital before discharge counseling and again via telephone 48 to 72 hours after discharge from the hospital. MUQ scores ranged from 0 to 3 and were normalized based on number of high-risk medications per questionnaire. Pre-MUQ and post-MUQ scores were analyzed using the Wilcoxon matched-pairs signed-rank test. Secondary end points included analysis of primary adherence barriers.

Results: A total of 27 individuals completed the pre-MUQ and post-MUQ, including 13 males and 14 females whose combined mean age was 69.3 years plus or minus 10.92. The median MUQ score was 2.5 (range of 0.5 to 3) before pharmacist counseling, which differed significantly from the median MUQ score of 2.7 (range of 2.1 to 3) after counseling (Z equals -3.36, P less than 0.001). The most common primary adherence barrier was failure to pick up new medications after discharge.

Conclusion: TOC pharmacist counseling significantly improved patient understanding of high-risk medications based on MUQ score. However, limitations included a small sample size and omission of some high-risk medications (i.e., opioids). Future studies might analyze the correlation between post-discharge medication understanding and hospital readmissions.

Poster Title: Impact of pharmacy intervention component of a community based care transitions program (CCTP) on readmission and emergency department (ED) utilization rates

Primary Author: Zoe Zhou, University of California San Diego Skaggs School of Pharmacy and Pharmaceutical Sciences, California; **Email:** qizhou@ucsd.edu

Additional Author (s):
Christine Cadiz
Jeremy Lee

Purpose: Nearly 1 in 5 Medicare patients is readmitted to a hospital within 30 days of discharge. Created under Section 3026 of the Affordable Care Act, the Community-based Care Transitions Program (CCTP) aims to improve care transitions from hospitals to other care settings and reduce readmissions for high-risk Medicare beneficiaries through the use of both intensive nurse coaching and pharmacist interventions including medication education and reconciliation. The objective of this study was to evaluate the impact of pharmacy discharge medication reconciliation by comparing readmission rates for patients who received pharmacist discharge medication reconciliation and those who did not.

Methods: This was a retrospective cohort study of high risk patients at Palomar Health referred for CCTP pharmacy intervention services in addition to intensive nurse coaching between June 1st 2013 and February 21st 2015. A total of 2641 patient charts were reviewed for data collection. Subjects were separated into two groups: patients who received pharmacist discharge medication reconciliation versus patients who did not. Subjects were excluded from analysis if they were enrolled in hospice or expired within the 30 and 60 day time frames for analyses. Chi squared and odds ratio tests were used for statistical analysis, with a predefined p value of less than 0.05 for statistical significance. The primary outcome measured for this study was 30 day overall readmission rate for the two groups. Secondary outcomes included 60 day overall readmission rate, 30 and 60 day post-discharge emergency department (ED) utilization rates, and 30 and 60 day composite of readmission and ED utilization rates. It was determined that total of 8240 subjects were needed to achieve 80 percent power with an alpha of 0.05.

Results: The 30 day overall readmission rate for the group with pharmacist discharge medication reconciliation was 11.88 percent compared to 13.95 percent for the group without pharmacist discharge medication reconciliation. This reflects a 2.07 percent absolute risk reduction (95 percent CI, 0.65 percent to 1.07 percent, P equals 0.13) for 30 day readmission rate for patients who received discharge medication reconciliation. Although also not statistically significant, the 60 day readmission rate was 1.91 percent lower (95 percent CI, 0.71 percent to 1.09 percent, P equals 0.23) for patients who received pharmacist discharge medication reconciliation. Other secondary outcomes demonstrated minimal changes due to pharmacist intervention, and showed no statistically significant difference between two subject groups.

Conclusion: This study was not sufficiently powered to detect a statistically significant difference in hospital readmission between patient groups with pharmacist discharge medication reconciliation and those without. However, 30 and 60 day hospital readmission rates reflected a downward trend towards reduced readmission associated with pharmacist intervention. Results suggested that a single pharmacist intervention at discharge may not be sufficient to prevent long-term readmissions, but may help reduce short-term readmission. Future studies may expand the scope of interventions studied and determine their effects on hospital readmission and emergency department utilization rates.

Poster Title: Prevalence of gastrointestinal adverse events with co-administration of dolutegravir and metformin

Primary Author: Ana Cruz, University of California, San Francisco School of Pharmacy, California; **Email:** ana.cruz@ucsf.edu

Additional Author (s):
Janet Grochowski
Parya Saberi

Purpose: Dolutegravir is known to increase metformin plasma concentration levels when used simultaneously in patients living with HIV (PLWH) and diabetes mellitus. However, there is no clinical data available to show the prevalence of gastrointestinal (GI) adverse events associated with the use of these two medications together. The purpose of this study was to determine the prevalence of GI side effects reported by patients taking dolutegravir and metformin synchronously.

Methods: The Positive Health Program at Ward 86 located at San Francisco General Hospital has approval from the University of California, San Francisco's institutional review board for this retrospective cohort study. We identified all patients taking 'Anti-HIV integrase inhibitor' medications and 'Biguanides' or 'Glucophage' from August 2013 to July 2016 in PLWH and receiving care at Ward 86. We narrowed down the initial list to patients who took dolutegravir and metformin concomitantly. We examined duration of overlap between the two medications, prevalence of GI adverse events, and self-reported associations between GI adverse events and either medication.

Results: Among the 35 patients taking dolutegravir and metformin simultaneously, 85.7% were male, mean age was 57 years old, and 48.6% were Caucasian. Patients took dolutegravir and metformin (17.1% on 500mg/day, 48.6% on 1000mg/day, 5.7% on 1500mg/day, 2.9% on 1700mg/day, 22.8% on 2000mg/day, and 2.9% on 2550mg/day) for a mean of 14 months (range 1-32 months). Overall, 11 (31%) reported experiencing GI adverse events. Of these, 7 (63.6%) reported symptoms associated with metformin, 2 (18.2%) associated symptoms with dolutegravir, and 2 (18.2%) could not determine if symptoms were associated with dolutegravir

or metformin. GI adverse events included diarrhea (6), nausea (4), bloating (1), flatulence (1), and constipation (1). Patients reported adverse events within a mean of 3 months after starting both medications. Of the 11 reporting GI adverse events, 5 were taking doses higher than 1000mg per day of metformin (1 on 1500mg, 1 on 1700mg, and 3 on 2000mg). When metformin dose was decreased to 1000mg per day, 3 reported improvement in symptoms. The remaining 2 maintained the same dose and eventually discontinued the use of metformin. Among the 6 individuals who had symptoms at 1000mg a day of metformin, 4 had minor symptoms while 2 eventually discontinued metformin use.

Conclusion: The prevalence of GI adverse events in patients taking dolutegravir and metformin concomitantly was lower than that reported in the metformin clinical trials and similar between those at 1000mg per day of metformin and those at higher doses. Diarrhea was the most commonly reported adverse event. Even though dolutegravir is known to increase metformin plasma levels when taken together, the use of the two medications, even at higher doses may be safe and well-tolerated.

Poster Title: Application of vapor containment protocol for closed system transfer devices to assess efficacy during pharmacy compounding and administration of hazardous drugs

Primary Author: Charlotte Forshay, University of North Carolina Eshelman School of Pharmacy, North Carolina; **Email:** mforshay@email.unc.edu

Additional Author (s):
Shawn Streeter
Stephanie Salch
Stephen Eckel

Purpose: Recent United States Pharmacopeia 800 guidelines require the use of closed system transfer devices (CSTDs) for hazardous drug administration. The National Institute for Occupational Safety and Health (NIOSH) released a proposed protocol to evaluate the vapor or liquid containment abilities of different CSTDs in order to provide meaningful comparisons for purposes of safety and efficacy. To date, no study has comprehensively evaluated various CSTDs against this protocol. The purpose of this study is to assess the ability of various CSTDs when following the methodology as outlined by NIOSH.

Methods: This study evaluated 6 different CSTD products when following the NIOSH vapor containment protocol. The testing process evaluated each CSTD system during both compounding (Task 1) and administration (Task 2). This is repeated for a total of 4 manipulations per device.
In task 1, the technician added 90 mL of isopropyl alcohol, using two 45 mL transfers from two 60 mL syringes and two 50 ml vials, to a 500 mL normal saline IV bag. The CSTD components evaluated under this task included one bag adapter, two vial adapters, and two syringe adapters.
In task 2, the technician prepared a 45 mL dose of isopropyl alcohol in each of two 60 mL syringes and injected each prepared syringe into the Y-site of the IV tubing. This simulated administering an IV push. The CSTD components evaluated under this task included two vial adapters, two syringe adapters, one bag adapter, and one IV port adapter.
Measurements were recorded at each step of both processes. Vapor release was detected by the Miran Analyzer and measurements were gathered in real time after each step of the

process. Readings below 0.3 parts per million were considered below the detection limit of the equipment. Data points were adjusted for background concentration and adjusted for the limit of detection of the equipment.

Results: Both Task 1 and Task 2 were conducted using 4 samples for each product, with vapor levels recorded after each of the 5 pre-specified steps throughout the task. The metric of interest was the highest adjusted data point for each sample. This resulted in 4 adjusted values per product for each task. The mean and 95 percent confidence intervals were calculated for each set of adjusted values to determine the ability of each CSTD to effectively contain isopropyl alcohol vapor.

In Task 1, the following mean values were observed for each set of adjusted values: 0.35, 0.48, 0.93, 2.68, 4.88, and 10.78 parts per million. In Task 2, the following mean values were observed: 0.30, 0.60, 0.60, 2.60, 5.40, and 14.85 parts per million. Some of the CSTDs tested were able to contain all of the isopropyl alcohol during Task 1 and 2, whereas others were unable to contain it.

Conclusion: A CSTD failed to effectively contain vapor if the 95 percent confidence interval of the mean contained greater than or equal to 1.0 part per million. Average values less than 1.0 part per million indicated a CSTD that successfully contains isopropyl alcohol vapor as per NIOSH protocol.

For Task 1, 2 CSTD products adequately contained the isopropyl alcohol vapor, and in Task 2, the same 2 products also contained the vapor with 1 additional product passing the testing protocol for that task. Based on the results of this study, only 2 out of 6 CSTD products function as closed systems.

Poster Title: Incidence of neutropenia with long-term ceftaroline therapy

Primary Author: Henry Saedi-Kwon, Pacific University School of Pharmacy, Oregon; **Email:** henry.sk@pacificu.edu

Additional Author (s):
Brigg Turner
Jacqueline Schwartz

Purpose: Ceftaroline is FDA approved for skin and skin structure infections and community-acquired pneumonia. Phase III trials demonstrated a favorable safety profile when the mean duration of therapy was approximately 7 days. With the increasing prevalence of methicillin-resistant Staphylococcus aureus (MRSA) infections, ceftaroline is being used for off-label indications such as bacteremia, endocarditis, and osteomyelitis, necessitating a longer duration of therapy. Several small reports suggest a higher than expected incidence of neutropenia with prolonged use. The purpose of this study is to assess the incidence of neutropenia with long-term ceftaroline therapy in a larger cohort.

Methods: A retrospective cohort analysis was performed from April 2011 to March 2016 of patients over the age of 18 who received ceftaroline for greater than or equal to 7 days during hospital admission. Patients with baseline neutropenia were excluded. The primary outcome was the development of neutropenia. Neutropenia was defined as an absolute neutrophil count (ANC) less than or equal to 1500 cells/mm3. Baseline and clinical characteristics between patients who experienced the primary outcome and those who did not were compared using Fisher's exact test and the Wilcoxon rank-sum test.

Results: A total of 77 patients met the inclusion and exclusion criteria. Median age was 52 years (range from 20 to 89 years). Median duration of ceftaroline therapy was 14 days (range from 7 to 79 days). Seven patients (9.1 percent) developed neutropenia with a median ANC nadir of 980 cells/mm3 after receiving a median of 23 days of ceftaroline therapy. Patients receiving 21 days of therapy or more were at much higher risk of developing neutropenia than those receiving shorter durations (27.3 percent versus 1.8 percent, P equals 0.002). The greatest risk was in those receiving greater than 6 weeks of therapy of which 50 percent experienced

neutropenia (4/8 patients). While not significant, females were twice as likely to develop neutropenia as males (6.7 percent versus 12.5 percent, P equals 0.44). Only 5 patients received ceftaroline at a higher dosing frequency of every 8 hours; however, none of these patients developed neutropenia. Body mass index did not appear to influence incidence of neutropenia (P equals 0.93). Of the seven patients who developed neutropenia, two had post-therapy data for determining resolution. One of these patient's neutropenia resolved during therapy and the other resolved within 4 days of ceftaroline discontinuation.

Conclusion: In phase III trials, neutropenia occurred in less than 2 percent of patients treated with ceftaroline for approximately 7 days. Seven patients (9.1 percent) in our cohort developed neutropenia when treated with ceftaroline for at least 7 days. Six of these seven patients (85.7 percent) received ceftaroline for 21 days or more, putting them at substantially higher risk. Patients who received 6 weeks of therapy or more were at the highest risk. The results of this study confirm that of previous findings but suggest the overall incidence of neutropenia is correlated to days of therapy.

Poster Title: Urinary kidney injury molecule-1 (KIM-1) as a marker of vancomycin associated kidney injury in rats

Primary Author: Cameron Cluff, Midwestern University Chicago College of Pharmacy, Illinois; **Email:** ccluff28@midwestern.edu

Additional Author (s):
John Day
John O'Donnell
Nathaniel Rhodes
Marc Scheetz

Purpose: Standard methods of determining renal function, blood-urea nitrogen (BUN) and serum creatinine (Scr), require a two-thirds reduction in nephron function before detectability. Urinary kidney injury molecule-1 (KIM-1) is both sensitive and specific for proximal tubular acute kidney injury (AKI). Unlike BUN and Scr, KIM-1 concentrations peak within 24 hours and maintain elevated concentrations for 5 days. This permits swifter detection and therapeutic decisions. Rats and humans experience rises in KIM-1 with renal proximal tubule injury, making the rat an appropriate model. We will study the relationship between vancomycin exposure and AKI using rat-specific pharmacokinetic data and urinary biomarkers in rats.

Methods: We will complete an interventional animal model study designed to determine the relationship between vancomycin exposure and AKI. Rats will be given varying doses between 150mg/kg/day and 200mg/kg/day of vancomycin. The dosing schedule will also vary between daily and twice daily dosing. The duration of therapy will be either 1 day, 3 days, or 7 days. A control of saline will be given for each duration and dosing schedule to control for any kidney injury due to the stress of injection. Plasma, serum, urine, and kidney samples will be collected and analyzed to determine exposure and extent of AKI associated with that exposure. Urinary KIM-1 will be quantified and correlated with vancomycin exposure as well as histopathology scores for each subject. Bayesian estimation techniques will be used to determine the PK parameters and exposure variables of interest for each rat under study. Maximum plasma concentration (Cmax), area under the curve (AUC), and minimum plasma concentration (Cmin)

will be used as indices in exposure-response analysis. Ultimately the aim of this study is to identify the exposure of vancomycin in which the rats will incur AKI.

Results: Preliminary results from the first 52 rats included 10 control rats and 42 experimental rats, which are subdivided into cohorts based on duration of treatment, dosage strengths, and frequencies. The Bayesian 2 compartment model of observed vs predicted vancomycin concentrations revealed a variance of 0.98 validating the accuracy of our pharmacokinetic model in rats. Plots of KIM-1 vs. pharmacokinetic parameters showed that the KIM-1 levels revealed a higher variance in with both Cmax and AUC and a lower variance with Cmin.

Conclusion: From the mathematical modeling, it is shown that Cmax and AUC are better predictors of AKI in rats than Cmin. Therefore, assessing trough values as the standard of assessing the degree of kidney insult is not recommended. Rather, Cmax or AUC would be better surrogate measures of kidney injury. Future experiments are laid out for controlled-infusion drug dosage schemes. This will further elucidate the causative, underlying factor in developing AKI.

Poster Title: Arizona Controlled Substance Prescription Monitoring Program: attitudes, beliefs, and usage by pharmacists and physicians

Primary Author: Antoinette Tran, Midwestern University, College of Pharmacy - Glendale, Arizona; **Email:** atran95@midwestern.edu

Additional Author (s):
Jeffrey Lam
Ellen Lee
Ryan Gries
Mary Gurney

Purpose: In 2011, the Centers for Disease Control identified prescription drug abuse as an epidemic in the US. Prescription drug monitoring programs are statewide electronic databases that track controlled substance (CS) prescriptions dispensed by pharmacists and other healthcare providers. The Arizona Controlled Substance Prescription Monitoring Program (AS CSPMP) is a mandatory report and voluntary look program that is housed within the Arizona State Board of Pharmacy. This project was designed to establish baseline data regarding the attitudes, beliefs, and the usage of the AZ CSPMP by Arizona pharmacists and physicians.

Methods: The institutional review board approved this cross-sectional, descriptive study of Arizona physicians and pharmacists. Lists of current Arizona licensed physicians (MDs and DOs) and pharmacists were obtained from the AZ Medical Board, the AZ Board of Osteopathic Examiners, and the AZ State Board of Pharmacy. Stratification (MDs, DOs, Pharmacists) and sampling was based on a 95% confidence interval, a + sampling error of 5%, 50/50 proportion with required numbers for each strata as follows: MDs = 373, DOs = 325, and Pharmacists = 365.
A total of 7026 MDs (n = 2486), DOs (n = 2107), and Pharmacists (n = 2433) in Arizona were contacted based on an anticipated 15% response rate. Study subjects were mailed a letter with the study explanation, the URL, and QR code to the electronic Qualtrics ® survey. A reminder letter was mailed 2 weeks later; the online survey was open for 6 weeks. The survey contained five sections: 1) demographics, 2) views on prescription drug abuse and diversion, 3) general prescribing practices, 4) AZ CSPMP usage, and 5) education and training. Data was analyzed

using Qualtrics® and IBM SPSS © 22.0; descriptive (parametric and nonparametric) statistics were used.

Results: The overall usable response rate was 5.3% (356/6670). Pharmacists provided 60% of the responses. Overall respondents were: 60% male; 40% were 56 years or older), 55% have practiced for 20 or more years; and 89% were Caucasian.
Overall, MDs, DOs, and pharmacists believe there is a prescription drug abuse problem in AZ (87%), county (85%), and city/town (80%). The level of concern about prescription drug abuse is over 90% for all at the state and city/town level, and less than 70% at the practice site. All groups rate the effectiveness of the CSPMP at 90% or higher; the exception is that only 80% of Pharmacists believe the CSPMP is effective in controlling prescription drug diversion. The top three reasons for accessing the CSPMP were: patients suspected of drug seeking (69%), new patient's history prior to dispensing CS (68%), and review an established patient's history prior to prescribing/dispensing a CS (52%). While 80% of pharmacists believe that healthcare providers should be required to access the CSPMP prior to writing a prescription for a CS; less than 25% of MDs and DOs believe so. Approximately 60% of all groups believe that healthcare providers should access the CSPMP prior to dispensing a CS.

Conclusion: Healthcare providers are concerned about prescription drug abuse at all levels; though each group believes that there is less of a concern at the level of their practice site. Overall, the CSPMP is viewed as a useful tool to monitor patient use of controlled substances and screen for suspected drug seeking. Physicians and pharmacists are in agreement that the CSPMP should be required to be accessed prior to dispensing. The greatest disconnect between physicians and pharmacists is that pharmacists believe that healthcare providers prescribing controlled substances should be required to access the CSPMP prior to prescribing a controlled substance.

Submission Type: Evaluative Study

Session-Board Number: 5a-193

Poster Title: Liposomal encapsulation of vancomycin for reduced nephrotoxicity

Primary Author: Harshwardhan Jain, Midwestern University, Illinois; **Email:** hjain37@midwestern.edu

Additional Author (s):
Jack Chang
Brooke Griffin
Marc Scheetz
Medha Joshi

Purpose: For patients infected with methicillin-resistant Staphylococcus aureus (MRSA), vancomycin remains a drug of choice. Used primarily in the hospital setting, vancomycin has been shown to induce nephrotoxicity within patients. As shown in previous studies, nephrotoxicity correlates with high kidney concentrations. Liposomes encapsulating vancomycin were prepared to reduce their absorption in kidneys vis-à-vis hoping to mitigate nephrotoxicity.

Methods: PEGylated and Non-PEGylated liposomes were prepared using (1) Freeze Thaw and (2) Reverse Phase Evaporation Methods. Both PEGylated and Non-PEGylated liposomes were similar except for the use of PEG-DPSE 2000 (1,2-distearoyl-sn-glycero-3-phosphoethanolamine-N-[maleimide(polyethylene glycol)-2000]) in PEGylated liposomes. In the Freeze Thaw Method, liposomes were prepared using the thin film hydration technique, dissolution in organic solvents, evaporation using a Rotavac (Buchi, Germany), and drying using nitrogen gas. The resultant film was hydrated with 1x PBS buffer solution containing vancomycin to form crude liposomes. Liposomes were subjected to 5 cycles of freeze thaw in liquid nitrogen and were thawed in ambient conditions. The liposomes were sized around 200 nm using an extruder (Lipex Northern Lipids, Canada). For the Reverse Phase Evaporation Method, phospholipids were dissolved in organic solvent and mixed with vancomycin solution in PBS, evaporated via Rotavac and exposed to nitrogen gas. Sizing was performed as above. Both the formulations for these liposomes were controlled for quality based on particle size and polydispersity index (PDI) using the Zetasizer Nano ZS (Malvern Instruments, UK). Vancomycin

loading and encapsulation in the liposomes was assessed via HPLC. Lastly, the release of vancomycin from the liposomes was tested using the dialysis bag method for 48 hours.

Results: PDI after extrusion was less than 0.2, demonstrating a stable homogenized particle size for both the PEGylated and Non-PEGylated liposomes. Freeze Thaw Method gave the highest encapsulation percentage (62 percent) for the PEGylated liposomes compared to the Reverse Phase PEGylated liposomes which had an encapsulation percent stage of 16.9 percent. For the Non-PEGylated liposomes, the Reverse Phase Evaporation Method gave the highest encapsulation (28.5 percent) and Freeze Thaw Method gave an encapsulation percent of 15.5 percent.

Conclusion: A nanosized stable liposomal preparation of vancomycin was obtained using two methods of encapsulation via Freeze Thaw and Reverse Phase Encapsulation Method. PEGylated liposomes provided the highest encapsulation using the Freeze Thaw Method; the highest encapsulation was via Reverse Phase Evaporation for the Non-PEGylated liposomes. The Freeze Thaw may be superior for vancomycin encapsulation because of formed multilamellar and multivesicular vesicles, resulting in an increased volume for the internal aqueous chamber.

Poster Title: Student pharmacists engagement in new collaborative efforts to provide antimicrobial stewardship education

Primary Author: Abigail Kraus, University of Pittsburgh, Pennsylvania; **Email:** azk20@pitt.edu

Additional Author (s):
Bonnie Falcione
Lucas Berenbrok

Purpose: Inappropriate use of antibiotics can lead to unnecessary emergency room visits due to adverse drug reactions and may also result in antimicrobial resistance which can limit first line therapies. A statement published by ASHP describes the pharmacist's role in antimicrobial stewardship (AS) including implementation of programs to educate individuals on appropriate antimicrobial use and infection prevention measures. A project was designed to involve student pharmacists from the University of Pittsburgh to collaborate with the Pennsylvania Department of Health (PADOH) and the Centers for Disease Control and Prevention (CDC) Get Smart About Antibiotics programs to promote AS.

Methods: In 2013, the University of Pittsburgh School of Pharmacy began collaborating with the PADOH and CDC Get Smart About Antibiotics programs to increase AS awareness in Pennsylvania. The PADOH provides outreach through four initiatives: communication, pediatric, pharmacy, and long term care. PittPharmacy supports student pharmacist participation in the PADOH pharmacy and pediatric initiatives in the first (P1) and second (P2) professional year curriculums. Student pharmacists in either year volunteer to the pediatric initiative by providing interactive demonstrations of proper hand hygiene at childcare centers. P2 student pharmacists participate in the pharmacy initiative, first, by attending an annual hands-on workshop focused on AS for a redesigned course with an integrated network of community pharmacies providing introductory pharmacy practice experiences (IPPE). The workshop incorporates an onsite presentation from the PADOH. Secondly, P2 students interact with patients at over 75 community pharmacies within the IPPE network using a dedicated outreach program to gauge patient attitudes and awareness about appropriate antibiotic use. Resources from the CDC, including a CDC quiz assessing patient antibiotic knowledge as well as Get Smart About

Antibiotics materials are used to deliver information and collect patient attitudes and awareness.

Results: Student pharmacists provided education on appropriate antibiotic use and infection prevention to over 2300 individuals in Southwestern Pennsylvania via the PADOH initiatives between 2014-2016. Every year, student leaders from the P2 class refine, plan, and deliver the annual hands on workshop and provide community outreach materials. Educational materials used during the community IPPEs are refined using feedback from students in the previous year to ensure yearly continuous improvement. Results from the antibiotic quizzes completed by patients in 2014 revealed areas for improvement and education points to emphasize. Evaluation of quizzes reveal gaps in knowledge where student pharmacists can intervene to educate future patients. This initiative has opened up channels of opportunities for student leadership and involvement. This year, P3 students are organizing a campus wide Get Smart week to involve students, including undergraduate and other health science professional students, in educating about appropriate antibiotic use. Additionally, student pharmacists have volunteered as ambassadors to other schools who have expressed interests in implementing similar AS initiatives.

Conclusion: Student pharmacist participation in educational outreach in collaboration with PADOH and CDC Get Smart About Antibiotic programs has promoted appropriate use of antibiotics in Southwestern Pennsylvania. By targeting appropriate and correct medication use, student led educational outreach programs are powerfully positioned to identify ongoing knowledge gaps, and ultimately may help to reduce antimicrobial related adverse medication events and other negative effects of inappropriate antibiotic use including antimicrobial resistance.

Poster Title: Comparison of ocular gel forming solutions of gellan and calcium gluconate with and without polyvinyl pyrollidone

Primary Author: Nathaniel Berger, Belmont University College of Pharmacy, Tennessee; **Email:** nathaniel.berger@pop.belmont.edu

Additional Author (s):
Caitlin Medley
Kenneth Reed

Purpose: When treating many conditions, drugs administered locally via eye drop, have a short duration of action and/or are eliminated quickly. One way to ensure enhanced ocular presentation of medication is to strengthen the viscosity of ophthalmic products by adding water soluble polymers. Previous research indicates that addition of polyvinyl pyrollidone (PVP) to an aqueous, low-acyl gellan/calcium gluconate gel forming solution (GFS) can reduce the rate of release of timolol from the polymer. This study focuses on the optimization of in situ gel forming properties of low-acyl gellan/calcium gluconate formulations both with and without PVP.

Methods: Fifty-three aqueous formulations of low-acyl gellan and calcium gluconate and 67 formulations of low-acyl gellan, calcium gluconate, and PVP were prepared to varying concentrations. Samples were subjected to viscosity measurements using a ViscoTester 550 at ambient temperature (22-24 degrees C). This process includes an initial measurement of the viscosity of the gel sample (RT K'), a shearing step, and then a secondary measurement of viscosity (RT K''). The RT K'' value is important identifying formulations able to be applied from a common ophthalmic package configuration. Each formulation is used to prepare a test sample, 5:1, of the original formulation sample to physiological artificial tear solution (PATS). The test preparations are subjected to viscosity measurements (ET K', ET K'') at the physiological temperature of the external eye (32-36 degrees C). The gel/PATS preparation simulates the formulation in the tear-filled environment of the eye. The ET K' value of the gel/PATS test preparation simulates the viscosity of the formulation in the external eye. The independent variables of viscosity data (K', K'') and the predictor variables of gellan, calcium gluconate, and PVP concentrations were mathematically modeled using multi-variate, non-

linear regression analysis. Drop size and expulsion pressure testing from an ophthalmic bottle determined the highest allowable K'' value which was used as a limiting factor in calculating the highest obtainable viscosities (K') of GFS both with and without PVP.

Results: The mathematically derived models are as follows for those sample preparations with no PVP:
Predicted (r = 0.89) RT K''value = -5.408 + (1122.934 · g/mL gellan) + (418.459 · g/mL Calcium Gluconate)
Predicted (r = 0.69) ET K' value = -4.667 + (1318.7907 · g/mL gellan) + (950.700 · g/mL Calcium Gluconate)
The mathematically derived models are as follows for those sample preparations with PVP:
Predicted (r = 0.84) RT K'' value = -6.889 + (1121.926 · g/mL gellan) + (2557.328 · g/mL Calcium Gluconate) + (31.193 · g/mL PVP)
Predicted (r = 0.86) ET K' = -9.0449 + (1701.451 · g/mL gellan) + (4325.176 · g/mL Calcium Gluconate) + (16.421 · g/mL PVP)
The data indicates that the addition of PVP to gellan/Ca gluconate GFS results in a slight increase in resultant ET K' values.

Conclusion: Optimizing rate of delivery of ophthalmic drugs is beneficial in treating chronic conditions or infections in which a more sustained delivery of drug to the eye could improve clinical outcomes or reduce dosing requirements. The data indicates that addition of PVP to ophthalmic gellan/Ca Gluconate formulations increases the viscosity of the gel in eye-like conditions. PVP in low-acyl gellan, calcium gluconate ophthalmic formulations has been shown to reduce the rate of release of timolol from the gel matrix. These properties of PVP in aqueous low-acyl/calcium gluconate gel solutions demonstrate their potential benefits in ophthalmic drug delivery.

Poster Title: Assessing the effectiveness of Beers criteria for medication review on fall risks in older community-dwelling adults

Primary Author: Jankhna Yadav, California Health Sciences University School of Pharmacy, California; **Email:** jankhnayadav@gmail.com

Additional Author (s):
Stanley Snowden
Cheryl Edgar
Peggy Trueblood
Patty Havard

Purpose: The departments of Physical Therapy and Kinesiology, School of Nursing and College of Pharmacy have provided interprofessional collaborative practice (ICP) activities for students through the Senior Awareness and Fall Education (SAFE) program since September 2014. The 2015 Updated Beers Criteria, is a guideline that lists potentially inappropriate medications to be avoided in older adults. One of the intents of the criteria is to serve as a tool for evaluating patterns of medication use in older adults. The purpose is to assess the effectiveness of the Beers Criteria in patients participating in the SAFE program.

Methods: Older adults with fall risks participated in the SAFE program following approval from their primary care provider. Medication lists, patient demographics, and pertinent medical history were collected from each patient. Each of these variables and their combined effects were used to evaluate a patient's risk of falling. We compared the patients' medication lists with the Beers Criteria to assess the frequency pattern of medication use in older adults with risk for falls. Analysis was done to identify the effectiveness of the Beers Criteria, which will help identify qualities in an assessment tool in order for it to be successful in the community-dwelling population. After review of the descriptive statistics, a determination of applicability of the assessment tools in the community population, along with suggestions for a more applicable assessment tool, can be made. IRB approval was granted from both California State University, Fresno and California Health Sciences University.

Results: 545 adults (55 to 97 years old) were interviewed during the SAFE screening program. Variables including their age, gender, ethnicity, medical history, and medications list including prescription, non-prescription, and supplements were obtained. The mean age was 76 years old. Of the 545 participants, 113 were male and 432 were female. The participants' ethnicities include: 72.9% Caucasian, 18.3% Hispanic, 4.4% Asian, 1.1% African American, and 2.4% unknown. The top five chronic conditions, in order from most to least reported, hypertension (61.3%), arthritis (57.4%), chronic back pain (45.4%), osteoporosis and fractures (26.3%), and diabetes (22.8%). A review of patient medications was completed, which includes prescription, non-prescription, and OTC NSAID products. Prescription medications and OTC NSAID products were emphasized during this review in order to make a more comparable comparison of the applicability of Beers Criteria. Of the 254 medications reviewed, 60 medications (23%) were identified as inappropriately prescribed medications via Beers Criteria. The top five medications were Aspirin, Thyroid replacement, Lisinopril, Atenolol, and Metoprolol. Of these, only Aspirin is listed in the Beers Criteria. The remaining 77% have been known to increase fall risk and are not included in Beers criteria.

Conclusion: Though medication review and patient assessment through the use of various assessment tools are pivotal in assessing a patient's fall risk, they are not all-encompassing, as seen with the Beers Criteria. This tool is drug focused, missing medications from specific classes or drug classes all together known to have adverse effects that can lead to falls. Assessment tool modification is needed for effective fall risk assessment.

Poster Title: Time and Motion Study of Non-Pharmacologic Delirium-Prevention Measures Performed by Nurses in an Intensive Care Unit Setting

Primary Author: Abby Meyer, University of Pittsburgh School of Pharmacy, Pennsylvania; **Email:** abby.meyer@pitt.edu

Additional Author (s):
Kathryn Ching
Rachel Cartus
Jessica Marini
Meghan McLinden

Purpose: The purpose of this study was to evaluate and categorize the amount of time nurses spend on delirium-prevention activities compared to other nursing activities within a medical intensive care unit (MICU) and to determine whether delirium prevention is appropriately implemented in a MICU setting at University of Pittsburgh Medical Center (UPMC), Presbyterian Hospital. We hypothesized that nurses would spend significantly more time performing non-delirium preventing activities such as obtaining and administering medications, helping other nurses within the unit, and charting or documenting.

Methods: Student pharmacists performed a time and motion study of nurses in the MICU at UPMC Presbyterian Hospital, a large tertiary medical center, through four hour increments during April 2016. Eighteen different nurses were observed, with most nurses caring for two patients and only one nurse caring for a single patient. Nurses were eligible for observation if they were at least 18 years old and had been working as a registered nurse for at least 6 months. Prior to data collection, nursing activities were categorized into different delirium preventing and non-delirium preventing activities. Preliminary sessions with students were held to help standardize methods of timing nursing activities. Categories of delirium preventing measures include: opening/shutting blinds, turning lights on/off, re-orienting patient through verbal communication, talking to patient about non-medical topics, offering eyeshade, helping patient with contacts and/or glasses, helping patient with hearing aids, and helping patient with ear plugs. Other timed activities were common nursing duties including charting, obtaining medications, administering medications, and helping other nurses. The amounts of time nurses

spent doing each activity was recorded. Data were summarized by median and ranges due to non-normal distributions. The Mann Whitney-U Test was used to compare the time non-pharmacologic delirium prevention activities were conducted versus the other nursing activities. We considered a p-value of less than or equal to 0.05 to be statistically significant.

Results: Nurses spent less time performing non-pharmacologic delirium prevention activities as compared to other patient care activities with total time (median (minutes), range (minutes)) of 158.413 minutes (1, 0-18.32) compared to 1216.85 minutes (29.4, 6.1-58.2), respectively (p less than 0.001). The most common delirium prevention activities involved talking to the patient directly. This was comprised of reorienting the patient, 28.631 minutes (0.33, 0-12.5) and talking to patients about non-medical related topics, which was done for a total of 37.479 minutes (0.175, 0-18.1). The least common delirium prevention activity was offering the patient an eyeshade and/or earbuds with a total of 0 minutes (0, 0-0). Significantly more time was spent charting, 528.08 minutes (12.675, 2.6-52.7), helping other nurses, 343.52 minutes (3.325, 0-154), and giving and obtaining medications, 199.08 minutes (3.35, 0-24.74) and 146.17 minutes (2.13, 0.07-20.2), respectively. Overall nurses spent 1.58% (68.32 min/4320 min) of the time observed helping to prevent delirium in their patients and 28.17% (1216.85 min/4320 min) on other activities. Additionally, the amount of time that blinds were open or closed was recorded. Blinds were open a total of 4062 minutes (114.9, 0-240) more than closed, 1732.8 minutes (0, 0-240).

Conclusion: Our data shows that nurses in the MICU spent significantly more time on non-delirium related activities and that delirium prevention only comprised of a small portion of the overall time observed. Out of all the delirium preventing activities, the most common measure was talking to the patient, while the least common measure was providing an eyeshade and/or earplugs.
While the use of non-pharmacologic delirium prevention strategies could prove to be beneficial, most nursing time in a large, tertiary medical center is spent performing more directed tasks focused on patient care (administering medications, charting) and getting their required daily duties done.

Poster Title: Pharmacists' perceptions of a newly-implemented discharge counseling initiative

Primary Author: Michael Curcio, Roseman University of Health Sciences College of Pharmacy, .Utah; **Email:** mcurcio@student.roseman.edu

Additional Author (s):
Nicole Tito-Agustin
Dustin Grant

Purpose: At many institutions around the country, pharmacists are optimizing patient care by providing clinical services throughout a patient's hospital stay. Pharmacists perform medication reconciliation upon admission, provide inpatient monitoring, and educate the patient upon discharge. Pharmacist-led discharge counseling has been shown to reduce medication errors, return visits to emergency departments, and hospital readmission rates. The purpose of this study was to identify pharmacists' perceptions of a new discharge counseling initiative at Intermountain Medical Center in Murray, Utah.

Methods: A link to an online survey was distributed via email to pharmacists and pharmacy residents in critical care, cardiology, medicine, transplant, and ambulatory patient care. All responses to the questionnaire were anonymous and participation in the survey was voluntary. The results of the survey were compiled after a two-week period.

Results: A total of 37 pharmacists completed the survey. Over 86% of participants (26) agreed or strongly agreed that discharge counseling is a valuable use of their time, and 83.3% (25) agreed or strongly agreed that they have made meaningful interventions while providing discharge counseling. The vast majority of participants (25, 86.2%) reported frequently making educational interventions regarding new medications at discharge, and nearly 1/3 reported frequently educating patients about pre-admission drugs or disease states. Around 1/3 reported that that they frequently make interventions regarding cost, wrong dose, and indications without an appropriate drug. Participants believed that interventions regarding new medication education, drug-drug interactions, and indications without an appropriate drug were the most impactful. About 3/4 of participants reported having a method of prioritizing patients for discharge counseling. Patients being discharged with new high-alert medications

and patients meeting BOOST or Core Measures criteria were the most commonly reported patients receiving higher priority.

Lack of time was a barrier to providing adequate discharge counseling reported by a majority of respondents (16, 55.2%). Participants suggested that hiring a dedicated pharmacist, receiving earlier notification about discharge patients, and improving communication with the care team would improve the discharge counseling process.

Conclusion: In general, the surveyed pharmacists find value in discharge counseling and feel like a valued member of the patient's care team while providing this service. Additionally, most surveyed pharmacists have been able to make meaningful interventions while providing this service to patients. Our study identified several gaps in the discharge counseling process and potential solutions to rectify these gaps.

Poster Title: Evaluation of vitamin D status and replacement regimens within an inpatient pediatric psychiatry population

Primary Author: BrookeAnne Blay, The Ohio State College of Pharmacy, Ohio; **Email:** blay.4@buckeyemail.osu.edu

Additional Author (s):
Kimberly Novak

Purpose: During human development, vitamin D is important for calcium homeostasis and skeletal development. The importance of vitamin D to the central nervous system (CNS) in both healthy and psychiatric populations is less appreciated and understood compared to its known impact on bone health. There is a growing concern that insufficient levels of vitamin D may affect brain function and mental health. To date, there have been few studies that have evaluated the incidence of vitamin D deficiency in a pediatric psychiatric population. Therefore, this study was conducted to determine the prevalence of vitamin D deficiency in a pediatric psychiatric population.

Methods: This was a single-center, retrospective, and observational cohort analysis with convenience samples. Institutional Review Board approval was obtained using expedited review. The primary objective was to determine the incidence of vitamin D deficiency and insufficiency in a pediatric psychiatric population. The secondary objective was to determine what replacement regimens used to treat vitamin D sufficiency and insufficiency were most effective in this population. Patients were identified electronically via an electronic medical record report of admissions to the inpatient psychiatric service at a large free-standing children's hospital. Patients ages 0 to 18 years who were admitted to the Behavioral Health unit for management of psychiatric illness between December 1, 2014 and May 31, 2016 with a 25-hydroxyvitamin D level measured on admission were eligible for inclusion. Patients who did not have a 25-hydroxyvitamin D level measured upon admission or who were diagnosed previously with cystic fibrosis, short bowl syndrome, or end-stage renal disease were excluded. Pertinent demographic and related data were collected including: age, sex, race, ethnicity, height, weight, body mass index (BMI), admission 25-hydroxyvitamin D level and subsequent levels during that admission, current home medication dose of vitamin D supplementation, vitamin D treatment

upon admission, discharge prescription of vitamin if applicable, and any levels upon readmission and/or clinic follow-up. Data were evaluated using descriptive statistics.

Results: Eight-hundred and twenty-eight patients were included with a mean age of 13 plus or minus 3 years. The mean admission 25-hydroxyvitamin D level was 28 plus or minus 12 ng/ml which correlated with deficiency in 170 (20.5 percent) patients, insufficiency in 399 (48.2 percent) patients, sufficiency in 257 (31 percent) patients, and elevated levels in 2 (0.2 percent) patients. Patients were categorized as vitamin D deficient if 25-hydroxyvitamin D levels were < 20 ng/ml, insufficient if levels between 20-30 ng/ml, sufficient if levels between 30-100 ng/ml, and elevated if levels were >100 ng/ml. Of the cohort, 77 (9.3 percent) patients were prescribed vitamin D prior to admission. Among these 77 patients, 6 (7.8 percent) patients had deficient levels, 29 (37.7 percent) patients had insufficient levels, and 42 (54.5 percent) patients had sufficient levels. Upon discharge, 313 (37.8 percent) patients were prescribed various vitamin D dosing regimens. One-hundred and twelve patients with deficient levels were prescribed vitamin D upon admission with the most common regimen being cholecalciferol 2000 international units (IU) daily (49 patients, 43.8 percent) followed by cholecalciferol 5000 IU daily (41 patients, 36.7 percent). This same trend was also seen in patients with insufficient levels and sufficient levels.

Conclusion: The study demonstrated a high incidence of vitamin D deficiency (20.5 percent) and insufficiency (48.2 percent) among pediatric patients presenting with psychiatric illness. Currently, there is no standard dosing for vitamin D deficiency for psychiatric pediatric populations. Dosing regimens frequently used are 2000 IU daily, 5000 IU daily, 50000 IU weekly, or 50000 IU weekly plus a daily dose until vitamin D level rises above 30 ng/ml, which were all observed in this study. Additional studies are warranted to further describe the relationship between vitamin D status and prevalence of psychiatric illness.

Poster Title: Impact of updated metformin renal dosing recommendations: a simulated study in elderly patients

Primary Author: Hongkai Bao, St. John's University College of Pharmacy and Health Sciences, New York; **Email:** hongkai.bao12@stjohns.edu

Additional Author (s):
Mary Gayed
Nicole Maisch
Maha Saad

Purpose: Metformin, a biguanide, is used as first-line therapy in type 2 diabetes. Metformin was previously contraindicated if serum creatinine (SCr) levels were 1.4 mg/dL or greater for women and 1.5 mg/dL or greater for men. However, SCr may inaccurately assess renal function in certain patients. Recently, the Food and Drug Administration revised the labeling of medications containing metformin and replaced SCr with estimated glomerular filtration rate (eGFR), a parameter that provides a more accurate assessment of renal function. The purpose of this study was to determine how many patients would be affected by this update in metformin dosing recommendations.

Methods: The institutional review board approved this retrospective chart review. Patients aged 65 and older admitted to Long Island Jewish Medical Center to a non-critical care area over a month period were included. Patients were excluded if they had acute renal dysfunction (defined as an elevation in SCr of greater than 0.5 mg/dL from baseline) or had end stage renal disease on dialysis. We utilized a data collection sheet which collected patient parameters such as age, gender, ethnicity, SCr, weight, and height. These parameters allowed us to calculate eGFR based on the Modification of Diet in Renal Disease-4 (MDRD4) and Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equations as well as creatinine clearance (CrCl) by the Cockcroft-Gault equation. Dosing recommendations based on the old and new labeling of metformin were simulated. The new recommendations state that metformin is contraindicated in patients with an eGFR less than 30 mL/min/m2. For those with an eGFR between 30 and 45 mL/min/m2, metformin should not be initiated and used cautiously in those already on it. The primary outcome of the study was to compare the number of patients who

were originally ineligible for metformin under the previous criteria and were now considered eligible. We calculated the number of patients who required discontinuation of metformin on the basis of not meeting the new eGFR criteria as well as compared overall eligibility.

Results: A total of 270 patients with a mean age of 79 years (65 to 99) were included. The average SCr was 1.29 mg/dL, CrCl was 55.1 mL/min, MDRD4 eGFR was 73.7 mL/min/1.73 m2, BSA-adjusted MDRD4 eGFR was 75.5 mL/min, CKD-EPI eGFR was 65.3 ml/min/m2, and BSA-adjusted CKD-EPI eGFR was 66.9 mL/min. Out of 270 patients, 56 percent were female. Thirty-eight percent were Caucasian, 17 percent were African-American, 12 percent were Asian, and 8 percent were Latino/Hispanic. Overall, eligibility for metformin was 80 percent based on serum creatinine compared to 88 percent by eGFR. Two point six percent (MDRD4) and 2.2 percent of patients (CKD-EPI) were originally ineligible for metformin based on serum creatinine criteria but became eligible based on the new criteria. Additionally, 5.6 percent of patients (MDRD4 and CKD-EPI) who were disqualified from continuing metformin by SCr became eligible for continuation. Moreover, 6.3 (MDRD4) and 6.6 percent of patients (CKD-EPI) were originally eligible but had to be reevaluated due to an eGFR between 30 to 45 mL/min. One patient (MDRD4 and CKD-EPI) was originally qualified but became ineligible. The eligibility status for the remainder of the patients was unchanged.

Conclusion: According to this study, the eGFR criteria allowed more patients with renal impairment to receive metformin; however, the majority of patients did not change their eligibility status. An increase in the number of patients that could remain on metformin with monitoring was observed. It may be necessary to examine eGFR dosing recommendations in younger populations with impaired renal function to determine the accuracy of these new recommendations, as this study focused on the elderly.

Poster Title: Evaluation of a phosphorus replacement protocol for ICU patients receiving continuous renal replacement therapy

Primary Author: Makenna Smack, Roseman University of Health Sciences, Utah; **Email:** msmack@student.roseman.edu

Additional Author (s):
Erin Roach
Simon Lam

Purpose: Phosphate homeostasis is largely regulated by the kidney, and hypophosphatemia is a common complication associated with continuous renal replacement therapy (CRRT). Prolonged hypophosphatemia can lead to seizures, dysrhythmias, acute respiratory failure, and musculoskeletal weakness. The benefits of protocol-driven interventions to direct electrolyte replacement have been illustrated in previous studies. A phosphate replacement protocol currently exists to direct replacement in patients in the ICU on CRRT who experience hypophosphatemia. This protocol allows nurses to administer phosphate replacement based on the severity of hypophosphatemia. This study was conducted to evaluate the effectiveness of and adherence to the current protocol.

Methods: This was a non-interventional, retrospective study of patients who received CRRT while admitted to the ICU at a large, tertiary medical center between June 2015 and June 2016. The current protocol specifies that phosphate levels less than or equal to 2.5 milligrams per deciliter warrant phosphate replacement at varying doses based on the severity of hypophosphatemia. Additionally, the protocol stipulates that labs should be drawn every 24 hours. Effectiveness was determined by the number of low phosphate levels corrected when replacement was administered in concordance with protocol parameters. Protocol adherence was evaluated by the timing of laboratory results and the number of patients with hypophosphatemia who received replacement as specified by the protocol. Additional analysis of the average dose required to normalize phosphate levels, regardless of protocol adherence, was performed to determine if current protocol dosing parameters are adequate. Analysis was conducted using descriptive statistics, with continuous data described as averages and standard deviations and nominal data reported as numbers and percentages.

Results: Of 612 patients in the ICU on CRRT, the phosphate replacement protocol was ordered for 603 patients. Phosphate levels were checked for 315 (52.2 percent) of the 603 patients and 187 (59.36 percent) of those 315 patients required phosphate replacement at least once during CRRT. A total of 1529 low phosphate levels were reported during the study time frame, and 301 (19.7 percent) of these levels were treated in concordance with the current protocol. A total of 67 (22.3 percent) of the levels treated according to the protocol resulted in a normalized phosphate level. A total of 239 low phosphate levels were corrected with replacement by the subsequent phosphate level report, which may or may not have been in concordance with the current protocol. Correcting the 239 low phosphate levels required an average phosphate dose of 26.8 plus or minus 12.6 millimoles. On average, phosphate replacement was administered within 4 hours and 40 minutes plus or minus 4 hours and 1 minute of laboratory results. Of the 4273 phosphate levels reported, 1588 (37.2 percent) labs were reported more than 24 hours apart.

Conclusion: In conclusion, this study demonstrates significant non-adherence to the current protocol. While phosphate replacement was administered in a relatively timely manner, on average, a very low percentage of patients actually received replacement in concordance with the current protocol. The majority of patients who received phosphate replacement in concordance with the protocol resulted in a subtherapeutic phosphate level. Additionally, the average phosphate dose required to normalize phosphate levels was significantly higher than the lowest dose recommended by the protocol. Based on these conclusions, education on protocol compliance is required and more aggressive phosphate dosing should be considered.

Submission Type: Descriptive Report

Session-Board Number: 5a-202

Poster Title: Student Societies of Health-System Pharmacy (SSHPs) clinical experience in institutional practice in first and second professional years for clinical skills enhancement.

Primary Author: Meredith Oliver, University of Mississippi Medical Center, Mississippi; **Email:** mboliver@go.olemiss.edu

Additional Author (s):
Lauryn Easterling
Hayden Hendrix
Anastasia Jenkins

Purpose: The ASHP-SSHP Executive Council at the University of Mississippi School of Pharmacy developed an institutional shadowing experience to provide first and second year pharmacy student SSHP members with clinical skills at the local Baptist Memorial Hospital-North Mississippi (BMH-NM). The 217 bed community hospital is located 1 mile from the University of Mississippi campus in Oxford, MS. The central goals of this program include enhancing pharmacy student's clinical skills, familiarizing students with health-system operations, and providing patient-centered care to improve patient outcomes through the continuum of care.

Methods: First and second year pharmacy student SSHP members volunteered for a one-hour time period at the BMH-NM. Students were given the opportunity to sign up for a maximum of three hours a semester. First year students were assigned to round with the two BMH-NM PGY1 pharmacy residents while second year students were paired with a fourth year APPE student to provide patient discharge medication counseling. Five BMH-NM pharmacists served as preceptors for the APPE students. A BMH-NM pharmacist provided students with a 30-minute orientation to BMH-NM at the University a week before the experience began. Students were expected to arrive 10 minutes prior to their assigned hour and to behave and dress professionally. This program was offered on Tuesdays and Thursdays from 9am-12pm for 9 weeks during the spring semester, allowing 54 first year and 54 second year student SSHP members to participate in the program. Students were requested to complete an open-ended feedback questionnaire regarding their experience.

Results: This inaugural program allowed students to gain experience in applying the following clinical skills: pharmacists' role in rounding with the health care team, communicating patient discharge counseling, completing medication reconciliation forms, and providing interventions during transitions of care. Student pharmacists also had the opportunity to ask questions of pharmacy staff, PGY1 pharmacy residents, and fourth year pharmacy APPE students regarding their professional career. Students reported receiving career counseling and mentorship from health care professionals that greatly impacted their career aspirations. Several students reported consideration of a career in institutional practice after completing this experience. Of the 108 one-hour time slots offered, 40 slots were filled. Each student had direct patient interaction while at the hospital. Student feedback suggested to modify the three 1-hour shifts to one 3-hour shift, which would allow more time to deepen their clinical skills as part of the healthcare team.

Conclusion: This institutional shadowing experienced provided first and second year pharmacy student SSHP members the valuable opportunity to apply and strengthen their clinical skills in an institutional setting. Students gained mentorship from professionals which helped to aid them in their decision to pursue a career in institutional practice. The leadership students demonstrated and patient-centered care they provided was valued by hospital staff, patients, friends, family, and the community. Student feedback helped shape programmatic improvement for subsequent years. This student led initiative aligns with the goals of the Practice Advancement Initiative (PAI) through ASHP within the University of Mississippi and Oxford communities.

Submission Category: Ambulatory Care

Submission Type: Evaluative Study

Session-Board Number: 5a-203

Poster Title: Effects of Medication Reconciliation on Medication-Related Problems in an Ambulatory Care Setting

Primary Author: Anne Schwartz, University of Missouri-Kansas City, Missouri; **Email:** ams5xc@mail.umkc.edu

Additional Author (s):
Jennifer Santee
An-Lin Cheng

Purpose: To determine whether obtaining a medication list over the phone prior to an office visit results in fewer medication-related problems in an ambulatory care setting.

Methods: The institutional review board approved this randomized, single-blind, controlled trial. Men and women over 18 years of age who provided informed consent were enrolled if they were taking at least 5 medications, had at least 3 chronic medical conditions, or were taking a narrow therapeutic index medication. Patients were excluded if they did not speak English or if they had a member of the same household already enrolled in the study. If the physician requested the pharmacist to review a subject's medication list at any time during the study period, the subject was withdrawn from the study and his or her data was removed from the database. Subjects were randomized into an intervention or control group. A pharmacy student called intervention subjects within 3 days prior to their office visit to obtain a medication history. The pharmacy student then forwarded subjects' medication lists to their physicians prior to the office visit. A pharmacy student called control subjects within 3 days after their office visit to obtain a list of medications they were taking prior to their office visit. This medication list was not available to the physician at their office visit. A pharmacist and physician blinded to group assignment reviewed each subject's medical record to identify any drug-related problems that occurred during the office visit.

Results: Seventy-two patients were enrolled in the trial: 42 in the intervention group and 30 in the control group. Subjects enrolled in the study were predominantly female (75%), were on average 51 years of age, were taking an average of 12 medications, and had on average 6 chronic medical conditions. No statistically or clinically significant differences were found

between the intervention and control groups with respect to gender, age, number of medications, and number of chronic medical conditions (p>0.05). The intervention and control group had a similar average number of drug-related problems (1.5 in both groups, p = 0.924). A larger percentage of intervention subjects (55%) had at least one medication related problem compared to control subjects (43%), but this difference was not statistically significant (p=0.339). The major limitation of this study was the lack of power to detect a statistically significant difference in the outcome (power = 0.158).

Conclusion: This study was not powered to detect a difference in the groups. Further research should include a larger number of subjects, investigate whether older patients may benefit more from the intervention, and investigate whether other factors (for e.g. socioeconomic status, race) may affect the efficacy of the intervention.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Evaluative Study

Poster Title: Proactive statin therapy needed for patients between 40-75 years of age.

Primary Author: Steve Nguyen, University of Arizona College of Pharmacy, Arizona (AZ); **Email:** stevenguyen@pharmacy.arizona.edu

Additional Author (s):
Luciano Castaneda
Andrea Kale

Purpose: Statin therapy has been shown to effectively reduce major cardiovascular event rates in both low- and high-risk patients and improving long-term health outcomes, especially in patients with diabetes mellitus (DM) over the age of 40. The American Diabetes Association (ADA) recommends all patients between the ages of 40-75 with type II diabetes mellitus be prescribed either a moderate- or high-intensity statin regardless of low density lipoprotein (LDL) levels. The purpose of this study was to determine the number of patients between the ages of 40-75 with type II DM on statin therapy to reduce cardiovascular events.

Methods: Men and women between the ages of 40-75 at a one retail pharmacy in the Southwest United States were screened for type II DM through prescriptions for metformin, a biguanide drug considered first-line therapy for type II diabetic patients. Each patient was analyzed for concurrent statin therapy. Statin therapy included rosuvastatin, atorvastatin, simvastatin, lovastatin, pravastatin, or fluvastatin. Patients who were not taking concurrent statin therapy were screened for potential drug-drug interactions (DDIs) that may occur if a statin medication was added to their current drug therapy. Data were analyzed using a Chi-Square test with an alpha level set at 0.05 performed in Microsoft Excel.

Results: A total of 88 patients were identified who met the ADA guideline recommendations for statin therapy. Forty-three patients met the guideline recommendations with concomitant therapy of at least a moderate-intensity statin. Forty-five patients did not meet the guideline recommendations. Of those 45 patients, 9 had a potential drug-drug interaction with the addition of statin medication. Thus, 36 total patients did not meet the ADA guidelines to reduce cardiovascular events. All 88 patients were expected to be on statin therapy per ADA

guidelines. Patients between the ages of 40-75 years of age with type II diabetes mellitus are not concomitantly on at least a moderate-intensity statin (p-value less than 0.01).

Conclusion: More than half of patients who qualify for statin therapy per ADA guidelines were not concomitantly on statin therapy. The ADA guidelines have shifted from monitoring cholesterol levels to recommending treatment to high-risk populations, such as those with diabetes. It is imperative that pharmacist ensure patients with diabetes are adequately treated to prevent complications.

Poster Title: Evaluation of pharmacist-provided discharge counseling and its impact on 30-day readmission rates for chronic obstructive pulmonary disease (COPD) patients in a community hospital

Primary Author: Vivian Wang, University of Washington School of Pharmacy, Washington; **Email:** vivian90wang@gmail.com

Additional Author (s):
Richelle McCabe

Purpose: Chronic obstructive pulmonary disease (COPD) is a progressive lung disease that leads to chronic airflow limitation causing increased morbidity and mortality. For multiple years, Valley Medical Center has had a pharmacist education program to target high risk patients, including those with COPD, but its efficacy on readmission rates has not previously been evaluated. The purpose of this study is to evaluate the impact of this pharmacist-provided discharge counseling on 30-day-readmission rates in COPD patients in a community hospital setting. Additional factors other than pharmacist-provided counseling that could possibly contribute to readmissions were also assessed in this study.

Methods: This study is a single center, retrospective, block-randomized, chart review of 148 patients admitted with a primary diagnosis of COPD exacerbation. Every admission with a primary diagnosis of COPD exacerbation and an active COPD intervention ("i-vent") during 1/1/16 – 6/30/16 was included. Patients that were deceased either during or within 30 days after an admission, patients who left the hospital against medical advice, patients who were discharged to a skilled nursing facility or an adult family home, and patients who did not have an active COPD i-vent were excluded. The total sample included 74 COPD patients that received pharmacist discharge counseling and 74 that did not. The primary endpoints were 30-day-readmission rates in patients that received pharmacy discharge counseling versus those who did not . The secondary endpoints included 30-day-readmission rates based on sex, age, number of respiratory-related discharge medications, total number of discharge medications, and number of respiratory-related comorbidities.

Results: The average overall COPD readmission rate was 16.9%. The readmission rate with counseling was 12% whereas the rate without counseling was 21.6%. This resulted in a non-statistically significant difference of 9.6% between the two patient groups (95% CI=0.1778, 0.0714, p=0.125). Sex, age, number of respiratory-related discharge medications, total number of discharge medications, and number of respiratory-related comorbidities also did not show any statistical differences in readmission rates. (95% CI=0.4082, 0.2564, p=0.332; 0.873; 0.112; 0.240; respectively, where p < 0.05 indicates significance).

Conclusion: Pharmacist-provided discharge counseling did not make a statistical significant difference in 30-day-readmission rates in COPD patients. Despite this, there appeared to be a positive clinical trend in readmissions with pharmacist intervention. There was almost twice the amount of COPD readmissions in patients that did not receive counseling than those who did. One limitation to this study was that it was single centered. Larger samples may determine stronger statistical and clinical significance. Another limitation is that multiple factors were not accounted for that could contribute to readmissions, such as social, economical, and other factors that are outside of a pharmacy's control.

Poster Title: Levetiracetam monotherapy use in the PICU for the treatment and prophylaxis of status epilepticus

Primary Author: Adirika Obiako, Auburn University Harrison School of Pharmacy, Alabama; **Email:** ajo0013@auburn.edu

Additional Author (s):
Allison Chung

Purpose: There have been limited safety and efficacy studies in pediatric critically ill patients who receive levetiracetam as a monotherapy agent. Open label studies have examined the use of levetiracetam as adjunctive therapy in pediatric populations, and have reported a 50% reduction in seizure frequency. Safety studies and clinical trials that involve levetiracetam monotherapy use have showed promise; however, there's limited data regarding its use as a first line monotherapy agent in the pediatric population. To address this deficit, the efficacy of levetiracetam as a monotherapy agent among the pediatric population (0-18 y/o) with status epilepticus in a PICU was evaluated.

Methods: A two year retrospective observational study was conducted of medical records in patients under the age of eighteen who were admitted to the PICU at an academic stand-alone pediatric institution. Patients were identified by utilizing a pharmacy derived list of all patients who received levetiracetam during the targeted two years. Chart reviews were conducted to identify those patients from the initial list who were in the PICU and who met the inclusion/exclusion criteria. For a patient to be included in the study, the patient had to be admitted to the PICU, be under the age of eighteen, and exhibited signs and symptoms of status epilepticus. Exclusion criteria of this study included patients greater than the age of eighteen, patients who exhibited no signs or symptoms of status epilepticus, and patient who received antiepileptic polytherapy during their PICU stay. The etiologies of seizures were classified according to the documented cause of seizures. Data collected included the length of PICU stay, reason for admission, prior levetiracetam use, levetiracetam dose, and indication of use. The primary outcome was incidence of seizures while in the PICU. Secondary outcomes included length of stay in PICU, length of treatment, and the optimal dose range of levetiracetam. Descriptive statistics were used to analyze the data.

Results: Over the 2-year study period, 59 PICU patients were identified on levetiracetam, 12 received levetiracetam monotherapy with an age range of 0-18 (mean age of 4.92). Demographically, of the 12 subjects that were studied, 58% were male and 42% were female. The percentage of Caucasian, African American, and Hispanic patients were 33%, 58%, and 8%, respectively. The average weight of participants was 32.04 kg ranging 3.2-116 kg. The average dose administered to subjects was 44.7 mg/kg/dose ranging from 17.2-107 mg/kg/dose with a corresponding daily dose of 55.3 mg/kg/day ranging 20.4 -107 mg/kg/day for status epilepticus and acute control of seizures. Sixty seven percent of these patients received oral levetiracetam and 33% received intravenous levetiracetam for treatment or prophylaxis of status epilepticus. The average length of stay spent in the PICU with patients on levetiracetam monotherapy was 6.25 days ranging 2-27 days. The average length of treatment was 9.5 days ranging 1-36 days. Of the 12 patients, 4 were treated acutely and seizures were controlled. Three of those 4 patients had no seizure history prior to treatment. One patient was treated prophylactically. The remaining 7 of the 12 patients were treated for seizures orally once the admission disease state was controlled.

Conclusion: It's of utmost importance to control status epilepticus expediently as possible in an acute setting. This study presents pertinent data from a 2 year retrospective observation study that was conducted at an academic stand-along pediatric institution. Higher doses of levetiracetam were utilized in this study than compared to previous studies. The efficacy of levetiracetam monotherapy was determined by the amount of seizures that were controlled acutely and prophylactically. It would be recommended to obtain further data in regards to seizure controlled in acutely treated patient and prophylaxis in acutely ill patients for future studies.

Poster Title: Evaluation of a novel time within therapeutic range metric for erythropoiesis stimulating agents in hemodialysis patients

Primary Author: Ben Robinson, University at Buffalo School of Pharmacy and Pharmaceutical Sciences, New York; **Email:** benrobin@buffalo.edu

Additional Author (s):
Calvin Meaney
Gauri Rao
Jamie Gaesser
Mandip Panesar

Purpose: Erythopoiesis-Stimulating Agents (ESAs) are the primary treatment for anemia in patients with end-stage renal disease on hemodialysis. The narrow hemoglobin target of 10 to 11 g/dL in this population leads to reactive dosing of ESAs and frequent excursions outside of the target range. Time within therapeutic range (TTR) is a novel metric of ESA pharmacodynamics, which has been validated for warfarin in large clinical trials. The purpose of this study was to characterize ESA response in terms of TTR and investigate factors that improve TTR.

Methods: This retrospective cross-sectional study, approved by the local institutional review board, included outpatients with end-stage renal disease on hemodialysis from April 1, 2014 to April 30, 2015. Inclusion criteria were age greater than or equal to 18 years, use of an ESA, and routine laboratory follow-up over the study period. Fifty patients were randomly selected from 165 at the outpatient dialysis center. Data collected included: demographics, comorbidities, anti-hypertensive medications, hospitalizations, laboratory data (hemoglobin, phosphate, albumin, ferritin, transferrin saturation [TSAT]), iron administration, ESA dose and type of ESA, number of dose adjustments, and route of administration. The TTR was calculated for each subject as the number of observed hemoglobin values within the 10 to 11 g/dL range divided by the total number of hemoglobin values over the study period. TTR greater than or equal to 50 percent was defined as a good response. Bivariate analyses characterized the differences between those with TTR greater than or equal to 50 percent compared to TTR less than 50 percent using T-tests, Mann-Whitney U-tests, or Chi-Square tests as appropriate. Logistic

regression models were fit to the TTR greater than or equal to 50 percent parameter. Predictor variables considered for the model included age, sex, ethnicity, co-morbidities, phosphate, albumin, hemoglobin, TSAT, ferritin, average weekly ESA dose, and ESA route of administration. All analysis was completed using SAS with alpha equals 0.05.

Results: Twenty patients had TTR greater than or equal to 50 percent, compared to 30 patients with TTR less than 50 percent. "Good responders" had a mean hemoglobin of 10.68 g/dL (range: 10.16 to 10.93 g/dL; standard deviation: 0.23 g/dL) compared to a mean value of 10.3 g/dL for "poor responders" (range: 8.38 to 13.33 g/dL; standard deviation: 0.87 g/dL) (P equals 0.0041).
Patients with TTR greater than or equal to 50 percent received a mean ESA dosage of 14,825 units per week, compared to 32,839 units per week for patients with TTR less than 50 percent (P equals 0.0110). Good responders had a mean albumin of 4.12 g/dL, compared to a mean value of 3.8 g/dL for poor responders (P equals 0.0467). Patients with hyperlipidemia were 5.13 times more likely to be good responders after adjusting for average weekly ESA dose and mean albumin concentration (P equals 0.0418). Hypertension status, route of ESA administration, and mean hemoglobin concentration all significantly differed between the two response groups in bivariate analyses, but were not significant in the multivariable model. Age, ethnicity, sex, phosphate, TSAT, ferritin, diabetes, coronary artery disease, heart failure, or hyperparathyroidism did not have a significant influence on response status.

Conclusion: Our study demonstrates that TTR for hemoglobin can be used as a measure for responsiveness to ESAs in hemodialysis patients. Subjects with a TTR greater than or equal to 50 percent had a higher mean hemoglobin and less variation in their hemoglobin than patients with a TTR less than 50 percent. Additionally, a multivariable model identified three predictors for a TTR greater than or equal to 50 percent: average weekly dose of ESA, mean serum albumin, and hyperlipidemia status. These factors could be considered when adjusting ESA doses to improve TTR.

Session-Board Number: 5a-208

Poster Title: Symptomatic constitution of Finnegan scores for infants born in Cabell County, West Virginia and treated for neonatal abstinence syndrome (NAS)

Primary Author: Tyler Flaugher, Marshall University School of Pharmacy, West Virginia; **Email:** tjflaugher@gmail.com

Additional Author (s):
Carson Terwilliger
Shekher Mohan
Leesa Prunty

Purpose: Neonates exposed in-utero to substances such as opioids, benzodiazepines, and cannabinoids can experience withdrawal symptoms after birth, a condition termed Neonatal Abstinence Syndrome (NAS). The Finnegan Scoring System quantifies the presentation of NAS-related symptoms, with higher scores being given for more numerous or severe symptoms. Scores are used to guide pharmacological therapy, primarily methadone initiation and titration, with a 3-score or 8-score average of 8 traditionally being a guiding threshold. This study assessed the symptomatic constitution of Finnegan Scores recorded within the first 168 hours of life for neonates born at Cabell Huntington Hospital and treated for NAS.

Methods: The Marshall University Institutional Review Board (IRB) committee approved this retrospective study. Data was obtained from patient charts at Cabell Huntington Hospital (CHH) in Huntington, WV, namely through the secure Cerner Millennium system. A survey design was utilized to standardize and streamline data collection. The survey was built using Qualtrics Survey Software, provided for by Marshall University. Each patient's NAS Finnegan scoring assessment charts were entered into the survey, with the cutoff being the end of the infant's 8th day of life to ensure that data would be collected through 168 hours after time of birth (TOB), as recorded on the patient's birth documentation. Patients were included in this study if they: 1) were born at CHH between January 01, 2015 and December 31, 2015; 2) were born after 28 weeks gestation; and 3) were diagnosed with NAS and/or received methadone as treatment for NAS. Patients were excluded if they 1) did not meet the preceding criteria, 2) lacked a completed "worksheet," which contained the mother's demographic and substance abuse information, or 3) were transferred out of CHH or discharged within 168 hours after TOB.

Results: 62 patients had a total of 3189 Finnegan scores and 16041 individual symptoms recorded within the first 168 hours after TOB. The mean Finnegan score was 8.02, with a median of 5 symptoms per score. 66.4 percent of symptoms (8850) involved the central nervous system. 94.7 percent of scores included "increased muscle tone," 84.7 percent included "mottling," 47.9 percent included "hyperactive moro reflex," 19.1 percent included "decreased sleep duration," and 6.0 percent included "excessive high-pitched crying." 2859 instances of tremors were recorded (89.7 percent of scores), with 80.9 percent being "tremors when disturbed" and 19.1 percent being more-severe "tremors while undisturbed." The mean tremor value was 2.06 per score. 22.0 percent (5182) of symptoms involved the autonomic nervous system, with 30.5 percent of scores including "nasal stuffiness," 24.6 percent including "fever," 13.2 percent including "sneezing," and 8.4 percent including "respiratory rate greater than 60." 12.7 percent (2009) of symptoms involved the gastrointestinal system, with 27.4 percent of scores including "excessive sucking," 17.4 percent including "diarrhea," 13.3 percent including "poor feeding," and 3.9 percent including "regurgitation."

Conclusion: Finnegan Scores primarily consisted of central nervous system (66.4 percent) symptoms, followed by autonomic nervous (22.0 percent) and gastrointestinal symptoms (12.7 percent). 94.7 percent of scores included "increased muscle tone" and 84.7 percent of scores included "mottling," which together account for 3 points in the protocol used at CHH. Additionally, 89.7 percent of scores included an average of 2 points for tremors. However, multiple factors affect symptom presentation, including nonpharmacologic care, pharmacologic treatment (methadone, clonidine, etc.), infant gender, and fetal substance exposure in-utero. Differences in symptom presentation must be determined in larger retrospective analyses.

Poster Title: Effectiveness of a call-back system for follow-up of culture results in patients treated for urinary tract infection in the emergency department of a community hospital.

Primary Author: William Moore, University of Georgia College of Pharmacy, Georgia; **Email:** moorewj@uga.edu

Additional Author (s):
Angelina Cho
Devin Lavender
Rachel Wilkes
Virginia Fleming

Purpose: Urinary tract infections are often treated in the emergency department (ED). Urine cultures are commonly collected from patients even if they are discharged from the ED without requiring admission. In these cases, empiric antibiotic prescriptions are given based on treatment guidelines and local resistance patterns. When resistant cultures return, a process for contacting patients must be in place to allow providers to change antimicrobial therapy. This pilot study evaluated the current process at our institution for follow-up on urine culture results in patients treated for urinary tract infection in the ED and discharged prior to pathogen results.

Methods: A retrospective medical record review of culture-positive patients treated in the emergency department of a 200-bed community hospital from January 1, 2015 to June 14, 2015 was performed. Patients with urinary isolates of greater than 100,000 cfu/ml and intention to treat by prescriber were included. Causative pathogens, antibiotic therapy prescribed, risk factors for drug-resistant pathogens, and drug susceptibilities were recorded. For patients with cultures resistant to prescribed therapy, medical records were reviewed for documentation of call back attempt(s), success/failure, and if change of therapy or course of action occurred. Patients were also classified as community-acquired or healthcare-associated UTI based on presence of specific risk factors for drug-resistant pathogens. Healthcare-associated risk factors included residence in long term care facility or nursing home, presence of an indwelling urinary catheter, immunosuppressive therapy or disease, hospital admission for 2 or more days in the previous 90 days, urologic procedure in the previous 90 days, and chronic hemodialysis in the previous 30 days. Risk factors for drug resistance such as previous

recent antibiotic therapy or history of previous or recurrent urinary tract infections were also collected. Evaluation of risk factors for impact on infection with a drug-resistant pathogen (resistant to empiric therapy prescribed in the ED) was performed and descriptive information about causative pathogens isolated, local resistance patterns, and frequency of various antibiotic agents prescribed was reported.

Results: Of 385 patients screened, 277 were included in the study, with 83.4 percent of patients being classified as community-acquired and 16.6 percent with healthcare-associated UTI. The most common pathogens isolated on urine culture were Escherichia coli (72.5 percent) and Klebsiella species (14.1 percent). Frequently prescribed antimicrobials were nitrofurantoin (36.4 percent) and cephalexin (35.7 percent). Cultures reported pathogens that were resistant to initial empiric antibiotic therapy for 21 percent of the ED-treated population. Attempted call-back to patients with resistant cultures was documented for 79 percent of those. Successful contact with patient was documented for 65.2 percent of call-back candidates. For the patients not initially reached by phone, messages were left for 15.2 percent while 19.6 percent of patients were unable to be successfully contacted. Follow-up calls were performed on an average of 3.9 days after cultures were drawn. Therapy was modified via phone in 52 percent of cases and 6.5 percent of patients were referred to another physician upon call-back. Of note, 13 percent of call-back patients achieved clinical cure, which was determined through directed questioning and no change was made despite culture-reported resistance to the prescribed antibiotic therapy.

Conclusion: Evaluation of the follow-up methods of resistant cultures in ED-treated UTI patients showed inconsistency in practice of how call-backs are performed and documented. A considerable number of patients contacted were left messages or not reached successfully. With effective communication, practitioners were able to determine clinical success or need for therapy modification via phone questioning. An implemented follow-up call-back system with UTI patients discharged from the ED before culture results return can be an effective method for ensuring clinical success but is limited by the ability to consistently contact the patient. Staff education and further study is needed.

Poster Title: Evaluating pharmacist driven smoking cessation interventions in a Southern outpatient HIV clinic

Primary Author: Lauren Drawdy, South Carolina College of Pharmacy, MUSC Campus, South Carolina; **Email:** drawdyl@musc.edu

Additional Author (s):
Madelyne Cearley Bean
Lauren Richey

Purpose: It is well known that patients with HIV infection have higher rates of tobacco use than the general population, and HIV populations have higher use in South Carolina than the national average. Smoking has well described health consequences for HIV positive patients, thus cessation strategies are key. Current clinic cessation interventions are provided by a clinical pharmacist, after physician referral. Non-physician interventions are ideal due to short visit times and many competing priorities during visits. Evaluation of our current smoking cessation program in clinic is necessary, as we consider an opt-out formal mechanism of offering cessation counseling to HIV patients.

Methods: The patients evaluated in this study were engaged in care in 2015 in the outpatient HIV clinic at the Medical University of South Carolina. The inclusion criteria were age greater than 18, HIV positive status, current smoking, and a pharmacist intervention followed by at least one outreach attempt documented in 2015. Patient information was collected via chart review. Information relevant to their HIV, smoking behaviors, and smoking cessation encounters with the clinical pharmacist were collected. We hypothesized that clinical pharmacist interventions would increase the likelihood of patient quit attempts and thereby a successful cessation. Statistical analysis was performed with SPSS (v24), using descriptive statistics, chi-square, and ANOVA tests.

Results: In total, 45 patients met the inclusion criteria. Patients were mostly insured (62percent), median age was 49 years, African American (71percent), and males (69percent). Most were on antiretroviral therapy (93percent), with virologic suppression (< 40 copies/mL, 69percent), and few had CD4 less than 200 (7percent). At baseline, on average, patients were

smoking 13.2 cigarettes/day [range 1-50]. Most patients were prescribed cessation medications (89percent), 16 (35percent) varenicline, 3 (7percent) each for bupropion and nicotine replacement therapy (gum/lozenge), 7 (16percent) for patches, and combination therapy for 11 (24percent). Patients had, on average, 4.98 (range 2-13) total outreach attempts, with an average of 2.87 attempts obtaining contact and an additional 1.56 visits without contact, but a message was left. Overall, 5 (11percent) patients successfully quit smoking. Outreach attempts with contact were associated with successful over unsuccessful quit attempts (mean 4.8 vs. 2.63 visits, p=0.001). Outreach attempts with contact were higher for patients with cessation success over those making a quit attempt, and both over those without a quit attempt (4.8 versus 2.37 versus 1.2 visits, p=0.000). Neither outreach attempts nor baseline cigarettes/day correlated with number of quit attempts. However, few patients had sufficient documentation of formal quit attempts, limiting these two analyses.

Conclusion: Outreach attempts achieving contact were higher for patients with cessation success and those making quit attempts, supporting that more contact and counseling increases the likelihood of cessation attempts and success. This contact may also reflect patients with higher motivation to quit, as they may have been easier to contact. As a result, at a minimum, 3 outreach attempts should be made following the initial encounter to increase contact with patients. We will improve documentation of quit attempts to further evaluate the program's success. Furthermore, to reach more patients, we will implement a pro-active approach to offer cessation within clinic.

Session-Board Number: 5a-211

Poster Title: Intravenous Acetaminophen Use in Pediatric Patients

Primary Author: Amanda Lowney, Ernest Mario School of Pharmacy, New Jersey; **Email:** nanuetgal@gmail.com

Additional Author (s):
Christine Robinson
Suzannah Kokotajlo
Douglas Bloomstein

Purpose: Intravenous (IV) acetaminophen is approved for management of fever and acute pain in patients two years of age and older. Safety concerns have been raised due to reported serious iatrogenic dosing errors. Additionally, significant cost difference between oral, rectal and IV preparations necessitated proactive cost-effective use of the IV product. To optimize safe and cost-effective use of IV acetaminophen, Morristown Medical Center developed an order form detailing appropriate use and standardized dosing in pediatric patients. The purpose of this study was to evaluate compliance with the order form, as well as safety and use of IV acetaminophen in pediatric patients.

Methods: The Atlantic Health System institutional review board approved this retrospective chart review. Patients admitted to Goryeb Children's Hospital, 19 years of age and younger, who received at least one dose of IV acetaminophen between September 1, 2014 to June 30, 2015 (period 1) and August 1, 2016 to September 12, 2016 (period 2). The data was collected in two separate time periods due to revisions of the original order form, which were implemented after period 1. Data collected during both time periods included patient demographics, contraindication to oral acetaminophen, rectal acetaminophen and/or IV ketorolac as well as indication for use, number of doses received, dosing and administration interval, effectiveness and adverse reactions. A Clinical Drug Utilization Report generated by Horizon Meds Manager was used as the source of study participants. Potential participants were then verified through chart review to confirm at least one dose of IV acetaminophen was received. Upon analysis of the data collected during period 1, revisions were made to the order form. After implementation of the revised order form, additional patients were evaluated. The primary outcome was to evaluate the percentage of IV acetaminophen use that was per protocol based

on the corresponding order form. Secondary outcomes included description of IV acetaminophen use such as indication, dose, number of doses received per patient and adverse effects.

Results: A total of 100 pediatric patients who received at least one dose of IV acetaminophen were included. The median age of the initial 70 pediatric patients who received doses based on the original form (period 1) was 10 years with the average patient receiving 3.5 doses. Of these patients, 26 percent received IV acetaminophen per protocol. The indications for use were pain (31 percent), fever (38 percent), blood product administration (5 percent) and a combination of the previous three indications (27 percent). The median age of the 30 pediatric patients who received doses based on the revised form (period 2) was 11 years with the average patient receiving 4.4 doses. Of these patients, 40 percent received IV acetaminophen per protocol. The indications for use were pain (53 percent), fever (23 percent), blood product administration (3 percent) and a combination of the previous three indications (20 percent).
The main criteria that were outside order form criteria were no evidence of compromised rectal absorption (34 percent), ability to take oral medications (25 percent) and no contraindication to ketorolac (28 percent). There were no documented medication errors or adverse effects.

Conclusion: Use of IV acetaminophen in the studied pediatric patients was safe. With safety of use shown in the initial data collection period, indications and dosing on the original order form were revised to allow for wider acceptable use and higher doses. Improvement in adherence with recommended uses of IV acetaminophen was seen with the revised order form; however, the majority of use still fell outside of institutional indications. Restricting use of IV acetaminophen in pediatric patients remains a challenge and future directions will focus on enforcing cost-effective use.

Session-Board Number: 5a-212

Poster Title: Evaluating the time-course of Pseudomonas aeruginosa killing in the presence of various azithromycin concentrations

Primary Author: Danielle Jezierski, Midwestern University Chicago College of Pharmacy, Illinois; **Email:** djezierski21@yahoo.com

Additional Author (s):
Bryan Berube
Alan Hauser
Mary Leonard
Nathaniel Rhodes

Purpose: Healthcare-acquired acute bacterial infections present an ongoing challenge due to increasing antibiotic resistance and pathogen virulence. Pseudomonas aeruginosa (PA) is commonly associated with drug resistance and a high degree of virulence. Azithromycin (AZM) is a macrolide antibiotic thought to be predominantly bacteriostatic against PA. Prior studies evaluating the effect of Azithromycin on PA utilized relatively low concentrations of Azithromycin. We hypothesized that concentrations approximating those achieved within immune cells might produce bactericidal activity. The purpose of this experiment was to identify the time course of PA killing over a range of Azithromycin concentrations in a static time-kill model.

Methods: To determine the concentration-killing response for a representative clinical strain of PA (PA99), we performed the following experiment. Bacterial isolates were cultured from frozen stocks onto fresh Luria Berneti (LB) agar and incubated overnight at 37 degrees C. Fresh LB broth was inoculated and bacteria were grown to log-phase overnight at 37 degrees C. Sterile LB broth (3 mL) was then inoculated with PA99 1:100 and various Azithromycin concentrations (Azithromycin = 0, 0.5, 1, 2, 4, 8, 16, 32, 64, 128, and 256 mcg/mL). We removed 100uL aliquots at 0, 2, 4, 8, and 24 hours after inoculation. Aliquots were serially diluted, plated, incubated overnight, and colonies counted to quantify viable colony forming units (CFU)/mL. Data were analyzed using GraphPad Prism 7.

Results: Azithromycin concentrations of 16 mcg/mL or less did not alter PA99 growth at 24 hr post-inoculation. Azithromycin concentrations of 32, 64, and 128 mcg/mL produced some growth defects but these changes in growth were not significantly different from control (P > 0.05). The largest and earliest change in CFU/mL was produced by Azithromycin at 256 mcg/mL and this was significantly different from control (P=0.01).

Conclusion: PA in vitro growth appears to be non-significantly inhibited by Azithromycin concentrations of 128 mcg/mL or less. However, Azithromycin concentrations approximating those achieved within immune cells (i.e., 256 mcg/mL) appear to significantly inhibit PA growth. Further investigation into the time-course of Azithromycin activity on PA and its role on clinical outcomes is warranted.

Poster Title: Treatment of chronic hepatitis C and the potential for hepatitis B reactivation in co-infected patients: A case report

Primary Author: Lin Tran, Temple University School of Pharmacy, Pennsylvania; **Email:** lin.tran@temple.edu

Additional Author (s):
Jennifer Andres

Purpose: This case report reveals the potential for hepatitis B virus (HBV) reactivation following the treatment of chronic hepatitis C virus (HCV) in a co-infected patient using direct acting antivirals (DAAs). The patient was first diagnosed with HCV during a pre-surgery screening, likely acquired via drug use. She reports that the last drug use was approximately 20 years ago. Immunity was found for hepatitis A virus, however, HBV DNA was detected at less than 20 IU/mL, and she did not have hepatitis B E antigen present. She was identified as inactive carrier state for HBV. Patient was found to have HCV genotype 1a and was treatment naïve. Despite a fibrosis stage of F0 and no signs of jaundice, fatigue, or edema, she was at risk for rapid hepatic disease progression due to diabetes and HBV co-infection. Due to her mental stability and social history, she was considered to be a good candidate for HCV treatment. Ledipasvir/sofosbuvir 90/400 mg for eight weeks was initiated. After two weeks of treatment, HCV RNA was still detectable at 50 IU/mL, a decrease from pre-treatment viral load of 670,740 IU/mL, and HBV DNA had increased to 70 IU/mL. During treatment, patient denied experiencing signs of hepatic decompensation such as jaundice or confusion. At the completion of ledipasvir/sofosbuvir, the patient showed an undetectable viral quantification of HCV RNA, but showed signs of HBV reactivation with a viral breakthrough of 2,560 IU/mL. She continues to be monitored for HCV clearance and HBV DNA. Patient did not present with elevated alanine aminotransferase (ALT) or aspartate aminotransferase (AST) at any point before, during, or after her HCV treatment. Several case reports have shown that a relationship between HCV and HBV replication during co-infection exists. For example, actively replicating HCV may suppress HBV replication, HCV replication may be inhibited by a HBV superinfection, or the viruses may have alternating phases of dominance. Additionally, patients with successful HCV clearance following treatment with peginterferon/ribavirin have been shown to exhibit HBV reactivation. As this case report suggests, co-infected patients treated with DAAs may experience reactivation of previously

inactive HBV upon successful HCV clearance. This case supports the importance of close HBV monitoring before, and especially during, the treatment of HCV, however further studies are needed to confirm this inverse viral relationship.

Poster Title: Assessing the impact of a technician training and competency assessment program in preparation for the implementation of a new electronic health record

Primary Author: Megan Bereda, Purdue University College of Pharmacy, Indiana; **Email:** mbereda@purdue.edu

Additional Author (s):
Detron Brown
John Lewin III
Samuel Culli

Purpose: On July 1, 2016, the Johns Hopkins Hospital converted its electronic health record to Epic. This transition necessitated significant changes in the workflow for pharmacy technicians. The entire staff received vendor-provided "Go-Live" training through a short, online module and a large-group classroom session lead by trainers provided by the vendor. In addition, the Critical Care & Surgery pharmacy developed a one-on-one training module and individual competency assessment program. The goal of this project was to assess the impact of a pharmacy technician training module and competency checklist in enhancing technician's confidence and comfort with anticipated workflow changes.

Methods: Technicians were first required to have completed all vendor-provided training, after which their confidence level was assessed via survey. The survey assessed the technician's own confidence on a 4-point scale, ranging from Not Very Confident (1 point) to Very Confident (4 points), in being able to successfully utilize six of the major functions on the technician dashboard in Epic. These functions included Reading Labels, Dispense Preparation, Compounding and Repackaging, Order History, Medication Messaging, and Dispense Tracking. After the survey was finished, each technician was trained individually on the same six functions, and their competency was then assessed via a checklist. After the training and checklist were completed, the survey was re-administered to assess the technician's confidence on those six functions.

Results: Nineteen pharmacy technicians, representing 86% of the full-time pharmacy technicians in the Johns Hopkins Critical Care and Surgery Pharmacy, participated in this study. Across all domains, the average change in confidence improved from 2 (Somewhat Confident) to 4 (Very Confident). Increases in median confidence levels ranged by 1-2 points out of 4 total in each individual function. Overall the technicians' self-reported confidence in using Epic increased from a median of 2 (Somewhat Confident) to 3 (Confident). All technicians verbally indicated they were more confident and felt more knowledgeable regarding each of the new functions after completion of the training module and checklist.

Conclusion: In conclusion, a one-on-one training program and competency assessment enhanced technician's self reported confidence level in performing the new functions expected of them associated with the roll out of a new electronic health record. This enhancement of confidence was above and beyond the confidence level established with solely vendor-provided training modules.

Poster Title: Discovering self perceptions of health in a predominantly Hispanic US-Mexico border community

Primary Author: Sandra de Anda, University of Texas at Austin College of Pharmacy/University of Texas at El Paso Co-op Program, Texas; **Email:** sandradeanda1@utexas.edu

Additional Author (s):
Jeri Sias
Eufemia (Pema) Garcia

Purpose: The US-Mexico border has high rates of overweight and obese people with a rate at 71 percent reported for one Far West Texas County. Further, only 11 percent of the county self-reported an intake of at least five fruits and vegetables a day. There is a direct relationship between diet and health. Thus, the aim of this project was to discover the beliefs of a predominantly Mexican-American population regarding their perception of being healthy.

Methods: Pharmacy students administered surveys at events supported by a community-university based program serving a rural US-Mexico border community between the summer of 2015 and the fall of 2016. The surveyors used convenience sampling, and participants completed the (bilingual Spanish-English) survey using an electronic tablet. The survey, based on literature regarding perceptions of health and weight, consisted of 25 multiple-choice questions. The community consisted of predominantly Hispanic participants who live in colonias and economically distressed areas.

Results: A total of 65 adult participants completed the survey, and the majority, 81 percent, of participants were female. Of the participants surveyed, 78 percent somewhat agreed, agreed or strongly agreed when asked if they believed they were healthy. Among the participants, 84 percent found it hard to eat healthy foods every day, did not make healthy eating a priority, or ate whatever they wanted. Of the 79 percent of participants that wanted to lose weight, 43 percent wanted to lose up to 10 pounds and 36 percent wanted to lose more than 10 pounds. When asked what changes participants would like to make, the top three choices were to eat more fruits and vegetables, 66 percent, eat smaller portions, 36 percent, and eat less junk food,

35 percent. Almost all of the participants, 95 percent, were somewhat ready, ready, or very ready to make a change to improve their families' health.

Conclusion: Even though the majority of participants believed they were healthy, about the same percentage wanted to lose weight and a higher percentage found it hard to eat healthy foods every day. The desire by the majority of participants to eat healthier indicates awareness of healthy choices. Seeing as how the majority of the participants were willing to start making changes, the current findings may provide a framework for the community agency to survey a larger population. This could lead to identifying barriers in order to determine feasible interventions to assist this community to practice habits that promote health.

Poster Title: Liraglutide and semaglutide: A mixed treatment comparison meta-analysis of cardiovascular and safety outcomes

Primary Author: Mariam Paracha, Massachusetts College of Pharmacy and Health Sciences University, Massachusetts; **Email:** mparacha116@gmail.com

Additional Author (s):
Matthew Silva

Purpose: Metformin has been associated with macrovascular protection in patients with type 2 diabetes though not all patients can endure metformin or achieve optimal glycemic management on metformin based treatments alone. GLP-1 agonists offer a unique advantage for add-on therapy or insulin alternative, facilitating weight loss and reducing insulin resistance. Semaglutide is administered once-weekly and shares 94% homology to endogenous human GLP-1. Liraglutide is administered once-daily and shares 97% homology to human GLP-1. This analysis indirectly compares and evaluates the cardiovascular outcome data for the two latest relatively long-term GLP-1 agonist trials since head-to-head studies have not yet been planned.

Methods: PubMed was searched to identify longer-term GLP-1 trials with a primary composite of first occurrence of death from cardiovascular causes, nonfatal myocardial infarction, or nonfatal stroke. Two randomized-controlled double-blind trials focusing on liraglutide and semaglutide, were selected: SUSTAIN-6 and LEADER. Bayesian mixed treatment comparisons (MTC) network meta-analysis methods using Markov chain Monte Carlo simulation were used to evaluate direct and indirect effects of treatment. The Aggregate Data Drug Information System (ADDIS; version 1.16.7) was used for network meta-analysis. Network geometry was created in Powerpoint with nodes scaled proportionally to the size of the combined treatment population. Direct pairwise treatment comparisons (connections) were also scaled proportionally to the number of included trials. Data were recorded as odds ratios and credible intervals for the comparison of liraglutide and semaglutide.

Results: SUSTAIN-6 and LEADER trials were identified and abstracted to find 2.1 and 3.5 number of years of GLP-1 treatment and follow-up, respectively. There were 14,991 patients with a mean age of 64 and 13.5 years of type 2 diabetes at enrollment and similar

cardiovascular disease burden. There were more person-years of treatment and follow-up with liraglutide (16,338 vs. 3,461 respectively) as the LEADER trial was longer. Liraglutide and semaglutide were consistently ranked higher than placebo in direct comparisons of the primary composite endpoint and individual cardiovascular endpoints. No statistically significant differences were observed when comparing estimated effect size of both GLP-1 agonists however, indirect treatment comparisons favor liraglutide for reduction of all-cause mortality (OR 1.23; 95% CI, 0.76, 2.01) while semaglutide is favored for reducing primary composite outcome (OR 0.84; 95% CI, 0.46, 1.60) and individual cardiovascular outcomes of nonfatal MI, nonfatal stroke, coronary revascularization, hospitalization for unstable angina pectoris, and nephropathy. Nausea and vomiting prompting discontinuation were observational and were common for both GLP-1 agonists.

Conclusion: Early indirect estimates of treatment effects and preliminary rankings suggest liraglutide may be associated with lower rates of all-cause mortality, though semaglutide may be associated with fewer cardiovascular events. It is important to note there are fewer patient-years of treatment with semaglutide and fewer years to accrue outcome events. Additional head-to-head RCTs and years of follow up will help better estimate effect sizes.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Evaluative Study

Session-Board Number: 5a-217

Poster Title: Increasing the cost effectiveness of insulin use at an institution while adjusting the repackaging insulin glargine doses in vials

Primary Author: Hee Ju, University of Arizona College of Pharmacy, Arizona; **Email:** heeju@pharmacy.arizona.edu

Additional Author (s):
Eric Bergstrom
Haeun Park
Saddam Ayub
Sohyun Park

Purpose: Since insulin glargine is only manufactured in 10ml vials, Tucson Medical Center (TMC) made 3ml vials similar to other insulin types manufactured for institutions. As TMC is fully electronic, each insulin vial must be dispensed and charged to each patient and cannot be shared between patients, which leads to wastage. The purpose of this study is to assess the insulin use at TMC, determine the appropriate size vial to manufacture, and evaluate the economic impact of repackaging 10ml vial of insulin glargine to 1.5ml vials instead of 3ml vials.

Methods: Approximately 900 nurses from varying areas of the hospital including emergency department, adult intensive care unit (ICU), adult medical/surgical, pediatric and pediatric ICU were surveyed on insulin usage at TMC using survey monkey. A follow-up survey would be sent after the intervention to measure satisfaction and effectiveness. Reports were also generated from TMC inpatients to see how many units of insulin were administered as well as the number of vials dispensed during their stay. Based on the average use of insulin glargine, the quantity within the repackaged vials was adjusted for less wastage. Follow- up reports from TMC inpatients were generated after the intervention to assess insulin glargine use. Finally, purchasing reports before and after intervention were collected to validate usage.

Results: There were 182 responses from nurses at TMC. About 80 percent agreed or strongly agreed that insulin waste is a problem. The average use of insulin glargine for the month of October 2015 was about 120 units per patient per admission. Changing of insulin regular or lispro was not determined to be cost effective. TMC reduced the amount to be repackaged

from 3ml to 1.5ml in April 2016 without additional labor and cost. The follow-up survey was received by 60 out of about 900 nurses, in which 93 percent felt that this intervention was effective and 95 percent agreed or strongly agreed to keep the intervention. The average use of insulin glargine per patient per admission for July and August 2016 was 105 units. Also, the purchasing of insulin glargine decreased from an average of 100 vials per month to an average of 66 vials. 360 ml of insulin glargine was saved after the intervention. Overall, this change saved TMC 3,080 dollars every month on average.

Conclusion: Since insulin glargine is not manufactured for institutions at amounts less than 10ml, it was cost effective for TMC to reduce the amount of repackaged insulin glargine from 3ml to 1.5ml for their patient population. This intervention may be applied to other institutions since it requires a simple manipulation of volume change. However, each institution must assess insulin glargine use per patient per admission to maximize cost effectiveness when repackaging this product.

Poster Title: Developing liquid chromatography-mass spectrometric method for the nicotine assay to facilitate drug discovery for smoking cessation

Primary Author: Paul Hoseph, Pacific university, Oregon; **Email:** jose1985@pacificu.edu

Additional Author (s):
Stephen Black
John Harrelson

Purpose: Considering its tremendous impact on human health, it would be helpful if there were more than two pharmacological treatments approved for nicotine addiction. Low nicotine plasma concentrations stimulate cigarette consumption, therefore, one therapeutic approach is to inhibit nicotine metabolism to extend the half-life. Previously, we discovered that cinnamaldehyde is an inhibitor of cytochrome P450 2A6, the human nicotine-metabolizing enzyme. The purpose of this project was to develop an in-house liquid chromatography-mass spectrometric (LC-MS) method to evaluate the potency of cinnamaldehyde and related analogs as inhibitors of nicotine metabolism using human liver microsomes and cytosol in the next phase.

Methods: Flow injection analysis was used to maximize the sensitivity of the LC-MS to detect nicotine and cotinine. This was followed by achieving optimal separation between nicotine and its metabolites using a C-18 Kinetex column. Variations in mobile phase composition, flow rate, column temperature were made systematically to obtain optimum separation. Based on previously published method, milrinone was selected as an internal standard for quantification purposes and to account for variability in analyte loss. An extraction method was developed to selectively isolate nicotine and its metabolites for LC-MS detection. Pentane, dichloromethane, diethyl ether, and mixtures of these solvents with isopropyl alcohol were evaluated as extraction solvents for the procedure. Sodium hydroxide, ammonia, and saturated sodium carbonate were evaluated as deprotonating agents for the extraction process. Human liver microsomes, cytosol, NADPH, and nicotine were incubated for 30 minutes at 37 °C with varying reagent concentrations to find the optimum conditions for measuring nicotine metabolism in vitro.

Results: An LC-MS method was developed to detect nicotine and cotinine at clinically relevant concentrations (5-200 ng/mL). Based on flow injection analysis, the optimum sensitivity was obtained with the following mass spec conditions: drying gas flow 12 L/min, nebulizer pressure 55 psi, drying gas temperature 350 °C, and capillary voltage 5000 V. Chromatographic separation was achieved with a gradient flow starting at 90% ammonia solution (2%) and 10% acetonitrile and switching to 65%/35% composition over a 15 minute interval. Good separation was achieved with nicotine and cotinine eluting at 13.6 min and 7 min, respectively. A mixture of ethyl acetate/isopropyl (80/20) provided the most complete extraction of nicotine, metabolites, and the internal standard; this mixture was selected as the extracting solvent for future studies. A saturated sodium carbonate solution was the most effective deprotonating agent. Incubations of human liver microsomes (0.5 mg/mL), cytosol (0.3 mg/mL), and nicotine (50 µM) were identified as the optimal incubation concentrations to generate detectable quantities of cotinine. Both nicotine and cotinine percentage recoveries from the extraction procedure were greater than 80%. Cotinine formation from nicotine metabolism was confirmed by the retention time from LC-MS analysis and comparison to purchased cotinine standards.

Conclusion: : A reliable and reproducible LC-MS method was developed for measuring nicotine and its major metabolite from incubations with human liver microsomes and cytosol. The method is sufficiently sensitive for conducting inhibition studies to identify potential candidates for smoking cessation. Cinnamadehyde and structurally-related analogs will be incubated with nicotine and human liver microsomes with cytosol. Cotinine formation will be measured using this method to identify the most potent inhibitors of nicotine metabolism. The method should also be useful for detecting nicotine and cotinine in serum or saliva samples for an in vivo evaluation of nicotine metabolism and inhibitor studies.

Poster Title: Pneumococcal vaccination rates among pediatric end stage renal disease and kidney transplant patients

Primary Author: Katelynn Doran, University of Oklahoma College of Pharmacy, Oklahoma;
Email: katelynn-doran@ouhsc.edu

Additional Author (s):
Rohit Hirani
Teresa Lewis

Purpose: Children with history of solid organ transplants are classified as immunocompromised and those with end stage renal disease have a higher risk of developing severe infections from Streptococcus pneumoniae. The Centers for Disease Control (CDC) recommend additional pneumococcal vaccinations beyond routine childhood immunizations for high-risk patients. Our goal is to improve vaccination rates and ensure immunologic protection against Streptococcus pneumoniae for pediatric nephrology patients. This quality improvement project reviewed how well the current pneumococcal vaccine schedule is followed for high-risk pediatric patients who have end stage renal disease or who are kidney transplant recipients and are managed at our facility.

Methods: A query was performed using a centralized electronic immunization registry, Oklahoma State Immunization System (OSIIS), to gather immunization records on current pediatric nephrology patients who were managed at our institution. Data were gathered for children with end stage renal disease and for children who received a kidney transplant. Patient vaccination history was compared to the current CDC Pneumococcal vaccination guidelines for those with high risk factors.

Results: Data from 113 pediatric nephrology patients were reviewed. Sixteen had end stage renal disease requiring dialysis and 97 were kidney transplant recipients on immunosuppressive therapy. Patients ranged in age from 1-year to 24-years-old with a mean age of 15.2 years. Seven patients did not have immunization records within OSIIS. Approximately twenty-seven percent (31/113) had their immunization history filed in OSIIS, but data related to pneumococcal vaccinations were not present. It was not known if the missing data were due to

patients' vaccinations not being entered appropriately into the centralized registry or if patients did not receive pneumococcal vaccinations at all. Fifteen percent (17/113) were up to date on their pneumococcal vaccinations while 58 percent (51/113) had not received the CDC recommended Streptococcus pneumoniae immunization doses.

Conclusion: Our findings revealed that a fairly large portion of patients in this high risk group either lacked vaccination records for Streptococcus pneumoniae or their vaccinations history showed incomplete doses of the recommended vaccines. We shared our findings and provided recommendations for catch-up vaccine doses for each child to the pediatric nephrologists within our institution who manages these patients. Improving vaccination rates is one way pharmacists can foster antimicrobial stewardship. Patients who are immunized against pathogens which cause invasive disease are less likely to develop the primary infection thus require less antimicrobial therapy.

Poster Title: Retrospective Review of the Utilization of Rabies Immune Globulin and Rabies Vaccine in a Community Hospital Emergency Department

Primary Author: Alexander Accinelli, University of Maryland Eastern Shore, School of Pharmacy, Maryland; **Email:** aaccinelli@umes.edu

Additional Author (s):
Laura Byrd

Purpose: Rabies vaccine and immune globulin are commonly prescribed for post-exposure prophylaxis in patients suspected of rabies exposure. In 2015, Peninsula Regional Medical Center (PRMC) spent $60,426 on rabies vaccines (Rabavert® and Imovax®), and $172,075 on rabies immune globulin (HyperRAB S/D®). The purpose of this study was to evaluate if patients at PRMC were being administered rabies vaccine and immune globulin in accordance with 2010 CDC guidelines, indications, and recommendations. The results may determine if a rabies vaccination protocol should be developed in order to improve appropriate patient identification, series administration and perhaps decrease costs.

Methods: Acudose® records were queried for patients who received rabies immune globulin and rabies vaccine between the dates June 2014 – May 2016. Medical record ID numbers were then used to access archived patient profiles in Pulsecheck, PRMC's emergency department monitoring system. Pulsecheck provided details regarding the patient's potential rabies exposure, including a description of the initial diagnosis at triage, history of present illness, and medication administration. 100 patient records were selected (50 from each year) to be analyzed using a random number generator. Primary outcomes measured included the appropriate indication and administration of rabies post-exposure prophylaxis. To be truly indicated to receive post-exposure prophylaxis, the described exposure-scenario in the patient's profile had to meet the qualifications listed in the CDC's 2010 Guidelines. In order for the series to be administered correctly, rabies immune globulin and rabies vaccine had to be given at the correct dose, on the correct days, and via the correct route and site. Secondary outcomes measured included yearly trends in patient populations, types of exposures, costs, and adverse reactions. This protocol was approved by PRMC's internal research review committee.

Results: Out of 100 queried patients: Post-exposure prophylaxis was given when it was not truly indicated in 31 cases. In 45% of cases, animals were not quarantined/tested when they could have been. In 39% of cases, contact with the involved-animal was definitively ruled out prior to administration of post-exposure prophylaxis. In 9% of cases, the health department advised that post-exposure prophylaxis was not necessary. In 4% of cases, the suspected animal was not quarantined for >10 days before administering post-exposure prophylaxis. In 3% of cases, patients received post-exposure prophylaxis >14 days after the initial encounter. Overall, 48,040 units (320mL) of immune globulin and 275 units (110mL) of vaccine were given when post-exposure prophylaxis was not truly indicated. Post-exposure prophylaxis was administered incorrectly in 42/100 cases. Individual cases often contained multiple errors in administration. In 60% of cases, patients did not receive full post-exposure prophylaxis because they never returned for follow-up. In 29% of cases, the vaccine was administered to an incorrect site. In 26% of cases, patients were given follow-up vaccines on an incorrect day. In 12% of cases, an incorrect dose of vaccine was administered. In 7% cases, patients received immune globulin >7 hours after the vaccine had been given.

Conclusion: Based on the results, a rabies post-exposure prophylaxis protocol should be developed to improve appropriate patient identification and series administration. This protocol should simplify the diagnostic process. Animal control should be contacted to capture the involved animal whenever possible. In cases when exposure has been definitively ruled out, measures should be in place to prevent administration of post-exposure prophylaxis. Appropriately identifying patients who are indicated to receive rabies post-exposure prophylaxis would prevent wasting of rabies immune globulin and vaccine, saving PRMC approximately 60,000$ per year. Measures to ensure correct dosing, administration-site and follow-up dates should also be incorporated.

Submission Category: Infectious Diseases

Submission Type: Descriptive Report

Session-Board Number: 5a-221

Poster Title: Assessing vancomycin per pharmacy in elderly patients over the age of 74 years

Primary Author: Geraldine Cadalin, Loma Linda University School of Pharmacy, California;
Email: gcadalin@llu.edu

Additional Author (s):
Linda Lumintaintang
Julie La
Martin Breen
Lee Nguyen

Purpose: Vancomycin is a glycopeptide antibiotic commonly used to treat gram positive infection, including methicillin-resistant Staphylococcus aureus (MRSA) infection. Pharmacy protocols to dose vancomycin have become more of a common practice and have resulted in more appropriate target trough attainments. The purpose of this study is to evaluate the rates of vancomycin trough target attainment in patients over the age of 74 years and grouped by three different serum creatinine ranges.

Methods: The institutional review board approved this retrospective study. All patients over the age of 74 that received vancomycin with appropriate trough levels from 01/01/2013 to 12/31/2014 were evaluated. Appropriate trough levels were defined as vancomycin levels acquired within 1-hour of the fourth dose. Patients were excluded from the study if they did not meet inclusion criteria, had no vancomycin trough levels drawn, had no vancomycin given, or did not meet the minimum age requirement. The patients were divided into three serum creatinine groups (LowSCr: < 0.8mg/dL, MidSCr: 0.8-0.9 mg/dL, HighSCr: ≥1 mg/dL) for evaluation. The primary outcome of this study was to determine rates of vancomycin trough target attainment based on the vancomycin dosing protocol. The secondary outcome of this study was to assess the time to target trough levels between the groups.

Results: Two hundred and four patients were included in the study. The numbers were divided as follows: LowSCr (n=67), MidSCr (n=91), HighSCr (n=46). The average age of the patients was 85.7 ±5.98 years. Median serum creatinine (mg/dL) by groups were as follows: LowSCr (0.6, IQR:0.5-0.7), MidSCr (0.8, IQR: 0.8-0.9), HighSCr (1.6, IQR:1.03-2.6), $p < 0.0001$. Median

vancomycin (grams/day) doses per group were as follows: LowSCr (1000, IQR: 750-1000), MidSCr (1000, IQR: 937-1375), HighSCr (750, IQR:750-1000), p=0.0005. The number of patients unable to achieve the target trough goals between groups were LowSCr: 61% vs HighSCr: 9%, p < 0.0001, and MidSCr: 48% vs HighSCr: 9%, p < 0.0001. There was no difference in target trough goal attainment between the LowSCr and MidSCr groups (61% vs 48%, p=0.109). Time (days, average ±SD) to target trough goals for each group was: LowSCr (5±3.8), MidSCr (4.1±2.3), HighSCr (3.6±1.8), p=0.14.

Conclusion: There is room for improvement in dosing vancomycin in patients > 74 years old. The patients with serum creatinine levels less than 1.0 mg/dL were less likely to achieve vancomycin trough goals in comparison to patients with serum creatinine 1.0 mg/dL or greater. For patients who achieved vancomycin trough goals, the time to trough attainment did not differ between the two groups. Multiple factors can contribute to the decrease rate of target attainment including patient size, rounding of serum creatinine, inter-pharmacist differences in dosing, and adequate loading doses of vancomycin.

Poster Title: Survey of community pharmacy based clinical trial patient recruitment

Primary Author: Nishaben Mavani, Roseman University of Health Science, Utah; **Email:** nmavani@student.roseman.edu

Purpose: Timely patient recruitment is acknowledged as an important aspect of successful clinical trials. According to a study done by Tufts Center for Drug Development, 11% of sites fail to enroll even one patient and 37% do not meet their enrollment goals. Patient education related to clinical trials and provider trust is very important to improve patient recruitment. According to the Meyocks Health Survey and McKesson Study, community pharmacists are the most trusted health care professionals. To improve patient recruitment, patient centered recruitment strategies are needed. My hypothesis is that community pharmacy can be a potential site for clinical trial recruitment.

Methods: A survey was developed based on a literature review and centering on the following five topics: pharmacist willingness to explore clinical trial and share clinical trials information with the patient, pharmacist thoughts on receiving an incentive to screen the patients and proving patient recruitment, and pharmacist thoughts on their relationship with their patients. Eighty community pharmacists in Utah were called and surveyed. Descriptive statistic was gathered on pharmacist opinion.

Results: The response rate for this survey was 71.25%. Of the respondents, 15.78% were not interested in implementing clinical trials into their workflow. Another 21.05% of respondents would be interested in enrolling clinical trials patients. While the remaining 63.15% would be interested only if they were incentivized. Six respondents suggested that clinical trials could work with medication therapy management services. A majority of respondents stated that they know their patient population by names.

Conclusion: Clinical study sites facing difficulties in meeting the growing demands for clinical subjects and more diverse patient populations. Community pharmacist based recruitment program could make a positive change for patient recruitment. We found that majority of pharmacists were willing to involve in clinical trials. Additionally, pharmacist felt that it could be

implemented through Medication Therapy Management. Pharmacist continued to be well trusted by patients and majority of pharmacist stated that they know patient by their name. Pharmacists can rebuild trust and help to bridge the education gap about the benefits and risks of clinical trials.

Poster Title: Initiating an international advanced pharmacy practice experiential (APPE) rotation in Ghana for first hand exposure to cultural differences in patient care

Primary Author: Katherin Keesling, Roseman University of Health Sciences College of Pharmacy, Nevada; **Email:** kkeesling@student.roseman.edu

Additional Author (s):
Jeffery Talbot
Darla Zarley
Daniel Amaning Danquah
Cynthia Amaning Danquah

Purpose: In the United States, people of all ethnic and cultural backgrounds are in need of healthcare; however, despite living in a diverse society, many students are not aware of how to accommodate such cultural differences. Therefore, an international Advanced Pharmacy Practice Experience (APPE) was designed to provide students exposure to health care practices and systems in Ghana, while immersed in the cultural, societal, and healthcare differences of a country other than their own. Experiencing another country's practices as students will allow better preparation to provide culturally-competent healthcare as practitioners.

Methods: The Ghana international APPE rotation was approved by the Curriculum Committee of the College of Pharmacy, after which approval was obtained by the preceptor in Ghana, the Director of Experiential Education, and legal department. Once approved, interested second-year students applied for the rotations as an elective experience. Planned activities included working with international collaborative organizations such as USAID Strengthening Health Outcomes through the Private Sector project, government officials at the Food and Drug Authority and Pharmacy Council, clinical pharmacists at 37 Military Hospital and Komfo Anokye Teaching Hospital, and professors, as well as students at Kwame Nkrumah University of Science and Technology School of Pharmacy and University of Ghana School of Pharmacy. Students had the opportunity to observe community pharmacies, hospitals, healthcare in rural locations, and the National Drug information Center conduct patient care in a setting that differed greatly from that offered in the United States. Students were also provided the opportunity to experience historical, environmental, and cultural aspects of Ghana, such as Elmina Castle; a

center for slave trade, Mole National Park and Kakum National Park canopy walk, and Art Centre in Accra. Students experiencing these different settings may help them develop an understanding of how the practices of another country may affect how patients seek care and what they expect from such care.

Results: The charter group consisted of four students, two males and two females, which completed the international APPE rotation in Ghana during two separate rotations in the fall of 2016. These four students were exposed to clinical, government, leadership, societal, cultural, and historical aspects of Ghana. It provided a better understanding of different cultures, how health systems are managed, as well as patient expectations. Over the course of the rotation, students worked in the pharmacy setting where they quickly discovered that a prescription from a physician is not necessary to purchase medications and it is the pharmacist's responsibility to make sure the patient is receiving the correct medication for their disease state. Working with different organizations and government sectors also shed light as to how patients are educated on personal health and what they expect from their healthcare providers. Though what each student took away from this rotation may have differed, they all had the same opportunity to see how a different culture views and practices healthcare, and to take away from this rotation a new view on patients from a different background that they may have in the future.

Conclusion: Students were allowed a breadth of experiences in every aspect of another country's healthcare system, from healthcare governing bodies, the education of their future healthcare providers, international collaborative organizations, local hospitals, and all the way to community pharmacy. This, along with historical and cultural lessons, helps build a better understanding of how patients of another country may differ from those in the United States. With this exposure students can view the needs of patients with diverse cultural backgrounds from a different perspective since this experience would allot them the opportunity to become more culturally aware.

Poster Title: Evaluation of urinary tract infection management in hematopoietic stem cell transplant recipients receiving pneumocystis prophylaxis with sulfamethoxazole/trimethoprim

Primary Author: Eric Kinney, West Virginia University School of Pharmacy, West Virginia; **Email:** emkinney@mix.wvu.edu

Additional Author (s):
Aaron Cumpston
Alexandra Shillingburg

Purpose: At West Virginia University Medicine (WVUM), sulfamethoxazole/trimethoprim is recommended both for initial therapy of a symptomatic suspected urinary tract infection as well as pneumocystis prophylaxis in stem cell transplant patients. There is no guidance for how to treat patients who are on prophylactic sulfamethoxazole/trimethoprim and then subsequently develop a urinary tract infection. This review is being performed to identify patients on prophylactic sulfamethoxazole/trimethoprim after hematopoietic stem cell transplant and determine the treatment approach chosen for their symptomatic urinary tract infection.

Methods: A retrospective chart review of the Electronic Medical Record (EMR) of WVUM was performed from January 2011 to December 2015 on stem hematopoietic cell transplant patients who were prescribed a prophylactic course of low-dose sulfamethoxazole/trimethoprim and then had a urine culture obtained. A prophylactic course of low-dose sulfamethoxazole/trimethoprim is defined by West Virginia University Medicine guidelines as a double-strength (800mg/160mg) tablet every MWF or a single-strength (400mg/80mg) tablet daily. Guidelines for urinary tract infection treatment include double-strength sulfamethoxazole/trimethoprim twice daily as the preferred first-line agent for initial therapy of a symptomatic suspected urinary tract infection. Patients were evaluated on the dose of sulfamethoxazole/trimethoprim at the time of urine culture, the results of the urine culture including organisms that grew and their sensitivities, and medication prescribed for management of the urinary tract infection.

Results: SMZ/TMP DS QMWF for PCP prophylaxis was preferred over the SS QD dose in 95% of the patients, which is consistent with program standards. Of the organisms cultured from urine samples of patients suspected of a UTI, SMZ/TMP resistance was high at 85% in total reported susceptibilities; Escherichia coli was found to be resistant to SMZ/TMP in 100% of the strains isolated in these patients. Escherichia coli was the most commonly found gram-negative bacteria followed closely by pseudomonas aeruginosa and klebsiella pneumonia respectively. Bacterial resistance forced treatment augmentation only once in the patients studied, in which case ciprofloxacin-resistant Escherichia coli, once cultured, led to the discontinuation of the ciprofloxacin therapy prescribed for the UTI. Also of note, quinolone resistance was significant at 45%. Although, gram-positive bacteria were less commonly found; streptococcus organisms and enterococcus faecalis were seen most frequently. Greater than half of patients (64%) did not have therapy augmented when already on SMZ/TMP for PCP prophylaxis and developing a UTI. Quinolones were the most frequently prescribed antibiotic (46%) when an augmentation agent was chosen. Consistent throughout each case investigated, current dose and frequency of the existing SMZ/TMP order was continued while treating the suspected UTI.

Conclusion: At WVU Medicine – Ruby Memorial Hospital, for a patient taking SMZ/TMP as PCP prophylaxis who then develops a UTI, most often no change to current therapy is made. Most often Escherichia coli was identified and was resistant to SMZ/TMP. Recommendations should be made to select an alternate therapy to treat UTI's in these patients.

Poster Title: Factors associated with nonadherence to antiretroviral therapy in migrants at the Tijuana-San Diego international border

Primary Author: Renne Basso, University of Baja California, Baja California, Mexico; **Email:** renebasso00@hotmail.com

Additional Author (s):
Iván Velasco-Barrios
José Román Chávez-Méndez
José Luis Sánchez-Palacio
Horacio Eusebio Almanza-Reyes

Purpose: HIV-AIDS is a problem that so far has no cure, but the correct use of antiretroviral therapy (ARVT) can control and prevent virus transmission. In Latin-American three of every four people infected with HIV are on ARVT; but coverage of antiretrovirals is not enough to improve health, it's also necessary to improve adherence, as in patients with HIV-AIDS this varies between 37-83% depending on the sociodemographic characteristics, thus, the purpose of this study was to assess the adherence to ARVT in migrants from the Tijuana (MEX) -San Diego (USA) border and identify the associated factors with it.

Methods: A prospective, cross-sectional, observational study was conducted in 99 migrants with HIV treatment who live in the Mexican side of the Tijuana-San Diego international border. Recruitment of patients was conducted from December 2014 to December 2015 in a care center for patients with sexually transmitted infections and AIDS. Patients of both genders were included only if they had HIV/AIDS infections and where on ARVT, with a time of less than one year of residency in the city of Tijuana. Individuals were excluded from the study if they do not accept to sign the informed consent or if they refused to answer at least one question of the assessment tool
Elimination criteria. All patients were applied a questionnaire which was designed for the collection of the following variables: socio-demographic data, socio-cultural issues, notes by the psychology service, pharmacotherapeutic information and of Drug Utilization Habits (DUH), also it included the Simplified Medication Adherence Questionnaire (SMAQ); where regarded as adherent patient, those who's adherence score was between 95 and 100%. Also were obtained

for each patient from the Mexican office for Antiretroviral Administration, Logistics and Security System (SALVAR in Spanish) at least two determinations of Viral Load (VL) in RNA copies/ml

Results: The average age of patients was 38.8 ± 25.9 years; 76.8% were of male and 23.2% of the female gender; 42.42% were on ARVT based on protease inhibitors (PI) and 57.58% based on inhibitors of reverse transcriptase non-nucleoside (NNRTI), 46.5% were taking more than one tablet of antiretrovirals and 26.3% had concomitant therapies; 55.6% were adherent and 44.4% non-adherent, Women were more adherent with a ratio of 0.565, in men was 0.553; 56% of patients had a history of abandonment of the antiretroviral therapy, 26.3% had concomitant therapy, 17.2% reported self-medication. Factors positively associated with non-adherence were: Alcohol (OR: 1.363; IC95% = 0.583 - 3.186). To take > 1 tablet / day (OR: 1.353; IC 95% = 0.607 - 3.014), use of drugs of abuse (OR: 1.258; IC 95% = 0.557 to 2.842), self-medication (OR: 1.136; IC 95% = 0.398 to 3.238); psychological disorders (OR: 1.867; IC95% = 0.747 - 4.665). Virological control was presented in 58.18% of adherent patients and 36.36% in the non-adherent. As for the presence of virologic failure, the factors with positive association were: self-medication (OR: 5.404; IC95% = 1.443 to 20.234) and the lack of adherence (OR: 1.365; IC95% = 0.615 -3.028).

Conclusion: It was determined that the pharmacotherapy, psychology and habits of the patient are associated with the lack of adherence; It was also observed that the adherence has an impact on the virological control of patients with HIV / AIDS, as was more frequent virological control in adherent patients compared to non-adherents. For this reason, it is essential the inclusion of the pharmacist in the Mexican health system to improve the response to ARVT in patients with HIV / AIDS, mainly through health education programs that enable and enhance good Drug Utilization Habits and therapy adherence.

Session-Board Number: 5a-227

Poster Title: Significance of implementing complementary alternative medicine (CAM) course into a pharmacy school curriculum

Primary Author: Sanjay KC, Touro College of Pharmacy, New York; **Email:** skc2@student.touro.edu

Additional Author (s):
Nana Asante
Olga Rashchupkina
Dipan Ray

Purpose: Complementary Alternative Medicine (CAM) use among patients with multiple chronic diseases has progressively expanded over the years. Being easily accessible, patients use CAM as monotherapy or as an adjunct to other medication therapies, thus increasing the complexity of multiple disease state management. Patient care continues to be compromised due to numerous drug-CAM interactions, and increasing safety concerns with the use of CAM. Despite the rise in popularity of CAM, the educational efforts in pharmacy schools are still insufficient. Thus, the objective of this study is to show the importance of CAM education among future pharmacist.

Methods: Extensive literature search was performed using the following sources: PubMed, Cochrane library, Natural Medicine Comprehensive Database, American Journal of Pharmaceutical Education, Center for Disease Control and Prevention (CDC), and Food and Drug Administration (FDA). The articles examined focuses on CAM use among people with multiple chronic conditions, drug-CAM interaction, number of pharmacy schools providing CAM education and top ten supplemental use of CAM products in various disease states.

Results: According to National Institute Health Survey (NIHS 2012) data, more than 25% of American adults have 2 or more chronic conditions. The survey data indicated higher frequency use of multivitamin/multimineral (57.1%), vitamins (42.8%), herbal therapies (22.0%). The NIHS 2012 data also reports the top ten most used CAM including fish oil (18.8 million), Glucosamine (6.5 million), Probiotic (3.9 million), Coenzyme Q10 (3.3 million), Melatonin (3.1 million), Echinacea (2.3 million), Cranberry (1.9 million), Garlic Supplements (1.9 million), Ginseng (1.8

million) and Ginkgo Biloba (1.6 million). These products may affect therapeutic effects of other prescription drugs without prescriber knowledge. For example, melatonin interacts with multiple medications namely anticoagulants, anticonvulsants, antihypertensive and contraceptives. In contrast the use of melatonin among adults doubled from 2007 to 2012.According to a national survey of schools of pharmacy (1997), CAM courses are either offered as an elective or the concepts are incorporated in other courses. A 1999 listing compiled by American Association College of Pharmacy (AACP) indicated that only 29 (33%) schools of pharmacy out of 88 schools offered CAM education. A literature review determined that more recent survey data have not been published on this topic, which demonstrated the need for further research.

Conclusion: The use of CAM is on the ascendency and poses threat to patient safety. The current accreditation and governing body does not enforce CAM inclusion in pharmacy schools curriculum. As such, the knowledge base on CAM products by practicing and future pharmacists are insufficient to appropriately counsel and educate patients on the proper use of such products. Given the utilization and the prevalence of CAM, it is important to implement CAM courses into pharmacy school curriculums so that future pharmacists can have adequate knowledge about CAM products.

Poster Title: Assessing knowledge of metabolic syndrome clinical values and willingness to implement health changes among Black men

Primary Author: Chibuokem Amuneke-Nze, The University of Texas at Austin College of Pharmacy, Texas; **Email:** amuneke-nze.2@osu.edu

Additional Author (s):
Benita Bamgbade
Jamie Barner

Purpose: Black men have the shortest lifespan expectancy along with the highest rates of obesity (47.8%) in the U.S. Concurrently, Black men are at risk for comorbid conditions like metabolic syndrome. In order, to impact health management behaviors, patients need to be knowledgeable regarding relevant clinical values and be willing to take an active role in managing their health. This study's objectives are to assess Black men's: 1) knowledge of relevant metabolic syndrome clinical values; 2) ability to recall clinical values at 3-month follow-up; and 3) willingness and actual help-seeking behavior after a metabolic health screening.

Methods: This research was part of a larger study that employed both quantitative and qualitative methods. Four focus groups of approximately 5-6 adult Black men were conducted. Participants were recruited from community centers, local business, and churches. Prior to the focus groups, participants were surveyed regarding: having metabolic syndrome diagnoses (diabetes, hypertension, dyslipidemia); timeframe of last check of metabolic syndrome lab values (6 categories ranging from: last week to >2 years ago); timeframe of last primary care physician (PCP) visit (5 categories ranging from: 6 months to >3 years); and knowledge of metabolic syndrome values and body mass index (4-5 categories with relevant ranges). Respondents could also indicate that they did not know for any of the questions. After the focus group, the men were screened for diabetes, hypertension, dyslipidemia and obesity. Subsequently they were given wallet cards documenting their values, the clinically accepted normal range and instructing them if they were in or outside of normal values. Three months post focus group, participants were contacted by telephone using a semi-structured interview format. The survey instrument assessed knowledge of relevant values whether they had any follow-up labs or provider visits. Participants were also asked if the focus group discussion

influenced them to see their provider, discuss their health with others or make health behavior changes.

Results: The Black male participants (N=23) were on average 45.2±16.2 years. Regarding the participants' initial clinical knowledge base a majority could not recall their metabolic numbers prior to the focus group. Of the group 68%, 70% and 52% could not recall their cholesterol, blood sugar, or BMI respectively, while 27.3 % and 47.8% could not recall their blood pressure and body fat, respectively. However, upon screening we discovered, the majority of the participants were within normal thresholds for most metabolic values except over 60% of participants had out-of-range BMI and % body fat. Additionally, mean systolic/diastolic blood pressure was 133/82. Of the participants in the follow-up (n=17) approximately 60% recalled their focus group values, approximately 50% either rechecked their metabolic values and/or scheduled an appointment with their PCP and 76% implemented a lifestyle change as a result of the focus group.

Conclusion: Black men have a higher likelihood of lower health management behaviors and outcomes specifically related to metabolic syndrome. This is due, in part, to gender, race/ethnicity, as well as being underserved. Thus, to decrease this health disparity gap, it is important to understand what underserved men perceive as standards for personal health management. In addition, there is a need to understand motivators for self-management and to tailor messages that incorporate their perceptions and promote willingness to seek help related to medication use.

Poster Title: Assessment of a medication safety activity designed to increase the over-the-counter product knowledge of participants at a health fair

Primary Author: Molly Ennis, Massachusetts College of Pharmacy and Health Sciences, New Hampshire; **Email:** menni1@stu.mcphs.edu

Additional Author (s):
Ashley Moulton
Cheryl Durand
Amanda Morrill
Kristine Willett

Purpose: There are a wide variety of over-the-counter (OTC) medications available to the public. As more medications become available OTC, it is important for pharmacists and pharmacy students to understand the knowledge gaps that the public has regarding OTC products. This purpose of this project is to assess public knowledge of proper and safe use of common OTC medications with regards to ingredients, dosing, and indications.

Methods: A 6 item survey regarding commonly used OTC medications was administered to assess participant's knowledge of OTC products. Corresponding medication packaging for each question was available for participants to refer to when responding. Additionally, demographic data including, age and gender were collected. Once surveys were completed, pharmacy students reviewed and discussed correct responses with the participants. Following the activity, the survey results were analyzed using numbers and percentages. Study protocol was approved by the University's Institutional Review Board. All participants were asked to sign an informed consent to participate.

Results: A total of 34 participants completed the survey, including 16 males and 18 females with a average age of 49 years old. Results reveal that 20.5% of participants could not accurately select the correct antihistamine that causes the most drowsiness, and more than half of participants could not accurately select the correct dose of acetaminophen for a child given the package directions. Further, approximately a third of the participants did not realize that the purchase of pseudoephedrine requires proper identification at the pharmacy. While

more than half of participants did not know that decongestants may be harmful for patients with uncontrolled high blood pressure, 85% of participants were able to select the correct antacid for pregnant women. The median and mean correct scores on the 6 question survey was a 2 and 2.5, respectively. (minimum 1, maximum 6).

Conclusion: Consumers are not often aware of the safety risks of accessible OTC medications. The survey identified areas of opportunity to provide more education to the public, including drug side effects and appropriate dosing for pediatric medications. It is important to highlight these knowledge gaps, as these medications are readily available to patients. Patients should be reminded that pharmacists are available to assist with questions and concerns.

Poster Title: Impact of a Birkman Method® Intervention on Pharmacy Preceptor and Faculty Self-Awareness and Self-Confidence

Primary Author: Stephanie Shealy, South Carolina College of Pharmacy - USC, South Carolina; **Email:** shealysc@email.sc.edu

Additional Author (s):
Whitney Maxwell
Worrall Cathy
Patricia Fabel
Bryan Ziegler

Purpose: The Accreditation Council for Pharmacy Education (ACPE) 2016 Standards requires key elements of faculty and preceptor development and engagement. In response to the increased emphasis ACPE places on development of self-awareness, the South Carolina College of Pharmacy (SCCP) implemented a Birkman Method® assessment and training program for students, preceptors and faculty. A prior study showed that through participation in this program, students experienced an increase in self-awareness. The purpose of this study was to determine the impact of the Birkman Method® intervention on preceptor and faculty self-awareness.

Methods: SCCP rotation preceptors and faculty members were recruited to participate in the Birkman Method® intervention. The intervention involved completing the Birkman Method® assessment, reviewing the results and attending a 2-hour live training from a certified Birkman training consultant. A pre-survey was administered electronically prior to the participant's exposure to the Birkman Method® assessment to gather the baseline self-perception data for each participant. The pre-survey was comprised of several 5-point Likert-base scale questions to determine self-confidence of participants along different parameters and several dichotomous pre-survey questions that mirrored the results of the Birkman results so that the results could be used as a benchmark to determine self-perception accuracy. The preceptors and faculty members attended separate live training sessions so that each session could be tailored to the attendees as preceptors or as faculty members. Following each live training session, attendees were asked to complete a post-survey. During completion of the post-

survey, attendees were monitored and asked not to refer to their Birkman profiles. The pre- and post-surveys were identical with the exception of a question that asked if the participants would be applying Birkman principles in the future. The pre- and post-surveys were compared for each patient to determine changes in self-confidence and self-perception accuracy.

Results: After Birkman testing and training, both faculty and preceptors experienced statistically significant changes in self-perceptions on several parameters, including usual communication style, communication style under stress, behavior style under stress, and communication style needed to prevent stress.Preceptors and faculty also had statistically significant increases in self-confidence on different parameters. Preceptors experienced an increase in self-confidence in the ability to tailor their coaching and leadership style to fit others' needs by an average of 0.63 points on a 5 point likert-based scale (p=0.0004). Faculty members experienced an increase in the ability to describe to others how to tailor coaching or leadership styles to best fit their needs by 1.0 point on a 5 point likert-based scale (p=0.0020). Both groups had statistically significant increases in self-perception accuracy, which was used as a surrogate for self-awareness changes. With a maximum self-perception accuracy score of 6 points, allocating 1 point for each parameter agreement, faculty members experienced an increase in self-perception accuracy an average of 1.20 points (p = 0.0020) and preceptors experienced an average increase of 1.77 points (p < 0.0001).

Conclusion: Personal development and enhancing self-awareness are increasingly important for Doctor of Pharmacy (PharmD) programs. Implementation of the Birkman Method® program at South Carolina College of Pharmacy facilitated increases in self-awareness among faculty and preceptors. The longitudinal goals are to create a conversation about personal preferences and drivers of communication and behavior, and to encourage reflection on the impact on patient care. Further analysis will determine longitudinal effects, but these results provide promising indications that through the implementation of a standardized personal development program, PharmD programs can create a culture among students, faculty, and preceptors that is dedicated to increasing self-awareness.

Poster Title: Baseline Academic Standards for Resident Applicants

Primary Author: Glenn Windmiller, Roseman University of Health Sciences, Utah Campus, UT;
Email: glennwindmiller@yahoo.com

Additional Author (s):
Carolyn Lathrope
Jolene Blaine
Tim Drake

Purpose: Many resident programs struggle with how to appropriately rank resident candidates based on their academic performance. Colleges of pharmacy that use a pass fail grading system further complicate this task. Some schools offer class rank to help address academic rank, but there is not a standard that compares class rank with GPA for graduate schools.

Methods: A survey instrument was created via google documents containing seven questions related to academic performance of pharmacy students. A link to this survey was emailed to one hundred and thirty four schools, listed on the Accreditation Counsel for Pharmacy Education. The survey was designed to obtain information on grading standards, grade point average, and interquartile range. The survey was available for access from September 1, 2016- September 29th, 2016.

Results: Fifteen institutions responded to the email link. The majority of the institutions that participated were traditional grading based systems using letter grading. Forty one percent of respondents were deans of the institutions, while fifty eight held other positions. The majority of the institutes had median grade point averages of 3.2 or greater. The highest grade point average for graduating students was 3.9 or greater, except for one institution listed 3.2 as the highest grade point average for their graduation students. The lowest grade point average was a 1.5, with majority of the grade point averages between 2.0-2.7.

Conclusion: The range of GPA from 1.5 to 3.9 with an average GPA of 3.2 gives a good range to compare class rank. If the 50 percent class rank mark is set at 3.2, and the top 10 percent class rank would be set at 3.9 or higher with the low 10 percent at 2.0 or lower. While this study

helps compare GPA to class rank, there was still differences in average GPA between collages. A standardized test like the PCOA exam may provide a better national standard to compare academic performance.

Poster Title: Concomitant fluoroquinolone and amiodarone induced cardiac events: retrospective cohort study

Primary Author: Benjamin Miao, Ernest Mario School of Pharmacy, New Jersey; **Email:** ben.miao8@gmail.com

Additional Author (s):
Luigi Brunetti

Purpose: Levofloxacin, a commonly used fluoroquinolone antibiotic, and amiodarone, an antiarrhythmic agent, are both known to prolong the QT interval. The evidence supporting this concern are limited to case reports and small case series. The purpose of this study was to investigate the impact of the concomitant usage of levofloxacin and amiodarone on QT interval prolongation and the occurrence rate of cardiac events in hospitalized adults.

Methods: All eligible hospitalized patients treated with levofloxacin and amiodarone between January 1, 2012 to August 31, 2015 were included in this retrospective chart review. Inclusion was limited to patients who were at least 18 years of age. Patients receiving amiodarone loading doses immediately upon admission were excluded from the study. Patients were stratified into two groups: concomitant usage of levofloxacin plus amiodarone and non-concomitant usage of levofloxacin and amiodarone. The primary outcome was occurrence of cardiac events, defined as ventricular arrhythmia or cardiac death, identified using validated ICD-9 codes and verified through patient chart review. The secondary outcome was change in adjusted QT interval (QTc) from baseline to post-treatment. The change in QTc interval was compared between groups. In addition, the concomitant group was further evaluated for predictors of primary outcome using logistic regression. All data were summarized using descriptive and inferential statistics.

Results: A total of 240 patients were included in the analysis, 164 of which received concomitant levofloxacin and amiodarone. Patients who received concomitant therapy were 5.4 times more likely to experience a cardiac event versus patients who received levofloxacin or amiodarone alone (12.8 percent versus 2.6 percent; OR equals 5.4, 95 percent CI, 1.24 to 23.81, P equals 0.025). The secondary analysis included 120 patients, 79 of which received

concomitant levofloxacin and amiodarone. There was a mean change from baseline in QTc interval of 32.40 milliseconds (ms) for the concomitant group and -2.17 ms for the non-concomitant group. The mean difference between the two groups was 34.57 milliseconds (95 percent CI, 18.52 ms to 43.69 ms, P less than 0.001). Age and angiotensin inhibitor therapy were identified as risk factors for cardiac events in patients who received concomitant therapy.

Conclusion: A statistically significant increase in cardiac events and QTc interval prolongation was found in patients given concomitant levofloxacin and amiodarone. This drug combination should be avoided.

Poster Title: University of South Alabama Student-Run Free Clinic: Recognizing Mental Health Care Inequalities of the Homeless

Primary Author: Austin Cook, Harrison School of Pharmacy, Alabama; **Email:** amc0095@auburn.edu

Additional Author (s):
William Parker
Sara Tarwater
Lauren Nelson
Nicole Slater

Purpose: The University of South Alabama Student-Run Free Clinic (USASRFC) was established in March 2014 to provide health check-ups, physician referrals, and health education to the homeless population of Mobile, AL. The Clinic operates out of 15 Place service center in Mobile, Alabama. Severe mental illness represents one of the most frequent and least-addressed issues within this patient population. To promote our patients' mental prosperity and ensure we are improving outcomes, we must first quantify the disparities in their access to mental healthcare. Thus, we implemented patient interviews using a structured questionnaire to assess these healthcare disparities.

Methods: We recruited 15 place members utilizing USASRFC to participate in an interview process. Our population consisted of 105 patients that were interviewed. The inclusion criteria consisted of 19+ years old, members of 15 Place. The interviewers were students from the USA College of Medicine and other Allied Health professional programs. The interviews were promoted to the patients through explanation of their needed input to improve our clinical services and the interviewers acquired informed consent prior to the start of the interview. The interview itself was conducted from a structured questionnaire and it was conducted one-on-one in private spaces, and no personal information was included on questionnaires. The data was then compiled and summarized using Microsoft Excel.

Results: We found that our general patient population consisted of mostly uninsured, middle-aged, black males with widely variable durations of homelessness and self-reported general

health statuses. While a minority of our patients expressed need for mental health counseling, there was a strikingly high prevalence of symptoms and behaviors indicating they would benefit from counseling on topics such as depression, frequent stress and chronic cigarette smoking. While patients reported decreased quality of life due to these symptoms and behaviors, many did not seek treatment, citing a variety of reasons demonstrating a lack of accessibility and awareness of such mental healthcare.

Conclusion: The results of this survey have already inspired changes in our clinic to promote the mental wellbeing of our patients, such as collaboration with psychiatrists, group sessions on coping with anxiety and depression, and open discussions on stress management and substance abuse. Moving forward, these data will help us evaluate our progress in improving the mental health outcomes of our patients.

Poster Title: Impact of a pharmacy intern on the transitional care of patients in an outpatient setting

Primary Author: Pegah Shakeraneh, Western New England University College of Pharmacy, Massachusetts; **Email:** pegah.shakeraneh@wne.edu

Additional Author (s):
Christina Andros
Jared Ostroff

Purpose: Hospital readmission rates continue to rise due to errors that occur throughout patients' transitions of care. Pharmacy interns can address ambiguity in medication profiles, identify inconsistencies between discharge summaries from a hospital and a patient's current medications, and recognize barriers to medication adherence. This study aims to determine the impact a pharmacy intern has on transitional care of patients in outpatient settings by examining re-admittance rates and the number of medication related problems found. This will be done by comparing results when a pharmacy intern is present during care versus when one is not present.

Methods: The pharmacy intern met with patients and discussed their primary diagnosis during their recent hospitalization, as well as reviewed their discharge plan, past medical history, and social history. The primary objective was to compare the patient's prescriptions at the pharmacy, discharge medications, and self-reported medications. Medication reconciliation was performed and follow up with the patient's pharmacy and doctors was completed as necessary. During this process, any medication related problems (MRPs) were noted and addressed by the pharmacy intern. MRPs included anything that came up during the medication reconciliation that required intervention, such as educating a patient on proper medication use, discontinuing an unnecessary medication, or addressing an adverse event due to use of a drug. Each MRP per patient was recorded. After 30 days had passed following the hospital discharge follow up visit, the patient's medical record was reviewed again to check for any subsequent emergency room visits or hospital readmissions.

Results: A total of 29 patients were observed from the dates 4/29/2016 to 6/22/2016. An intern was present from the dates 5/24/2016 to 6/22/2016. A log was kept for each patient documenting the number of medication related problems they experienced as well as if they were readmitted to the hospital after discharge during this time period. During the dates where an intern was not present (4/29/2016 to 6/22/2016), three observed patients were readmitted. During the dates where an intern was present (5/24/2016 to 6/22/2016), one patient was readmitted. While an intern was present, thirty medication related problems were identified compared to eighteen medication related problems identified without an intern present.

Conclusion: The presence of a pharmacy intern during the transitional care of patients from a hospital to an outpatient or home setting can be positively impacted by decreasing re-admittance rates, and a greater amount of medication related problems can be properly identified for a patient as a result of their interventions. The information that a pharmacy intern can obtain during this patient interview provides an added benefit to the transitional care of a patient, ultimately leading to a decrease in hospital readmission rates.

Submission Type: Case Report

Session-Board Number: 5a-235

Poster Title: Pulmonary arterial hypertension: a case report of unexpectedly severe anemia with endothelin receptor antagonist therapy

Primary Author: Helen Sweiss, University of Illinois at Chicago College of Pharmacy, Illinois; **Email:** hsweis2@uic.edu

Additional Author (s):
Rebekah Anguiano

Purpose: Anemia serves as a marker of worsened clinical outcomes in patients with pulmonary arterial hypertension (PAH). Patients receiving endothelin receptor antagonist (ERA) therapy may experience anemia soon after starting treatment. For example, with the ERA ambrisentan an average drop in hemoglobin of 0.82 g/dL was identified during clinical trials that generally stabilized and persisted after a few years of treatment. However, the etiology of anemia in patients receiving ERA treatment is unknown, and a lack of literature exists to evaluate what patient factors may increase the risk of anemia with ERA use. We report a case of a patient with PAH WHO Group 1, Functional Class II-III who experienced approximately a 4 g/dL drop in hemoglobin levels after one year of treatment with ambrisentan. The patient's past medical history included hepatitis C/alcoholic cirrhosis, Type II diabetes, and portal hypertension. The patient has a positive 30-year history of substance abuse, with a patient-reported abstinence since 2009. The patient was diagnosed with PAH in May 2010 after a right heart catheterization (RHC) was conducted which revealed the presence of right atrial pressure (RAP) of 9 mmHg, a mean pulmonary artery pressure (mPAP) of 42 mmHg, and a pulmonary capillary wedge pressure (PCWP) of 6 mmHg. Also reported were pulmonary artery oxygen saturation of 63 mm 62% and a cardiac output of 5.2 liters per minute and a pulmonary vascular resistance of 684 dyne/seconds/centimeters to the fifth power. A nitric oxide challenge was conducted during the RHC with the patient showing no response. His presenting vital signs revealed a temperature of 36.9 degrees Celsius, blood pressure 125/63 mmHg, heart rate 69 beats/min. Baseline renal function was normal, however liver function tests were elevated. Upon diagnosis, the patient was initiated on sildenafil; inhaled trepostinil was added to the treatment regimen approximately one year later. After continued deterioration, the patient was subsequently initiated on ambrisentan in March 2012, with a stable pre-ERA hemoglobin level of 14.3 g/dL. After one month of therapy, hemoglobin levels dropped to 12.4 g/dL. Hemoglobin

levels were measured monthly thereafter and revealed further reduction to 10.5 g/dL, 11.4 g/dL, and 10.9 g/dL for months 2 thru 8. Hemoglobin levels were 10.2 g/dL, 10.6 g/dL, and 10.5 g/dL for months 10, 11, and 12. After one year of ERA therapy, the patient experienced an overall 3.8 g/dL drop in hemoglobin. Levels for hemoglobin showed an average of 9.1 g/dL at year two, and 8.38 g/dL at year 3. On October 19, 2014, the patient's hemoglobin dropped to 6.8 g/dL for which he received a blood transfusion resulting in an increase to 10.3 g/dL. The patient's hemoglobin remained approximately 8-9 g/dL until expiring on February 10, 2015. Overall, the patient experienced an unexpectedly large drop in hemoglobin after initiating ERA therapy; the effect of this dramatic drop on patient outcome is unclear. Throughout ERA treatment, this patient experienced 21 hospitalizations, none of which were documented as being related to PAH. Although this patient had a history of liver disease, no other risk factors for anemia were established and prior to initiating ERA treatment, this patient had a consistently stable hemoglobin level. This case demonstrates the need for further research in this patient population to identify patient factors that may increase the risk of severe anemia with ERA's in the treatment of PAH.

Poster Title: Risk factors associated with surgical site infection in pediatric cardiac surgery patients who require delayed sternal closure

Primary Author: Kelsey Stalvey, Pacific University School of Pharmacy, Oregon; **Email:** stal8269@pacificu.edu

Additional Author (s):
Brigg Turner

Purpose: In a previous study, our group identified pediatric cardiac surgery patients requiring delayed sternal closure and those less than 1.5 years of age to be at much higher risk of surgical site infection (SSI). Quality improvement attempting to modulate modifiable risk factors may assist in reducing the rate of surgical site infections in this challenging population. In this study, we aim to identify risk factors of surgical site infection in this population with hopes that identification of these factors will lead to quality improvement and continued study.

Methods: This was a retrospective cohort study conducted from April 2011 to April 2016. All pediatric cardiac surgery patients who required delayed sternal closure were included. The primary outcome was the incidence of surgical site infection defined by the CDC/NHSN surgical site infection criteria. Patients meeting the primary outcome of surgical site infection were compared to those not meeting the primary outcome. Demographic and clinical characteristics were compared between these two groups. Bivariate analysis was conducted using the Fisher's exact test for nominal variables and Wilcoxon rank-sum test for continuous variables. The hospital institutional review board approved this study.

Results: During the study period, a total of 805 surgeries were performed on 715 patients. Of these, only 82 patients (10.2%) required delayed sternal closure. Median age at time of surgery was 5 days. Median time till sternal closure was 3.2 days (range 1.1 to 12.2 days). Six patients (7.3%) died within 30 days. A total of 10 patients (12.2%) met criteria for a surgical site infection; this was much higher than the incidence of surgical site infection in patients not requiring delayed sternal closure (1.5%) at our institution (P < 0.001). None of the patients developing SSIs died within 30 days. Average time to closure was longer in the group that developed surgical site infections, but this did not reach significance (median 3.1 vs. 3.6 days,

P=0.29). Bivariate analysis identified only patients requiring additional mediastinal procedures to be at higher risk of SSI (unadjusted odds ratio 8.3, P=0.001). Due to low incidence of surgical site infection, multivariate analysis was not able to be conducted.

Conclusion: In this challenging cohort, the incidence of surgical site infection was much higher than in patients not requiring delayed sternal closure. We identified patients necessitating additional mediastinal procedures to be at highest risk of SSI. Further study is needed in order to identify strategies that can reduce surgical site infections in this population.

Submission Type: Descriptive Report

Session-Board Number: 5a-237

Poster Title: Implementation of electronic prescription label printers during a medical brigade serving remote Ecuadorian villages

Primary Author: Eric Kapuscinski, D'Youville College School of Pharmacy, New York; **Email:** kapuse02@dyc.edu

Additional Author (s):
Kirsten Butterfoss
Michelle Lewis
Amy Wojciechowski

Purpose: Operating medical brigades in remote areas pose unique challenges for healthcare professionals. Limited resources call for the adaptation of available technology to ensure efficient workflow among all providers. The need for an alternative to hand-written prescription labels was identified during prior medical brigades, based on the length of time required to write the label and the risk of transcription errors. This project was designed to show how a standard label printer and accompanying software could be implemented in a remote, resource-limited setting for the design of individualized prescription labels parallel to those used in modern pharmacies.

Methods: Through a partnership with Timmy Global Health, pharmacists, pharmacy students, and various healthcare providers traveled to several villages in Chontapunta, a remote area in the Amazon region of Ecuador to set up and operate temporary public health clinics. Patients from each village registered to participate in clinics by providing basic demographic information and chief complaints, which were recorded using previously designed electronic medical record (EMR) software. Recorded information was made available to all clinicians via a local area connection linking all in-network devices. Patients progressed through each station; registration, triage, labs, examination and then proceeded to the pharmacy station to receive medications based on their diagnoses. Orders submitted by the providers per patient EMR were made available for pharmacy processing after examination. Pharmacy students filled orders using patient EMRs to type into a label template with areas designated for; patient name, EMR number, drug name, dose, directions, quantity and drug expiration date. Adhesive labels were printed and affixed to the appropriate order and verified by the pharmacists.

Results: Over a five-day period, 455 patients were seen in five separate villages. The pharmacists observing pharmacy operation workflow noted significant increases in productivity and efficiency relative to previous brigades that utilized hand-written labels. Label printer implementation reduced the time each order spent in production and verification leading to expedited dispensing to patients, increasing overall clinic efficiency. The potential for transcription errors was also reduced due to the ability to copy and paste patient names from the EMR directly into the label software program for printing. Feedback received from patients during the project suggested that the aesthetic appeal and navigability of the prescriptions dispensed using the prescription label printers improved overall patient satisfaction.

Conclusion: Implementation of electronic label printers in a remote pharmacy practice setting improved pharmacy workflow, increased overall clinic efficiency, and improved patient satisfaction. Future efforts should focus on implementing additional pharmacy resources into medical brigades and evaluating the outcomes of technology implementation in regard to clinic efficiency, patient perceptions, and outcomes of therapy.

Poster Title: Data-driven strategies for automated dispensing cabinet (ADC) optimization: Examples from Massachusetts General Hospital

Primary Author: Alexander Miller, Northeastern University School of Pharmacy, Massachusetts; **Email:** xand.miller@gmail.com

Additional Author (s):
Michelle McCrea

Purpose: Massachusetts General Hospital (MGH) is a 999 bed teaching hospital with 46 inpatient units. Medications in the 118 automated dispensing cabinets (ADCs) on these units are financially "on consignment" when stocked. This creates a financial exposure for the pharmacy that was identified as an area for potential cost avoidance, as medications stored on the unit are more likely to expire unused. At the initiation of this project in October 2015, the total valuation of all medications stored in ADCs was estimated at $1,331,195.42, with some individual cabinets routinely stocking more than $40,000 in medications.

Methods: An ADC inventory report was built in the central automation server and set up to generate overnight once weekly. This report exported to a spreadsheet, and an item-by-item valuation was calculated using average wholesale cost data supplied by the purchasing division. These data were then cleaned and analysed by the authors, enabling the identification of high-valuation items. Further vendor supplied and custom built reports were used to gather item usage data, allowing for analysis of transaction histories and item use as a function of par levels. Based on this information, the authors then targeted items for removal or par level adjustment.
Unused items were considered for complete removal from the ADCs if the items in question were able to be cost-effectively dispensed from the central pharmacy. If the items were used infrequently, usage reports were employed to determine the maximum historical use in a single day, and par levels were reduced accordingly. Emergency medications, such as alteplase and anaphylaxis kits were never removed entirely from the ADCs, however, the par levels were reduced on several floors where usage history and clinical judgement allowed. Dispensing data was used to evaluate pick volumes from central pharmacy to ensure technician workload was not being increased, and that patient-specific unit dose volume was not increasing significantly.

Results: Over ten months, the total valuation of billable cabinets in the hospital was reduced by approximately 35%, or $458,144, with the most recent two months of valuation data having a standard deviation of $6,472.95 (0.4%). Throughout this reduction in ADC inventories, there was no appreciable change in technician or central pharmacist workloads, and no notable instances of medication removal from the units impacting patient care. Some challenges faced during this project resulted from MGH transitioning to a new electronic health record system, during which staff availability was extremely limited. As part of this transition, reporting data was generated by different systems, but without any notable change in inventory data.

Conclusion: Data-driven inventory optimization represents an underutilized area of potential cost avoidance with relatively easy implementation in many hospitals. The methods described here could be easily implemented in any ADC equipped hospital. During the first four months of this project, an average of 2-6 intern/technician hours and 1-2 pharmacist hours per month were spent exclusively on this project. The last six months of data reported involved no more than 2 intern/technician hours weekly, and less than 0.5 pharmacist hours per week, showing a sustained decrease in inventory carrying costs with limited long-term time commitments.

Submission Category: Infectious Diseases

Session-Board Number: 5a-239

Poster Title: Evaluating antimicrobial prescribing and clinical outcomes associated with carbapenem-resistant and carbapenem-susceptible Acinetobacter baumannii at an academic hospital.

Primary Author: Nilomi Shah, Loma Linda University School of Pharmacy, California; **Email:** nishah@llu.edu

Additional Author (s):
Anna Arocho
Mi-Hye Rhee
Sabrina Co
Lee Nguyen

Purpose: Acinetobacter baumannii is a multi-drug resistant bacteria, which most frequently causes nosocomial infections. It has resistance to at least three different classes of antimicrobials, and as a result has become a challenging organism for appropriate antimicrobial therapy. The therapeutic options to treat A. baumannii infections are scarce and are associated with clinical limitations. This study was designed to evaluate which antibiotics are commonly employed to treat A. baumannii and the resulting clinical impact based on bacterial resistance or susceptibility to carbapenems.

Methods: The institutional review board approved this retrospective study. The study included all hospitalized patients between the ages of 18-89 years old with a positive culture for multidrug resistant (MDR)-carbapenem-resistant (CR)/carbapenem-susceptible (CS) Acinetobacter baumannii who required antimicrobial therapy. The data collection period was from January 1, 2013 to December 31, 2015. Multidrug resistant is defined as an acquired non-susceptibility to at least one agent in three or more antimicrobial categories. Patients were excluded from the study if they did not have a MDR A. baumannii, did not receive antibiotics as treatment, or were younger than 18 years or older than 89 years of age at the time of culturing. Therapy response was categorized by complete response, partial response, and non-response. Non-response included failure, relapse, and death. Time to achieve clinical stability was defined as return of altered mental status and abnormal vital signs to normal baseline values (heart rate ≤100 beats/min, systolic blood pressure ≥90 mm Hg, respiratory rate ≤24/min, oxygen

saturation ≥90% and temperature ≤37.28C). The primary outcomes of this study were evaluating empiric antimicrobial therapy and clinical success associated with MDR-CR and MDR-CS A. baumannii. Secondary outcomes of this study included length of hospitalization, 30-day all-cause hospital mortality, and time to clinical stability.

Results: One hundred and eleven patients were included in the study. The average age of the patients was 58.7±18.7 years. The majority of the bacterial isolates were recovered from the ICU (n=64, 58%). The sources of infection included urine (n=16, 14%), blood (n=4, 3.6%), wound (n=28, 25%), respiratory (n=56, 50%), bone (n=3, 2.7%), and other (n=4, 3.6%). The most common empiric antibiotic was a beta-lactamase inhibitor combination (n=47, 42%) and followed by a cephalosporin (n=17, 15%) or fluoroquinolone (n=17, 15%). The piperacillin-tazobactam was the most commonly prescribed directed therapy in both groups (CS: 28% & CR: 20%), but the ampicillin-sulbactam was utilized more frequently in the CR (9.3%) group than the CS group (4%). The 111 subjects were divided into CS (n=25, 23%) and CR (n=86, 87%). Clinical response (complete+partial) were similar between the groups, CS (72%) & CR (75%), p=0.76. All-cause mortality was similar between the groups, CS (28%) & CR (19%), p=0.31. Total length of hospitalization (days, median [IQR]) was shorter in the CS (11, [4-23]) than the CR (15, [9-35.5]) group, p=0.046. The time to clinical stability (days, median [IQR]) was shorter in the CS (3.5 [2-7.75]) vs CR (5 [2-16]), but did not reach statistical significance (p=0.11).

Conclusion: Beta-lactamase inhibitor combinations are an integral part of the antimicrobial armamentarium against MDR Acinetobacter baumannii. Drug resistance can limit therapeutic options and may play a role in prolonging hospitalization. At our institution, the majority of MDR Acinetobacter baumannii were carbapenem resistant. The significance of drug resistance must be examined further to better develop an understanding of its impact on patient care.

Poster Title: Incidence and relationship of kidney injury and proteinuria in patients receiving an infusion of bevacizumab: a retrospective observational study

Primary Author: Kristyn Sanders, Midwestern University-College of Pharmacy Glendale, Arizona; **Email:** kristyn.sanders@outlook.com

Additional Author (s):
Jacob Frick

Purpose: Bevacizumab is a vascular endothelial growth factor inhibitor most frequently used as first line therapy for metastatic colorectal cancer. Proteinuria is a common adverse reaction in patients receiving bevacizumab and it is recommended that patients undergo serial urinalysis during therapy. Current literature on the relationship between kidney injury and proteinuria in patients receiving bevacizumab is limited and mainly consists of single patient case reports. In this study, we set out to determine the relationship between kidney injury and proteinuria in patients receiving bevacizumab at an outpatient oncology clinic.

Methods: A computerized database identified the first 50 patients that received bevacizumab between January 1, 2012 and March 31, 2016. Patients were included if they were greater than 18 years of age and received bevacizumab in the predetermined time frame. Patients were excluded if proteinuria occurred greater than 60 days after receiving bevacizumab therapy or if patients were still receiving bevacizumab after the study period end date. In addition to baseline demographics, max serum creatinine, serum creatinine associated with proteinuria, serum creatinine that met the risk, injury, failure, loss, or end stage renal disease (RIFLE) criteria for acute kidney injury (AKI), grade of proteinuria, and dose of bevacizumab received prior to proteinuria were recorded. The primary outcome was occurrence of kidney injury within 60 days of receiving a bevacizumab infusion according to RIFLE criteria. Secondary outcomes included median serum creatinine in proteinuria patients, median dose given to patients prior to proteinuria, average grade of proteinuria, and number of patients with grade 2 or higher proteinuria that received a 24 hour urine collection.

Results: Data was collected on 50 patients, 23 patients met inclusion criteria for analysis. Of the patients with proteinuria 11 were male, 12 female, with a median age of 68. Out of 23 patients, there was a total of 57 occurrences of proteinuria, and 53 recorded serum creatinine values. There were a total of 5 grade 2 or higher proteinuria occurrences. Median serum creatinine in patients with proteinuria was 0.805 milligrams per deciliter and the total patients that met RIFLE criteria for AKI was 1. A linear regression was obtained for both proteinuria occurrence in relation to bevacizumab dose and serum creatinine in relation to proteinuria levels. The coefficient of determination for proteinuria in relation to bevacizumab dose was 0.0191. The coefficient of determination for serum creatinine in relation to proteinuria was 0.0091.

Conclusion: This study demonstrated that there was no relationship between kidney injury and proteinuria in patients receiving bevacizumab based off of a commonly used criteria for measuring kidney injury. There was also no significant relationship between bevacizumab dose and proteinuria occurrence or grade, and no relationship between serum creatinine values and proteinuria occurrence or grade. Based on these results, future studies may be required to determine the necessity of serial urinalysis on patients receiving bevacizumab infusions. The most significant limitations to this study was the small sample size and the utilization of only one criteria for measuring kidney injury.

Poster Title: Effect of a vancomycin management program on the number of days of vancomycin therapy before and after implementation

Primary Author: Abigail Trezise, St. John Fisher College Wegmans School of Pharmacy, New York; **Email:** alt04775@sjfc.edu

Additional Author (s):
Deidre Pierce

Purpose: The purpose of this study was to evaluate the effectiveness of a vancomycin management program (VMP) in reducing the number of days of inappropriate therapy with intravenous vancomycin.

Methods: The VMP was implemented in March through December of 2015. A formalized vancomycin management policy was created, which included dosing and monitoring guidelines, improvements in communication between pharmacists and medical providers, competencies for pharmacists, Methicillin Resistant Staphylococcus Aureus Polymerase Chain Reaction nasal screen implementation to facilitate vancomycin de-escalation in pneumonia and bacteremia patients. To measure the impact of the VMP on vancomycin usage, a report was generated for all patients that received vancomycin in the months of February through April in 2014 and 2016. A medication use evaluation was performed to compare days of therapy before and after the VMP was implemented. Patients were included if they received greater than one dose of vancomycin, had a diagnosis of bacteremia, pneumonia, or other respiratory infection. Exclusion criteria included use of vancomycin for surgical prophylaxis, urinary tract infection, cellulitis, obstetrics/gynecology, hospice/comfort care, dialysis, or cancer patients. Also measured, were the number of patients who needed to restart vancomycin based on a positive culture after discontinuation.

Results: The median number of days of vancomycin therapy in the 2014 group were 3.0 days (n=28) and in the 2016 group were 2.5 days (n=27). No patients needed to be restarted on vancomycin due to positive cultures.

Conclusion: Results of the VMP showed a decrease in median number of days of vancomycin therapy.

Poster Title: Retrospective review of proton pump inhibitor use in cystic fibrosis patients initiating lumacaftor-ivacaftor (Orkambi) treatment

Primary Author: Kiersten Roth, The Ohio State University, Ohio; **Email:** kierstenroth@yahoo.com

Additional Author (s):
Kimberly Novak

Purpose: Proton pump inhibitors (PPIs) are often used in patients with cystic fibrosis to assist with gastroesophogeal reflux disease (GERD) symptoms or improve pancreatic enzyme therapy efficacy. Upon FDA approval in 2015, many patients have been initiated on lumacaftor-ivacaftor therapy for cystic fibrosis (CF) treatment. Lumacaftor is a cytochrome P450 enzyme inducer and may decrease serum concentrations ofPPIs, leading patients to experience breakthrough GERD symptoms or malnutrition due to inefficient absorption of nutrients. The purpose of this study was to analyze local practice in PPI dosing with concomitant lumacaftor-ivacaftor use in an effort to determine a more standardized PPI dosing regimen.

Methods: The institutional review board approved this retrospective chart review. Patients 12 years of age and older who were prescribed lumacaftor-ivacaftor and a concomitant PPI between July 2, 2015 and July 26, 2016 were enrolled in the study. Patients younger than 12 years of age, patients not taking a PPI at the start of lumacaftor-ivacaftor initiation, patients who started lumacaftor-ivacaftor prior to FDA approval, and patients who discontinued lumacaftor-ivacaftor therapy within 30 days were excluded from the study. Electronic medical records were reviewed for those patients meeting inclusion criteria to collect data related to patient demographics, PPI demographics, adjunctive acid suppressants used, and reported efficacy and adverse effects. The primary objective was to determine the impact of lumacaftor-ivacaftor on the efficacy of PPIs. Secondary objectives were to quantify the need for adjunctive acid suppression, to describe complications of concurrent use, and to quantify the need for higher doses of PPIs after lumacaftor-ivacaftor initiation. Data were evaluated using descriptive statistics.

Results: Of the 60 patients who met the inclusion criteria, the CF clinical pharmacist recommended to adjust PPI dosage based off of patient symptoms in 54 (90%) of the patients, whereas empiric adjustment was recommended in 6 (10%) of the patients. Of the symptom-based recommendations, 39 (65%) of the patients did not need any PPI therapy adjustments, while 15 (25%) of the patients adjusted PPI dose due to breakthrough symptoms. Of the empiric dose adjustment recommendations, 2 (33.3%) of the patients did not make any adjustment, 1 (16.67%) of the patients made an adjustment based off of breakthrough symptoms, and 3 (50%) of the patients followed the empiric recommendation. Out of both groups of patients, 41 (68.33%) of the patients were well controlled on their starting PPI dose and only 16 (26.67%) of the patients required an adjustment. The other 3 (5%) of patients were well controlled on their empiric adjustments. The most common side effects experienced were reflux/heartburn (33.3%), abdominal pain (31.67%), and loose or oily stools (28.3%). 17 (28.3%) of the patients required additional therapy to assist with side effect management. The most common recommendations for adjunctive therapy were polyethylene glycol (52.9%), calcium carbonate (23.5%), and ranitidine (17.6%).

Conclusion: The addition of lumacaftor-ivacaftor treatment to cystic fibrosis patients already receiving PPI therapy led some patients to require a PPI dose adjustment. However, the majority of the patients did not require any adjustments. In order to maintain patients on the lowest effective PPI therapy, dose adjustments should be performed on an as-needed basis when patients experience breakthrough symptoms.

Submission Type: Evaluative Study

Session-Board Number: 5a-243

Poster Title: Study of Penicillin Tolerance in Streptococci

Primary Author: Anh Duong, Touro College of Pharmacy, New York; **Email:** aduong2@student.touro.edu

Additional Author (s):
Mir MahMood
Jennifer Tsan
Thu Nguyen

Purpose: Group B streptococcus are opportunistic and gram positive bacteria. They are usually found in both digestive and reproductive tracts. Group B streptococcus can cause serious infection in neonatal, maternal, and immunocompromised adults. Penicillin G has been used as a choice of therapy for these infections; however, there are numerous reports demonstrated of failed treatments. Penicillin tolerance is one of the reasons for ineffective therapeutic treatment in some patients with Group B streptococcus infection. The purpose of this study is to measure penicillin tolerance in 2 lab strains of Streptococcus and characterize them as susceptible or tolerant to penicillin G.

Methods: In this study, we examined two different Group B streptococcus strains, Streptoccus. agalatiae strains A909 and O90R by examining their tolerance levels to the Penicillin G regimen as they are usually exposed to in vitro therapy. MBC: MIC ratio and cell lysis assay via optical density measurements and colony counts were used to classify either strain as a penicillin tolerant or susceptible strain.
Tolerance using the MIC: Group B streptococcus strains A909 and O90R were exposed to different Penicillin G tolerance and performed colony count to determine the lowest 90% killing of antibiotic concentration from original inoculums (MIC90).
Measuring Penicillin induced lysis: Penicillin induced lysis was conducted to observe the cell cultures response to 100xMIC90 Penicillin G using OD600

Results: After 24 hours of penicillin exposure, Group B streptococcus A909 strains demonstrated more of a rapid decline in survival rate compared to 09OR strains. There were greater incidences of bacterial growth after 48 and 72 hours of penicillin exposure seen in 09OR than A909. Higher OD600 were obtained from O90R than A909 after "22 hours" of penicillin treatment indicating that O90R tolerant strains are subjected to less cell lysis than A909 susceptible strain.

Conclusion: Group B streptococcus A909 showed decreased colony counts at low penicillin G concentration levels while these same doses did not whittle down Group B streptococcus O90R counts, but needed higher penicillin G concentrations to achieve the same effect. Based on the MBC: MIC ratio and the lysis observed, we determined that Group B streptococcus O90R is a Penicillin G tolerant strain while Group B streptococcus A909 can be classified as a penicillin G susceptible strain.

Poster Title: Provider adherence to guideline recommended prescription of beta blockers for patients with reduced ejection fraction heart failure

Primary Author: Abby Hendricks, University of North Carolina Eshelman School of Pharmacy, North Carolina; **Email:** abby_hendricks@unc.edu

Additional Author (s):
Kenny Kang
Timothy Ives
Betsy Bryant Shilliday
Jamie Cavanaugh

Purpose: The 2013 ACCF/AHA guidelines recommend beta blockers (BB) as first line agents for patients with structural heart disease. The 2016 QUALIFY Trial revealed that BB are commonly under-utilized and under-dosed in outpatient adults with heart failure. Beta blockers were prescribed for over 80% of patients in QUALIFY but less than 15% of those on BB therapy were at recommended target dose. This study assessed prescriber adherence to guideline recommendations for BB prescription in patients with reduced ejection fraction (≤40%) heart failure (HFrEF) in an academic-based internal medicine clinic.

Methods: The Institutional Review Board approved this study. This is a descriptive, retrospective observational study of outpatients from a single academic based internal medicine clinic at the University of North Carolina Medical Center. Patients included in the data analysis were ≥ 18 years of age with a diagnosis of HFrEF and a documented visit in the University of North Carolina Internal Medicine Clinic between January 2015 - July 2016. Patients enrolled in hospice, receiving palliative care, or who were pregnant during the study period were excluded. The primary endpoint of this study was a composite of the following: 1) Proportion of patients prescribed to target doses of guideline recommended beta blockers and 2) Proportion of patients not prescribed to target doses of a guideline recommended agent due to contraindication to initiation or titration of a beta blocker. Secondary measures looked at the general prescribing patterns of all BB therapies and contraindications to initiation or titration of these agents. Contraindications assessed in the analysis were co-morbidities, intolerable side effects, bradycardia, and hypotension. Patient demographics, total number of clinic visits in the

preceding 12 months, current BB prescription (including specific agent and dose), and potential BB clinical contraindications were collected and assessed from the electronic health record. Data were analyzed using descriptive statistics including counts, proportions, means, and interquartile ranges.

Results: 157 patients were included with a mean age of 63 years, a mean ejection fraction of 29.7%, and an average of 3.9 visits to the internal medicine clinic in the preceding 12 months. 60 patients (38.2%) patients were prescribed guideline recommended BB therapy or had a clinical characteristic limiting treatment with BB agents, and thus met the definition for the primary endpoint. Of these 60 patients, 12 patients (7.6%) were prescribed target dose, guideline recommended BB therapy. The other 48 patients (30.6%) met the criteria for contraindication to beta blocker therapy initiation or titration, and therefore were included in the primary outcome, due to one of the following: diagnosis of COPD, 2nd/3rd degree heart block, HR < 55, and SBP ≤ 80mmHg. 134 (85.3%) patients were on any BB therapy, with 115 (73.2%) patients prescribed any dose of a guideline recommended BB.

Conclusion: This study demonstrates low prescriber adherence to guideline-recommended beta blocker therapy with just 38.2% of patients meeting the definition for the primary study endpoint. Moreover, the majority of patients were included in the primary measure due to one or more contraindications to BB therapy. These findings reflect the outcomes of previous trials and suggest an opportunity for improvement of both guideline recommended BB prescription and BB dose titration for patients with HFrEF in this clinic.

Submission Type: Descriptive Report

Session-Board Number: 5a-245

Poster Title: Implementation of Interprofessional Experiential Education between Pharmacy and Nursing Students

Primary Author: Katherine Bergado, Pacific University, Oregon; **Email:** berg9811@pacificu.edu

Additional Author (s):
Inva Begolli
Khloth Lim
Nataliya Greene
Samantha Stockmann

Purpose: The purpose of this experience between pharmacy and nursing students was to explore the foundational knowledge of interprofessional teamwork while on Advanced Pharmacy Practice Experiences (APPEs) and nursing clinical rotations. While gaining knowledge about their different health professions, students collaborated during morning medication passes, patient presentations, and nursing topic discussions to better understand the healthcare field as a whole and overall impact of a more integrated interprofessional collaboration providing better patient care.

Methods: The interprofessional education experiences took place at Providence Portland Medical Center (PPMC) and Providence St. Vincent Medical Center (PSV), two large tertiary teaching hospitals located in Portland, Oregon. Three Pacific University APPE students and six University of Portland advanced clinical nursing students participated at PPMC while three APPE students and ten clinical nursing students were at PSV, making it a total of six pharmacy students and sixteen nursing students. The student groups included one pharmacy student per two nursing students in PPMC, and one pharmacy student per about three nursing students in PSV.
The student groups at PPMC were assigned two medication pass activities, followed by three interdisciplinary patient presentations, and two nursing topic discussions. For the student groups in PSV, each pharmacy student was assigned a patient and, based on the obtained information from medication pass experience and data in the electronic medical record, three patient presentations were delivered by pharmacy students and three presentations were

delivered by nursing students from their perspective and experience. A faculty member from each program oversaw all activities, presentations, and discussions.

Results: Two interdisciplinary sessions, each of which were a total of four hours, were held one week apart. Each session consisted of a medication pass activity on Tuesday morning (two hours), followed by patient presentations and topic discussions on the following Wednesday afternoon (two hours).

The medication pass activity was led by nursing students. Pharmacy students observed the workflows of removing patient medications from Pyxis, drawing up medications in syringes (such as insulin), manually crushing medications, entering medications into the patient's medication administration record (MAR), and observing the challenges nurses face with administering medications.

The presentation involved each profession first clinically reviewing a predetermined patient and then discussing the case to the group. This activity allowed each profession to see how different healthcare providers studied and dissected a patient profile under a different professional lens. Each session concluded with Q&A between nursing and pharmacy to recognize each other's roles in the healthcare field and/or topic discussions (such as in health literacy). During these sessions, it became apparent that while many concepts and routines between nursing and pharmacy are unfamiliar to the other profession, the challenges that occur during both medication distribution and administration are very relevant for all.

Conclusion: Although different professions approach patient cases in different ways, the common purpose is to provide the best and most efficient care for patients. With healthcare shifting to an interdisciplinary approach, it is important to understand the fundamentals of other healthcare professions and how to effectively collaborate. Through this interprofessional experiential education, we have expanded our understanding of the importance of interdisciplinary communication and teamwork and its importance in providing exceptional patient-centered care. In the future, it is essential to continue to expand this interprofessional experience for pharmacy and nursing students to understand each other's approaches to care and challenges therein.

Poster Title: Effectiveness and safety of indomethacin for decreasing chest tube duration after coronary artery bypass graft surgery

Primary Author: Brenton Hall, University of North Texas System College of Pharmacy, Texas;
Email: brenton.hall@my.unthsc.edu

Additional Author (s):
Caitlin Gibson
Meredith Howard

Purpose: Early removal of chest tubes in coronary artery bypass graft (CABG) patients is a factor that positively affects length of hospital stay. Indomethacin is sometimes used in one community hospital to reduce chest tube output via reduction in inflammation in an attempt to shorten chest tube duration. Nonsteroidal anti-inflammatory drugs, including indomethacin, are contraindicated in the setting of CABG due to a boxed warning regarding increased risk of cardiovascular thrombotic events. The aim of this study was to determine if the use of indomethacin in CABG patients is safe and effective in shortening the duration of chest tube placement.

Methods: This was a retrospective chart review of patients in a 348 bed community hospital receiving indomethacin therapy after CABG surgery. The records of all adult patients receiving CABG surgery between 2010 and 2015 were systematically screened for receipt of at least one dose of indomethacin while chest tubes remained inserted. Charts with admit diagnoses of cardiac arrest or stroke were omitted from review. Identified subjects were individually matched based on demographics, medical history, and concomitant cardiac surgeries. Data collected included patient comorbidities, daily chest tube output, duration of chest tube placement, and concomitant medications. The primary outcome measure was change in time from first dose of indomethacin until removal of chest tubes compared with duration of insertion of chest tubes in control patients. The secondary outcome measure was total duration of chest tube insertion. Safety endpoints included occurrence of thrombotic events, TIMI bleeding in the setting of CABG, or death. Descriptive statistics were utilized. This study was approved by the institutional review board.

Results: Sixteen patients received indomethacin and were eligible for inclusion. They were matched 1:1 to 16 patients not receiving indomethacin. Two of the patients in the indomethacin group received heart valve replacement at time of CABG and were able to be matched only on sex and type of valve replaced. The median age was 55 years in the indomethacin group and 56 years in the control group. Twenty-four subjects were male. Indomethacin was associated with a shorter duration of chest tube insertion when comparing time from first dose of indomethacin to chest tube discontinuation with duration of insertion in control. The median decrease in duration of chest tube insertion in the indomethacin group was 14.5 hours. The median total duration of chest tube insertion in indomethacin and control patients was 214.3 and 91.2 hours, respectively. No patients experienced thrombotic events, bleeding, or death during admission.

Conclusion: Indomethacin decreased chest tube insertion times, however the clinical impact of this reduction is uncertain. Although it has shown to be safe in this cohort study, more studies are needed to determine if indomethacin has a place in the setting of CABG surgery.

Poster Title: Know Your Numbers: Implementation of a Community Health App

Primary Author: Vi Nguyen, Mercer University College of Pharmacy, Georgia; **Email:** elizabeth.v.nguyen@live.mercer.edu

Additional Author (s):
Michelle Vu
Soumya Vishwanath
Courtney Wolfe
Sweta Patel

Purpose: Mobile health applications (apps) are growing in popularity as health promotion tools that encourage user self-management of chronic conditions. A free mobile health app, Know Your Numbers (KYN), was developed to assist community members to track their health numbers. Know Your Numbers programs aim to increase public awareness of health numbers, such as blood pressure, glucose, and cholesterol values. Student pharmacists have the capability to bridge technology with healthcare by incorporating KYN into patient-care events. The study objectives were to analyze frequency of app usage and perceptions of community members towards health numbers, pharmacists, and health apps.

Methods: Health numbers were defined as blood pressure, glucose, and cholesterol readings. The KYN app's features included health number logs, a patient advocacy survey, disease-state information, and upcoming health fair event notifications.
The target population for app users was underserved communities within Atlanta, Georgia. Student pharmacists recruited study participants through community clinic and health fair events. Community members 18 years or older with any Android device of versions 5.1 or lower were eligible for study enrollment. App usage, defined as a user logging health numbers, checking upcoming events, or answering a questionnaire about their health numbers and attitudes towards pharmacists was tracked for 56 days, then the post-survey was administered. This study utilized a pre- and post-survey study design to compare perceptions before and after use of the KYN app, utilizing a 4-point Likert scale, with 1 being "strongly agree" to 4 being "strongly disagree". Eligible participants completed a 22-item pre-survey, divided into five domains that assessed user demographics (5), medical history and insurance status (3),

understanding of health numbers (5), health app usage/non-usage and perception (5), and perceptions of the pharmacy profession (2). Both surveys were incentivized with gift-card raffles. Data was analyzed using SAS 9.3 using descriptive statistics and paired t-tests for matched pre- and post-surveys. This study was approved by the Mercer University Institutional Review Board.

Results: Thirty-three community members were enrolled into the pilot study. The average age was 53.8 plus or minus 11.5 years old. The majority of participants were African-American (93.9 percent) and earned less than 50,000 US dollars in household income annually (56.7 percent). Thirty-three percent of the participants had two or more comorbidities, and 34 percent did not have a primary care physician. Only 6.06 percent of users reported having previously used a mobile health app. On average, participants had 3.98 interactions per week with the app. Before using the app, 84.8 percent of users had felt comfortable using a health app; however, only 9.0 percent used one regularly. After the app pilot study, 100 percent of users felt comfortable using a health app, and 88.9 percent used one regularly (p=0.44, p=0.0001). There was a statistically significant increase in the number of users who strongly agreed or agreed that a health app had helped them to meet their health goals (24.4 percent to 100 percent, p=0.0006). More than 90 percent of participants agreed in both the pre- and post-survey that it is important to check their health numbers regularly and that they trust their pharmacist. The post-survey response rate was 27.2 percent.

Conclusion: The KYN app pilot study introduced an underserved community to the value of mobile health apps. These findings support the benefits of the KYN health app in its usability and in helping users meet health goals and regularly self-testing. Further development of the beta version in areas of expanding operational system compatibility and improved aesthetics is warranted. Also, a longer study period would address the sustainability of app use. Know Your Numbers is an emerging technological tool that promotes chronic disease self-management and the representation of the pharmacy profession.

Poster Title: Incorporating a student co-director position as an interprofessional education experience to assist with integration of behavioral health services into an interprofessional team-based primary care clinic

Primary Author: Katie Rau, University of Kansas School of Pharmacy, Kansas; **Email:** katierau30@yahoo.com

Additional Author (s):
Sarah Shrader
Jana Zaudke
Anna Cleland-Leighton

Purpose: Interprofessional (IP) team-based health care is an important delivery model to improve healthcare quality. Offering students authentic interprofessional education (IPE) experiences in practice-based settings is important to train future healthcare professionals. In IPE and team-based healthcare, it is important to integrate behavioral health. While current data shows 20-40% of primary care patients have behavioral health needs, no information exists about using IPE to integrate behavioral health services into primary care. This study evaluated the role of initiating student co-director positions into a primary care practice model, called the Interprofessional Teaching Clinic (IPTC), and improvements in depression screening and patient outcomes.

Methods: Four interprofessional students, including medical, pharmacy, occupational therapy, and doctoral clinical psychology, were selected for an extracurricular IPE experience as the IPTC student co-directors from May 2015-2016. The role of the student co-directors in this study was to guide and assist IP clinical rotation students with completion and documentation of depression screenings for patients receiving primary care in the IPTC. Student co-directors were available in clinic daily to provide assistance to IP students by guiding a huddle at the start of clinic and serving as a resource for maximum utilization of behavioral-health consultation and services. From January 1, 2015 through June 30, 2015, 493 patients were seen in the IPTC and provided outcomes for the baseline to six-month comparisons. A subset of 311 out of these 493 participants were seen again between July 1, 2015 and December 31, 2015, and provided outcomes for the six-month to twelve-month comparisons. Participants were screened annually

for depression with a verbal administration of the Patient Health Questionnaire (PHQ) 2 and 9, documented in the electronic health record (EHR). A PHQ 2 score over 3 triggered administration of the PHQ 9 and consultation with clinical psychology students and preceptors. A positive PHQ9 triggered follow up and, when appropriate, a mood disorder diagnosis was documented in the EHR. A retrospective analysis was conducted and SAS software was used for statistical analysis.

Results: The mean age of patients in this cohort was 45.6 years old, the majority being female (75.7%) and private insurance holders (51.7%). Self-pay patients and Medicare and Medicaid holders were also represented. At baseline, the annual PHQ screening rate was 9.13% with a prevalence of depression at 22.5%. The baseline to six-month comparisons showed an increased depression screening rate with PHQ of 39.41% (+30.6%, $p < 0.0001$) and an increased prevalence of depression at 26.37% (+3.87%, $p < 0.0001$). The six-month to twelve-month comparisons showed a further increase of PHQ screening rate of 74.28% (+25.73%, $p < 0.0001$) and a further increase in prevalence of depression of 31.51% (+5.14%, p=0.1797). Overall, an increase of 56.33% from baseline was observed for patients who were screened annually for depression, and an overall increase of 9.01% was observed for depression prevalence within the IPTC.

Conclusion: The purpose of screening for depression annually in primary care settings is to provide appropriate treatment for otherwise undiagnosed depression. With the addition of the role of student co-directors within IPTC, the outcomes from integrating behavioral health within IPTC increased significantly within twelve months. This enhancement of behavioral health integration not only provided student co-directors with an opportunity to see the importance of psychology within an IP team-based primary care setting but also significantly improved the overall care of patients within this clinic.

Poster Title: Evaluation of analgesia and sedation management in patients admitted to the neuroscience intensive care unit requiring prolonged mechanical ventilation

Primary Author: Stephanie Colucci, Massachusetts College of Pharmacy and Health Sciences University, Massachusetts; **Email:** sacolucci@partners.org

Additional Author (s):
Megan Barra
Lindsay Urben
Patricia Krause

Purpose: Current guidelines for the management of pain, agitation, and delirium in adult patients in the intensive care unit (ICU) recommend an analgesia-first approach to sedation management. Implementation of sedation protocols has been associated with favorable clinical outcomes such as decreased duration of mechanical ventilation and decreased ICU length of stay. However, this recommendation derives from studies in surgical and medical ICU populations, making it difficult to extrapolate to patients with primary neurological illnesses. The purpose of this study is to evaluate current analgesia and sedation practices in a neuroscience ICU population, identify patterns in care, and determine areas for improvement.

Methods: We performed a retrospective analysis of patients 18 years of age or older admitted to the neuroscience and neurosurgical ICU with primary neurological illnesses. Brigham and Women's Hospital's electronic medical record system was utilized to identify patients from December 2015 to August 2016. We included patients who were mechanically ventilated for a minimum of 48 hours. We excluded patients whose primary care team was a hospital service other than neurology or neurosurgery. Outcome measures included provider choice of continuous sedation and analgesic agents and total doses of sedatives and analgesics administered while the patient was mechanically ventilated. Frequency and magnitude of pain during mechanical ventilation was assessed using the critical care pain observation tool (CPOT), depth of sedation was assessed using the richmond agitation-sedation scale (RASS), and development of ICU-delirium using the confusion assessment method for the ICU (CAM-ICU). Additional outcomes measured were duration of mechanical ventilation, incidence of re-

intubation, percentage of patients requiring a tracheostomy, patient ICU length of stay, hospital length of stay, and in-hospital mortality.

Results: 134 patients were included with a mean age of 59.4 years old. In total, 67.9% of patients were admitted to Neurology service and 32.1% to Neurosurgery. Propofol was utilized in 100% of patients, with midazolam administered concurrently in 14.2% of patients. The mean propofol dose was 18,188 mg over a mean of 5.4 days. The mean dose of midazolam was 623 mg over a mean of 3.4 days. The mean hospital length of stay was 16.7 days and mean ICU length of stay 11.8 days. Patients were mechanically ventilated for a mean of 6.7 days. Approximately 21.6% of patients required reintubation, 22.4% of patients required a tracheostomy and in-hospital mortality rate was 25.4%. On average, 29.1 + 19.4 RASS scores were collected per patient while intubated, with a median RASS score of – 2 (IQR -3.3 to -1.2) . An average of 2.4 CPOT scores were documented per day of mechanical ventilation per patient, with 71.1% of CPOT scores being 0 while 17% were > 2. In total, 94% of patients exhibited severe pain at least once while intubated. Thirty three patients (24.6%) were documented to have a positive CAM-ICU at any point during the period of mechanical ventilation.

Conclusion: We found in the neuroscience patient population at our institution, the primary sedative utilized was propofol and primary continuous analgesic agent administered was fentanyl. Most patients had light-moderate sedation during mechanical ventilation. Approximately 17% of CPOT scores documented indicated that the patient was in severe pain. Delirium was prevalent in our patient population as well. Future quality improvement initiatives should focus on the use of analago-sedation for mechanically ventilated patients who suffer from a primary neurological illness to optimize patient outcomes.

Poster Title: Feasibility of point-of-view camera use to quantify workload in a sterile compounding hospital setting

Primary Author: Nathan Faes, Skaggs School of Pharmacy University of Colorado, CO; **Email:** nathan.sfaes@gmail.com

Additional Author (s):
Magdalena Dankowska

Purpose: The Denver-metro area has seen a 7.5% population growth rate since 2010. As the primary Children's Hospital in the area, we have seen increased patient demands and a 2-fold increase in medication dispenses, as a result. To adequately match this increased workload, we sought to develop a method to evaluate how accurately our technician hours, as measured in full-time equivalent (FTE) hours, met the time requirements to prepare and dispense medications in our primary sterile compounding clean room.

Methods: Data was compiled over the course of March 1, 2016 - March 31, 2016, which consisted of all compounded sterile preparations completed at Children's Hospital Colorado Main Campus. Medication dispenses were tallied using Tableau Business Intelligence software, in conjunction with medication order tracking from Epic Software Systems. Based on this compiled medication list, we began a testing phase using a head mounted camera rig to record clean room technician activity, in the pharmacy department's primary sterile compounding room. We obtained multiple sets of time trials across various shifts and test subjects, in order to record the time it took to prepare individual medication orders, from task initiation to completion. This interval was defined as acquiring a medication label to completion and presentation for pharmacist double-check. Using these time intervals, we calculated average times for each medication sampled. These averages were then multiplied by medication counts from Tableau, to approximate the total time spent preparing each medication, during March. Medications were then classified into one of 20 discrete categories, such as controlled substance continuous. We also took median values for each medication, due to incomplete distributions in our medication samples. From these final counts, we compared whether our employee FTE's adequately matched the time needed to meet medication demands.

Results: Technician FTE units were calculated, for the month of March and totaled 1,209 total hours. These hours were compared to the total time of the top 120 medications dispensed (e.g. - Vancomycin, ranitidine, fluid bags with additives), over the same time period. The total medication preparation time, was found to exceed the total employee time of 1,209 FTE hours. Even though this finding seemed to be counter-intuitive, it was explained by the fact that our pharmacists were not solely relegated to a double-checking responsibility. They are were also involved in preparing medications, along with technicians, which made up for difference in FTE time and medication preparation time. Beyond the scope of our current analysis, real-time pharmacy technician FTE's are also needed for tasks such as USP 797 requirements for 2016 standards of operation. This limited our ability to accurately match real time workflow, as technicians don't always complete tasks without interruptions, as they did for these time trials.

Conclusion: In order to retain our high standards for meeting optimal patient care, these findings justify the need for adjusting technician FTE units to match the growth of in-hospital medication needs. Furthermore, this process helped to develop a framework for a basic method of evaluating medication dispense volume and employee FTE capacity, for matching further population and medication fluctuations. For future studies, an economic approach and analysis would help determine whether our current system is more or less cost-effective than employing additional technician FTE's to match growing demands.

Poster Title: Role of miRNA in the regulation of ATF5

Primary Author: Zahrah Ali, Washington State University College of Pharmacy, Washington;
Email: zahrah.ali@wsu.edu

Additional Author (s):
Kari Gaither
David Liu

Purpose: Activating Transcription Factor 5 regulates survival, proliferation, and differentiation of cells, and is involved in homeostatic cellular stress response. Normally, ATF5 gets degraded, due to post-translational modifications, and has a short half-life; however, as observed in MCF7 breast cancer cells, ATF5 gets upregulated under cellular stress. While ATF5's role in stress response is apparent, cellular regulation of ATF5 is not fully understood. MicroRNA (miRNA), which contribute to the regulation of gene expression at the translational level, may play a role in the regulation of ATF5 expression levels, as miRNA expression is altered during cellular stress in a variety of diseases.

Methods: We evaluated the role and ability of specific miRNA in the downregulation of ATF5 in breast cancer cell lines. The initial miRNA candidates selected for evaluation in ATF5 regulation were miRNAs 129-5p, 433-3p, 193b, and 520b, and they were identified using methods such as TargetScan, miRanda, and other in silico modeling programs. Luciferase assays were used to validate the selected miRNA candidates. The role of these miRNA in the regulation of ATF5 was studied through the analysis of protein expression levels. Cells were cultured and seeded for transfections using precursor miRNA, followed by incubation in various stress conditions, such as heat stress, oxidative stress, and serum and amino acid deprivation. The expression levels of ATF5, under the various physiological conditions, were then measured (qualitatively) via Western Blot analysis.

Results: Data show that the selected miRNA play a role in regulating ATF5 expression, and are effective for downregulating the expression of ATF5 at the translational level. This has been observed in MCF10A mammary epithelial cells undergoing transformation via induction of

estrogen receptor (ER-Src), where miRNA 520b was shown to downregulate the expression of ATF5.

Conclusion: These data identify an aspect of ATF5 regulation, which is one pathway that affects cellular homeostasis. By gaining a better understanding of how ATF5 is regulated, and by being able to alter it's response to cellular stress, we may be able to better understand, and identify targets for treatment, in a variety of malignancies, such as glioma, and ovarian and breast cancers.

Submission Category: Ambulatory Care

Submission Type: Descriptive Report

Session-Board Number: 5a-253

Poster Title: Evaluation of appropriate monitoring of diabetic patients on ACE-I or ARB therapy within a federally qualified health center

Primary Author: Kamryn Plechot, Pacific University School of Pharmacy, Oregon; **Email:** plec0193@pacificu.edu

Additional Author (s):
John Begert

Purpose: Diabetes is the leading cause of chronic kidney disease (CKD). Angiotensin converting enzyme inhibitors (ACE-I) and angiotensin receptor blockers (ARBs) are commonly prescribed to diabetic patients because of their kidney protectant effects. Due to their activity in the kidneys, monitoring renal function in addition to other agent specific parameters should be performed at least annually during treatment with an ACE-I or ARB, if not sooner. Our purpose is to evaluate our monitoring compliance of our diabetic population who are also receiving an ACE-I or ARB.

Methods: The goal of this study was to evaluate ACE-I and ARB monitoring of diabetic patients at Virginia Garcia Memorial Health Center, a federally qualified health center in Hillsboro, OR. Patients were included if they were diagnosed with type 1 or 2 diabetes and were also receiving either an ACE-I or ARB. Pertinent data including age, sex, prescription medications, date of ACE-I or ARB initiation, date of last serum creatinine lab draw, and serum creatinine value was collected. For this observational study, data was retrospectively collected from February 2005 to July 2016. The data was then evaluated to determine the percent of patients who received appropriate ACE-I or ARB lab monitoring within specific time periods from time of prescription.

Results: Of the 5,087 diabetic patients included, 2,433 patients were excluded due to lack of ACE-I or ARB treatment. Among the 2,654 diabetic patients initiated on either an ACE-I or ARB, 100% of patients had lab monitoring performed within 5 years, 84% within 3 years, 49% within 2 years, 32% within 1 year, and 16% within 6 months.

Conclusion: Considering that diabetes is the leading cause of CKD, renal monitoring becomes increasingly important particularly during treatment with an ACE-I or ARB. In our study, most patients underwent monitoring within the last 2 years of treatment. In order to ensure patient safety and medication efficacy, it is important to follow and enforce appropriate monitoring recommendations.

Submission Category: Pain Management

Submission Type: Descriptive Report

Session-Board Number: 5a-254

Poster Title: Cannabinoid use for chronic neuropathic pain treatment

Primary Author: Andrew Lee, University Of Maryland Eastern Shore School of Pharmacy, Maryland; **Email:** alee@umes.edu

Additional Author (s):
Gregory Hayes

Purpose: The Department of Health and Human Services recognizes that opioid abuse has reached epidemic levels in the US. In 2014 opioid abuse was the leading cause of accidental death. With at least half of the overdose deaths in the US involving prescription opioids, the US Attorney General has declared that prescription opioids are the gateway drugs to heroin, not marijuana. Simultaneously, the benefits of medical marijuana have led to legalization in roughly half the country. Although research is limited, cannabinoids could offer a safe alternative to opioids for pain management that benefits patient care and combats this growing epidemic.

Methods: Using Pubmed, articles were found that studied various forms of cannabis use for chronic neuropathic pain treatment. In one study conducted by the McGill University Health Center, 23 adults with chronic neuropathic pain were randomly assigned to receive cannabis over four 14-day periods. Patients inhaled doses through a pipe three times daily with daily average pain intensities and side effects recorded. In a second single group, double-blind, placebo-controlled, crossover study using smoked cannabis conducted by researchers from the University of California San Diego, participants with refractory HIV-associated distal sensory predominant polyneuropathy were observed over 7 weeks. On selected study days participants were dosed 4 times a day under the supervision of a study nurse. Participants were titrated to a target dose affording the best achievable pain relief without adverse side effects while their pain levels were measured using the Descriptor Differential Scale at pretreatment baseline and the end of each treatment week. In a third randomized, double-blinded, placebo controlled crossover study conducted by the University of California San Diego, 16 participants with diabetic neuropathy were exposed to a placebo or varying strengths of THC. Over 4 single dosing sessions, pain was monitored and cognitive testing was performed.

Results: In the study by McGill University, 21 participants completed the trial. On an 11 point scale of average pain intensity, participants receiving the highest concentration of THC (9.4%) averaged 5.4 versus 6.1 for participants receiving the placebo (p value = 0.023, 95% CI 0.02-1.4). Participants receiving THC also reported higher quality sleep than those receiving the placebo. In the second study on HIV-related neuropathy, 28 participants receiving cannabis reported a 3.3 point difference in DDS pain scores over the placebo. The proportion of participants achieving at least a 30 percent pain relief compared to the placebo were 0.46 (95% CI 0.28, 0.65). The third study included 16 participants with diabetic neuropathy, using a 10 point pain scale, average pain scores were 0.44 higher for placebo than in the lowest concentration dose of cannabis. There was a difference of 0.42 points when the placebo was compared to medium dose and 1.2 points when compared to high dose. The statistical difference was insignificant between low and medium doses (p = 0.92) with an average pain score difference of 0.73-0.75 between high and medium/low doses (P < .001), indicating a dose dependent relationship. Side effects were minimal in all studies reviewed.

Conclusion: The scheduling of marijuana as a schedule I drug has significantly limited the size, duration, and scope of research concerning its use for medical purposes. The size of all the studies reviewed was a seriously limiting factor. However, the data they provide shows that cannabinoids may have efficacy in pain management and that further study is warranted. Currently, as more states legalize medical marijuana it is being used inconsistently without clear guidelines or safety data. The current opioid epidemic and limited research data indicate that cannabinoid rescheduling and further research should be a priority in neuropathic pain management.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Descriptive Report

Session-Board Number: 5a-255

Poster Title: Implementing pharmacy intern driven follow-up counseling and quality assurance program for discharge prescription bedside delivery program in a health system community pharmacy

Primary Author: Kimberly Goehring, University of Pittsburgh School of Pharmacy, Pennsylvania; **Email:** kcg19@pitt.edu

Additional Author (s):
Sharon Miller

Purpose: Reduction in hospital readmission is important to assure quality care. A discharge prescription bedside delivery program reduces the proportion of prescriptions that are not filled upon discharge. However, there still may be misunderstanding and noncompliance after discharge. This project was designed to follow-up with patients who had previously received discharge prescriptions to address any concerns they may have encountered since returning to home. In addition, the project was created to assess the satisfaction of patients with the bedside delivery service to ensure ideal execution of the program.

Methods: Student pharmacist interns at a health system community pharmacy conduct a follow-up encounters via phone call to patients who received discharge prescriptions through the bedside delivery program at least 2 days prior to the date of the phone call. All counseling will be performed under the supervision of a pharmacist. Primary outcomes addressed will include whether or not the follow-up counseling provided patients with new knowledge and understanding about their medication regimen, the number of potential drug therapy problems avoided as a consequence of the follow-up encounters, and whether or not patients were satisfied with the bedside delivery service. Secondary outcomes will include the percentage of patients who did not initially have questions but gained new knowledge from the counseling and the proportional categories of the potential drug therapy problems prevented.

Results: The results of this study will demonstrate the impact of follow-up phone call counseling. Results will show the number and percentage of patients receiving new information through these encounters. The project will also show the number and type of drug therapy problems avoided. Finally, the results will demonstrate the percentage of patients satisfied with the bedside delivery service.

Conclusion: While delivery of discharge prescriptions to the patient's bedside before leaving the hospital is a strategy to reduce readmissions, a second component to readmission reduction is adherence after reestablishment at home with the prescription medications. This project will work to increase patient understanding with the potential to prevent drug therapy problems that can result in readmission. In addition, it will help to optimize the program for future implementation.

Submission Type: Evaluative Study

Session-Board Number: 5a-256

Poster Title: Levels of evidence for pharmacogenomic dosing recommendations at an integrated behavioral health center

Primary Author: David Ahn, The University of Arizona College of Pharmacy, Arizona; **Email:** dahn@pharmacy.arizona.edu

Additional Author (s):
Sunghyun Kim
Toral Patel
Christina Trinh
Patrick Campbell

Purpose: Pharmacogenomics is the study of the genetic variation of drug-metabolizing enzymes, transporters, and receptors and how these impact drug responses. Pharmacogenomic testing has the potential to improve patient outcomes by allowing prescribers to customize therapy to a patient's specific genetic profile to increase success of therapy and decrease adverse drug reactions. Early adopting institutions have initiated pharmacist-lead pharmacogenomic services that use single-gene and/or panel-gene tests to inform patient care decisions.

Methods: Pharmacogenomic testing was initiated at an integrated behavioral health center in October 2015. The test utilizes a proprietary algorithm to assess commonly prescribed medications and supplements given the patient's specific genetic profile. The results provided to clinicians list medications that have clinically significant dosing recommendations and those that do not. Patients that received pharmacogenomic testing and were prescribed a medication with clinically significant recommendations were included in the analysis. The level of evidence (classified as level 1a/b, 2a/b, 3, or 4) for each drug-gene pair labeled as clinically significant was determined by using the reference single-nucleotide polymorphism number for the associated drug-gene pair using the Pharmacogenomics Knowledgebase website. The Pharmacogenomics Knowledgebase is a pharmacogenomics resource that encompasses clinical information (dosing guidelines and drug labels), potentially clinically actionable gene-drug associations, and genotype-phenotype relationships.

Results: A total of 151 medications with clinically significant pharmacogenomic dosing recommendations were assessed. Depending on the gene modification, some medications did not have any available evidence in the Pharmacogenomics Knowledgebase website, whereas others had varying levels of evidences depending on the recommendation type (toxicity/adverse drug reaction, metabolism/pharmacokinetic, and dosage). Most medication-gene recommendations were level 2b (37.1 percent) or 3 (30.5 percent), while level 1a recommendations accounted for 14.6 percent. The sample included 80 patients with varying ethnicity (56 Caucasian, 14 Hispanic, 4 African American, 1 Asian, 2 other, and 3 not provided). A chi-square test was performed to see if there was any relation between ethnicity and drug-gene recommendation level of evidence. A p-value of 0.99 illustrated that there was no relationship between patient ethnicity and dosing recommendation level of evidence.

Conclusion: Levels of evidences are ranked by the Pharmacogenomics Knowledgebase based on the amount of evidence available for the significance of a drug-gene pair. Out of all of the drug-gene pairs represented as clinically significant by the pharmacogenomic testing panel, a majority of them showed a level 2b or 3, indicating these recommendations do not have guidelines for implementation and are based on limited evidence. This information can be used to help the testing site to critically evaluate the results of the testing, and potentially come up with an internal evidence based practice to better interpret patient test results.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Poster Title: Evaluation of aripiprazole use at a non-teaching community hospital

Primary Author: Charles Dorflinger, Northeast Ohio Medical University, Ohio; **Email:** cdorflinger@neomed.edu

Additional Author (s):
Brett Rodgers
Jessica Brennan

Purpose: Aripiprazole is an atypical antipsychotic with an oral tablet formulation FDA indicated for the treatment of various disease states, most prominently bipolar I disorder, schizophrenia, and adjunct treatment of major depressive disorder. Aripiprazole and its active metabolite dehydroaripiprazole have an elimination half-life of approximately 75 and 94 hours, respectively, allowing for once daily dosing. This drug use evaluation will evaluate anticipated cost savings based on a proposed therapeutic interchange to once daily dosing and converting orally disintegrating tablets to regular tablets. Additional cost savings analysis will compare the cost of prepacking aripiprazole versus current practice of purchasing unit dose aripiprazole.

Methods: This drug use evaluation is categorized as a cost savings initiative, and therefore does not require review by the Institutional Review Board. Order data for all oral aripiprazole formulations was collected for January 2015 through December 2015. Investigators collected the following data: order start and end times, formulations, strengths, frequencies, and cost of acquisition for each strength and formulation. Doses administered two times daily and three times daily were converted to once daily dosing. Orally disintegrating tablets were changed to regular tablets, as the regular tablet formulation can be crushed for easier administration in patients who cannot swallow. Total acquisition cost was calculated using the total length of therapy and the frequency of the dose, multiplied by the cost per tablet. Additional cost analysis compared the cost of unit dose aripiprazole tablets to the cost of locally prepacking from a bulk bottle. This analysis included the cost of technician and pharmacist labor in addition to the acquisition cost per tablet and materials for prepacking. Technician time was calculated at a rate of 0.25 dollars per minute, assuming 5 minutes for 30 tablets, and 7 minutes for 100 tablets. Pharmacist time was calculated at a rate of 1.00 dollar per minute, assuming 2 minutes

to check prepacking regardless of number of tablets. Material cost was calculated at a rate of 0.08 dollars per tablet.

Results: Over the evaluation timeframe, there were 3,963 tablets of oral aripiprazole dispensed. Of these, 908 tablets were two times daily orders, and 66 of these were three times daily orders. Converting orally disintegrating tablets to regular tablets in addition to converting all doses to once daily dosing resulted in an 11 percent decrease in acquisition costs. The analysis also found that the cost of prepacking one tablet is 16 percent of the cost of purchasing one unit dose tablet. Changing from unit dose to locally pre-packed tablets would result in an 80 percent decrease in total cost.

Conclusion: In conclusion, converting two times daily and three times daily aripiprazole regimens to once daily dosing identified a potential cost savings opportunity. Orally disintegrating tablets are significantly more expensive than regular tablets, and are utilized for patients that have difficulty swallowing. The authors concluded that switching these tablets to regular tablets to be crushed into food identified an additional cost savings opportunity. Prepacking aripiprazole tablets as opposed to purchasing unit dose tablets showed a significant decrease in cost, as this is a high-cost, low-utilization medication at this institution.

Poster Title: Anaphylaxis severity in relation to the delay of epinephrine administration in Maryland schools (2012-2016)

Primary Author: Linvan Chen, University of Maryland School of Pharmacy, Maryland; **Email:** loc5161@umaryland.edu

Additional Author (s):
Alan Lin
Cheryl De Pinto
Alicia Mezu
Mona Tsoukleris

Purpose: Delayed epinephrine administration is a risk factor for fatal anaphylaxis. Requirement of more than 1 epinephrine dose signals more severe anaphylaxis. However, a report of 95 reactions, 18 requiring more than 1 epinephrine dose, showed that delayed administration in food-induced anaphylaxis was not a risk factor for receipt of multiple doses. Our objective was to explore relationships between administration delay and requirement of a second epinephrine dose in anaphylaxis cases occurring in Maryland schools.

Methods: School personnel reported anaphylaxis events occurring in Maryland schools across 4 academic years (2012-2016). Reports included demographics, symptoms, dosing, and outcomes. Reports were excluded if they did not contain information regarding delay or use of a second dose. Delay was defined as epinephrine administration time greater than 5 minutes from symptom onset. Non-normally distributed continuous variables are reported as median plus/minus interquartile range (IQR). Statistical analysis included descriptive statistics, Chi Square test for categorical variables and Wilcoxon Rank Sum test for non-normally distributed continuous data.

Results: 799 reports of anaphylaxis were received between 2012 and 2016. 427 reports were included in this analysis. Anaphylaxis occurred most frequently in students (95.8 percent) than in staff. Patients were age 12 (plus/minus 6) years, female (57.6 percent), white (37.9 percent), African American (35.5 percent) and Latino ethnicity (19.4 percent). A second epinephrine dose was administered in 24 (5.6 percent) patients and 127 (29.7 percent) had an administration

delay (greater than 5 minutes from time of anaphylaxis symptom onset). No delay (less than or equal to 5 minutes) was reported in 70.3 percent. Median time between anaphylaxis symptom onset and epinephrine administration was 2 (plus/minus 8) minutes with mode=0 (43.3 percent) and range of 0-140 minutes. Time between symptom onset and epinephrine administration in those requiring a second epinephrine dose was 3 (plus/minus 9) vs. 2 (plus/minus 8) minutes in those without a second dose (p=0.3460). There was no significance between administration delay (greater than 5 minutes) and requirement for a second dose (p=0.3921).

Conclusion: In this study of anaphylaxis reports across 4 academic years in Maryland schools, the majority of epinephrine was administered within 5 minutes of anaphylaxis onset. Although some patients received administration with lengthy delays (up to 140 mins) from symptom onset, there was no association between administration delay and requirement for multiple epinephrine doses. Prompt recognition of anaphylaxis and close access to epinephrine can shorten delays and prevent potential negative outcomes. Schools should make additional efforts to reduce administration delays when epinephrine is indicated.

Poster Title: Assessment of liposomal bupivacaine's effectiveness in controlling post-operative opioid consumption and pain

Primary Author: Julia Powers, University of Buffalo School of Pharmacy and Pharmaceutical Sciences, New York; **Email:** juliapow@buffalo.edu

Additional Author (s):
Christian Bernhardi
Ciera Patzke
Michael Ott
Eugene Przespolewski

Purpose: The purpose of this study is to evaluate liposomal bupivacaine's (LB) effectiveness in decreasing post-operative opioid use across various procedures at Erie County Medical Center. Secondary outcomes include evaluating LB's effect on decreasing pain score. Due to its unique formulation, LB sustains therapeutic levels up to 72 hours post-infiltration. The longer duration has the potential to reduce length of stay post-operatively and increase patient satisfaction compared to standard of care without LB.

Methods: This study is a retrospective, cohort chart review. Subjects were identified through an inquiry of billing records and the electronic medical records. Data collected included: baseline demographics, pain scores and opioid use measured in morphine equivalents; serum creatinine levels; Charlson Comorbidity Index; hospital location prior to and after surgery; surgical procedure; surgery duration; type and duration of anesthesia; time to extubation; time spent in the post-anesthesia care unit; dose and time of liposomal bupivacaine administration; type, dose, and time of opioid used peri-operatively; and post-operative pain scores. Opioid consumption and pain scores were evaluated at the following pre-determined time intervals: 1, 2, 4, 6, 12, 18, 24, 48, 72, and 96 hours post-operative. Surgical types include orthopedic; cardiothoracic; bariatric; ear, nose, and throat; dermatologic; breast; ophthalmologic; and general surgery.

Results: Nine hundred and fifty patients meet the inclusion criteria (489 LB, 461 standard of care). There were no significant differences in baseline characteristics including age, sex, body mass index, baseline serum creatinine, Charlson Comorbidity Index, or type of surgery. Cumulative opioid consumption was significantly less during the first 24 hours (38.2 milligrams of morphine equivalents versus 56.72 milligrams of morphine equivalents, p equals 0.0048) in LB group compared to standard of care. Cumulative opioid consumption was no different at 48 hours in either group. Pain scores were significantly different at 1 hour post-operative (2.49 versus 2.95, p equals 0.0156) in the LB group compared to standard of care. The benefit was lost at 2 hours post-operatively, however. At 6 hours post-operative, there was a significant decrease in pain scores (4.47 versus 5.54, p equals 0.0048) in the LB group compared to the standard of care.

Conclusion: LB provides a small statistically significant change in pain scores compared to standard of care for only 1 hour post operatively. In addition, it also provides a decreased consumption of opioids through the first 24 hours postoperatively of approximately 19 milligrams of morphine equivalents. After these time points, however, the benefit of using LB is lost compared to standard of care. The utilization of LB versus standard of care is only beneficial regarding pain control for approximately 24 hours post-operatively.

Poster Title: Methadone, an option for complex refractory pain syndromes with a neuropathic component

Primary Author: Robertine Nzesse Kapguep, University of Maryland Eastern Shore, Maryland; **Email:** rnzessekapguep@umes.edu

Additional Author (s):
Donald D'Aquila

Purpose: The complexity of managing chronic pain, the controversy, and the related abuse potential of opioids have led to the necessity of implementing new strategies to control pain, reduce opioids abuse, and most importantly improve the quality of life of patients. This case illustrates the benefit of using methadone to control complex nocioceptive pain with a neuropathic component. A 58-year-old Caucasian male presented to the comprehensive pain clinic with the complaint of lower back and bilateral knee pain. Patient's pain started at work and was described as shooting, stabbing, sharp, and aching. His pain was typically worst in the afternoon during inactivity. In addition, because of his job as an HVAC technician, he was required to lift heavy objects which resulted in escalating pain intensity. Previous pain management techniques included spinal injections, chiropractic manipulation which were not successful. Moreover, the escalating doses of opioids were ineffective. At the clinic, patient was prescribed Morphine capsule ER 60 mg TID, Oxycodone capsule, 10 mg PO Q6H PRN and Ativan 0.5 mg PO daily. After 17 months of escalating opioid doses, therapy and follow-up, he returned to the clinic with further complaints of lower back pain. He reported experiencing numbness of the skin, arms, and intermittent episode of stinging sensations in left great toe. Treatment was initiated with the addition of trazodone, klonopin, tizanidine and loratidine. Despite this, his condition worsened and the pain intensity did not improve. Additional history revealed that with his medication regimen, he experienced excess sleepiness at his job and unfortunately was terminated. At this point to help alleviate his pain the pharmacist recommended that his MS Contin regimen should be switched to methadone, and a baseline ECG was ordered. A month later, MS Contin was discontinued, Oxycodone was then used as breakthrough, and methadone was initiated at 5 mg PO BID. At the follow-up two weeks after the initiation of methadone, patient reported feeling better with a pain improvement of greater than 30%. As a result, he increased his physical activity, creating extra pain. Methadone dose was increased to 10 mg in

AM, 5 mg at Midday, and 10 mg QHS; the breakthrough dose was also increased, and Gabapentin was initiated. Two months later, he reported significant pain relief, and was asked to continue with his current therapy as directed. Currently patient's pain score is 3/10 with 90% relief, and more importantly, the use of clonazepam is reduced. This case illustrates the tremendous benefit of utilizing methadone in patients with complex neuropathic pain refractory to traditional pain strategies. Although the patient using methadone is not completely pain free, the quality of life is improved, the use of breakthrough mediation is reduced, and more importantly, the use of benzodiazepine is decreased. Because of the new CDC guideline requirement for healthcare providers to reduce the use of opiates, polypharmacy, and the abuse of medications by patients, the recognition of this medication in the management of neuropathic pain by healthcare providers will not only save lives, but will decrease healthcare cost and adverse reactions. However further investigation is needed to show the benefit of methadone in a larger scale of patients.

Poster Title: Defining precision medicine and its impact on clinical pharmacists

Primary Author: Annette Vidal, Nova Southeastern University, Florida; **Email:** av748@nova.edu

Additional Author (s):

Lianny Garcia

Priyanka Yalamanchili

Berry Bleidt

Purpose: Precision medicine is defined as an innovative approach that takes into account individual differences in a person's genes, environment and lifestyle to create a personalized therapeutic intervention for that patient. Clinical pharmacists could use precision medicine to be at the forefront of healthcare delivery. They could analyze patients' genetic tests in order to prescribe the most adequate medications while working with patients to reduce the impact of harmful environmental factors and educating patients about appropriate lifestyle changes. Our goal is to clarify misconceptions about precision medicine and inform clinical pharmacists about new, possible roles.

Methods: Relevant research concerning precision medicine was identified by searching databases for primary literature. A total of 6 research databases, including PubMed and Embase, were searched for publications from 1990 to 2016, with key articles obtained primarily from Hein Online, Elsevier and the Journal of American Pharmacists Association. In order to ensure that relevant studies were not missed, the search terms remained broad. These were "precision medicine or individualized medicine or personalized medicine", plus "pharmacist", plus "hospital", plus "legislation" anywhere in the title or abstract. Articles researched were restricted to the English language. In PubMed, precision medicine, individualized medicine and personalized medicine were all synonyms. PubMed defined precision medicine as clinical, therapeutic and diagnostic approaches to optimal disease management based on individual variations in a patient's genetic profile. The term "precision medicine" was added to PubMed in 2010. In Embase, the preferred term was personalized medicine, but precision medicine and individualized medicine were used as synonyms. The term "precision medicine" was added to Embase in 2011.

Results: The field of precision medicine is growing extensively and is now transitioning into daily practice among clinical pharmacists. However, precision medicine still requires adequate funding and pharmacists need proper training with pharmacogenomic testing and analysis of results. Several organizations may refuse to invest in this area until benefits have been demonstrated. Additionally, existing barriers such as data collection, participant consent, time, commitment to the program and lack of confidence of healthcare professionals may prevent engagement in precision medicine services.

Conclusion: Precision medicine can improve patient care by identifying risk factors of individuals susceptible to develop a certain disease. Furthermore, it could also be useful in the prevention of disease progression. Precision medicine has short term and long term goals. Its short term goals primarily focus on treating cancers while its long term goals concentrate on treating a wide range of diseases. Along with sufficient resources and funding, sustained commitment, time and energy and adequate training of healthcare professionals, precision medicine can reach its full potential to give individuals a chance at better health.

Poster Title: RGS4 is a positive and selective modulator of the antidepressant-like effects of fluoxetine

Primary Author: Glenys Castro, Roseman University of Health Sciences, Nevada; **Email:** gcastro@student.roseman.edu

Additional Author (s):
Cienna Nielsen
Bernice Ponce de Leon
Jeffery Talbot

Purpose: Conventional treatments for depression increase serotonin (5-HT) levels with selective serotonin reuptake inhibitors (SSRIs). Despite their widespread use, SSRIs may cause unwanted side effects, and take weeks to months for therapeutic benefit. This implicates the need for improved understanding of mechanisms regulating mood and antidepressant drug action. The purpose of this study was to test our hypothesis that endogenous regulator of G protein signaling (RGS4) is a positive modulator of the antidepressant-like effects of SSRI fluoxetine in vivo.

Methods: Evidence suggests that the antidepressant actions of serotonin are modulated by endogenous regulators of G protein signaling (RGS) proteins. However, there is limited information characterizing the nature of this regulation and the specific RGS proteins that influence SSRI drug action in vivo is not yet known. In this study, mice homozygous for the genetic deletion of RGS4 (homozygous recessive) were compared to wild-type littermates following administration 10 mg/kg intraperitoneal injection of SSRI fluoxetine (Prozac; FLX) using mood-related behavioral assays, including the tail-suspension test (TST), novelty-induced hypophagia (NIH) test, locomotor activity (LA) test, and the social defeat stress and social avoidance test. Desipramine (Norpramin; DSP), a selective inhibitor of norepinephrine (NE) reuptake, was used to assess the selectivity of drug-induced antidepressant-like behaviors. Chronic isolation stress (single housed mice for 10 days) was compared to non-stress (group housed mice) and used to determine the role of RGS4 in regulating the mood-altering effects of stress. Immobility times in the tail-suspension test (TST) were used to measure antidepressant-like phenotype.

Results: Genetic deletion of RGS4 had no effect on basal antidepressant-like and locomotor behaviors. In the tail-suspension test, fluoxetine (10 mg/kg, twice daily) significantly reduced immobility scores in wild type mice compared to vehicle-treated littermates (98 plus or minus 21 sec versus 168 plus or minus 12 sec, p less than 0.001) but was ineffective in mice with RGS4 homozygous genetic deletion (141 plus or minus 11 sec versus 161 plus or minus 11 sec, p equals 0.462). In contrast, the antidepressant-like effects of desipramine (10 mg/kg, twice daily) were unaltered by RGS4 expression. Similar effects were observed following chronic (21 days) administration of fluoxetine and desipramine (10 mg/kg, twice daily) in the novelty-induced hypophagia test. Fluoxetine significantly reduced drinking latency times in RGS4 wild type mice compared to vehicle controls (577 plus or minus 110 sec versus 284 plus or minus 50 sec, p equals 0.037) but had no effect in RGS4 homozygous recessive littermates (392 plus or minus 134 sec versus 454 plus or minus 101 sec, p equals 0.720). In contrast, the antidepressant efficacy of desipramine in the novelty-induced hypophagia test was identical between RGS4 wild type and RGS4 homozygous recessive mice.

Conclusion: These data suggest that RGS4 is required for the antidepressant-like effects of fluoxetine but not for the antidepressant-like effects of desipramine. These findings point to RGS4 as a positive and selective modulator of the antidepressant-like effects of serotonin reuptake inhibitors. When subjected to chronic isolation stress, RGS4 homozygous recessive mice developed antidepressant-like phenotypes whereas non-stressed RGS4 homozygous recessive mice exhibited basal behaviors similar to both non-stressed and stressed RGS4 wild type littermates. Furthermore, RGS4 expression differentially influences the antidepressant-like behaviors following chronic stress. These data establish a role for RGS4 in the regulation of mood-related behavior in vivo.

Poster Title: Impact of binge alcohol consumption on morning-after blood alcohol concentration

Primary Author: Allyssa Mae Nalula, University of the Pacific Thomas J. Long School of Pharmacy and Health Sciences, California; **Email:** a_nalula@u.pacific.edu

Additional Author (s):
Justin Louie
Sachin Shah

Purpose: Based on the Center for Disease Control, the overall prevalence of binge drinking (greater than 4 drinks for women, greater than 5 drinks for men) among U.S. adults is over 17 percent. People typically consume 7.9 drinks per occasion over 4 times per month. As such, the Federal Aviation Regulations restricts crewmembers from having a blood alcohol concentration (BAC) over 0.04 percent and a BAC over 0.03 percent is thought to affect concentration. Avoiding medication errors is an important aspect of a pharmacist's job. Whether a night of heavy drinking would significantly impact BAC the following morning needs better understanding.

Methods: This is a pilot proof-of-concept project. The primary endpoint is the BAC the morning after a night of heavy alcohol consumption. A young healthy volunteer will consume at least 5 shots to reach a BAC level 0.1 percent and maintain a BAC of 0.1 percent for 2 hours of the night. The initial amount to consume will be estimated using the Widmark formula. BAC will be measured using a standard device at baseline, at the end of 5 shots, towards the end of 2 hours and the morning after. Subject will then sleep for 7-8 hours and wake up before 10 o'clock in the morning the following day. Fluid and food intake will be controlled and documented for the day leading up to the trial and controlled during the trial. Data will be reported using descriptive statistics.

Results: A 29-year-old Caucasian male, otherwise healthy, weighing 175 pounds (height 6 feet) volunteered for this pilot assessment. He consumed 5 shots (1.5 fluid ounces each) in the first 30 minutes with another 2 shots 30 minutes apart to maintain a BAC level above 0.1 percent. The BAC at baseline, 30 minutes shots and 2 hours was 0.0 percent, 0.113 percent and 0.134

percent respectively on the night of alcohol consumption. As such, the volunteer vomited after and suspects the last shot may not have been fully absorbed. The following morning BAC was 0.043 percent. A severe headache was experienced but resolved following 400mg of ibuprofen administration.

Conclusion: Our results indicate that the BAC is elevated the morning after a night of heavy alcohol consumption. Future studies would be warranted to assess the impact of morning-after BAC post binge drinking on job functionality and error rate from pharmacists. Bearing in mind the frequency of binge drinking, measures to improve the metabolism of alcohol and counter the associated symptoms would be beneficial.

Poster Title: Characterization of fentanyl use in therapeutic hypothermia versus targeted temperature management

Primary Author: Christine Scarlis, University of Washington School of Pharmacy, Washington;
Email: scarlis@uw.edu

Additional Author (s):
Andrea Bedlington
Ashley Rosenquist
Sylvia Wong
Rachel Beardshear

Purpose: The purpose of this study was to compare the use of fentanyl in survivors of cardiac arrest who were cooled to either 33 degrees Celsius or 36 degrees Celsius. The intent was to characterize the amount of fentanyl administered to each cohort to determine whether one group required more fentanyl administration than the other. The null hypothesis was that there is no difference in the quantity of fentanyl administered between the two cohorts.

Methods: This was a retrospective, cohort study at an academic medical center. The study included patients cooled during a 14 month period prior to and after the update in the institutional cooling after cardiac arrest protocol: from February 2013 to March 2014 the therapeutic hypothermia (TH) cohort was cooled to 33 degrees Celsius and from August 2014 to September 2015 the targeted temperature management (TTM) cohort was cooled to 36 degrees Celsius. The primary outcome was the average amount of fentanyl used per cohort (TH vs TTM) from hospital admit time to 96 hours. This study was approved by the University of Washington institutional review board.

Results: This study assessed 250 total patients, 126 patients were cooled using the TH protocol and 124 patients were cooled using the TTM protocol. Patients were excluded if they had an inpatient cardiac arrest and/or were not given fentanyl. Conclusively, 86 patients from the TH group and 75 patients from the TTM group were given fentanyl during the first 96 hours following hospital admission. There was no difference in the average amount of fentanyl (mcg)

administered per patient between the two cohorts: 1341.3 mcg (SD=1974.4) for TH vs 1401.9 mcg (SD=1974.4) for TTM (p=0.8625).

Conclusion: This study found that there was no difference in the amount of fentanyl administered to the TH and TTM patient cohorts during the measured time frame. Further research is recommended in order to better understand the analgesic needs of patients cooled following cardiac arrest.

Poster Title: Impact of an international medical brigade on student pharmacists' professional development

Primary Author: Olivia Costa, D'Youville College School of Pharmacy, New York; **Email:** costao29@dyc.edu

Additional Author (s):
Amy Wojciechowski
Michelle Lewis
Butterfoss Kirsten

Purpose: International medical brigades are a unique opportunity for health care professionals to develop important skills while helping patients in need. Student pharmacists, in particular, can benefit from this type of experience as they are in a critical period of building and advancing their clinical skills. The purpose of this study was to evaluate the perceived impact of a medical brigade on student pharmacists.

Methods: A ten question survey was taken by students two weeks prior to the medical brigade to Tena, Ecuador, asking individuals to answer questions on a five point Likert scale. These questions related to how well they can deliver patient-centered care, work with a team of health professionals, and apply didactic material outside of the classroom. The individuals then participated in a 10-day medical brigade to during which 455 patients across five different remote Ecuadorian villages were evaluated and treated. Throughout brigade, students worked in a variety of roles including triaging patients, taking a history of present illness, scribing for physicians, and working in the pharmacy to dose, intervene, and dispense medications. Upon return, students had two weeks after the medical brigade to take the same survey in an effort to access how those categories had been impacted by their service trip. All surveys were kept anonymous and data were not analyzed until both pre-trip and post-trip surveys had been completed.

Results: Following the medical brigade all questions had an improved score compared to the pre-trip survey. Of the ten questions asked, six had a score increase greater than 10 percent and two of those questions had a statistically significant higher score in the post-trip surveys. Student pharmacists before the trip felt neutral about their ability to provide medical care in a foreign country and after the trip each student agreed that they felt comfortable doing so (mean equals 3.42 vs. 4.14, p equals 0.046). Additionally, students' understanding of the roles of other healthcare professionals was significantly improved with all students having a strong comprehension by the end of the trip (mean equals 4.29 vs. 5.00, p equals 0.008). Finally, all student pharmacists agreed that the experience contributed to their development as a health care professional and that the information gained during the brigade could not have been learned in a didactic setting.

Conclusion: Students who participated in a medical brigade to Tena, Ecuador, achieved improved confidence in their ability to care for patients in a unique clinical setting. Given the opportunity, participation in a medical brigade can expand the knowledge and clinical skill set of student pharmacists beyond what is taught in the classroom to enhance their professional development.

Poster Title: Effects of over the counter omega-3 fish oils in modulating inflammatory responses

Primary Author: Jacqueline Ball, St. John Fisher College Wegmans School of Pharmacy, New York; **Email:** jdb06103@sjfc.edu

Additional Author (s):
Maria Bertrand
Ngoc-Yen Pham
Ramil Sapinoro

Purpose: The omega-3 fatty acids, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), are needed to generate anti-inflammatory and inflammation resolving mediators within the body. Pharmacists could benefit from comparative studies that explore the differing ratios of omega-3-fatty acids. In this study, we evaluated the inflammatory response induced by lipopolysaccharide (LPS) in RAW264.7 macrophages after treatment with different concentrations of fish oils. The purpose of this study is to determine whether there is a change in production of inflammatory mediators such as nitric oxide, interleukin 6 (IL-6), and tumor necrosis factor alpha (TNF-alpha) in LPS activated macrophages when treated with fish oil.

Methods: In this study, RAW264.7 mouse macrophages were grown in tissue culture plates to optimal confluency and used to assess inflammatory response. The cells were plated in triplicate and assigned to the following groups: 1) no treatment, 2) fish oil alone, 3) LPS alone, and 4) fish oil and LPS. Collected samples were assayed using three methods: Griess, enzyme-linked immunosorbent assay (ELISA), and Western Blot. A western blot was performed to separate proteins and the membranes were then incubated with labeled antibodies and developed to reveal the presence of inducible nitric oxide synthase (iNOS). The ELISA assay was utilized to measure the expression of inflammatory cytokines, IL-6 and TNF-alpha. Lastly, nitrite production concentration was determined using the Griess assay.

Results: Treatment with fish oil showed reduced production of LPS induced nitric oxide. Samples treated with fish oil displayed lower expression of iNOS activity and resulted in decreased expression of the inflammatory cytokine IL-6. Fish oil treatment did not show a significant reduction in the expression of TNF-alpha in LPS-activated macrophages.

Conclusion: There were observed changes in the expression of inflammatory cytokine IL-6 when RAW264.7 cells were induced for inflammatory response and treated with different concentrations of fish oil. There were minimal changes in the expression of TNF-alpha in cells treated with fish oil. Further investigation is needed to compare other brands of fish oil supplements in terms of anti-inflammatory responses. Future direction in OTC product comparison will allow pharmacists to better help patients choose a more effective product.

Poster Title: Evaluation of availability and access to antidotes and reversal agents in a tertiary care medical center.

Primary Author: Julie Le Pham, University of Houston College of Pharmacy, Texas; **Email:** jlepham@houstonmethodist.org

Additional Author (s):
Ibrahim Chowdhury
Ryan Hughes
Victoria Fisher

Purpose: Administering an antidote within the appropriate amount time to a poisoned or overdosed patient is often critical to patient outcomes. It is therefore necessary to ensure appropriate medications are available in appropriate quantity, with proper drug information and ability to dispense. This project focused on the systematic assessment of antidote and reversal agent availability and accessibility at Houston Methodist Hospital (HMH), as proposed in the Institute for Safe Medication Practices 2016-2017 Targeted Medication Safety Best Practices for Hospitals.

Methods: Consensus guidelines published in 2009 were compared with the Texas Poison Control Center (TPCC) antidote chart to determine which products are considered time critical antidotes and reversal agents. A previous version of the antidote chart for Houston Methodist Hospital was used as a baseline to determine hospital needs. The current maximum and minimum stocking levels were assessed through inventory review, then compared to the amount needed to treat one 100 kg patient for 24 hours to determine if the current inventory par levels met the recommended amount for patient treatment. Additionally, select reversal agents were assessed to determine if clinical decision support guidance was available for each item.

Results: A total of fifty-four antidotes were assessed. Ten antidotes were removed from the list based on conventional use in the hospital, such as naloxone and lorazepam. Eleven antidotes were determined not to be currently stocked at Houston Methodist Hospital. All thirty-three

remaining antidotes are accessible through the Houston Methodist Hospital central pharmacy with a select few that can also be accessed from an automated dispensing cabinet.

The 2009 national consensus guideline recommended twenty-four antidotes to be stocked at institutions that provide emergency services. Of those, the TPCC recommendations included twenty of these items, or eighty percent. The four that were not included, were determined not needed. However, twelve antidotes recommended by the TPCC were not mentioned on the national consensus guidelines.

Of the thirty-eight antidotes recommended by the TPCC, the Houston Methodist Hospital baseline chart included eighty percent of the recommendations. The eight medications that were not included in the references were polyethylene glycol, syrup of ipecac, antivenin snake: micrurus fulvius, botulism antitoxin, dextrose in water, regular insulin, lipid infusion, and hyperbaric oxygen. In addition, six antidotes recommended by Houston Methodist Hospital were not mentioned on the TPCC chart including benztropine, bromocriptine, L-carnitine, cyproheptadine, dantrolene, and ethanol.

Conclusion: A comprehensive antidote chart was created to identify opportunities to improve Houston Methodist antidote availability. This reference chart includes information on antidotes, their use, sufficient quantity and designated location. Compared to the TPCC, Houston Methodist has three antidotes that are currently not in inventory and five without appropriate indication. Alternate therapies or medications have been implemented to treat conditions in place of these missing antidotes. For example, syrup of ipecac is a gastrointestinal irritant that induces emesis to treat overdoses. Although this antidote is found on the TPCC, Houston Methodist has other therapies available, such as activated charcoal.

Poster Title: Interventions made by student pharmacists during in-room patient visits at an interprofessional student-run free clinic: A pilot study

Primary Author: Tiffany Vu, Campbell University College of Pharmacy and Health Sciences, North Carolina; **Email:** ttvu1006@email.campbell.edu

Additional Author (s):
Douglas Currington
Manali Patel
Scott Perkins
Katie Trotta

Purpose: As Doctor of Pharmacy students progress in their curriculum, it is expected that their ability to make clinically-appropriate recommendations improves. This study seeks to determine the impact the current professional year of student pharmacist has on their ability to contribute to an interprofessional student health care team at a student-run free clinic. The pilot study will use this information for the purpose of improving the number and quality of recommendations made by all student pharmacists.

Methods: This study is an observational prospective cohort approved by the Campbell University Institutional Review Board. Student teams worked together in caring for patients at a university student-run free clinic and consisted of a first-year osteopathic medical student (MS1), second-year osteopathic medical student (MS2), and student pharmacist (first [P1] through fourth [P4] year). Teams go into patient rooms and interview patients, determining their full medical history, primary problem for the visit, and preliminary plan. Care plans developed by student pharmacists and student physicians are presented by the team to an attending, generally a supervising volunteer physician. At the end of each clinic night, each pharmacy student is asked to complete a survey documenting all interventions they made that night for each patient they saw. Interventions were counted and categorized based on type. The primary outcome measure is the number of accepted interventions among student pharmacists in their P1 through P4 year. Secondary outcomes include the rate at which interventions made by each professional year are accepted by the attending physician, category of interventions made by each professional year, percentage of prescriptions with errors

received at the in-clinic pharmacy, and the number of interventions students make based on the number of times they volunteered at the clinic. Descriptive statistics were used to asses the results.

Results: A total of 56 students volunteered for the free clinic during the period of May 3, 2016 to August 30, 2016. Of these, 40 students completed the intervention survey at the end of the night; 7 were P1s, 3 were P2s, 19 were P3s, and 11 were P4s. Clinic was held once weekly for a total of 18 clinic days during the study period, and an average of 3 students volunteered each week. A total of 72 interventions were made. In evaluating the professional year of student volunteers and the number of recommendations that were accepted per student: 0.4 recommendations per P1 student were accepted, 1.3 per P2 student, 1.4 per P3 student, and 3.2 per P4 student. The most common type of intervention made by the pharmacy student was therapeutic selection.

Conclusion: In the pilot phase of this study, there was a positive correlation between accepted interventions and professional year. Student pharmacists from all professional years impacted interprofessional student teams with accepted recommendations. While there was limited representation from P1 and P2 students, P4 students had more accepted recommendations than other years and made a larger impact. Pairing P4 students with students in other professional years or including them in a mentor role may improve recommendations within the clinic.

Submission Category: Quality Assurance/ Medication Safety

Poster Title: Development of hypertonic saline policy and optimization of the electronic medication record

Primary Author: Hazel Ann Zaballero, Pacific University, Oregon; **Email:** zaba1280@pacificu.edu

Additional Author (s):
Mike Wyant
Nyssa Stant
Keeley Damon
Rani Scranton

Purpose: Hypertonic saline administered intravenously is commonly used to treat severe hyponatremia and to alleviate high intracranial pressures in brain injury. Increasing severity of these conditions are associated with high morbidity and mortality, requiring immediate treatment. Hypertonic saline, if monitored improperly, can result in adverse events such as sodium toxicity and irreversible osmotic demyelination syndrome. The need to standardize the use and monitoring of hypertonic saline to provide guidance to healthcare professionals has led to the development of a hypertonic saline policy and optimization of the electronic medication record.

Methods: Methods implemented to form a hypertonic saline policy and enhance the electronic medication record include a literature review that focused on hypertonic saline use within guidelines and related primary literature; in addition, experienced clinical pharmacists, physicians, and nurses within the healthcare system was formed to provide formal review before approval. Meanwhile, the electronic medication record format was revised to include pertinent and detailed information that align with the policy and provide guidance. The inclusion of appropriate prescribing information was added to be utilized by both the providers and the pharmacists.

Results: The hypertonic saline policy include required and recommended labs necessary to maintain appropriate monitoring, including but not limited to BMP, regular sodium monitoring, and serum osmolality. Vital signs and neurological exams performed at a range of 1 to 4 hours to monitor patient improvement or decline. Hypertonic saline is recommended to be

administered through central line. Should the need of hypertonic saline arise and central intravenous access is unavailable, suggestions regarding peripheral venous administration are outlined. Each provider is to establish patient-specific sodium goals for every 24 hours throughout the duration of hypertonic saline use. In the event of over-correction, the nursing staff is to halt the infusion and contact the provider for further direction.

Conclusion: Hypertonic saline is important to treat conditions that can lead to significant morbidity and mortality. In order to prevent adverse events, proper administration and monitoring must be implemented. To attain these, standardization of use along with recommendations to guide therapy through the development of a hypertonic saline policy and medication record optimization were completed. Future directions include plans to provide the hospital staff with continuing education that will foster greater understanding with the risks associated from erroneous ordering and monitoring. Meanwhile order sets specific to disease states can be developed to further enact appropriate medication monitoring and administration.

Poster Title: Collaborative practice competition

Primary Author: Rozta (Rozette) Fawzy, Manchester University College of Pharmacy, Natural & Health Sciences, Indiana; **Email:** rfawzy2018@manchester.edu

Additional Author (s):
Tung Nguyen
Pearl Pfiester

Purpose: The purpose of this project was to bring health care students from different professions together to collectively and collaboratively practice interdisciplinary "rounding", apply clinical knowledge and skills, and exercise soft skills for effective communication and leadership development.

Methods: The competition is designed to simulate a collaborative rounding experience. An interprofessional team of students is first given a part of a patient case. Then one of the team members interacts with a standardized patient (standardized patients who are made up of the judges who are faculty members from the different schools participating) to gather more information such as labs, medication history, family history, and past medical history. The team is then able to evaluate the patient to perform their parts and together diagnose and develop a patient care plan by looking at the patient as a whole. The team presented their care plan to the judges. After the judges have submitted the scores, an award ceremony followed. The event is a competition graded based on the interaction with the patient, verbal/powerpoint presentations, and the written care plan. Standardized resources were provided to all teams. A standardized grading rubric was provided to judges and standardized patients.

Results: A total of twenty-four participants, twelve volunteers and 12 judges/standardized patients joined together to participate in this unique interprofessional competition.Twenty-four students actively participated in the competition. The students were composed of both pharmacy students from Manchester University college of pharmacy, nursing students, and nurse practitioner students from IPFW nursing program. All participants indicated that they were more confident and less anxious going into a rotational environment. All judges judged according to the standardized rubrics created for the event. Six of the 12 judges disagreed on

the judging procedure they wanted to be able to deliberate and offer feedback to the groups in person rather on the score sheets. Time of the event needed to be extended to accommodate for the judge's wishes. We learned that students are more comfortable presenting powerpoint presentations rather than verbal presentations. All judges and faculty advisors felt that this competition was a great innovative way to practice clinical skills, network with other healthcare professionals, and develop respect for each healthcare profession. All students felt that this experience helped build their confidence, competence, clinical skills, and communication skills with other healthcare professionals before practicing in the real world or on rotation.

Conclusion: The CPC has proven to be unique, successful and beneficial for a first-time event. All judges and advisors felt that this competition was a great innovative way to practice clinical skills and professionalism with other healthcare professionals. All students felt that this experience helped develop their confidence and multiple clinical skills with other healthcare professionals before practicing in the real world or on rotation. Many professional schools have contacted us to participate in the next competition. We look forward to expanding and share our experience with other schools to help better prepare their students for rotations or residencies.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Descriptive Report

Session-Board Number: 5a-271

Poster Title: Use of Standardized Bowel Regimen Protocol to Improve Quality of Care for Pediatric Patients on Opioids

Primary Author: Betty Lee, University of Arizona College of Pharmacy, Arizona; **Email:** bettyl@email.arizona.edu

Additional Author (s):
Caroline Joseph
Alexandria Tellez
Jisu Chung
Megan Brandon

Purpose: A known side effect of opioids is constipation. Approximately 40% of patients experience constipation related to opioid therapy for non-cancer pain. Opioid-induced-constipation can be severe and affect quality of life and length of hospital stay. Hospital discharge processes mandate admitted patients on opioids must have produced at least one bowel movement before discharge. Gastrointestinal motility disturbances can be mitigated using a combination of supportive therapeutic laxative classes.

Methods: Patient data was collected from the pediatric hematology-oncology and pediatric hospitalist service units at Banner University Medical Center at Diamond Children's Medical Center. Pre-intervention patient data was collected to establish baseline frequency of types of bowel regimen medications prescribed. The intervention consisted of a pediatric bowel regimen badge drug card distributed to physicians and residents, which provided key-dosing information based on different pediatric age groups. Post-intervention patient data was collected and used to compare the frequency of bowel regimens prescribed and the average length of hospital stay. Both t-test and Chi-squared tests ($\alpha \leq 0.05$) were used to assess the overall clinical outcome of this intervention. Additionally, a follow-up survey was created to assess whether the badge cards were utilized by prescribing physicians and residents.

Results: Fifty-six pediatric patients were eligible to be included in the study in both the pre-intervention and post-intervention groups. The mean duration of hospitalization showed a shortened duration of hospitalization after the intervention, although it was not statistically significant (pre: 8 ± 4.9 days, post: 5.8 ± 8.3 days, p-value: 0.09). The number of patients who were prescribed a bowel regimen post-intervention was marginally higher at 58.9%, compared to the pre-intervention group at 55.3%, but values were not statistically significant. The number of patients who produced a bowel movement after the bowel regimen was taken for post-intervention patients was marginally higher at 28.6%, compared to pre-intervention of 25% of patients (p = 0.4). A follow-up survey revealed that residents who received the intervention found the bowel regimen badge cards to be useful, but improvements to portability and a smaller size could have led to increased on-hand availability and increased use.

Conclusion: This study emphasized the importance of adjunct prescription of opioids and bowel regimens in pediatric patients. Although findings are not statistically significant, standardized bowel regimen badge cards can serve as reminders to the importance of preventing opioid-induced-constipation. Limitations of the study included inconsistent or missing documentation of bowel movements in EPIC charts by nursing staff, lack of financial expense data of bowel regimens on length of hospital stay, missing documentation of non-pharmacological interventions such as prune juice, and inherent variation in patient disease states that vary the number of opioid medications and bowel regimens prescribed.

Submission Type: Evaluative Study

Session-Board Number: 5a-272

Poster Title: Evaluating the effect of dates of approval within therapeutic areas on pharmacy benefit managers' exclusion lists

Primary Author: Kevin Ma, Ernest Mario School of Pharmacy at Rutgers, The State University of New Jersey, New Jersey; **Email:** klm289@scarletmail.rutgers.edu

Additional Author (s):
Alison Lieu

Purpose: Pharmacy benefit managers (PBMs) have become an integral part of the healthcare system. The purpose of PBMs include maximizing drug effectiveness while minimizing drug costs to patients and prescribers. PBMs accomplish this by managing formularies, performing drug utilization reviews, and mail order claims. Additionally, exclusion lists were introduced, first by CVS Health in 2012, followed by Express Scripts (ESI) in 2013. Since the creation of exclusion lists, both PBMs have annually increased their exclusion lists. This research aims to analyze the relationship between FDA approval dates of medications by therapeutic category on these exclusion lists for CVS Health and ESI.

Methods: A systematic review of approval dates was conducted for drugs listed on the 2017 exclusion lists of CVS Health and Express Scripts as published by Pembroke Consulting. Drugs from both lists were organized by the following therapeutics areas: Cholesterol and Hypertension; Central Nervous System; Dermatological; Diabetes and Weight Management; Eyes, Ear, Nose, Throat, and Respiratory; Gastrointestinal, Urological, Obstetrics, and Gynecology; Hematology and Oncology; Hepatitis; Inflammatory Conditions and Immunosuppressants; and Endocrinology and Supplements. Drugs that did not have regulatory timelines available on the Drugs @ FDA website were removed from the analysis. The years and months between date of approval and the time of analysis (September 1, 2016) were extracted for the remaining drugs, and a statistical analysis was done within the therapeutic categories for both PBMs, individually and combined.

Results: There are 129 combined drugs on the exclusion lists for the top two PBMs. 69 drugs were analyzed from ESI, and 34 drugs were analyzed for CVS Health. 7 drugs appeared on both lists. No drugs were analyzed from ESI in the Cholesterol and Hypertension category nor from CVS Health in the Dermatological or Inflammatory Conditions and Immunosuppressants category. For ESI, Hematology and Oncology drugs had the longest average time on market at 16.97 years. For CVS Health, Cholesterol and Hypertension drugs had the longest average time on market at 25.83 years. Hepatitis drugs had the shortest average time on market for both ESI and CVS Health at 3.88 years and 1.38 years, respectively. Overall, ESI's exclusion list had a shorter average time on market at 9.67 years compared to CVS Health's exclusion list, which had an average time on market at 12.55 years.

Conclusion: While there are many factors that are considered when evaluating a drug's placement on an exclusion list, the length of time on the market, especially in the context of certain therapeutic areas, appears to influence PBM decision making differently. ESI is more apt to exclude newer drugs than CVS Health except in the case of Hematology and Oncology products. Both PBMs excluded relatively new drugs in the Hepatitis category, which indicates a comparable decision making process in evaluating those medications.

Poster Title: Increasing formulary compliance through changes to the non-formulary review process at the Johns Hopkins Hospital

Primary Author: Alexa DeVita, Drake University College of Pharmacy & Health Sciences, Iowa; **Email:** alexa.devita@drake.edu

Additional Author (s):
Celia Proctor

Purpose: The acquisition and utilization of non-formulary medications can increase costs and decrease patient safety due to lack of integration within medication use systems and policies. The hospital policy encourages pharmacists to provide formulary alternatives when available for non-formulary orders. However, if the cost of the medication was less than a specific threshold (500 dollars per dose) there was no formal review or approval process in place. A second level pharmacist review process for non-formulary medication orders was implemented to decrease non-formulary use and understand the volume and resource needed to implement a non-formulary approval process.

Methods: Pharmacists that receive a non-formulary order evaluate and discuss alternatives with the prescriber. If following the initial discussion the non-formulary medication is still requested for use, the medication order is escalated to a non-formulary pharmacist reviewer. These reviewers serve as an additional layer of review and track the outcome of the encounter. These outcomes were manually logged in an excel document by the reviewers. The outcomes tracked included, endorse, do not endorse, do not endorse: changed, do not endorse: discontinued, verified off hours: would endorse and verified off hours: would not endorse. The non-formulary reviewer encounters were tracked and collected for 20 weeks. Non-formulary dispensed data was used to evaluate overall impact on non-formulary orders dispensed. The report was pulled from our pharmacy electronic health system on a monthly basis. Dispensed data was also pulled and reviewed the 6 months prior to implementation.

Results: After six weeks of the second level pharmacist review process, there was a 30 percent decrease (approximately 1,000 orders per month to approximately 700 orders per month) of non-formulary orders dispensed. The non-formulary reviewer data was collected for 20 weeks from April 25th 2016 through September 9th 2016. Within 6 weeks of implementation, 385 orders were escalated to a process. Of these orders, 45 percent were converted to a formulary alternative after additional review and discussion with the non-formulary reviewer. The outcome of each non-formulary request was categorized into reported outcomes categories including: endorse, do not endorse, do not endorse: changed, do not endorse: discontinued, verified off hours: would endorse and verified off hours: would not endorse. The reported categories were broken down into their reported outcomes category and also by therapeutic area. There were 13 unique therapeutic areas that were identified with complementary and alternative medications, analgesia, cardiology and gastrointestinal therapeutic areas having the highest number of medications. The data was also analyzed to identify high use non-formulary medications with no formulary alternatives so they could be taken through the formulary review process. The full 20 weeks of data has just been collected and is being analyzed.

Conclusion: The goal of this initiative was to improve patient safety and decrease overall cost by decreasing the use of non-formulary when clinically appropriate. The implementation of the pharmacist second level review for non-formulary medication orders significantly decreased the number of non-formulary medications dispensed overall. The positive results from the first 6 weeks of data supported moving forward with a second level review process. The data collected is being used to support the establishment of a formulary approval process for all non-formulary medications.

Poster Title: Effects of pharmacist-directed motivational interviewing on behavioral change in patients with diabetes in a medically underserved rural community pharmacy setting

Primary Author: Maheder Dachew, University of Maryland Eastern Shore, Maryland; **Email:** mydachew@umes.edu

Additional Author (s):
Lana Sherr
Geoffrey Twigg
John Motsko

Purpose: Motivational Interviewing (MI) is a patient centered and goal oriented counselling technique used in various settings to empower patients to better manage their health. MI, originally applied in addiction counseling, has been extended for use in chronic disease management. Expanding their horizons by offering their knowledge and experience in improving patient outcomes, pharmacists have adopted MI techniques in counselling individuals with diabetes. This collaborative approach allows patients to be their own advocates of change. The purpose of this quality improvement study is to assess the effects of pharmacist-directed MI in individuals coping with diabetes.

Methods: 308 patients, including men and women aged 18 and older, with pre-diabetes, type 1 diabetes, or type 2 diabetes enrolled in an AADE™ accredited diabetes education program at Apple Discount Drugs, a community pharmacy, during 2014 and 2015. This patient education curriculum is part of a framework of patient centered diabetes self-management education (DSME) programs. The AADE7™ program identifies seven self-care behaviors that include healthy eating, being active, monitoring, taking medication, problem solving, reducing risk, and healthy coping. Aggregated data on patients applying each one of the seven AADE7™ self-care behaviors was analyzed to measure patient outcomes. Descriptive statistics including percentage change, mean, minimum, maximum, mode, and median were used to characterize data. For those who completed the diabetes education program, aggregate patient outcome was assessed by measuring changes in A1C, BMI, weight, foot and dilated eye exams. BMI was calculated using the National Heart, Lung, and Blood Institute (NHLBI) BMI Calculator. The primary measure of patient outcome was a change in baseline A1C and BMI measured 12-

months following initiation of the AADE7™ program. This study was exempted under category four of the Institutional Review Board.

Results: Out of 308 patients who participated in AADE7™ Self-Care program, the number of patients who signed up for each category included 88 (healthy eating), 69 (being active), 34 (monitoring), 22 (taking medication), 26 (problem-solving), 92 (reducing risks), and 46 (healthy coping). Patients who achieved their goals in each of these behavioral change categories were 71.59% (healthy eating), 71.01% (being active), 85.29% (monitoring), 63.64% (taking medication), 73.08% (problem-solving), 73.91% (reducing risks), and 76.09% (health coping). The average reduction in baseline A1C and BMI was 0.66 and 2.91, respectively.

Conclusion: Implementation of pharmacist-directed motivational interviewing as part of the AADE7™ Self-Care diabetes education program provides a noticeable and significant improvement in patient outcomes as measured by changes in A1C and BMI. This is demonstrated by improved medication adherence, therapeutic outcomes, as well as behavioral change in patients with diabetes who participated in this program. Community pharmacists are often the most accessible health care professionals for rural residents. This study showed how much patients with chronic health conditions could benefit from pharmacist-directed support programs.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Descriptive Report

Session-Board Number: 5a-275

Poster Title: When pink is not your color: Evaluating the risk factors associated with novel synthetic opioid U-47700

Primary Author: Tyler Gunderson, University of Utah College of Pharmacy, Utah; **Email:** tyler.gunderson@pharm.utah.edu

Additional Author (s):
Jeremy Daugherty
Logan Peterson

Purpose: Recent emergence of deadly exposures to the novel synthetic opioid U-47700, otherwise known as "pink" or "pinky", have created a national disturbance among both law and drug enforcement agencies. Media reports and public warnings have been issued regarding adverse events in connection with this psychoactive substance. Although U-47700 is relatively unknown, harboring limited scientific data, it is fairly inexpensive and easily obtained online. Pharmacists are often relied upon to understand and address the imminent health risks posed by harmful designer drugs. This evaluation was performed to identify the risk factors, and appropriate care management, involved with the ingestion of U-47700.

Methods: Pharmacists trained in drug information and the evaluation of novel compounds were consulted in this report. A literature search was performed utilizing PubMed, EMBASE, and the Cochrane Library from January 1st, 2015 to current for case reports, case series, and media reports related to U-47700. Drug potency and adverse effect comparisons were made with commonly employed opioids currently used in practice. Data for U-47700 case reports in the state of Utah were analyzed for comparative measure to national findings. Published reports of naloxone reversal and supportive care were assessed in U-47700 overdose cases.

Results: U-47700 is selective for the mu receptor, showing 7.5 times the binding affinity of morphine. 16 out of 20 deaths due to overdose of synthetic opioids in postmortem casework tested positive for U-47700 from October 2015-March 2016. Of these 20 cases, only one did not involve the ingestion of other illicit and/or prescriptions substances along with U-47700 . Unknown doses were found in 2 fatal case reports. Unlike other opioids, U-47700 is detected in

the serum. In 4 published reports of naloxone reversal, one patient recovered with 0.4mg IV, other opioids were also present in the urine.

Conclusion: U-47700 is a novel, selective opioid agonist that produces significant respiratory depression and mortality in untreated overdose. Naloxone doses required to reverse toxicity remain unknown, however repeated dosing has demonstrated reversal. U-47700 poses an imminent hazard to public safety. More research, along with appropriate education, is needed in order to curb the misuse of "pink".

Submission Type: Descriptive Report

Session-Board Number: 5a-276

Poster Title: Calcinosis relating to tissue hypoxia in the setting of systemic sclerosis

Primary Author: Mitchell Miller, Albany College of Pharmacy and Health Sciences, New York;
Email: mitchell.miller@acphs.edu

Additional Author (s):
Jessica Farrell
Lee Shapiro

Purpose: Systemic sclerosis (SSc) is a rheumatic disease characterized by autoimmunity, vasculopathy, and fibrosis. Calcinosis is a frequent complication, where calcium crystals deposit in the subcutaneous tissue, most commonly in the fingertips. The vasculopathy in SSc is characterized by small blood vessel damage coupled with insufficient neoangiogenesis, causing decreased density of small blood vessels, multiple regions of tissue hypoxia, activation of hypoxia-inducible factor-1 (HIF-1), activation of osteoclasts and bone resorption, and we hypothesize that it may have a role in development of calcinosis as well.

Methods: An extensive literature review was performed examining the link between hypoxia and calcinosis. There is limited data published on calcinosis, and even less published on calcinosis and hypoxia. This necessitates evaluation of other disease states which cross over with SSc, and using established associations with calcinosis to elucidate the mechanisms involved.

Results: Key associations have been noted between calcinosis and acro-osteolysis, digital ulcers, osteoporosis, and pulmonary arterial hypertension. These manifestations are each related to hypoxia and/or HIF-1, providing support of its role in calcinosis. HIF-1 is induced by nearly all cell types and controls genes involved in angiogenesis, metabolism, differentiation, and apoptosis/apoptotic resistance, ultimately aiding in short-term cell survival. This protein also has a role in activation of osteoclasts and bone resorption. Calcinosis in SSc is dystrophic (occurs under conditions of normal serum calcium and phosphorous). Therefore, we hypothesize that the calcium in calcinosis is due to enhanced bone resorption by action of HIF-1. Ultrastructural and crystallographic analysis of calcinosis revealed that the major constituent of the deposits is hydroxyapatite, a main inorganic component of bone, providing further

evidence that the source of the calcium is the bone. In an unpublished case report, a patient with SSc and pulmonary fibrosis was prescribed treprostinil, a potent vasodilator, for management of her pulmonary arterial hypertension. After approximately 6 months of therapy, the patient presented to her rheumatologist noting that she had dramatic improvement in her calcinosis, confirmed on imaging. These data provide some evidence supporting the relationship between hypoxia and calcinosis in Scleroderma.

Conclusion: Vasculopathy in SSc results in the creation of a microenvironment in the digits which is hypoxic, hypothermic, favors bone resorption, and favors calcium deposition. Chronic hypoxia and induction of HIF-1 is responsible for enhanced bone resorption, which is the suspected source of the calcium in calcinosis. Therefore, examination of bone mineral density and degree of hypoxia going in the digits may be a predictor for calcinosis.

Poster Title: Appropriateness of medication in a pediatric hospital of Mexico

Primary Author: Elvira Nieto, Universidad Autónoma de Baja California, Baja California; **Email:** elvira.nietoelicerio@uabc.edu.mx

Additional Author (s):
Evelyn Favila
Hermelinda de la Cruz
Jose Sanchez

Purpose: In Mexico health services are implementing the process suitability of the medication. When assessing the pharmacotherapy adverse drug events (ADEs) medication errors (MEs) are common. These have a greater incidence in the processes of prescription and transcription. Although the MEs are frequent, most do not cause harm. However, should be monitored in any institution of health to prevent ADEs and promote the proper use of medicines in the patients. The purpose of this work is to show the results of the follow-up to the process of prescription and pharmacist intervention in the prevention of ADEs in a pediatric hospital.

Methods: This was a prospective, cross-sectional study open with the information contained in the medical prescriptions generated in the hospital specifically in the ambulatory surgery center, the period March 2015 to March 2016. Where the pharmacist made an analysis of the information contained in the leaves of medical prescriptions to be generated for each patient in the hospital, in regard to medication indicated, dose, route of administration, dosage form, therapeutic duplicity, allergies, drug interactions, possible adverse reactions to drugs, among others. The MEs were classified by its type, medication process and gravity. The intervention was made by the pharmacist. Finally, we documented the prevalence of error prevented and consequently of MEs.

Results: We evaluated 191 sheets of medical indications, of which the total number of surgeries practiced were orthopedics (63%), lip and palate (27%), plastic surgery (18%) and other surgeries (1%). Found 1,142 medication errors. The most common were by: drug interactions (12%), a dose greater than the indicated (10%), medication contraindicated (36%), allergies to medication (2%), duplicity therapeutics (2%), and errors of omission (38%). Of the latter, the

most common omissions are: the dose per weight (45%), route of administration (23%), duration of therapy (19%), pharmaceutical form (5%), dosing interval (4%) and dose (4%). From the MEs found, 97% are prevented by the timely intervention of the pharmacist.

Conclusion: When assessing the sheets of medical indications were found 1,142 MEs in the stage of prescription. Medication errors were in the following order omission errors (38%), medication contraindicated (36%), drug interactions (12%), among others. Of the errors detected in the service 97% were prevented by the timely intervention of the pharmacist.

Poster Title: Justification for an emergency department cumulative antimicrobial susceptibility report and treatment algorithm for community-acquired Escherichia coli urinary tract infections

Primary Author: Syeda Fatima Rizvi, Midwestern University Chicago College of Pharmacy, Illinois; **Email:** srizvi56@midwestern.edu

Additional Author (s):
Gary Peksa
Carolyn Toy
Sheila Wang

Purpose: Escherichia coli (E. coli) is the most common uropathogen associated with urinary tract infections (UTIs) in the emergency department (ED). Empiric use of fluoroquinolones (FQ) is common for UTIs. However, resistance rates are on the rise with warnings of FQ use associated with tendon damage, central nervous system effects, QTc prolongation, impaired glucose homeostasis, and collateral infections. Knowledge of uropathogens and their sensitivities towards antibiotics is essential for successful empiric treatment selection. The purpose of this study is to justify the need for an ED cumulative antimicrobial susceptibility report (CASR) and use of empiric FQ-sparing agents.

Methods: A single center, retrospective cohort study of patients in the ED at RUSH University Medical Center (RUMC) was conducted between February 2016 and August 2016. The inclusion criteria were age 18 years or older, diagnosis of community-acquired acute uncomplicated urinary cystitis or pyelonephritis, and urinary culture with growth of E. coli. Data points collected included diagnosis, microbiological susceptibility reports, and antibiotic prescribed for empiric treatment. Patients with repeat UTIs had only their first visit included. Results from the ED CASR were compared to the hospital-wide (HW) CASR for E. coli. Findings were assessed to develop an empiric treatment algorithm for community-acquired acute uncomplicated urinary cystitis and pyelonephritis in the ED. Statistical validity and development of the CASR was in accordance with the Clinical and Laboratory Standards Institute, M39-A04 guidelines. The investigators aimed to include 151 E. coli urinary isolates assuming a difference of 10 percent (85 percent versus 95 percent susceptibility for a given agent) for E. coli resistance between the

ED and HW CASR; a statistical power of 0.8 and an alpha of 0.05. This study was submitted to the appropriate Institutional Review Boards for approval.

Results: Two hundred and twenty three UTIs in the ED from February to August 2016 were initially evaluated, identifying 184 urine cultures (83 percent) with E. coli as the primary pathogen. Of these 184, 154 unique cases of adult community-acquired acute uncomplicated urinary cystitis (n equals 94, 61 percent) and pyelonephritis (n equals 60, 39 percent) met inclusion criteria. Susceptibility rates for E. coli isolates used for the ED CASR (n equals 154) and the HW CASR (n equals 886) were compared. The following antibiotics showed significant difference in percent susceptible (p value less than 0.05): ampicillin (ED 63 vs. HW 44), ampicillin/sulbactam (ED 69 vs. HW 49), cefazolin (ED 80 vs. HW 62), ceftriaxone (ED 99 vs. HW 88), cefepime (ED 99 vs. HW 90), aztreonam (ED 99 vs. HW 89), levofloxacin (ED 90 vs. HW 65), trimethoprim/sulfamethoxazole (ED 84 vs. HW 67), gentamicin (ED 96 vs. HW 90), and tobramycin (ED 96 vs. HW 88). Resistance rates for nitrofurantoin and trimethoprim/sulfamethoxazole did not exceed 20 percent in our ED. Fifty three percent of cases were prescribed a FQ, followed by nitrofurantoin (24 percent), beta-lactams (12 percent), and trimethoprim/sulfamethoxazole (6 percent).

Conclusion: Significant differences were identified between the ED and HW CASR specific for E. coli in patients with acute uncomplicated urinary cystitis and pyelonephritis. Over half of the treated UTIs included in our study received a FQ. FQ-sparing agents such as nitrofurantoin and trimethoprim/sulfamethoxazole remain susceptible according to our ED CASR. Results from our ED CASR will help guide the development of an empiric treatment algorithm for E. coli associated community-acquired UTIs and justifies the use of fluoroquinolone-sparing agents as first or second-line treatment options.

Poster Title: Use of Vaxchora (PXVX0200) as an active immunization against cholera: Evaluation of clinical trials

Primary Author: Jinhee Lee, Palm Beach Atlantic University, Florida; **Email:** ginny0211@gmail.com

Purpose: As there are a growing number of travelers from the US to over 50 cholera endemic countries, vaccination for cholera has become important. However, there has not been a vaccine that was approved by FDA until Vaxchora, the only cholera vaccine licensed for use in the US from June 2016. The purpose of this study was to evaluate whether Vaxchora satisfies the need for a prophylaxis of cholera that requires only one dose while still maintaining safety and efficacy.

Methods: FDA approved three different phase 3, randomized, double-blind, and placebo-controlled group studies. For each study, patients completed informed consent and screening procedure, and met inclusion criteria and not exclusion criteria before randomization. The first study assessed efficacy and safety of a single dose of PXVX0200 against Vibrio cholera O1 E1 Tor Inaba at 10 days or at 3 months post vaccination in healthy volunteers aged 18-45. The primary outcome was the occurrence of moderate or severe diarrhea to assess the vaccine efficacy. The secondary outcome was evaluating effect of vaccination on disease severity. The second study demonstrated the consistency of three different production lots of the vaccine. Patients who participated in this study were also aged 18-45 and each individual was scheduled for at least three visits for screening. The primary outcome was to assess vibriocidal activity against the classical Inaba biotype of Vibrio cholera with pre-specified the two-sided 95 percent CI around each pairwise ratio of GMTs being within 0.67 to 1.5. The third study assessed the equivalence in immune response of PSVX0200 in older adults aged 46-64. The primary outcome was assessing seroconversion by vibriocidal antibody against Vibrio cholera O1 E1 Tor Inaba at 11 days after vaccination with lower limit of the CI being within 10 percentage of the rate in young adults.

Results: In the first study, the single dose of PXVX0200 demonstrated vaccine efficacy of 90.3 percent with 95 percent CI (68.8 percent to 99.2 percent) at 10 days against moderate or severe diarrhea and it demonstrated vaccine efficacy of 79.5 percent with 95 percent CI (51.1 percent to 96.3 percent) at 3 months against moderate or severe diarrhea. In the second study, the two-sided 95% CI for each pair of lots was within the pre-specified CI interval of 0.67 to 1.5. In the third study, 90.4 percent of older adults had seroconverted by traditional Inaba vibriocidal antibody with 95 percent CI (86.4 percent to 93.5 percent). The lower limit of the two sided 95 percent CI on the difference in seroconversion between older and younger adults were -7.2 percentage points which was within the pre-specified margin range. All the primary outcome were met for the three studies and non-inferiority of the vaccine efficacy for individuals aged 45-64 versus those aged 18-45 has met for the third trial.

Conclusion: Based on the three trials, Vaxchora (PXVX0200) has proven efficacy and safety against vibrio cholerae serogroup O1 in adults aged 18-64 traveling to cholera-affected areas and shown the lot consistency of the vaccine. Additionally, Vaxchora offers a better dosing regimen by requiring a single dose compared to previous vaccines which required two doses. The limitation of the studies was that the safety and efficacy of Vaxchora have not been established in individuals living in cholera-affected areas and immunocompromised individuals. Furthermore, long term safety and benefits regarding control of cholera should be studied to assess overall clinical relevance.

Poster Title: Evaluation of hepatitis C genotype prevalence and their treatment approach at a healthcare system

Primary Author: Xaviera Pascale Djoko Mekouguem, Texas Southern University, Texas; **Email:** xapascale@yahoo.fr

Additional Author (s):
Chisom Ejekam
Candace Cooke
Abdul Gabisi Jr
Enock Anassi

Purpose: Hepatitis C virus (HCV) has high degree of genomic variability and rapid mutations. It chronically affects up to an estimated 180 million people globally. It is the principal cause of death from liver disease in the United States. Due to the varied genotypes and subtypes, treatment response for HCV is unpredictable at best. Until recently, interferons and ribavirin remained the main stay of therapy. The purpose of this study is to assess the genotype prevalence of HCV at healthcare system and analyze the current treatment approach and outcome considering the advent of new drug regimens.

Methods: The institutional pharmacy and therapeutics committee approved the evaluation of drugs used for treatment of hepatitis C. A report of patients that were being treated for hepatitis C infection was obtained for a period of one year. A total of 88 patients were identified and evaluated with regards to the drug regimen and the outcome measures were documented. The following data were collected for each patient; gender, race, weight, HCV genotypes, tests including liver biopsy, assessment of tolerability, side effects, safety of each drug regimen, cost, duration of therapy, drug regimen changes and reasons for change. In addition to data collected above, the efficacy or treatment response using rapid virological response (RVR), early virological response (EVR), sustained virological response or null responders were documented. Cost analysis of the various drug regimen and potential cost savings were performed. An assessment of the cost for treating side effects of each drug regimen such as interferon and ribavirin was documented. Also, the impact of patient assistance program in treating HCV was evaluated.

Results: Of the 88 patients, 29 were Black, 22 were Caucasian, 20 were Hispanics, 8 were Asian, and 8 were unidentified. There were 38 subtypes 1a, 8 subtype 1b, 16 subtype 2b, 9 subtype 2 unknown, and 17 subtypes 3a. Hepatitis score for biopsied patients showed 15 patients with mild scores, 10 moderate scores, and 2 with severe scores. Sixty-four of patients evaluated were naïve patients. Fifteen patients had failed interferon with ribavirin while one patient was on a repeat therapy of ribavirin and sofosbuvir. Another patient was on a repeat treatment with ribavirin, interferon and sofosbuvir while eight patients had failed some undocumented therapy. Sixty percent patients achieved a rapid virological response (RVR) at four weeks. By 12 weeks of treatment 74 percent (65) of the patients had undetectable levels of HCV. By the end of treatment of 12 or 24 weeks, 11 percent (10) were unable to achieve detectable levels. The treatments of 4 of these 10 patients were discontinued due to side effect. Fifteen percent (13) had unknown HCV levels upon completion of their regimen. All of the 88 patients were treated with medication obtained from patient assistance program therefore was cost free to the institution.

Conclusion: Significant advances have been made in the treatment of HCV infection when you take into account the use of the new highly expensive class of drugs with different mechanism of actions and less side effects. Of the six main hepatitis C genotypes, subtype 1a was the most prevalent at out institution. The use of the new drugs decreased the duration of therapy and caused few less side effect compared to old drug regimen. The use of patient assistance program has afforded our institution to treat this fatal infection without incurring cost.

Submission Type: Descriptive Report

Session-Board Number: 5a-281

Poster Title: Evaluating the value of the Rothman Index (RI) in predicting and reducing hospital readmission

Primary Author: Michelle Chawla, Ernest Mario School of Pharmacy, New Jersey; **Email:** mgchawla31@gmail.com

Additional Author (s):
Gyu Hyun Bae
Brenda Ho

Purpose: Hospital readmission is a major issue in the United States healthcare system today, with most hospitals failing to identify high risk patients. The Rothman Index is a clinical tool used by hospitals that summarizes a patient's data, allowing physicians, nurse practitioners, and pharmacists to track a patient's status. The purpose of the study done at Yale-New Haven Hospital was to evaluate whether the Rothman Index effectively predicts patients who are at high risk for readmission, which would then allow healthcare providers to make interventions that would reduce readmission rates as well as costs.

Methods: Utilizing information from the hospital EMR system, the Rothman Index automatically generates a single score every hour using 26 clinical elements which include vital signs, laboratory values, and nursing assessments. RI score ranges from 0 to 100, with lower scores indicating poorer condition. Data on patients' RI scores at discharge and their frequencies of readmission were collected from 2,700 patients during a 5 month period. Readmission information was used to rank the Rothman Index scores into 4 categories containing patients at highest risk (RI < 70), medium risk (RI = 70–79) , low risk (RI = 80–89), and lowest risk (RI > 90). Data analysis was done to determine the statistical association between high risk groups and the likelihood of readmission within 30 days.

Results: Using the 4 risk categories established by researchers, the study found a correlation between the Rothman Index and readmission rates. Patients in the highest-risk category, with a Rothman Index less than 70, had a 20% readmission risk. Meanwhile, the risk for readmission was only about 10% for patients placed in the lowest-risk category, which corresponds to a Rothman Index of 90 or greater. Comparing the two risk categories, researchers determined

that within 30 days of discharge, patients placed in the highest risk category were two and a half times more likely to be readmitted than patients in the lowest risk category, and the correlation was statistically significant.

Conclusion: The Rothman Index is a helpful clinical tool that promotes efficient patient care in hospitals. Through earlier detection of patients at high risk for readmission, the Rothman Index can initiate communication among healthcare professionals to provide more effective interprofessional care to patients which would ultimately lead to reduction of hospital costs. The Rothman Index adds value to all areas of the hospital, including the clinical pharmacist, who could use the Index to optimize treatment options for these patients and provide interventions through counseling and medication planning at discharge.

Poster Title: Defining humanized dosing strategies of cefepime.

Primary Author: Leighton Becher, Midwestern Universitry Chicago College of Pharmacy-Downers Grove, Illinois; **Email:** lbecher55@midwesteren.edu

Additional Author (s):
Cristina Miglis
Gwen Pais
Marc Scheetz

Purpose: Treating bacterial infections is becoming increasingly difficult with rising antibiotic resistance, necessitating higher concentrations of broad spectrum antibiotics to be used. Cefepime is a broad spectrum cephalosporin used in Gram negative bacterial infections. Neurotoxicity is a known dose limiting side effect; however, little is known about the actual cause of the neurotoxicity. Thus animal models, such as the rat model, are important to understanding the exposure-toxicity relationship. We are developing a humanized exposure scheme to mimic human exposure profiles in the rat.

Methods: Male and female Sprague Dawley rats (~300g) were used for the experiments. Clinical grade cefepime was infused in a step-wise decreasing rate intended to mimic human exposure profiles (i.e. 1 gram given over 30 minutes). Exposure profiles were determined from internally held data on both human and rat pharmacokinetics for cefepime. Simulations were performed in Monolix (Lixoft, Antony, France). The cefepime was infused to the rat through a dedicated venous jugular catheter, blood samples were obtained from the contralateral catheter. Rats were connected to an infusion system that allows for free movement in the cage. Blood samples were obtained at 30, 60, 150, 240, 330, and 360 minutes, with normal saline replacing withdrawn volume. Plasma was prepared, and cefepime levels were determined using a validated high performance liquid chromatography assay. Data were modeled in Monolix using a 2-compartment structural model, and pharmacokinetic parameters were calculated in Stata V.14 (Stata Corporation, College Station, Texas).

Results: Two rats have successfully completed the protocol. A simulation of mean human exposure profiles for cefepime 1 gram given over 30 minutes resulted in an area under the concentration curve of 102.01 mg*h/L (time 0 to Tmax) and a Cmax of 58 mg/L. Infusion schemes in the rat of 200 mg/hr (1 hr), 100 mg/hr (1.5 hr), 66.7 mg/hr (1.5 hr), 46.7 mg/hr (1.5 hr) and 33.3/hr (0.5 hr) resulted in a similar profile. Rat pharmacokinetic parameters were: area under the concentration curve of 98 mg*h/L (time 0 to Tmax) and a Cmax of 65 mg/L.

Conclusion: Humanized profiles of cefepime are possible in a rat model.

Poster Title: Student pharmacist efficiency in reducing medication reconciliation errors in the emergency department

Primary Author: Daniel Whitehouse, The Ohio State University College of Pharmacy, Ohio; **Email:** whitehouse.34@osu.edu

Purpose: Medication reconciliation is an essential step to admitting patients from the emergency department (ED). By completing this service, the hospital ensures patients continue therapy with all current medications, have complete medication history on record, and decrease the likelihood of adverse drug events. Hospitals with comprehensive medication reconciliation programs have been shown to decrease patient medication errors, adverse events, and readmissions. The purpose of the study was to evaluate student pharmacists' ability to correct medication history errors after focused medication reconciliations completed by other healthcare professionals in the ED. Student pharmacists interviewed and completed full medication reconciliation sessions with patients.

Methods: A retrospective study analysis was conducted on data gathered between July 2013 through June 2016. Student pharmacists' impact was evaluated by the number of discrepancies they identified during medication reconciliation sessions. These were classified in three categories: addition of medications, removals of discontinued or incorrect medications, and clarifications of medications such as frequency or dose changes compared to histories completed by previous staff members. Student pharmacists left a note with recommendations and any actions taken on the patient medication lists with a chart note. These chart notes were reviewed and co-signed daily by ED pharmacists. While all notes were reviewed, approximately 20 percent of student pharmacists' notes were randomly audited for accuracy by a licensed pharmacist throughout the study period. These audits served as the data pool evaluated during this study.
Primary outcomes aimed to quantify and qualify student pharmacists' changes to medication lists in the ED. Secondary outcomes quantitatively assessed the time it took for individual student pharmacists to complete medication reconciliation sessions over the course of the study period.

Results: Primary outcomes found student pharmacists made at least one change to an average of 82.5 percent of medication histories they reviewed. There were 1,286 additions, 1,553 removals, and 2,396 clarifications with an average of 0.5 errors per medication reviewed. A total of 11,999 medications were analyzed. An average 2.5 changes per patient was made ranging from 0 to 9 additions, 0 to 11 removals, and 0 to 28 clarifications. The number of discrepancies increased linearly with the number of medications the patient was taking. Secondary outcomes found student pharmacists spent an overall average of 22.9 minutes on each medication reconciliation review session. The average time spent on each session decreased from 26.2 minutes to 20.0 minutes from the program's initiation. The length of time for medication reconciliations increased related to the number of patient's medications. Additional findings discovered the more medication reconciliation sessions that a student pharmacist completed, the lower their average time spent per session.

Conclusion: Student pharmacists identified many medication reconciliation history errors in the ED. They were able to identify 1 error for every 2 medications, even after nurses or prescribers completed and updated patient medications. Student pharmacists had both the time and knowledge to focus on obtaining accurate and complete medication reconciliation in the ED. Moreover, they were able to perform more sessions in less time, with the same accuracy, as the number of completed sessions increased. Student pharmacists' services can be utilized with patients to ensure the safe and effective continuation and initiation of medication therapies during their inpatient hospital stay.

Submission Type: Evaluative Study

Session-Board Number: 5a-284

Poster Title: Validity of exceptions used in cost-saving clinical algorithms

Primary Author: Tosan Isemede, University of Arizona College of Pharmacy, Arizona; **Email:** isemede@pharmacy.arizona.edu

Additional Author (s):
Anthony Sandoval
Paloma Apodoca
David Nguyen
Shepin Werner

Purpose: Drug-drug interactions are preventable medication errors that increase mortality. We analyzed clinical algorithms developed by SinfoníaRx—a telephone based ambulatory care pharmacy that provides Medication Therapy Management (MTM) for Medicare Part D enrollees and commercial health plans. This healthcare company uses clinical algorithms to check for cost-saving opportunities, dose optimization, guideline-based interventions, adherence issues, drug-drug interactions, drug-disease interactions, and duplicate therapy. These algorithms are programmed to not recommend drugs that can interact with patients' current medication lists during the medication reconciliation process. The objective of this study was to evaluate the validity of the drug-drug interactions used by these algorithms.

Methods: In this quality improvement project, we identified errors of 'commission' and 'omission' in SinfoníaRx's exception list of 326 drugs for the following four drug classes: bisphosphonates, overactive bladder medications, nondihydropyridine and dihydropyridine calcium channel blockers. A drug exception was defined as the presence of a drug that makes the SinfoníaRx recommendation inappropriate, such as a drug-drug interaction with concomitant medications. When a patient meets a drug exception, SinfoníaRx's algorithm will not populate the cost-savings recommendation for the patient. The medications that SinfoníaRx recommends to patients were inputted into four reputable clinical resources: Micromedex, Facts and Comparisons, Lexicomp, and Medscape, LLC. The results were then compared against drugs that comprise SinfoníaRx's list of exceptions to determine if drug-drug interactions were present. Drugs included in SinfoníaRx's list of exceptions, but not noted in the four clinical resources were labeled 'errors of commission'. Key drug interactions missing from SinfoníaRx's

list of exceptions were deemed 'errors of omission'. Error rates were calculated by taking the total amount of errors in each class of medications and dividing by the total number of medications present on the exception list. For errors of omission, the denominator used was the total number of exceptions including the new drugs to be added.

Results: Among the 326 drug exceptions evaluated, there were nine bisphosphonates, 105 overactive bladder medications, 198 nondihydropyridine calcium channel blockers, and 14 dihydropyridine calcium channel blockers. Descriptive statistical analysis yielded a zero percent commission error rate for the bisphosphonates, overactive bladder medications and dihydropyridine calcium channel blockers. The nondihydropyridine calcium channel blockers had a commission error rate of 0.5 percent. The omission error rates were 10 percent, 6.2 percent, and 39.1 percent for the bisphosphonates, nondihydropyridine calcium channel blockers and dihydropyridine calcium channel blockers, respectively. The overactive bladder medications had an omission error rate of zero percent. The identified errors were reviewed by SinfoníaRx's clinical committee and adapted into their formal clinical algorithms.

Conclusion: With the reduction of drug interactions and other medication-related problems, medication therapy management services have the potential to alleviate financial burden on patients, increase adherence, and improve patient outcomes. The percentage of errors identified within each of the four clinical algorithms demonstrates the need for ongoing review to ensure appropriateness and patient safety. One limitation of the study included different severity ratings among the four clinical resources that may have led to inter-rater bias. It is crucial that SinfoníaRx continuously review its evidence-based data to ensure that their algorithms are accurate.

Poster Title: Healthcare curriculum influences on mental illness stigma; Focused interventions and MHFA certification improves student perceptions

Primary Author: Whitney Sargent, University of New England, Maine; **Email:** wsargent@une.edu

Additional Author (s):
Ashley Chace

Purpose: Healthcare professionals' lack of training in the treatment of psychiatric patients, coupled with the obstacle of stigma, prevents patients from seeking and receiving appropriate care. The purpose of this study is to assess if targeted course interventions and Mental Health First Aid USA Certification can improve student stigma toward mental illness.

Methods: This quasi-experimental study was approved by the University of New England (UNE) Institutional Review Board. Twenty third-year (P3) pharmacy students were surveyed using the Opening Minds Scale for Healthcare Providers (OMS-HC) before and after completing the two-credit elective course "Treatment of Psychiatric Patients." The development of this elective was driven by a previous IRB approved study in 2013 at UNE which utilized the OMS-HC to evaluate stigma in healthcare students (95/79 pharmacy, 47/38 nursing, 12/11 social work) pre and post didactic psychiatric coursework. These 2013 findings showed no statistical improvement of stigma, and therefore a need for more focused training. The elective course addressed the negative social impact providers can impose on patients and the barriers it creates for proper treatment. This course was the first to include 8-hour training for Mental Health First Aid USA Certification from the National Council for Community Behavioral Healthcare and NAMI Maine. The course also included a panel of speakers through NAMI to discuss living with a mental illness, a book review of an autobiography by a woman with schizophrenia, a review of neurobiology causing psychiatric illness, and focused topic reviews in primary psychiatric disorders (schizophrenia, mood disorders, dementia, substance abuse, child and adolescent disorders, and ethical dilemmas in psychopharmacology relating to cognitive performance enhancing medications).

Results: Change in stigma was measured both pre and post didactic psychiatry coursework for pharmacy, nursing and social work students. This didactic coursework influenced no significant statistical changes in all three majors. Students enrolled in the psychiatric pharmacy elective course demonstrated statistically significant decrease on each question of the survey (p< 3.558×10^{-3} - to 2.29×10^{-8}). Pre-coursework survey results from the twenty pharmacy students demonstrated a mean total score of 37.00 (±5.32, range 28-45). When compared to post-course survey results, the mean total score decreased to 26.05 (±4.62, range of 17-32), thus demonstrating statistical significance (p=1.429×10^{-10}).

Conclusion: A mental health diagnosis carries many social implications that negatively affect patients' access to quality care. Healthcare providers should be more aware of the barriers patients endure to ensure their own personal stigma does not compromise patient treatment. Previous research suggests didactic curriculum does not likely reduce stigma toward mental illness. The impact of a focused elective on how to best treat psychiatric patients statistically improved attitudes for personal disclosure and attitudes toward people with mental illness. This suggests that focused psychiatric interventions have a positive impact on reducing stigma, making implementation into pharmacy curriculum an essential consideration.

Primary Author: Ashley Tinney, Campbell University College of Pharmacy and Health Sciences, North Carolina; **Email:** artinney0511@email.campbell.edu

Additional Author (s):
Kristopher Kindborg
Timothy Hinson
Michael Jiroutek

Purpose: Guidelines for the treatment of hyperlipidemia have always emphasized lifestyle modifications in addition to pharmacological interventions. The use of statins to treat hyperlipidemia has decreased serious cardiovascular events and their use has expanded with changes to the guidelines. Recent studies show that statin users are not adhering to a proper diet which suggest a lack of diet/nutrition education counseling by physicians.

Methods: Cross sectional study design using the 2006-2010 NAMCS, with a total study population of 2,370 patients. Primary objective is to determine if there is an association between the year of visit and the proportion of patients provided diet/nutrition education counseling. Secondary objective is to determine if there is an association between the year of visit and the proportion of patients provided exercise education counseling. Tertiary objective is to determine if there is an association between the proportion of patients provided diet/nutrition education counseling and each of the following variables: year, age, race, sex, ethnicity, BMI, geographic region, primary care physician, MSA, diabetes and hypertension. Quaternary objective is to determine if there is an association between the proportion of patients provided exercise education counseling and each of the following variables: year, age, race, sex, ethnicity, BMI, geographic region, primary care physician, MSA, diabetes and hypertension. Perform a chi-square test of homogeneity for primary/secondary objectives. Perform a chi-square test of association for the tertiary/quaternary objectives and include any variable with a $p < 0.2$ in a multivariate logistic regression. Sample size estimate of 3,620 patients and have an 89% chance to detect as little as a 5% difference between the groups.

Results: For the primary analysis, 30.8% of patients in the study population for the years 2008-2012 received diet/nutrition education counseling, compared to 39.1% of the patients in the study population for the years 2006-2007 (OR 0.69 [95% CI 0.46-1.04], p=0.08). For the secondary analysis, 24.8% of patients in the study population for the years 2008-2010 received exercise education counseling compared to 24.6% of patients for the years 2006-2007(OR 1.01 [95% CI 0.65-1.57], p=0.97). For the tertiary analysis, the only variables that were significant were Region West vs. Northeast, Region South vs. Northeast and receiving a diagnosis of diabetes. For the quaternary analysis, Sex (OR 0.72 [95% CI 0.56-0.93]) and diabetes diagnosis (OR 1.86 [95% CI 1.31-2.65]) were found to be significant in the multivariate model.

Conclusion: Our study found a lack of diet/nutrition & exercise education counseling, as less than half of the statin using population is receiving proper education counseling. This may help explain the poor dietary habits of statin users explained in previous studies. There is a need for more educational resources to properly educate physicians on providing diet/nutrition education counseling. If physicians are unwilling or unable to provide proper counseling, greater interprofessional collaboration among healthcare professionals can help fill this gap.

Poster Title: Evaluation of students' perceptions of physical assessment videos

Primary Author: Marvin Ortiz, Western University of Health Sciences College of Pharmacy, California; **Email:** mrortiz@westernu.edu

Additional Author (s):
Divvjyot Singh
Maribel Garcia
Hyma Gogineni
Marie Davies

Purpose: Physical assessment (PA) training should be incorporated into PharmD curriculum as part of accreditation standards and to continue advancing pharmacy practice. Since many pharmacy preceptors do not perform physical exams, students on experientials do not always get hands-on training. To help students become proficient in performing physical exams, student-produced videos covering vitals, HEENT, cardiac, pulmonary, abdominal, musculoskeletal, and neuromuscular examinations were created to supplement instruction. The purpose of this study was to assess students' perceptions of these videos and their confidence in PA and evaluate if student perceptions correlated to predictors in performance on a PA written exam and practicum.

Methods: This IRB-approved study included P1 students during 2015-2016. P2 Students produced 7 PA videos and posted them on Blackboard for P1 students viewing during 2 semesters (fall and spring) in which PA is taught in curriculum. P1 Students take their comprehensive PA practicum and written exam in the spring of 2016. P1 students Student perceptions were assessed via a post-course survey utilizing a 4-point Likert scale (A = strongly agree; D = strongly disagree). A non-investigator, linked the survey responses to individual student performance (written exam and practicum) via random ID numbers. Statistical analysis included chi square for categorical data and linear regression for continuous data.

Results: Of 112 P1 students, the average score on the written exam was 88% and the average score on the practicum was an 81%. Every student completed the survey and 106 students watched at least one PA video. Of the 106, 79% reported they could not have achieved the same results without the PA videos. Over 80% of students agreed/strongly agreed on 10 of 12 survey items assessing increased perceived confidence in PA skills including abdominal, neuromuscular, musculoskeletal, HEENT, and pulmonary exams, in addition to obtaining vitals and using cardinal techniques: inspection, auscultation, and palpitation. The most viewed video was the abdominal examination, viewed by 98 students. Students who use PA skills at work or rotations were more likely to score above average on the written exam (P=0.03). Students who watched the PA videos two or more times were more likely to score above average on the written exam than students who watched the PA videos once or not at all (P=0.005). There were no statistically significant predictors for the practicum scores.

Conclusion: Student-produced PA videos were well received by students. Students who watched the videos twice or more and students who utilized PA skills outside of the classroom were more likely to score above average on the written examination.

Poster Title: Evaluation of appropriateness of carbapenem usage and the incidence of multi-drug resistant microorganisms for potential carbapenem restrictions by antibiotic stewardship program (ASP)

Primary Author: Stacy Harmon, University of the Pacific Thomas J. Long School of Pharmacy, California; **Email:** s_harmon2@u.pacific.edu

Additional Author (s):
Lena Kang-Birken

Purpose: Since the implementation of an Antimicrobial Stewardship Program (ASP) at an acute, teaching hospital, the overall antibiotic usage decreased significantly. However, a recent antibiotic utilization report showed a higher usage of ertapenem in comparison to other hospitals regionally and nationally. Furthermore, inappropriate usage of meropenem was thought to be increasing, prompting the ASP to consider restricting carbapenems. This study was designed to evaluate the appropriateness of meropenem and ertapenem prescriptions and to assess the prevalence of multi-drug resistant (MDR) microorganisms including extended spectrum beta-lactamase (ESBL) producing gram-negative bacilli to determine the need to restrict carbapenems.

Methods: Daily anti-infective list from Allscript was used to collect patients who received at least one dose of meropenem or ertapenem between August 15 to September 16, 2016. Patients were excluded if they received a carbapenem in the emergency department and was not continued after admission. Chart review was performed prospectively. Demographics data included age, gender, weight, and comorbidities. Risk factors for antibiotic resistance were collected such as place of residence, recent history of hospitalization and antibiotic use. The location of the patient and the prescribing physicians were noted to identify a particular prescribing pattern in a service. Criteria of appropriateness of the indication for empiric use was derived from clinical practice guidelines such as surgical prophylaxis and febrile neutropenia from the Infectious Diseases Society of America. Other criteria included history or documentation of ESBL or MDR microorganisms, clinical failure after a prolonged exposure of broad spectrum antibiotics or recommendation by infectious disease specialist or ASP. Length

of therapy was collected and de-escalation was documented based on the microbiologic outcome and clinical response.

Results: During 5 weeks, there were 86 carbapenem orders. Of 49 ertapenem cases, average age was 60 years (19-94). About half of the patients had co-morbidities, primarily diabetes, pulmonary, and renal impairment (50, 42, and 33 percent, respectively). Most came from home, but 35 percent received antibiotics recently. Majority of usage was appropriate (96 percent), and the most common indications were intra-abdominal infection or surgery (43 and 16 percent, respectively). Seven patients had a history of an ESBL organism. Average length of therapy was 3.4 days (1-14). De-escalation was made in 14 patients, but delayed in 8 of those patients. Of 37 meropenem patients, average age was 67 years (26-91). Seventy percent of patients had co-morbidities, primarily diabetes and renal impairment (42 percent, both). About half of the patients had recent history of hospitalization or antibiotic use (43 and 51 percent, respectively). Eighty-six percent received meropenem appropriately. The most common indication was severe sepsis, unresolved on broad spectrum antibiotics (49 percent). Seven patients had histories of ESBL or MDR organism, but there were 2 new cases of MDR Pseudomonas aeruginosa and ESBL E. coli. Average length of therapy was 4.8 days (1-20). De-escalation was made in 26 of potential 28 patients.

Conclusion: While the appropriate usage was high in ertapenem, there was a delay in de-escalation. Meropenem was prescribed appropriately less often and the length of therapy was longer, suggesting the need to not only restrict the usage but to develop appropriate criteria. Furthermore, the high prevalence of ESBL and MDR microorganisms demand the judicious use of carbapenems. The ASP will present the findings to the staff as well as the appropriate usage guideline. Finally, both meropenem and ertapenem orders will be reassessed by the ASP after 72 hours for opportunities to de-escalate more timely.

Poster Title: Assessment of student leadership effectiveness in an interprofessional collaborative program to reduce falls in older adults

Primary Author: Michael Farr, California Health Sciences University, California; **Email:** farr314@chsu.org

Additional Author (s):
Luma Munjy
Huma Ibrahim
Julie Marty-Pearson
Toni Tyner

Purpose: The inter-professional collaborative practice (ICP) core competencies underpin the student-led Senior Awareness and Fall Education (SAFE) program. The SAFE program conducts assessments led by physical therapy, pharmacy, nursing and kinesiology students to determine fall risks in older adults. In December of 2014 pharmacy students were integrated into SAFE inter-professional teams. Two student leaders were appointed to 1) develop a SAFE-specific online video that reinforced ICP core competencies, 2) serve as student preceptors for incoming pharmacy students; and 3) assess medications with fall risks. The purpose of this study is to assess pharmacy students' leadership effectiveness in improving the SAFE program.

Methods: A script for an online training video was developed in collaboration with California Health Sciences University and the Department of Physical Therapy and School of Nursing at California State University of Fresno. This SAFE-specific online video was created which focused on 1) risk factors for falls and 2) ICP core competencies on roles and responsibilities, team work, communication, and values and ethics. All new students to the SAFE program were encouraged to attend an ICP orientation and simulation workshop prior to the SAFE screening program with all involved disciplines. During the ICP orientation, the pharmacy student leaders trained the new pharmacy students to the roles and responsibilities of the pharmacist and the use of resources to review medications with potential fall risks. On the day of screening, the pharmacy student leader served as a team captain to assure effective team performance. A Likert scale of 1 = strongly disagree; 2 = Disagree; 3 = Neutral; 4 = Agree; 5 = Strongly agree was used in the

survey questionnaire to assess leadership effectiveness. The study received IRB exemption approval.

Results: A total of 19 pharmacy students participated in the SAFE orientation and simulation workshop as well as the SAFE screening. Eighteen pharmacy students completed the post-activity survey for the most recent SAFE balance screening, a 94.7% response rate. A total of eight students reported as first timers to the SAFE program. Sixteen of the 18 students (88.9%) either agreed or strongly agreed that the video enhanced their understanding of the pharmacy student's roles, responsibilities, and scope of practice at the screening program. All students either agreed or strongly agreed that the SAFE student leaders communicated effectively to first-time pharmacy students to improve inter-collaborative group processes in assessing a client's risk for falls. Sixteen of the 18 students (88.9%) either agreed or strongly agreed that the SAFE student leaders exhibited leadership that enhanced their confidence to interview older adults and assess medication risk for falls to the new pharmacy students in the SAFE program. All students either agreed or strongly agreed that the SAFE student leaders enhanced team work and dynamics, served as a helpful resource to identify medications with fall risks, and advanced values of professionalism on the day of screening.

Conclusion: The opportunity to serve as SAFE student leaders has contributed to the development of leadership and professionalism. More importantly, the contribution in the development of educational resource tools, such as the online training video, and train the trainer program has significantly improved the quality and sustainability of an outpatient inter-professional collaborative program to reduce fall risks in older adults.

Poster Title: Student pharmacists' perspective on the use of marijuana in and out of the medical setting

Primary Author: Greta Park, University of Maryland Eastern Shore

School of Pharmacy and Health Professions, Maryland; **Email:** gspark@umes.edu

Purpose: Marijuana has become a controversial topic among the medical community. Currently twenty-five states, the District of Columbia, Guam, and Puerto Rico that have approved the use of medical marijuana. As the use of marijuana becomes more prevalent in society it is important that student pharmacists are prepared for any questions that they may receive. A survey was sent out to the pharmacy students of the University of Maryland Eastern Shore (UMES) School of Pharmacy and Health Professions. The program is a three year program, this survey was sent by email and participation was voluntary. This survey contained 16 questions, collecting information about the student's demographics, their history with marijuana, their political perspective in regards to societal problems, and to assess their clinical knowledge of marijuana. One hundred and fifteen students completed the survey. Of these participants, forty were from the first year class (P1), thirty-four were from the second year class (P2), and forty-one were from the third year class (P3).

The majority of the students in this survey (82.6 percent) agreed that the School of Pharmacy should include training about the risks and benefits of medical marijuana. Eighty percent of students also agree that the School of Pharmacy should include training of how to counsel a patient on the use of medical marijuana.

Most of the third year students (63.4 percent) stated that a patient should clinically fail other prescription drugs first, while only 25 percent of the P1 students and 17.6 percent of the P2 students agreed (p less than 0.05). Interestingly the P2 class had the highest rate in favor of legalization of marijuana for medical use (P1 equal to 65 percent, P2 equal to 91 percent, P3 equal to 73 percent; p less than 0.05), although the majority of all students were in favor the legalization.

It was interesting to see that even if a student knew someone who had abused marijuana to the point where it negatively impacted that person's life or if they knew someone that had been arrested because of marijuana, it did not have an effect on if they thought marijuana should be legalized for medical use or decriminalized for recreational use.

There was also no significant relationship between whether a student described themselves as liberal, moderate, conservative, or libertarian in regards to social issues and whether they thought that marijuana should be decriminalized for recreation or legalized for medical use. The majority of students thought that marijuana should be legalized for medical use regardless of their political philosophy. The split was more even when they were asked if marijuana should be decriminalized for recreational use, but there was not any relationship seen with political philosophy.

The Drug Enforcement Agency (DEA) currently lists marijuana as a Schedule I drug, meaning that is has high potential of abuse and that it does not have an accepted medical use. However, more states continue to legalize the use of medical marijuana and decriminalize the recreational use. Therefore it is necessary that pharmacy school prepare their students to be able to counsel on the use of medical marijuana.

Poster Title: Development of a structured approach to assess the competency management needs for a health-system pharmacy

Primary Author: Emily Tsiao, Auburn University Harrison School of Pharmacy, Alabama; **Email:** egt0004@auburn.edu

Additional Author (s):
Todd Nesbit

Purpose: In order to select a sustainable competency assessment framework for the health-system pharmacy, an internal needs analysis was conducted to determine what features and characteristics of a competency management system (CMS) would be most beneficial for the users. Specific requirements were identified, which allowed stakeholders to evaluate the commercially available competency management systems based on the organizations' needs.

Methods: A needs analysis was conducted by interviewing the leadership and key stakeholders throughout the organization. Questions focused on how the organization currently manages competency assessments and operational problems. Strategic, operational, and technical drivers were identified and used as guideposts to ensure that the selection criteria and defined requirements align with the organization's goals and priorities. The identified requirements were organized into three categories: functional, technical, and cost. Functional requirements described what the system must be able to do from a competency management perspective. Technical requirements characterized how the system would fit into the existing infrastructure. Cost requirements identified budget considerations, constraints and expectations. Technical standards and constraints were considered as well. A set of vetting criteria was established to exclude non-qualifying products. Vendors were contacted when further description about a product's ability to support each vetting criterion was required.
The strength of a vendor's customer base and financial position were analyzed to determine the level of vendor support for the product and the likelihood that they would continue to improve their product through research and development. Customer references, live demonstrations and a trial version of the CMS products under consideration were requested. Questions posed to customer references were formulated to encourage illustrations of

potential problems and to gauge vendor responsiveness after implementation. For the public companies, financial reports were checked.

Results: The clearly defined and documented requirements, identified through the needs analysis, formed the basis of the CMS selection criteria. The evaluation of the available products was improved through the revising of our requirements to reflect clear, discrete and thoroughly characterized needs rather than a solution. Prioritizing the requirements and focusing on specific user functions within the CMS helped stakeholders decide how well each product met each of the detailed requirements. Stakeholders who were involved in the evaluation activities seemed to have more ownership of the resulting decisions.

Conclusion: A funnel approach was used to narrow the dozens of product options down to the several that best matched the defined requirements. The live demonstrations and access to trial versions provided evidence of a product's capabilities to help either validate or disprove vendor promises. The key element of this approach was the acquisition of buy-in and support from primary stakeholders.

Poster Title: Evaluating the outcome of pharmacy speaker events on student perceptions of the evolving role of pharmacists

Primary Author: Mercy Roman, Roseman University of Health Sciences, Nevada; **Email:** mercyannroman@gmail.com

Additional Author (s):
Anum Rizvi
Desiree Chang
Christina Madison

Purpose: The Roseman University of Health Sciences chapter of the Student College of Clinical Pharmacy introduced an initiative from August 2014 to September 2016 with the core purpose of educating students about clinical pharmacy specializations. To increase knowledge and disseminate information about emerging pharmacy career opportunities, the chapter established a guest speaker series. The series consisted of presentations by healthcare professionals practicing in specialized fields of pharmacy in the Las Vegas metropolitan area. The purpose of our study is to measure the impact of the series on students' awareness, interest, and knowledge of career advancement in pharmacy.

Methods: The chapter hosted 17 presentations, featuring pharmacists and physicians practicing in specialties including cardiology, ambulatory care, clinical pharmacy education, community pharmacy, and academia. The guest speaker events were open to any P1, P2, or P3 student at the Roseman University of Health Science Henderson campus. Attendance was recorded for each event. Students who participated in at least one guest speaker event were asked to complete a survey by September 15, 2016. The study excluded students who did not attend a guest speaker presentation. The survey consisted of ten questions using a measured Likert-type scale, assessing baseline knowledge of clinical pharmacy, student benefit, variety of specializations, quality of presentations, and additional questions regarding interest in residency programs. Subsequently, the data was analyzed to determine the end result of the guest speaker series on awareness, interest, and knowledge of various clinical pharmacy specialties.

Results: Students who participated in the series attended some or all of the lectures. Of the 259 students who participated, 196 (76 percent) students completed the survey. The majority of students indicated the presentations provided more insight into clinical pharmacy, with 59 percent reporting average baseline knowledge of clinical pharmacy prior to attending. Additionally, 66 percent agreed the topics presented will help them decide a professional path in clinical pharmacy. Furthermore, 87 percent of students agreed that the information that was presented benefited them, while 81 percent "strongly agreed" their knowledge of pharmacy would benefit from the implementation of a residency/fellowship education program.

Conclusion: Through the application of structured guest speaker events, our chapter gave student pharmacists the opportunity to gain information regarding career opportunities and promote students to pursue careers as clinicians. Our results demonstrate that attending these guest speaker events improved students' knowledge regarding post-graduation opportunities in clinical pharmacy. We conclude the series provided student pharmacists with beneficial awareness of clinical pharmacy specialties and students are more likely to pursue postgraduate training.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Session-Board Number: 5a-293

Poster Title: Evaluation of the use of Ceftaroline or Daptomycin or Vancomycin

Primary Author: Richard Lee, University of Washington, Washington; **Email:** richwlee@uw.edu

Purpose: The purpose of this drug use evaluation (DUE) is to evaluate the usage of antibiotics used to treat methicillin-resistant staphylococcus aereus (MRSA) and other resistant organisms. CHI Franciscan and MultiCare use a range of antibiotics to treat resistant organisms based on patient factors. To save costs and maximize care we will investigate the usage of Vancomycin in comparison to Daptomycin and Ceftaroline. The objective of this drug use evaluation (DUE) was to help assess proper medication selection to help the Pharmacy & Therapeutics (P&T) committee review the appropriateness of medication selection.

Methods: A sample retrospective case control cohort was followed from April 2015 – Feburary 2016 involving 77 patients. Patients were examined in regards to their antibiotic treatment regimens via investigative chart reviews. Patients were de-identified and anonymized. Information regarding medication name, medication dose, dosage form, dosing interval, order changes, admission date, provider, indication, culture, duration of therapy, and length of stay were analyzed. Patient records were reviewed to determine if treatment was successful, if patients had adverse drug reactions or drug allergies, and to understand the rational for drug selection. Data was analyzed for trends and a literature review of the 3 medications in this study were conducted.

Results: 77 patient charts with active orders for either Ceftaroline and or Daptopmycin were reviewed. When categorized by length of stay versus duration of therapy a high incidence of longer average length of stays and longer duration of therapy was evident in patients treated with both Ceftaroline and Daptomycin. When categorized by infectious disease provider the trend of a greater use of Daptomycin was evident in comparison to Ceftaroline. A review of the various indications compared to treatment options again reflected a greater incidence of Daptomycin use across all major categories such as bacteremia, bone/joint infection, endocarditis, SSTI, and UTI. Upon review of the use of Daptomycin and Ceftaroline by indication Daptomycin was used exclusively for UTI infections. Furthermore, Ceftaroline was never used for the treatment of endocarditis. The number of patients that actually had MRSA were

consistent at about 30% for both patient groups which involved those treated with Ceftaroline and those treated with Daptomycin. However, the 3rd patient group treated with both ceftaroline and daptomycin had a higher rate of MRSA.

Conclusion: Overall based on qualitative analysis of patient information, the use of alternative agents to Vancomycin were appropriately considered. Factors such as allergy, kidney function, and efficacy were all considered appropriately by ID providers. There are cost considerations in mind, for example Daptomycin costs almost twice as the daily cost of Ceftaroline. A further analysis of why Daptomycin was selected over Ceftaroline or vice versa should be studied in greater depth while considering most cost effectiveness analysis. This further evaluation can help guide future therapy with a cost effectiveness approach to provide clinical sound cost effective pharmaceutical care.

Submission Category: Ambulatory Care

Submission Type: Descriptive Report

Session-Board Number: 5a-294

Poster Title: Description of home-based medication therapy management services in an interprofessional transitional care program aimed at reducing 30-day hospital readmissions

Primary Author: Diana Li, University of North Texas Health Science Center - System College of Pharmacy, Texas; **Email:** dyl0012@my.untschc.edu

Additional Author (s):
Ben Nguyen
Shara Elrod

Purpose: Since the establishment of the Hospital Readmission Reduction Program (HRRP), preventing 30-day unplanned hospital readmissions is crucial for reimbursement by Centers for Medicare & Medicaid Services. Published reports have shown pharmacist interventions after hospital discharge are associated with a smaller incidence of medication errors 30 days after hospital discharge, but most of these reports include pharmacists making follow-up phone calls. No published reports have described home-based pharmacy services as a part of transitional care programs designed to reduce unplanned 30-day hospital readmissions. This project describes the inclusion of a pharmacist as a part of an interprofessional transitional care team.

Methods: Safe Transitions for the Elderly Patient (STEP) is a transitional care program for Medicaid-eligible adults at least 50 years of age who have been recently discharged from the hospital in Tarrant County, TX. Enrolled patients receive an intake home visit from a medical provider within the first 72 hours after discharge which includes referral to other STEP providers (e.g. pharmacists, physical therapists and social workers). Patients on high-risk medications, who are believed to be non-adherent to medications or need short-term medication management were referred to the pharmacist (0.3FTE) for home-based medication therapy management (MTM) services. All patient encounters are documented in an electronic health record (EHR). Risk stratification scores were calculated by including the total sum of each the following parameters: problem meds, psychiatry, polypharmacy, health literacy, patient support, prior hospitalization, and palliative care. High risk stratification scores were defined as those with 5 having or more risk factors. Descriptive statistics were used to characterize the study population. Pearson's chi-square was used to examine the association between categorical variables. Results with a p value less than .05 were considered statistically

significant. Patients enrolled in the STEP program during the time pharmacists provided services were included in this analysis (August 2014 to January 2015 and October 2015 to July 2016).

Results: A total of 366 patients were enrolled in STEP during the specified time frame with 79 being seen by the pharmacist. The mean ages in those who were and were not seen by the pharmacist were 63.4 years (range 50-92) and 66.5 years (range 50-98), respectively (p=0.02). The majority of the patients seen by the pharmacist were women (72%, n=57), which was not significantly different than those not seen by the pharmacist (p=0.44). The median number of medications in those who were and were not seen by the pharmacist were 15 (range 3-38) and 11 (range 1-32), respectively (p=0.0002). Of the patients seen by the pharmacist who reported race/ethnicity, 35.4% identified as Black or African American (n=28). The proportion of all STEP patients with calculated risk stratification score was 93% (n=342). The proportion of patients with high risk stratification scores for those who were and were not seen by the pharmacist were 49% and 57%, respectively (p=0.22). The most common discharge diagnoses for patients seen by the pharmacist were heart failure and COPD exacerbations. Hospital readmission rates were not found to be significantly different in those who were seen by the pharmacist versus those who did not (10%, 14%, p=0.34).

Conclusion: Hospital readmission rates were not significantly different between those patients who were seen by a pharmacist as part of a home-based interprofessional transitional-care team versus those who were not. Overall hospital readmission rates were low for both groups. In this program, patients who saw the pharmacist were more likely to be younger and be taking more medications than those who did not see the pharmacist. Patients who saw the pharmacist did not have significantly higher risk stratification scores than those who did not see the pharmacist. More research is needed to demonstrate the benefit of home-based pharmacy transitional care services.

Submission Type: Evaluative Study

Session-Board Number: 5a-295

Poster Title: Reduction of time to tissue plasminogen activator as a result of pre-hospital lab draws by the Emergency Medical Services.

Primary Author: Abigail Hulsizer, University of North Texas System College of Pharmacy, Texas; **Email:** abigail.hulsizer@my.unthsc.edu

Additional Author (s):
Hiral Gandhi
Caitlin Gibson

Purpose: Tissue plasminogen activator (tPA) is beneficial when given within 4.5 hours of acute ischemic stroke onset, giving patients an increased likelihood to recover without any significant disability within a 3-month time period. Delays in diagnosis and laboratory data can place patients outside the tPA window. In an attempt to shorten time to tPA administration, some emergency medical services (EMS) companies have begun drawing blood for labs in the ambulance. The aim of this study is to determine if laboratory draws inside the ambulance shorten the time to tPA administration.

Methods: This study is a retrospective chart review of patients admitted to a 348 bed community hospital for acute ischemic stroke who received tPA. Patients were included if they were greater than 18 years old, who arrived at the hospital via EMS, have had an ischemic stroke with a clearly defined time of onset, and have met the inclusion criteria for tPA. Each patient's past medical history was obtained and a definitive diagnosis of hypertension or diabetes was used for data collection as well as any past or present history of smoking to assess risk factors for stroke. Patients were excluded if they arrived with rapidly improving symptoms signaling a transient ischemic attack, if they did not have a definitive ischemic stroke diagnosis, and/or if they had the stroke on site and did not have the opportunity to arrive via EMS vehicle transport. The primary outcome was to determine if receiving labs in the EMS significantly reduced door to needle time compared to receiving labs in the emergency department. The secondary outcome was to determine if there were better health outcomes, as determined by discharge NIH scores, in patients receiving tPA within a shorter amount of time due to getting labs in an ambulance. Safety outcomes were adverse events related to tPA, such as

angioedema, intracranial hemorrhage and anaphylaxis within 24 hours. Descriptive statistics were utilized.

Results: Thirty-two patients met inclusion criteria with one patient suffering a repeat stroke making two visits in the past year. Data was only available for 30 of the emergency department visits. The mean age and door to needle time (DTN) were 58.8 years-old and 77.5 minutes respectively. Hypertension, diabetes and smoking history were present in 78.1 percent, 43.7 percent, and 30 percent of patients, respectively. Of those who came by ambulance and data was collected, only 36.6 percent (n equals 11) had labs drawn in route to the hospital. The average DTN for those with labs drawn in the EMS was 77.7 minutes. From the remaining 63.3 percent (n equals 19), the average DTN for the patients who had labs drawn at the hospital was 86.3 minutes. During the study, two patients expired from hemorrhage complications of tPA.

Conclusion: EMS lab draw in patients suspected of acute ischemic stroke was associated with a 8.6 minute decrease in door to needle time compared to patients who had labs drawn at the hospital. The clinical significance of this reduction is small.

Submission Type: Evaluative Study

Session-Board Number: 5a-296

Poster Title: Expression of constitutive RSK1 and phosphorylated RSK1 in breast cancer MDA-MB231 and MCF-7, and prostate cancer PC3 and DU-145 cell lines

Primary Author: Hillary Kerns, Midwestern University, Illinois; **Email:** hkerns88@midwestern.edu

Additional Author (s):
Christopher Osterbauer
Alejandro Mayer
Mary Hall

Purpose: The purpose of this study was to determine if the breast cancer cell lines MDA-MB231 and MCF-7 as well as the prostate cancer cell lines PC3 and DU-145 express both constitutive RSK1 and phosphorylated RSK1 (pRSK1) as a specific drug target in cancer cell therapy. The 90kDa ribosomal S6 kinases (RSK) are serine/threonine kinases that are expressed in a variety of cancers and have been implicated in regulation of cell growth, proliferation and motility.

Methods: MDA-MB231 and MCF-7 are human breast cancer cell lines and were derived from invasive ductal carcinoma. PC3 and DU-145 are derived human prostate cancer cell lines. Protein extracts from the breast cancer (MDA-MB231 and MCF-7) and prostate cancer (PC3 and DU-145) cell lines were prepared and probed by Western blot analysis using constitutive RSK1 (Cell Signaling) and pRSK1 (Epitomics) antibodies.

Results: Constitutive RSK1 and pRSK1 were expressed in the breast cancer MDA-MB231 and MCF-7 as well as the prostate cancer PC3 and DU-14 cell lines. The results show that these enzymes are present in different cell lines of breast and prostate cancer, and thus are potential targets for cancer cell-mediated therapy.

Conclusion: Breast cancer MDA-MB231 and MCF-7 as well as the prostate cancer PC3 and DU-14 cell lines express both constitutive RSK1 and pRSK1. As the RSK family regulates cell growth and proliferation drugs, inhibiting these kinases may reduce the growth of these breast and prostate cancer cell lines. Further research is necessary to evaluate the inhibitory properties of these enzymes to establish their role in the future of cancer treatment.

Session-Board Number: 5a-297

Poster Title: Improving Healthy Lifestyle Attitudes With F.I.G.H.T Nights

Primary Author: Mariam Khan, University of Arkansas for Medical Sciences, Arkansas; **Email:** mkhan2@uams.edu

Purpose: Patients participated in F.I.G.H.T. Nights. These sessions were designed to improve patients' health and wellness through educational seminars, cooking and exercise demonstrations. The goal of the study is to identify barriers that hinder changes in lifestyle and areas for increased education through our F.I.G.H.T Nights.

Methods: F.I.G.H.T. Nights was created to encourage healthy lifestyles in patients by equipping them with the proper tools and educational resources. During each night, patients' participating completed an anonymous pre- and post-survey to assess their attitudes and knowledge regarding their eating habits, exercise, and other obstacles to improve their health and wellness. This was done to track quality improvement for healthy lifestyle changes over the timeframe of the event as well as the benefits of conducting F.I.G.H.T. Nights for all attendees. Demographic information including age, income, and education level are collected.

Results: To date, 27 patients have completed pre- and post-surveys with the anticipation of more patients completing surveys during additional F.I.G.H.T. Nights throughout this year. The results from our pre/post survey's thus far show that most of our participates had little to no knowledge that their current diet was not healthy. As a result of Fight Night more than 70% of our participates had a better understanding of healthy eating and 81% wanted to work out at least 3-4 times/week.

Conclusion: Using the results of the surveys from F.I.G.H.T. Nights, the program can be better tailored to the needs of patients. Additionally, unique insight will be gained to further understand what health care provided interventions could motivate patients to live a healthier lifestyle. Overall we wish to find ways to help lessen the disparity between learning about living a healthy lifestyle and actually acting upon living a healthy lifestyle. Our F.I.G.H.T Nights have provided us the opportunity to be accessible to our patients in a way that is both practical and feasible.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Descriptive Report

Session-Board Number: 5a-298

Poster Title: Medication-use evaluation of concomitant psychostimulant and benzodiazepine prescriptions at a veteran affairs healthcare system

Primary Author: Tram Pham, Washington State University College of Pharmacy, Washington; **Email:** trampham4594@gmail.com

Additional Author (s):
Mckenzie Cody
Kelly Moran

Purpose: Benzodiazepines are often used to treat common comorbidities of adult attention deficit hyperactivity disorder (ADHD) including anxiety and insomnia. While effective for both conditions, benzodiazepines' adverse reactions such as sedation, cognitive impairment and risk of dependence often defers their application to second-tier therapy after other alternatives have failed. Inappropriate regimens of psychostimulants and benzodiazepines increase the risks of adverse reactions. This medication-use evaluation will evaluate the appropriateness of concomitant stimulant and benzodiazepine prescriptions within a rural veterans affairs healthcare system, and identify patients where further investigation and pharmacist intervention may be warranted to improve therapeutic outcomes and patient safety

Methods: This project was approved by the Pharmacy and Therapeutics Committee prior to implementation. Current outpatient prescription data was extracted to identify patients with concurrent psychostimulant and benzodiazepine prescriptions between 3/1/2016 to 6/30/2016. Retrospective electronic medical chart review was conducted to review the initial start dates of both stimulant and benzodiazepine prescriptions, the initial prescribers of both substances, the indications for which a stimulant and benzodiazepine were prescribed, dosing and frequency of both prescribed substances, as well as co-morbid conditions that warranted special treatment considerations such as substance use disorders. Medical history and progress notes were reviewed to identify whether the patient had a failed trial of non-controlled medications to treat anxiety or insomnia before a benzodiazepine was prescribed. All patients were included in the analysis. Medication appropriateness index was employed as a supporting tool for this medication-use evaluation

Results: At the completion of chart reviews, 13 patients were identified to have concurrent stimulant and benzodiazepine prescriptions/orders. Twelve patients were prescribed methylphenidate or amphetamines to treat ADHD; one patient was prescribed modafanil for treatment of fatigue associated with Multiple Sclerosis. Methylphenidate, dextroamphetamine, amphetamine-dextroamphetamine combo were found to be equally prescribed and accounted for 92 percent of psychostimulant prescriptions. Modafanil accounted for the other 8 percent of the total prescribed stimulants. Benzodiazepines were prescribed to five patients with diagnosis of insomnia, to four patients with diagnosis of anxiety, and to three patients to treat both insomnia and anxiety disorder. Commonly prescribed benzodiazepines included clonazepam and lorazepam, which accounted for 54 percent and 15 percent of total number of benzodiazepine prescriptions, respectively. Diazepam and temazepam were equally prescribed; and together, they accounted for 16 percent of prescribed benzodiazepines. Zolpidem prescriptions for the treatment of insomnia in ADHD patients were also included in this study, which made up the other 16 percent of benzodiazepine prescriptions. Out of the 13 patients, five patients did not have a previous trial of a non-benzodiazepine alternatives. Eleven patients were started on stimulants and benzodiazepines by the same prescribers. The prevalence of appropriate stimulant-benzodiazepine regimen was 38 percent.

Conclusion: The result of this evaluation was presented to the Pharmacy and Therapeutic Committee. Clinical education will be provided to prescribers and pharmacists on the recommendation of current practice guidelines toward non-pharmacologic approaches and safer alternative treatment for insomnia and anxiety disorders. Interventions will also focus on preventing the prescribing cascade of controlled substances, whereby a benzodiazepine is prescribed to treat insomnia as an adverse reaction to a stimulant prescription. Using a multidisciplinary approach, appropriate treatment regimen will be formulated to enhance therapeutic outcomes and patient safety.

Submission Category: Geriatrics

Submission Type: Descriptive Report

Session-Board Number: 5a-299

Poster Title: Impact of student led medication reviews on adherence and comprehension of medication therapy in geriatric patients

Primary Author: Anum Rizvi, Roseman University of Health Sciences, Nevada; **Email:** arizvi@student.roseman.edu

Additional Author (s):
Glenys Castro
Christina Madison

Purpose: Brown bag medication reviews serve as a means of medication therapy optimization and reconciliation. Brown bag events allow student pharmacists to apply their pharmacy knowledge to better patient outcomes and advance the role of pharmacists as medication experts. Brown bag events hosted by Student College of Clinical Pharmacy at Roseman University of Health Sciences function as an integral member of the community through outreach and involvement. The purpose of this study is to evaluate patients' adherence and comprehension of medication therapy before and after a brown bag medication review in a geriatric setting.

Methods: Student pharmacists conducted patient interviews. During patient interviews student pharmacists assessed disease states, identified medication interactions and adverse effects, and ensured proper medication usage by providing comprehensive brown bag medication reviews, under pharmacist supervision between November 2014 to May 2016. The study included patients from 5 senior communities within Clark County of Southern Nevada. Patients were given a survey before and after each medication review. This survey was used to assess patients' knowledge of therapy, adherence, chronic medical conditions, number of visits with their primary care provider yearly, and number of current medications. Therapies reviewed consisted of prescription medication, over-the-counter medication, herbal supplements, vitamins, and medical supplies.

Results: Surveys from 78 patients were assessed. Average age of patients was 68 years old (59 - 79 years old) with an average of 8 medications per patient. Before medication review, 40 percent and 54 percent reported knowledge of and adherence to therapy respectively.

Following review, percentages of knowledge and adherence increased to 85 percent and 75 percent respectively. Furthermore, 30 percent of participants reported annual visits with their provider while 58 percent reported 2 or more visits yearly. Patients with hypertension and diabetes reported 2 or more visits yearly. Patients with memory loss and arthritis reported not visiting their primary care provider in over one year. Patients were also surveyed for being first time participants of student led medication reviews. Additionally, 75 percent of patients reported being first time brown bag medication review participants and 15 percent reported having their medications reviewed in the past year.

Conclusion: Student pharmacists participating in brown bag events present a great opportunity to impact senior communities. Brown bag events led to an increase in both patients' adherence and knowledge about their medication therapy. Since elderly patients are more at risk for complications due to chronic disease states, brown bag medication reviews can decrease this risk by reducing inappropriate medication therapy, medication duplication, polypharmacy, medication adverse effects, and fall risks. To optimize patient care, interventions made during each brown bag event can be communicated with the patient's primary care physician. This can improve disease state management and decrease adverse drug reactions.

Submission Category: Emergency Medicine/ Emergency Department/ Emergency Preparedness

Submission Type: Descriptive Report

Session-Board Number: 5b-001

Poster Title: Implementation of a clinical pharmacist in the emergency departments of Puerto Rico hospitals

Primary Author: Suasy Acevedo-Muñiz, Nova Southeastern University, Puerto Rico; **Email:** sa1281@nova.edu

Additional Author (s):
Carlos Hernández
Jesús García
Lianne Meléndez
Lizayra Chapa

Purpose: The pharmacy profession has evolved from dispensing medications to offering clinical pharmacy services to different institution departments, including the emergency department. The objectives are to review the role of the pharmacist within the emergency department on the literature and published data, assess the need of an emergency pharmacist in Puerto Rico hospitals, and contribute ideas on how to implement clinical pharmacy services in the emergency department of hospitals in Puerto Rico.

Methods: A search on Elton B. Stephens company database (EBSCO), Ovid, PubMed, and Latin American and Caribbean Health Sciences Literature (LILACS) was conducted. The articles were selected by title and abstract according to their relevance to the topic. After applying the inclusion criteria, articles were classified to different categories qualitatively by the types of interventions done by the pharmacists. Also, an electronic survey was distributed by email to different health care professionals of hospitals in Puerto Rico.

Results: From 47 articles that were chosen, 26 met the inclusion criteria. Articles were classified under: service modalities, training for pharmacist, cost and medication error avoidance when implementing pharmacy services, pharmacist responsibilities and roles, time to receive services in the emergency department , among others. Data collected from the survey showed that 7 of 12 (58.3 percent) of the respondents institutions' had direct clinical pharmacy services in the emergency department. A total of 6 of 12 (50 percent) respondents totally agree that having a pharmacist in their institution's emergency department is necessary. Another 4 of 12 (33.3

percent) totally agree that having a pharmacist at their institution's emergency department is viable.

Conclusion: A review of the literature revealed that pharmacists play an important role in the emergency departments. The addition of a clinical pharmacist to the emergency department of the hospitals in Puerto Rico could be beneficial for the institutions and the patients. The implementation can be done by phases in order to facilitate the transition.

Jerod Nagel

Purpose: CAP is the eighth leading cause of death in the United States. Traditionally, antibiotic duration for CAP treatment was 7-14 days, however, ATS/IDSA guidelines recommend short-course therapy (5 days) if patients are clinically stable and rapidly defervesce. There is minimal data evaluating compliance with guidelines and stewardship intervention impact on antibiotic duration. Additionally, ATS/IDSA guidelines list respiratory fluoroquinolones and cephalosporins as treatment options but are associated with higher risk of Clostridium difficile infection (CDI). At University of Michigan Health System (UMHS), CAP guidelines were updated to minimize high-risk CDI antibiotic use and provided therapy duration recommendations consistent with ATS/IDSA guidelines.

Methods: A single-centered pre-post quasi-experimental study, approved by the institutional review board, was completed at UMHS in Ann Arbor, MI with the primary goal of decreasing excessive antimicrobial duration of antibiotic therapy, without adversely affecting patient outcomes. Secondary objectives included evaluating the use of high-risk CDI antibiotics, and associated CDI rates. Adults (18 years or greater) diagnosed with CAP and admitted to a general medicine unit were cohorted into two groups: pre-intervention group (November 2014 - April 2015) and intervention group (November 2015 - April 2016). Patients with other pneumonia diagnosis, complicated pneumonia, and positive respiratory culture not consistent with CAP were excluded.
Pre-intervention data was collected using ICD-9 codes for pneumonia and reviewing patient charts. Stewardship intervention consisted of education to physicians about updated UMHS

CAP guidelines and verbal recommendations through prospective audit and feedback. Patients in the intervention group were identified real-time through daily stewardship team review (Monday-Friday), which made recommendations on antibiotic selection and duration of therapy.

It was determined that a sample size of 300 to yield 80% power was needed to assess the impact of stewardship intervention on duration of antibiotic therapy. Comparison of the pre- and post-intervention cohort was performed using unpaired t-test for continuous data and two-tailed Fischer's exact test for categorical data. P-values less than 0.05 was considered significant.

Results: There were 334 patients included: 169 patients in the pre-intervention group and 165 patients in the post-intervention group. Stewardship intervention reduced the total duration of antibiotic therapy from a median of 8 days to 6 days (p < 0.0001). Prior to intervention, 14.2% of the patients received the appropriate duration of antibiotic therapy compared to 57.0% in the post-intervention group (p < 0.0001). Ceftriaxone significantly decreased in the post-intervention group (p < 0.0001) and an increase use of amoxicillin/clavulanate and amoxicillin/sulbactam (p < 0.0001) was seen during hospitalization. In addition, there was a decrease in discharge prescriptions for cefpodoxime and levofloxacin and an increase in prescriptions for amoxicillin/clavulanate after the antimicrobial stewardship intervention (p < 0.0001). 30-day mortality rates, 30-day readmission rates and CDI rates did not differ between the pre- and post-intervention groups.

Conclusion: Antimicrobial stewardship effectively reduced the duration of antibiotic days of therapy from 8 days to 6 days post-intervention, without adversely impacting outcomes. Additionally, stewardship team intervention reduced the utilization of high-risk CDI antibiotics of levofloxacin and ceftriaxone.

Poster Title: Analysis of students' self-assessment of performance on an interprofessional team

Primary Author: Lindsey Zeplin, University of Michigan College of Pharmacy, Michigan; **Email:** slzeplin@med.umich.edu

Additional Author (s):
Burgunda Sweet

Purpose: In order to meet the increasingly complex demands of the healthcare industry, the practice model is moving away from the traditional physician-centered team to the team-based model of the Patient Centered Medical Home. Interprofessional education (IPE) helps foster this collaborative environment by having students of different professions learn about, from, and with each other. An IPE course was implemented at the University of Michigan to help develop teamwork skills on interprofessional teams. This study evaluated how student self-assessed performance on an interprofessional team changed after the semester-long course.

Methods: Students from dentistry, medicine, nursing, pharmacy, and social work were assigned to a team for the semester, with each team having at least four disciplines represented. Teams rotated through a series of discipline-specific modules where they worked together to solve patient care cases. All enrolled students were included in the analysis, with the exception of two who opted out (n=255). At baseline and the end of the semester, students completed two questionnaires, the Pollard scale, which assesses individual contributions to the team, and the Team Development Measure (TDM), which assesses team functioning. Students also completed an end of semester open-ended reflection in which they identified areas where their team performed well, struggled, and what they learned about teamwork.

Results: The majority of students (170, 74.6%) had a baseline positive self-assessment of individual contributions to the team. After a semester of TBCDM 188 (82.6%) reported positive self-assessment. The test of proportions showed a non-significant shift towards improved positive self-assessment (p=0.2). Of the 35 teams, most were at developmental stages four (building clarity of goals, 29%) or five (cohesiveness established, 54%) at baseline. Stages increased for 46% of teams, while 37% had no change and 17% saw a decrease. There was a significant increase in the proportion of teams with a TDM stage of six (communication

established) or greater (p = 0.01). Analysis of end of semester TDM reflections for common themes contributing to change in TDM score failed to yield any definitive patterns.

Conclusion: A semester of IPE improved the stage of development for the majority of teams and increased the percentage of students' with a positive self-assessment of communication and teamwork skills. Strategies utilized in TBCDM appear to help improve students' ability to function on an interprofessional team.

Poster Title: Building Bridges in Transitions of Care: Pharmacist-led Home Care Services in Puerto Rico

Primary Author: Julio Rodriguez Vazquez, Nova Southeastern University, Puerto Rico; **Email:** jr2312@nova.edu

Additional Author (s):
Marilia Brunet
Francesca Rios
Nicolle Rivera
Sharol Rodriguez

Purpose: Almost one in five Medicare patients discharged from a hospital are readmitted within 30 days.1 In the home, health care providers can observe a patient's medical and social issues, such as challenging living conditions. 2 Implementing a post discharge home based medication management service, has proven to improve patient knowledge as well as the continuity of patient care during the transition from hospital to home, and reduce hospital readmissions.

Methods: To assess the need and the feasibility of a transitions of care service in Puerto Rico we conducted stakeholder interviews and a literature search using Embase, Medline, Pubmed, International Pharmaceutical Abstracts and CINAHL Complete. Based on this initial market and literature research, we developed a pilot project for the implementation of a post-discharge pharmacist home visit service as a transitional care method in Puerto Rico. Our primary objective is to decrease the rates of hospital readmissions within 30 days of discharge. Our secondary objectives are to improve patient adherence and reduce medication related problems. During the post-discharge home visit, the pharmacist will complete a medication reconciliation, Comprehensive Medication Review (CMR), address patient education and adherence, among others.

Results: After the visit, the pharmacist will create a recommendation list for the patient and his providers and will follow up with the patient at week 1 and week 4. Our main marketing strategy will be direct pitching presentations in potential customer institutions. We will network

through healthcare and professional associations, personal contacts, professional meetings, healthcare conventions in the island and healthcare professional referrals.

Conclusion: With our service, we are building a bridge between the hospital bed and the patient's home, creating a path to recovery and well-being, guided by the ultimate medication expert: the pharmacist.

Poster Title: Systematic review of validated methods for identifying metabolic syndrome using administrative claims data

Primary Author: Briana Fisher, Bernard J. Dunn School of Pharmacy, Shenandoah University, Virginia; **Email:** bfisher12@su.edu

Additional Author (s):
Kalyn Kiziah
Shaminder Kalkat
Amit Raval
Isha Patel

Purpose: Metabolic syndrome is common in the United States affecting nearly 34 percent of the US population. It is characterized by any of three risk factors: large waistline, high triglyceride level, low HDL cholesterol level, high blood pressure, or high fasting blood sugar. It is also related to being overweight and obese. The risk for heart disease, diabetes, and stroke increases proportionally to the number of metabolic risk factors present. The purpose of this study was to perform a systematic review of published articles that have validated algorithms to identify metabolic syndrome cases using an administrative claims data.

Methods: Systematic review was conducted following the standards guidelines of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) Statement. PubMed and Medline (Ovid) search was performed to identify citations applicable to metabolic syndrome. Level 1 abstract reviews and level 2 full-text reviews were performed to find research articles that used claims and administrative database to identify metabolic syndrome as outcome of interest, including validation estimates of the coding algorithms.

Results: Abstracts and articles were reviewed by three study investigators to determine their relevance based on predetermined criteria. The initial search strategy identified 393 abstracts through electronic databases. Out of the 393 abstracts, 17 articles were selected for full text review. The 17 studies that were identified used non-validated algorithms to identify metabolic syndrome. The selected articles showed considerable difference in sample, setting and methods.

Conclusion: There is no evidence about the validity of algorithms to identify metabolic syndrome in an administrative claims data. More research should be designed for assessing the predictive power, sensitivity and specificity in validation studies to test algorithms for identifying metabolic syndrome using administrative claims.

Poster Title: College Students' Interest and Knowledge of At-Home Genetic Testing

Primary Author: Leslie Davis, University of Mississippi School of Pharmacy, Mississippi; **Email:** ledavis0426@gmail.com

Additional Author (s):
Anastasia Jenkins

Purpose: The use of direct-to-consumer personal genomic testing kits has been controversial. 23andMe, the first device of this kind, was ordered by the FDA to discontinue marketing as a health-related genetic testing kit in 2013 due to concerns about how patients would interpret their results. The purpose of this project was to determine the interest in, as well as knowledge and interpretation of, information provided by these devices in a college population.

Methods: A survey was administered to students at the University of Mississippi. Students who had purchased 23andMe or had genetic testing performed in the past were excluded. Incomplete surveys were also excluded. Baseline characteristics of participants and their responses were analyzed using descriptive statistics.

Results: 286 surveys were collected. 11 surveys were excluded because they were incomplete and 9 were excluded because the student had previously undergone genetic testing. 266 surveys were included in the final analysis. 80% (n=213) of students had never heard of at-home genetic testing devices, but 76% (n=201) expressed interest in taking a test of this sort. 74% (n=196) answered that they would be "very likely" to see a healthcare professional if they tested positive for a gene that increases their risk of developing a disease. Conversely, only 18% (n=48) answered that they would be "very likely" to see a healthcare professional if they found out that they tested negative for the same gene. After taking the survey, 74% (n=196) were interested in learning more about at-home genetic testing devices.

Conclusion: Most students had limited knowledge of at-home genetic testing devices prior to this survey, but were interested in learning more after completing the survey. Most students indicated that they would be likely to see a healthcare professional if they tested positive for a

gene that could predispose them to certain diseases, but that they would not be likely to do so if they tested negative for the gene.

Poster Title: Use of direct oral anticoagulants in patients with impaired renal function

Primary Author: Amy Pelletier, Massachusetts College of Pharmacy and Health Sciences, New Hampshire; **Email:** apell1@stu.mcphs.edu

Additional Author (s):
Chang Kim
Kristine Willett
Amanda Morrill

Purpose: Warfarin has been the mainstay therapy for prevention of thromboembolic events in patients with atrial fibrillation (afib). However, the use of direct oral anticoagulants (DOACs), such as dabigatran, rivaroxaban, apixaban, and edoxaban, is rising for this indication. Despite increased cost, patients may prefer the reduced monitoring associated with these agents. Unlike DOACs, warfarin does not require renal dosage adjustments. However, most DOACs aren't yet sufficiently evaluated for safety in this population. The purpose of this analysis is to review the safety and efficacy of DOACs in patients with renal impairment and describe considerations based on patient preference and cost.

Methods: A literature search using Medline (1996- September week 1 2016) was conducted using terms dabigatran, rivaroxaban, apixaban, and edoxaban. These were combined separately with chronic kidney disease, renal impairment, cost effectiveness, patient preference, quality of life, or adherence. Seventeen case reports and trial sub-analyses were investigated and evaluated, as well as eight articles regarding cost effectiveness and quality of life. A clinical consensus was determined utilizing of the results of each article.

Results: There are several studies and published case reports evaluating the efficacy and/or safety of dabigatran in the renally impaired population. Patients with renal impairment taking dabigatran experienced major bleeding at doses of 150mg, but less with the 110mg dose. Rivaroxaban 10mg once daily had similar efficacy in patients on hemodialysis as 20mg daily in healthy patients. Further data indicates that elderly patients, regardless of renal function, using rivaroxaban have a greater bleeding risk compared to those taking warfarin. Apixaban 2.5mg twice daily in patients with renal impairment was associated with decreased major bleeding

compared to warfarin in one sub-analysis. Another trial showed apixaban 2.5mg and 5mg twice daily decreased risk of stroke and embolism in patients with stage 3 chronic kidney disease (CKD) without significant differences in adverse events compared to aspirin. Studies suggest edoxaban 15mg once daily is safe and effective in patients with reduced renal function. Patient satisfaction studies suggest that many patients are interested in DOACs due to fewer provider visits and dietary restrictions. Barriers to switching included safety and efficacy and cost. Numerous cost–effectiveness studies have been completed to assess the burden of these agents and indicate all DOACs studied are cost-effective compared to warfarin.

Conclusion: Evaluated case reports and data from sub-analyses indicate dabigatran may be associated with increased bleeding risk in patients with renal impairment. Rivaroxaban 10mg has been associated with increased bleeding in elderly patients with decreased renal function and thus should be used with caution. Studies indicate that apixaban 2.5mg for patients with stage 3 CKD is safe and effective. Finally, edoxaban 15mg once daily is overall safe in severely renally impaired patients. Considering the enhanced interest amongst patients in the use of DOACS, providers must balance recommending safe and effective therapy with patient preference and economic burden for patients with afib.

Submission Type: Evaluative Study

Session-Board Number: 5b-008

Poster Title: Community pharmacy patients' knowledge of acetaminophen and its associated adverse effects

Primary Author: Paige Slay, University of Mississippi School of Pharmacy, Mississippi; **Email:** pddukes@go.olemiss.edu

Purpose: Acetaminophen-containing products are in the top-selling category of over the counter medications. However, the danger of acetaminophen is pressing, in that 48 percent of all acute liver failure diagnoses are attributed to acetaminophen. Recent studies have been performed that assess patients' knowledge of acetaminophen and its dangers in clinic and hospital settings. However, few studies assess patients' knowledge of the detrimental effects of acetaminophen in the community pharmacy environment, where acetaminophen products are easily accessible. The aim of this study is to assess patients' general knowledge of acetaminophen and its adverse effects at Rhodes and Robby Drugs in Pelahatchie, Mississippi.

Methods: Adult patients were given concise 5-question surveys assessing their knowledge of acetaminophen and its associated adverse effects as they picked up their prescriptions. Each patient that was willing to participate was given a brief consent form to review prior to completing the survey. Patients who could not speak English, who were under the age of 18, or who claimed that they were not able to read were excluded. The surveys were administered over a 3-day period to ensure that the minimum goal of 70 survey respondents was achieved. The completed surveys were reviewed and descriptive statistics were used to analyze the data. The demographics of the surveyed patients were analyzed as well as the proportion of each question answered correctly.

Results: Surveys from 72 patients were completed and included in the data analysis. Of the 72 participants, 79 percent were female, 21 percent were male, 19 percent were African American, and 81 percent were Caucasian. The average age of the participants was 49 years. Survey questions regarding the indications of acetaminophen as well as concomitant alcohol use were answered correctly by over 94 percent of participants. However, survey questions pertaining to maximum dosage, organ toxicity, and toxicity symptoms were answered correctly by 18, 68, and 86 percent of participants, respectively.

Conclusion: The results of this study indicate that patients of Rhodes and Robby Drugs in Pelahatchie, Mississippi are familiar with acetaminophen indications and the effects of concomitant alcohol use. However, they are generally unfamiliar with the appropriate dosing and toxicity of acetaminophen. A larger study with a more diverse patient population is needed to further explore patients' knowledge of the adverse effects of acetaminophen. Although it was a geographically limited study, the results clearly indicate the need for additional education to community pharmacy patients regarding acetaminophen and its appropriate dosages, dangers, and adverse effects.

Poster Title: Society's perception of the flu vaccine

Primary Author: Courtney Dukes, University of Mississippi School of Pharmacy, Mississippi;
Email: ccdukes@go.olemiss.edu

Purpose: Only 46 percent of Americans received the flu shot in 2013. In Mississippi specifically, only 40 percent of the population received the flu shot. Only 32 percent of adults aged 18-64 received the flu shot in 2013, and the low rate of vaccination could be due to negative perceptions of the flu vaccine. The purpose of this study was to assess society's perceptions of the risks and benefits of the flu vaccine so that pharmacists can be more knowledgeable about how to discuss the importance of the flu vaccine with patients.

Methods: A survey-based prospective observational study was conducted. The survey was designed to assess participants' perception of the risks and benefits of the flu vaccine. Age and gender questions were included in the survey to collect demographic information. A nine-question survey was administered through Facebook using Qualtrics survey software in January of 2016. Participants had to be 18 years of age or older and had to be Mississippi residents. Descriptive statistics were used and reported as percentages.

Results: A total of 255 surveys were completed. Eighty-six percent of participants believe the flu vaccine to be safe, while 14 percent of participants do not believe it to be safe. Fifty-four percent of participants believe the flu vaccine prevents the flu, while 46 percent do not believe the vaccine prevents the flu. When asked if the flu shot makes people sick, 27 percent of respondents said yes and 73 percent of respondents said no. 25 percent of participants said they would get their child vaccinated against the flu this year while 17 percent of participants said they would not get their child vaccinated against the flu this year. When asked if they would receive the flu shot this year, 63 percent of participants said yes and 37 percent said no.

Conclusion: This study suggests that while there are many people who perceive the flu vaccine to be beneficial, there are several people who do not believe it is beneficial and even some who believe the vaccine to be harmful. The results suggest a need for pharmacists to educate patients on the ample benefits and minimal risk of the flu vaccine. A strength of the study is

that the goal number of surveys to be completed was 80, and a total of 213 surveys were completed. A limitation was that 85 percent of the respondents were female.

Submission Category: Infectious Diseases

Submission Type: Descriptive Report

Session-Board Number: 5b-010

Poster Title: Implementing an antimicrobial stewardship program in a community hospital

Primary Author: Jerlin Jermae Dizon, Notre Dame of Maryland University, Maryland; **Email:** jdizon1@live.ndm.edu

Additional Author (s):
Kimberly Couch

Purpose: The growing cases of antimicrobial resistance is a major public crisis. New resistance mechanisms are emerging and spreading globally, threatening our ability to treat common infectious diseases, resulting in prolonged illness, disability, and death. As a means of battling this ongoing dilemma, an antimicrobial stewardship program (ASP) is adopted by many hospitals. However, due to lack of resources, implementing an ASP is especially difficult for some community hospitals. With the new antimicrobial stewardship standard mandated by The Joint Commission (TJC), the purpose of this project is to uncover plausible ways of implementing ASP in a community hospital.

Methods: Guidelines for Implementing an Antimicrobial Stewardship Program (ASP) were reviewed and a multidisciplinary committee was formed. Items listed in the guidelines as tasks of an ASP were discussed within committee. A policy for an ASP in a community hospital was developed. A budget for an ASP in a community hospital was formulated. Tasks were divided into priority groups based on factors. Factors included already in place, satisfies TJC requirement, ease of implementation, and presence of tools to complete task. A computerized method for tracking the ASP tasks specific to individual patients was developed.

Results: The ASP consists of seven core elements required by TJC. This includes leadership commitment, accountability, drug expertise, action, tracking, reporting and education. The ASP committee has selected specific actions to meet these core elements. Actions include developing facility-specific guidelines for common ID syndromes and using organization-approved multidisciplinary protocols, targeting antibiotics with high association of Clostridium difficile, implementing pharmacokinetic monitoring and adjustment programs for aminoglycosides and vancomycin, implementing programs to increase appropriate transition of parenteral to enteral therapy, implementing guidelines and strategies to reduce antimicrobial

use to the shortest effective duration, developing an annual antibiogram, selecting routine antimicrobials to be tested for susceptibility in conjunction with the microbiology lab, using rapid viral testing for rapid diagnosis, doing dosing/frequency adjustments, incorporating adjustments to laboratory tests for appropriate monitoring and assessing adjunct therapies. Antimicrobial use is evaluated through monitoring and reporting the amount of antimicrobials administered per patient day. ASP actions are tracked electronically and reported to the staff. Educational materials on antibiotic use are provided to practitioners, patients, and caregivers.

Conclusion: TJC ASP requirements are ambiguous in specifying what tasks need to be performed to meet the required core elements. This allows the hospital-based ASP creativity to design ASP actions that are feasible for the site. In the case of community hospitals, implementing ASP can be done by creating organization-approved multidisciplinary protocols and guidelines and taking action on improvement opportunities identified by ASP.

Poster Title: Evaluating the safety and efficacy of immunosuppressive therapy in patients with Crohn's disease (CD) undergoing gastrointestinal surgery

Primary Author: Millie Mo, University of Michigan College of Pharmacy, Michigan; **Email:** momillie@umich.edu

Additional Author (s):
Emily Peltier
Scott Regenbogen
Rima Mohammad

Purpose: The contribution of pre-operative exposure to immunosuppressive medications (biologics, azathioprine, and 6-mercaptopurine) on post-operative complications after surgery for CD remains controversial. There is even less understanding of the safety of immunosuppressive medications used post-operatively. The primary objective of this study was to assess 30-day post-operative infection rates in patients who received any immunosuppressive therapy (biologics, azathioprine, or 6-mercaptopurine) within 30 days after surgery compared to patients who received immunosuppressive therapy after 30 days post-operatively.

Methods: This was an institutional review board approved retrospective cohort study in adult Crohn's Disease patients (at least 18 years of age) that have undergone gastrointestinal surgery during hospitalization at the University of Michigan Health System between January 2012 and December 2014. Patients who received post-operative exposure to any immunosuppressive therapy (biologics, azathioprine, or 6-mercaptopurine) were included in the study. Patients were excluded if they had poor clinical records documenting 30-day post-operative clinical outcomes. Patients were divided into two groups: early treatment versus delayed treatment. The early treatment group included patients who received any immunosuppressive therapy within 30 days after surgery and the delayed treatment group included patients who received any immunosuppressive therapy greater than 30 days after surgery. Data points collected and evaluated included baseline characteristics, surgical procedure, immunosuppressive medications, post-operative infection, length of stay, readmission rate, and hospital mortality.

The primary outcome was 30-day post-operative infection rate. Secondary outcome included 30-day readmission rate.

Results: Fifty-five patients were included in the early treatment group and 39 included in the delayed treatment group. Patient characteristics (age, race, gender), comorbidities, pre-operative infection rate, prior antibiotic use, and type of gastrointestinal procedure were similar between groups. There was a significant difference between early versus delayed groups in patients taking any immunosuppressive therapy prior to surgery (94.5 percent versus 79.5 percent, respectively; p equals 0.047). More patients received azathioprine prior to surgery in the early group (66.7 percent versus 12.1 percent, respectively; p less than 0.001); however, there was no difference in patients receiving 6-mercaptopurine (7.4 percent versus 9.1 percent, respectively; p equals 1), steroids (28.3 percent versus 48.5 percent, respectively, p equals 0.058) or biologic (72.2 percent versus 88.2 percent, respectively; p equals 0.11). There was no significant difference in elective versus emergent surgery between groups (p equals 0.1). There was no difference in 30-day post-operative infection rate between groups (27.3 percent versus 12.8 percent, respectively; p equals 0.126). Additionally, there was no difference in 30-day readmission rate between groups (20 percent versus 28.2 percent, respectively; p equals 0.355) or in hospital length of stay (6.84 days versus 9.46 days, respectively; p equals 0.128).

Conclusion: Use of immunosuppressive therapy (biologics, azathioprine, or 6-mercaptopurine) within 30 days versus greater than 30 days of surgery did not result in a difference in 30-day post-operative infection rate. There was a significant difference between the early and delayed groups in patients taking immunosuppressive therapy prior to surgery, but the impact of this difference on clinical outcomes remains unknown at this time. Future studies on this subject should be prospective, include a larger number of participants, and further analyze the relationships between pre- and post-operative immunosuppressive therapy and post-operative complications.

Submission Category: General Clinical Practice

Submission Type: Descriptive Report

Session-Board Number: 5b-012

Poster Title: Residency showcase implementation of video, group discussion, and keynote speaker to extend outreach and opportunities beyond state lines

Primary Author: Brittany Bailey, South Dakota State University College of Pharmacy, South Dakota; **Email:** brittany.bailey@jacks.sdstate.edu

Additional Author (s):
Stephanie Demers
Hannah Schmidt
Caitlin Aul

Purpose: South Dakota State University College of Pharmacy annually hosts a residency showcase for pharmacy students to attend. This is an opportunity to learn about the residency application process and to speak with local South Dakota pharmacy residents and residency program directors (RPDs). While the showcase is traditionally local, advances to the program were made with the goal of extending outreach to include information for residencies in-state and out-of-state. To accomplish this, video presentations from residents across the United States, as well as handouts with a question and answer section were added to the event.

Methods: To assess the effectiveness of the showcase, surveys were implemented to gain attendees' perspectives as a means to improve future showcases. The showcase was prepared, hosted, and evaluated by four pharmacy students and mentored by an American Pharmacists Association - Academy of Student Pharmacists faculty advisor. The event included a PowerPoint presentation by a former Veteran Affairs resident and faculty member to discuss the application process and how to prepare for a residency interview. The event progressed with two video submissions from out-of-state residents discussing their experiences. Attendees were also given an additional handout of resident responses to student requested survey questions. Lastly, students were given a chance to break out into groups and discuss residencies one-on-one with RPDs and residents from local programs. After the showcase, 50 students and 21 pharmacist, including residents and RPDs, were emailed post-event surveys to provide input on the effectiveness of the showcase and make suggestions for improvement. The surveys included both Likert scale questions and short answer response sections.

Results: The survey results suggest the residency showcase was well received. The addition of information from residents in programs outside of South Dakota was a welcome addition to the program. Regarding the addition of the video interviews, 68.75 percent of pharmacists agreed that out-of-state resident video interviews where a good addition to the event. While students and residents saw it as a beneficial addition to the program, results indicated that one video would be enough and more videos should be available online for viewing. The small group activity was chosen in the post-event survey by 46.67 percent of students to be the most helpful or informative part of the showcase. Multiple comments provided feedback in favor of providing set times to rotate between small groups to gain different perspectives. Attendees also suggested set questions be provided to residents and RPDs to stimulate conversation, and that a panel of residents should be interviewed first before breaking out into groups.

Conclusion: The annual residency showcase was a successful event in a number of areas. Survey results completed by students, residents, and RPDs provided overall positive responses with constructive feedback. The addition of resident information from out-of-state locations was well received. The post-event survey data provided applicable information which can be used in reformatting the small group discussions as well as resident question and answer sessions with the goal of improving the residency showcase.

Submission Category: Pediatrics

Submission Type: Evaluative Study

Session-Board Number: 5b-013

Poster Title: Satisfied patients and pediatricians: Results from a cross sectional survey study

Primary Author: Travis Chapman, Shenandoah University, Virginia; **Email:** tchapman09@su.edu

Additional Author (s):
Isha Patel
Fabian Camacho
Rajesh Balkrishnan
Steven Feldman

Purpose: We examined and compared patient satisfaction towards their pediatricians and primary care physicians (PCPs), and characterized factors associated with higher patient satisfaction in these two groups.

Methods: A random coefficient model with random slope and intercept was fit to the data, with patient satisfaction as a function of pediatrician/other PCPs, covariates, and physician random effects. Effect heterogeneity was assessed by allowing slope to vary as a function of covariates. Mediation analysis using the random coefficient model was conducted to calculate average total effect, average natural direct effect, and average indirect effect of pediatrician/other PCPs on satisfaction mediated by waiting/visit times.

Results: A total of 5,327 pediatricians and 33,726 other PCPs were rated by 9,577 and 85,301 people respectively. Pediatricians had higher predicted satisfaction ratings than PCPs (total effect equals 4.8 ,95-percent CI 3.7 to 5.9), with population averaged means of 82.2 (0.54) vs 77.4 (0.13). The direct effect was 3.9 (2.8 to 5.0) and indirect effect 0.9 (0.9 to 0.9), suggesting part but not all of the total effect can be explained by pediatricians having decreased waiting/visit times leading to increased satisfaction. Predictions by subgroup suggested pediatricians have lower ratings than PCPs for first visit, but higher ratings for all other covariate strata considered. Having longer waiting times, and decreased visit times coincided with closer mean ratings between pediatricians and PCPs.

Conclusion: Pediatricians scored higher patient satisfaction ratings than the combined group of other primary care physicians. Patient satisfaction for pediatricians with lower waiting times and longer visit times was higher compared to other primary care providers with lower waiting times and longer visit times.

Poster Title: Phytochemical comparison between Chinese (smooth) and Indian (rough) cultivars of Momordica charantia (bitter melon or gourd).

Primary Author: Thu Phan, Shenandoah University - Bernard J. Dunn School of Pharmacy, Virginia; **Email:** tphan13@su.edu

Additional Author (s):
Wendell Combest

Purpose: Bitter melon has been used in Asia and surrounding countries for glycemic control. However, the components of bitter melon are not fully understood. The purpose of this study is to determine the phytochemical constituents in various anatomical parts of the fruit in two prominent cultivars of Momordica charantia. An Indian bitter melon cultivar derived dietary supplement (one with a 2011 expiration date and another with a 2018 expiration date) was also analyzed and compared to the fresh fruit.

Methods: Two different cultivars of bitter melon were analyzed: Chinese bitter melon (smooth) and Indian bitter melon (rough). Fruits were purchased from a local market in Winchester, Virginia and dissected into outer peel, rind, pulp, and seed. Plant tissue was cut into thin slices and air dried at room temperature inside a chemical fume hood. Dried plant material was extracted in 30 volumes (w/v) of 70% methanol for 20 min at 70°C following 2 minutes of ultrasonication. Following centrifugation (10,000xg for 10 min) a 20 µl of the supernatant was analyzed via high-performance liquid chromatography (HPLC: Shimadzu 20AD with a UV-vis photodiode array detector utilizing a C18 analytical column). Juice for vitamin C analysis was freshly squeezed using a garlic press and was analyzed within 5 minutes. The Indian bitter melon cultivar was manufactured by Solaray Inc., Park City, UTAH

Results: The Indian (rough) cultivar contained much higher levels of phytochemical constituents compared to the Chinese (smooth) variety. Most prominent constituents were found in the seed and juice of both plants. Vitamin C was prominent in the expressed juice of both plants. The Solaray dietary supplement (Indian cultivar) HPLC profile resembled the seed extracts of the fresh dried Indian cultivar. The 2018 expiration date supplement was found to have ~ 10x higher constituent levels compared to the 2011 expiration date supplement.

Conclusion: The Indian (rough) cultivar had a much higher level of phytochemical constituents compared to the Chinese (smooth) cultivar; therefore, would likely have greater medicinal value. The seed appears to contain an important constituent in the bitter melon fruit. Stability appears to be an issue in that expired dietary supplements of bitter melon may have lost most of their medicinal activity.

Poster Title: Understanding patient perspectives with self-care in heart failure

Primary Author: Michael Yee, University of Michigan College of Pharmacy, Michigan; **Email:** myee310@gmail.com

Additional Author (s):
Michael Dorsch

Purpose: Self-management of a low-sodium diet, fluid restriction diet, and weight are the critical component of heart failure treatment. There's an uptrend of hospitalization with congestive heart failure in the older population. The purpose is to assess a better understanding of heart failure patients with their self-management with sodium, fluid, and weight.

Methods: The institutional review board approved this qualitative descriptive study. A survey was distributed at the University of Michigan Health System in Ann Arbor, MI after the heart failure patients have concluded their appointment. Each of the one-on-one interview sessions was approximately 15 to 30 minutes in length, which included a total of 12 questions about sodium restriction, fluid restriction, and weight management. The primary outcome was the understanding of patient's heart failure self-management, which the data will be managed through NVivo 10.0, a qualitative software used for coding and analysis. The audiotapes were transcribed verbatim and later the transcripts were re-examined and verified by both interviewers. Two coding sessions were done to assure consistency, kept annotations, notes and left an audit trail.

Results: There were 33 out of 34 respondents to the survey. Certain populations with low-sodium and fluid restriction diet needed help from their healthcare team to follow the diet, 51.35 percent and 41.41 percent, respectively. Additionally, the population has each of their own regimens in keeping track with their sodium and fluid restriction, 67.65 percent and 75.00 percent, respectively. Still, patients struggle with their sodium and fluid restriction diet, 81.82 percent and 66.67 percent, respectively. The most common struggle was beyond their control once outside their home. Overall, the respondents reported they weigh themselves daily and having an innovative scale would be beneficial.

Conclusion: The study should aid in a better understanding of patient's current self-management of heart failure treatment and further promote innovative strategies for improving the quality of care of patients.

Poster Title: Quality of life and pharmacoeconomic comparisons of chemotherapy regimens in pediatric rhabdomyosarcoma

Primary Author: Stephanie Sollis, University of Mississippi School of Pharmacy, Mississippi;
Email: stephaniesollis@me.com

Additional Author (s):
Andrew Ostrenga

Purpose: Pediatric rhabdomyosarcoma is a soft tissue, skeletal muscle, malignant tumor. Vincristine, dactinomycin, and cyclophosphamide (VAC) chemotherapy has been the treatment standard for those with intermediate-risk disease. This therapy has also been associated with increased incidence of febrile neutropenia. One chemotherapy alternative is VAC-VI (vincristine, dactinomycin, and cyclophosphamide alternating with vincristine and irinotecan). While an outcome study has been established, no previous study has compared pharmacoeconomic and quality of life benefits of these two therapies. The study purpose was to identify if VAC-VI treatment for pediatric rhabdomyosarcoma had greater pharmacoeconomic and quality of life benefits as compared to VAC treatment.

Methods: This retrospective case series study began in October 2015 and was completed in August 2016. The study included all patients up to age 17 who had been treated for rhabdomyosarcoma with a VAC or VAC-VI therapy protocol on or before October 2015. Patients must have been treated at Blair E. Batson Hospital for Children in Jackson, Mississippi. Non-English speaking patients were excluded due to potential inability to complete the survey portion. It was approved by the Institutional Review Board of the University of Mississippi Medical Center. A retrospective chart review was utilized to document doses and costs of chemotherapy, number of hospital and clinic visits, readmissions, doses of filgrastim, and distance traveled to study site. The Epic electronic health record was utilized along with paper chart supplementation. For quality of life analyses, the validated KINDL Oncology questionnaire was mailed to all living study patients. This survey utilized a likert scale response system to determine patient physical, mental, social, and educational well-being. Descriptive statistics and Student's t-test for the comparison of two means were used for data analysis. Statistical significance was achieved at a two-tailed p-value of less than 0.05.

Results: Fifteen patient met study criteria. Average hospital readmission days were 2.17 with VAC and 2.8 with VAC-VI (p equals 0.703). Readmission rates were 40 percent (VAC) and 60 percent (VAC-VI). Filgrastim analyses showed average total cost of $34,329 per patient (VAC) and $27,285.51 (VAC-VI) (p equals 0.6049). Travel costs averaged $20.93 per patient (VAC) and $31.68 per patient (VAC-VI) (p equals 0.3661). Total costs of therapy averaged $99,044.59 per patient (VAC) and $114,692.67 per patient (VAC-VI) (p equals 0.6231). One KINDL questionnaire was returned, therefore data is unable to be statistically analyzed.

Conclusion: We were unable to show pharmacoeconomic benefit of VAC-VI therapy as compared to standard VAC therapy, and quality of life conclusions could not be determined. Further studies are warranted to make substantial conclusions, and these studies should include larger populations. If validated, both therapies may become standard treatments for pediatric rhabdomyosarcoma. Currently, one should consider patient-specific factors in determining appropriate therapy, which may include such elements as distance from the treatment site. While statistical and clinical significance could not be determined, the study could be modeled in order to compare other drugs from both pharmacoeconomic and quality of life perspectives.

Poster Title: Examining first year pharmacy students' satisfaction in using a virtual program to learn medication dispensing in a laboratory setting

Primary Author: Kayla Ambroziak, University of Michigan College of Pharmacy, Michigan; **Email:** kambrozi@med.umich.edu

Additional Author (s):
Vincent Marshall
Sarah Kelling

Purpose: There is significant variation in the amount and type of experience related to pharmacy practice that students have prior to entering a professional pharmacy program. The purpose of this study was to determine whether the use of a virtual simulation program (MyDispense) focused on medication dispensing could create an engaged learning environment for all students within a course construct where previous background experiences directly impact engagement and learning.

Methods: First year (n=85) pharmacy students at the University of Michigan College of Pharmacy enrolled in Pharmacy Practice Skills I (PPS1), in the Fall 2015 semester were taught medication dispensing primarily using a virtual online medication dispensing program. Each week, students were required to complete two modules and had access to six optional, non-graded practice modules. These modules correlated with the topic being taught the week of, and emphasized the skills the students need to know by the time they attend their required recitation session. Exercises were designed to provide students with immediate, formative feedback on their performance. At the end of the semester, students completed an online survey that collected information about their previous pharmacy experience and used open- and closed-ended questions to assess their perceptions of the use of the virtual medication dispensing program. To interpret the results, descriptive statistics and a thematic analysis was performed.

Results: Forty-two (49.4%) students responded to the survey administered at the end of the semester. The majority of students—both with (88.9%) and without (84.0%) prior pharmacy experience—found virtual simulation to be a helpful tool for learning about medication

dispensing in the outpatient setting, including the topics of: preparing a medication label (with prior pharmacy experience: 74.1%, without prior pharmacy experience: 95.2%), analyzing a prescription (88.9%, 100.0%), identifying and preventing medication errors (81.5%, 100.0%), using drug information resources (96.3%, 95.2%), accepting new prescriptions over the phone (85.2%, 90.4%), transferring prescriptions (40.7%, 71.4%) and analyzing patients' medication profiles (74.1%, 76.2%). Unlike the other components of the program, transferring of prescriptions was not as well received by students, especially those with prior paid pharmacy experience. The most common elements of PPS1 that students reported helped them to learn medication dispensing were MyDispense and other hands-on laboratory practice. Areas for improvement include decreasing technology issues and ensuring that practice exercises are consistent with the material presented in other sections of the course.

Conclusion: Incorporation of the virtual simulation program resulted in positive feedback from students. Due to the high percentage of satisfaction associated with use of the program, it will continue to be used during future semesters of the course. This program will be incorporated into other courses in the curriculum in order to reinforce and teach skills related to dispensing medications.

Poster Title: Extended interval tobramycin pharmacokinetics in a pediatric patient with primary ciliary dyskinesia

Primary Author: Kristi Higgins, Virginia Commonwealth University School of Pharmacy, Virginia; **Email:** higginskl@vcu.edu

Additional Author (s):
Cady Ploessl
Jeremy Stultz

Purpose: This case report provides unique information regarding aminoglycoside dosing in pediatric patients with primary ciliary dyskinesia (PCD). Due to the rarity of PCD, treatment regimens have not been defined and are often extrapolated from cystic fibrosis (CF) guidelines. A 10-year-old female with PCD was admitted to our institution after several months of worsening lung function. Her FEV1 was 41% predicted on admission, which was lower then her baseline three months prior of 64% predicted. On admission, her blood urea nitrogen (BUN) and serum creatinine (SCr) were 10 mg/dL and 0.37 mg/dL, respectively. She was started on levofloxacin 250 mg IV (7.3 mg/kg/dose) every 24 hours and tobramycin 320 mg IV (10.3 mg/kg/day) infused over 30 minutes every 24 hours due to concern for Pseudomonas aeruginosa infection.

Pharmacokinetic monitoring was performed after her second dose to ensure efficacy and safety of tobramycin. Tobramycin concentrations were obtained approximately 2 and 8 hours after the start of the infusion in order to calculate the elimination rate constant (Ke), volume of distribution (Vd), maximum concentration at the end of the infusion (Cmax), 24-hour trough (Cmin), and area under the curve (AUC0-24h). The target ranges for management of gram-negative pulmonary infections are an extrapolated serum Cmax of 20-30 mg/L and an extrapolated serum Cmin of less than 1.0 mg/L, with an AUC0-24h of 80-110 (mgxhr)/L. In pediatric patients without CF, Vd and Ke have been reported as 0.24 ± 0.08 and 0.32 ± 0.06. For patients with CF, the Vd and Ke have been reported as 0.33-0.45 L/kg and 0.292-0.413 hr-1, resulting in an initial tobramycin starting dose of 10 mg/kg/day.

Pharmacokinetic analysis of her initial tobramycin dose of 10.3 mg/kg/day revealed subtherapeutic extrapolated serum concentrations (Cmax: 18.8 mcg/mL, Cmin: 0.0053, AUC0-24h (58.86 (mg x hr)/L, Vd 0.51 L/kg, Ke 0.346 hr-1). Her dosage was subsequently increased to

12.8 mg/kg/day. After the dosage increase on day of treatment four, the patient's FEV1 showed an increase to 58% predicted. Repeat pharmacokinetic analyses were performed on tobramycin 12.8 mg/kg/day and extrapolated peak and trough concentrations (Cmax: 27.6 mcg/mL, Cmin: 0.0035 mcg/mL), AUC0-24h (75.35 (mg x hr)/L, Vd 0.38 L/kg, Ke 0.385 hr-1) were found to be within goal ranges. Our patient had a higher Vd and similar or greater Ke than reported in studies from non-CF patients, indicating a treatment approach similar to that of a CF patient was warranted.

On the fifth day of treatment, respiratory cultures revealed moderate Haemophilus parainfluenzea, beta-lactamase positive. Tobramycin was continued for the duration of therapy due to clinical improvement. At the time of the final pharmacokinetic analysis (day 11 of treatment), her BUN was 13 mg/dL, SCr was 0.45 mg/dL, and FEV1 was 80% predicted. The patient was discharged after completing 12 days of IV tobramycin and levofloxacin therapy with significantly improved lung function and no adverse events (e.g., renal insufficiency) experienced from treatment.

This was the first case report of aminoglycoside pharmacokinetics in a pediatric patient with primary ciliary dyskinesia. The administration of higher than normal doses (up to 12.8 mg/kg/day) of extended-interval tobramycin was needed in this patient to achieve serum concentrations appropriate for treatment.

Poster Title: Comparison of the frequencies of cytochrome P450 2D6 polymorphisms between Mexican and Caucasian populations

Primary Author: Pauline Lay, Shenandoah University - Bernard J. Dunn School of Pharmacy, Virginia; **Email:** play13@su.edu

Additional Author (s):
Julieta Garcia
Cody Bottenfield
Elijah Kidd
Michael Fusco

Purpose: Polymorphisms in the cytochrome P450 2D6 (CYP2D6) gene can affect the metabolism of a large number of medications including many tricyclic antidepressants, serotonin reuptake inhibitors, neuroleptics, beta-blockers, and antiarrhythmics. These genetic variations can result in diverse therapeutic outcomes for patients. It is known that these genetic polymorphisms can occur at different frequencies in diverse populations. The aim of this study was to analyze and compare the frequencies of the most common single nucleotide polymorphisms in the CYP2D6 gene in Caucasian and Mexican populations.

Methods: The Shenandoah University Institutional Review Board approved this cross sectional study. The samples were from previous studies with informed consent to genotype for genetic variations in drug response. Subjects were self-identified as Mexican or Caucasian. The samples were genotyped for CYP2D6*2, *4, *6, *10, *17, *29, *39, and *41 variant alleles. All genotyping was performed by allelic discrimination using real time PCR 5' nucleases on an Applied Biosystems QuantStudio 6 Flex. Pearson's chi-square test and Fisher's exact test were used to compare genotype and allele frequencies between the two groups. A p-value less than 0.05 was considered to be statistically significant.

Results: A total of 235 Mexican and 230 Caucasian samples were analyzed. The frequency of the CYP2D6*2, *4, *10, and *41 variant alleles was significantly lower in the Mexican group compared to the Caucasian group. The frequencies of these variant alleles are as follows: CYP2D6*2 was 23.5% in the Mexican group compared to 33.8% in the Caucasian group (p <

0.001); CYP2D6*4 was 2.4% in the Mexican group compared to 20.5% in Caucasian group (p < 0.001); CYP2D6*10 was 8.1% in the Mexican group compared to 22.2% for the Caucasian group (p < 0.001); and CYP2D6*41 was 4.2% in the Mexican group compared to 9.3% in the Caucasian group (p=0.002). There were no statistically significant differences between the two groups for CYP2D6*6 (p=0.143), CYP2D6*17 (p=0.124), CYP2D6*29 (p=0.624), and CYP2D6*39 (p=0.676).

Conclusion: From this study, the frequencies of CYP2D6*6, *17, *29 and *39 were not different between the two populations, but there was a significantly lower frequency of CYP2D6*2, *4, *10, and *41 for Mexicans compared to Caucasians. These differences could affect the way Mexicans metabolize medications that are CYP2D6 substrates compared to Caucasians. However, other CYP2D6 variant alleles that are less common in Caucasians may exist at higher frequencies in Mexicans. Further studies should evaluate other CYP2D6 variant alleles not examined in this study.

Session-Board Number: 5b-020

Poster Title: Topoisomerase I Inhibition increases G-Quadruplex Formation and Modifies Promoter Activity

Primary Author: Kori Daniels, University of Mississippi, Mississippi; **Email:** kedaniel@go.olemiss.edu

Additional Author (s):
Tracy Brooks

Purpose: G-quadruplex (G4) is abundant in promoter regions close to the transcription initiation site. It often prevents transcription, and are often found in oncogene promoters. Stabilizing it by compounds, such as TMPyP4, can downregulate oncogenes and suppress tumor growth. MYC and kRAS are found in 80% and 30% of cancers, respectively. G4s form because of negative superhelicity induced by torsional stress generated during transcription. Topoisomerase I alleviates torsional stress and SN-38, the active moiety of Irinotecan, is a strong inhibitor. This study examined the cooperative activity of SN-38 and TMPyP4 on MYC and kRAS promoter G4 structures and subsequent transcriptional activity.

Methods: Human Epithelial Kidney (HEK293) cells, seeded at 1 x 105 cells/well in 24-well plates, were transfected with Renilla plasmid (250 ng) and firefly luciferase plasmids (500 ng) containing the promoter of either MYC (Del4) or kRAS (FL). Transfected cells were then treated with either SN-38 alone (2 hr), TMPyP4 alone (46 hr) or a combination of the two agents concurrently or with varying sequential order. The dual-luciferase assay (Promega) was used to measure luciferase expression/activity from both the renilla and the firefly luciferase plasmids. Dunnett's test compared the various conditions to the control, and a one-way ANOVA determined if any of the conditions yielded significant results.

Results: For the kRAS- plasmid, the SN-38 alone condition (for 2 or 48 hr) showed there was an increase in plasmid activity of 10 – 44%; TMPyP4 alone (46 – 48 hr) had a decrease in plasmid activity by up to 75%, as compared to the control. Sequentially adding SN-38 for 2 hr and then P4 for 46 hr decreased plasmid activity to 13.5% compared to the control; for comparison, estimations from the individually treated conditions predicted only a 70% decrease in promoter

activity. For the MYC- plasmid, no such cooperative activity was noted with topoisomerase I inhibition.

Conclusion: Pre-treating kRAS-, but not MYC-, promoter driven luciferase plasmids with topo I inhibiting SN-38 positively effected the activity of G4-stabilizing TMPyP4. Future works will examine this cooperative activity in cells and with a larger array of G4-stabilizing compounds, particularly those selective for individual promoter structures. Topo I and G4-targeted combination therapy is a promising avenue for drug development with selective downregulation of key oncogenes.

Poster Title: Evaluation of the implementation of an electronic venous thromboembolism risk assessment tool in pediatric patients

Primary Author: Victoria Butterfield, University of Michigan College of Pharmacy, Michigan;
Email: vbutter@med.umich.edu

Additional Author (s):
Deborah Wagner

Purpose: Despite increasing trends in the incidence of pediatric venous thromboembolism (VTE) there are no current standards for pediatric VTE risk assessment in healthcare institutions. The purpose of this study was to evaluate the implementation of an electronic standardized venous thromboembolism risk assessment tool and chemoprophylaxis recommendations for pediatric patients. The primary goal of this study was to gain a better understanding of the relationship between patient specific risk factors and risk scores in pediatric patients.

Methods: Pediatric patients aged 13 to 17 years admitted to the University of Michigan C. S Mott Children's Hospital from July 1, 2015 to December 31, 2015 had a provider assessment of VTE risk within 24 hours of admission via the electronic medical record. A notification within the electronic medical record alerted providers to enter patient related risk factors, and a VTE total risk factor score was calculated. A high-risk score, greater than or equal to 5, created a Best Practice Advisory recommending the VTE Prophylaxis Pediatric Order Set. The order set included recommendations for agents and dosing for chemoprophylaxis, as well as an opt out option for chemoprophylaxis. VTE events were counted and compared for pediatric patients with a high-risk VTE risk score, greater than or equal to 5, and for pediatric patients with a low to moderate-risk VTE risk score, less than 5. The frequency and type of VTE risk factors recorded in the electronic medical record were counted. Additionally, the frequency and types of chemoprophylaxis ordered through the VTE Prophylaxis Pediatric Order Set were counted.

Results: There were 998 patients 13 to 17 years old admitted to C.S. Mott Children's Hospital between July 2015 to December 2015. 779 patients received a pediatric VTE risk assessment and 199 patients did not. Among the patients' risk assessed, 603 were given the risk assessment

within the first 24 hours of admission and 196 of the patients assessed were given the assessment after the first 24 hours of admission. The risk scores ranged from 0 to 13. 775 patients received a low to moderate-risk score less than 5 and 24 patients received a high-risk score greater than 5. The most frequent risk score reported was 0 and the mean risk score for each age group was below 1.1. The most frequent risk factors reported were surgery, disease, and mobility-related. Of the 998 admitted pediatric patients, 1 patient in the low to moderate-risk group had a reported VTE event. In the low to moderate-risk score group, there were 31 orders (4 percent of patients) for chemoprophylaxis and in the high-risk score group, there was 1 order (4 percent of patients) for chemoprophylaxis. The most frequent chemoprophylaxis prescribed was enoxaparin.

Conclusion: There was high compliance to the administration of the VTE risk assessment in pediatric patients 13 to 17 years old. The majority of patients received a low risk score less than 5. Overall, there was a low frequency of documented VTE events. The most frequent risk factors reported were surgery, disease, and mobility-related. The rates of chemoprophylaxis orders were similar in the low to moderate risk and the high-risk group. There was a low frequency of documented VTE events. Currently, this pediatric VTE risk assessment was not predictive of actual pediatric VTE events.
