Purpose: National consensus guidelines recommend the use of antiemetic agents as prophylaxis for chemotherapy-induced nausea and vomiting (CINV), including combinations of 5-HT3 receptor antagonists, dexamethasone, olanzapine, and NK1 receptor antagonists. The utilization of these regimens results in improved quality of life for patients, especially for those receiving highly-emetogenic and moderately-emetogenic chemotherapy regimens. The purpose of this study was to describe and assess the use of fosaprepitant according to national consensus guidelines, at Johns Hopkins Bayview Medical Center (JHBMC), and to evaluate the cost-effectiveness of alternative CINV prophylaxis regimens with respect to a fosaprepitant-based regimen.

Methods: In this single-center, retrospective chart review, all adult patients who received intravenous fosaprepitant at the Sidney Kimmel Comprehensive Cancer Center (SKCCC) in JHBMC between December 1, 2015 and July 1, 2016 were screened for inclusion using electronic medical records. Patients were included if they had an Eastern Cooperative Oncology Group Performance Score (ECOG PS) 0-2, or Karnofsky Performance Score (KPS) 60-100 percent. Patients were excluded if they were enrolled in an investigational trial, were not treated at JHBMC, were treated with an ineligible chemotherapy regimen, had an ECOG PS greater than 2 or KPS less than 60 percent, or did not receive intravenous fosaprepitant. The data was aggregated into a spreadsheet for analysis. The primary outcomes were to describe the use of fosaprepitant at SKCCC at JHBMC, and to assess the use of fosaprepitant for appropriateness as determined by national consensus guidelines for CINV. Secondary endpoints included a cost-analysis of the current usage of fosaprepitant at SKCCC at JHBMC, and the cost-

benefit of using an aprepitant- or olanzapine-based regimen per national consensus guidelines. This project is currently pending institutional review board approval.

Results: Three hundred and eleven patient charts were reviewed. Sixty-eight patients met inclusion criteria, and 66 charts (97 percent) were deemed to have utilized fosaprepitant appropriately per national consensus guidelines for CINV. Of these included charts, 38 (58 percent) were used in highly-emetogenic chemotherapy regimens and 28 (42 percent) were moderately-emetogenic chemotherapy regimens.

The total cost of fosaprepitant-based antiemetic prophylaxis regimens over a 6-month period at SKCCC in JHBMC was 52,992.72 dollars. On average, each patient received 3 doses of fosaprepitant over 3 cycles during the 6-month period, where the average total cost of a 6-month regimen is as follows: fosaprepitant-based regimen is 792.33 dollars, aprepitant-based regimen is 1,831.76 dollars, olanzapine-based regimen with palonosetron is 472.39 dollars, and olanzapine-based regimen with ondansetron is 15.02 dollars. This information is derived from regimens endorsed in national consensus guidelines.

In a six-month period, SKCCC at JHBMC has the potential to save 52,002.72 dollars using an olanzapine-based regimen with ondansetron, or 21,815.64 dollars using an olanzapine-based regimen with palonosetron. The cost to SKCCC increases, however, to an additional 67,921.92 dollars if an aprepitant-based regimen for CINV prophylaxis is used.

Conclusion: The majority of fosaprepitant-based antiemetic regimens were used appropriately at the SKCCC at JHBMC per national consensus guidelines for CINV, but there may be a more cost-effective option, an olanzapine-based prophylaxis regimen, for select patients. Based on group purchasing organization (GPO) pricing, an aprepitant-based regimen is the least cost-effective option. By transitioning from a fosaprepitant-based regimen, JHBMC can potentially incur a savings of approximately 98 percent when switching to an olanzapine-based regimen with ondansetron.

Submission Category: Practice Research/ Outcomes Research/ Pharmacoeconomics

Submission Type: Evaluative Study

Session-Board Number: 5b-023

Poster Title: Pharmacoeconomic evaluation of an enoxaparin assistance program

Primary Author: Caroline Boydstun, University of Mississippi School of Pharmacy, Mississippi;
Email: lcboydst@go.olemiss.edu

Additional Author (s):
John Cleary

Purpose: In December of 2013, the pharmacy department at St. Dominic Hospital, located in Jackson, MS, began an enoxaparin assistance program. By offering this service, the hospital hopes to reduce overall healthcare expenditures and lower readmission rates. The purpose of this study is to assess St. Dominic's enoxaparin assistance program by evaluating if 5-days of enoxaparin bridge therapy with warfarin is enough to achieve a therapeutic INR level (2-3), while also evaluating re-admission rates for this group of patients.

Methods: A retrospective single-center analysis of patients enrolled in an enoxaparin assistance program was conducted from August 2013 to March 2016 at St. Dominic Hospital. Patients included in this study were required to be on both enoxaparin and warfarin, for the purpose of bridging to a therapeutic INR level. Exclusion criteria included patients that were not on warfarin, or patients who lacked initial data. Twelve months of data was collected, including: patient demographics, enoxaparin evaluation, 30-day readmissions, and INR/therapeutic attainment. Both descriptive and inferential statistics were used for data analysis.

Results: Of the 125 patient charts reviewed, only 88 patients were enrolled in this study (mean age, 53.45 years; 65.9% female; mean weight, 94.94 kg; 61.3% African American; 38.6% noninsured), with 68 (77.2%) returning for follow-up visits. The most common enoxaparin indication was DVT treatment (27.3%). Enoxaparin therapy averaged 5.43 days at a dispensed dose of 98.94 mg. There were 27 (30.7%) patients re-admitted within 30 days post discharge, mostly [19 (21.6%)] related to the original enoxaparin indication. Only 44 of the 68 patients had complete data. Sixteen (23.5%) reached therapeutic INR values after using enoxaparin bridge therapy compared to 28 (41.2%) patients who did not reach a therapeutic INR level.

Conclusion: Among patients using enoxaparin for the purpose of bridging to warfarin, 5 days is not enough time to achieve a therapeutic INR level, as indicated by the large percentage of readmission rates related to the original enoxaparin indication. Based on the results in this study, more than 5 days of bridge therapy is needed to reach therapeutic INR levels; however, further studies are needed to determine how many days are necessary.

Poster Title: Hospital admission rates seen with bipolar disorder patients receiving psychotherapy

Primary Author: Alisha Donat, The University of Mississippi School of Pharmacy, Mississippi; **Email:** addornbu@go.olemiss.edu

Additional Author (s):
Allison Bell

Purpose: Bipolar disorder (BPD) causes severe shifts in mood, activity levels, and ability to perform activities of daily life. It affects about 5.7 million adult Americans. Successful treatment depends on a combination of factors. Pharmacotherapy alone is often not enough to keep a bipolar patient well. A combination of pharmacotherapy and psychotherapy proves to be the best way to treat BPD. Lower hospitalization rates were seen with patients who participated in combination treatment versus pharmacotherapy alone. The aim of this study is to determine hospital admission rates among diagnosed BPD patients receiving a combination of psychotherapy and pharmacotherapy versus pharmacotherapy alone.

Methods: Patients were at least 18 years old, diagnosed bipolar disorder I or II, and seen at Communicare Oxford clinic were included. Patients hospitalized for problems not related to bipolar disorder were excluded. Data from June 2014- June 2015 were collected via retrospective chart review. Descriptive statistics and Chi square tests were used for data analysis.

Results: A total of 83 patients were included in the study. Twenty-three were hospitalized for problems related to bipolar disorder. Of the 23 patients, 17 were currently on combination therapy and 6 on pharmacotherapy alone. There was no difference in hospitalization rates between the combination and pharmacotherapy alone groups (p value equals 0.79). Of the 83 patients, 17 had insurance and 51 uninsured. There was no difference between the insurance and uninsured groups in terms of hospitalization rates (p value equals 0.12).

Conclusion: Hospitalization rates did not correlate with use of combination therapy or pharmacotherapy alone. Payment status did not affect whether patients received combination therapy or pharmacotherapy alone.

Poster Title: Individualized prediction of endoxifen concentration during tamoxifen treatment

Primary Author: Emily Van Wieren, University of Michigan College of Pharmacy, Michigan;
Email: emivanwi@med.umich.edu

Additional Author (s):
Kelly Kidwell
Allison Deal
Daniel Hertz

Purpose: Endoxifen concentration, which may predict efficacy of tamoxifen treatment, is primarily determined by CYP2D6 activity with a minor contribution of additional clinical and genetic parameters including CYP2C9 and CYP2C19. The objective of this study was to use an independent dataset to assess the accuracy of an endoxifen prediction algorithm previously published by Teft et al. and create a new algorithm that includes all associated clinical and genetic variables.

Methods: Analysis was conducted in a previously enrolled cohort of 500 women 18+ years old with estrogen receptor positive breast cancer taking tamoxifen 20 mg/day ≥ 4 months and not on moderate or strong CYP2D6 inhibitors. Clinical parameters, endoxifen concentrations, and genotype were determined at time of enrollment. Pearson correlation coefficients assessed the association between predicted endoxifen using the Teft algorithm and observed endoxifen. Univariable regression models were used to identify clinical and genetic variables associated with endoxifen concentration to build a multivariable prediction algorithm.

Results: There was a weak, but highly significant, association between the actual endoxifen concentration and that predicted by the Teft algorithm (r=0.24, p < 0.0001). Our final endoxifen prediction algorithm included weight (Beta coefficient=-0.07, p=0.048) and genotype-predicted activity of CYP2D6 (Beta coefficient=6.06, p < 0.0001), CYP2C19 (Beta coefficient=1.55, p=0.042), and CYP2C9 (Beta coefficient=2.39, p=0.042).

Conclusion: The Teft algorithm does not yield a sufficiently strong prediction for observed endoxifen for clinical use. A new predictive algorithm was developed that could be useful to inform individualized tamoxifen dosing if endoxifen concentration is validated to be a biomarker of tamoxifen efficacy.

Submission Category: Ambulatory Care

Submission Type: Evaluative Study

Session-Board Number: 5b-026

Poster Title: Evaluation of a chronic care management program in the ambulatory care setting

Primary Author: Alexa Han, Shenandoah University Bernard J. Dunn School of Pharmacy, Virginia; **Email:** ahan13@su.edu

Additional Author (s):
Alicia Vickers
Michelle Rager

Purpose: The purpose of this study was to describe the patient population of the CCM program in a family medicine practice, evaluate the effectiveness of the CCM program by determining the difference in the number of hospital stays and emergency department (ED) visits needed for patients before and after enrollment in a CCM program, and evaluate the change in clinical status of chronic diseases before and after enrollment in a CCM program.

Methods: A retrospective chart review was conducted for patients enrolled in the CCM program at a family medicine practice. A list of all patients enrolled in the program was printed. Of the total 136 patients, ninety-five patients were selected at random for chart review. Enrolled patients were excluded only if records were incomplete. Information regarding patient age and gender, number and type of high-risk chronic disease states such as heart failure, diabetes, COPD, or cerebrovascular disease, type of insurance, number of hospital/ ER visits before and after enrollment in the CCM program, length of stay, new and discontinued medications, pharmacy interactions, and clinical status of chronic disease states was gathered. Descriptive statistics were used to describe the population of patients and a independent t-test was used to determine differences before and after enrollment in the CCM program. Statistical significance was set at p < 0.05. The project was approved by the Shenandoah University IRB.

Results: The population of the CCM program included 57.9% females and patients with an average age of 78 (+ 10.1). Patients had an average of 7.52 disease states (including diabetes 42.1%, 16.8% COPD, and 28.4% with an indication for anticoagulation) and 8.86 medications. In the 12 months prior to enrollment in CCM, the average hospital admission per patient was 0.74 with 42.7% of patients having at least one hospitalization. Mean hospital admission per patient after enrollment decreased, but was not statistically different (0.58, p=0.399). There was no

significant difference in hospitalizations for patients previously hospitalized before CCM enrollment compared to those who had not had a hospitalization in the 12 months prior (p=0.313). In the 12 months prior to enrollment in CCM, the average ED visit per patient was 0.41 with 30% of patients having at least one visit. Mean ED visit per patient decreased, but was not statistically different after enrollment (0.30, p=0.456) with only 24 patients utilizing the ED. The mean A1c was significantly lower (7.3% versus 7.6%) after participation in the CCM program (p= 0.079). Given limited data, monitoring parameters such as INR levels, bleeding events and spirometry were not evaluated.

Conclusion: While patients currently enrolled in the CCM program had significant past medical history for chronic diseases and high medication utilization, they had a limited number of hospital and ED visits prior to enrollment. Therefore, it is not surprising that enrollment in the CCM program did not impact the rate of hospitalization and ED visits overall for the time period studied. Patients were relatively well controlled prior to CMM enrollment for some chronic diseases like diabetes, although significant improvement in A1c was still seen. Results shows that patients who may benefit significantly from this program may not have been enrolled.

Submission Type: Descriptive Report

Session-Board Number: 5b-027

Poster Title: Impact of pharmacy staff led medication reconciliation in patients receiving outpatient cancer treatment: a pilot study.

Primary Author: Nicholas Ngo, Shenandoah University Bernard J. Dunn School of Pharmacy, Virginia; **Email:** nngo13@su.edu

Additional Author (s):
Roudabeh Faghri
Kacey Carroll

Purpose: The optimization of medication therapies in patient care is an important component in the pharmacy department's scope of practice. Medication reconciliation can be a useful tool in determining any discrepancies and improving patient care through optimization of drug therapy. Patients receiving chemotherapy may experience many toxicities associated with their regimens potentially due to unoptimized medication regimens. This project was designed as a pilot study in order to determine the impact of a pharmacy led medication reconciliation at an oncology infusion center.

Methods: Patients receiving outpatient chemotherapy or sandostatin were identified and given the option of having a medication reconciliation completed by a pharmacy student. Medication, dosage strength, route and frequency were reviewed for all current medications found in the electronic health record (EHR) and any patient reported medications. Patients were asked about their pain status, chemotherapy-induced nausea and vomiting and changes in bowel movements. Drug-drug interactions were identified via a drug reference resource. Patient questions or concerns and any identified interventions were discussed with the oncology pharmacist, nursing staff and oncology physician. Interventions were quantified based on a scale of relative importance. Scaled interventions were categorized into: medication recommendations, medication education, medication discrepancies, or 'no recommendation'. Medication recommendations were considered high impact, and given 1 point. Medication education was considered moderate impact, and given 2 points. Medication discrepancies were considered low impact, and given 3 points. No recommendations were considered zero impact, and given 4 points. Medication recommendations included changes/additions/discontinuations in drug therapy and were first approved by the pharmacy staff prior to being discussed with the

patient. Patients were assigned a unique identifying number. A separate log of the identification number and patient name were kept in case there was a need for further information. All information was kept confidential and unidentifiable. Results of the study were compared to published literature.

Results: Eleven identified patients elected to be interviewed. Ten patients required interventions from the pharmacist. Five patients received medication recommendations from the pharmacist which were categorized as high impact interventions. Three patients required further education regarding their medication use and were categorized as moderate impact interventions. Ten of the patients required updates to their EHR which were categorized as low impact interventions. Only one patient did not require any intervention from the pharmacist and was categorized as no recommendations. The patients expressed that they were confident in the pharmacy staff's ability to recognize potential issues and put their care as priority.

Conclusion: Medication reconciliation has been shown to be effective in optimizing medication therapy in patients receiving treatment in an outpatient oncology treatment center. Specifically, a pharmacy staff led medication reconciliation can be found to have high impact in improving patient care in this setting.

Poster Title: Retrospective analysis of peri-operative administration of intravenous acetaminophen and post-operative opioid use in pediatric tonsillectomies and adeno-tonsillectomies

Primary Author: Ashley Sauro, University of Michigan College of Pharmacy, Michigan; **Email:** alwolf@med.umich.edu

Additional Author (s):
Deborah Wagner
Shobha Malviya
Sinead Revard
Terri Voepel-Lewis

Purpose: Tonsillectomy or adeno-tonsillectomy is a high-risk outpatient surgery due to the patient population, primarily children, and the potential for airway complications. The risk for airway complications is further increased by the use of post-operation opioids for pain control. Acetaminophen, another component of the standard pain regimen, may have potential opioid-sparing effects. This study aims to investigate whether peri-operatively administered intravenous acetaminophen reduces the quantity of opioids needed for pain control.

Methods: This study was a secondary retrospective analysis of pediatric patients ages 4-17 in the University of Michigan Health System who had a tonsillectomy or adeno-tonsillectomy between May 2011 and December 2015. Individuals were placed into one of two cohorts based on peri-operative pain regimen: IV acetaminophen or other, which included oral acetaminophen use or no acetaminophen use. Primary outcome looks at the difference in the mean of total morphine equivalents taken in each group. Secondary analysis included the mean of morphine equivalents taken intra-operatively and in the PACU.

Results: A total of 186 patients met eligibility criteria. Of those, 115 received IV acetaminophen and 71 patients were in the other cohort which was composed of 46 patients who received no acetaminophen and 25 patients who received oral acetaminophen. Groups were similar with respect to gender, weight, and BMI. The only significant differences were that there were more patients in the IV acetaminophen group with obstructive sleep apnea, and less patients in the IV

acetaminophen group with additional doses of acetaminophen in the PACU. Between cohorts no difference in the amount of morphine equivalents taken intra-operatively or in the PACU was found. But, there was significantly less total morphine equivalents taken by the IV acetaminophen group (P= 0.016).

Conclusion: Intravenous acetaminophen has the potential to reduce the mean morphine equivalents utilized for pain control in pediatric tonsillectomies or adeno-tonsillectomies compared to oral acetaminophen use or no acetaminophen use. Further studies are needed to determine the opioid-sparing effects of intravenous acetaminophen over oral acetaminophen.

Session-Board Number: 5b-029

Poster Title: Retrospective analysis of icatibant use for the treatment of angioedema at a six-hospital health system

Primary Author: Lauren Shelley, Virginia Commonwealth University School of Pharmacy, Virginia; **Email:** shelleyle@vcu.edu

Additional Author (s):
Jason Hoffman
Melissa Hobbins

Purpose: Icatibant is a bradykinin B2 receptor antagonist which is Food and Drug Administration approved for the treatment of acute angioedema due to hereditary angioedema (HAE). There is data supporting icatibant use off label for the treatment of angiotensin-converting enzyme inhibitor (ACE-I) induced angioedema. Icatibant has shown to be highly efficacious in resolving these types of angioedema; however, the acquisition cost is over 8000 dollars per dose. The purpose of this medication use evaluation was to evaluate the utilization of icatibant following formulary approval for the treatment of HAE and ACE-I induced angioedema across a six hospital health system.

Methods: The institutional review board (IRB) categorized this evaluation as a quality assurance/improvement activity exempt from IRB oversight. All patients who received icatibant at any hospital within the system between 7/1/2015 and 6/10/2016 were included. Each electronic medical record (EMR) was reviewed for provider notes, medication orders, medication administration, allergies, flow sheets, and respiratory vital signs. Airway symptoms were recorded and defined as noted difficulty breathing or swallowing. Traditional therapy was defined as any combination of antihistamines, corticosteroids, and epinephrine. Icatibant use was divided into three categories: indicated, possibly indicated, and not indicated. Indication criteria were determined based on current health system restrictions and defined prior to evaluating each EMR. Current restrictions include prescribing limited to emergency medicine, intensive care unit, and hospitalist providers for patients with severe airway restriction that may or will require intubation related to HAE or ACE-I induced angioedema. Icatibant was indicated if the patient's condition met current restrictions. It was not indicated if the EMR explicitly noted that the patient's respiratory status was improving prior to icatibant

administration, swelling was not progressing and the patient did not have difficulty breathing, or if there was another likely cause of the angioedema, other than ACE-I use or HAE. It was possibly indicated if the patient did not fall into either of the other two categories. Descriptive statistics were utilized to analyze the results.

Results: A total of 15 patients received icatibant at three different facilities within the health system. All doses of icatibant were ordered in the emergency department (ED) and 13 of 15 doses (86.7 percent) were ordered by physicians, while the remaining two orders (13.3 percent) came from a resident and physician assistant. Two patients had confirmed or suspected HAE. Of 13 patients treated for suspected ACE-I induced angioedema, two cases were deemed to be due to a medication other than an ACE-I. Twelve of 13 patients (92.3 percent) presented with some tongue swelling and six (46.2 percent) had edema in multiple locations. Five of 13 patients (38.5 percent) presented with difficulty breathing and six (46.2 percent) did not experience airway symptoms. Nine of 13 patients received traditional therapy prior to icatibant. Four of 13 (30.7 percent) patients required intubation as a result of their angioedema. ACE-I were added as an allergy in the EMR for nine of 13 cases (69.2 percent). Based on the indication criteria, icatibant was indicated in seven cases (46.7 percent), not indicated in five cases (33.3 percent), and possibly indicated in three cases (20 percent).

Conclusion: The majority of icatibant uses were determined to be possibly or not indicated, which resulted in a large cost to the health system. The five cases deemed to be inappropriate resulted in a direct medication cost of over 40,000 dollars. Recommendations included the addition of required indications when ordering icatibant, requiring ACE-I addition to the allergy list following ACE-I induced angioedema, and restricting use to patients who have HAE or who are taking an ACE-I where the angioedema has no other probable cause and is progressing, not responsive to traditional therapy, or where icatibant may prevent intubation.

Poster Title: Prothrombin Complex Concentrate Usage in a Large Academic Medical Center: A Case Series

Primary Author: Taylor Loosier, University of Mississippi School of Pharmacy, Mississippi; **Email:** taloosie@gmail.com

Additional Author (s):
Caroline Bobinger
Richard Ogletree

Purpose: The purpose of this case series is to determine prothrombin complex concentrate (Kcentra) usage over the last calendar year, July 2015 to July 2016. This study aims to report similarities and variances in pre and post dose international normalized ratio, drug dose used, concomitant vitamin K administration, side effects, and indication.

Methods: This is a case series detailing 10 cases of Kcentra administration at the University of Mississippi Medical Center. Pharmacy electronic health records from July 2015 to July 2016 were accessed. University of Mississippi Medical Center generated a list of patients who have received Kcentra over the past calendar year. Pharmacy records of these particular patients were accessed using the University of Mississippi Medical Centers' online database to determine the following: international normalized ratio at baseline, concomitant Vitamin K administration, weight-based dose of Kcentra given, international normalized ratio post dose, side effects after or during administration, and indication for use. These items were collected and documented using a data collection form in which variances and similarities were then analyzed.

Results: Ten patient electronic health records were included in the analysis. International normalized ratio at baseline ranged from the lowest, 2.09, to the highest 5.99. The average baseline international normalized ratio was 3.288. The international normalized ratio post dose ranged from the lowest, 1.3, to the highest 2.97. The average post dose international normalized ratio was 1.994. Kcentra dosage varied ranging from the lowest dose of 680 units to the highest dose of 3,840 units. The average Kcentra dose administered was 2,399 units. Vitamin K was administered concurrently with Kcentra to 50% of patients (n=5). There were no

documented side effects from Kcentra administration. Indication for use varied across all 10 patients with the most common indication being hemorrhage.

Conclusion: Kcentra is often used at the University of Mississippi Medical Center in trauma situations. Administration of concurrent vitamin K should be a goal of therapy when Kcentra is used. However, only 50% of patients in the last calendar year received concurrent vitamin K at the University of Mississippi Medical Center demonstrating a need for education for all healthcare providers. All patients in this analysis who were given Kcentra did experience baseline international normalized ratio reduction and did not report any documented side effects. The results of this analysis demonstrate Kcentra's effectiveness and safety in a large academic medical center.

Poster Title: Barriers to venothromboembolism prophylaxis: A retrospective analysis of patients admitted to a community hospital that experienced hospital-acquired venothromboembolic events

Primary Author: Sarah Nowalk, Virginia Commonwealth University, Virginia; **Email:** nowalks@vcu.edu

Additional Author (s):
Martha Healy

Purpose: Venous thromboembolism (VTE), specifically pulmonary embolism (PE), remains the most preventable cause of hospital death. In addition to the pain and risk of bleeding which coincide with VTE treatment in the acute period, further consequences for the patient and provider can include increased length of stay, readmission, recurrent VTE, mortality, increased medical bills, and denied reimbursement. Additionally, appropriate prophylaxis for VTE is administered at suboptimal rates, for reasons which vary among institutions. The purpose of this study is to identify barriers to appropriate VTE prophylaxis therapy in a community hospital and to identify interventions to improve appropriate VTE prophylaxis.

Methods: Data from August 2015 through June 2016 were collected retrospectively from the electronic medical record. All patients were identified with ICD-10 codes I26: "Pulmonary Embolism" and I82: "Other Venous Embolism & Thrombosis." Diagnoses were confirmed with positive imaging results via duplex ultrasound or computed tomography angiography. Patients less than 18 years old, with VTE present on admission, or with superficial thromboses were excluded from the study population. VTE risk scores at time of admission were calculated using two validated risk assessment models (RAMs). Bleeding risk was then calculated as well using two validated RAMs. Patients with a "high VTE risk" score by either RAM were then assessed for appropriate thromboprophylaxis from admission to time of VTE development. To determine the ability of multiple healthcare team members to use the RAMs, a pharmacy student, pharmacist, nurse, and physician individually rated each patient. Kappa scores were calculated to assess inter-rater reliability. Appropriate prophylaxis was defined according to the most recent American College of Chest Physicians Guidelines for Prevention of VTE in Nonsurgical Patients as well as the VTE-6 Inpatient Quality Measure dictated by The Joint Commission.

Finally, barriers to prophylaxis were identified and analyzed manually in a categorical and descriptive fashion.

Results: Eighteen patients developed a hospital acquired (HA-) VTE during the study period (PE 22 percent, upper extremity deep vein thrombosis (DVT) 44 percent, lower extremity DVT 39 percent). All patients were at high risk for VTE at admission according to at least one RAM score. The majority of patients (94 percent) received appropriate prophylaxis within 24 hours of admission. However, only 44 percent of patients received appropriate prophylaxis throughout their admission. The most common barriers to appropriate prophylaxis (33 percent) were either active bleeding or perceived bleeding risk, which resulted in missed doses for each of the patients. Of these patients, two of six had bleeding risk scores of low to moderate, indicating that they could still benefit from chemoprophylaxis according to guidelines. Five patients (28 percent) had prophylaxis held for invasive procedures, and two of these patients did not resume prophylaxis in a timely manner (within 24 hours). Two patients (11 percent) missed doses due to patient or family refusal. Finally, eight patients (44 percent) had subtherapeutic prophylaxis for various reasons including perceived contraindications and use of mechanical prophylaxis rather than chemoprophylaxis.

Conclusion: This analysis identified several barriers to VTE prophylaxis and areas of potential improvement in patient care. One intervention that could impact VTE rates would be to institute a formal protocol for VTE and bleeding risk assessments as well as providing appropriate chemo- or mechanical prophylaxis orders according to risk levels, and instructions regarding holding and restarting prophylaxis around invasive procedures. Until such an intervention can occur, provider and staff education as well as pharmacist and/or student monitoring may improve the level of appropriate VTE prophylaxis and possibly decrease incidence of HA-VTE events at this institution.

Submission Category: Cardiology/ Anticoagulation

Session-Board Number: 5b-032

Poster Title: Assessment of thrombosis based on time in therapeutic range after left ventricular assist device placement

Primary Author: Julia Lea, Virginia Commonwealth University School of Pharmacy, Virginia; **Email:** leajc@vcu.edu

Additional Author (s):
Catherine Floroff
Amanda Ingemi
Andrew Yao

Purpose: Left ventricular assist devices (LVAD) serve as circulatory support for patients with heart failure. Complications associated with their use include pump thrombosis requiring chronic anticoagulation that increases risk of bleeding. It is not known whether time within the therapeutic international normalized ratio (INR) range for patients with LVADs on warfarin therapy is associated with improved outcomes. The goal of this study is to assess the relationship between time in therapeutic range (TTR) at different time periods prior to suspected or confirmed pump thrombosis for patients with LVADs on chronic warfarin therapy as well as patient parameters associated with pump thrombosis.

Methods: A retrospective case-control study was conducted at an academic medical center to evaluate adult patients aged 18-89 on chronic warfarin therapy with INR monitoring after LVAD implantation. Exclusion criteria included patients with implantable devices other than HeartMate II (Thoratec Corp., Pleasanton CA), HeartMate III, or HeartWare (HeartWare Inc., Framingham, MA) continuous-flow LVADs. Patients were assessed for lactate dehydrogenase (LDH) greater than 600 IU/L and documentation of suspected or confirmed pump thrombosis. The thrombus group consisted of patient characteristics, including TTR, during 3 months leading up to the pump thrombosis. Patients served as their own controls using TTR data from 6 months to 3 months prior to the pump thrombosis for a non-thrombus associated comparison (control group). The two groups were compared based on a standardized 2 to 3 INR goal range. The primary outcome was change in TTR between the thrombus and control group. Secondary outcomes included differences in patient characteristics as well as outcomes between the

groups. A separate analysis was completed using a standardized 0 to 1.99 time below range (TBR).

Results: A total of 24 were patients were included in the study. All patients were implanted with a HeartMate II device. The mean difference in TTR between the groups 1 month prior to event was -0.0575 percent (95 percent CI, -0.1796 to 0.0646, P equals 0.3385). The mean difference in TTR 2 months preceding the event was 0.0389 percent (95 percent CI, -0.0911 to 0.1688, P equals 0.5422) and 3 months prior to the event was 0.0475 (95 percent CI, -0.0562 to 0.1512, P equals 0.3528). The mean difference in TBR between the groups 1 month prior to event was 0.0140 (95 percent CI, -0.1168 to 0.1449, P equals 0.8259). The mean difference in TBR 2 months preceding the event was -0.0610 (95 percent CI -0.1863 to 0.0644, P equals 0.3250) and 3 months prior to the event was -0.0671 (95 percent CI, -0.1676 to 0.0335, P equals 0.1808).

Conclusion: Percent times below and in therapeutic INR range did not differ leading up to pump thrombus compared to a thrombus-free time period. The time period for thrombus development is unknown, and it is possible that the 3 month period chosen is not an adequate time interval to differentiate thrombus and non-thrombus time. Further investigation is needed to compare the differences in antiplatelet medications, pump settings, and other risk factors during these time periods.

Poster Title: What to do next? Insights about the factors, logic, use, and validity of clinical pharmacy work prioritization tools

Primary Author: Jerika Nguyen, University of Michigan College of Pharmacy, Michigan; **Email:** jerikan@med.umich.edu

Additional Author (s):
Hanjie Mo
Allen Flynn
Bruce Chaffee

Purpose: The aim of this study is to understand which factors drive clinical pharmacy work prioritization tools, how those factors were selected, how pharmacy informatics experts think about the prioritization factors, logic, and use of these tools, and the degree to which these tools have been validated.

Methods: This study employed a mixed approach using both quantitative and qualitative methods. Before initiating this study, our research protocol was reviewed by the Institutional Review Board of the University of Michigan and it was determined that this study involved research on organizations and not human subjects research. Nevertheless, all interviewees were consented and all interview data was anonymized. Pharmacy informatics experts were selected for recorded telephone interviews (tele-interviews) using purposive sampling. A detailed interview guide was developed and used to elicit subjects' thoughts during the tele-interviews. The interview guide also included a series of open‑ended questions and some specific requests for demographic and descriptive facts. Interviews were transcribed and analyzed using qualitative data analysis software. Interview responses were coded and then those codes were iteratively analyzed to develop 12 themes about clinical pharmacy work prioritization tools.

Results: Nineteen tele-interviews were included in our study. Thirty different prioritization factors applied to clinical pharmacy work were described, including 10 patient-specific factors (e.g. acuity, renal function), 12 different therapeutic categories of medications (e.g. antibiotics, anticoagulants), and 8 potential interventions (e.g. patient education, medication

reconciliation). The use of these thirty individual prioritization factors varied widely among institutions. With respect to assessment of the validity of these tools, 2 (10.5%) and 3 (15.8%) of the tools were assessed for content and criterion-related validity, respectively, with some tools evaluated for more than one type of validity. No tools were assessed for construct validity. Qualitatively, 12 themes about the factors, logic, use, and validity of clinical pharmacy work prioritization tools emerged: (1) Pharmacist consensus‑based design, (2) Complexity of logic, (3) Not a substitute for clinical judgment, (4) Importance of automated lists, (5) Not comprehensive, (6) Maintenance, (7) Intuitive, non-standardized factor weights (points), (8) Tension between a task-oriented versus a patient-oriented practice, (9) Comfort, (10) Motivators for tool use, (11) Practice mirror, and (12) Challenge of validation. A majority of subjects provided comments that indicated that prioritization factors required continual reviewing and updating to remain relevant in clinical pharmacy work prioritization.

Conclusion: A group of pharmacy informatics experts believe that clinical pharmacy work prioritization tools are complex and hard to maintain, are not comprehensive, and that pharmacists should use them only as aids and not substitutes for clinical judgment. Our research provides a glimpse into existing validation processes and identified that pharmacy informatics experts find tool validation challenging due to a lack of knowledge and resources. While many subjects perceived their tools as valid, there is a general lack of empirical evidence to support these beliefs.

Poster Title: Multidisciplinary approach to improve utilization and cost savings of PCR respiratory pathogen testing in a large community hospital

Primary Author: Ashleigh Lancaster, Auburn University Harrison School of Pharmacy, Alabama; **Email:** ral0016@auburn.edu

Additional Author (s):
Kylie Noles
Steven Lee
Jonathan Edwards

Purpose: Polymerase Chain Reaction (PCR) technology for precise detection of infectious pathogens has the potential to improve antibiotic stewardship through accelerated de-escalation of therapy, rapid identification of pathogens, and detection of resistance genes. However, its place in therapy is uncertain due to high costs of testing, absence of pathogen susceptibility information, and lack of physician confidence in utilizing results. The purpose of this study was to improve utilization and cost savings of PCR respiratory pathogen testing in a large community hospital.

Methods: This single center, retrospective chart review consisted of two medication use evaluations (MUE). All patients with an order for a complete or basic PCR respiratory panel were included in the study. Patients were excluded if the patient was discharged or deceased prior to result reporting or if there was an insufficient specimen quantity to perform the test. Each patient was evaluated for appropriate respiratory panel collection site and antibiotic regimen changes within 48 hours of respiratory panel results. The first MUE was conducted from October to December 2015 and evaluated how the PCR respiratory panels were being utilized initially in antibiotic decision-making. A multidisciplinary approach to improving how these respiratory panels were ordered and utilized included the expertise of clinical laboratory supervisors, information technology technicians, pharmacists, Infectious Diseases (ID) physicians, and the Chief Medical Officer (CMO) of Huntsville Hospital. Three primary interventions were enacted as a result of this first review, including restricting comprehensive respiratory panel ordering to ID physicians, taking PCR respiratory panels off of all order sets, and eliminating nasal swabs as a source option for PCR respiratory panels in the clinical

information system. A second MUE was conducted from May to August 2016, and re-evaluated the utilization and costs of PCR respiratory panels following these interventions.

Results: The total number of respiratory panels ordered decreased substantially from 462 respiratory panels ordered pre-intervention (three months) compared to 195 post-intervention (four months). From the panels that met inclusion and exclusion criteria, the number of basic respiratory panels ordered increased from 13 percent pre-intervention to 87 percent post-intervention. The decline in number of total respiratory panels ordered and in the percentage of complete respiratory panels ordered saved an average of 13,225 dollars monthly. Respiratory panels were ordered to be collected on an inappropriate source 8 percent of the time by non-ID physicians and 3.5 percent by ID physicians. This was a substantial decrease from 77 percent and 34.5 percent, respectively, compared to pre-intervention analysis. This resulted in a cost reduction of approximately 3,500 dollars monthly spent on inappropriate testing sites. The primary respiratory panel collection site shifted post-intervention, with 90.5 percent of panels taken from nasopharyngeal swabs or sputum. Appropriate action was taken following the results 42.9 percent of the time by non-ID physicians and 48.1 percent of the time by ID physicians, which is a slight decrease from the 50 percent and 52.6 percent, respectively, of pre-intervention actions.

Conclusion: PCR respiratory panels allow the potential to de-escalate antibiotic therapy sooner compared to traditional culture results. Careful restrictions on panel ordering have helped ensure appropriate use and cost containment from this expensive test. Restrictions on collection site have effectively eliminated a majority of inappropriate PCR respiratory panel ordering and could save up to 42,000 dollars annually. Elimination of PCR respiratory panels from order sets and restrictions of complete respiratory panel ordering to ID physicians could potentially save 160,000 dollars annually. Future directives include eliminating nasopharyngeal swabs as a collection site and continuing restriction of complete respiratory panels to ID physicians.

Session-Board Number: 5b-035

Poster Title: Assessing the potential need for pharmacist intervention based on discharge summary errors

Primary Author: Jordan McEwen, Virginia Commonwealth University School of Pharmacy, Virginia; **Email:** mcewenj@vcu.edu

Additional Author (s):
Ashley Fontan
Megan Hoesly
Catherine Floroff
Jon Horton

Purpose: According to the National Quality Forum, 21 billion dollars are spent each year on medication errors, with 7 million errors being preventable. Discharge errors are thought to account for 12 percent of preventable errors. The goal of this study was to determine the number and types of medication errors on discharge summaries and after visit summaries to establish a need for pharmacist review.

Methods: A random sample of patients discharged from Sentara Virginia Beach General Hospital (SVBGH) and Sentara Norfolk General Hospital (SNGH) between the dates of August 1-18, 2016 were included. Discharge summaries were reviewed for pre-determined types of errors. These errors included incorrect dose, incorrect medication, incorrect frequency, missing information, missing medications, no indication, and duplicate medications. Errors on high alert and high readmission medications were collected. High alert medications were defined as new anticoagulants and new hypoglycemic agents. High readmission medications were defined as antiplatelet agents (excluding aspirin), anticoagulants, oral hypoglycemics, insulins and long-acting opiates. Errors were also stratified based on presence of a medication history taken by a pharmacy technician during the hospital admission. Readmission within 30 days was examined and stratified based on discharge and after visit summary errors. Lastly, discrepancies between the patient's discharge summary and after visit summary were examined.

Results: A total of 136 patients were included in the study (59 from SVBGH and 77 from SNGH). Overall, 47.8 percent of patients had at least one medication error on the discharge summary. Patients who did not have a medication history taken on admission had a higher percentage of errors compared to patients who did have a medication history taken. Additional discrepancies were found between discharge and after visit summaries.

Conclusion: The percentage of medication errors found on discharge summaries indicates pharmacist involvement could play an important role in reviewing discharge orders prior to printing the after visit summary. This has the potential to reduce errors, readmissions and patient harm upon discharge.

Poster Title: Clostridium difficile infection: Treatment guideline adherence and impact on clinical cure

Primary Author: Nicole Heeren, South Dakota State University College of Pharmacy and Allied Health Professions, South Dakota; **Email:** nicole.heeren@jacks.sdstate.edu

Additional Author (s):
Brianna Jansma
Kaitlyn Kuske
Thaddaus Hellwig

Purpose: Clostridium difficile infection (CDI) is one of the primary leading causes of hospital-associated gastrointestinal illnesses. Many risk factors have been identified for CDI such as extended inpatient hospitalization, exposure to antimicrobials, and use of acid-suppressing medications. Previous studies have shown that guideline-concordant therapy reduces CDI complications, recurrences, and mortality. The purpose of this study was to assess practitioners' adherence to CDI guidelines and its impact on clinical cure.

Methods: The institutional review board approved this retrospective, chart review study of 131 adult patients with a positive fecal Clostridium difficile toxin test between December 1st, 2014 and November 30th, 2015, at Sanford University of South Dakota Medical Center in Sioux Falls, South Dakota. Patients were classified by disease severity to mild-moderate, severe, severe-complicated, first recurrence, and second or later recurrence CDI according to the Infectious Diseases Society of America/Society for Healthcare Epidemiology of America (IDSA/SHEA) and the American College of Gastroenterology (ACG) guidelines. Therapy compliance to guidelines was assessed using disease severity and the medication administration record to further classify each case as sub-therapeutic treatment (ST), therapeutic treatment (TT), or over-treatment (OT). Clinical cure was defined as no need for therapy escalation, diarrhea free for 2 consecutive days, and survival to discharge. Bacteriologic cure was defined as a negative Clostridium difficile toxin or bacteriologic test during hospital stay or upon discontinuation of antibiotic therapy. Clinical cure was also stratified based on severity of CDI. Clinical cure and severity were also evaluated for a relationship with ATLAS scores, a bedside scoring system for

CDI using 5 characteristics (age, treatment with systemic antibiotics, leukocytes, albumin, and serum creatinine).

Results: The two primary outcomes were treatment guideline adherence based upon severity of CDI, and clinical cure based upon treatment guideline adherence. The primary outcome of treatment vs. severity resulted in a statistically significant negative correlation (r = -0.399, p-value < 0.05); this means as severity decreased the risk of over-treating the infection increased. The primary outcome of clinical cure for ST vs. TT had an odds ratio (OR) of 1.8, and OT vs. TT was 1.08 with p-values of 0.203 and 0.873, respectively. Secondary outcomes included assessing the relationship between CDI severity and the outpatient/inpatient use of proton pump inhibitors (PPI's), histamine 2 receptor antagonists (H2RA's), probiotics and antibiotics. These were not shown to have a relationship with severity of CDI. ATLAS scores were shown to have a direct relationship with severity (p-value = 0.002), but no relationship with clinical cure.

Conclusion: In our study, it was shown that practitioners were more likely to over-treat less severe cases of CDI. Outpatient and inpatient probiotics, antibiotics, H2B and PPI's were not shown to have a relationship with CDI severity. ATLAS scores correlated with a higher CDI severity, but not clinical cure rates.

Poster Title: Mobile apps for individuals with intellectual and developmental disabilities

Primary Author: Alexa Fedrigon, University of Michigan College of Pharmacy, Michigan; **Email:** fedrigon@umich.edu

Additional Author (s):
Karen Farris
Teresa Salgado

Purpose: Several mobile apps for medication management exist; however, few have been specifically designed for individuals with intellectual and developmental disabilities (IDDs). This project aimed to 1) identify existing smartphone apps designed as medication management tools and and compare their features and 2) evaluate the visual appeal, importance and usability of features of existing medication management apps, specifically to be used in a population of young adults with IDDs. The ultimate goal was to identify mechanisms to improve medication self-management by individuals with IDDs.

Methods: A systematic review was conducted to identify existing medication management apps. Apps were examined to categorize their features and identify the most common features shared among apps. Based on these results, a questionnaire was designed to target the three most common features and ask about other potential features. The Delphi technique was used to garner consensus among experts, identified based on their experience with IDDs. Experts participated in up to three rounds of the questionnaire. The questionnaire consisted of four modules designed around each of the three most common features plus a module for additional features. Each module included multiple questions including rank order of screen shots assessing visual appeal and Likert scale assessing importance of features. In addition, open-ended questions for additional comments and choosing the most and least important additional features for inclusion in an app were also included. Consensus was defined as greater than 90%, 80% and 75% for rounds 1, 2 and 3, respectively. The results were analyzed after each round and those items which achieved consensus were removed. Visual appeal was determined via highest rating, whereas importance and usability were determined via consensus. Additional features were ranked by the number of individuals selecting that feature.

Results: The most common features among medication management applications were medication lists, medication reminders and medication administration reports. Rounds 1, 2 and 3 gathered responses from 30, 24 and 21 experts, respectively. A preferred visual design was identified for each of the three most common, based on cumulative rankings from all three rounds of the questionnaire. No features achieved consensus for exclusion, however, many features achieved consensus for inclusion. The additional features identified as most important included a record of known drug allergies, the ability to share medication information from the app with provider, family, friends and caregivers, emergency contact list and prescription refill reminders. The additional features most likely to be utilized by patients and caregivers were the ability to share medication information from the app with provider and prescription refill reminders. The top three most important additional features were pharmacy automatic refill mechanism; ability to share medication information from the app with the provider; and ability to share medication information from the app with family, friends or caregiver. The top three least important additional features were a link to an official drug information resource; privacy settings and password protection; and prescription refill reminders.

Conclusion: Although several mobile apps for medication management exist, few to none are specifically designed for individuals with IDDs. It is important to prioritize features for inclusion in order to provide a simple, easy to use, but comprehensive app. Visual appeal, importance and usability of features should also be considered. An ideal medication management app would be tailored to the needs of its intended population and, ultimately, promote independence and improve health of individuals with intellectual and developmental disabilities.

Poster Title: Treatment of methicillin-susceptible Staphylococcus aureus bacteremia with ceftriaxone

Primary Author: Rachel Lowe, University of Mississippi, Mississippi; **Email:** ralowe1@go.olemiss.edu

Additional Author (s):
Katie Barber
Jamie Wagner
Kayla Stover

Purpose: Methicillin-susceptible Staphylococcus aureus (MSSA) comprises approximately half of all S. aureus isolates identified and is implicated as the leading cause of hospital-acquired infections. Standard of care therapies (SOCT), including anti-staphylococcal penicillins and cefazolin, display high treatment success. However, use is limited by frequency of dosing, allergies, and clinically relevant nephrotoxicity. Ceftriaxone represents an alternative to these agents with infrequent dosing, and no renal impairment. The hypothesis of this retrospective case series is that ceftriaxone will be as effective for the treatment of MSSA bloodstream infections as SOCT.

Methods: Electronic health records were reviewed retrospectively at the University of Mississippi Medical Center in Jackson, Mississippi for all adult inpatients with a positive blood culture for MSSA between February 2015 and January 2016. Adult inpatients with positive MSSA blood cultures who received ceftriaxone for ≥ 48 hours were included. Exclusion criteria were receipt of vancomycin or concomitant systemic antimicrobials with in vitro activity against MSSA, polymicrobial infections, and pregnant patients. Additional data collected included demographics, source/site of infection, treatment regimen, and clinical outcomes. The primary endpoint was clinical cure, defined as normalization of white blood cell count and temperature within 7 days of the first positive blood culture and clearance of bloodstream infection within 7 days. Descriptive statistics were utilized.

Results: A total of 74 patients were screened; 15 patients were included. The most frequent reasons for exclusion were definitive SOCT or vancomycin therapy. Eleven patients received SOCT prior to ceftriaxone while 4 patients were initiated on ceftriaxone. Clinical and microbiological cure were observed in 6/15 (40%) and 10/15 (67%), respectively. Clinical failure due to leukocytosis at day 7 occurred in 5/9 (56%) patients. Only 1 patient was readmitted with an MSSA infection, which was subsequently eradicated within 4 days after initiation of ceftriaxone therapy.

Conclusion: Ceftriaxone appears to be a reasonable alternative treatment for prevention of recurrence or readmission for MSSA bacteremia when given initially or when prescribed for outpatient usage after SOCT.

Poster Title: Survey of students' perception of SOAP note writing in advanced pharmacy practice experiences (APPEs)

Primary Author: Joanne Dang, Auburn University Harrison School of Pharmacy, Alabama; **Email:** jtd0027@tigermail.auburn.edu

Additional Author (s):
Nicole Slater
Allison Meyer
Miranda Andrus
Cherry Jackson

Purpose: Clinical pharmacists commonly document their interventions via SOAP note. Student pharmacists are expected to translate SOAP writing skills taught in didactic courses to clinical scenarios during their APPE rotations. It is unclear if the subject material students learn in the first three years of the curriculum is comparable to the activities performed during the fourth year, and if the use of a standardized grading rubric would aid in student documentation. A standardized SOAP note grading rubric was collaboratively developed by 10 ambulatory care faculty members in April 2015 to assess student performance when writing SOAP notes in a clinical setting.

Methods: Fourth year student pharmacists completing primary care rotations were surveyed at the end of their APPEs to determine their comfort level and confidence with writing SOAP notes. Throughout each primary care rotation, students were asked to write three comprehensive SOAP notes and were graded using the standardized rubric, which students were provided at the beginning of the rotation block. The survey also collected data to help determine the usefulness of the rubric. The survey was developed using the Auburn University Qualtrics tool which was also utilized to analyze the responses. The study was approved by the Institutional Review Board (IRB) Auburn University.

Results: The survey was sent to 135 students who completed primary care rotations from May 2015 – April 2016; 83 (61.5%) opened the survey and 53 (39.3%) answered all questions. Roughly half of students believed the rubric correlated well with concepts in earlier courses

throughout the curriculum in the first-third professional years (49.1-66.0%). The majority of students (88.7%) felt they had a clear understanding of the expectations for SOAP notes after reviewing the rubric, and 92% felt more confident in their ability to write SOAP notes after the rotation block had ended.

Conclusion: On clinical pharmacy rotations, student pharmacists are expected to know how to write comprehensive SOAP notes. Although the response rate was less than 50%, the results of this study demonstrated that the use of a grading rubric improved student perception of their ability to document clinical information using SOAP notes on primary care APPEs.

Submission Category: Ambulatory Care

Submission Type: Descriptive Report

Session-Board Number: 5b-040

Poster Title: Student pharmacists' level of confidence providing diabetes self-management education (DSME) prior to entering advanced pharmacy practice experience rotations

Primary Author: Regan Wade, Auburn University Harrison School of Pharmacy, Alabama; **Email:** rzw0013@auburn.edu

Additional Author (s):
Kathryn Chappell
Kristi Kelley
Pamela Stamm

Purpose: Due to the prevalence of diabetes in the United States, fourth year pharmacy students will likely encounter and educate patients with diabetes during their advanced pharmacy practice experience rotations. The purpose of this study was to assess the confidence of third year pharmacy students at an established, public four-year pharmacy school in their knowledge regarding DSME skills. The study also involved determining lack of exposure to aspects of DSME and students' opportunities to counsel diabetic patients. Results from the Doctor of Pharmacy class of 2018 were analyzed alone and then compared to previous results from the class of 2017.

Methods: The institutional review board approved the release of a voluntary, anonymous survey to be conducted via email to third year pharmacy students. The survey consisted of four multi-part questions that assessed DSME using numerical ranges, select all that apply, and ranking scales based on confidence level, which ranged from not confident to very confident. One question consisted of students' confidence level in DSME knowledge in various categories. One question assessed lack of exposure to DSME in pharmacy school. Two questions assessed exposure to patients with diabetes and opportunities to provide DSME. Students had approximately two weeks to complete the survey. The initial email containing the survey was sent in September, with two reminder emails sent one week and one day prior to survey closure. At this point in time, students had been exposed to diabetes education in skills labs and an integrated pharmacotherapy course.

Results: Forty-five third year student pharmacists graduating in 2018 completed the survey compared to thirty-five students surveyed the previous year. For the majority of categories, students felt confident or very confident, reflecting 64 to 100 percent of responses. Categories containing the most very confident responses, greater than 50 percent, were "Storage and Disposal of Insulin Pens and Needles," "Self Monitoring Blood Glucose," "Glucose and HbA1C Goals," "Signs, Symptoms, and Treatment of Hyperglycemia," "Exercise Recommendations," and "Preventative Care." Students were least confident with categories including "Mechanism of Action," "Healthy Coping," "Diabetic Foot Care," and "Administration of Diabetes Medications." Outcomes were similar with previous results. Students indicated least exposure to "Healthy Coping," "Referring to Ophthalmologist and Podiatrists," and "Footcare and Preventative care." During weekly introductory pharmacy practice experience, students reported managing care for 0.11 type 1 diabetes patients and 1.26 type 2 diabetes patients, on average. Comparing the two classes, approximately 82.9 percent in the 2018 class and 74 percent in the 2017 class had five or fewer opportunities to provide DSME to patients seen during weekly introductory pharmacy practice experiences. 70.3 percent of the 2018 class and 86 percent of the 2017 class had five or fewer opportunities outside of school.

Conclusion: More than half of students reported feeling confident or very confident in all fifteen DSME categories. Most often students were least confident in DSME areas in which they lacked educational exposure. Surveying third year pharmacy students helps to identify areas of comfort and lack of exposure with regard to DSME. This data may be helpful from an academic standpoint for adjusting DSME targeted curriculum for better preparedness prior to entering their advanced pharmacy practice experience. One limitation of the study was less than one-third of the 2018 class completed the survey.

Submission Type: Evaluative Study

Session-Board Number: 5b-041

Poster Title: Overall Cost Comparison of Children Receiving Methotrexate for Acute Lymphoblastic Leukemia

Primary Author: Colleen Riley, University of Mississippi Medical Center, Mississippi; **Email:** cmriley@go.olemiss.edu

Additional Author (s):
Andrew Ostrenga

Purpose: Treatment regimens for Acute lymphoblastic leukemia (ALL) often contain inpatient high-dose Methotrexate(HD-MTX) therapy or outpatient Cappizzi Methotrexate(C-MTX). Delayed clearance has been identified as one of the major contributing factors for toxicity, often leading to increased financial costs. The purpose of this project is to compare the medical costs of C-MTX and HD-MTX and further compare the medical costs of HD-MTX standard clearance to HD-MTX delayed clearance.

Methods: A retrospective review of electronic medical records along with a questionnaire measuring direct medical costs was performed for pediatric patients, ages 2 to 18 years old, who received either HD-MTX or C-MTX for ALL at the University of Mississippi Medical Center. The total cost for each patient included intravenous fluid costs, cost of methotrexate therapy, additional costs for delayed clearance, cost of hospital stay or office visit, and estimated cost of travel. These were calculated for each patient and descriptive statistics along with a student's t-test were used to analyze the data.

Results: A total of 16 patients(4 HD-MTX standard clearance, 6 HD-MTX delayed clearance, 4 C-MTX, 2 both C-MTX and HD-MTX) met inclusion and exclusion criteria. The average total cost of therapy for HD-MTX was $12,930 compared to $1,740 for the C-MTX patients ($p < 0.002$). The mean total cost of therapy for patients with standard clearance was $10,084 compared to patients with delayed clearance $15,775 ($p= 0.220$).

Conclusion: This study demonstrates that on average the use of C-MTX compared to HD-MTX may lead to lower financial costs, regardless of standard or delayed clearance in pediatric patients treated for ALL.

Poster Title: Tenfovir alafenamide compared to tenofovir disoproxil fumarate in the management of Human Immunodeficiency Virus with a focus on safety

Primary Author: Maya Patterson, Hampton University School of Pharmacy, Virginia; **Email:** maya.patterson@my.hamptonu.edu

Additional Author (s):
Bisrat Mulugeta

Purpose: Tenofovir disoproxil fumarate (TDF) is the most commonly recommended nucleoside reverse transcriptase inhibitor (NRTI) used in HIV/AIDs treatment regimens. However, data suggests TDF has been associated with decreased bone mineral density and renal toxicities, potentially through a mechanism of high circulating plasma levels. Tenofovir alafenamide (TAF) is a recently Food and Drug Administration approved tenofovir prodrug derivative with a 90 percent reduction in plasma tenofovir concentration. The purpose of this study is to determine whether TAF is non-inferior to TDF in the virological suppression of HIV in treatment naive HIV patients and its impact on renal function and bone density.

Methods: Respective institutional review boards approved these two phase 3 double blind, non-inferiority clinical trials. Men and women 18 years or older who provided informed consent were enrolled if they were treatment naive, HIV infected with an RNA viral load of at least 1,000 copies per mL, and an estimated glomerular filtration rate of at least 50 mL per min. Patients were excluded if positive with hepatitis B surface antigen, hepatitis C antibody or a new AIDS-defining illness within 30 days of screening. Patients were randomly assigned in a 1 to 1 ratio to receive a once daily combination tablet containing 150 mg elvitegravir, 150 mg cobicistat, 200 mg emtricitabine, and 10 mg tenofovir alafenamide (ECF TAF) or 300 mg tenofovir disoproxil fumarate (ECF TDF). The primary outcome measures was the proportion of patients with plasma HIV 1 RNA less than 50 copies per mL at week 48 and pre-specified renal and bone endpoints. There were four key safety endpoints including: spine mineral density, hip mineral density, and treatment emergent proteinuria changes. It was determined that a sample size of at least 840 patients in each study would provide 95 percent power to establish non-inferiority between the two treatment groups.

Results: Combined primary outcomes concluded ECF TAF was non-inferior to ECF TDF at week 48, 800 patients (92 percent) vs 784 patients (90 percent) with plasma HIV 1 RNA less than 50 copies per mL, respectively (adjusted difference 2.0 percent, 95 percent CI -0.7 to 4.7). Safety endpoints showed significantly less proteinuria (median percent change -3 vs 20; p less than 0.0001), significantly smaller decrease in spine bone mineral density (mean percent change form baseline -1.30 percent vs -2.86 percent; p less than 0.0001) and significantly smaller decrease in hip mineral density (mean percent change form baseline -0.66 vs -2.95; p less than 0.0001) in patients given ECF TAF combination therapy at week 48. Adverse effects were comparable between the two groups.

Conclusion: ECF TAF in treatment naive patients was shown to be non-inferior to ECF TDF. Patients in the ECF TAF treatment group experienced significantly less bone and renal adverse effects. Innovative medication therapies for patients infected with the HIV has shifted from merely maintaining a low viral load to providing better quality of life and minimizing comorbid risks. Further studies are needed to evaluate TAF impact on patients with advanced disease and those co-infected with hepatitis B.

Poster Title: Retrospective analysis of 4-Factor Prothrombin Complex Concentrate administration across a six-hospital health system

Primary Author: Skylar White, Virginia Commonwealth University School of Pharmacy, Virginia; **Email:** whitesn@vcu.edu

Additional Author (s):
Colleen Nguyen
Jason Hoffman
Melissa Hobbins

Purpose: Four-Factor Prothrombin Complex Concentrate (4F-PCC) is indicated for rapid reversal of acute life-threatening bleeds or need for urgent surgery. Dosing errors with 4F-PCC may result in severe adverse effects, such as prolonged bleeding or venous thromboembolic events. Utilizing 4F-PCC to reverse bleeding without an indication results in unnecessary hospital costs. The primary objective of this analysis was to determine appropriateness of 4F-PCC usage with respect to indication and dose as defined by hospital guidelines and a maximum dosing weight of 100 kg. This study also examined the percentage of 4F-PCC administrations entered through the order set.

Methods: The institutional review board (IRB) categorized this analysis as a quality assurance/quality improvement activity exempt from IRB oversight. Electronic medical records were utilized to identify patients that received 4F-PCC from any hospital within the system from May 3, 2015 to May 6, 2016. A total of 295 4F-PCC administrations were identified. Patients were divided into two groups by body weight: those weighing greater than or equal to 100 kg and those weighing less than 100 kg. All patients weighing greater than or equal to 100 kg were included and a random selection of the patients weighing less than 100 kg were chosen. Indication, INR just prior to administration of 4F-PCC, and use of other reversal agents were recorded for all selected 4F-PCC administrations via examination of provider notes, labs, medication administration record, and problem lists from the corresponding hospital encounter. The hospital system's evidence-based Reversal of Life Threatening Bleeding guideline was utilized to assess appropriateness. A margin of 250 units was applied to all 4F-PCC administrations when determining dose appropriateness to account for the variability of Factor

IX units in each 4F-PCC vial and pharmacists' ability to round to the nearest vial. For patients weighing more than 100 kg, a maximum weight of 100 kg was used to determine dosing appropriateness. Data was analyzed using descriptive statistics.

Results: A total of 155 administrations were evaluated, which included 74 administrations for patients weighing greater than or equal to 100 kg and 81 administrations for patients weighing less than 100 kg. Based on hospital guidelines, 102 out of 155 (66 percent) administrations had an appropriate indication, while 28 of 155 (18 percent) administrations were inappropriate because the patient was not prescribed an anticoagulant. The remaining 25 (16 percent) administrations were inappropriate because 4F-PCC was not the first line agent for reversal of heparin, enoxaparin, or antiplatelet agents. Examining administration of additional reversal agents, 124 of the 155 (80 percent) administrations also received vitamin K even though only 82 of 155 (53 percent) administrations were for reversal of warfarin. When 4F-PCC was ordered for reversal of heparin, enoxaparin, or antiplatelet agents, only 8 of 32 (25 percent) administrations received other indicated reversal agents before 4F-PCC. Of the 102 administrations with an appropriate indication, 54 (53 percent) administrations were appropriately dosed, including 34 administrations for patients less than 100 kg and 20 administrations for patients greater than or equal to 100 kg. Of the total 295 4F-PCC administrations identified, only 34 (12 percent) orders utilized the order set.

Conclusion: Despite existing guidelines and a readily available order set, a large number of 4F-PCC doses were administered without an appropriate indication. Mandatory use of the order set could improve both appropriateness of indication for use and appropriateness of dose based on body weight. Use of the order set should also reduce the use of vitamin K in bleeding reversal for medications other than warfarin. Future research should examine the impact of requiring all 4F-PCC orders to go through an order set and an evaluation of venous thromboembolic rates following 4F-PCC administration.

Poster Title: Student pharmacist evaluation of penicillin allergies in a veteran's health care system

Primary Author: Melissa Shively, Auburn University Harrison School of Pharmacy, Alabama; **Email:** mms0032@auburn.edu

Additional Author (s):
Spencer Durham

Purpose: As many as 25 percent of all patients report an allergy to an antimicrobial drug. In particular, approximately 15 percent of patients report an allergy specifically to a beta-lactam antibiotic, with penicillin being most common. Clinicians often mistake penicillin intolerances for true allergies due to inadequate documentation in the medical record. Improper documentation of such allergies can result in the use of less appropriate antibiotic therapy and increased health care costs. This quality improvement project was designed to determine the accuracy of true penicillin allergies within the health system.

Methods: This quality improvement project was approved by the institutional review board. Patients with a documented penicillin allergy were identified through the information technology department of the health system. A student pharmacist performed a chart review for each patient to determine sex, race, age, allergic reaction, and any additional comments on the allergy listing. Patients were then categorized into the following severity categories: "true allergy", "adverse reaction", or "no reaction listed". A true allergy was defined by reactions including hives, rash, urticaria, anaphylaxis, shortness of breath, dyspnea, etc. Adverse reactions included events such as nausea, vomiting, anxiety, dizziness, etc.

Results: The study population included a total of 3,256 patients: 2,756 men and 500 women. Caucasians and African Americans comprised 56.5 percent and 37.6 percent, respectively. Nine hundred and three patients (28 percent) did not have a documented reaction, and thus could not be assessed. True allergic reactions to penicillin were reported in 2,057 of the 2,353 patents with a reaction listed (87.4 percent). Reactions such as rash, urticaria, hives, and anaphylaxis were documented in 1,102 patients (46.8 percent), 341 patients (14.5 percent), 251 patients (10.7 percent), and 85 patients (3.6 percent) of the subset of the population with a listed

reaction, respectively. Of the 2,353 patients with a documented penicillin allergy, 296 patients (12.6 percent) actually experienced an adverse reaction as opposed to a true allergy. Some examples of adverse reactions listed included 110 patients (4.7 percent) with nausea and/or vomiting, 6 patients (0.3 percent) with drowsiness, and 5 patients (0.2 percent) with anxiety.

Conclusion: Most patients reporting an allergy to penicillin did report true allergic reactions. However, few were considered serious or life threatening, with simple rash being most common. More than one quarter of patients reporting an allergy to penicillin did not have a documented reaction, making appropriate antibiotic selection difficult in these patients. Efforts are currently underway within the health system to clarify these allergies. Chart reviews were helpful in identifying patient profiles with missing reaction data for the documented penicillin allergy. Identifying and correcting these gaps may allow for more appropriate antibiotic therapy in future clinic or hospital visits.

Poster Title: Evaluation of pharmacist-led interventions in a long term care facility (LTCF)

Primary Author: Kathleen Daniell, Auburn University Harrison School of Pharmacy, Alabama; **Email:** kdd0005@auburn.edu

Additional Author (s):
Haley Phillippe

Purpose: To examine the benefit of a clinical pharmacist and pharmacy student team at a long-term care facility (LTCF). To review medication related interventions and evaluate the clinical relevance of those interventions.

Methods: One pharmacist and several pharmacy students provided weekly chart reviews over a five year period. Results of each chart review were then verbally reported to the physician team. All patients 65 years of age or older residing in the facility for at least 4 weeks were included. A specified data collection form was used to review all patient charts. Interventions regarding indication, dosing (including renal and hepatic), monitoring, adverse reactions, drug interactions, allergies, nutrition status, Beers criteria, fall risk, and omitted therapy were recorded.

Results: A total of 623 patient charts were reviewed. The following interventions were identified and found to be clinically relevant: 889 major drug interactions were identified and adjustments recommended; 1113 renal dose adjustments were recommended; 4 hepatic dose adjustments were recommended; 753 labs related to drug monitoring were recommended; 178 adverse reactions were identified; 1324 medications were identified as potentially inappropriate medications per Beers criteria; 791 medications were found to increase fall risk; 576 patients were found to have omitted therapy for 1 or more disease states.

Conclusion: Although there were limitations to this retrospective analysis, the results of this study demonstrate that a clinical pharmacist and pharmacy student team improve the management of medication therapy. The pharmacy team provides a consistent approach to medication therapy management, and is an asset that should be utilized in caring for patients in LTCF.

Poster Title: Evaluating the effect of employee training modules on medication errors in adult foster care homes

Primary Author: Austin Brown, University of Michigan College of Pharmacy, Michigan; **Email:** austpaul@med.umich.edu

Additional Author (s):
Steven Erickson

Purpose: Due to mental disabilities, some patient populations are unable to provide care for themselves, and are reliant on the care of either family members or direct care staff. Providing care sometimes requires the use of multiple medications, which presents increased potential for medication errors. Baseline medication knowledge is required by the direct care staff in order to pass medications safely and efficiently to ensure the best therapeutic outcomes for a patient. This study investigated if medication training for direct care employees can improve medication error rates for mental health patients who cannot administer their own medications.

Methods: A pre/post-analysis study design compared medication error rates in patients with mental/physical disabilities residing in adult foster care (AFC) homes four months before and after a medication training intervention. Direct care staff members responsible for medication administration of the facility participated in the study per request of their employer. Prioritization of training is based on the number of errors that have occurred in all facilities contracted with the CMH in the past. An IRB exempt status was attained due to de-identified data collected by the principal investigator. Incident reports (IRs) submitted by the AFC homes participating in the study were evaluated. A voluntary questionnaire was distributed at the end of the session to determine baseline characteristics of the direct care staff. Medication errors were defined as any IR submitted regarding incorrect drug therapy, and are categorized in the following manner: wrong dose, wrong time, wrong medication, wrong patient, medication destroyed, and missed dose. The primary investigator monitored the total number of IR reports turned into the primary investigator over the course of four months. It was determined the sample size needed to maintain a p-value < 0.05 and a power of 80% was 150 error reports.

Results: 123 incident reports were submitted within the pre/post four-month timeframe. From these reports 87 medication errors met the study criteria. There was a statistically non-significant increase in the number of reported medication errors in the four-month period after the educational intervention compared to the four-month period prior to the educational intervention. The most common error in both the pre and post intervention groups was a missed dose (83.3% and 82.2% respectively).

Conclusion: Based on these analyses, the training session had no effect on the reduction of errors post intervention. A closer look at the types of errors made help guide future studies to show that not all medication error types can be corrected via the educational process. Rather changes may be required in the medication management process used in individual homes, suggesting a standardization protocol for medication administration for AFC patient populations.

Poster Title: Use of Mu Opioid Antagonists and Pharmacological Punishers in the Development of Abuse-Deterrent Opioid Analgesics

Primary Author: Lillie Floyd, University of Mississippi School of Pharmacy, Mississippi; **Email:** lmfloyd@go.olemiss.edu

Additional Author (s):
Edward Townsend
Kevin Freeman

Purpose: The number of deaths attributable to prescription opioids has more than quadrupled over the last decade, with many of these deaths due to misuse of these medications. To combat this epidemic, the United States Food and Drug Administration (FDA) released guidance to inform the evaluation and labeling of abuse-deterrent formulation (ADF) opioids with a decreased liability for abuse. Among the categories outlined in the guidance, the "aversion" strategy appears to be the most underutilized. The current review will focus on the effects of adding potentially aversive pharmacological agents to opioid analgesics, in terms of both abuse liability and therapeutic efficacy.

Methods: Peer-reviewed articles pertaining to the effects of mu opioid antagonists and pharmacological punishers on both the abuse-related and antinociceptive effects of opioids were reviewed. Findings from basic science investigations of the effects of mu opioid antagonists and pharmacological punishers on the abuse-related and therapeutic effects of opioids were also considered.

Results: Two major classes of ADF opioids meet the FDA guidance's definition of aversion: 1) Mu opioid receptor agonist/antagonist medications, and 2) mixtures that contain agents that can produce aversive effects at sufficient doses (i.e., punishers). Agonist/antagonist medications are commonly used, but these drugs only have the potential to produce aversive effects under limited circumstances. The antagonist portion of the medication is intended to precipitate withdrawal in opioid-dependent individuals if used through the intravenous or intranasal route, but this effect does not always occur. Notably, the therapeutic efficacy of these medications seems to be largely unaffected by the addition of the antagonist if

administered through the oral route. Although there currently are no FDA-approved opioid analgesics that use a pharmacological punisher to discourage dose escalation, this strategy has been applied to prevent abuse of an anti-diarrheal opioid (i.e., Lomotil® (diphenoxylate hydrochloride and atropine sulfate)). Several classes of drug punishers have been shown to be effective in reducing the abuse-related effects of opioids, with varying impacts on therapeutic efficacy observed between punishers.

Conclusion: ADF opioids that use the agonist/antagonist approach have been demonstrated to be effective in treating pain while reducing the likelihood for abuse in certain situations. However, the agonist/antagonist approach is not an effective deterrent of oral misuse (i.e., consuming more opioid than prescribed), which is the most common route of abuse among prescription opioid abusers. A major challenge in the development of opioid analgesics with pharmacological punishers involves appropriate dosing of the punisher. The balance between adequate punishing effectiveness and patient tolerability appears to be delicate, and more work is needed to characterize the feasibility of this strategy.

Submission Category: Critical Care

Submission Type: Evaluative Study

Session-Board Number: 5b-048

Poster Title: Evaluation of insulin glargine in critically ill patients receiving nutrition support

Primary Author: Quintarious Perdue, Auburn University Harrison School of Pharmacy, Alabama;
Email: qmp0001@auburn.edu

Additional Author (s):
Jill Fuller
Amber Hutchison
Sarah Cogle

Purpose: Hyperglycemia frequently occurs in critically ill patients receiving specialized nutrition support and has been associated with increased morbidity and mortality. Most guidelines recommend a target blood glucose (BG) range of 140 to 180 mg/dL for critically ill patients. Continuous intravenous (IV) insulin infusions are recommended to treat hyperglycemia in critically ill patients, although insulin glargine, a long-acting basal insulin, is often employed to achieve target BG without initiating a continuous IV insulin infusion. The aim of this study is to evaluate the efficacy and safety of insulin glargine in critically ill ICU patients who are also receiving specialized nutrition support.

Methods: This was a retrospective study approved by the institutional review board. Electronic medical records were used to identify all patients who received insulin glargine in the medical-surgical or cardiovascular intensive care units (ICU) between February 1, 2015 and August 1, 2016. Patients who received concomitant insulin glargine and nutrition support with either enteral nutrition (EN) or parenteral nutrition (PN) for at least 3 days were included. Patients less than 19 years of age or who received overlapping insulin glargine and nutrition support outside of the ICU setting were excluded.
Data were collected for up a maximum of 7 days while receiving concurrent insulin glargine and nutrition support therapy. Efficacy of insulin glargine was evaluated by the number of hours spent in the hyperglycemic range (BG greater than 180 mg/dL). Safety was evaluated by determining the number of patients who experienced at least one incidence of mild hypoglycemia (BG 40 to 69 mg/dL) or severe hypoglycemia (BG less than 40 mg/dL) and the number of hours spent in either of the hypoglycemic ranges. Additional endpoints assessed included the type of nutrition support, incidence of infection during ICU stay, mean BG, and

mean daily doses of glargine and supplemental insulin. Non-nominal data were expressed as mean plus or minus standard deviation.

Results: A total of 42 patients receiving concomitant insulin glargine and nutrition support were enrolled for study. The mean age of patients was 68.4 plus or minus 10.1 years. Most patients received nutrition support with enteral nutrition (88.1 percent), had a diagnosis of Type 2 diabetes mellitus (97.6 percent), and had an infection (92.9 percent). Patients received a mean insulin glargine daily dose of 18.3 plus or minus 12.1 units per day, with 19.7 plus or minus 13.8 units of supplemental insulin. The mean blood glucose (BG) was 185.8 plus or minus 38.6 mg/dL. Hyperglycemia (BG greater than 180 mg/dL) occurred in 97.6 percent of patients and patients spent 12 plus or minus 6.6 hours per day in the hyperglycemic range. Hypoglycemia occurred in 9 patients (21.4 percent), with 8 patients (19 percent) experiencing mild hypoglycemia (BG 40 to 69 mg/dL) and 1 patient experiencing severe hypoglycemia (BG less than 40 mg/dL).

Conclusion: The results of this study indicate insulin glargine inadequately controls BG in ICU patients receiving nutrition support therapy, as patients spent approximately half of the day in the hyperglycemic range and a fifth of patients experienced hypoglycemia. Due to these findings, consideration of increased institutional usage of continuous IV insulin infusions rather than insulin glargine to attain glycemic control in this patient subset is warranted.

Submission Type: Descriptive Report

Session-Board Number: 5b-049

Poster Title: Who knows when to dispose; the storage and handling of commonly administered vaccinations

Primary Author: Caitlyn Lancaster, MCPHS University, New Hampshire; **Email:** caitymae5@gmail.com

Additional Author (s):
Nathan Sylvain
Cheryl Durand
Cheryl Abel

Purpose: Pharmacists in the United States have become more involved with vaccine administration in recent years. The stabilities of these products are frequently called into question during administration and storage. This project was designed to collect and provide information to pharmacists regarding the stability of some commonly administered vaccines, including details that are not fleshed out in the product's package insert. Package inserts often do not include stability guidelines aside from ideal storage temperatures, whether or not the product can be frozen, and if the product should be protected from light.

Methods: Stability information of CDC-approved vaccines was collected from manufactures. Data collected included product stability when stored outside the recommended temperature, light, or radiation requirements. Additionally, information was gathered regarding the percentage of vaccinations that were returned to the manufacturer for a myriad of reasons, including questionable stability due to handling etiquettes

Results: Fourteen manufacturers were contacted regarding the twenty-four individual vaccinations and their guidelines. Additional details regarding storage and handling were obtained for these vaccinations, as well. Each manufacturer was able to provide a detailed summary of the handling protocols, as well as discarding parameters for the vaccination(s).

Conclusion: Storage specifications of vaccines should be addressed on a case-by-case basis, as not all vaccinations require the same handling protocols. By increasing pharmacists' knowledge of data regarding vaccine storage, pharmacists can guarantee the safety and efficacy of their

vaccination stock, as well as reduce the associated medication and monetary waste from improper storage or lack of storage information.

Poster Title: The association of cytochromes P450 and transporter genetic variation with steady-state endoxifen concentration

Primary Author: Lauren Marcath, University of Michigan College of Pharmacy, Michigan; **Email:** lmarcath@med.umich.edu

Additional Author (s):
Allison Deal
Howard McLeod
William Irvin
Daniel Hertz

Purpose: Bioactivation of tamoxifen to endoxifen is primarily mediated by CYP2D6, however, substantial endoxifen variability is unexplained by CYP2D6 activity. Most pharmacogenetic research has focused on CYP2D6 and common SNPs in a few candidate genes. Our objective was to conduct a comprehensive assessment of the effect of genetic variation in tamoxifen-relevant enzymes and transporters on steady-state endoxifen concentrations.

Methods: 302 breast cancer patients receiving tamoxifen 20 mg/day for at least four months, without impaired kidney or liver function and not concurrently taking a moderate or strong CYP2D6 inhibitor were enrolled. Germline DNA collected at enrollment was genotyped for CYP2D6 on the Roche Amplichip and for 191 SNPs in 36 genes on the iPLEX ADME PGx Panel by Agena Bioscience. Metabolic activity phenotype was predicted from genotype data for CYP1A1, CYP1A2, CYP2A6, CYP2B6, CYP2C19, CYP2C8, CYP2E1, ABCC2 and ABCG2. Univariate associations were analyzed using linear regression, and then adjusted for CYP2D6 diplotype and other covariates.

Results: In univariate analysis, increasing CYP2C8 activity was associated with higher endoxifen concentrations (p=0.023, β= 0.22, 95% CI: ±0.40). Increasing CYP2C19 activity had a similar trend after adjustment for age, weight and CYP2D6 diplotype (p=0.069). In a multivariable model, CYP2C8 and CYP2C19 contributed independently to endoxifen concentration, despite known linkage disequilibrium (D'>0.9, CYP2C8, p=0.018; CYP2C19, p=0.089).

Conclusion: CYP2C8 and CYP2C19 activity are associated with endoxifen concentration in tamoxifen treated patients. Further research is needed to identify additional predictors of endoxifen concentration to guide individualized dosing to improve treatment efficacy.

Submission Category: Infectious Diseases

Submission Type: Evaluative Study

Session-Board Number: 5b-051

Poster Title: Retrospective evaluation of high-dose piperacillin-tazobactam and cefepime dosing on clinical outcomes in patients with Gram-negative bacteremia or pneumonia in the intensive care unit

Primary Author: Erika Price, University of Michigan College of Pharmacy, Michigan; **Email:** erikamp@med.umich.edu

Additional Author (s):
Jerod Nagel
Rikki-Leigh Gaudet

Purpose: Gram-negative bacteria are responsible for life-threatening infections, especially in patients in the intensive care unit. These infections are commonly treated with two broad-spectrum antibiotics: piperacillin-tazobactam and cefepime, a penicillin/beta-lactamase inhibitor and fourth generation cephalosporin, respectively. Effective treatment with these drugs requires sufficient time above the minimum inhibitory concentration (MIC) to eradicate pathogenic organisms. A high-dose schedule is one method to optimize time spent above the MIC, but these regimens have not been extensively studied. This study evaluated high-dose versus standard-dose regimens of piperacillin-tazobactam and cefepime on clinical outcomes for the treatment of Gram-negative bacteremia and pneumonia in critically ill patients.

Methods: This retrospective, observational cohort study was conducted at the University of Michigan Health System (UMHS) and approved by the Institutional Review Board. Subjects 18 years or older who were hospitalized in the medical intensive care unit (ICU) or surgical ICU between January 1, 2010 – September 1, 2015 with a positive Gram-negative respiratory or blood culture were included. Additionally, subjects must have received piperacillin-tazobactam or cefepime for at least 72 hours. Patients were excluded if their infection was resistant to piperacillin-tazobactam or cefepime, they had a history of cystic fibrosis, were transferred to UMHS after 72 hours at an outside institution, or there was insufficient clinical evidence of pneumonia despite a positive sputum culture. Patients who received piperacillin-tazobactam 4.5g every 6 hours or 3.375g every 4 hours, cefepime 2g every 8 hours, or a renally adjusted equivalent dose as outlined in the study protocol were assigned to the high-dose experimental group; all others were included in the control group. The primary outcome was 30-day all-cause

mortality. Secondary outcomes included 30-day re-hospitalization, recurrence of an infection caused by the same organisms as the original infection, length of hospital stay, length of ICU stay, and new or worsened altered mental status during antibiotic treatment. The primary and secondary endpoints were analyzed using the chi-square test and Student's t test.

Results: This study included a total of 214 patients (31 patients in the high-dose group and 181 in the standard dose group). For the primary endpoint, the 30-day all-cause mortality was significantly lower in the standard dose group (14.9% vs. 41.9%, p=0.0003). There were no significant differences between high-dose and standard dose treatment in regard to 30-day re-hospitalization (0/31 vs. 1/181 patients), recurrence of index infection (no patients in either group), and ICU length of stay (6.7 vs. 8.9 days, p=0.103). The average length of hospital stay was significantly shorter in the high-dose group (17.03 vs. 23.4 days, p=0.01), while new or worsened altered mental status while on piperacillin-tazobactam or cefepime was significantly greater in the high-dose group (29% vs. 8%, p=0.0008).

Conclusion: This study showed that using high-dose piperacillin-tazobactam or cefepime did not reduce 30-day all-cause mortality in ICU patients with Gram-negative bacteremia or pneumonia, as compared with standard dosing. In addition, utilizing a high-dose regimen may potentially cause or worsen altered mental status.

Submission Category: Ambulatory Care

Submission Type: Descriptive Report

Session-Board Number: 5b-052

Poster Title: Impact analysis of interventions by fourth-year student pharmacists and a clinical practice faculty in internal medicine resident clinics

Primary Author: Lauren Gilmore, Auburn University Harrison School of Pharmacy, Alabama; **Email:** leg0015@auburn.edu

Additional Author (s):
Kellsey Bishop
Kristi Kelley

Purpose: To assess possible cost savings from interventions conducted and logged over a four-year period by fourth-year pharmacy students during advanced pharmacy practice experiences in an outpatient internal medicine resident clinic.

Methods: Students at this outpatient clinic provide medication counseling and reconciliation services, pharmacotherapy recommendations to resident physicians, and see patients for individual appointments. Under the supervision of a pharmacy faculty member and with IRB approval, all clinical interventions documented in the Quantifi web-based system by pharmacy students from 2012-2016 were retrospectively analyzed. The amount of dollars saved per intervention category was provided by the Quantifi web-based system.

Results: In the four-year study period, 47 pharmacy students documented 2,077 interventions. The most frequently documented interventions were chart review (44%), patient medication history (21.5%) and medication reconciliation (17.5%). Patient medication history was the individual intervention category associated with the greatest cost avoidance over the four years, totaling to $68,391. Medication reconciliation was a close second, totaling to $55,692 in potential cost savings. The total estimated cost savings for all interventions documented was $151,684.

Conclusion: In an outpatient clinic setting, interventions completed by fourth-year pharmacy students had a significant impact on cost avoidance in relation to patient care. Pharmacy students are capable of preforming a wide range of clinical interventions that can be directly associated with cost savings, especially medication history and reconciliation services. It should

be noted that some interventions completed during the study period may not have been logged, giving the potential for even larger total cost savings than seen in this analysis. This data could be useful to help expand the role of fourth-year pharmacy students in outpatient clinic rotation practice sites.

Submission Type: Descriptive Report

Session-Board Number: 5b-053

Poster Title: Retractions in pharmacy literature

Primary Author: Joshua Hynson, Shenandoah University Bernard J. Dunn School of Pharmacy, Virginia; **Email:** jhynson09@su.edu

Additional Author (s):
Thomas Ellington

Purpose: Research article retractions can occur in pharmacy literature. There is no database documenting retracted articles in the pharmacy literature and this could cause retracted articles and thus, referencing of incorrect data in research. Assessing the number of retractions in current literature would help determine the need for such a database and educate on which journals are less reliable due to having a high percentage of retracted articles.

Methods: The 2016 list of American Association of Colleges of Pharmacy (AACP) Core Journals was obtained and it was determined which were available in PubMed. The journals were then divided into groupings determined by AACP. Each journal was searched using a specific procedure in the time span of four days. The number of published articles and retractions were recorded for each journal and the percentage of retractions per journal was calculated by dividing the number of retractions by the total number of articles in PubMed for that journal. The total number of retractions for each grouping was calculated by using the sum of the total number of retractions per each journal in the grouping and the retraction percentage was taken by calculating the mean of the individual journals' retraction percentages. Retraction notices were obtained and the reason for retraction was recorded and marked as one of seven different categories. These categories were misconduct (MC), honest error (HE), duplicate publication (Dup), plagiarism (Pl), unethical research (UR), or withdrawn, no reason given (WNR). The percentage of each reason for retraction was calculated by dividing the total number of retractions in a specific category by the total number of retracted articles.

Results: A total of 281 journals were searched on PubMed from August 15th through August 18th and 274 (97.5%) journals were included in the study. The remaining 7 journals were not found in the PubMed database. All journals were divided into 66 groupings per AACP Core Journal listings. A total of 2,501,634 articles were found through the PubMed search for each of

the AACP Core Journals available. The investigation yielded 547 retractions [0.022%]. Many journal groupings tied for the lowest retraction percentage [0%] while Pulmonology yielded the highest retraction percentage [0.1941%]. Phytotherapy Research scored the highest retraction percentage for an individual journal [0.28%]. There were 182 articles retracted due to MC [33.27%], 202 articles retracted due to HE [36.75%], 68 articles retracted due to Dup [12.43%], 29 articles retracted due to Pl [5.30%], 52 articles retracted due to UR [9.51%], and 9 articles retracted due to WNR [1.65%]. There were 5 [0.91%] retracted articles that could not be accessed and were not placed into any of the reason for retraction categories. These articles were still included in the total number of retractions when calculating the percentage for reason for retraction because a retraction notice was indicated in the PubMed Search.

Conclusion: This analysis found a small number of retractions in the AACP Core Journals indexed in PubMed and it is not likely to affect most research. There were no specific journals identified as more unreliable compared to others. While some do have higher retraction percentages, this can be attributed to factors other than the quality and reliability of the journal. Even with these results, it still is important for retracted articles to be tracked and identified as they can ruin the validity of the literature if referenced.

Submission Category: Drug-Use Evaluation/ Drug Information

Poster Title: Evaluation of the use of intravenous immunoglobulin (IVIG) in a community hospital setting

Primary Author: Chloe Ko, Virginia Commonwealth University, Virginia; **Email:** kimcs7@vcu.edu

Additional Author (s):
Emily Roth

Purpose: IVIG is a medication derived from human plasma that contains immunoglobulin G (IgG). Although primary FDA approved indications of IVIG are primary humoral immunodeficiency (PI) and immune thrombocytopenic purpura (ITP), studies have supported its use for various off-label indications. In November 2015, Bon Secours St. Mary's Hospital's Pharmacy & Therapeutics (P&T) committee approved a change to using ideal body weight (IBW) for IVIG dosing. The objective of this study is to assess different indications for IVIG usage at St. Mary's Hospital, adherence to the P&T-approved dosing protocol, and cost savings associated with the change to dosing based on IBW.

Methods: The study was a retrospective, single-center, chart review of patients who were treated with IVIG at St. Mary's Hospital in Richmond, Virginia. IVIG administration records from November 1, 2015 through July 31, 2016 were obtained from the electronic health record. The following data was collected: patient age, gender, total body weight (TBW), height, indication for IVIG usage, dose, frequency of administration, and ordering provider service. The primary endpoint was frequency of IVIG indication. The secondary endpoints were ordering provider service, percent of orders that adhered to the P&T-approved dosing protocol, and cost savings associated with the dosing protocol. Patients were included if they were greater than 2 months old and received IVIG during the designated study period. Patients who received doses of IVIG over multiple admissions as part of one longitudinal dosing regimen were counted as one patient.

Results: A total of 39 patients met inclusion criteria. The most common indications for IVIG usage were ITP (31%), Kawasaki disease (13%), and dermatomyositis (13%). Other indications included Guillain-Barre Syndrome (10%), myasthenia gravis (8%), juvenile dermatomyositis (5%), possible viral myocarditis (2.5%), polymyositis (2.5%), small fiber neuropathy (2.5%),

necrotizing myopathy (2.5%), inclusion body myositis (2.5%), hypogammaglobulinemia (2.5%), and hemolytic disease of the newborn (2.5%). The indication of the other 2.5% was unclear due to lack of information. All of these indications are supported by current literature except for necrotizing myopathy. The most common specialties of the ordering providers were rheumatology (28%), pediatrics (28%), hematology/oncology (13%), and neurology (13%). TBW was used for 56% of the orders and IBW was used for 41% of the orders. The weights used for the other 3% of orders were unspecified. In adults, 67% of the orders were dosed using IBW, whereas in pediatric patients, only 6% of the doses were ordered using IBW. The transition of dosing from TBW to IBW has resulted in cost savings of approximately $88,000 annually. Adherence to the protocol of using IBW for all orders could potentially lead to additional cost savings of approximately $12,000 annually.

Conclusion: The most prevalent indication for IVIG use at St. Mary's Hospital was ITP. Overall, only 41% of the orders were dosed using IBW despite the P&T approved protocol that recommends all IVIG orders use IBW. Using IBW could potentially lead to additional cost savings of $12,000 annually. Therefore, to increase protocol adherence, further education will be provided to all pharmacists and providers with specialties that commonly order IVIG.

Poster Title: Pharmacist post-discharge telephone follow-up for high-risk veterans transitioning from hospital to home: a pilot project

Primary Author: Jeffrey Spalding, Shenandoah University, Virginia; **Email:** jspaldin13@su.edu

Additional Author (s):
Marci Salow
Jeffrey Thompson

Purpose: Effective transitions of care models have shown reductions in hospital readmissions, emergency department visits, and mortality. It is estimated that 50% of all hospital related medication errors and 20% of adverse drug reactions are due to lapses in communication at discharge. Many factors may increase patient vulnerabilities during care transitions, such as multiple medication changes, multiple co-morbidities, or declining cognitive function. This pilot identified high risk veterans for pharmacy post-discharge telephone follow-up by a pharmacy student and pharmacist.

Methods: Patients discharged from acute and general medicine units were screened daily by a pharmacy student and pharmacist. Patients were categorized according to risk factors to include advanced age (>75 years old), three or more medication changes upon discharge, a diagnosis of dementia or heart failure, and/or a high CAN (Care Assessment Needs) report score. The CAN report provides a composite score of 0-99 dependent upon number of diagnoses, number of emergency department visits and inpatient discharges over the last 2 years. Following initial screening of daily discharges, the student conducted an in-depth electronic chart review of inpatient progress notes, admission, discharge, and active medication lists for accuracy and potential discrepancies, fall risk and anticholinergic burden, where applicable. These findings were reviewed with the pharmacist to formulate a tentative plan prior to calling the patient. During the telephone call, the following elements were discussed and reviewed with the patient: medication management system at home, adherence, a medication review to include potential discrepancies identified during chart review, fall risk assessment, and potential anticholinergic side effects. An electronic progress note describing discharge medication changes, an up to date medication list, and any identified discrepancies and relevant information was entered by the student and approved by the pharmacist.

Interventions and patient concerns were relayed to the primary care provider (PCP) team for follow-up.

Results: Twenty patients received an in-depth telephone call. Fourteen patients had a medication discrepancy upon review of key medication lists. Discrepancies upon review were defined as drug omission from the discharge plan, drugs with no active order (expired med or drug not ordered at discharge), drug commission, and errors in dosing, frequency, or directions. Eighteen patients had at least one discrepancy identified during interview. Discrepancies upon interview were defined as the patient taking an extra medication, not taking an active medication, or taking a medication differently than prescribed. PCPs were alerted for questions, discrepancies, or telephone interventions for 14 patients.

Conclusion: Medication discrepancies were frequently identified in patients screened. CAN scores may be beneficial in identifying high risk patients for post-discharge intervention. This pilot provided additional evidence for resource allocation within the pharmacy department to support transitions of care and the discharge process.

Poster Title: Racial disparities relating to health-system utilization behaviors and medication use among older adults with cancer

Primary Author: Jennifer Liang, University of Michigan College of Pharmacy, Michigan; **Email:** jhliang@umich.edu

Additional Author (s):
Karen Farris

Purpose: The total cancer incidence in the United States is projected to increase approximately 45 percent from 2010 to 2030, driven by cancer diagnosed in older adults and minorities. However, previous literature shows that non-white cancer patients experience delayed treatment initiation and worse outcomes compared to white cancer patients across several types of cancer. This study was designed to examine racial disparities in self-reported health outcomes, cancer screening, and adverse medication events (AMEs) among older cancer patients using a nationally representative data sample.

Methods: This retrospective, observational, longitudinal study used publicly available data from the 2006 and 2008 Health and Retirement Study (HRS) and from the 2007 Prescription Drug Study (PDS) which was administered to a subset of HRS respondents. HRS is a longitudinal study launched by the University of Michigan in 1992 (supported by the National Institute on Aging and the Social Security Administration) that surveys a representative sample of approximately 20,000 Americans over age 50 every two years. The number of individuals who responded to both HRS and PDS and who indicated receiving cancer treatment in the 2006 numbered 157. Race was analyzed by comparing Caucasian to African-American groups. Chi-square tests were used to compare the two defined racial groups' frequencies on six dependent variables: self-reported health, cancer improvement, whether the individual had seen their doctor for cancer, whether the individual had received a mammogram or prostate exam (appropriate to their sex), and whether the individual experienced an adverse medication event. Four models of sequential logistic regression were performed to determine whether the effect of race on self-rated health persisted, when controlling for demographic factors including age, sex, number of prescription medications and cancer change (same or worse, better).

Results: The respondents from HRS included in this study were predominantly Caucasian (91.1 percent), non-Hispanic (96.2 percent) individuals with a median age of 77. Many subjects had one or more chronic conditions in addition to their cancer and were taking an average of 5.78 drugs, with a mean monthly cost of $54.95 out-of-pocket for the medications. A greater proportion of Caucasian subjects reported very good to excellent health compared to African-American subjects (26.6 percent vs 14.3 percent in 2006, P equals 0.049; 28.4 percent vs 21.4 percent in 2008, P equals 0.005). When controlling for demographic factors, African-American respondents were 2.79 times more likely than Caucasian respondents were to indicate poorer health status in either year, although this difference was not statistically significant (P equals 0.39 in 2006, P equals 0.35 in 2008). The number of prescription medications was a significant factor in predicting self-rated health in 2008, with individuals taking five or more medications reporting 2.7 greater odds of poorer health status (P equals 0.04). No significant differences based on race were observed regarding cancer change within the last two years, cancer screening with a mammogram or prostate exam, seeing a doctor for cancer care, or adverse medication events.

Conclusion: An analysis of longitudinal data among older adults with cancer showed disparities with regards to self-rated health for African-Americans compared to Caucasians. Health-related factors such as number of medications, perhaps an indicator of disease severity, played an important role in self-rated health.

Poster Title: Comparison of leukopenia in pediatric heart transplant patients receiving low dose and standard dose trimethoprim/sulfamethoxazole for Pneumocystis jiroveci pneumonia prophylaxis

Primary Author: Emily Belarski, University of Michigan College of Pharmacy, Michigan; **Email:** belarski@med.umich.edu

Additional Author (s):
Kurt Schumacher
Regine Caruthers

Purpose: The International Society of Heart and Lung Transplantation (ISHLT) recommends trimethoprim/sulfamethoxazole after heart transplant to prevent Pneumocystis jiroveci pneumonia (PJP), but the guidelines do not include recommendations for pediatric dosing. Pediatric dosing has been extrapolated from pediatric oncology data. This dosing has been associated with leukopenia, which is undesirable in the transplant patient and can lead to modifications in the immunosuppressant regimen. Ongoing studies in the pediatric oncology population have shown an improved side effect profile with lower doses of trimethoprim/sulfamethoxazole. However, this has not been demonstrated to date in the pediatric heart transplant population.

Methods: This retrospective review included pediatric heart transplant patients at C.S. Mott Children's Hospital transplanted between January 1, 2008 and December 31, 2014. The University of Michigan Health System Institutional Review Board approved all methods of this review. The study evaluated whether trimethoprim/sulfamethoxazole doses based on trimethoprim 2.5 mg/kg once daily twice per week (maximum of trimethoprim 80 mg daily) effectively prevented PJP infection and lowered rates of leukopenia when compared to trimethoprim 5 mg/kg once daily two to three times per week (maximum of trimethoprim 160 mg daily). Data collected included demographics of the patients, dose and frequency of trimethoprim/sulfamethoxazole therapy, length of time of trimethoprim/sulfamethoxazole therapy, complete blood counts with differential, and incidence of PJP infection. Descriptive statistics compare rates of occurrence of PJP infection, length of therapy, rates of neutropenia

(defined as white blood cell [WBC] count < 4.0x109/L), and rates of trimethoprim/sulfamethoxazole discontinuation secondary to neutropenia.

Results: A total of 49 patients received heart transplants from 2008 to 2014. Of the 49 patients, 23 were male and the average age at transplantation was 6.44 years. Thirteen patients (sixteen patient encounters) received trimethoprim/sulfamethoxazole for PJP prophylaxis. No occurrences of PJP were reported. The average start date of prophylaxis was 18 days post-transplant. A variety of dosing regimens were observed in the study population; therefore, comparisons were made based upon frequency of dosing. Daily trimethoprim/sulfamethoxazole dosing was given in 3 patient encounters, three times weekly dosing was given in 1 patient encounter, and twice weekly dosing in 12 patient encounters. The average length of prophylaxis in each dosing group (i.e. daily, three times per week, two times per week) was 208 days, 168 days, and 333 days, respectively. One year of prophylaxis was completed in 33 percent, zero percent, and 66 percent, respectively. The average white blood cell count (x 109/L) on therapy was 8.9, 7.0, and 9.2, respectively. The percentage of patients experiencing neutropenia while on trimethoprim/sulfamethoxazole therapy was 66 percent, 100 percent, and 58 percent, respectively.

Conclusion: The patients receiving twice weekly prophylaxis completed a longer average duration of therapy, were more likely to complete one year of prophylaxis, and had a higher average WBC count while on therapy. The major limitations to this study were the small number of patients receiving trimethoprim/sulfamethoxazole prophylaxis and the variable dosing regimens. No cases of PJP infections were reported. From our limited data set, it may be beneficial to consider less frequent dosing of trimethoprim/sulfamethoxazole for PJP prophylaxis in a larger cohort of pediatric heart transplant patients.

Poster Title: Retrospective evaluation of peg-filgrastim utilization in the outpatient setting in a large community hospital

Primary Author: Devon Burhoe, Harrison School of Pharmacy, Alabama; **Email:** dnb0007@auburn.edu

Additional Author (s):
Steven Lee
Jonathan Bunn
Matthew Eckley

Purpose: Granulocyte colony stimulating factors (GCSFs) are used for febrile neutropenia prophylaxis in cancer patients. Use is dependent upon chemotherapy regimen, risk factors, and clinical judgment. Evaluation of total spend on peg-filgrastim increased concern for utilization relying more on clinical judgment than guideline-directed recommendations, leading to potentially inappropriate prescribing and increased costs. The purpose of this study was to evaluate current peg-filgrastim prescribing habits in the outpatient setting compared to National Comprehensive Cancer Network (NCCN) and American Society of Clinical Oncology (ASCO) guidelines, with hopes to improve cost efficiency and documentation of guideline-directed indications prior to use.

Methods: This study was a retrospective chart review. All patients that received at least one dose of peg-filgrastim in the outpatient setting from January 1st to June 30th, 2016 were included in the study. Patients who underwent autologous stem cell transplant and patients at the St. Jude affiliate clinic in Huntsville, AL were excluded. Data collected on each patient included age, gender, diagnosis, chemotherapy regimen, intent of chemotherapy (curative versus palliative), chemotherapy cycle(s) that peg-filgrastim was administered, risk factors, and febrile neutropenia risk (less than 10 percent, 10-20 percent, greater than 20 percent). All patients will be categorized into a "high", "intermediate" or "low" risk category based on chemotherapy regimen. Based on NCCN guidelines, the only absolute clinical indications consist of whether the patient is on a "high" febrile neutropenia risk regimen or if the patient develops febrile neutropenia on a lower risk regimen without peg-filgrastim for that cycle. "Intermediate" risk is determined based on chemotherapy regimen and patient risk factors

which include age greater than 65, previous chemotherapy or radiation, bone marrow involvement by the tumor, recent surgery or open wound, etc. "Low" risk is determined solely based on chemotherapy regimen.

Results: During the six month period, 85 patients were identified for receiving peg-filgrastim at least once in the outpatient setting. The average age was 58.9 years old and the range was 22-83 years old. The majority of patients were female (59/85, 69.4 percent). The three most common cancer diagnoses were ovarian cancer (21/85 patients, 24 percent), colon cancer (13/85 patients, 15 percent) and small cell lung cancer (12/85 patients, 14 percent). Of the 85 patients, 10 were "high" risk based on regimen (11 percent) and five patients (5 percent) had documented febrile neutropenia from a cycle without peg-filgrastim administration, making a total of 16 percent of patients have a true clinical indication of "high" febrile neutropenia risk. There were 38/85 patients with "intermediate" risk regimens; 30/38 (78.9 percent) had at least one risk factor, which according to guidelines allows for clinical consideration of peg-filgrastim. Among all patients, 61/85 (71.7 percent) had at least one risk factor. The cost of peg-filgrastim is approximately 4,000 dollars per injection. The average number of injections per patient was three, which equals approximately 12,000 dollars per patient.

Conclusion: Peg-filgrastim use is highly dependent on chemotherapy regimen and patient risk factors. It is vastly overused in the outpatient setting as witnessed by the low percent of absolute indication per guidelines. A more concise criteria of use using guideline recommendations could potentially decrease inappropriate use and cost to the patient. The improvement of utilization of peg-filgrastim will be recorded in a future prospective study using criteria development from this data.

Poster Title: Evaluation of efficacy and safety of thiopurine therapy in Crohn's Disease patients undergoing gastrointestinal surgery

Primary Author: Emily Peltier, University of Michigan College of Pharmacy, Michigan; **Email:** epeltier@med.umich.edu

Additional Author (s):
Millie Mo
Scott Regenbogen
Rima Mohammad

Purpose: Thiopurines, azathioprine and mercaptopurine, demonstrate benefit in induction of remission and preventing recurrence in post-operative CD patients and are often used as standard of therapy. However, when re-starting thiopurines post-operatively, patients are at higher risk of immunomodulary adverse effects, including myelosuppression and infections. Post-operative therapy is not thoroughly studied or well understood in this patient population. This study was designed to compare 30-day post-operative infection rate in patients who received post-operative thiopurines within 30 days to patients who did not receive thiopurines within 30 days.

Methods: The institutional review board approved this retrospective cohort study in adult CD patients (at least 18 years old) that have undergone gastrointestinal surgery during hospitalization at the University of Michigan Health System between January 2012 and December 2014. Patients were included if they were on pre-operative maintenance thiopurine regimens and received post-operative thiopurine therapy. Patients were excluded if they were treated with maintenance medications other than thiopurines or biologics, or if there were poor clinical records documenting the 30-day post-operative outcomes. Patients were divided into early treatment group (patients who received thiopurines within 30 days post-operatively) or delayed treatment group (patients who received thiopurines greater than 30 days post-operatively). Age, gender, race, comorbidities, type of surgical procedure, pre-operation infection, antibiotic use within 30 days, hospital length of stay, and gastrointestinal surgery history were collected and evaluated. The primary outcome was 30-day post-operative infection rate. Mean 30-day readmission rate was assessed as secondary outcome.

Results: Forty patients were included in the early treatment group and 8 patients were included in the delayed treatment group. Patient characteristics such as age, race, gender, comorbidities, type of gastrointestinal procedure, preoperative infection rate, and body mass index were similar between groups. Most patients received an elective gastrointestinal procedure (77 percent in the early treatment group versus 87 percent in the delayed treatment group). All patients received an immunomodulator agent pre-operatively followed by biologic therapy (66.7 percent versus 50 percent, respectively; p equals 0.65) and steroid therapy (26.3 percent versus 66.7 percent, respectively; p equals 0.07). There were no differences in 30-day post-operative infection rates (30 percent versus 25 percent, respectively; p equals 1) or 30-day readmission rates (20 percent versus 25 percent, respectively; p equals 0.67) between the early treatment group compared to delayed treatment group. There were no significant differences in mean post-operative length of stay (7.5 days versus 17 days, respectively; p equals 0.18) between the two groups.

Conclusion: Thiopurine exposure within 30 days of surgery compared to treatment greater than 30 days after surgery showed no difference in 30-day clinical outcomes. However, this study is small and larger, prospective studies are needed to determine the risk of post-operative complications in CD patients undergoing gastrointestinal surgery.

Poster Title: Comparison of diabetic numeracy skills in patients that regularly self-monitor blood glucose one or more times daily compared to a few times a week

Primary Author: Lauren Fox, Shenandoah University Bernard J. Dunn School of Pharmacy, Virginia; **Email:** lfox09@su.edu

Additional Author (s):
Rebecca Falter

Purpose: Health literacy is the ability to find, understand, and use health related information, while health numeracy is the ability to understand and use numbers in everyday life. Numeracy plays a large role in diabetes management to adjust mediations and maintain a well balanced diet. The primary objective of the study is to establish if the diabetic numeracy test (DNT-5) scores are higher in patients that regularly self-monitor blood glucose (SMBG) one or more times a day compared to patients that test a few times throughout the week or not at all.

Methods: The institutional review board approved this voluntary survey for both men and women over the age of 18, with type-2 diabetes, who provided consent. The study was conducted at a primary care clinic. Eligible patients were identified through ICD codes or through prescribed diabetic medications. Patients were subsequently recruited by asking them to participate in the study and given a short survey to obtain consent and verification of eligibility. The survey included demographical questions, including the number of times of self-monitoring of blood glucose during the day. A second 5-item written survey was completed containing questions assessing the patient's diabetes numeracy skills using the DNT-5. A Pearson chi-squared test was used to analyze the data where a low DNT-5 score was defined as three or lower, and a high DNT-5 score was defined as a four or a five.

Results: Of the 74 surveys analyzed, 62 percent (n equals 46) SMBG one or more times per day; 28 patients had low DNT-5 scores while 18 patients had high DNT-5 scores. There was no significant difference (p equals 0.625) found between DNT-5 scores in patients that SMBG one or more times a day versus a few times a week or not at all. The average age of the patients was 68 years old with 41 percent (n equals 31) being female. More patients scoring higher on the DNT-5 had a higher level of education in comparison to those that scored lower.

Conclusion: Frequency of SMBG did not seem to impact health numeracy as determined by the DNT-5 survey, though further research is warranted to include a larger patient population to possibly show any statistical or clinical significance.

Session-Board Number: 5b-061

Poster Title: Evaluation of Epstein-Barr virus after allogenic stem cell transplantation

Primary Author: Sarah Young, The University of Michigan College of Pharmacy, Michigan;
Email: sarahey@med.umich.edu

Additional Author (s):
David Frame
Denise Markstrom

Purpose: Epstein-Barr virus (EBV) is a major cause of morbidity and mortality in patients who are status post allogenic bone marrow transplantation (BMT) due to immunosuppression. EBV can cause mononucleosis, lymphomas, and post-transplant lymphoproliferative disease (PTLD). PTLD is one of the deadliest outcomes of EBV therefore, it is vital that EBV risk factors are identified so that PTLD can be prevented. Additionally, B cell depleting agents have shown to be effective in both preventing and treating EBV. The objective of this study was to determine EBV risk factors and determine the effectiveness of rituximab in preventing and treating EBV.

Methods: This retrospective study was approved by The University of Michigan's institutional review board. All adult BMT patient (n equal to 416) data recorded in the institution's allogenic BMT database were included in this study as there were no exclusion criteria. Emerse was used to search the database for known risk factors for developing positive EBV titers such as acute graph versus host disease (AGVHD), cytomegalovirus (CMV) titers, the addition of T cell depleting agent thymoglobulin to BMT conditioning regimen, and BMT recipient CMV serostatus prior to transplantation. Additionally, Emerse was used to search for positive EBV titers (defined as greater than or equal to 2000 copies per mL) and rituximab doses and dates given for EBV positive titer treatment. The primary outcome was a positive EBV titer up to a year after BMT. The secondary outcome was a diagnosis of PTLD up to a year after the last positive EBV titer.

Results: Rituximab was added to conditioning regimens of 39 patients and of those 39 patients, only one developed a positive EBV titer (P less than 0.044, 97 percent EBV prevention). Additionally, when rituximab was given as treatment for EBV, the four dose regimen was 100 percent effective in preventing future positive EBV titers. Neither the addition of thymoglobulin

(P equal to 0.231) nor recipient positive CMV serostatus (P equal to 0.054) were found to be significant risk factors for developing a positive EBV titer. However, AGVHD was a significant risk factor for developing a positive EBV titer (P less than 0.0001).

Conclusion: Acute graph versus host disease was a significant risk factor for developing a positive EBV titer. Patients who received rituximab as an additional agent to their BMT conditioning regimen were significantly less likely to develop a positive EBV titer. Furthermore, these data suggest that regular EBV titer monitoring should be performed in patients who are at high risk for developing a positive EBV titer, such as those with AGVHD, so timely treatment can be given.

Poster Title: Utilization of the T2 Candida Panel for rapid Candida species detection in a large community hospital

Primary Author: Beth Jobson, Harrison School of Pharmacy, Auburn University, Alabama; **Email:** bmj0008@auburn.edu

Additional Author (s):
Garett Claassen
Emily Brocato
Hayley Kateon
Jonathan Edwards

Purpose: The T2 Candida Panel is a newly approved diagnostic test that allows for rapid (3-5 hours) species-specific detection of fungal pathogens from whole blood sample. This test detects five species of Candida (C. albicans, C. tropicalis, C. parapsilosis, C. krusei, and C. glabrata). This panel could enable clinicians to initiate anti-fungal treatment quicker, deescalate therapy faster, and possibly decrease mortality. It is projected that approximately 500 tests will be performed this year. The purpose of this study is to implement and evaluate the utilization of T2 Candida Panel in a large community hospital.

Methods: This retrospective, observational analysis consisted of 274 patients who met predefined criteria. The T2 Candida Panel was restricted to two specialty departments, Infectious Disease (ID) and Oncology. This list was further restricted to patients with febrile neutropenia without observed cause; patients in the ICU for at least 72 hours, with central venous line and unexplained fever, use of broad spectrum antibiotics, also in addition to one of the following: acute pancreatitis, recent major surgery, total parenteral nutrition, neutropenia, renal failure/hepatic failure, corticosteroids; patients with central venous line and unexplained fever, sepsis. Endpoints were defined as medication use, patient characteristics and risk factors, T2 Candida Panel results, corresponding blood cultures, time to de-escalation, and duration of therapy (DOT). Endpoint analysis will determine the feasibility of continuing the use of T2 testing and monitor clinical and economical outcomes.

Results: Of 345 T2 tests evaluated, 34 (9.0%) were positive. The resulting species were: 15 C. albicans/topicalis, 13 C. parapsilosis, and 4 C. krusei/glabrata. Three patients were positive for both C. albicans/tropicalis and C. parapsilosis and one patient had both C. parapsilosis and C. krusei/glabrata. Approximately 29% of the positive T2 patients had a corresponding positive blood culture. The average duration of therapy (DOT) of micafungin for patients with negative T2 results was 8.7 days. The average time to de-escalation of therapy for negative T2 patients was 45 hours. The average age of patients was 61 years old, of which 148 (54%) were male. Patients commonly had multiple comorbidities, most commonly HTN, HLD, T2DM, CKD, and/or COPD. Many patients had multiple risk factors, some of which overlapped, including: 64 patients (23%) malnourished or receiving a TPN,91 patients (33%) who had renal failure, 38 patients (12.8%) had intra-abdominal infection/surgery, and 96 patients (34.9%) were immunocompromised (cancer, chemotherapy, chronic steroid use, febrile neutropenia). Approximately 59.2 % of patients were in the ICU. The time to de-escalation/discontinuation of therapy was 40.8 hours.

Conclusion: The FDA approved T2's claim of 96.4% sensitivity in 2015 and granted a superiority claim over blood cultures. T2Candidemia Panel demonstrated greater sensitivity to Candida infection compared to blood cultures and produced results with a much faster result time leading to quicker therapy de-escalation. When the endpoints were reviewed, there was a difference among average DOT of micafungin, as well as, time to de-escalation of therapy, demonstrating inconsistent utilization of the test.

Poster Title: Impact of ambulatory pharmacist driven anticoagulation patient education and monitoring

Primary Author: Julianne Fallon, Virginia Commonwealth University School of Pharmacy, Virginia; **Email:** bonifieldjm@vcu.edu

Additional Author (s):
F. Marie Perucci-Bailey
Michael Palkimas
Surabhi Palkimas

Purpose: Anticoagulants offer life-extending benefits, but if taken incorrectly can pose significant risk of bleeding or thrombosis. Recognition of this potential for harm and introduction of the direct oral anticoagulants (DOACs) has provided the stimulus to improve patient care by changing current ambulatory pharmacy practice at the University of Virginia Health System. These ambulatory pharmacists are in a unique position to improve transitions of care by reinforcing safe and effective anticoagulant use. The purpose of this study was to assess outcomes of anticoagulation education alone or education with a monitoring call provided for patients newly prescribed an anticoagulant.

Methods: The University of Virginia Health System institutional review board approved this retrospective study that included patients 18 years or older who were dispensed a new anticoagulant prescription from the outpatient pharmacy between January 1st and June 30th 2016. First-fill education was attempted for all anticoagulant prescriptions and a monitoring call was made for prescriptions dispensed after April 1st, 2016. Pharmacists completed a standard anticoagulant education worksheet and monitoring questions for patients receiving a monitoring call to ensure all patients received consistent counseling. Data was collected through the EPIC electronic medical record system and from the standard anticoagulant education worksheets filled out by pharmacists at the time of medication dispensing. All patients identified were divided into two groups. Group A included patients dispensed a new anticoagulant prescription and group B included patients dispensed a new anticoagulant prescription who also received a monitoring call 23 to 30 days after the initial fill. The primary objective was the number of hospital admissions for any reason within 30 days, 31-60 days, and

the number of oral anticoagulant prescriptions written for a thirty-day supply or less with at least one refill that were not refilled or transferred within 60 days. Secondary objectives included hospital admission related to anticoagulant use within 30 days, within 31-60 days, and prescriptions never refilled and any admission or related admission within 31-60 days.

Results: There were 237 patients with a new anticoagulant prescription in group A and 269 patients in group B during the study period. The baseline characteristics of groups A and B were similar except for education delivery by phone (21.2 and 30.6 percent, respectively; P equals 0.017). The completion rate for initial education was 99.6 percent in group A and 98.5 percent in group B (P equals 0.378). Patients in both groups primarily received enoxaparin (41.8 vs. 39.8 percent), apixaban (40.1 vs. 40.9 percent), warfarin (9.3 vs. 12.6 percent), or rivaroxaban (7.1 vs. 5.2 percent). There was no significant difference between groups A and B for 30-day admission (13.1 vs. 16 percent; P equals 0.356), 31-60 day admission (9.3 vs. 8.6 percent; P equals 0.773), or number of prescriptions not refilled or transferred (40.7 vs. 41.3 percent; P equals 0.934). There was no significant difference between groups A and B for the number of related admissions within 30 days (29 vs. 14 percent; P equals 0.111), within 31-60 days (27.3 vs. 21.7 percent; P equals 0.666), or overall admissions or related admission within 31-60 days for prescriptions that were never refilled or transferred (P equals 0.165 and 1, respectively).

Conclusion: This study reinforces the role of ambulatory pharmacists associated with a health system in providing anticoagulation patient education to a large number of patients to ensure safe and effective use of these high-risk medications. While the introduction of a monitoring call to first-fill education was not associated with significant outcomes compared to first-fill education alone, ambulatory pharmacists were able to provide additional touch points in transitions of care. Further investigation of the impact of a monitoring call and ways to increase the usefulness of this intervention are required to continue to improve the health and safety of patients taking anticoagulants.

Poster Title: Late administration of botulism immune globulin in a 1 month-old infant.

Primary Author: Anthony Jackson, Auburn University Harrison School of Pharmacy, Alabama;
Email: acj0017@auburn.edu

Additional Author (s):
Allison Chung
Sheryl Falkos
Brandy Merritt
Reza Sadeghian

Purpose: This case illustrates the importance of considering botulism toxicity and administering botulism immune globulin late in an infantile patient that presents with neuromuscular paralysis and a history of honey ingestion. A previously healthy 1- month-old Asian female (4.1kg) presented to an outlying hospital in respiratory failure. Initially, the symptoms of infant botulism appeared 3 days prior to admission with slow and progressive development. Symptoms included less oral intake, numerous spitting after each feed, and decreased activity. Due to symptoms, the infant was taken to the pediatrician and diagnosed with a viral illness. On the day of admission, the infant started to have intermittent shortness of breath and gasping associated with perioral cyanosis, which prompted an Emergency room (ER), visit via EMS. The infant was intubated upon ER arrival and given a dose of IV vancomycin and ceftriaxone for suspected sepsis. After stabilization, the patient was transferred to the Pediatric Intensive Care Unit (PICU) for further management. Initial laboratory analysis, radiological exams, and cerebrospinal fluid showed no abnormalities. The meningitis and respiratory rapid multiplex PCR tests were negative for pathogens tested. Ceftriaxone and vancomycin (with therapeutic levels between 15-20 mcg/ml), were continued for suspected meningitis for a total duration of 7 days. Upon physical exam in the PICU, the infant had a weak cough, was unresponsive to painful stimuli with very limited movement after approximately 10 minutes of stimulation, had an overall floppy tone, and no gag reflex upon suctioning. The recognition of the extent of the abnormalities was delayed until day 8 of admission secondary to sedation for mechanical ventilation. Fatigability test was performed. Her pupils were initially constricted and responsive to light, but after ~30 seconds, both pupils were dilated and unresponsive to further light stimuli. The patient then developed significant constipation. Upon further questioning, her

mother stated the child was having a weak cry, poor sucking, decreased neck/head tone, decreasing swallowing, increased drooling, and slight downward gaze prior to admission. Eventually, it was discovered that, as a cultural tradition, her mother was using honey as a remedy to remove white patches from the patient's tongue for the past few weeks. Given the clinical scenario, a stool to test for Clostridium botulinum was sent to the Alabama Department of Public Health for confirmation of the diagnosis. Prior to confirmation of C. botulinum type A, Botulism Immune Globulin (BIG) was administered (Day 9 of admission) at a dose of 50 mg/kg (210mg/4.2ml) to our infant. After administration of immunoglobulin, the infant improved clinically over a period of two weeks and was able to be extubated. Improvements included eye tracking, responding to stimuli with much-improved muscle tone, and improved cough, gag, and respiratory effort. This case report suggests even with late administration of immunoglobulin along with the potential increase in lysis of Clostridium from broad-spectrum antimicrobials and increased toxin burden, immunoglobulin is still efficacious despite cost of approximately $45,000.

Poster Title: Evaluation of State Compounding Regulations

Primary Author: Kelli Tiong, Bernard J. Dunn School of Pharmacy at Shenandoah University, Virginia; **Email:** ktiong13@su.edu

Additional Author (s):
Kate Headlee
Amber Darr
Lia Merila
Nicole Persun

Purpose: Incidents such as the New England Compounding Center meningitis outbreak have lead to the development of federal compounding legislation. However, oversight of traditional compounding is still a responsibility of individual state boards of pharmacy. Historically, states have developed and enforced pharmacy-compounding regulations. The United States Pharmacopeia provides enforceable standards for compounding. Many boards of pharmacy have since adopted all or part of these standards but there remains inconsistency in the utilization of these standards. A systematic review of state regulations will benefit pharmacists as they provide input to their state boards of pharmacy regarding future revisions.

Methods: An extensive literature search was conducted to determine the need for a descriptive summary of state compounding regulations. A list of questions was developed to identify the extent to which USP standards are incorporated into state pharmacy laws and regulations, when the compounding regulations were last updated, and whether the regulations differentiated between sterile and non-sterile compounding. Each of the 50 state board regulation documents was accessed electronically and systematically reviewed to first determine if a separate compounding section was included. For those states with a separate section on compounding, the extent of USP standard inclusion was determined and categorized as complete adoption of USP compounding chapters, partial adoption of USP standards with individual state-developed guidelines, and absence of USP standards. The documents were also evaluated to determine when the compounding sections were last updated if that information was available. One additional criteria that was examined was whether states boards require

pharmacists to complete compounding-specific continuing education. All the information was compiled and the descriptive statistics were determined.

Results: There are 40 states that have a separate compounding section in the laws and regulations, which allows for efficient retrieval of information by pharmacists. For the remaining states, compounding regulations are addressed in a variety of sections. Since the New England Compounding Center incident in 2012, 10 states have not updated their compounding regulations. Out of the 50 states, nine reference only USP < 797> and two reference only USP < 795>. Of the remaining 39 states, 19 refer to both USP chapters and 20 states do not refer to either USP < 797> or < 795>. Eight states require adherence to all USP guidelines, not specifically those related to compounding. Massachusetts is the only state to require compounding specific CE hours for those pharmacists who engage in compounding practices.

Conclusion: Most states contain a separate compounding section within the pharmacy laws, regulations or practice standards. Individual state boards of pharmacy are responsible for developing practice standards and determining what is deemed appropriate. This review of state laws and regulations identified differences in compounding standards and organization of information. Not all states have adopted USP compounding standards. Pharmacists should understand respective practice standards when engaged in compounding. Consolidation of compounding standards into an easily retrievable document may be beneficial. Further revision of laws and regulations are needed to ensure quality compounding and safe medication delivery throughout all 50 states.

Poster Title: Clinical Outcomes of Acetylcysteine in Non-Acetaminophen Induced Acute Liver Failure

Primary Author: Kayla Aleshire, Eugene Applebaum College of Pharmacy and Health Sciences, Michigan; **Email:** kaleshi1@hfhs.org

Additional Author (s):
Meghan Glynn
Nimisha Sulejmani
Bradford Mcdaniel

Purpose: There is no established standard of care for the treatment of non-acetaminophen induced acute liver failure (ALF). Recent evidence suggests the use of acetylcysteine in non-acetaminophen induced acute liver failure may have an impact on transplant-free survival. The purpose of this study is to assess the use of acetylcysteine for treatment of non-acetaminophen induced acute liver failure at an academic medical center.

Methods: This study was approved by the local Institutional Review Board. This is a retrospective chart review of patients receiving acetylcysteine for non-acetaminophen induced ALF from September 2015 through June 2016. Patients were excluded if they were under the age of 18 years or had liver failure that was due to acetaminophen toxicity. The variables of interest included baseline demographics, etiology of liver failure, clinical response, adverse effects, and survival measures. Clinical response was assessed with liver function tests (LFT) such as aspartate transaminase (AST) and alanine transaminase (ALT), International Normalized Ratio (INR), serum creatinine, and Model for End stage Liver Disease (MELD) scores. Clinical response was measured at 24, 48, and 72 hours and at the time of transplant-free discharge, death, or transplant. Survival measures included overall survival, transplant-free survival, and time to transplantation. Descriptive analysis was performed.

Results: Of the 50 patients included, 24 were male (48 percent) with an average age of 47 years. Twelve (24 percent) of the patients had grade I-II encephalopathy and 11 (22 percent) had grade III-IV encephalopathy. The most common etiology of ALF was ischemic 22 (44 percent). The median duration of acetylcysteine use was 21 hours (Interquartile Range (IQR) 17-

36). The median baseline ALT, AST, and MELD were 1604 (IQR 724-2060), 1598 (IQR 584- 5153), and 24 (IQR 16-34), respectively.

Thirty-three patients were discharged transplant-free, 16 patients died, and one patient received a liver transplant. The patient who received a liver transplant developed ALF due to acute hepatitis B infection with a MELD score of 40. Five out of the 12 patients with grade I-II encephalopathy and 5 out of the 11 with grade III-IV encephalopathy died. The median duration of use for acetylcysteine in grade I-II encephalopathy was 22 hours (IQR 21- 34) compared with 23 hours (IQR 21-53) in grade III-IV encephalopathy. Two patients experienced adverse events leading to early discontinuation of acetylcysteine therapy. One patient experienced abdominal pain and shortness of breath the other experienced oxygen desaturation.

Conclusion: Acetylcysteine was found to be safe in the study population with only two reported adverse events. There were a total of 16 deaths and one patient received a liver transplant. Eight patients experienced increase in liver enzymes despite initiation of acetylcysteine, however only 2 of these patients died. Further investigation in a large number of patients with a comparator group would be needed to determine the impact of acetylcysteine in non-acetaminophen induced acute liver failure.

Poster Title: Monte Carlo Simulation (MCS) of colistin dosing in critically ill patients receiving Continuous Renal Replacement Therapy (CRRT)

Primary Author: Niloufar Daneshvar, University of Michigan College of Pharmacy, Michigan; **Email:** ndaneshv@med.umich.edu

Additional Author (s):
Susan Lewis
Bruce Mueller

Purpose: Colistin is an antibiotic used to treat gram-negative bacterial infections primarily caused by Pseudomonas aeruginosa, Acinetobacter baumannii, and resistant Klebsiella species. Colistin is formulated as a prodrug, colistin methanesulfonate (CMS), which is converted into the active moiety, colistin. The original pharmacokinetic (PK) studies did not differentiate between CMS versus colistin. Furthermore, there is lack of guidelines for the dosing of CMS in patients undergoing Renal Replacement Therapy (RRT). The purpose of our study is to build a PK model of CMS and colistin during Continuous Renal Replacement Therapy (CRRT) using published PK data, and to determine its optimal dosage regimen.

Methods: A one-compartmental mathematical PK model for the colistin prodrug, CMS, was built based on the most relevant colistin PK studies found in the literature. Monte Carlo Simulation (MCS) techniques (Crystal Ball Classroom Edition, Oracle) were used to construct a 5000 virtual cohort, and individual colistin serum concentration profiles for each dosing regimen were generated. Simulated dosing regimens were chosen based on regimens previously utilized in the literature, as well as new regimens hypothesized to be effective. We selected the optimal colistin regimen as determined by pharmacodynamic target attainment of free area under the curve: minimum inhibitory concentration (fAUC/MIC) ratio of 10 in greater than or equal to 90 percent of virtual patients. Furthermore, we defined toxic trough levels as values above 0.4 ug/ml and 0.9 ug/ml, corresponding to free colistin trough levels of 10 percent and 80 percent respectively. The lowest possible dose that attained this target was chosen, in order to avoid toxic concentrations.

Results: The simulation results for 8-hour and 12-hour dosing regimens were not sufficient to maintain efficacy targets after 48-hours. Our chosen regimen for CMS was loading dose: 800 mg, maintenance dose: 300 mg every 24 hours, with an effluent flow rate (Quf) of 25 ml/kg/hour. This regimen maintained an average 120-hour fAUC/MIC ratio greater than 10 for 94 percent of the virtual subjects (MIC of 1 ug/ml), and the percentage of patients achieving toxic trough levels were lower than other regimens (80 and 10 percent for free colistin trough above 0.4 and 0.9 ug/ml, respectively). When comparing a stable dose regimen of loading dose: 800 mg, maintenance dose: 300 mg every 24 hours, with Quf of 25 ml/kg/hr versus Quf of 35 ml/kg/hr, we observed increased efficacy target attainment with Quf of 25ml/kg/hr. When an effluent rate of 35 ml/kg/hr was utilized, a higher maintenance dose was needed. According to our results, the regimen of choice for Quf of 35 ml/kg/hr is loading dose: 800 mg, maintenance dose: 450 mg CMS every 24 hours, which resulted in 91 percent target attainment at 120-hours, and 4 to73 percent toxic concentration targets for free colistin trough levels above 0.4 and 0.9 ug/ml respectively.

Conclusion: MCS analysis reveals that CRRT clears both CMS and colistin. The effluent rate and body weight has substantial influence on efficacy target attainment. Any CMS dosage regimen that achieves efficacy targets will also achieve toxicity targets. MCS suggests that for a Quf of 25 ml/kg/hr, a regimen of 800 mg loading dose, 300 mg maintenance dose every 24 hours, and for a Quf of 35 ml/kg/hr, 800 mg loading dose, 450 mg maintenance dose every 24 hours, will likely achieve efficacy targets with the lowest chance of achieving toxicity targets. These MCS projections need to be validated in clinical trials.

Poster Title: Take my breath away: Evaluation of steroid prescribing in acute chronic obstructive pulmonary disease (COPD) exacerbations

Primary Author: Mri Kolicaj, Wayne State University, Michigan; **Email:** mkolica1@hfhs.org

Additional Author (s):
Kaitlyn Nadalin
Jessica Efta
Jane McDonnell

Purpose: Hospitalized chronic obstructive pulmonary disease (COPD) exacerbations are associated with a significant decline in lung function. Administration of corticosteroids during this acute state not only improves lung function but also decreases the length of hospital stay. The Global Initiative for Chronic Obstructive Lung Disease (GOLD) guidelines recommend a regimen of prednisone 40 mg daily which corresponds to our institutional guideline which recommend prednisone 40mg orally daily. The purpose of this study is to assess the use of corticosteroids in COPD exacerbations on a general practice unit, as there is currently no internal data examining our compliance with institutional guidelines.

Methods: In this institutional review board approved internal review, our institution's prescribing practices for steroids in COPD exacerbation were assessed. Patients admitted to an internal medicine general practice unit with an ICD-10 documented diagnosis of COPD exacerbation from January 1, 2016 to June 30, 2016 were first evaluated for inclusion and exclusion criteria. To avoid any discrepancies, patients with a diagnosis of asthma or with maintenance chronic oral steroids were excluded from this study. The investigators reviewed each patient's prescribed steroid regimen throughout their hospital stay in a standardized method and then identified if it complied with the institutional guidelines. A compliant regimen was defined as one containing oral prednisone 40mg daily or an alternative oral steroid at equipotent dose. Patients that were included also had their glycemic control reviewed for a safety outcomes analysis. Retrieved data was then analyzed using descriptive statistics.

Results: 150 patients (49 percent male, 51 percent female) were included in this study. Mean age was 64 years. Median steroid dose in prednisone equivalents administered was 40 mg (IQR 40-50.5). Only 11.7 percent of steroid doses were administered intravenously. Among the 150 total steroid regimens, 92 (61.3 percent) were compliant with institutional guidelines. Hyperglycemic events occurred in 71 (47.3 percent) patients within this study. Among patients receiving less than or equal to 40mg of prednisone equivalents daily, 48.9 percent experienced hyperglycemic events. In patients receiving greater than 40mg of prednisone equivalents daily 44.8 percent experienced a hyperglycemic event.

Conclusion: The majority of patients receiving steroids for a COPD exacerbation were compliant with our institutional guidelines. Additionally rates of hyperglycemic events were similar between those receiving compliant steroid doses and those receiving higher than recommended steroid doses. While overall rates of compliance with institutional guidelines were good, there are still opportunities for optimization through prescriber education and potential pharmacy interventions.

Poster Title: Computerized approach for the appropriate selection of non-prescription therapy

Primary Author: Heidi Pérez Ruiz, Nova Southeastern University, Puerto Rico; **Email:** hp301@nova.edu

Additional Author (s):
Lisandra Blanco
Angelie Del Valle
Patricia Delgado
Lesley Arcelay

Purpose: Guidance and monitoring of non-prescription medications by pharmacists is an important aspect of self-care. The aim our project was to develop an innovative easy-to-use tool to assist patients and caregivers in the process of selecting non-prescription medications within the community pharmacy setting during instances where they have limited or no direct access to the pharmacist, and to help reduce the potential misuse of over-the counter (OTC) medications.

Methods: A 6-item questionnaire was administered to a convenience sample of 20 elderly patients. This survey allowed us to assess patient's knowledge about the proper selection, indications, interactions, and common side effects of OTC drugs. In addition, participants were asked to select which tool would they preferred to assist them in the selection of an OTC medication (i.e. app for mobile, web page, or a touch-screen at the pharmacy). We also interviewed five practicing pharmacists in order to determine which of the tools mentioned above would they support.

Results: According to our findings, the touch screen option was preferred by both patients and pharmacists. As such, our touch screen device was designed to assist and guide patients throughout OTC selection according their symptoms, and concomitant health issues. The prototype touch screen device is intended to be marketed to community pharmacies and professional organizations focused on retail pharmacies.

Conclusion: The implementation of this assistance tool is expected to help patients select and use OTC's appropriately. This may result in better utilization of these drugs, decrease potential drug interactions, and improve health related outcomes among patients who decide to use self-care approaches in addition to current therapies or as a resource to treat their ailments.

Poster Title: Do people enrolled in Medicare Part D plans re-evaluate their plans yearly?

Primary Author: Lindsay Thomas, The University of Mississippi School of Pharmacy, Mississippi;
Email: lothomas@go.olemiss.edu

Additional Author (s):
Michael Warren

Purpose: Medicare members are eligible to receive Medicare Part D benefits, which provide prescription drug coverage. Each year during open enrollment, those who have existing Medicare Part D plans may re-evaluate their plans and switch plans if deemed necessary. This study was designed to assess the participants' knowledge of how often they can switch Part D plans, with additional assessment for those who had previously switched plans.

Methods: The University of Mississippi Institutional Review Board approved this study to determine the participants' knowledge of Medicare Part D plan evaluation and reasoning for plan adjustment. A 14- question survey was created to assess these points. The inclusion criterion included people who were older than 18 years of age and currently enrolled in Medicare. Those who were enrolled in Medicare but did not have Medicare Part D were excluded. Eligible members of St. Luke's United Methodist Church in Jackson, MS and Main Street United Methodist Church in Hattiesburg, MS were provided with the informed consent form and the survey. The survey was administered between November 2015 and January 2016.

Results: A total of 47 surveys were distributed, but only 35 surveys were qualified for the study. The 12 completed surveys not included in the data analysis were due to lack of Medicare coverage (n=1) or lack of Medicare Part D coverage (n=11). Descriptive statistics were used to evaluate the responses for each survey questions. Of the 35 participants, 9.09 percent (n=3) were unaware of the ability to re-evaluate their Medicare Part D plans. All of those, who were aware they could switch Medicare Part D plans, knew it would be evaluated yearly. Participants were questioned on number of Medicare Part D plans since enrollment: 70 percent (n=21) had their original plan, 23.33 percent (n=7) have had two to three different plans, 6.67 percent (n=2) did not know. Of the 7 participants who have had multiple Medicare Part D: 42.86% (n=3) switched to a more affordable plan, 14.29% (n=1) changed as result of the plan no longer being

available in their area, 28.57 (n=2) were switched due to participation in the government's low-income subsidy program, and 14.29% did not provide clarification.

Conclusion: This study demonstrated the majority of people are aware of the option to evaluate their Medicare Part D plan yearly, but only a small portion of people take advantage of changing their plans. The main reason for switching to a different Medicare Part D plan was cost. Although this study shows people have knowledge of their Medicare Part D benefit options, a larger populated study would be needed for external validity.

Submission Category: Pain Management

Submission Type: Evaluative Study

Session-Board Number: 5b-071

Poster Title: Liposomal bupivacaine versus ropivacaine compounded solution for pain control after total hip arthroplasty: a retrospective cohort analysis

Primary Author: Jarrid Casimir, Harrison School of Pharmacy, Alabama; **Email:** jdc0055@tigermail.auburn.edu

Additional Author (s):
Lauren Johnson
William Johnson
Michelle Ducharme
Stephen Barrington

Purpose: Liposomal bupivacaine, available as a brand name medication, is utilized for post-surgery pain control. At Jackson hospital of Montgomery, Alabama this medication was used for total hip arthroplasty procedures until it was recently removed from the formulary and replaced with a compounded ropivacaine solution, citing cost concerns. When performing hip arthroplasty, liposomal bupivacaine or ropivacaine is utilized as an anesthetic to relieve pain through the procedure and after. This study was conducted to determine if liposomal bupivacaine provided a significant advantage over the compounded ropivacaine.

Methods: The population for the study was gathered over a 3-month period and a retrospective study was performed. The population was approximately even between males and females with an average age of 65. During those 3 months, 67 patients had undergone a hip arthroplasty procedure performed by the same surgeon at Jackson hospital. A total of 29 patients who received liposomal bupivacaine and 38 who received the ropivacaine solution were included in the trial. Total morphine equivalent within 24 hours of surgery, greater than 24 hours after surgery and throughout stay was measured along with max pain score within 24hours of surgery and after 24 hours of surgery. The length of stay, and pain score on day of discharge were also measured. An unpaired t test was utilized to cross-examine the two different groups for these outcomes but a log-rank test was used for length of stay.

Results: In comparing the two groups, within 24 hours of surgery, patients who received liposomal bupivacaine reported an average max pain score 1.1 units higher than ropivacaine and 1.04 units higher on day of discharge. Both would prove to be statistically significant with P-vales of 0.0288 and 0.0255 respectively. The average pain score after 24 hours was nearly significant with a p-value of 0.0547. There was no statistical difference in the outcomes of total morphine equivalent within 24 hours of surgery, greater than 24 hours, and throughout their stay. The max pain score under 24 hours, and over 24 hours was not statistically significant along with length of stay. Liposomal bupivacaine patients however, on average received more total morphine within 24hrs of surgery and throughout their stay. Liposomal bupivacaine patients on average used 76.8mg of total morphine within 24 hours and 121.1mg throughout the stay compared to ropivacaine's 67.7mg and 117mg respectively. The liposomal bupivacaine group also reported higher pain scores during their stay at the hospital and on their day of discharge. Patients on ropivacaine also spent less time in the hospital.

Conclusion: Liposomal bupivacaine administration during hip arthroplasty does not appear to decrease the use of morphine throughout the patient's stay nor the length of their stay when compared to the institutional ropivacaine solution. Liposomal bupivacaine also yielded higher max pain score when compared to ropivacaine. This study did not show any justification for the increased expense of liposomal bupivacaine.

Submission Category: Infectious Diseases

Submission Type: Evaluative Study

Poster Title: Evaluation of Ertapenem Use at a Large Academic Teaching Hospital

Primary Author: Jasmin Badwal, Eugene Applebaum College of Pharmacy - Wayne State University, Michigan; **Email:** eh1049@wayne.edu

Additional Author (s):
Rachel Kenney
Susan LeRoque Davis
Mark Mlynarek

Purpose: Carbapenems are a protected class of antibiotics used in the treatment of certain drug-resistant organisms. Many institutions have specific criteria in place to guide and restrict use, however these are not always followed. At our site, ertapenem use is reserved for documented ESBL/AmpC organisms, community-onset polymicrobial infections, transition to once-daily outpatient therapy, or through Infectious Diseases approval. Exposure to these agents has been associated with the development of resistant organisms and adverse effects. The purpose of this study was to evaluate the appropriateness of ertapenem use, assess outcomes of use, and identify areas for antimicrobial stewardship intervention.

Methods: This investigation was a single-center, cross-sectional study of ertapenem use approved by the Investigation Review Board at Henry Ford Hospital in Detroit, Michigan. Patients older than 18 years who received ertapenem in June of 2016 were included. The first 50 patients were consecutively chosen from the earliest order date in June that met inclusion and exclusion criteria. Patients were excluded if they only received one dose of ertapenem before being discharged or one dose before an operative procedure. If patients had a repeat admission during the selected time period with another order of ertapenem, only their first admission was included in the study. Data collected included demographics, SIRS criteria, indication, dosage, duration, concomitant antibiotic use, microbiology results, adverse effects, and clinical response. The primary endpoint was appropriateness of ertapenem use defined as meeting at least one of the specific criteria set by Henry Ford's Antimicrobial Stewardship Program. Secondary endpoints included treatment pattern characteristics, adverse effects of ertapenem therapy, and clinical outcomes. Standard descriptive statistics were used to analyze

all study endpoints. Categorical data will be presented as number (percent) or median (interquartile range).

Results: 50 patients (52 percent male, 48 percent female) were included in the study. 74 percent of patients received 1 gram once daily, and 98 percent of patients were dosed correctly. Use of cefepime (48 percent) was most prevalent when looking at historical antimicrobial use, while the most common concomitant antibiotic was vancomycin (24 percent). Overall, 41 patients (82 percent) received ertapenem appropriately, while use in 9 patients (18 percent) did not meet any criteria. Criteria met included Infectious Diseases approval (58 percent), ESBL infection treatment (50 percent), transition to once-daily dosing for discharge (34 percent), and treatment of community-acquired polymicrobial infections (12 percent). Out of the 9 inappropriate cases, 2 received multiple doses for surgical prophylaxis, 2 for intra-abdominal infections, 3 for lower respiratory tract infections, and 2 for urinary tract infections. Six percent of patients experienced adverse effects based on progress note documentation. 36 percent of patients were discharged on ertapenem, 12 percent completed treatment before discharge, and 18 percent underwent escalation of therapy. 26 percent of patients developed a secondary bacterial infection within 30 days of ertapenem exposure. At the end of inpatient ertapenem therapy, 66 percent of patients showed improvement in response.

Conclusion: Through this retrospective study, we were able to assess appropriateness, safety, and outcomes of ertapenem use in reference of our institutions specified criteria. Overall, majority of ertapenem use was appropriate based on criteria. Ertapenem was generally well tolerated, and as expected efficacy was not in question. Opportunities for antimicrobial stewardship exist among patients who did not meet institutional criteria for use and those who received ertapenem for surgical prophylaxis.

Session-Board Number: 5b-073

Poster Title: Evaluation of tbo-filgrastim in adult oncology patients at a large community teaching hospital

Primary Author: Shabnam Dakwala, Virginia Commonwealth University, Virginia; **Email:** dakwalas@vcu.edu

Additional Author (s):
Genevieve Moore
Leila Mohassel
Casey Washington

Purpose: Myelosuppresion is a dose-limiting toxicity of chemotherapy resulting in increased morbidity, mortality, and costs. Tbo-filgrastim is a granulocyte-colony stimulating factor (G-CSF) recommended for prevention and treatment of chemotherapy-induced neutropenia (CIN) in patients at high risk for infectious complications. In 2013, Inova Fairfax Medical Campus (IFMC) published an institution-specific guideline for appropriate use of tbo-filgrastim in adult oncology patients. This document was based on American Society of Clinical Oncology guidelines to promote cost-effective G-CSF use in hospitalized cancer patients. The purpose of this study was to assess the current use of tbo-filgrastim for CIN and evaluate adherence to institution-specific tbo-filgrastim guidelines.

Methods: This study was reviewed and approved by the Institutional Review Board. This was a retrospective analysis of adult cancer patients treated with tbo-filgrastim from January 1, 2015 to December 31, 2015. Patients who received tbo-filgrastim for stem cell mobilization or non-oncologic indications and patients with incomplete medical records were excluded from the analysis. Data collection included baseline demographics; type of malignancy; chemotherapy regimen; goal of treatment; tbo-filgrastim indication, dose, and duration; absolute neutrophil count (ANC); and patient-related factors that increase risk for neutropenic complications. Secondary endpoints included dose and duration of G-CSF therapy, time from completion of chemotherapy to initiation of G-CSF, ANC at initiation and discontinuation of G-CSF therapy, incidence of febrile neutropenia (FN), and severity and duration of neutropenia.

Results: 121 patients were screened and 100 patients were identified for inclusion in the study. Reasons for exclusions included: incomplete medical records (n equals 3), stem cell mobilization (n equals 3), and tbo-filgrastim for non-oncologic indications (n equals 15). The most common type of cancers were acute leukemias in 24 patients and non-Hodgkin's lymphoma in 17 patients. Approximately half the patients received G-CSF for prophylaxis. Of these, 22 percent, 17 percent, and 8 percent were classified into high, intermediate, and low FN risk categories, respectively. Tbo-filgrastim was administered in combination with antibiotics for FN treatment in 24 percent of patients. Additionally, 16 percent received tbo-filgrastim for afebrile neutropenia. Overall adherence to IFMC guideline recommendations was only observed in 59 percent of patients. Tbo-filgrastim was dosed and timed correctly in over 80 percent of the cases. The mean ANC at the time of initiation of G-CSF for treatment of FN was 301 cells/uL. The mean ANC at the time of discontinuation of G-CSF for prophylaxis, treatment, and afebrile neutropenia was 9808 cells/uL, 2413 cells/uL, and 4210 cells/uL, respectively. The mean duration of G-CSF therapy was 5 days. There were 13 episodes of FN in patients receiving G-CSF for primary or secondary prophylaxis.

Conclusion: This study highlights the significant usage of tbo-filgrastim outside published recommendations and the need to improve adherence to Inova Fairfax Medical Campus guidelines. Pharmacists can play an essential role in improving care and ensuring safe, cost-effective use of myeloid growth factors in oncology.

Submission Type: Evaluative Study

Session-Board Number: 5b-074

Poster Title: Characterization of the use of fosfomycin in adult inpatients at Virginia Commonwealth University (VCU) Health

Primary Author: Arzo Hamidi, Virginia Commonwealth University, Virginia; **Email:** hamidia2@vcu.edu

Additional Author (s):
Lauren Cherry
Lindsay Hoffman

Purpose: Fosfomycin is a unique antibiotic that inhibits bacterial wall synthesis with Federal Drug Administration (FDA) approval for the treatment of uncomplicated urinary tract infections (UTI). Since it has relatively broad aerobic gram negative and gram positive coverage, there has been interest in using it in complicated UTI. Fosfomycin is an attractive option for treatment due to its oral formulation and coverage that includes difficult to treat organisms, such as extended-spectrum beta-lactamase-producing (ESBL) Escherichia coli and vancomycin-resistant Enterococcus (VRE). Since increased use at VCU Health is suspected, this study aimed to characterize the utilization of fosfomycin in an inpatient setting.

Methods: A retrospective chart review was performed on 64 admissions to VCU Health during which at least one dose of fosfomycin was prescribed between January 1, 2015 – December 31, 2015. VCU Health is an academic medical center with approximately 800 beds, and this study was approved by the VCU Institutional Review Board (IRB). Patients were included if they were over the age of 18 and received at least one dose of fosfomycin during their inpatient stay. Demographics, allergies, and other relevant history were collected from the electronic medical record (EMR). Risk factors, including history of multi-drug resistant (MDR) organisms, catheter use, transplant history, and paraplegia, were also evaluated. The organisms grown, susceptibilities, and indication were recorded to allow for appropriateness of fosfomycin to be determined. The EMR was reviewed for up to 30 days after discharge. Documentation within 30 days of recurrent UTI, visit to the emergency department (ED), or readmission was assessed for treatment failure.

Results: A total of 74 bacteria were identified and treated with fosfomycin: Enterococcus faecalis (17.6 percent) with 2.7 percent VRE faecalis, Enterococcus faecium (17.6 percent) with 10.8 percent VRE faecium, Methicillin-resistant Staphylococcus aureus (MRSA) (2.7 percent), Staphylococcus lugdunensis (1.4 percent), beta-hemolytic Streptococcus (2.7 percent), Escherichia coli (28.4 percent) with 9.5 percent ESBL Escherichia coli, other Enterobacteriaceae species (16.2 percent), Morganella species (1.4 percent), and Pseudomonas species (12.2 percent). During eight admissions, no organisms were identified in patients receiving fosfomycin. Of the 74 bacteria identified, nine isolates were tested for fosfomycin susceptibility data. The total number of fosfomycin doses prescribed varied significantly: one dose (42.2 percent), two doses (7.8 percent), three doses (31.2 percent), four doses (9.4 percent), five doses (1.6 percent), eight doses (1.6 percent), 14-day supply (4.7 percent), and weekly prophylaxis in renal transplant patient with recurrent urinary tract infections (1.6 percent). Seven patients (10.9 percent) were readmitted within 30 days of discharge for UTI producing the same bacterial organism as the previous admission. Organisms included Enterococcus faecium, VRE faecium, Escherichia coli (n equals 2), ESBL Klebsiella species, Enterobacter cloacae, and Pseudomonas species.

Conclusion: As evident by local prescribing patterns, the use of fosfomycin at VCU Health is more often for complicated UTI than uncomplicated UTI as well as commonly being used in patients with MDR organisms. Further evaluation of the clinical outcomes with the use of fosfomycin would be useful to determine whether this is appropriate.

Poster Title: Pharmacy and physician assistant student interprofessional experience – pharmacy student perspective

Primary Author: Pilar Mackey, Wayne State Eugene Applebaum College of Pharmacy and Health Sciences, Michigan; **Email:** pemackey28@gmail.com

Additional Author (s):
Joseph Fava
Stephanie Gilkey
Amy Dereczyk
Mary Beth O'Connell

Purpose: The new pharmacy education standards require interprofessional education (IPE). Real world IPE could help students improve skills to practice in the complex healthcare environment. The purpose of this project was to evaluate changes in Pharmacy (PharmD) student attitudes towards healthcare teams, team work, interprofessional education and IPE program satisfaction after a four day IPE experience with physician assistant (PA) students.

Methods: Twelve fourth-year PharmD and twelve second-year PA students were paired based on zip codes. Students and preceptors received IPE program orientation. Students then practiced together for 2 days in a community pharmacy and 2 days in a medical clinic or emergency room. Students self-evaluated their team performance daily. Students anonymously completed a validated Attitudes Toward Healthcare Team Survey (23 items) before and after the IPE program; and a post program survey (25 Likert, 6 yes/no, 3 demographic and 4 open-ended items) on Qualtrics. Data analyzed with descriptive and Mann Whitney U statistics (SPSS v22). P-value less than or equal to 0.05 was considered significant. Research received Institutional Review Board exemption.

Results: Ten PharmD students (4 women, 6 men) completed the IPE. Rotation contract issues prevented completion by two students. Since pre-program attitudes toward healthcare teams survey responses were mostly positive (ceiling effect), few significant changes occurred after IPE. The two attitudes that significantly became more positive were teams are more responsive to patient emotional and financial needs (p=0.048) and teamwork improves understanding of

other health professional roles (p=0.048). All PharmD students (100%) agreed that this IPE experience increased their ability to communicate with patients, understanding of patient clinical problems, and improved quality of care. They were also in agreement that working in a team reduces error (100%) and increases efficiency (90%). All students (100%) felt learning with other students would help them become a better team member and enhance their education. Students found the IPE experience worthwhile (90%) and that it should continue to be required (70%) as part of the PharmD curriculum. Forty percent of students did not feel more IPE days were needed. PA survey responses were similar (most not statistically different) to PharmD student responses.

Conclusion: This real-world IPE resulted in students learning about team functioning, team care, and discipline roles. Students felt IPE enhanced their clinical skills and education. Prior to the program, the pharmacy students' initial attitudes towards team healthcare were very positive. Therefore, the Attitudes Toward Healthcare Survey, although a validated tool, might not be an appropriate real world IPE assessment measure.

Poster Title: Impact of targeted pharmacotherapy on hospital readmissions in heart failure with diastolic dysfunction

Primary Author: Keith Polovich, Auburn University Harrison School of Pharmacy, Alabama; **Email:** kjp0018@auburn.edu

Additional Author (s):
Kaitlin McGinn
Michael Scalese

Purpose: The use of angiotensin converting enzyme inhibitors (ACE-I's), angiotensin receptor blockers (ARB's), beta-blockers, aldosterone antagonists, and isosorbide dinitrate/hydralazine have well documented morbidity and mortality benefits in heart failure with systolic dysfunction. However, the role of these agents in diastolic dysfunction is less clear. Currently, the 2013 ACCF/AHA Heart Failure Guidelines recommend these therapies for symptomatic relief or management of comorbid conditions rather than slowing disease progression or preventing hospital readmissions. The objective of this study is to determine the impact of targeted heart failure therapy on hospital readmission rates in patients with diastolic dysfunction.

Methods: The effect of heart failure targeted medication therapy on hospitalizations was evaluated in this retrospective, single-center, observational study of patients admitted for acute decompensated heart failure from January 2004 through December 2014. Patients were excluded if their ejection fraction was less than or equal to 40% without echocardiogram evidence of diastolic dysfunction or if they died during the index hospital admission. Descriptive statistics were used to evaluate baseline characteristics and rehospitalization rates based on medication use. Medications analyzed included diuretics, ACE-I's, ARB's, beta-blockers, aldosterone antagonists, isosorbide dinitrate/hydralazine, and digoxin. Subgroup analyses were performed to evaluate the impact of medications on patients with diastolic dysfunction only and those with combined systolic & diastolic dysfunction.

Results: An interim analysis of 100 patients was performed from December 2012 through December 2014 . Of those included, the average age was 57.2±14.9 years, 49% were female, and 72% were African American. The most common comorbid conditions included hypertension (81%), diabetes type II (50%), and hyperlipidemia (45%). Most patients were prescribed appropriate medication therapy at discharge including loop diuretics (82%), beta-blockers (81%), and ACE-I/ARB (68%). Ten and seven patients also received aldosterone antagonists and combination hydralazine and isosorbide dinitrate respectively. The average length of index hospital admission was 4.4 ±4.0 days with mean time to rehospitalization occurring at 284.2± 295.5 days. Of the 46 patients with diastolic dysfunction only, the average age was 60.8 ±12.6 years, 65.2% were female, and 69.6% were African American. Heart failure therapy at discharge included loop diuretics (80.4%), beta-blockers (80.4%), and ACE-I/ARB (56.5%). The average length of index hospital admission and mean time to rehospitalization was similar between patients with diastolic dysfunction alone and combined heart failure (3.7 ±2.9 days vs 4.9±4.7 days, p=0.147; 232.7± 257.9 days vs 329.6±322.0 days, p=0.193, respectively).

Conclusion: The interim analysis demonstrates that index hospitalizations and time to readmission appear to be similar in patients with diastolic dysfunction alone versus those with combined heart failure. The majority of patients in our cohort were prescribed appropriate targeted therapy.

Poster Title: Evaluating the use of an insulin administration protocol in patients receiving parenteral nutrition (PN)

Primary Author: Dana Blanchard, University of Michigan College of Pharmacy, Michigan; **Email:** dlblanch@med.umich.edu

Additional Author (s):
Rima Mohammad
Roma Gianchandani
Simona Butler
Melissa Pleva

Purpose: Glucose variability (GV), hyperglycemia and hypoglycemia, affect outcomes in hospitalized patents especially infection rates. Hospitalized patients requiring parenteral nutrition (PN) are especially vulnerable to GV. Previous studies have shown that hyperglycemia during PN is an independent predictor of increased hospital and intensive care unit (ICU) length of stay (LOS), immunologic and cardiovascular complications, and mortality. Limited data exist on the use and success of insulin and PN protocols for medical and surgical patients receiving PN. This study's purpose was to evaluate the impact of a hospital PN and insulin protocol for blood GV and outcomes, including infection and hospital mortality.

Methods: An insulin and PN protocol was designed by a multidisciplinary committee. Dextrose amounts in PN and insulin to carbohydrate ratios were used to dose insulin and PN adjusted on average prior 24-hour blood glucose (BG). BG goal for all patients on PN was between 110mg/dL and 180mg/dL.
Data was collected from hospitalized adult (at least 18 years of age) patients who received PN for at least two consecutive days between 3/14/2016 and 7/1/2016. Patients admitted to the intensive care unit and patients who initially received cycled PN were excluded from the study. Baseline characteristics, glucose levels, insulin, dextrose doses and PN calorie, and clinical outcomes including infection rates and mortality were collected. GV was categorized as hypoglycemia tertiles (less than 70mg/dL and 40mg/dL) and hyperglycemia tertiles (greater than 150mg/dL, 250mg/dL and 400mg/dL).

Results: Sixty-six patients were analyzed. Mean age was 53 years, mean body mass index was 25 and 44 percent were male. Mean admission blood glucose was 132mg/dl and serum creatinine 0.93mg/dL. Thirty-five percent of patients had hypertension and 12 percent had known diabetes mellitus. Mean duration of PN was 13.5 days.

GV occurred in 54.5 percent of patients. Hyperglycemia was present in 54.5 percent of patients. 52 percent had a BG greater than 150mg/dL, 23 percent had BG greater than 250mg/dL, and 6 percent had BG greater than 400mg/dL. Hypoglycemia (BG less than 70) was experienced by 4 percent of patients, but none had severe hypoglycemia (BG less than 40mg/dL). Approximately 56 percent of patients had a documented infection during or after PN. There was no difference in infection rates between patients with and without glucose variability (p equal 0.93). Hospital mortality was 0 percent.

Conclusion: After implementation of a protocol for BG control during PN, 50 percent of BG were under 150 mg/dl without any episodes of severe hypoglycemia. GV occurred in 55 percent of patients, the majority attributed to hyperglycemia.

Poster Title: Impact of acid suppression therapy on iron supplementation in the pediatric intensive care unit

Primary Author: Emily Hailstone, Auburn University Harrison School of Pharmacy, Alabama; **Email:** ezh0016@auburn.edu

Additional Author (s):
Allison Chung
Rosa Vidal
Sheryl Falkos
Ashley Jones

Purpose: Patients admitted to the pediatric intensive care unit (PICU) routinely receive stress ulcer prophylaxis in addition to receiving oral iron supplementation to prevent iron deficient anemia (IDA) from frequent blood draws. Currently, it is believed that antacids may interfere with iron absorption because of the increase in gastric pH. We conducted a prospective, observational single blind trial to determine whether or not a patient's iron stores, hemoglobin (Hgb) and hematocrit (Hct) are maintained or altered while receiving either oral or IV ranitidine or esomeprazole and oral ferrous sulfate supplementation during their PICU stay.

Methods: This prospective, observational trial was IRB approved and occurred over 2 years in a 14-bed PICU within an academic pediatric institution. Included patients were less than18 years old, PICU admits, had blood draws once or more a day, and could receive oral iron supplementation, acid suppression therapy, and consented to participate. Exclusion criteria included patients previously diagnosed with chronic anemia, anemia of chronic disease, history of CKD, glucose-6-phosphate dehydrogenase deficiency, or hemochromatosis, NSAID use, 1 pint of cow's milk in 24 hours or more, Helicobacter pylori infection within 6 months, history of active short bowel syndrome, gastrointestinal bleed, ulceration requiring transfusion or causing hemodynamic instability, frank bleeding from nasogastric tube or rectum, or small bowel resection. Hemoglobin levels were the primary outcome of anemia and Hct was an additional indicator. Secondary outcomes were serum iron levels and gastric pH. Based on physician preference; patients received iron supplementation plus an H2 antagonist or a PPI. Hgb and Hct were monitored once a day or more, up to every 4 hours depending on the patient's needs.

CBC and iron panels were drawn at baseline with repeat levels for both 3 days after treatment was initiated. Baseline characteristics, serum iron, gastric pH, Hgb, and Hct were assessed by descriptive statistics. Serum iron, Hgb, and Hct were further analyzed using paired t-test. Statistical significance was P less than 0.05.

Results: Thirty-four patients met the inclusion and exclusion criteria, 44 percent males and 56 percent females. The majority were Caucasian, 53 percent, followed by African American, 38 percent. Weight of the 30 patients was 10.6 plus or minus 10.6 kg, and age was 24 plus or minus 42.5 months. The baseline means for iron were 43.2 plus or minus 34.9 mcg/dL, Hgb 8.9 plus or minus 1.13 g/dL, Hct 26.6 plus or minus 3.48 percent, and gastric pH 4.97 plus or minus 1.95. The iron levels increased to 50.9 plus or minus 24.6 mcg/dL by day 3. The mean difference of day 3 iron levels from baseline was 0.4061 mcg/dL (95 percent CI, 0.13-0.69, P equals 0.0056). Gastric pH decreased to 4.68 plus or minus 1.49 on day 5. The mean of Hgb and Hct increased on day 5 to 10 plus or minus 1.06 g/dL and 29.6 plus or minus 3.27 percent respectively. The mean difference of Hgb from baseline was 1.1800 g/dL (95 percent CI, 0.44-1.91, P equals 0.0030). The mean difference of Hct from baseline was 3.1259 percent (95 percent CI, 0.98-5.28, P equals 0.0061).

Conclusion: The use of either oral or IV ranitidine or esomeprazole along with oral ferrous sulfate supplementation did not affect the absorption of iron. Iron, Hgb, and Hct all showed statistically significant increases despite combined antacid and iron therapy. Thus despite use of antacids, combination use showed statistically significant increase in iron, Hgb and Hct. As this was a small trial, a larger, long-term study is needed to evaluate the clinical significance of this effect.

Poster Title: The effect of vitamin D deficiency treatment on glycemic control in patients with type 2 diabetes

Primary Author: Rachel Collins, Auburn University Harrison School of Pharmacy, Alabama; **Email:** rec0017@auburn.edu

Additional Author (s):
Emily McCoy
Elizabeth Ezell

Purpose: More than 29 million people in the U.S. have diabetes, with type 2 diabetes mellitus (T2DM) accounting for 90-95 percent of all cases. Vitamin D deficiency may occur in 91 percent of patients with diabetes; recent studies have proposed that vitamin D plays a role in glycemic control through impact on β-cell activity and insulin sensitivity. Results of interventional studies have been conflicting, but data suggests potentially greater treatment effect in patients with higher baseline HbA1c. The purpose of this study was to determine whether treatment of vitamin D deficiency led to improved glucose control in patients with T2DM.

Methods: This retrospective chart review included 33 patients at an outpatient internal medicine clinic in Mobile, AL. Patients were included if they were age 19 and older and had a diagnosis of both type 2 diabetes and vitamin D deficiency based on ICD-10 coding using E11 and E 55 or 65 diagnostic codes. Vitamin D deficiency was defined by a serum 25-hydroxyvitamin D [25(OH)D] less than 30 ng/mL. There were no defined exclusion criteria. The primary outcomes measured were changes in vitamin D levels after treatment of deficiency and changes in HbA1c levels at 3, 6, 9 and 12 months following treatment of vitamin D deficiency. Secondary outcomes included changes in HbA1c lowering between patients with an HbA1c less than 8 percent vs. 8 percent or greater, changes in lipid profiles, blood pressure, and weight. Differences between groups were assessed using a two-sample t-test. Statistical significance was defined as p value less than or equal to 0.05.

Results: Deficient vitamin D levels significantly improved with treatment (16.5 ng/mL vs. 33.7 ng/mL; p less than 0.0001). Compiled data revealed no significant differences in HbA1c levels after treatment of vitamin D deficiency at 3, 6, 9 or 12 months (p equals 0.867, 0.19, 0.088, and 0.529, respectively). However, in patients with a baseline HbA1c of 8 percent or more (mean 10.5 percent), HbA1c levels improved at 3 months (8.8 percent; p equals 0.003), 6 months (8.4 percent; p equals 0.005), 9 months (8.1 percent; p equals 0.001), and 12 months (8.9 percent; p equals 0.03) after treatment. No significant differences in lipid levels, blood pressure, or weight were found.

Conclusion: Correction of vitamin D deficiency improved glucose control in diabetic patients with an HbA1c of 8 percent or higher but did not result in significant improvement in lipid profiles, blood pressure, or weight. These findings may suggest utility of vitamin D replacement in diabetic patients with poor glycemic control. Further studies should be conducted to strengthen the evidence of this correlation.

Poster Title: Defining phenotypic relationships between smoking and opioid using patients and assessing pain severity and function

Primary Author: Cassandra Diamond, University of Michigan College of Pharmacy, Michigan; **Email:** casmardi@med.umich.edu

Additional Author (s):
Chad Brummett
Jenna Goesling
Stephanie Moser

Purpose: More than 100 million Americans live with chronic daily pain and many use opioid analgesics to manage their pain symptoms. Patients also use tobacco simultaneously to cope with some of the pain symptoms they experience. The purpose of this study was to define the phenotypic relationship between smoking and opioids and to understand how comorbid tobacco use among opioid users is associated with patient's self-reported pain relief, functioning after taking opioids and confidence in ability to manage pain without opioids. By exploring this relationship, providers can design future interventions to aid opioid users and smokers in cessation.

Methods: The Institutional Review Board (IRB) approved this retrospective, cross-sectional, questionnaire-based study. Data were collected from new patients who presented at the Back and Pain Center at the University of Michigan in Ann Arbor between April 2015 and January 2016. Patients who completed the new patient questionnaire and provided information about their smoking habits and opioid medication use were included in the study. Patient's questionnaires were entered into the Assessment of Pain Outcome Longitudinal Electronic Data Capture (APOLO EDC) database. Patients were divided into four groups: 1) patients who did not smoke and did not use opioid medication, 2) patients who smoke but do not use opioid medication, 3) patients who do not smoke but use opioid medication, and 4) patients who both smoke and use opioid medication. Statistical analyses focused on questions about opioid medications use, smoking habits, pain severity, physical activity, and overall well-being of the patient. Patient's opioid medication regimen was converted to oral morphine equivalency (OME) in order to assess the differences between smokers and non-smokers in terms of daily

oral morphine equivalency. Further analysis was done to compare smokers and non-smokers in pain relief after opioid use, functionality after opioid use and confidence to stop opioid medication.

Results: Six hundred and thirty four new patient questionnaires were included in our study, 227 non-opioid non-smokers, 51 non-opioid using smokers, 268 opioid using non-smokers and 88 opioid using smokers. Patients who reported they were opioid using smokers had the worst overall score in pain, depression and anxiety. Non-opioid using smokers reported significantly better neuropathic pain scores (Pain Interference), and better functioning scores (Oswestry Disability Index; p=0.005 for both) when compared to opioid using smokers. Opioid using non-smokers along with non-opioid non-smokers had significantly less anxiety when compared to opioid using smokers (p=0.007 and p=0.002, respectively). Patients who identified as opioid using smokers used on average 10mg more oral morphine equivalents than the non-smoking opioid using group (p=0.009). Among all opioid users, there were no significant differences between smoking and non-smoking patients when asked about relief provided by opioids, function after taking opioids or confidence in ability to stop opioid medications (p=0.94, p=0.277 and p=0.101, respectively).

Conclusion: Opioids and cigarette smoking are both major public health problems. We found that patients who do not use opioids report better outcomes when compared to those using opioids, and patients who smoke used higher opioid doses. Similar contributory mechanisms between smoking and pain triggering could explain the correlation between these two. With the knowledge that relief provided by pain medications and the confidence to stop opioid medications are not different between smokers and non smokers who use opioids, providers can use this information to guide their practice, specifically suggesting other alternative remedies to help patients cope with pain.

Poster Title: Longitudinal measurement of empathy in pharmacy students

Primary Author: Christopher DeWald, University of Michigan College of Pharmacy, Michigan; **Email:** dewaldc@med.umich.edu

Additional Author (s):
Sarah Kelling
Burgunda Sweet
Paul Walker

Purpose: Empathy has long been considered an important core element in healthcare provider-patient relationships. Thus, empathy and its development among providers (physicians, nurses, dentists and pharmacists) have been the focus of considerable research. Empathy of medical, dental and nursing students, as well as medical residents, has also been assessed longitudinally over the course of their training. However, little is known about empathy development among student pharmacists. Student pharmacists are taught about empathy and provided many opportunities to develop empathy skills throughout their four-year professional education. This study assessed empathy and how it changes in first-year (P1) student pharmacists.

Methods: Eighty-five P1 student pharmacists from the University of Michigan College of Pharmacy Class of 2019 participated in the study. Empathy was assessed using the Jefferson Scale of Empathy – Health Profession Student version (JSE-HPS), a validated instrument that provides a self-report of empathy (Thomas Jefferson University, Philadelphia, PA). The JSE-HPS was administered using an online survey at the beginning of the first professional year (week 8 of fall semester 2015); the online survey was administered a second time toward the end of the first professional year (week 14 of winter semester 2016). Students independently completed the survey during a Communications course in fall 2015 and a Self-Care Therapeutics course in winter 2016. Demographic information about the student (age, gender, work experience, previous patient interactions) was also collected. The JSE-HPS was scored using the prescribed algorithm. Data were analyzed using descriptive statistics, paired Student's t-tests, and analysis of variance. This study was granted exempt status by the Institutional Review Board of the University of Michigan (HUM# 00103485).

Results: Eighty-five students completed the JSE-HPS survey in the fall; 83 completed it in the winter. Three fall surveys and one winter survey were dropped as incomplete. Eighty-two paired surveys were analyzed. Mean empathy scores did not change between fall and winter semesters, 111.8 ± 10.6 vs. 109.61 ± 13.71, respectively (p=0.105). No effect of gender was observed in overall scores (males, 113.89 + 2.5 vs. females, 113.63 + 2.23; p=0.94); no changes were observed between fall and winter semesters. To evaluate the effect of age, students were classified into three categories: 19-21 years of age, 22-24 years of age, and 25 years of age or older. Empathy scores decreased significantly from fall to winter among students aged 22-24 years (112.08 + 11.05 vs. 108.12 + 14.5; p=0.0403); scores did not change significantly among other age groups. Fall empathy scores of students with prior pharmacy work experience were not significantly different from scores of students without prior work experience (p=0.099); no significant differences were observed between fall and winter scores. Overall empathy scores of students with previous patient interactions were similar to those of students without previous patient interactions (p=0.84); scores did not change significantly from fall to winter.

Conclusion: Overall, self-reported empathy of P1 student pharmacists did not change significantly over the first academic year. Gender, age, past work experience and experience interacting with patients did not have a significant effect on empathy scores. Continued longitudinal evaluation of empathy scores will be needed to understand how empathy development of student pharmacists progresses during their professional education.

Poster Title: Outlining the use of 4-Factor Prothrombin Complex Concentrate in patients not receiving vitamin K antagonist therapy

Primary Author: Michael Frei, Wayne State University Eugene Applebaum College of Pharmacy and Health Sciences, Michigan; **Email:** mfrei1@hfhs.org

Additional Author (s):
Maya Abdullah
Carolyn Martz
Mathew Jones
Michael Peters

Purpose: Literature provides limited information regarding the utilization of 4-Factor Prothrombin Complex Concentrate (4F-PCC) for indications other than vitamin k antagonist (VKA) reversal. This study characterized the use of 4F-PCC outside of its approved indication.

Methods: A retrospective chart review utilizing the electronic medical record was conducted on patients who received 4F-PCC from December 1, 2013 to August 31, 2016. Patients were included if they were 18 years or older and received 4F-PCC during the specified time frame. Patients were excluded if they used a VKA prior to 4F-PCC administration or were pregnant during the admission. The following data was collected: pertinent patient demographics, indication for 4F-PCC, INR trends 24 hours from administration of 4F-PCC, adverse events potentially related to 4F-PCC within 30 days of 4F-PCC administration, rate of initiation of procedures within 8 hours of 4F-PCC administration, and the use of adjunctive hemostatic therapies in combination with 4F-PCC. Descriptive statistics were used to characterize the data as appropriate.

Results: Twenty-three patients were included in the study. Patients were mostly Caucasian females with a baseline INR of 2.55 and serum creatinine of 1.45 mg/dL. The most common dose of 4F-PCC was 25 units/kg. Fifteen (65%) patients were given 4F-PCC for reversal of bleeding, 5 (21%) for an emergent procedure, 1 (4%) for reversal of elevated INR, 1 (4%) for apixaban reversal, and 1 (4%) for gift of life. Two (9%) patients had a Child-Pugh score of A, 7 (30%) with a score of B and 14 (61%) with a score of C. The median INR reduction from baseline

to immediately after 4F-PCC administrations was 0.65 (IQR 1.09), with the median time to first INR draw being 120 minutes (IQR 287.75). One (4%) patient with cirrhosis was diagnosed with portal vein thrombosis two days after 4F-PCC administration. Seven (33%) patients received cryoprecipitate, 17 (74%) received fresh frozen plasma (FFP), 4 (17%) received aminocaproic acid, 20 (87%) received either IV or oral vitamin K, 9 (39%) received platelets, 2 (9%) received desmopressin, and 1 (4%) did not receive any adjunctive therapies.

Conclusion: The most common off-label indications for 4F-PCC use in this evaluation was reversal of bleeding events, followed by need for emergent procedures. The median INR was decreased however, it is unknown if this was solely due to 4F-PCC administration as a majority of patients received adjunctive therapies. The significance of 4F-PCC use in situations other than VKA reversal must be determined in a larger, long-term clinical trial.

Poster Title: Evaluation of appropriate metabolic monitoring for patients prescribed atypical antipsychotics in a hospital based ambulatory care clinic

Primary Author: Katherine King, Auburn University Harrison School of Pharmacy, Alabama; **Email:** kfk0007@auburn.edu

Additional Author (s):
Lori Hornsby

Purpose: Atypical antipsychotics are associated with various metabolic side effects. In 2004, the American Diabetes Association (ADA), American Psychiatric Association (APA), American College of Endocrinology (ACE), and the North American Association for the Study of Obesity (NAASO) established consensus guidelines recommending scheduled monitoring of body mass index (BMI), waist circumference, hemoglobin A1c (HbA1c), fasting plasma glucose, fasting lipid panel, blood pressure, and personal/family history in these individuals. The purpose of this study was to determine if patients receiving care through our ambulatory care clinic and prescribed atypical antipsychotics are being appropriately monitored for metabolic effects based on the 2004 consensus guidelines.

Methods: This retrospective chart review was approved by the institutional review board. Patients receiving an atypical antipsychotic from August 1, 2011 – August 31, 2016 were identified. Patients were included if they received an atypical antipsychotic for at least 6 months and were seen by their primary care provider at least twice for a non-acute visit during the time of treatment. The following information was collected from the patient's electronic medical record: antipsychotic prescribed and indication; measures of BMI, weight, HbA1c, fasting plasma glucose, fasting lipid panels (total cholesterol, high-density lipoproteins, low-density lipoproteins, and triglycerides), and blood pressure; diagnosis of or worsening of any metabolic abnormalities during treatment. The primary objective was to determine the percentage of patients appropriately monitored for metabolic effects per 2004 consensus guidelines. The secondary objectives were to determine 1) the percentage of patients with a greater than 5 percent weight gain at any time during therapy and 2) the percentage of patients with a) evidence of an undiagnosed metabolic condition, b) a diagnosis of a metabolic condition made after antipsychotic initiation or c) worsening of and/or requiring adjustment in treatment

of a diagnosed metabolic condition after antipsychotic initiation. The results were analyzed using descriptive statistics.

Results: Eighty-one patients were included after reviewing 137 charts. Blood pressure and weight were obtained at each visit per standard triage procedures. Eleven patients had a preexisting diabetes diagnosis. Of the remaining 70 patients, a HbA1c was ordered or obtained in 3 percent (n equals 2) at the recommended time of 3 months after beginning therapy and in 20 percent (n equals 14) at any time during therapy. Ten percent (n equals 7) had a plasma glucose obtained 3 months after starting therapy. Forty patients had a preexisting hyperlipidemia diagnosis. Of the remaining 41 patients, a lipid panel was ordered or obtained in 7 percent (n equals 3) at the recommended time of 3 months after beginning therapy and in 59 percent (n equals 24) at any time during therapy. Forty-nine percent (n equals 40) had a weight gain of greater than 5 percent during therapy. Six percent (n equals 5) met diagnostic criteria for a metabolic condition (excluding obesity) but was not diagnosed, and 19 percent (n equals 15) were diagnosed with a metabolic condition after antipsychotic initiation. Of those with a preexisting metabolic condition, 38 percent (n equals 25) had worsening of and/or required therapy adjustments after antipsychotic initiation.

Conclusion: Based on data from this study, we conclude the need for education and implementation of more stringent monitoring of patients prescribed atypical antipsychotics in order to identify and manage metabolic conditions in this high-risk population.

Poster Title: Relationship of lithium in drinking water to suicide and Alzheimer's mortality across fifteen Alabama counties

Primary Author: Anna Palmer, McWhorter School of Pharmacy, Samford University, Alabama; **Email:** apalmer2@samford.edu

Additional Author (s):
Greg Gorman
Marshall Cates

Purpose: Lithium is currently used as a treatment for bipolar disorder and depression and has shown reduced suicide in those patients. Recent studies have supplied evidence that lithium may also be effective at reducing suicide at much lower doses, such as those found in drinking water. Additionally, some research has found stabilization of Alzheimer's at similar low levels. The purpose of this study is to compare suicide and Alzheimer's mortality rates to natural lithium levels in the drinking water of Alabama. Due to the modern increase in bottled water consumption, lithium levels in seventeen brands and one spring were also determined.

Methods: Water samples were collected from 15 Alabama counties: the 5 with the highest suicide rates, the 5 with the lowest suicide rates and the 5 counties with the highest population. These counties were chosen to provide as much variety in demographic characteristics as possible, while ensuring a broad range of rates. Five water samples from each county were collected using uniform containers from homes, restaurants and other public spaces. Lithium levels were measured using an inductively coupled plasma emission spectrophotometer. The average of the five measurements was used to represent the lithium level for each respective county. Suicide and Alzheimer's mortality rate data was collected from the Alabama Center for Health Statistics and the Centers for Disease Control and Prevention (CDC) for the years 1999-2013. The average rate for this 15 year range was then plotted against the mean lithium level for each county to determine the correlation coefficient (r). Significance was decided using Spearman's rank correlation test with an alpha value of 0.05. Several potential confounding variables were also compared to suicide rate including: age, sex, income, poverty and divorce. For the bottled and spring water one sample from each source was

collected and measured using inductively coupled plasma emission spectrophotometry. The lithium values were then compared to those found in the county samples.

Results: The plot of suicide rate versus lithium concentration showed an inverse linear relationship with a correlation coefficient of r equals -0.6286. Two counties were distinct major outliers; when removed the new r equals -0.8781. Spearman's rank correlation test gave a two-tailed p value of 0.0141 and without outliers p equals 0.0003. The correlation coefficient for suicide rate versus age-standardized Alzheimer's mortality rate was -0.2714 and p equals 0.3278. The male only suicide rate versus lithium concentration data remained significant, however, female only was significant only without the presence of outliers. Other confounders, with the exception of poverty, were not significant. Of the bottled waters sampled only 8 had a lithium concentration greater than 1 part per billion (ppb). The range of lithium concentrations for the counties was 0.4166 ppb to 32.88 ppb. The bottled water lithium concentrations ranged from 0 ppb to 12.5 ppb.

Conclusion: Lithium concentration in drinking water is inversely correlated with suicide rate but not with Alzheimer's mortality rate in 15 Alabama counties. The majority of sampled bottled water brands do not contain significant amounts of lithium. Further research into the nutritional essentiality of lithium is warranted.

Poster Title: Evaluation of an interprofessional patient safety education program: Student pharmacists' perspectives

Primary Author: Bethany Hill, Eugene Applebaum College of Pharmacy and Health Sciences, Wayne State University, Michigan; **Email:** hillbethany3@gmail.com

Additional Author (s):
Alice Hu
Diane Levine
Mary Beth O'Connell

Purpose: Annually, medical errors cost about $17 billion (Health Affairs 2011) and result in about 210,000 preventable deaths in a hospital (Journal Patient Safety 2013). All healthcare professionals need to help prevent these errors, thus students need patient safety training. Wayne State University developed an interprofessional student patient safety program to educate pharmacy and medical students together to prevent, analyze, and report medical and medication safety errors. The purpose of this research is to evaluate program effectiveness on teaching pharmacy students about patient safety, event analysis, reporting, and error prevention; and the impact of interprofessional learning.

Methods: Before the program, students completed the Healthcare Professionals Patient Safety Assessment Curriculum Survey (Nurse Education Today 2015) and an investigator-created survey assessing patient safety knowledge and opinions. The 5-hour session included brief didactic lectures, a Grey's Anatomy episode portraying a medical error, and interprofessional group work. Groups included 1-2 pharmacy and 7-8 medical third-year students. Group work focused on error statistics and analysis tools, just culture, human factors engineering, FDA Medwatch program, error reporting, and patient safety committees. After the program, students completed the original survey that included additional program learning and evaluation items. Students created a unique identifier resulting in de-identified databases. Project given IRB exemption. Only students completing both surveys were included. All Likert-like opinion-questions (4 point comfort, agreement, or familiar scales) were analyzed using Wilcoxon signed rank sums with descriptive statistics for demographics (SPSS version 22). Pre and post knowledge-questions scored as 0 (no or wrong answer), 1 (partial), and 2 (correct) by

2 investigators with differences adjudicated and then analyzed with Chi square. P value < 0.05 was considered significant. Open-ended learning-questions were analyzed qualitatively. Two investigators assigned 2-3 initial codes for each open-ended question response and developed simultaneously a codebook. Differences in initial codes were adjudicated by the research group. Initial codes were grouped into focus codes, which were followed by theme creation to generalize the findings.

Results: Seventy-six pharmacy students attended the program. Matched surveys existed for 67 students (88%). Prior to the program, almost all students knew errors with no harm need to be addressed (95%) and valued interprofessional patient safety teams (100%). Students became more comfortable reporting a patient safety error to preceptor (64% to 90%, p = 0.000) and being able to analyze an error for causes (51% to 91%, p = 0.000) after the program. Student agreement significantly increased for patient safety being included in schooling (46% to 68% strongly agree, total agreement 94% to 100%, p = 0.002); solutions to resolve errors should be evaluated by an interprofessional committee (42% to 64% strongly agree; total agreement 98% to 100%, p = 0.001), and non-healthcare professionals should be members on a patient safety committee (82% to 88% total agreement, p = 0.001). Assessment of knowledge demonstrated significantly more students (p=0.000) could define root cause analysis, just culture, and human factors engineering after the program. The most important themes learned about medication error and prevention were error analysis, patient safety improvements, and human accountability. Themes for interprofessional patient safety learning included enhanced learning, improved patient safety outcomes, and collaborative practice.

Conclusion: Case discussions, team work, and a television show facilitated interprofessional patient safety communication and application of knowledge. After the interprofessional patient safety education program, pharmacy students' knowledge about patient safety, error analysis, error prevention, patient safety committees, and interdisciplinary involvement improved. All students agreed interprofessional patient safety education is important didactic learning. The interprofessional patient safety education will be continued with exploration to add another Interprofessional education program day with additional patient safety topics and inclusion of additional healthcare professionals.

Poster Title: Retrospective evaluation of directions for liquid medication dosage forms in pediatric patients at Concord Hospital Family Health Center

Primary Author: Bassem Almalki, Massachusetts College of Pharmacy and Health Sciences (MCPHS University), New Hampshire; **Email:** balma1@stu.mcphs.edu

Additional Author (s):
Jennifer Towle

Purpose: This study reviews prescribing practices for liquid medication dosage forms in pediatric patients at Concord Hospital Family Health Center (CHFHC). The purpose of this study is to assess a sample of liquid medications prescriptions for non-milliliter units such as teaspoon (tsp) versus millimeters (mL) versus the use of both. Also reviewed were types of units available on measuring devices at local pharmacies. This study and best practices will be used to develop a new computerized physician order entry system. Education will also be provided to healthcare providers about the results and best prescribing practices for liquid medication dosage forms.

Methods: A retrospective review of 42 pediatric prescriptions for liquid medications between 09/01/2015 to 09/01/2016 was conducted. The data was extracted from a report generated by the clinics IT department and included the patient's age, language, prescription directions, and medication. GraphPad software was utilized for statistical analysis. The second part of this study, reviewing measurement devices dispensed to patients, was conducted at eight local community pharmacies. All major chain pharmacies for this area were included as well as independent pharmacies. The analysis of the medication measurement devices included review of the types of measurements on the devices. Review of the best practices and the devices within the community was used to make recommendations for medication profile builds in the new computerized order entry database.

Results: The median age of patients was 7 years (range: less than 1 to 16 years old) and 10 patients (about 24%) were non-English speakers. Directions on all 46 prescriptions were written as tsp unit and only 11 prescriptions (23%) contained mL units within the directions as well. One prescription, of the 11 prescriptions, indicated cc referring to mLs. Acetaminophen and

antibiotics were the most prescribed liquid medication dosage forms. The data that was collected from pharmacies demonstrates different available liquid medication devices including syringe, spoon, cup, and dropper. Eight pharmacies provide syringes with liquid medications and five provide spoons. All devices were marked with mL and 42% were additionally marked in teaspoons.

Conclusion: Recommendations for prescribing practices for liquid medication dosage forms include writing orders in mL unit only and also the inclusion of the dose for example: 5 mg (10 mL) BID. The use of mL only for measurement is preferred to limit the confusion with other types of spoons within the patient's home. The need for this may be particularly important for those patients coming from a foreign country, 24% of our study population, where the avoirdupois system is not used. The availability of liquid medication devices that measure mL unit in the local pharmacies supports these recommendations.

Poster Title: Evaluation of the frequency of Cytochrome P450 2C19 variant alleles in a Mexican population compared to a Caucasian population

Primary Author: Sarah Trinh, Shenandoah University Bernard J. Dunn School of Pharmacy, Virginia; **Email:** strinh13@su.edu

Additional Author (s):
Dania Segura
Lia Merila
Robert Kidd

Purpose: CYP2C19 is a cytochrome P450 enzyme involved in the metabolism of clopidogrel, carisoprodol, proton pump inhibitors, and certain antidepressants/antiepileptics. Genetic variations can lead to changes in drug metabolism, which can be associated with adverse events and/or therapeutic failure. Extensive pharmacogenetic studies have been completed in Caucasians, but less research has been performed in Mexican-Americans. Detection of genetic variations in drug metabolizing enzymes can help identify patients at risk for adverse drug reactions and/or therapeutic failure at standard dosages. This study compared the frequency of genetic variations in CYP2C19 in a Mexican population compared to a Caucasian population.

Methods: The Shenandoah University Institutional Review Board approved this cross-sectional study prior to its commencement. The DNA analyzed for this study utilized previously obtained samples with informed consent to allow for further studies relating to the pharmacogenetics of drug metabolism. All the subjects were greater than 18 years of age and self-identified as Mexican or Caucasian. A polymerase chain reaction (PCR) was then performed to test for the presence of CYP2C19*2 (rs4244285) and CYP2C19*17 (rs12248560) on a Applied Biosystems Quantstudio 6 Flex and a 7300 real-time PCR systems. The genotypes and allele frequencies were compared between groups using the Pearson X2 test and Fisher's exact test, when appropriate. A $p < 0.05$ was considered to be statistically significant.

Results: A total of 188 Mexican and 179 Caucasian samples were analyzed. The frequency of the CYP2C19*2 variant allele was 7.2% in the Mexican group compared to 16.0% in the Caucasian group ($p < 0.001$). The genotype frequencies were also significantly different

between the two groups (p=0.002). The frequency of the CYP2C19*17 variant allele was 6.0% in the Mexican group and 22.4% in the Caucasian group (p < 0.001). The genotype frequencies were also significantly different between the two groups (p < 0.001).

Conclusion: The CYP2C19 genotype and allele frequencies were significantly different between these Mexican and Caucasian populations. These results reveal that Mexicans are less likely to possess these two CYP2C19 genetic variations, which are most common in Caucasians. Further research needs to determine if other CYP2C19 variant alleles less common in Caucasians may occur at a higher frequency in the Mexican population.

Poster Title: The Relationship Between Gender-Affirming Hormone Therapy and Depressive Symptoms in an Urban Transgender Population

Primary Author: Katherine Cho, University of Michigan College of Pharmacy, Michigan; **Email:** kcho@med.umich.edu

Additional Author (s):
Jenny Yuan
Jenish Patel
Stuart Rockafellow
Brayden Misiolek

Purpose: Transgender/gender non-conforming individuals face higher risks of depression than the general public. Although true prevalence is unknown, estimates of depression range from five to ten times the national average, as high as 62%. Depression is often driven by discrimination and marginalization. Medically transitioning to one's authentic gender identity is one method of decreasing gender dysphoria and improving quality of life. However, further data is needed regarding the role of hormone therapy (HT) and other factors in lowering the risk for depression. This study evaluated the relationship between the presence of depressive symptoms and HT use in addition to other characteristics.

Methods: Using a community-participatory model, a transgender advocacy organization developed an on-line survey that gathered information about daily discrimination burden, coping skills and impact of discrimination among self-identified transgender/gender non-conforming adults at least 18 years old. Data were collected beginning June 2016 with University of Michigan researchers contracted for de-identified database analysis. IRB approval was obtained prior to analysis. Data pertaining to this study included responses about medical transitioning, hormone therapy, the Patient Health Questionnaire-2 item scale (PHQ-2), and the Generalized Anxiety Disorder 7-item Scale (GAD-7), common screening tools for depressive and anxiety symptoms respectively, and demographic and socioeconomic data. Responses to the PHQ-2 were categorized as indicating a risk of depressive symptoms if the PHQ-2 score was 2 or greater. GAD-7 responses were categorized as indicating generalized anxiety if the GAD-7 score was 10 or higher. GAD-7 scores of 15 or higher were categorized as indicating severe anxiety.

Using SPSS, data were analyzed using binomial logistic regression to calculate odds ratios (OR) for depressive symptoms. The primary outcome was the likelihood of depressive symptoms with concurrent HT use. Secondary outcomes included the odds of depressive symptoms based on education level, (high school or GED vs. minimum some college education), annual income (less than vs. greater than or equal to $25,000), age (less than or equal to vs. greater than 25 years), and comorbid severe anxiety.

Results: Sixty-one individuals were included in the database; 1 was deleted due to age less than 18 years. Of the 60 respondents analyzed, mean age was 28 (plus or minus 13) years. The majority was Caucasian (81.67%) and had a high-school diploma or a GED (73.33%). About one-half (51.8%) had an annual household income of at least $25,000. Forty-five respondents (75%) had a PHQ-2 score of 2 or higher, 31 (51.67%) had a GAD score of 10 or higher, and 22 (35%) had a GAD-7 score of 15 or higher.

Several factors lowered the risk of depressive symptoms. HT users had 76.6% lower risk (OR=0.23, p=0.06). Those who had some post-secondary education had a lower risk of 67.7% (OR=0.32, p=0.15). A significantly lower risk was found with an annual income of at least $25,000 (OR=0.30, p-value less than 0.05). Older age (greater than 25 years) was associated with a higher likelihood (OR=1.15, p=0.85).

When severe anxiety was added to the regression model, a significant higher risk for depressive symptoms was found (OR=17.38, p-value less than 0.01). Hormone therapy, education, and annual household income continued to show a lower, but statistically insignificant, risk. Older age remained a risk factor for depressive symptoms.

Conclusion: Depression and its associated relationship to suicide is a major concern in the care of transgender/gender non-conforming individuals. Slightly more than half of survey respondents were at risk of depression. Gender-affirming HT use was associated with lower likelihood of depressive symptoms. Education, annual income and younger age also appear to lower risk. Severe generalized anxiety significantly increased the risk of depressive symptoms. Our results emphasize the need to include depression screenings in the care of transgender/gender nonconforming patients and the importance of hormone therapy and anxiety treatment in the care of this population.

Poster Title: Prescribing habits of practitioners for upper respiratory tract infections: Are antibiotics being overprescribed in pediatric patients?

Primary Author: Megan McCarter, McWhorter School of Pharmacy, Samford University, Alabama; **Email:** mmccarte@samford.edu

Additional Author (s):
Katie Lomax

Purpose: The Centers for Medicare and Medicaid Services are implementing PRQS (physician quality reporting system) measures to evaluate appropriate prescribing habits from physicians. These measures have been implemented as a cost-savings program to prevent unnecessary prescribing of medications to patients. The American Academy of Pediatrics has recently published guidance on the treatment of upper respiratory tract infections (URI). Most URI's are viral in nature, rendering an antibiotic useless, yet prescribers often prescribe antibiotics for a diagnosis of URI. This chart review is aimed at the PQRS measure evaluating a physician's prescribing habits when diagnosing a pediatric patient with a URI.

Methods: This retrospective chart review included patients from 3 months to 18 years of age who presented to the Baptist Hoover Clinic within the past year and received a diagnosis of URI. Data to be collected includes gender, age, diagnosis, and medication prescribed. Patients were identified by the ICD-9 code assigned for a URI.

Results: Thirteen patients were identified and included in the chart review who presented to clinic with cold or flu like symptoms and subsequently received a diagnosis of URI. Of the 13 patients diagnosed, 8 patients (62%) were prescribed antibiotics for their URI.

Conclusion: Primary care physicians who prescribe antibiotics for pediatric patients with URIs could be hindering their place of work from receiving a reimbursement due to the prescribing of antibiotics for unnecessary diagnoses. The overprescribing of antibiotics in pediatric patients with URIs could ultimately lead to antibiotic resistance. Diligent prescribing habits need to be reinforced in order to properly treat the patient, prevent unnecessary costs, and also generate revenue for the clinic.

Poster Title: Evaluation of bacteremia in pediatric patients in Mississippi's only children's hospital

Primary Author: Tia Collier, The University of Mississippi School of Pharmacy, Mississippi;
Email: tecollie@go.olemiss.edu

Additional Author (s):
Elisabeth Schneider
Kayla Stover
Katie Barber

Purpose: Bloodstream infections are well defined in adult populations, with Staphylococcus aureus, Staphylococcus epidemidis, Enterococcus spp, and Streptococcus pneumoniae representing the most common causes. Staphylococcus aureus, generally considered the most pathogenic of those, results in a mortality rate of 20 to 40 percent. However, less is understood about the causes of bacteremia in pediatric patients, particularly those in a rural state. The purpose of this study was to establish the primary causative agents of bacteremia in pediatric patients admitted to Mississippi's only children's hospital to determine if these pathogens differ from the adult population.

Methods: This retrospective epidemiologic evaluation included pediatric patients 18 years or younger admitted to the University of Mississippi Medical Center between January 1, 2013 through December 31, 2015. Patients with a definitive positive blood culture identified by the TheraDoc surveillance system were reviewed. Patients admitted on several different occasions with different organisms were considered to be separate cases and were included, but relapsing episodes with the same initially identified pathogen were excluded. For those who had repeat cultures with the same pathogen, only the first positive culture was included. Positive blood cultures with organisms that are known contaminants (i.e. Bacteroides spp., diphtheroids) were excluded.

Results: 913 patient isolates had a positive blood culture, with 92 unique organisms identified. The most frequently identified organisms were Staphylococcus epidemidis (207/913, 22.67 percent), followed by Staphylococcus aureus (136/913, 14.90 percent). Methicillin-resistance

was observed in 60.30 percent of these strains. Other pathogens recorded included viridans group streptococci (49/913, 5.37 percent), Staphylococcus hominis (43/913, 4.71 percent), Enterococcus faecalis (37/913, 4.05 percent), and Escherichia coli (34/913, 3.72 percent). Organism frequencies varied yearly. Of the two most commonly identified pathogens, there were 64(23.02 percent) Staphylococcus epidemidis and 40 (14.38 percent) Staphylococcus aureus cultures in 2013. In 2014, there were 76(23.53 percent) Staphylococcus epidemidis and 45(13.93 percent) Staphylococcus aureus cultures, but 2015 identified 67(21.47 percent) Staphylococcus epidemidis and 51(16.35 percent) Staphylococcus aureus cultures. Variations in organism isolation were observed pending unit of the hospital. In the neonatal intensive care unit, 112 Staphylococcus epidermidis isolates were identified compared to 28 and 41 in the pediatric intensive care and emergency department. Staphylococcus aureus was most frequently identified in the emergency department with 58 positive cultures compared to 23 and 24 from the neonatal and pediatric intensive care units.

Conclusion: It was determined that the most common cause of pediatric bacteremia was Staphylococcus epidermidis followed by Staphylococcus aureus. Our results were found to be similar to the adult population. Upon further evaluation of the two most common pathogens cultured, our results revealed 2014 had the most positive cultures followed closely by 2015 then 2013. The emergency department resulted in the most cultures, including Staphylococcus aureus, with the neonatal intensive care unit, patients admitted to the floors, and pediatric intensive care unit following behind, respectively. Further analysis will be required to determine if the organisms cultured are pathogenic or contaminants.

Poster Title: The Effect of Trimethoprim-Sulfamethoxazole Dosing Regimen on the Incidence of Early Urinary Tract Infections in Pediatric Kidney Transplantation

Primary Author: Hayley Van Hook, Samford University McWhorter School of Pharmacy, Alabama; **Email:** hvanhook@samford.edu

Additional Author (s):
Deidre Schmidt
Michael Seifert

Purpose: Urinary tract infections (UTIs) and other infectious complications are common after renal transplantation, likely resulting from the high intensity of immunosuppression needed to prevent acute graft rejection. Trimethoprim-sulfamethoxazole (TMP-SMX) is frequently used both as prophylaxis against UTIs and Pneumocystis jiroveci (PCP) in the early post-transplant period, but the optimal duration of prophylaxis is unknown. The purpose of this study was to evaluate the association between duration of TMP-SMX prophylaxis and the incidence of UTIs during the first year post-transplant.

Methods: This was a retrospective cohort study of 121 pediatric renal transplant recipients transplanted between July 31, 2008 and December 31, 2014. Patients were divided into two groups based on duration of TMP-SMX prophylaxis, defined as subjects who received TMP-SMX prophylaxis for ≤ 3 months (Short) or those who received TMP-SMX between 3-12 months post-transplant (Long). The primary outcome was a culture-confirmed diagnosis of UTI during the first year post-transplant. Secondary outcomes include acute kidney injury, hospitalization for UTI, and TMP-SMX-resistant UTI. Due to the increased risk for UTIs, we examined congenital anomalies of the kidneys and urinary tract (CAKUT) as a secondary exposure, defined as CAKUT or non-CAKUT causes of end-stage renal disease (ESRD).

Results: TMP-SMX was used for PJP and/or UTI prophylaxis in 113 of the 121 patients (93%), with an alternative agent being used in the remainder of subjects. Of those receiving TMP-SMX, 96% received once daily dosing and 57% were in the Short prophylaxis group. CAKUT was the cause of ESRD in 43/121 (36%) of subjects. In the first year post-transplant, UTIs were diagnosed in 23/121 (19%) of subjects. Of those, 11/23 (48%) had a TMP-SMX-resistant UTI.

There was no difference in the incidence of UTI in the Short versus Long prophylaxis groups (15% versus 25%, P=0.15) or by cause of ESRD (26% CAKUT versus 15% Non-CAKUT, P=0.17). Acute kidney injury occurred in 9/23 (39%) of subjects with UTI, with no differences in the Short versus Long prophylaxis groups. Overall, 18/121 (15%) were hospitalized for management of UTI, with no differences by duration of TMP-SMX prophylaxis or cause of ESRD.

Conclusion: In this large retrospective cohort of pediatric kidney recipients, a longer duration of TMP-SMX prophylaxis did not reduce the incidence of UTI in the first post-transplant year. Only half of UTIs were resistant to TMP-SMX. Despite the perception that CAKUT increases the risk for post-transplant UTI in children, we found no difference in the incidence of UTIs in CAKUT versus non-CAKUT subjects. These data suggest that the desired length of PJP prophylaxis should drive the duration of TMP-SMX prophylaxis in the early post-transplant period, not the cause of ESRD or an effort to prevent early UTIs.

Poster Title: Analysis of the prevalence of screening mammographies in Mississippi Fee-for-Service and Managed Medicaid plans and identification of predictors of screening mammographies

Primary Author: Kelsey Stephens, The University of Mississippi, Mississippi; **Email:** kcstephe15@gmail.com

Additional Author (s):
Kyle Null
Joshua Fleming
Namita Joshi

Purpose: The American Cancer Society estimates approximately 1 in 8 (~12%) of American women will develop an invasive type of breast cancer during their lifetime. When detected early, breast cancer is considered to be one of the most treatable cancers. The aim of this study was to evaluate sociodemographic and clinical characteristics that influence the likelihood of obtaining breast cancer screening mammographies in a Medicaid population.

Methods: A retrospective cohort study was used to determine the influence of geographic location, family history, and age on the prevalence of screening mammographies among women enrolled in Mississippi Medicaid. Prevalence of screening mammographies was compared between Mississippi Medicaid Fee-For-Service (FFS) and Managed Medicaid plans. Females aged 40 years and older, continuously enrolled for 3 years, and no long-term coverage were identified. Individuals with Medicare/Medicaid dual eligibility, previous breast cancer diagnosis, diagnostic mammography screening, and previous mastectomy were excluded. County codes from the data were used to classify the enrollee's residential location in a federally classified county of need or other Mississippi area. PROC GEOCODE in SAS 9.3 was used to calculate distance to the closest FDA certified screening mammography center. A logistic regression model was estimated to determine the influence of the aforementioned variables on the likelihood of receiving a screening mammography.

Results: After accounting for demographic and clinical variables in the logistic regression model, individuals with a family history of breast cancer were 6.1 times more likely to undergo mammography screenings. No statistically significant difference was found between the Mississippi Delta residents compared to other Mississippi county residents in obtaining a screening mammography (OR=0.9, 95% CI [0.8-1.0]). The likelihood to obtain a screening mammography (OR=1.2, 95% CI [1.2-1.3]) was higher among women of 55 to 64 years as compared to younger women. Caucasian women had lower odds of obtaining a screening mammography (OR=0.77, 95% CI [0.7-0.8]). Among women enrolled in FFS, obtaining a screening mammography (OR=0.3, 95% CI [0.30-0.38]) was lower than women enrolled in the Medicaid Managed Care plan. Overall, in Mississippi Managed Medicaid, the period prevalence of screening mammographies was 24.82% (3927 out of 15,823 individuals) compared to Mississippi Fee-for-Service Medicaid, where the period prevalence of screening mammographies was 10.37% (327 out of 3154 individuals).

Conclusion: Few studies have assessed access and risk factors associated with obtaining a screening mammography in a state Medicaid program. This study provides insight regarding influencing factors of obtaining screening mammographies in the Mississippi Medicaid population. Interventions and/or development of screening programs should be implemented to target women who were found to be less likely to obtain a screening mammography: 40-55 years, Caucasian race, lack of family history of breast cancer, and enrollment in a Fee-for-Service plan. Pharmacists can play an active role in encouraging women, especially those found to be less likely, to obtain a breast cancer screening mammography.

Poster Title: Evaluation of renal risk index and acute kidney injury in liver transplant patients

Primary Author: James Shen, University of Michigan College of Pharmacy, Michigan; **Email:** shenj17@gmail.com

Additional Author (s):
Jennifer Erley
Joslyn Neal
Yihan Sun
Jeong Park

Purpose: Acute kidney injury (AKI) is a common complication after liver transplantation (LT) that can lead to the development of end-stage renal disease (ESRD) and increase mortality. In order to improve outcomes, patients at high risk for AKI should be identified, and appropriate interventions should be implemented in a timely manner. Renal Risk Index (RRI) is a validated scoring tool that can predict post-LT ESRD and mortality. However, RRI has not been evaluated for predicting post-LT AKI. Therefore, this study sought to evaluate the prognostic ability of the RRI to predict post-LT AKI risk.

Methods: A retrospective chart review was conducted at the University of Michigan Health System (UMHS) for LT patients between January 1, 2010 and September 30, 2015. Patients were included if they were older than 18 years of age and underwent a first-time deceased-donor LT while receiving tacrolimus-based immunosuppressive regimen with or without basiliximab according to UMHS protocol. Patients were excluded if they had a history of ESRD prior to LT, defined as requiring renal replacement therapy (RRT) for at least three months, previous kidney transplant, simultaneous liver and kidney transplant, or other multi-organ transplant. RRI was calculated by an online calculator (https://rri.med.umich.edu) using 13 pre-transplant patient characteristics, and levels of AKI within 7 days post-LT were classified according to the Kidney Disease Improving Global Outcomes (KDIGO) criteria of no AKI (stage 0), stage 1, stage 2, and stage 3, based on serum creatinine (SCr) and urine output data. Kruskal-Wallis test was used to assess overall differences in RRI scores among the four AKI stages. Mann-Whitney test was used to determine specific differences between the AKI stages 0-2 and the AKI stage 3. Renal function at 1 year post-LT was assessed based on the KDIGO

chronic kidney disease (CKD) criteria. A predictive model of RRI for AKI stage 3 was examined using a receiver operating characteristic curve. A p-value less than 0.05 was considered statistically significant.

Results: Of 297 adult LT patients included in this study, 269 patients (90.6 percent) developed AKI stages 1-3 and 42 patients (14.1 percent) required RRT within 7 days post-LT. Baseline characteristics among the four AKI groups were similar in age, SCr, glomerular filtration rate (GFR), hepatocellular carcinoma, gender, and race, with a non-significantly higher proportion of men and African American patients presenting with stage 3 AKI. Mean RRI scores differed among the four AKI groups (p equals 0.005). The mean RRI score for the AKI stage 3 group was significantly higher than the AKI stages 0-2 group (3.30 plus or minus 4.14 vs. 1.78 plus or minus 1.63, p less than 0.0001). The majority of patients recovered from AKI. Although GFRs were not significantly different between the two groups (63.1 plus or minus 30.1 vs. 66.1 plus or minus 24.6 ml/min/1.73 m2, p equals 0.181), more patients in the AKI stage 3 group progressed to the stage 4 or higher CKD at 1 year post-LT (16.7 percent vs. 3.8 percent, p equals 0.001). The RRI score was modestly predictive for development of AKI stage 3 within 7 days post-LT (AUC 0.602, 95 percent confidence interval 0.534-0.670).

Conclusion: Early post-LT AKI was common and was associated with progression to severe CKD at 1 year post-LT. A higher RRI score at time of LT was associated with development of severe AKI in the early post-LT period. Predictive efficacy of RRI score for early post-LT AKI was only modest. Strategies for renal protection targeting high RRI patients should be tested to decrease the incidence of post-LT AKI and progression to CKD.

Poster Title: Guideline-directed antiplatelet therapy for patients with coronary artery disease (CAD): A chart review

Primary Author: Sarah Gunter, Samford University McWhorter School of Pharmacy, Alabama; **Email:** sgunter@samford.edu

Additional Author (s):
Valerie Prince

Purpose: Approximately 1 in 4 deaths in the United States is caused by heart disease. Performance measures ensure that patients with heart disease are being treated appropriately. This project is designed to analyze the percentage of patients with coronary artery disease (CAD) who were appropriately prescribed an antiplatelet medication at a large internal medicine clinic. This information will be used to help the physicians of this practice improve the quality of care that they are providing to their patients and to meet performance standards adopted by insurance providers.

Methods: Permission for this retrospective chart review was granted by both the president and administrator of Internal Medicine Associates of Opelika, Alabama as well as the institutional review board of Samford University. Patients with a diagnosis of coronary heart disease who had a recorded office visit between January 1 and December 31, 2015 and who were at least 18 years old were selected for inclusion. Coronary artery disease was defined as a diagnosis of a myocardial infarction, angina, atherosclerosis of a coronary artery, chronic total occlusion of a coronary artery, other chronic ischemic heart disease, or unspecified ischemic heart disease, according to International Classification of Diseases 9 or 10 codes. To be included, each patient must have had at least 2 face-to-face visits with the physician within the above time-frame. The primary endpoint is the percentage of patients with documented use of an antiplatelet agent at any time during 2015. Secondary endpoints include the percentage of patients who were prescribed aspirin and the percentage of patients who were prescribed clopidogrel.

Results: Initially 102 patients were located for possible inclusion in the study. Of these patients, sixteen had only one visit with a physician during 2015 and were therefore excluded. The remaining patients (n equals 86) were used for data analysis. The mean patient age was 75.5

years (plus or minus 10.8 years standard deviation), with a range of 54 to 98 years of age. Sixty patients were male (69.8 percent) and 26 were female (30.2 percent). When calculating the primary endpoint, it was found that 82.6 percent (n equals 71) patients had at least one antiplatelet medication listed in their medical record profile during 2015, while 17.4 percent (n equals 15) had no recorded antiplatelet use during that time. Of the antiplatelet agents, aspirin alone was the most common (n equals 43), followed by a combination of aspirin plus clopidogrel (n equals 12) and clopidogrel alone (n equals 11). Aspirin plus dipyridamole, ticagrelor, and cilostazol use were also rarely observed.

Conclusion: The heavy majority of patients diagnosed with coronary artery disease did have documented use of an antiplatelet agent, which is recommended by treatment guidelines. However, it is important to note that aspirin, the most commonly used agent, is typically purchased over the counter and most patients do not receive or fill a prescription for it. Even if aspirin use is documented within the patient chart, insurance providers may not have an accurate way of accessing this information and may mistakenly conclude that patients are lacking appropriate antiplatelet therapy.

Poster Title: Reduction in Readmission Rates by Inclusion of Clinical Pharmacist across Smartphone Application.

Primary Author: Gabriella Dieppa, Nova Southeastern University, Puerto Rico; **Email:** gd514@nova.edu

Additional Author (s):
Patricia Faría
Daibelis León
Sonia Muñoz
Denisse Torres

Purpose: The economic burden of hospital readmissions has a tremendous impact on the healthcare system. In an effort to manage this burden, transitional care has emerged as a practical strategy to strive for improvements in patient outcomes while reducing healthcare costs. Findings from evidence-based literature suggests that pharmacists involved in transitional care have a positive impact through medication reconciliation, patient education, and post discharge follow-ups. The purpose of our project was to design an electronic tool to assist in the provision of transitional care services, which can be linked to the hospital's system allowing continuous interaction between pharmacists and discharged patients.

Methods: An evidence-based literature review was conducted among secondary databases to evaluate published literature about the pharmacist role in transitional care as well as the existence of electronic tools targeted to assist pharmacists in the provision of this service. Literature search was limited to articles published in English or Spanish between the years of 2010 to 2016. In addition, we conducted oral interviews to a group of five pharmacists and stakeholders in order to assess their perceived need for pharmacists who embrace the provision of transitional care services in Puerto Rico. Furthermore, we also screened their willingness and receptiveness to adopt innovative technology as part of the tools targeted to provide transitional care services by pharmacists and how they think this technology could impact the patient's health and the finances of the healthcare institution.

Results: Findings from our literature search and interviews performed to participants suggest a tremendous need for increasing the number of pharmacists involved in transitional care services. We also observed a lack of interactive technology tools available to assist pharmacists and other healthcare providers in the provision of transitional care activities, which opened an opportunity for us to present our innovative technology device as a tool to introduce and assist pharmacists who would like to become transitional care providers. According to participants, the role of the pharmacist in transitional care is very limited or almost non-existent, although highly needed. The group agreed that a technological device would be a great tool to facilitate the participation of pharmacists in transitional care services as well as to increase the access of patients to this healthcare professional. Participants recognized that direct pharmacist interaction with patients through medication reconciliation, discharge counseling, and post-discharge follow-up would decrease the number of adverse drug events, decrease readmission and plays an overall positive role in transitional care.

Conclusion: There is a need of pharmacists embracing transitional care in Puerto Rico, and also a need for technology tools available to ease the participation of these professionals in endeavor. Our pharmacists driven mobile application has been designed as a tool to assist pharmacists in providing innovative transitional care services to patients in a fashionable and easy to use application by making the pharmacist available to patients at all times. The implementation of this application is expected to contribute to decrease patient readmissions based on the accessibility and continuity of pharmaceutical care to discharged patients.

Poster Title: Self-monitored blood glucose patterns among patients with diabetes: are they doing it right?

Primary Author: Dakota Taylor, University of Mississippi School of Pharmacy, Mississippi; **Email:** dtaylor@go.olemiss.edu

Purpose: There are over twenty-nine million Americans that are affected by diabetes mellitus, a complicated chronic disease that can be difficult to manage. However, self-monitored blood glucose results prove to be beneficial in helping both clinicians and patients control diabetes. Each year the American Diabetes Association publishes recommendations for self-monitored blood glucose to guide practitioners and patients in diabetes management. This study looked to characterize the general diabetic population's knowledge of self-monitored blood glucose and investigate current self-monitored blood glucose patterns.

Methods: Participants took a 15 question survey that was uploaded to Facebook on October 1, 2015 and remained open until January 1, 2016. Patients who were 18 years of age and older who had either type 1 or type 2 diabetes were included in the study. Demographic data was collected from patients in addition to information about the participants' self-monitored blood glucose knowledge and monitoring patterns among participants. This study used descriptive statistics to determine the amount of patients who were monitoring their blood glucose levels according to the American Diabetes Association Standards of Medical Care in Diabetes, 2015 Guidelines.

Results: There were a total of 56 responses to this survey. Two participants were excluded due to age, and 22 responders did not have diabetes and, therefore, were excluded. A total of 32 surveys were included in the final analysis. Twenty seven participants (84%) had type 2 diabetes and 53% were diagnosed greater than 5 years ago. Of the 32 participants included, 29 monitored their blood glucose levels daily at home, with most measuring levels one to two times a day (31% and 38%). 79% of individuals knew their preprandial blood glucose goal while only 69% knew their postprandial goal. The most commonly reported self-monitored blood glucose patterns among participants included: monitoring when waking up in the morning (76%), monitoring before going to bed (55%), monitoring before meals (45%), and monitoring

whenever the participant suspected hypoglycemia (45%). Commonly reported barriers to self-monitored blood glucose included: lack of time and/or business, forgetfulness, and cost of measuring at home.

Conclusion: Many patients with diabetes monitor their blood glucose levels at home on a daily basis. Additionally, some aspects of the sample population's self-monitored blood glucose patterns align with the American Diabetes Association guidelines. However, these results also indicate there is much room for improvement in self-monitored blood glucose patterns to help manage diabetes.

Poster Title: Determinants of Success Associated with APPE Performance in a Pharmacy Program

Primary Author: Cameron Heidenga, University of Michigan College of Pharmacy, Michigan; **Email:** cheideng@med.umich.edu

Additional Author (s):
Widad Alchurbaji
Nancy Mason

Purpose: The term success is vague and has multiple meanings. Yet pharmacy school admissions officers, curriculum committees and students often make difficult decisions based on the premise of predicting who will be successful. Studies have investigated success in pharmacy using grade point averages or standardized test scores. However, they may not be accurately measuring those skills that make students successful pharmacists. This study investigated both preadmission variables and pharmacy coursework grades against a chosen endpoint of success, fourth year direct-care Advanced Pharmacy Practice Experience (APPE) scores to determine which variables contributed the most to student performance in the APPE clinical setting.

Methods: This study was a retrospective cohort study conducted at the University of Michigan (UM) College of Pharmacy for the classes of 2014-2016. This study was considered exempt by the UM Institutional Review Board. Data were collected and de-identified for a total of 250 students, which included the pre-pharmacy variables (undergraduate grade point average [UGPA]), science-GPA, math-GPA, composite PCAT [Pharmacy College Admission Test] score, and PCAT chemistry sub-score). Pharmacy program variables included the average GPA of selected pharmacy school course sequences (therapeutics (5 courses), pharmaceutical sciences (4 courses), medicinal chemistry (3 courses) and a combination of direct care and disease management clinical skills courses (DC/DM). The outcome variable of average direct care APPE score was calculated by averaging the score/100 points assigned to all inpatient and ambulatory care APPE's. Statistical analyses were performed using IBM SPSS statistics suite 20.0. Characteristics were summarized by means and standard deviations for continuous variables. Pearson's r correlation was used to measure the strength of correlations between APPE

performance and both pre- and current pharmacy variables. Stepwise linear regression was performed to determine the significance of the variables. The priori of significance level was 0.5. A further analysis utilizing binary logistic regression was conducted. APPE scores were sorted into two categorical variables using the median APPE score of 82 to classify APPE performance as successful or non-successful.

Results: Of the 285 students, 283 were included in the final analysis. Select means and standard deviations include: PCAT composite 80.7 ± 14.1, undergraduate GPA 3.42 ± 0.30. Therapeutics course sequence 3.23± 0.26 and DC/DM course was 3.81 ± 0.22. The mean APPE score was 80.4 ± (6.68). Multivariate stepwise regression produced two significant models. DC/DM correlated significantly with APPE scores ($r=0.368$, $p < 0.001$). When both DC/DM and Therapeutics were combined, the correlation increased to $r=0.434$, $p < 0.001$. None of the pre-pharmacy variables or the medicinal chemistry or pharmaceutical sciences course series' were found to be significantly correlated with APPE scores in the multivariate stepwise regression. Using binary logistic regression, it was found that Therapeutics (OR=6.65, $p < 0.021$) and DM/DC (OR=14.36, $p < 0.001$) were predictive of success in APPE performance. Additionally, the inclusion of the two variables listed increased the predictive power from the 50% null model to approximately 70%. Comparing pre-pharmacy variables against the two predictive pharmacy variables, DC/DM and Therapeutics, via stepwise regression analysis, it was found that both UGPA ($r=0.364$, $p < 0.001$) and the combination of UGPA with PCAT composite score ($r=-0.410$, $p < 0.001$) were significantly correlated with therapeutics. Additionally UGPA ($r=0.244$, $p < 0.001$) and UPGA and PCAT composite ($r=0.283$, $p < 0.001$) were significantly correlated with DM/DC.

Conclusion: The results of our study show that pharmacy school variables were the most predictive of student success on direct-care APPEs. Once a student entered the pharmacy program, it was their performance and knowledge in pharmacy school that mattered as students began their advanced practice experience. Courses that focused on therapeutic knowledge and patient care skills were most highly associated with success in APPE's. This study may raise the awareness of the importance of incorporating more clinical courses and patient-related experiences within the pharmacy curriculum.

Poster Title: Review of antibiotic use in patients with reported beta-lactam allergies at Johns Hopkins Bayview Medical Center

Primary Author: Stephen Seo, Shenandoah University School of Pharmacy, Virginia; **Email:** sseo13@su.edu

Purpose: Reported beta-lactam allergies leads to deviations from the standard of care antibiotic therapies. The majority of self-reported beta-lactam allergies are found to be false positive. The deviations from standard of care antibiotic regimens due to beta-lactam allergy reporting have been associated with antimicrobial resistance and changes in the overall cost of treatment. The purpose of this study was to determine if the use of alternative antibiotics at Bayview Medical Center due to reported beta-lactam allergies are resulting in deviations from preferred antibiotic regimens and higher medication costs when compared to the recommended standard of care antibiotic regimens.

Methods: The institutional review board approved this retrospective study. Patients aged 18 years and older who were admitted to Johns Hopkins Bayview Medical Center between August 1, 2015 and August 31, 2015 and received antibiotics during their inpatient stay with a reported beta-lactam allergy including penicillins, cephalosporins, carbapenems, and monobactams were included in this study. Patients were identified using the electronic medical record system. The cost of the antibiotics used for each patient was calculated using average wholesale prices available through the facility's medication ordering database. In order to assess if there was any deviation from standard of care therapy, the 2016-2017 John Hopkins Medicine Antibiotic Guide was referenced. All antibiotic deviations were noted and the hypothetical costs of the preferred antibiotic regimens were calculated again referencing the facility's medication ordering database. The primary outcome was the number of patients who were treated with an alternative antibiotic due to a documented beta-lactam allergy. The secondary outcome was cost difference between the alternative antibiotic regimen that was used and the recommended first line antibiotic regimen. Data was collected into a spreadsheet and analyzed using the Mann-Whitney U. Statistical significance was defined as p value of less than 0.05.

Results: Out of the 128 patients who fit the inclusion criteria for this study, 74 deviations from standard of care antibiotics due to the reported beta-lactam allergies were revealed. These numbers indicate that in the population studied at John Hopkins Bayview Medical Center, 57.8 percent of patients with beta-lactam allergies received an antibiotic that strayed from first line standard of care therapy. The mean cost difference per course of therapy was found to be 23.34 dollars and the median cost difference per course of therapy 10.34 dollars. Through the use of Mann-Whitney U test, the cost difference between antibiotics used due to reported beta-lactam allergies and the hypothetical cost of standard of care was calculated to be statistically significant. (Mann-Whitney U equals 6877, n1 equals n2 equals 128, p less than 0.05, two-tailed). The Mann-Whitney U test was used because data was not normally distributed.

Conclusion: This study supports that patients with reported beta-lactam allergies at John Hopkins Bayview Medical Center are receiving antibiotics that diverge from recommended therapy. The cost difference between the antibiotics prescribed due to reported allergies and the standard of care regimen if no allergy existed was statistically significant. The clinical and economic significance of these antibiotic substitutions should be made in larger and more long-term studies. When the economic significance of using a non-preferred agent is being evaluated, the cost difference due to length of stay and antibiotic monitoring in addition to the cost of medication should be considered.

Poster Title: Comparison of warfarin dosing strategies after management of patients admitted with bleeds

Primary Author: Gina Sykes, University of Michigan College of Pharmacy, Michigan; **Email:** gsykes@med.umich.edu

Additional Author (s):
Kristin Elzey

Purpose: The National Action Plan for Adverse Drug Reaction estimates that bleeding occurs in 15 to 20 percent of patients on warfarin and of that, 1 to 3 percent of those events are life-threatening or fatal. Practitioners are often faced with a dilemma when resuming warfarin therapy due to the risks of thrombosis if therapy is held or recurrence of bleed if anticoagulation is resumed. Because of these concerns, there are often two approaches that practitioners use when resuming warfarin therapy: resuming a patient's previous home dose or giving a bolus dose prior to resuming the home dose.

Methods: Adult patients who were on warfarin therapy prior to admission to the University of Michigan Health System (UMHS) and followed by the UMHS outpatient anticoagulation clinic admitted for either a major or minor bleed between January 2014 and December 2015 were included in this study. A major bleed was defined as a drop in hemoglobin greater than or equal to 2g/dL or 2 units packed red blood cells or bleeding at a critical site (intracranial, intraocular, intra spinal, intra articular, intramuscular, pericardial, or retroperitoneal) requiring medical or surgical intervention and a minor bleed was defined as any other bleed. A retrospective chart review of these patients was conducted using a computerized prescriber order entry database (CPOE) and data collected was analyzed between the two dosing approaches: resuming a patient's previous home dose (non-bolus group) or giving a bolus dose (bolus group). The first aim of this study was to compare the length of stay, time to therapeutic international normalized ratio (INR), readmission rate, and number of adverse events between the two approaches. The second aim was to establish guidelines that would provide practitioners recommendations on warfarin dosing when resuming therapy in patients admitted for bleed(s).

Results: A total of twenty-one patients were enrolled in the study and further divided into two groups based on dosing approach: eight patients in the bolus group and thirteen patients in the non-bolus group. The baseline characteristics of these two groups were similar. The average length of stay for the bolus group was 8.63 plus or minus 3.5 days compared to 7.46 plus or minus 4.5 days for the non-bolus group (p=0.5400). The time to reach therapeutic INR between the two groups was also not statistically significant (p= 0.2204) with the bolus group reaching therapeutic INR after an average of 5.13 plus or minus 4.29 days and the non-bolus group reaching therapeutic INR after an average of 14.0 plus or minus 19.33 days. Statistical analyses on thirty-day readmission rates and adverse event rates were unable to be conducted due to insufficient data. Lastly, dosing guidelines were unable to be established due to small sample size.

Conclusion: There does not appear to be any difference in effectiveness or safety of the outcomes studied in either dosing approach in our study. Further evaluation should be done to determine a benefit of either dosing strategy in order to develop guidelines for practitioners.

Submission Category: General Clinical Practice

Submission Type: Evaluative Study

Poster Title: Management of hyperglycemia in patients with an acute exacerbation of chronic obstructive pulmonary disease

Primary Author: Anna Bush, Auburn University Harrison School of Pharmacy, Alabama; **Email:** aem0017@auburn.edu

Additional Author (s):
Annya Plotkina
Nathan Pinner

Purpose: Acute exacerbations of chronic obstructive pulmonary disease are characterized by a worsening of symptoms leading to increased rescue inhaler use, and frequently, hospital admission. Acute exacerbations of chronic obstructive pulmonary disease are traditionally treated with high doses of systemic corticosteroids, despite consensus guidelines recommending low-dose corticosteroids. This can become a problem in patients with concomitant diabetes mellitus due to elevations in blood glucose associated with corticosteroid use. The purpose of this study was to evaluate the management of hyperglycemia in patients admitted to the hospital for an acute exacerbations of chronic obstructive pulmonary disease with concomitant diabetes mellitus.

Methods: This retrospective study included men and women of all ages who were admitted to Princeton Baptist Medical Center for an acute exacerbations of chronic obstructive pulmonary disease who also had concomitant diabetes mellitus. Demographic and clinical data was collected using electronic health records. Only unique patients were included and the most recent hospitalization was used for patients admitted with multiple exacerbations over the past 3 years. Patients admitted due to associated pneumonia were excluded. Data collected included the initial dose of intravenous corticosteroid, number of hospital days until taper to oral corticosteroid, and blood glucose control with basal insulin. Fasting blood glucose levels, most recent HbA1c, and other patient comorbidities were also collected. The primary outcome was the impact of uncontrolled fasting blood glucose (defined as a mean fasting blood glucose greater than or equal to 180 mg/dl) on the length of hospital stay. Secondary outcomes included the proportion of patients initiated on basal insulin who were not on insulin prior to

hospitalization, mean initial dose of corticosteroids, and mean time spent before dose reduction of corticosteroids occurred.

Results: There was a total of 100 patients evaluated for this study. The patient population had a mean HbA1c level of 7.4 plus or minus 1.7 and a mean body mass index of 32.2 plus or minus 9.3. Fifty-five (55 percent) patients were found to have an uncontrolled mean fasting blood glucose with a corresponding length of stay of 6.22 plus or minus 4.4 days, whereas 45 (45 percent) patients had a controlled mean fasting blood glucose with a length of stay of 5.69 plus or minus 4.8 days [95 percent CI, -1.3 percent to 2.4 percent, P value equals 0.57]. There were 71 patients that received basal insulin in the hospital and 21 (29.6 percent) of those were not on a basal insulin regimen prior to hospitalization. The majority of patients (93 percent) received initial intravenous corticosteroids, with 87 percent receiving methylprednisolone. The mean initial dose of methylprednisolone was 112 mg. Only 7 patients received initial oral corticosteroids with a mean dose of 38 mg. The mean time until corticosteroid taper was 4.6 plus or minus 3.6 days.

Conclusion: Patients with an uncontrolled fasting blood glucose had a slightly longer hospital length of stay compared to those with a controlled fasting blood glucose; however, this difference was not statistically significant. Initial corticosteroid doses are still mostly high-dose intravenous steroids, and this is continued beyond the emergency department. Increased education is still needed to reduce the routine use of high-dose corticosteroids.

Submission Category: Ambulatory Care

Submission Type: Evaluative Study

Session-Board Number: 5b-101

Poster Title: Effectiveness of a multidisciplinary endocrine clinic for management of diabetes mellitus in adult kidney transplant patients

Primary Author: Surin Lee, University of Michigan College of Pharmacy, Michigan; **Email:** surinlee@med.umich.edu

Additional Author (s):
Erika Perpich
Jamie Park

Purpose: Kidney transplant patients may receive suboptimal management of chronic diseases following transplantation due to a gap in the transition of care to a primary care provider (PCP). On September 23, 2014, a multidisciplinary clinic, consisting of an endocrinologist, a clinical pharmacist, and a dietitian, was established within a University-affiliated transplant center to improve continuity of care for diabetes mellitus (DM). The purpose of this study was to assess the effectiveness of a collaborative endocrine clinic in improving management of DM for kidney transplant patients during the early post-transplant period.

Methods: This was an institutional review board approved, retrospective, single-center, cohort study of adult kidney transplant patients with Type 2 DM or post-transplant DM. The intervention group included patients who were referred to the transplant endocrine clinic within 180 days post-transplant and received DM care for at least 90 days between September 23, 2014 and December 31, 2015. Patients with Type 1 DM, multi-organ transplants, or missing HgbA1c were excluded. The control group included patients whose DM was managed through usual care by transplant nephrologists or PCP between January 1, 2014 to December 31, 2015. Each case was matched to a control for age and time from transplant. Changes in HgbA1c from the initial visit to the 3-month follow-up visit were compared between the intervention and control groups by a Student t-test. In the intervention group, the management of hypertension and hyperlipidemia and the assessment of microvascular complications were evaluated against recommendations by the American Diabetes Association (ADA) Standards of Medical Care in Diabetes 2015.

Results: Patients in the intervention and control groups (n equals 32 in each group) were well matched for baseline characteristics, including HgbA1c (7.0 plus or minus 1.25 percent versus 6.7 plus or minus 0.99 percent, respectively; p equals 0.254). The changes in HgbA1c over 3 months were not statistically different between the intervention and control groups (0.21 plus or minus 1.48 percent versus 0.68 plus or minus 1.20 percent, respectively; p equals 0.17). In a subset of patients with baseline HgbA1c greater than or equal to 7 percent, there was a decreasing trend in HgbA1c (minus 0.62 plus or minus 1.37 percent) in the intervention group; however, it did not reach a statistical significance compared to the control group (0.06 plus or minus 1.13 percent; p equals 0.19). At the 3 month follow-up visit, 80% percent of the intervention group patients with hypertension were started on an angiotensin-converting-enzyme inhibitor or angiotensin receptor blocker as clinically indicated, 78.1 percent were on appropriate statin therapy, and 78.1 percent and 87.5 percent were up to date on their eye and foot examinations, respectively.

Conclusion: The patients enrolled in the transplant endocrine clinic did not have statistically significant improvements in glycemic control compared to standard of care. However, this study was likely under powered with a short-term follow-up. The multidisciplinary clinic model demonstrated the potential for improved glycemic control for patients with uncontrolled DM and high adherence rates to the ADA recommendations in the management of comorbidities and complications. Additional larger, long-term studies may determine the true impact of the multidisciplinary endocrine clinic in management of DM for the kidney transplant patient population.

Poster Title: Frequency and management of secondary bacterial infection in pediatric patients with respiratory syncytial virus (RSV)

Primary Author: Anna Cochrane, Samford University McWhorter School of Pharmacy, Alabama; **Email:** acochran@samford.edu

Additional Author (s):
Kim Benner
Michele Kong

Purpose: Respiratory syncytial virus (RSV) infection results in upper and lower respiratory tract illness in the pediatric population and is a common cause of hospitalization during the winter months. Studies suggest the increased intensity of symptoms seen in some children with RSV lung disease is caused by secondary bacterial infections as opposed to RSV alone. Understanding the relationship between co-infection with RSV and bacteria can help guide therapy decisions. The purpose of this study was to determine the incidence of secondary bacterial infections in patients with RSV as well as common pathogens and antibiotics use to treat the bacterial infection.

Methods: The institutional review board approved this retrospective chart review. All patients admitted to the Pediatric Intensive Care Unit (PICU) of Children's of Alabama with confirmed RSV infection from 2012-2016 were enrolled. Data collected included patient demographics such as age, gender, race, and weight. Patients' lengths of hospital stay and treatment measures (including type and duration of antibiotics, need for mechanical ventilation, length of supplemental oxygen support) were also collected. When applicable, additional patient culture data was gathered. Data collected was used to determine incidence of secondary bacterial infection in patients with RSV. Results were analyzed using descriptive statistics in order to determine incidence of bacterial co-infection, common antibiotics used, and durations of antibiotics.

Results: A total of 130 patients were included in the study. Sixty-two patients (47.7%) were found to have a secondary bacterial infection. The most common sites of infection were the lungs, urine, and blood representing 26.3%, 24.6%, and 19.3% of infections respectively. Haemophilus species (except H. flu) and MRSA infection occurred with the same frequency and represent the most common bacterial pathogens. The next most common pathogens were Pseudomonas aeruginosa and MSSA. Of the 107 patients who received antibiotics, the antibiotic regimen included vancomycin for 84 patients (78.5%), ceftriaxone for 48 patients (44.9%), and cefotaxime for 40 patients (37.4%). Cefepime, clindamycin, and ampicillin were each used in approximately 19% of patients. The average treatment duration for all antibiotics was 7.3 days. The longest treatment duration was 29 days (for a patient on vancomycin).

Conclusion: Pediatric patients with RSV infection who are admitted to the PICU are at increased risk for having a secondary bacterial infection. Further prospective studies are necessary to determine the true incidence and disease burden of bacterial co-infection in the setting of severe RSV infection.

Poster Title: Assessment of the Provision of Professional Liability Insurance for Students

Primary Author: Michelle Leatherwood, Samford University McWhorter School of Pharmacy, Alabama; **Email:** mleathe1@samford.edu

Additional Author (s):
Renee DeHart
Rachel Slaton
John Galdo

Purpose: Student pharmacists engage in patient care services through volunteerism, experiential education, and employment. All of these situations pose malpractice risk, and unlike any other health care professions, student pharmacists are licensed with state boards. Students may obtain professional liability insurance (PLI) in a variety of ways, individually or in conjunction with the school. This project was designed as a needs assessment to determine if there is a standard for pharmacy programs delivering education about PLI, requiring PLI, and/or providing PLI to student pharmacists.

Methods: This project is a needs assessment regarding the provision of PLI for students and consisted of an IRB-approved survey administered through Qualtrics online survey software. Participants identified were pharmacy programs' dean or administrator involved with student affairs. Participants were invited to take part in this study via email.
The email contained a hyperlink of the survey and an introduction to the study. Informed consent was obtained electronically on the first page of the survey by providing participants with an informational letter. The informational letter explained participation in the study, and that identifying information would not be collected. Participants took the survey requiring a maximum of 10-15 minutes giving information regarding their program's involvement with PLI for students. Survey questions included collecting basic demographics about the program, information regarding the schools policy on PLI, how students obtain PLI, what activities students participate in, and faculty/preceptor PLI status.
Data was collected over a three-week period through Qualtrics, and was accessible only through a secure user account available to the researchers. Data was analyzed using descriptive

statistics and Kruskal-Wallis ANOVA to examine variance within the independent ordinal data. No follow up was required for this study.

Results: Twenty-three percent of pharmacy programs completed the survey, with fairly even representation of public and private institutions. The majorities of programs were 2+4 programs (48.48%), offer dual degree programs (66.67%), and do not have satellite campuses (75.76%). The mode response for a program's average annual tuition was $30,001-$40,000 (36.67%), annual student fees (excluding book costs) being >$700 (33.33%), and an average number of 76-100 graduates per year (34.38%).

Fifty-six percent of pharmacy programs reported having a university level policy only. Programs primarily educate students about PLI by integrating into course content (43.48%) or encouraging it at an event (39.13%). A majority of programs require students to have PLI (56.52%) or encourage students to have PLI (30.43%). Students purchase PLI independently (43.48%), purchase PLI through a program-facilitated transaction (26.09%), or have PLI purchased for them by the program (30.43%). If the program provides PLI, majorities do not add additional costs to students (65.22%). A majority of programs do not require either their preceptors (54.55%) or full-faculty with active licenses (50%) to have PLI.

Conclusion: The results of this project indicate that student pharmacists may not have adequate liability coverage. The majority of the pharmacy schools who responded only maintain a policy for school related functions, and therefore students are unprotected during work and extracurricular volunteerism. This project has helped bring attention the potential risk to student pharmacists. Schools of pharmacy should reevaluate policies and procedures to ensure optimal coverage of malpractice insurance.

Poster Title: Use of a pharmacy patient medication assistance program in the prescribing of direct oral anticoagulants to improve transitions of care

Primary Author: Meghan Zukowsky, Virginia Commonwealth University, Virginia; **Email:** mez4uv@hscmail.mcc.virginia.edu

Additional Author (s):
Svetlana Goldman
Donna White

Purpose: Direct oral anticoagulants (DOACs) are high-risk medications that have the potential to cause serious adverse effects. These medications are costly; therefore, patients are frequently discharged with a free coupon card. However, this only provides a one-month supply of medication. The Pharmacy Patient Medication Assistance Program (PPMAP) assists patients who require medications but have inadequate financial resources. PPMAP is made possible through manufacturer assistance programs to provide free prescription drugs to qualifying individuals. The objective was to review prescriptions processed through PPMAP and the associated documentation in MedData to determine any lapse in therapy or delays in receiving these high-risk medications.

Methods: This was a retrospective descriptive study analyzing data from the outpatient pharmacy at the University of Virginia Health System (UVA) between January 1, 2016 and September 22, 2016. The data collected included the first-time fill of a DOAC that was billed through PPMAP. We looked at whether the prescription was written for a 30-day supply versus a 90-day supply, coupon usage prior to PPMAP, and the number of prescriptions previously billed through the patient's financial screening. Direct pharmacist involvement in patient-care was also noted. Pharmacist involvement consisted of counseling and communication with PPMAP. Furthermore, MedData, a prescription assistance software system utilized by UVA PPMAP was reviewed. Compliance with documentation by the PPMAP technician was assessed and included the date the application was created, date the patient returned financial screening forms, date the application was sent to the manufacturer, and date the medication was received.

Results: A total of 82 prescriptions for DOACs were billed through PPMAP in the study period with 40 of these being first-time fills. Of these, apixaban was prescribed most often (n=37, 92.5 percent) while edoxaban made up the remainder of DOACs prescribed (n=3, 7.5 percent). Prescriptions were written for a 30-day supply 25 (62.5 percent) times. Prior to billing through PPMAP, coupon cards and financial screening were utilized 18 (45 percent) and 10 (25 percent) instances, respectively. Pharmacists were directly involved in PPMAP application processing a total of 17 (42.5 percent) occurrences. In regards to MedData, complete documentation occurred 7 (17.5 percent) times. The date of application creation was documented a majority of the time (n=36, 90 percent), followed by the date the medication was received (n= 20, 50 percent), date the application was sent to the manufacturer (n=15, 37.5 percent) and finally the date the patient returned financial screening forms (n=8, 20 percent).

Conclusion: PPMAP at UVA provides medications to patients who are unable to afford them; however, there is a lapse in care as the enrollment process is complex and time-consuming. Patients are frequently discharged with a 30-day supply of the medication with aid from a one-time use coupon card and limited financial screening. In addition, there is a lack in utility of the MedData system as documentation is often incomplete and unreliable. As a result, it is difficult to determine the status of an application causing gaps in fills and non-compliance. This can ultimately lead to significant adverse effects and hospital readmissions.

Poster Title: Assessment of Total Body Weight versus Adjusted Body Weight Dosing Of Daptomycin in the Obese Population

Primary Author: Alice Hu, Wayne State University Eugene Applebaum College of Pharmacy and Health Sciences, Michigan; **Email:** cq4652@wayne.edu

Additional Author (s):
Lama Hsaiky
Raymond Cha

Purpose: Research on weight based antibiotic dosing in obese patients is limited. Daptomycin is a potent weight-based antibiotic used for gram positive infections. Total body weight dosing (TBWd) of daptomycin in obese patients may be associated with high drug exposure when compared to lower adjusted body weight dosing (AdjBWd). The relationship between daptomycin dosing and drug related adverse effects are unknown in obese populations. Therefore, this study will explore the clinical efficacy and safety of daptomycin TBWd versus AdjBWd in obese subjects.

Methods: This is a retrospective cohort study at Beaumont Hospitals from 2012 – 2015. Participants with body mass index (BMI) ≥ 35 kg/mm2 and on daptomycin for a minimum of 72 hours were included. Participants were stratified into two groups: TBWd and AdjBWd for daptomycin. Baseline characteristics (i.e. weight, BMI), comorbidities, type of infection and pathogen, and daptomycin dosing regimen were reviewed. The primary endpoint is clinical efficacy and safety. The secondary endpoint assesses the length of stay (LOS), recurrent infections, readmission, and 30 day all-cause mortality. Statistical analyses of primary and secondary endpoints are performed using univariate analysis.

Results: Patients with BMI ≥ 35 kg/mm2 on daptomycin were screened (n = 230). After screening, 19 and 14 participants were included in TBWd and AdjBWd group, respectively. No differences were observed between TBWd and AdjBWd groups for weight (123±35 kg vs 135±29 kg), BMI (44±9 kg/m2 vs 47±7 kg/m2), comorbidities, daptomycin dose (689±249 mg vs 554±103 mg), and daptomycin duration (6.4±3.2 d vs 5.9±3.3 d). Infection types and organisms were diverse, with MRSA bacteremia being the most common in TBWd and demonstrating even

distribution in the AdjBWd group. There is no statistical difference between TBWd and AdjBWd in clinical success (50% vs 50%) and adverse effects, including CPK elevations (11% vs 7%). However, TBWd had statistically more clinical improvements and observed less clinical failures than the AdjBWd group. There is no statistical difference in LOS for TBWd and AdjBWd (14.7±10.6 d vs 12.8±18.9 d), recurrent infection, or all-cause mortality. However, there was a significant statistical difference in readmission rates (33% in TBWd vs 21% in AdjBWd).

Conclusion: Our preliminary data suggests there is no statistical difference in clinical success or adverse effect rates. TBWd showed more favorable clinical improvements with less clinical failures than the AdjBWd group. However, TBWd had significantly more readmission rates than AdjBWd. Therefore, further sampling is warranted to encompass greater power to detect differences between outcome and population variables between both groups.

Poster Title: Incidence and reasons for under-reporting of paclitaxel-induced neuropathy among women with breast cancer: a qualitative study

Primary Author: Caroline Quinn, University of Michigan College of Pharmacy, Michigan; **Email:** csq@med.umich.edu

Additional Author (s):
Teresa Salgado
Daniel Hertz
Karen Farris

Purpose: Although studies have documented discrepancies between the incidence of patient-reported and physician-recorded neuropathy during treatment with chemotherapy, reasons for under-reporting remain unclear. The purpose of this study was to identify whether breast cancer patients treated with paclitaxel purposefully under-reported neuropathy symptoms to their oncologist, and if so, what post-treatment beliefs influenced the decision to under-report. Specifically, beliefs explored pertained to how the patients' oncologist, cancer, and treatment may have contributed to the decision to under-report neuropathy. This decision is important for patient outcomes, as the occurrence of neuropathy may require treatment delay or discontinuation and symptoms can be life-long.

Methods: This was an exploratory qualitative study using semi-structured interviews. Subjects included 24 women with breast cancer who completed adjuvant/neoadjuvant treatment with paclitaxel recruited from the University of Michigan Comprehensive Cancer Center (UMCCC). The study was approved by the University of Michigan IRBMED. Participants were contacted about this study by the principal investigator of a larger study from which participants were recruited. Interviews were conducted in-person or over the telephone by four members of the research team using an interview guide. The interview guide was reviewed by UMCCC Breast Cancer Patient Advocates Advisory Committee and revised after the first two interviews. Information about six primary topics was obtained, including: relationship with the medical oncologist, interaction with other providers during appointments, perception of benefits and risks of paclitaxel therapy, side effects experienced during paclitaxel treatment, risks and benefits of continuing therapy after experiencing neuropathy, and neuropathy symptoms

during and after therapy. Interviews were recorded and transcribed verbatim, and the transcripts were analyzed by two members of the research team using NVivo software and an inductive approach.

Results: Of the 24 patients interviewed, 21 experienced peripheral neuropathy. Four major themes emerged including 1) patient description of neuropathy was multi-faceted, 2) physicians underestimate neuropathy experienced by patients, 3) patients acknowledge circumstances when they would consider under-reporting adverse effects, and 4) patients lack knowledge of the long-term consequences of neuropathy. Physicians tended to underestimate the occurrence of mild neuropathy, yet patients understood a "threshold", although not explicitly defined, at which the level of neuropathy could affect treatment decisions (delay or discontinuation). This perception of threshold may have affected the extent to which neuropathy was reported if patients did not view mild neuropathy as problematic enough. Three patients suggested instances in which they would consider under-reporting adverse effects. These patients were more likely to consider under-reporting when paclitaxel treatment was of high necessity yet they lacked knowledge of the long-term effects of neuropathy; alternatively, a high level of trust in the oncologist was a motivating factor for honest reporting. Finally, patients had an incomplete knowledge of the possible duration and severity of long-term neuropathy. Long duration of symptoms and a significant impact on functionality were critical for discontinuing treatment.

Conclusion: Two specific issues that may impact neuropathy reporting by these participants to their oncologists include the oncologists' "lower" assessment of patients' neuropathy severity and a lack of knowledge about the consequences of neuropathy, particularly with regards to the impact on patients' day-to-day life. A limited number of participants identified circumstances in which they would under-report their neuropathy. Future research should focus on enhancing methods of communication between physicians and patients in an effort to lessen this discrepancy, as well as assessing a more diverse patient population.

Poster Title: The impact of a pharmacist managed smoking cessation program within two university affiliated clinics

Primary Author: Michele Richardson, Harrison School of Pharmacy Auburn University, Alabama; **Email:** mzr0013@auburn.edu

Additional Author (s):
Brook Yordy
Bradley Wright
Miranda Andrus
Haley Phillippe

Purpose: One out of every five adult deaths in the United States occurs due to cigarette smoking. According to the CDC, in 2014, nearly 40 million adults smoked cigarettes. Cigarette smoking is the leading cause for preventable disease and death which is why smoking cessation counseling is a key component to a patient's overall health. The purpose of this study is to evaluate the impact of pharmacist provided smoking cessation services in two university-affiliated outpatient clinics.

Methods: This institutional review board approved retrospective cohort study evaluated pharmacist and physician provided smoking cessation services in the University of Alabama Birmingham internal medicine and family medicine clinics. Patient-physician encounters in these clinics are typically 15 to 30 minutes in length, while patient-pharmacist encounters are scheduled in 30 to 60 minute appointments and include extensive behavioral counseling. Patients aged 21-80 years old who received smoking cessation counseling and therapy from pharmacists or physicians and had documentation of smoking status post-counseling documented in the electronic health record were included. Patients within the clinic were identified from the electronic health record based on documentation of prescriptions for smoking cessation therapy, including bupropion, varenicline, or nicotine replacement therapy. Patients were placed into a pharmacist or physician provided counseling group based on the provider who provided counseling at the time therapy was prescribed. The primary outcome measure was documented successful abstinence at a clinic visit after the patient's smoking

cessation counseling visit. Data collection occurred via the electronic health record and included: age, sex, race, success of quit attempt, and smoking cessation therapy prescribed.

Results: Thirty patients were included in the pharmacist group and 60 patients in the physician group for this analysis. The average age of the pharmacist group was 58 years old and 51 years old for the physician group. Therapy initiated between counseling groups followed a trend of more patients receiving nicotine replacement therapy for treatment with 46.7 percent in the pharmacist group and 56.6 percent in the physician group. Bupropion was initiated in 36.7 percent of patients in the pharmacist group and 28.3 percent in the physician group. Varenicline was initiated in 13.3 percent of patients in the pharmacist group and 10 percent in the physician group. Combination therapy was initiated in 3.3 percent of patients in the pharmacist group and 5 percent of patients in the physicians group. Abstinence rate was higher in the patients counseled by pharmacist (40 percent) versus physician's (10 percent). Regarding therapies in patients achieving abstinence, in the pharmacist group 50 percent achieved abstinence using bupropion and 41.3 percent using nicotine replacement therapy. In the physician group, 50 percent achieved abstinence using bupropion and 50 percent achieved using nicotine replacement therapy. No patients achieved abstinence on combination therapy in either group.

Conclusion: Patients receiving smoking cessation counseling from pharmacists resulted in greater rates of abstinence when compared with patients only counseled by physicians in the UAB Family medicine and internal medicine clinics. Limitations of this retrospective study include reliance on documentation by providers of smoking status post smoking cessation counseling in the electronic health record. Future studies are needed to further evaluate the clinical impact of pharmacist provided counseling and follow-up on smoking cessation.

Poster Title: Retrospective cohort analysis of electronic flag placement in pre-diabetic patients to increase early diabetes mellitus detection

Primary Author: Kristi Laxson, Auburn University Harrison School of Pharmacy, Alabama; **Email:** kas0029@auburn.edu

Additional Author (s):
Mary Claire Estess
Jonathan Gray
Jingjing Qian
Heather Whitley

Purpose: American Diabetes Association (ADA) guidelines recommend screening patients who are at risk for developing type 2 diabetes every 3 years, but it has been found that rescreening rates are low in patients at high risk. In an Alabama rural family medicine clinic, electronic flags were placed onto patients' profiles who were considered high risk for developing diabetes, to re-signal rescreening at one year. The efficacy of these flags was evaluated as a tool to improve rescreening for early diagnosis of diabetes.

Methods: Retrospective cohort design was used to evaluate the effect of the intervention of flag placement on the rate of rescreening for diabetes one year later, versus a control group with no flag placed followed during the same time period. All patients were at least 45 years of age. Patients were included in the intervention group if the baseline A1c was 5.7-6.4% or 6.5-7%. Patients were excluded if they were on treatment for diabetes or were pregnant. Electronic medical records were assessed to collect patient information and data from baseline (from March 2013 to April 2014) and follow-up clinic visits after one year. Approval from the managing physician of the clinic, as well as from the Auburn University Institutional Review Board, was obtained. Subsequent A1c measurements and blood glucose measurements were collected from point-of-care or basic metabolic panels. Pertinent comorbidities were also recorded, such as hypertension and dyslipidemia. Chi-square test was used to compare A1c rescreening rate after one year between intervention and control groups. Multivariable logistic regression model was used to identify factors associated with rescreening after one year. In

addition, change in diabetic status at one year follow up from baseline diabetic status was also evaluated.

Results: Among patients in the intervention group (n=89), 74 patients were rescreened (83%); 32 of them by A1c (36.0%). Among patients in the control group (n=74), 63 patients were rescreened (85%); 16 of them by A1c (21.6%). Therefore, the intervention group had a higher rescreening rate by A1c than the control group (p=0.0453). Among patients in the intervention group, baseline BMI (p=0.012) and dyslipidemia (P=0.0027) were statistically significant factors associated with diabetic rescreening. Patients who were obese and had dyslipidemia were associated with higher likelihood of returning for rescreening. Additionally, patients in the intervention group had improved diabetic status compared to those in the control group. Specifically, more pre-diabetic patients at baseline were no longer pre-diabetic after one year in the intervention group compared to the control group (43.1% vs. 27.7%), and more diabetic patients at baseline became pre-diabetic or no longer diabetic after one year in the intervention group compared to the control group (88.9% vs. 50.0%).

Conclusion: The A1c rescreening rate was found to be statistically significant in favor for the intervention group, which suggests that electronic flag placement is a potential tool in prompting practitioner's stricter attention of obtaining subsequent A1c readings at follow-up clinic visits. Comorbidities such as dyslipidemia and obesity might help practitioners to identify patients for diabetic rescreening and further target those who might not come back for rescreening. The improved A1c rescreening for early diagnosis of diabetes might promote better control of patient's pre-diabetic and diabetic status and outcomes.

Submission Type: Evaluative Study

Session-Board Number: 5b-109

Poster Title: Assessment of urinary tract infection treatment in the long-term care facility of a veteran's health system

Primary Author: Ebony Jackson, Harrison School of Pharmacy, Alabama; **Email:** ezc0007@auburn.edu

Additional Author (s):
Spencer Durham

Purpose: Urinary Tract Infections (UTIs) are one of the most common reasons for antimicrobial use in long term care facilities (LTCFs). Overuse of antimicrobials can lead to increased antimicrobial resistance and the development of multidrug-resistant organisms. These resistant organisms can result in increased rates of recurrent infections, treatment failure, and overall morbidity. The purpose of this project was to determine the appropriateness of empiric treatment of UTIs in the LTCF of a veteran's health system.

Methods: This quality improvement project was approved by the institutional review board. A student pharmacist conducted a retrospective chart review for all patients residing in the LTCF and diagnosed with a UTI between June 1, 2015 and May 30, 2016. Data collected included the following: gender, ethnicity, age, height, weight, ideal body weight, serum creatinine, temperature, details of symptoms if present, results of urinalysis and urine culture, presence of a Foley or condom catheter, white blood cell count, antimicrobial regimen prescribed, and duration of therapy.

Results: Data was analyzed for a total of 135 individual patient encounters, representing 61 patients. Fifty-eight patients were male (95 percent) and 3 were female (5 percent), with 38 patients being African American (62 percent) and 22 (36 percent) being Caucasian. The mean age was 72.04 years. Thirty-seven patients (60.6 percent) had chronic urinary catheters in place, 30 being indwelling Foley catheters and 7 being condom catheters. Of the 135 individual encounters, urinalyses and urine cultures were performed in 112 (83 percent) and 109 (80.7 percent) encounters, respectively. In most cases, the reasons for obtaining the urinalyses and urine cultures were unclear as UTI signs and symptoms were reported in only 20 (14.8 percent) encounters. Fifty-two cultures grew greater than 100,000 colony forming units of one organism,

41 cultures were inconclusive (indicated as 3 or more bacterial organisms present), and 16 reported no growth. The antibiotics used for empiric treatment included: trimethoprim/sulfamethoxazole (39 encounters), ciprofloxacin (28 encounters), amoxicillin (19 encounters), levofloxacin (18 encounters), cephalexin (13 encounters), ertapenem (10 encounters), cefepime (3 encounters), cefdinir (2 encounters), cefuroxime (2 encounters), and nitrofurantoin (2 encounters). One patient received dual therapy with trimethoprim/sulfamethoxazole and ciprofloxacin. The duration of therapy ranged from 3 to 14 days.

Conclusion: Based on culture data, many patients may not have experienced true UTIs, making the use of antimicrobials questionable. More than half of the patients had chronic urinary catheters in place; the urinalyses of these patients are expected to be abnormal, but clinicians may have mistaken these abnormalities for true infections. A variety of antimicrobials were used for empiric treatment, with no apparent consistency for selecting an antimicrobial. Based on these results, efforts are currently underway to provide clinician education on the appropriate treatment of UTIs, and to develop a UTI treatment protocol to better aid with antimicrobial selection.

Submission Type: Evaluative Study

Session-Board Number: 5b-110

Poster Title: Utilization of ertapenem in a large community hospital

Primary Author: Connor Roth, Auburn University Harrison School of Pharmacy, Alabama; **Email:** cgr0006@auburn.edu

Additional Author (s):
Fernando Diggs
Jonathan Edwards

Purpose: Within our facility we have noticed an increase in ertapenem use in both the emergency department and hospital-wide. Ertapenem is a carbapenem antibiotic with broad spectrum activity, including activity against extended-spectrum B-lactamase (ESBL) producers, AmpC-producing Enterobacteriaceae and anaerobic bacteria. Ertapenem also has convenient once-daily dosing, thus making it a common empiric choice when an intra-abdominal infection is suspected. Currently, the long-term effects of ertapenem use on resistance patterns is not well understood; however, experts are concerned that overuse may accelerate carbapenem resistance. The objective of this study is to analyze appropriateness of ertapenem use hospital-wide using predetermined criteria.

Methods: A retrospective chart review was performed to analyze the use of ertapenem within our facility. Patients that received at least 1 dose of ertapenem between January 2016 and July 2016 was included in the study. Data collection included: patient demographics, microbiology results, antibiotics used, length of stay, cost of admission, and readmission rates. Appropriateness was assessed using pre-approved preliminary criteria for use for ertapenem. The criteria for use included (1) current non-pseudomonal ESBL infection or suspected recurrent ESBL infection, (2) colorectal surgery, (3) Intra-abdominal infection (IAI) with contraindications or resistance to cefazolin/ceftriaxone/cefepime + metronidazole, cefoxitin, piperacillin-tazobactam, or levofloxacin + metronidazole, and (4) one-time dose prior to discharge for home health purposes. Currently, an Infectious Disease consult is not required when prescribing ertapenem at our facility.

Results: 75 patient cases were reviewed. Overall ertapenem use was appropriate in 43 (57.33%) cases and inappropriately used in 32 (42.67%). Colorectal surgery accounted for 31 (41.33%) of all cases. Excluding colorectal surgery from the patient population, only 12 (27.27%) cases were appropriate and 32 (72.72%) inappropriate. 12 of the 32 (37.5%) inappropriate cases were due to abdominal pain or suspected intraabdominal infection. These cases could have narrowed antibiotic selection to cefazolin/ceftriaxone/cefepime + metronidazole, cefoxitin, piperacillin-tazobactam, or levofloxacin + metronidazole. Other conditions that had inappropriate use included empiric treatment for urinary tract infections, sepsis/bacteremia, pneumonia, and skin and skin structure infections.

Conclusion: Overall, ertapenem use was appropriate within our facility; however, there is a lot of room for improvement, especially when excluding colorectal surgery. Currently, little is known about the overuse of ertapenem on resistance patterns, but antimicrobial resistance continues to rise while antibiotic development is lagging. Experts are concerned that overuse of ertapenem might hasten carbapenem-resistant Enterobacteriaceae, Pseudomonas, and Acinetobacter species. This study suggests that our facility could benefit from restricting the use of ertapenem to an Infectious Disease consult and colorectal surgeries.

Poster Title: Evaluation of sildenafil treatment guidelines in neonates with pulmonary artery hypertension associated with bronchopulmonary dysplasia

Primary Author: Parin Shah, University of Michigan College of Pharmacy, Michigan; **Email:** parinsh@umich.edu

Additional Author (s):
Varsha Bhatt-Mehta

Purpose: Sildenafil is used for treatment of bronchopulmonary dysplasia associated pulmonary artery hypertension (PAH-BPD). In 2012, the FDA recommended against use of sildenafil in children with PAH due to reports of mortality at high doses. In 2014, the FDA clarified that cautious use is acceptable. The current recommended dose is 0.5-1mg/kg three to four times daily in children < 1 year. We developed guidelines at our institution for diagnosis and treatment of PAH-BPD using echocardiogram (ECHO) criteria and sildenafil doses consistent with current guidelines. Our purpose is to determine whether these guidelines are successful in the diagnosis and treatment of PAH-BPD.

Methods: We conducted a retrospective study at our institution which included pre-term infants diagnosed with PAH-BPD between January 2012 and June 2016. For infants with birth weight (BW) < 1500 grams, BPD was defined as oxygen (O2) requirement (after an O2 challenge test) at 36 weeks corrected gestational age. For infants with BW greater than or equal to 1500 grams, BPD was defined as O2 requirement on day of life 28. These babies were evaluated for PAH because they were >4 weeks old with an FiO2 >40% and positive pressure >4cm CPAP equivalent or had right ventricular pressures (RVP) >½ systemic pressures (SP). Weekly sildenafil dose, ECHO results and patient status were collected until sildenafil discontinuation or patient discharge.

Results: Nine patients qualified for inclusion in our study. All doses are reported as mean +/- standard deviation. Initial sildenafil treatment dose was 0.53 +/- 0.36 mg/kg/dose and total daily dose (TDD) was 1.59 +/- 1.07 mg/kg/day. Prior to sildenafil initiation, 7 patients had RVP >½ SP and 2 patients had RVP less than or equal to ½ SP as shown by ECHO. At the end of treatment, sildenafil dose was 1.30 +/- 0.64 mg/kg/dose and TDD was 3.91 +/- 1.93 mg/kg/day.

Six patients (67%) experienced reduction in RVP as shown by echocardiogram and 3 patients (33%) remained at baseline RVP. Three patients died during treatment and TDD was 4.17 +/- 2.39 mg/kg/day at the time of death. Of the remaining six patients discharged from the hospital, five patients were discharged on a TDD of 3.75 +/- 1.12 mg/kg/day.

Conclusion: These data suggest that PAH-BPD diagnosis and treatment occurred according to protocol in the majority of patients and there was wide variability in sildenafil TDD. The majority of patients experienced improvement in pulmonary artery hypertension as shown by reduction in RVP in echocardiogram. No patients showed worsening of pulmonary artery hypertension during sildenafil treatment.

Poster Title: Evaluation of ambulatory zolpidem prescribing post-FDA alert at an academic medical center

Primary Author: Pooja Kirpekar, Virginia Commonwealth University, Virginia; **Email:** pakirpekar@vcu.edu

Additional Author (s):
Craig Kirkwood

Purpose: In 2013, the Food and Drug Administration (FDA) issued a MedWatch alert for prescription brand name (Ambien, Ambien CR, Edluar, and Zolpimist) and generic drugs containing zolpidem. The alert highlighted that ingestion of higher doses may put patients, especially female patients, at risk for impaired morning activities due to lingering drug concentrations in the bloodstream. Following the alert, steps were taken to improve prescribing at VCU Health System (VCUHS) and an initial assessment was performed in November 2014 through January 2015. This analysis is a follow-up assessment of prescribing practices over one year later.

Methods: This quality improvement based, institutional review board approved, retrospective descriptive analysis was conducted using data from zolpidem prescriptions filled at VCUHS outpatient pharmacies from February 2016 through August 2016. Patients 18 years of age and older were included in the study. Patients prescribed zolpidem for a reason other than insomnia (e.g., participation in a sleep study) were excluded. Patients prescribed zolpidem by VCUHS providers who had prescriptions filled at other pharmacies were not included. Using Microsoft Excel, prescription dosing, frequency and duration of therapy were analyzed from both the prescription and patient perspectives. Dosing was characterized as optimal or suboptimal based on the FDA's recommendations for female patient, with immediate-release and extended-release doses greater than 6.25 mg being considered suboptimal. Dosing practices for female patients were compared between physicians and mid-level practitioners (nurse practitioners and physician assistants).

Results: A total of 729 zolpidem prescriptions were filled for 269 patients (n equals 537 [74 percent] for female patients). Most patients prescribed zolpidem were female (n equals 186 [69 percent]). Patients' ages were 25-83 years for females and 28-69 years for males, with 12 female patients and 2 male patients at 65 years of age or older. For the female patients, 269 prescriptions (50 percent) were prescribed at an optimal dose, representing 113 females (60 percent). For female patients, 57 percent of prescriptions (and 127 patients) were prescribed zolpidem pro re nata (PRN), while 43 percent of prescriptions (and 78 patients) were prescribed the drug with scheduled dosing. For the 12 geriatric female patients, 65 percent of the prescriptions were written PRN. For the male patients, 75 percent were prescribed doses at 10 mg or greater, and 58 percent of prescriptions (54 patients) were prescribed as PRN. Dose-range instructions (such as take 1-2 tablets) were provided in prescriptions for five female patients and four male patients. Fifty-five patients received multiple prescriptions to supply at least six months of treatment with zolpidem. Physicians' prescriptions were more often optimal (53 percent) compared to mid-level practitioners' prescriptions (39 percent).

Conclusion: This assessment demonstrates the continued opportunities to improve zolpidem prescribing, especially for female patients. Prescribing was improved relative to the prior assessment; however, half of the female patients received doses higher than the FDA's recommendations. Areas for improvement in prescribing include clarification of PRN and "dose-range" instructions. From the prescription and patient perspectives, physicians demonstrated more optimal dosing than mid-level providers. The assessment is scheduled for presentation to the Medication Safety Committee and Pharmacy and Therapeutics Committee, and the specific action plan will be guided by those discussions.

Poster Title: Efficacy of anti-hypertensives in metastatic renal cell carcinoma with vascular endothelial growth factor inhibitor-induced hypertension

Primary Author: Jing Xiao, University of Michigan College of Pharmacy, Michigan; **Email:** jixi@med.umich.edu

Additional Author (s):
Soo Kyun Hur

Purpose: Vascular endothelial growth factor (VEGF) inhibitors are the cornerstone of metastatic renal cell carcinoma (mRCC) therapy. However, a common side effect of VEGF inhibitors is hypertension. VEGF inhibitor-induced hypertension has been shown to potentiate morbidity and cardiovascular complications, such as coronary heart disease, stroke and heart failure. There are no clear guidelines on the management of mRCC patients with VEGF inhibitor-induced hypertension. The purpose of this study is to determine which class of anti-hypertensives, specifically angiotensin-converting enzyme (ACE) inhibitors/angiotensin II receptor blockers (ARBs) or calcium channel blockers (CCBs) is most effective in treating VEGF inhibitor-induced hypertension.

Methods: This is a retrospective, observational, paired longitudinal study. Subjects originally included 240 mRCC patients 18 years and older at the University of Michigan Health System (UMHS) Cancer Center who were/are concurrently on one or more of four VEGF inhibitor treatments (axitinib, pazopanib, sorafenib, or sunitinib) with ACE inhibitor(s)/ARB(s) and/or CCB(s). After stratification, 65 patients were included in the study. Patient data included systolic blood pressure (SBP), diastolic blood pressure (DBP), treatment start and end date, gender, age, date of diagnosis, and comorbidity, including chronic kidney disease (CKD) and diabetes. Additionally, the antihypertensive class(es) that each patient was/is taking was recorded. Lastly, the date of progression, date of last progression and date of death were collected to determine overall survival (OS) and progression-free survival (PFS) in these patients. The primary outcome was the efficacy of blood pressure treatments, determined by evaluating the changes in SBP and DBP over 7 months from the time of first VEGF treatment. This was done using mixed models and controlling for types of treatment. The secondary outcomes were OS and PFS, which were analyzed using Kaplan-Meier methods.

Results: Sunitinib was the most common first-line therapy (37 patients [57 percent]). Out of 65 patients, 24 patients (37 percent) were on one antihypertensive, eleven patients (17 percent) on two, 21 patients (32 percent) on three, and nine patients (14 percent) on four to six. ACE inhibitors/ARBs were used in 58 patients (89 percent), CCBs in 37 (57 percent), and combination of the two in 30 (46 percent). The primary choice for ACE inhibitor/ARB was lisinopril (40 patients [69 percent]) and CCB was amlodipine (34 patients [94 percent]). Changes in the first 7 months on first-line VEGF inhibitor showed that on average, patients treated with CCBs had an increase in SBP at a rate of 2.7 mmHg per month and DBP at 2.6 mmHg per month. In patients treated with ACE inhibitors/ARBs, SBP decreased by 0.2 mmHg per month and DBP by 0.1 mmHg per month. In patients treated with combination therapy, SBP decreased by 2.2 mmHg per month and DBP by 1.2 mmHg per month. The median overall survival was 58.2 months, and the median progression-free survival was 17.5 months.

Conclusion: VEGF inhibitors are the mainstay therapies for patients with mRCC. Hypertension is a common side effect of these medications, which usually warrants patients to be on additional ACE inhibitor/ARB and/or CCB therapy. For the primary aim, use of ACE inhibitor/ARB and CCB combination had the greatest effect on both SBP and DBP, followed by ACE inhibitor/ARB monotherapy. Since VEGF inhibitor-induced hypertension is a common complication for mRCC patients, either monotherapy with ACE inhibitor/ARB or combination therapy with ACE inhibitor/ARB with CCB rather than CCB alone should be considered for management of hypertension.

Poster Title: Evaluation of vancomycin-associated nephrotoxicity incidence in Native American patients with and without concomitant piperacillin-tazobactam: a retrospective cohort study

Primary Author: Sandy Lim, Shenandoah University, Virginia; **Email:** sandylim2017@gmail.com

Additional Author (s):
Jin Kim

Purpose: Several recent reports have documented the association between nephrotoxicity and vancomycin with concomitant piperacillin-tazobactam therapy; however, the combination continues to be extensively used in hospitals as an empiric antibiotic regimen to provide sufficient coverage for drug-resistant microorganisms. In the setting of arid climates and scarce running water, however, severe dehydration and subsequent poor renal perfusion are long-standing risk factors predisposing individuals to a much greater likelihood of developing acute kidney injury (AKI). This study was designed to evaluate the incidence of AKI from intravenous vancomycin therapy with and without concomitant intravenous piperacillin-tazobactam therapy in Native Americans living in desert atmospheres.

Methods: This was a single-center, retrospective chart review screening 1389 patient visits from March 2015 through February 2016 that involved initiating intravenous vancomycin therapy with or without concomitant piperacillin-tazobactam. Study participants were included if they were aged 18 or older, initiated on intravenous vancomycin therapy for at least two consecutive days during which at least two serum creatinine values were obtained and documented in their paper charts, and had a baseline serum creatinine of 1.5 mg/dL or less prior to vancomycin therapy initiation. Patients were excluded if there was pertinent data missing from their paper charts, or their paper charts could not be obtained for review. Data collection involved patient age; gender; height; weight; vancomycin indication, duration, and dosage regimen; vancomycin trough goal range and actual trough levels; serum creatinine and blood urea nitrogen (BUN) levels; and concomitant piperacillin-tazobactam therapy. SPSS software was used to analyze the data.

Results: One-hundred ninety four patients were included in the study, of which 120 patients received monotherapy with intravenous vancomycin, and 74 patients received concomitant intravenous vancomycin and piperacillin-tazobactam therapy. AKI developed in 7 of 120 patients (5.8%) treated with intravenous vancomycin, compared to 18 of 74 patients (24.3%) in concomitant intravenous vancomycin and piperacillin-tazobactam-treated patients. Based on a sample size of 194 patients, there was no difference observed in the incidence of AKI in the Native American population as compared to the 5-35% range of published incidence of AKI development in patients treated with intravenous vancomycin. There was, however, a significantly greater incidence of AKI observed in patients receiving concomitant intravenous vancomycin and piperacillin-tazobactam therapy. Age (P = 0.433) and BMI (P = 0.220) were independent risk factors for AKI that were found to be non-statistically significant in the study population.

Conclusion: This retrospective cohort study found that Native Americans patients residing in desert climates receiving intravenous vancomycin therapy are on the lower end of the published ranges for developing AKI, while those receiving concurrent intravenous vancomycin and piperacillin-tazobactam have a four-fold higher likelihood of developing AKI. Larger prospective studies are needed to confirm that there is indeed no difference in the incidence of nephrotoxicity in Native Americans considering the prevailing dehydration observed in this population. These further studies may help provide guidance to clinicians as to more optimal empiric antibiotic therapy for similar patient populations.

Poster Title: Pharmacist contribution to the University of Michigan GRACE program

Primary Author: Tyler Fenton, University of Michigan College of Pharmacy, Michigan; **Email:** tfenton@med.umich.edu

Additional Author (s):
Tami Remington

Purpose: Escalating costs of healthcare in the United States are a burden for health systems, payers, and patients. At the University of Michigan, the Geriatric Resources for Assessment and Care of Elders (GRACE) Program, is an outpatient interdisciplinary team that works with complex older adults and their primary care providers to manage their health care with the goal of reducing utilization of acute care resources. The aim of this study is to describe and assess the pharmacist's role as part of this interdisciplinary team.

Methods: Patients enrolled in the GRACE program had a complete medication review (CMR) by a clinical pharmacist upon enrollment into the program and periodically thereafter. Recommendations were communicated to the GRACE team during weekly team meetings. A control group was identified using the same criteria as for patients enrolled in GRACE, but were assigned to primary care sites not yet working with the GRACE program. These patients also had a CMR by a clinical pharmacist, but drug therapy recommendations were not shared with the patients' prescribers. The primary objective was implementation rate of drug therapy recommendations between the two groups. For the secondary objectives, patients from the GRACE program had their medications compared against the CMS 2015 High Risk Medications list and Medication Appropriateness Index to assess the quality of the prescribing they received prior to admission into the GRACE program.

Results: A total of 198 patients were evaluated, with 96 being placed into the experimental group and 102 being placed into the control group. A total of 160 recommendations were made for patients in the experimental group and 215 were made for control group patients. Drug therapy recommendations were implemented more often for patients on the GRACE service compared to controls (55.6 percent vs 19.5 percent, p value less than .05). A total of 88 recommendations were implemented for GRACE patients with 54 (61 percent) of the

recommendations being related to discontinuation of medications. Assessment of quality of prescribing prior to GRACE enrollment revealed that 10 out of the 96 patients (10 percent) were admitted to the program while on at least 1 medication from the CMS High Risk Medications list. Using the Medication Appropriateness Index, the average score on admission to the program was 2.7.

Conclusion: This study demonstrates that involving a clinical pharmacist as part of the GRACE program interdisciplinary team results in more drug therapy changes. This could be attributable to the education and expertise that pharmacists possess in the realm of medication management, along with the trust that other health professions have in a pharmacist when they are making recommendations. When considering the initiation of any kind of outpatient program similar to the one described in this study, the contributions of a clinical pharmacist should not be overlooked in gauging possible strategies for improving patient health.

Poster Title: Impacts of Spirituality on Depression

Primary Author: Seema Zahir, Shenandaoh University, Virginia; **Email:** szahir13@su.edu

Additional Author (s):
Nazila Salamkhail

Purpose: To assess the impacts of spirituality in depressed patients and evaluate whether the degree of depressive symptoms has a correlation with the degree of spirituality

Methods: Our participants included 24 individuals who were admitted to Novant Health Prince William Medical Center's inpatient behavioral health unit for depression treatment and participants of an Islamic community center. Participants were interviewed briefly; individuals who were willing to participate in the study signed a consent form that was provided by the investigators. The participants then would complete two surveys. If the participants had trouble reading through the surveys, the interviewers would read the surveys for them.
The two surveys utilized were The Depression Inventory (BDI) and The Daily Spiritual Experience Scale (DSES). Rated on a 4- point scale, ranging from 0 to 3, BDI is a 21-item multiple- choice inventory. The minimum score can be as low as 0 while the maximum total score is 63. The breakdown of raw scores correlation to depression severity is listed below:
1-10-------- These ups and downs are considered normal
11-16------- Mild mood disturbance
17-20------- Borderline clinical depression
21-30------- Moderate depression
31-40------- Severe depression
Over 40----- Extreme depression
The DSES is a 16-item self-report survey that assesses ordinary experiences of connection with the transcendent in daily life. A greater spirituality refers to experiencing these measures (such as awe, gratitude, mercy, inspiration) many times a day or every day compare to lower spirituality where individuals reports experiencing these measures never or once in a while.

Results: Based on the results of DSES, patients reporting greater spirituality had lower measures of hopelessness, disappointment, and depressive symptoms. Those who believed in a higher power had a lower mean score than those who did not on the BDI. 18 out of 24 participants had an average score of 12, and the remaining 6 participants had an average score of 36 on the BDI.

Conclusion: The findings suggest that greater spirituality is associated with less severity of depressive symptoms, hopelessness, and disappointment; therefore, through our findings, we can conclude that the degree of depressive symptom severity, hopelessness, and disappointment were inversely correlated with one's level of spirituality.

Poster Title: Implementation of a revised pharmacy technician "core" training program

Primary Author: Kristin Griebe, University of Michigan, Michigan; **Email:** kmgrieb@umich.edu

Additional Author (s):
Cassandra Diamond
Michael Kraft
Chadi Abbas

Purpose: Effective training is critical to ensure pharmacy technicians are well-prepared to provide patient care, especially given increasing responsibilities, regulatory requirements (e.g., USP < 797>), and practice requirements (e.g., certification, licensure). Technician training was previously completed on-line in each work area. We implemented a core training program (off-line) prior to completing area-specific training (on-line) for inpatient pharmacy technicians utilizing a pharmacy space that was no longer used for patient care. This allowed individuals to train in a less-stressful environment away from patient care. The purpose was to improve pharmacy technician preparedness and satisfaction with training by establishing foundational knowledge and skills.

Methods: We informally surveyed several peer institutions about their approaches to pharmacy technician training. Using this information and our own processes, we developed a core training program (phone and computer system orientation, oral medications training, aseptic technique and sterile compounding, and automated dispensing cabinet processes). Core training requires approximately 1 week to complete, and technicians must complete an objective, standardized clinical examination (OSCE) for each station to pass and move on to area-specific training. A survey was developed to assess pharmacy technicians' perceptions of the training they received, how prepared they felt, and their satisfaction with training received. Each question was evaluated using a Likert scale (1 – 5, with 5 being best/very prepared/very satisfied). Prior to implementation of the core training (old training group), pharmacy technicians who had completed our current training process were asked to complete the survey, and were stratified into two groups – technicians who had worked at UMHS for more than six months, and technicians who worked at UMHS for less than six months. After implementation of the core training (new training group), the same survey was sent to new

employees at the completion of their full training (core training and area-specific training). Feedback was given and a consistent theme across all technicians was the inconsistency of training across all inpatient areas.

Results: The survey was completed by 24 pharmacy technicians: 12 technicians who underwent the old training program (prior to implementation of core training) and 12 technicians who completed the new training (after implementation of off-line core training). When asked how prepared they felt to perform their job after training, technicians who completed new training reported a mean score of 3.8 +/- 0.7 versus a mean of 3.4 +/- 1.1 among technicians who completed the old training (on a scale of 1 – 5, with 5 being very prepared) (p =0.3128). When asked how satisfied they were with the training received, technicians who completed the new training reported a mean score of 4.2 +/- 0.8 compared to a mean score of 3.2 +/- 1.0 amongst technicians who completed the old training (p =0.0129). With regards to overall satisfaction of the amount and usefulness of resources, the mean for technicians who completed the new training was 4.1 +/- 0.9 versus 2.8 +/- 1.1 for technicians who did not receive core training (p=0.0044). Overall themes from feedback about the old training included a lack of standard training and an undesirable "learn-on-the-go" approach. These themes were not noted after implementation of the new core training.

Conclusion: Implementation of a core pharmacy technician training using an off-line training center significantly improved the overall satisfaction of training received as well as the amount/usefulness of resources available. Feedback suggesting concerns about inconsistency in training and discomfort with training in the live environment was reduced. Implementation of a core training program outside of patient care may improve pharmacy technician training and reduce safety concerns with training in the patient care environment. Future improvements may include changes to improve preparedness, standardization among different areas, optimizing the duration of training, and assessment of outcomes.

Submission Category: Clinical Services Management

Submission Type: Descriptive Report

Session-Board Number: 5b-118

Poster Title: Implementation of a pharmacy-driven, COPD medication counseling service : A pilot study at a community hospital provided by clinical pharmacists and fourth year pharmacy students

Primary Author: Justin Thornton, Shenandoah University Bernard J. Dunn School of Pharmacy, Virginia; **Email:** jthornto13@su.edu

Additional Author (s):
David Nguyen
Katerina Petrov

Purpose: The Centers for Medicare and Medicaid Services (CMS) now recognize COPD exacerbations as one of the most preventable reasons for hospital readmissions. This pilot was designed to help launch a pharmacy-driven COPD medication management and discharge counseling service as an addition to an established core measure (CM) care coordination hospital process. Goals of the study were to develop the counseling service, provide COPD medication counseling and describe its impact on readmissions. Patient data on clinical outcomes was collected for future analysis.

Methods: The pilot study took place from June 6th to September 22nd, 2016 at Inova Loudoun Hospital in Lansdowne, Virginia. The pharmacy team consisted of a clinical pharmacist, rotating fourth year pharmacy students, and a hospitalist. It was designed as a value added expansion to a core measure team consisting of case managers, nurses, and physicians. The CM team generated a daily report identifying COPD "index" (target) patients. These patients were placed in 3 categories: first admission with COPD as primary diagnosis, readmission unrelated to existing COPD diagnosis, and readmission due to COPD exacerbation. The proposed pharmacy-driven service provided medication and disease counseling to all hospital COPD target admissions. To launch the service, the pharmacy team was added to the target admission report. With the help of pharmacy students, the team developed a daily COPD monitoring sheet, a patient education handout and a visual aid of all available inhalers. Pharmacy students were primarily responsible for medication counseling of all target COPD patients. Students also assessed daily patients' COPD medications, pertinent labs, and any ongoing antimicrobial therapy for appropriateness, efficacy, safety, and adherence. Recommendations to adjust

therapy were reviewed by a clinical pharmacist and approved by a hospitalist. An electronic intervention was documented in the EHR for each patient counseling. All COPD pilot patient data was de-identified and reviewed for any 30 day readmissions.

Results: To implement and provide the COPD counseling service, the pilot pharmacy team developed a patient monitoring sheet, a COPD education handout, a visual chart for all inhalers, and a COPD counseling electronic intervention. The clinical pharmacists were also added to the CM daily report of "index" (target) COPD admissions. A total of 67 target admissions took place during the pilot service period. The distribution of admissions into the 3 index groups were as follows: 43 (91.4%) admissions were categorized as first admission with COPD diagnosis, 14 (20.9%) admissions were categorized as readmissions with COPD exacerbation and 10 (14.9%) admissions were categorized as readmission unrelated to COPD diagnosis. Of the readmissions within 30 days, 9 (13.4%) were due to COPD exacerbations and 5 (7.4%) were admitted for causes unrelated to COPD. A total of 59 (88%) patients were counseled on their COPD medications and provided a handout with documented follow up electronic interventions. Patient monitoring sheets were collected for future analysis.

Conclusion: The national average for COPD readmissions within 30 days in 2015 was 20%. Recently, CMS reported ILH COPD readmission rate as "no different than the national rate." In contrast, our results show a 30 day readmission rate of 13.4%. These findings warrant further investigation. However, we speculate that pharmacy-driven medication counseling service was a valuable addition to the CM team. Plans for future development include the addition of a post discharge phone call and incorporating the service into the workflow with the continued help from pharmacy students. Formation of multidisciplinary CM rounding team will help to optimize clinical outcomes.

Poster Title: Implementation of a pharmacist-driven wellness clinic in Puerto Rico

Primary Author: Marina Babilonia Leon, Nova Southeastern University, College of Pharmacy, Puerto Rico; **Email:** mb2720@nova.edu

Additional Author (s):
Gabriela Falto Mas
Nishka Mercado Morales
Gabriela Navarro Velez
Ferdinand Morales Estremera

Purpose: A Wellness Clinic drives it services not only toward wellness, but also to disease prevention, health promotion, and health education. Currently, in Puerto Rico, the type of wellness clinic that we are addressing to is not available. Chronic conditions are the leading cause of morbidity, mortality, and disability in the United States, for which Puerto Rico is not an exception. Proper screening, prevention, treatment, and education can lead to a reduction in long-term health expenditures. Therefore, we see a need to help our community by offering a place in which they can receive all-in-one high quality health and wellness services.

Methods: To investigate about the impact of a wellness clinic, we conducted a dedicated search under the following databases: PubMed, International Pharmaceutical Abstracts, Medline, EBSCO, Academic search premier, Business source premier and EMBASE. To determine health related needs of our population, we conducted stakeholder interviews. The interview was performed to five (5) persons that represented the population we want to address the services to. Every stakeholder considered very convenient to have all-in-one resources to evaluate their health status since they haven't much time to spend going to different physicians in order to get preventive healthcare. They are willing to go once or twice a year to benefit from the prevention services. The services that some of the stakeholders are expecting from a Wellness Clinic are: pharmacist services including counseling on smoking cessation, medication therapy management, management of chronic conditions like diabetes, hypertension, and dyslipidemia, nutrition services provided by a nutritionist, dental services, fitness, physician consults, and a laboratory to obtain their results in one place. The willingness

to pay varies throughout the stakeholders since it is correlated with the services provided with a range of $100 to $500.

Results: The variety of services that we decided to provide at the clinic comprise the following: blood pressure monitoring, total lipid panel monitoring, fasting glucose checkup, administration of adult immunizations, smoking cessation strategies, HIV testing, stress management, rapid hemoglobin test, and nutritional counseling. The expected revenue on year one was $311,917.06 and the expected revenue on subsequent years was $344, 804.00. Revenue per Patient was shown as the estimated revenue per patient including the smoking cessation service ($112.80) and without the smoking cessation service ($92.80). To obtain the expected annual profit, 20 patients would have to visit the wellness clinic per day. Defining potential markets as a group of individuals, firms, and organizations in a particular market who have some level of interest in a particular product or service, private community pharmacies, universities, hospitals, and private companies could be potential markets interested in our wellness clinic. Marketing strategies would have to be developed in order to promote our services in a way that satisfies the potential investors.

Conclusion: Through our extensive research we have determined that with adequate design, a pharmacist driven wellness clinic is a suitable option for a community. We will provide healthcare access to improve and maintain wellness and health in the working class of Puerto Rico. With the services offered in our wellness clinic, we will promote the expansion of the pharmacist role in the overall community, increase prevention and health education, build trust relationships with our patients, provide the opportunity of experiential education for our pharmacy volunteers and students, and help decrease healthcare-related expenditures for individuals and government.

Poster Title: Appropriate use of vitamin K in patients on warfarin with supratherapeutic international normalized ratio: Evaluation of practice in a medical facility

Primary Author: Faith Ihongbe, Bernard J. Dunn School of Pharmacy, Shenandoah University, Virginia; **Email:** fihongbe13@su.edu

Additional Author (s):
Katerina Petrov

Purpose: CHEST guidelines recommend no administration of vitamin K for patients with an international normalized ratio (INR) less than 10. For patients with an INR greater than 10 without significant bleeding, vitamin K 2.5-5 mg orally is recommended. For patients with major bleeding, vitamin K 5-10 mg intravenously is recommended. This study aims to evaluate the appropriate use of vitamin K in patients on warfarin with supratherapeutic INR, patients scheduled for surgery, and bleeding patients, in comparison with the current CHEST guidelines.

Methods: This cross-sectional descriptive study was conducted at a small community hospital in Virginia. Patient medical records were screened from May 2015 to April 2016. Study population included patients (N=43) who were admitted on warfarin. International normalized ratio values prior to administration of vitamin K were recorded and divided into three categories - less than 4.5, 4.5-10, and greater than 10. Administered dose and route of vitamin K were also recorded. The study sample was divided into 3 groups based on indication for vitamin K use - patients scheduled for surgery, patients who were bleeding and patients with supratherapeutic INR from warfarin therapy.

Results: Twenty patients (46.5%) were scheduled for surgery, 9 (20.9%) had bleeding events and 14 (32.6%) had supratherapeutic INR. Of the 14 patients with supratherapeutic INR, 8 had INR 4.5-10 and were administered 2.5mg (4 patients) and 5mg (4 patients) oral vitamin-k. Of the remaining 6 patients, 5 patients with INR 4.5-10 were administered intravenous vitamin-k (1 patient, 2mg; 3 patients, 5mg; and 1 patient, 10mg) and the remaining patient with INR greater than 10, was administered intravenous vitamin k 5mg. Among the 9 patients with bleeding events, 3 had INR less than 4.5 and were administered 2mg (1 patient) and 10mg (2 patients) intravenous vitamin-k. The fourth patient with INR 4.5-10 received 5mg intravenous

vitamin-k. Of the remaining 5 patients, 4 patients with INR 4.5-10 were administered oral vitamin-k (3 patients, 2.5mg and 1 patient, 10mg) and the remaining patient who had INR less than 4.5, received oral vitamin-k 5mg. Twenty patients had surgical procedures of whom 12 received oral therapy [(11 with INR less than 4.5 received 2.5mg (6 patients), 5mg (4 patients) and 10mg (1 patient)] and 8 received intravenous therapy [7 with INR less than 4.5 received 2.5mg (1 patient), 5mg (3 patients), and 10mg (3 patients)].

Conclusion: This study shows that vitamin K use in this facility was not consistent with the current CHEST guidelines. Judicious use of vitamin k will help improve patient outcome, as well as reduce health-associated costs.

Poster Title: The Effectiveness of Online Learning Modules on Student Performance and Knowledge Retention

Primary Author: Sahar Habhab, University of Michigan College of Pharmacy, MIchigan; **Email:** habhabs@umich.edu

Additional Author (s):
Mustapha Beleh
Burgunda Sweet

Purpose: To assess students knowledge in the areas of physiology and statistics along with evaluating the effectiveness of web-based statistical learning modules in remediation of knowledge deficiencies uncovered by the baseline assessment.

Methods: Students were required to complete a baseline assessment test in both physiology and statistics. First year pharmacy (P1) students were designated to take the physiology assessment and second year pharmacy (P2) students were required to take a baseline statistics assessment as part of their courses. P2 students will then be required to take a post-module statistics assessment after the administration of online learning modules. P2 students' scores on the baseline assessments and post-module scores were be compared to assess short-term retention. The study also looked at the effectiveness of these modules on struggling students versus the general student population by examining scores of the students scoring in the lower quartile and those scoring below the average. Lastly, third year pharmacy (P3) students were administered the baseline statistics assessment a year after using the learning modules to evaluate long-term retention of statistical information.

Results: The average score on the physiology assessment taken by first-year pharmacy students was 50.5%. All the topics covered in the assessment were low, with the biggest deficit in the renal system (33%). There was a statistically significant difference between the assessment scores based on the institution in which the physiology course was taken (U of M vs. other institution; 59.% vs 45.2%). There also was a statistically significant difference in the assessment scores based on the year the course was taken (2015 vs prior to 2015; 62.1% vs 47.3%). In regards to the statistics assessment, there was a statistically significant improvement in post-

module scores for all six modules administered (p < 0.001) based on the past 5 years of data collected. The same trend was seen for the class of 2017. The "at risk" group, those that scored below the average on the baseline statistics assessment, showed significant improvement in all six modules based on their post-assessment score(p < 0.001). In regards to retention of information post-module use, we found that there was a statistically significant improvement in reassessment scores during students P3 year of pharmacy school in the majority of the modules when compared to their baseline assessment scores.

Conclusion: The use of assessments to uncover students baseline knowledge and deficits is important for an educational institution to know in order to adjust their curriculum appropriately. The use of web-based modules is an appropriate method in remediating some of the knowledge on both a short-term and long-term basis.

Poster Title: Inpatient criteria for Hemin in acute intermittent porphyria (AIP); the development of a protocol

Primary Author: Matthew Henry, Shenandoah University, Virginia; **Email:** mhenry13@su.edu

Additional Author (s):
Martha Healy

Purpose: Acute intermittent porphyria (AIP), a rare heme disorder caused by low levels of porphobilinogen deaminase. Often times, patients may be latent in which they have no symptoms; however, they may have an acute attack leading to hospitalization due to abdominal pain, hyponatremia or neurological symptoms. Due to the rarity of this disease, many institutions, including Inova Loudoun, do not have a protocol to treat these patients. Institutions initially give Hemin, which costs $8,000 per dose which not all patients require. Implementing a protocol will prevent the overuse of Hemin, which is beneficial to both the patient and the hospital.

Methods: Being that there is no protocol at Inova Loudoun on how to treat AIP patients, research was performed to determine what testing would need to be completed in patients having an acute attack prior to the administration of Hemin. Appropriate testing according to protocol was to determine patient porphobilinogen (PBG) levels. Once the protocol was determined, the Chief Medical Officer of the hospital evaluated and approved the protocol for implementation. Hospital records were then reviewed for patients with AIP who had been admitted and treated with Hemin over the past 18 months. Two patients had been treated at the hospital during this time period. The patients' records were then evaluated to determine if proper testing had been completed before the administration of Hemin.

Results: It was determined that each patient had not been properly tested prior to the administration of Hemin. PBG testing should be completed at admission of every AIP patient. The most recent testing for this patient was done one year prior to this admission. The second patient had testing completed, but it was not until after the first dose of the medication was given. Had the hospital had a protocol in place prior to the admission of the patients and the

administration of Hemin, they could have potentially saved $40,000 due to the number of doses that were potentially not needed.

Conclusion: Although AIP is a rare disease, with the increasing number of patients that Inova Loudoun has experienced with the disorder and the cost of each dose to treat the patients, the implementation of a protocol will help prevent overspending and overuse of the medication.

Poster Title: Comparison of two methods of urine mRNA quantification for Hypoxia Inducible Factor 1 as a biomarker of hypoxic kidney disease.

Primary Author: Sasha McClain, Shenandoah University, Virginia; **Email:** tpho13@su.edu

Additional Author (s):
Tina Pho
Shahrzad Movafagh

Purpose: Use of urine as a non invasive diagnostic tool for kidney pathologies and therapeutics has been extensively studied. We have previously shown that HIF-1 urinary mRNA could serve as a potential biomarker of hypoxic kidney diseases. Timely processing of urine specimens can impact downstream mRNA quantification yield. The Zymo Urine RNA Isolation Kit allows for immediate processing with minimal supplies which could potentially improve the yield of mRNA compared to traditional methods. In our study, we sought to compare the yield and quality of urinary HIF-1 mRNA processed with the Zymo Urine RNA Isolation Kit to the existing protocol.

Methods: Healthy donors were recruited in accordance with Shenandoah University IRB guidelines after obtaining informed consent. After collecting the urine samples, the samples were divided into two groups to be analyzed in parallel using two different approaches for the initial RNA isolation. Urine samples were collected and 50 mL was immediately stored at -80° C per our current method and the other 50 mL was immediately processed using the Zymo Urine RNA Isolation kit. These urine samples were put through an initial lysis step after which the lysate was stored at -80° C for a later RNA isolation. RNA isolation was completed for each sample in parallel using the Qiagen RNeasy Plus Mini Kit and the Zymo Urine RNA isolation kit. cDNA was then synthesized from both the RNA isolates of the parallel methods and then ACTB and HIF-1a expression levels were assayed by RT PCR. The resulting expression levels were compared between the RNA isolated from the two methods to assess if there was a difference in yield by the level of expression.

Results: The resulting CT values for ACTB and HIF-1a in our initial sample group of 8 donors showed similar levels of amplification in specimens processed using the Zymo Urine RNA Isolation Kit compared to our current established method. Additional urine specimens are being screened to confirm these preliminary results.

Conclusion: The Zymo Urine RNA Isolation Kit has shown comparable urinary HIF-1 mRNA yield compared to our current methods. Additionally, the protocol is more convenient and less labor intensive than our current method and can serve as a viable alternative for urine specimen processing for downstream molecular based experiments.

Poster Title: Incidence of bronchopulmonary dysplasia following caffeine prophylaxis in extremely premature neonates

Primary Author: Todd Hershberger, University of Michigan College of Pharmacy, Michigan; **Email:** toddeh@med.umich.edu

Additional Author (s):
Varsha Bhatt-Mehta

Purpose: This study was conducted to determine the incidence of bronchopulmonary dysplasia (BPD) in extremely premature neonates, 28 weeks gestational age (GA), who received caffeine for prevention of BPD according to the University of Michigan Brandon Neonatal Intensive Care Unit's respiratory distress syndrome (RDS) protocol. The RDS protocol adopted caffeine prophylaxis based on the results of a study by Schmidt B. et al. 2006. This study, which was designed to examine the use of caffeine for the treatment of apnea of prematurity, showed a beneficial effect of caffeine on the prevention of BPD in a secondary data analysis.

Methods: The institutional review board approved this open-label, retrospective cohort study. All inborn neonates between March 1st, 2010 and June 30th, 2015 at the University of Michigan who were 28 weeks GA with adequate caffeine and supplemental oxygen data at 36 weeks corrected GA (definition of BPD) were included in the study. Outborn neonates and neonates missing caffeine or oxygen data were excluded from the study. The Vermont Oxford Network database was used to identify eligible patients. Caffeine dosing data were derived from electronic medication administration records. The primary outcome of interest was the incidence of BPD among neonates receiving caffeine for BPD prophylaxis. Data analyses also included comparisons between BPD and Non-BPD neonates for demographics such as GA, birthweight, and sex as well as caffeine data such as average weekly maintenance doses and total caffeine exposure at 36 weeks corrected GA.

Results: The incidence of BPD among the 75 included neonates receiving caffeine for BPD prophylaxis identified in this study was 64% (48/75). Demographic comparisons between groups with 95% confidence intervals showed a mean GA of 25.9 0.37 weeks in BPD neonates compared to 26.9 0.36 weeks in Non-BPD neonates, a mean birthweight of 839 58 grams in BPD

neonates compared to 954 77 grams in Non-BPD neonates, and of the 48 neonates with BPD, 47.9% were male and 52.1% female. The total caffeine exposure at 36 weeks corrected GA was 506 44 mg/kg for neonates with BPD and 476 66 mg/kg for neonates without BPD.

Conclusion: The use of caffeine for BPD prophylaxis resulted in a 64% incidence of BPD among extremely premature neonates. Although limited by a small sample size, the reported incidence rate greatly surpasses the 36.3% incidence of BPD in caffeine treated neonates seen by Schmidt B. et al. 2006. The increased incidence seen in this study may suggest that, when limited to neonates that are extremely premature (28 weeks GA), caffeine may not provide a benefit in the prevention of bronchopulmonary dysplasia.

Submission Category: Practice Research/ Outcomes Research/ Pharmacoeconomics

Submission Type: Evaluative Study

Session-Board Number: 5b-125

Poster Title: Phytochemical composition of the root bark during growth of the antimalarial plant Artemisia annua (Sweet Annie): screening for possible antimicrobial activity

Primary Author: Kalyn Kiziah, Shenandoah University Bernard J. Dunn School of Pharmacy, Virginia; **Email:** kkiziah13@su.edu

Additional Author (s):
Joseph Naval
Wendell Combest
Jennifer Bryant

Purpose: To determine the phytochemical constituents in the outer root bark of Artemisia annua at various stages of growth, and between different parts of the root including the taproot, lateral root, and root hairs. To develop optimal solvent extraction and high performance liquid chromatography (HPLC) methods to quantify and eventually identify and purify selected root constituents. The extracted root bark phytochemical constituents will then be screened for possible antibacterial and antifungal activities.

Methods: Root samples of Artemisia annua were collected from the Shenandoah River Cool Spring campus near Berryville, Virginia and outside the Health Professionals Building in Winchester, Virginia in late spring and summer. For the developmental study, the dried outermost bark from the taproot at various stages of plant growth (12-100 inches in height) were scrapped, finely chopped, sieved (less than 0.5mm) and extracted in 30 vols (w/v) of 70 percent methanol at 70 degrees C for 20 min following homogenization via ultrasonication. Following centrifugation a 20ul sample was analyzed by HPLC (Shimadzu 20AD with a UV-vis photodiode array detector utilizing a C18 analytical column). Sample of root bark were also extracted with ethlyl acetate and ethanol as described above and air-dried (warm hair dryer) and reconstituted with either ethanol or DMSO. The extracted samples were tested for antimicrobial activity using the disk diffusion antibiotic sensitivity method (Kirby-Bauer antibiotic testing). Yeast (BY4741) and E.coli (HB101 K-12) were the yeast and bacteria utilized for testing. Known antibacterial and antifungal agents, Ampicillin (Sigma) and Fluconazole (Sigma) respectively were used as controls.

Results: The level of major phenolic phytochemical constituents (hydroxycinnamate derivatives (HC), p52-61 cluster, and p70) present in the taproot outer bark increased as the plant grew: 12, 18, 36, 54, 72, and 100 inches. The level of p70 was 0.1, 5-7, and 27 units/mg at 12-18, 36-54, and 72 inches respectively. The lateral roots at 36-100 inches generally contained higher levels of phytochemicals compared to the taproot and significantly lower in the root hairs. Ethyl acetate (EA) extracted a total of 1.2, 3.4, and 22.6 percent of total outer lateral root bark content of HC, p52-61 cluster, and p70 respectively. EA extracted 81.5 percent of the total extractable (22.6 percent) constituents during the first extraction followed by 17.6 percent after the 2nd and 0.9% after the 3rd extraction. This relative extraction selectivity excludes most water-soluble constituents to allow for a more concentrated and lipophilic p70 to be used for further purification and to screen for possible pharmacological activity.
EA, ethanol, and 70 percent methanol extracted, DMSO and ethanol reconstituted lateral root bark preparations were screened for antimicrobial activity using a disk diffusion method. Slight E. coli growth inhibition was noted in EA extracted and DMSO reconstituted root bark extracts.

Conclusion: Root bark constituents appear in root bark as early as 14 days after seed germination and reach maximal mature levels at 6 feet in height. Thus, to maximize root bark constituents, harvesting should be done when the plant is 6 feet tall and before the plant flowers. Most of the root-bark phytochemicals are water-soluble and poorly extracted, therefore two EA extractions is necessary to get 99 percent of the extractable p70.
Higher concentrations of extracts and more purified p70 preparations should be tested with a variety of gram-positive and gram-negative bacteria and fungi to better assess root bark antimicrobial activity.

Submission Category: Practice Research/ Outcomes Research/ Pharmacoeconomics

Submission Type: Evaluative Study

Session-Board Number: 5b-126

Poster Title: Phytochemical analysis of several popular green leafy vegetables: Comparison of organic, non-organic, and dietary supplement formulations of curly leaf kale

Primary Author: Young Joo Ryu, Shenandoah University Bernard J. Dunn School of Pharmacy, Virginia; **Email:** yryu13@su.edu

Additional Author (s):
Audrey Le
Truong Le
Wendell Combest

Purpose: There is a pre-conceived notion that organic vegetables are believed to be superior than non-organic vegetables. To explore this notion, this study was designed to develop a solvent extraction and high-performance liquid chromatography (HPLC) methodology to separate, identify, and quantify phenolic phytochemical constituents in several popular green leafy vegetables. Using this "fingerprint analysis" method, we identified plant specific phytochemical markers for accurate analysis of plant greens or dietary supplement formulations. Additionally, we determined if organic curly leaf kale has a different phytochemical composition compared to non-organic kale, as well as an available organic dried kale dietary supplement.

Methods: Vegetable greens for this study was obtained from local supermarkets and were all grown in California. Fresh leaf samples were cut into thin slices and air dried in a chemical fume hood overnight. Portions of the air dried samples were further dried in a 58 degrees Celsius oven for two days to obtain leaf dry weights. A sample of chopped and sieved (less than 0.5mm) dried leaf was extracted in 30 volumes (weight/volume) of 70 percent methanol for 20 minutes at 70 degrees Celsius following homogenization via ultrasonication. After centrifugation, 20 microliters of the supernatant was analyzed via HPLC (Shimadzu 20AD with a UV-vis photodiode array detector utilizing a C18 analytical column). Organic kale dietary supplement capsules were obtained from Solaray Inc, Park City, Utah.

Results: HPLC chromatograms of methanolic extracts of dried leaves of curly leaf kale (Brassica oleracea), spinach (Spinacia oleacea), Swiss chard (Beta vulgaris), and watercress (Nasturtium officinalis) showed distinctive species specific compounds allowing each to be identified in a mixture of all four plants. Furthermore, leaves of five different species of Brassica (i.e. kale, collard and turnip greens, bok choy, and mustard greens) showed distinctive identifiable HPLC profiles. Statistically significant differences were found between organic and non-organic curly leaf kale. Most notable was a 50 percent higher level (N equals 4; P less than 0.01) of 12 specific glucosinolates in organic kale. Two additional phenolic compounds showed a 86 percent (N equals 4; P equals 0.01) and 245 percent increase (N equals 4; P less than 0.01). HPLC profiling revealed that the dried organic kale leaf dietary supplement made by Solaray matched the typical fingerprint of kale with no evidence of any adulterations. Using characteristic glucosinolates derivatives as markers, the air dried kale contained 7.8 fold higher difference of glucosinolate derivatives than the dietary supplement. Based on this measurement, one capsule daily dose of 440 mg would give only 0.4 percent of the kale phytochemicals found in 100 gram serving of kale.

Conclusion: Green leafy vegetables even within the same species of the Brassica genus have distinctive phytochemical constituents making possible accurate analyses of the nutrient composition and possible adulteration in dietary supplements and food products. Organic kale may have a higher nutritional value as well as being pesticide and herbicide free based on our HPLC analysis. Compared to taking a dried leaf dietary supplement, eating a 100 gram serving of fresh or steamed kale is far better than taking a dietary supplement, in addition to being much less expensive.

Submission Category: Practice Research/ Outcomes Research/ Pharmacoeconomics

Submission Type: Evaluative Study

Session-Board Number: 5b-127

Poster Title: A comparison of two different intervention documentation methods for assessing the impact of an early pharmacy practice experience program

Primary Author: Lauren Sellers, Auburn University Harrison School of Pharmacy, Alabama;
Email: lvs0003@auburn.edu

Additional Author (s):
Pamela Stamm
Margaret Williamson

Purpose: The doctor of pharmacy curriculum at Auburn University Harrison School of Pharmacy includes a required longitudinal early Pharmacy Practice Experiential (PPE) education course. First through third year student pharmacists visit patients in the community and document their visits in "progress notes" within an electronic health record and third year students document interventions in an online intervention system. The study objective is to compare the number and types of interventions identified through a retrospective analysis of progress notes versus those entered into the online intervention system in order to gauge the full impact of the Early Pharmacy Practice Experiential (PPE) program.

Methods: This retrospective study was submitted to the Institutional Review Board for approval. The course director randomly selected all progress notes for 20% of the student teams to roughly represent 20% of the enrolled patients in the program from August to December 2014. Investigators initially reviewed notes for three patients together in order to develop a consensus and improve inter-rater reliability. Reviewers used an Excel spreadsheet to categorize interventions documented by student pharmacists in their required progress notes. Two investigators reviewed each progress note and tracked interventions documented within them using a data collection form. In case of a disagreement, a third investigator reviewed the note and resolved the discrepancy. Patients were excluded if major discrepancies existed between progress notes over time and the sequence of events in the patient history could not be easily determined. An existing report was utilized and downloaded from the online data system (Quantifi, Pharmacy One Source 2016). Data were summarized according to the type of intervention as well as the outcome (accepted, declined, or unknown) of the intervention. Descriptive statistics were utilized to describe frequency data.

Results: Notes and interventions from six teams were analyzed. The teams included 96 students (15-18 students per team and 2-4 faculty members) supervised by 15 faculty members. Together these teams completed 265 visits for 57 patients. Overall, 64 (1.1 interventions per patient) interventions were identified from Quantifi versus 327 (5.7 interventions per patient) through progress note review. The most common interventions documented within progress notes were disease state counseling (n=50), labs assessed (n=41), patient counseling other (n=35), drug counseling (n=32), and patient referral (n=28). The most common interventions by Quantifi were vaccine recommended (n=20), patient counseling (n=13), and OTC recommendation (n=6). Two teams accounted for the majority (46.9%) of the Quantifi interventions. The other teams ranged from a low of 38 interventions to a high of 79 interventions.

Conclusion: In conclusion, more interventions were identified through progress note review than were documented on the online intervention system. Progress note review revealed greater impact than what was suggested through the online intervention system. These results suggest the need within the program for universal documentation instruction which warrants further investigation. Overall, the review does suggest that the program is substantially impacting the community through education and medication recommendations.

Poster Title: Evaluating the labeled and off-label indications of hospital-administered intravenous immunoglobulin therapy

Primary Author: David Parker, Shenandoah University School of Pharmacy, Virginia; **Email:** dparker13@su.edu

Additional Author (s):
Sasha Beselman
Jim Monolakis
Jill Lowman
Antoine Azar

Purpose: Intravenous immunoglobulin therapy provides passive immunity for primary and secondary immunodeficiencies by increasing the antibody titer and antigen-antibody reaction potential. It is currently approved for several indications including: primary humoral immunodeficiency, chronic immune thrombocytopenic purpura, chronic inflammatory demyelinating polyneuropathy, multifocal motor neuropathy, chronic lymphocytic leukemia, and Kawasaki syndrome. However oftentimes, if clinicians perceive a patient benefit, intravenous immunoglobulin is utilized for off-label indications. The primary objective of this study was to evaluate and report findings for approved indications as well as non-approved indications for intravenous immunoglobulin therapy at Johns Hopkins Bayview Medical Center.

Methods: This was a single-center, retrospective chart review approved by the institutional review board at the Johns Hopkins Bayview Medical Center. The hospital is a tertiary care center primarily for adult patients. All patients who received intravenous immunoglobulin therapy from September 1, 2011 to September 1, 2016 were included. Data extraction software was used to obtain the records of patients who received inpatient administration. Patients who did not receive immunoglobulin therapy were not included. Age, gender, weight, name of intravenous immunoglobulin product, indication for use, and dose administered were collected from each record. The manufacturer labels for each intravenous immunoglobulin product were used to confirm approved indications.

Results: Health records were reviewed from 137 patients, all of whom received hospital-administered intravenous immunoglobulin. Ages ranged from newborn infants to 94 years with an average of 48 years. Privigen, the most frequently used intravenous immunoglobulin agent, was administered to 128 patients. Gamunex was administered to 9 patients. Intravenous immunoglobulin therapy was used for 35 different indications. Out of 137 patients, 47 patients received treatment for labeled indications: 34 percent of patients received intravenous immunoglobulin for idiopathic thrombocytopenic purpura, 21 percent for chronic inflammatory demyelinating polyneuropathy, and 10.6 percent for Kawasaki syndrome. 90 patients were treated for off-label indications: 16 percent for Guillain-Barre Syndrome, 8.7 percent for dermatomyositis, 8 percent for paraneoplastic syndrome, 5.1 percent for myasthenia gravis, 5.1 percent for necrotizing myositis, 5.1 percent for hyperbilirubinemia, 2.9 percent for scleroderma, 2.9 percent for pyoderma gangrenosum, and 2.1 percent for systemic lupus erythematosus.

Conclusion: This preliminary study identified potential off-label indications for the use of intravenous immunoglobulin therapy. Expanding the search of immunoglobulin therapy use to other hospitals, and collecting detailed information on the response to therapy and dosage used, can provide valuable information as to how immunoglobulin therapy is being used, and which conditions respond to immunoglobulin therapy. Ultimately, this data may lead to designing future placebo-controlled randomized trials that would evaluate the effectiveness of intravenous immunoglobulin therapy and subcutaneous immunoglobulin therapy for conditions that do not have current guidelines, consensus, or FDA indications.

Poster Title: Grants record of clinical faculty in the department of pharmacy practice

Primary Author: Isha Jariwala, Hampton University School of Pharmacy, Virginia; **Email:** isha.jariwala@my.hamptonu.edu

Additional Author (s):
Hua Ling

Purpose: Scholarship and research are generally expected for clinical faculty in the department of pharmacy practice as part of their responsibilities, however a general lack of comfort in the ability to design and conduct research was reported, which is consistent with the decline in the average scholarly productivity. Besides publishing manuscripts, grant application is also a major component of scholarly activities, which has not been reported before. Our study checked the numbers and types of grant received by clinical faculty in an effort to better understand the current status of scholarly productivity in clinical faculty in the department of pharmacy practice.

Methods: A quantitative observational study was conducted to determine the number and types of grants received by clinical faculty in the department of pharmacy practice of pharmacy schools in the past 2.5 years in the US. The American Association of Colleges of Pharmacy (AACP) online news, "Faculty News" from January 2014 to June 2016 was utilized as the source to obtain grant data. The eligibility criteria for including data were as follows: 1) the recipient of grant must be a clinical faculty with active pharmacist licensure, 2) the recipient of grant must belong to the department of pharmacy practice, and 3) the research topic for the grant must be practice-based or academic-based. Grants in pharmacy administration and biomedicine, as well as Institutional awards, were excluded. In addition to the primary focus of the study, information such as recipient university, funding institute, grant type, and award amount were collected to analyze secondary endpoints. The data was analyzed using Microsoft Excel 2016.

Results: As of July 2016, there are 136 pharmacy schools in the US. On the contrary, only a total of 141 grants were awarded to the clinical faculty in the department of pharmacy practice in the past 2.5 years. The state or federal departments awarded 28 percent of the grants, while non-federal institutions awarded the rest 71.8 percent. Of the non-federal grants, 30.3 percent

were received from a variety of foundations, 21.1 percent from pharmacy and pharmaceutical companies, 10.6 percent form universities, and 9.9 percent from various organizations. The mean and median of the amount received from the state and federal departments were $429,159 (mean (SD) =600,681) and $148,331, whereas from non-federal sectors they were $122,172 (mean (SD)= 328,759) and $36,203, respectively. Even though state and federal funding agencies provided the least percentage of grants, they provided with the most amount. In addition, 70 percent of the pharmacy schools that received grants belonged to public universities, whereas only 30 percent belonged to private universities. Finally, Purdue University, a public university, received the most number of grants, namely 30 grants.

Conclusion: The study provided the statistics of grants received by the pharmacy practice faculty in the US from January 2014 to June 2016. The results demonstrated that the percentage of grant received by pharmacy practice faculty from federal funding agencies was much less in comparison to non-federal funding agencies. Moreover, the results depicted that out of all the non-federal funding institutes, various foundations awarded the maximum number of grants, followed by pharmacy and pharmaceutical companies. Unfortunately, "Faculty News" is generated from self-report of each pharmacy school, therefore our results may be limited by self-report bias and inaccuracy of the source data.

Submission Type: Descriptive Report

Session-Board Number: 5b-130

Poster Title: Implementation of an antimicrobial stewardship program on a medical unit at a community hospital compliant with 2017 Joint Commission standards: a 30-day pilot study

Primary Author: Mimosa Lim, Shenandoah University School of Pharmacy, Virginia; **Email:** mlim13@su.edu

Additional Author (s):
Katerina Petrov
May Chang

Purpose: The Department of Health and Human Services, Centers for Medicare and Medicaid Services and Joint Commission proposed new rules in June 2016 requiring antimicrobial stewardship programs in all hospitals as conditions of participation in Medicare and Medicaid. In compliance with latest accreditation standards, Inova Loudoun Hospital expanded their antimicrobial stewardship from daily monitoring of all target broad-spectrum antimicrobials to include daily antimicrobial monitoring service on a medicine unit. This study was a 30-day pilot to the proposed antimicrobial expansion. The purpose of the pilot was to optimize clinical outcomes, and describe the type, frequency, and acceptance rate of antimicrobial recommendations.

Methods: Inova Loudoun Hospital, a 183-bed community hospital in Lansdowne, Virginia, conducted a 30-day pilot study, which included daily antimicrobial monitoring service of all patients on a 39-bed medicine unit. This initiative was added to an existing antimicrobial stewardship program, which monitors daily the use of the following target broad-spectrum antimicrobial agents- piperacillin/tazobactam, meropenem, ertapenem, linezolid, daptomycin, and aztreonam. The pilot study team included an attending infectious disease physician, two clinical pharmacy specialists and a fourth year pharmacy student. The pharmacy student rounded daily on all medicine unit patients receiving antimicrobials to evaluate their use for appropriate indication, selection, spectrum of activity, duration of therapy as well as appropriate use of broad specrum antibiotics, and therapy for longer than seven days. The use of a probiotic for primary prevention of Clostridium difficile-associated diarrhea was monitored in compliance with Inova Loudoun Hospital's policy for Clostridium prophylaxis. Objective parameters were collected from each patient including basic demographic information,

underlying diseases and infections, pertinent laboratory data including culture and susceptibility, and radiographic data. The student's antimicrobial stewardship recommendations were reviewed and approved by the clinical pharmacists and the infectious diseases physician. The number of accepted antimicrobial stewardship interventions was documented including the type of intervention, prescribing physician, and whether intervention was accepted or rejected.

Results: A total of 254 unique patients were screened during the pilot study from August 16th to September 20th, 2016. The average monitoring duration was 2.47 days, with a range of 1 to 14 days. A total of 104 unique antimicrobial interventions were suggested to Inova Loudoun Hospital physicians. The interventions made are as follows: 74 probiotic interventions for Clostridium difficile prophylaxis, 21 therapy de-escalations, 5 dose adjustments, 2 indication changes, 2 for duration of therapy change, none for selection. A total of 64 patients (29.5 percent) had an ID consult. Piperacillin/tazobactam was used most frequently used in 57 patients, followed by meropenem 20, ertapenem 6, linezolid 1, daptomycin 1, and aztreonam 1. Pharmacy documented two accepted interventions with regards to de-escalation of piperacillin/tazobactam therapy. The infectious diseases physician was consulted on at least 50 percent or higher of all the target antibiotics cases. No cases of target antimicrobial therapy longer than 7 days were documented. Non-target antimicrobials were varied and encompassing. Ceftriaxone (28 percent) was most frequently used in this category, followed by vancomycin (16 percent) and levofloxacin (12 percent). Vancomycin had the most interventions (8) with 2 (50 percent) accepted.

Conclusion: This pilot study was utilized to describe antimicrobial use for all patients on a medicine unit. Most frequently used antibiotics included piperacillin/tazobactam, carbapenem, ceftriaxone, vancomycin, and levofloxacin. This study was the pilot step in expanding Inova Loudoun Hospital's antimicrobial stewardship program according to new Joint Commission requirements. It helped identify areas of improvements where antimicrobial education should be provided to hospital prescribers and pharmacy staff. The study was also a valuable indicator for challenges and time commitment if implemented into the pharmacy workflow. Ultimately, multidisciplinary antimicrobial rounds on each hospital unit will be most beneficial to optimize clinical outcomes.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Session-Board Number: 5b-131

Poster Title: Phytochemical analysis of stems, leaves, rhizome and roots of the medicinal plant Fallopia japonica (Japanese Knotweed)

Primary Author: Gina Fu, Bernard J. Dunn School of Pharmacy Shenandoah University, Virginia; **Email:** gfu09@su.edu

Additional Author (s):
Wendell Combest

Purpose: Develop a solvent extraction and high performance liquid chromatography (HPLC) methodology to separate, identify, and quantify phenolic phytochemical constituents in different parts of the plant Fallopia japonica. Using this methodology we will: 1. Compare the levels of resveratrol, the resveratrol glucoside piceid and the anthraquinone emodin in stems, leaves, leaf petioles, and rhizomes of the plant. 2. Determine if the geographical location of the plant affects its phytochemistry.

Methods: Samples of Japanese Knotweed was harvested in August 2015 from several locations in the states of Vermont, New York, and Pennsylvania. Plant material was dried in a chemical fume chopped, sieved (< 0.5mm) and extracted in 30 volumes (w/v) of 70% methanol for 20 min at 70°C following homogenization utilizing a ultrasonication probe (Fisher Scientific). After centrifugation 20 µl of the supernatant was analyzed via HPLC (Shimadzu 20AD with a UV-vis photodiode array detector utilizing a C18 analytical column) utilizing a 3-100% acetonitrile gradient.

Results: HPLC fingerprinting chromatograms of methanolic extracts of various parts of the plant revealed a distinct pattern of phenolic compounds. Marked differences were also seen in the various layers of the rhizome bark with the most prominent compounds found in the middle yellow portion of the rhizome and root bark. The highest levels of resveratrol were found in the orange and yellow regions of the rhizome bark
Plants from various locations along the US east coast showed minor differences but most prominent phytochemicals were very similar in all rhizome samples.

Conclusion: The middle orange/yellow layer of the outside bark from plant rhizomes contains the highest levels of most of the phytochemicals especially reseveratrol found in Fallopia japonica. Some differences were noted in rhizome samples from different growth locations from Vermont to Pennsylvania perhaps due to known hybridization between plants between Fallopia japonica and Fallopia sachalinensis (Giant Knotweed). The rhizomes of this abundant often invasive plant provides a plentiful renewable resource for the important antioxidant dietary supplement resveratrol.

Poster Title: Assessment of common health conditions self-treated by Hampton University's pharmacy community

Primary Author: Novia Watson, Hampton University, Virginia; **Email:** novia.watson@my.hamptonu.edu

Additional Author (s):
Isha Jariwala
Charmi Patel
Aranyce Whitaker
Wanda Azu Owoh

Purpose: Over-the-counter (OTC) products are the products that can be purchased without a prescription and can be used for self-treatment of many health conditions. Self-treatment using OTC products is commonly observed amongst healthcare professionals. The purpose of this study was to assess the most common health condition being self-treated by student pharmacists and pharmacists at Hampton University, Hampton, VA using the OTC products, and to identify the most important factor affecting the decision of student pharmacists to self-treat with OTC products.

Methods: This institutional review board approved questionnaire-based cross-sectional study with sample size of 158 for student pharmacists and seven for pharmacists was conducted during the spring semester of 2016 to assess the use of OTC products for self-treatment of health conditions such as allergies, cold/flu, sleep deprivation, pain and for first-aid care. Student pharmacists from the four professional school years and pharmacists from the department of pharmaceutical sciences were included in the study. The study participants were read an oral consent that described the study and they provided consent by turning in the questionnaire. The participants that denied participation were excluded from the study. A five-point Likert scale was utilized to assess participants' attitude towards taking OTC products for the above-mentioned conditions. The participants were also asked to rank their preference to self-treat each of the conditions as well as to determine the most important factor affecting their decision to self-treat with OTC products. The primary objective of the study was to determine the most common condition being self-treated by student pharmacists using the

OTC products and the secondary objective was to determine the most important factor affecting the decision of student pharmacists' to self-treat with OTC products. The results obtained from analyzing the questionnaires of student pharmacists were then compared to that of the pharmacists to identify the trend between the two sample groups.

Results: Self-treatment preference questionnaires of 158 student pharmacists and seven pharmacists were analyzed using five-point Likert scale.The data demonstrated that 84.2 percent of the 158 students either agreed or strongly agreed to self-treat for pain, while only 9.5 percent either disagreed or strongly disagreed to self-treat. Whereas 64.6 percent of the student pharmacists either disagreed or strongly disagreed to self-treat for sleep deprivation, only 20.9 percent agreed. Based on the top two ranking preference choices, 58.78 percent of the student pharmacists preferred pain to be self-treated with OTC products, followed by allergies (51.4 percent), cold/flu (43.6 percent), first-aid care (34.0 percent), and lastly, sleep-aid (14.09 percent). Amongst pharmacists, 71.43 percent preferred allergies to be self-treated the most, while sleep deprivation to be self-treated the least (14.29 percent) with OTC products. 37 percent of the student pharmacists chose "easy access" as the most important factor affecting their decision to self-treat with OTC products. This was followed by minor illness (28 percent), sufficient pharmacological knowledge (21 percent), more cost effective (eight percent), and finally, other (six percent of the seven pharmacists, easy access, minor illness, and sufficient pharmacological knowledge were equally the most important factors affecting their decision to self-treat with OTC products.

Conclusion: Based on the results obtained from the analysis of the self-treatment preference questionnaires, it is concluded that pain is the most common condition to be self-treated using OTC products by student pharmacists, and easy access to OTC products is the most common factor affecting student pharmacists' decision to self-treat with OTC products at Hampton University. Amongst the pharmacists at Hampton University, allergies is the most common condition to be self-treated using OTC products, and minor illness, easy access, and sufficient pharmacological knowledge are all equally preferred most common factors affecting their decision to self-treat with OTC products.

Poster Title: Effectiveness of topical extemporaneously compounded formulation of timolol 0.5% gel in patients with infantile hemangioma.

Primary Author: Saul Castaneda, Faculty of Chemical Sciences and Engineering, Autonomous University of Baja California, Mexico; **Email:** saulcashe@gmail.com

Additional Author (s):
Pedro A Leon
Esbeydy Garcia
Hermelinda De la Cruz
Jose Luis Sanchez P.

Purpose: Infantile hemangioma (IH) is the most common vascular tumor in childhood, with prevalence in the first year of age of 10%. Propranolol is currently an effective treatment option; and because of his systemic effect, but only is indicated in patients older than 6 months of age. Timolol a beta blocker used in eye glaucoma also has shown effectiveness as topical formulation in neonates and pediatric patients with IH in European populations.
The porpouse is to Evaluate the therapeutic effectiveness of topical extemporaneously compounded formulation of timolol 0.5% gel in a group of patients with diagnosis of superficial infantile hemangioma.

Methods: An open prospective observational study at the Children's Hospital of the California´s in Mexico was performed in childrens diagnosed with infantile hemangioma, between the ages of 1 to 8 months. Patients were treated with extemporaneously compounded formulation of timolol 0.5% gel prepared by the pharmacist, administered topically every 12 hours. The treatment efficacy was assessed using a visual scale clinical improvement by the dermatologist, and safety of timolol was determined based on the adverse effects reported.

Results: 51 patients were treated in the period of May 2015 to 2016, 47% female and 53% male. The IH location was mainly in head and neck (59%). The effectiveness was presented in 88% of the patients with a rating of excellent and good treatment, reflected in the decrease in size and coloration of the hemangioma. Treatment had an average duration of 5.0 ± 2.2

months. Side effects were presented in 8% of the patients. Along the study 375 extemporaneously compounded formulations of timolol were elaborated by the pharmacist.

Conclusion: Topical timolol 0.5% gel proved to be an effective and safety option to reduce the size and coloration of infantile hemangioma in neonate and pediatric patients. In addition to being an important alternative to considered when systemic treatment is contraindicated.

Poster Title: Review of urinary tract infection management for patients admitted to the emergency department: assessment of adherence to guidelines and identification of hospitalization criteria

Primary Author: Ramdani Alaa, Aix-Marseille university, France; **Email:** aramdani.pharmacien@gmail.com

Additional Author (s):
Stanislas Rebaudet
Nadine Beni-Chougrane
Guillaume Penaranda
Emilie Coquet

Purpose: Community-acquired urinary tract infection (UTI) is one of the most common indications for antibiotic prescription. Previous studies on the adherence to guidelines on antibiotic use reported a prevalence of inappropriate prescriptions varying from 20 to 50%, both in the community and hospital settings. The misuse of antibiotics not only have an important economic impact but can also lead to therapeutic impasses.
This study aimed at establishing the current management of UTIs for patients admitted to the emergency department (ED) of our hospital.

Methods: In this retrospective observational study conducted between January 2015 and May 2016, consecutive patients admitted to the ED for a suspected UTI were included, including patients hospitalized (n=50) or discharged (n=50) after their ED admission. Assessment of adherence to guidelines for antibiotic prescription was conducted using the guidelines of the French-speaking society of infectious disease (SPILF).

Results: In the hospitalized group, 22 (44%) antibiotic prescriptions initiated at the ED did not comply with national guidelines. The two main causes for inappropriate prescriptions were the use of two antibiotics in patients with no severity criteria (15, 68%) and/or the use of a non-recommended drug (6, 27%). In this group, 17 (35%) antibiotic prescriptions ordered by the urologist on patients' discharge did not comply with national guidelines. The two main causes

of inappropriate prescriptions were the use of a non-recommended drug (9, 53%) and an inadequate duration of treatment (9, 53%).

In the discharged group, 29 (60%) of the antibiotic prescriptions ordered at the ED did not comply with national guidelines. The two main causes of inappropriate prescriptions were an inadequate duration of treatment (23, 79%) and the use of a non-recommended drug (19, 66%).

We could also identify discrepancies between reasons for hospitalization in our cohort compared to the criteria for hospitalization mentioned in the national guidelines.

Conclusion: This study has identified areas of improvement for the management of UTIs in our hospital. Our suggestions for optimisation include educational materials and a decision tree displayed at the ED, and specific therapeutic protocols in our computerized prescription system.

Poster Title: Evaluation of a Digestive tract Selective Decontamination protocol in an critical care unit

Primary Author: Alba Leon, HOSPITAL UNIVERSITARIO DE CABUEÑES, Spain; **Email:** barbosa.leon.alba@gmail.com

Additional Author (s):
Aitor Ruiz
Ana Blázquez
Ruben Sanchez
Maria Teresa Braña

Purpose: To evaluate the adequacy of Digestive tract Selective Decontamination (DSD) protocol and the impact on the incidence of nosocomial infections (NIs) and multi-drug resistant bacteria (MRB) among patients hospitalized in an critical care unit (CCU).

Methods: Retrospective, descriptive study of patients included in the protocol for 6 months (from 02/01/2015 to 08/31/2015). The protocol consists of the following administration: 1. Broad-spectrum antibiotic during first 4 days; 2. Topical non-absorbable antimicrobials for the oropharynx (cream) and digestive tract (oral suspension (OS)) as compounding containing colistine, tobramycin, nystatin +/- vancomcyn; 3. Hand hygiene and sanitation; 4. Cultures at hospitalization and then weekly to control efficacy and resistance. Compounding, prepared by the Pharmacy Department, were dispensed in unit doses, reducing the risk of contamination. The MIXED DSD protocol included: cream, mupirocin cream (nasal route) and OS; STANDARD DSD protocol: cream and OS. Demographics data, average length of stay in CCU, symptoms and reason of prescription were gathered through electronic health record. These last two data were compared with the ones specified in the protocol. Symptoms: a) Orotracheal intubation >72 hours (OTI); b) Decreased level of consciousness (GCS≤11); c) Necrohemorrhagic pancreatitis; d) Radical esophagogastrectomy; e) Neutropenia. Prescription options: 1. MIXED a) Patients from other hospital (EXTERNAL) and patients admitted in our hospital for more than 72 hours (INTERNAL) and MRSA negative samples; b) Carriers of MRSA before and during hospitalization) 2. STANDARD (remaining patients). Data collected from the Spanish National

Study of Nosocomial Infection Control were utilized to measure the frequency of infection, comparing this period with the one without DSD (from 02/01/2014 to 08/31/2014).

Results: In this protocol were included 96 patients with a mean age of about 59 years and an average length of stay in CCU of 16 days. The distribution of symptoms was as follows: 75% OTI, 21% GCS≤11 and 4% neutropenia. Of the 96 patients, 47% started the MIXED treatment (67% INTERNAL, 23% EXTERNAL and 10% carriers of MRSA); 23% changed the treatment to a STANDARD one after MRSA negative samples. The remaining 53% started a STANDARD treatment. When evaluating the adequacy to the protocol, 91% of prescriptions fulfill the criteria for use, being the main cause of failure the wrong way of prescription.
The number related to incidence of NIs decreased from 19.14 to 7.14 for each 100 patients (reduction of 62.69%); ventilator-associated pneumonias (VAPs) from 2.4 to 1.74 per 1000 days of mechanical ventilation (MV) (reduction of 27.5%); central venous cateter-associated bloodstream infections (CVC-BSIs) from 8.66 to 4.8 episodes per 1000 days of CVC (reduction of 44.57%). There wasn´t any MRB to antimicrobials associated with DSD.

Conclusion: There was a high protocol compliance.
We reached the expected reduction related to incidences of NIs and CRBSIs according to published bibliographic data, being VAP susceptible to be reduced.

Poster Title: Efficacy and Safety of Tigecycline for patients with Multidrug-Resistant Acinetobacter baumannii Infection

Primary Author: Kyoung Eun Kim, Chonbuk National University, Korea; **Email:** roddmsl85@naver.com

Additional Author (s):
Jin Seon Beom
Hyo Cho Ahn
Ju Sin Kim

Purpose: Acinetobacter baumannii(A. baumannii) is one of the major cause of nosocomial infections and sepsis in severe ill patients. Carbapenem antibiotics are used for serious A. baumannii infection, however, carbapenem-resistant A. baumannii is increasing worldwide. In recent years, multidrug-resistant A. baumannii (MDRAB) has been an emerging problem and the treatment of it's infection is difficult. Because treatment options are limited for MDRAB infection, tigecycline is considered to be the drug of choice for MDRAB infection. In this study, we aimed to evaluate the efficacy and safety of tigecycline for patients with MDRAB infection.

Methods: We retrospectively analyzed medical records of patients who received tigecycline for longer than 4 continuous days intravenously for MDRAB infection from January 2010 to December 2015. We reviewed WBC, hs-CRP, procalcitonin (PCT) and negative conversion of cultures in order to determine the clinical effect.

Results: Among 61 patients who received tigecycline treatment for MDRAB in this period, 43 patients were included in this study. The 27 (62.7%) patients were male, and mean age of patients was 62.9 ± 15.2 years. The average treatment duration of the tigecycline was 15.9 ± 10.5 days and median length of the stay in hospital was 68.8 ± 43.6 days. There were no significant differences in WBC before and after tigecycline treatment (p=0.538) but hs-CRP, PCT was significantly reduced (p $\langle$ 0.05). Twenty-two patients (51.2%) received tigecycline monotherapy and 21 patients in combination with other antibiotics. There were no significant differences in clinical efficacy between the two groups (p=0.907). In outcomes measure, the total therapeutic response rate showed 62.8%. Twelve patients was shown to increase hepatic

enzymes or bilirubin. And three patients were experienced GI problems including nausea, vomiting and hiccup. But serious adverse event was not observed.

Conclusion: Our findings suggest that tigecycline may be safe and effective option for seriously ill patients with renal failure in the treatment of MDRAB infections. However, more prospective, controlled trials are required to objectively evaluate the efficacy and safety of tigecycline in MDRAB infection.

Poster Title: Salivary biomarkers in Alzheimer's disease

Primary Author: Gustavo Santos, Anhanguera University - Doctoral Program, Brazil; **Email:** gustavo_santos@uol.com.br

Additional Author (s):
Paulo Pardi

Purpose: Currently, there are several studies for the early diagnosis of AD through saliva. It seeks to identify the presence of substances such as Aß peptide and p-tau, as biomarkers. These tests are non-invasive and subsequent analysis is performed by the ELISA method, which is highly sensitive. Salivary levels of Ab42 can be seen as a potential marker of AD, cooperating to the exclusion of other types of degenerative disorders. Ab42 levels differ in control subjects without mild dementia, and risk markers for the development of AD patients.

Methods: This is a case-control study in patients with probable diagnosis and cognitively healthy patients without AD, which had as research centers the cities of São Paulo and Cuiaba, respectively the capitals of the states of São Paulo and Mato Grosso , in Brazil.Were invited to participate in this experiment, 120 elderly, arranged:
without AD Group: 60 cognitively healthy individuals without diagnosis of AD, aged over 60 years old, coming from the Laboratory of Vestibular Rehabilitation Master's Program in Vestibular Rehabilitation and Social Anhanguera University Inclusion in São Paulo - SP.
Group DA: 60 patients with probable diagnosis of AD, coming from the Geriatric Center in Cuiabá - Mato Grosso.Saliva was collected using vials Salivette® type, which consist of plastics tubing containing a cotton roll and a plastic filter. Immediately after the collection, the saliva were stored in refrigerator under the temperature of - 20 ° C, and kept stored up to p time they were processed to read the results.
After being removed from the freezing temperature, the saliva were subjected to centrifugation for five minutes at 3000 revolutions per minute (rpm).
At this point, call processing of samples, cotton Salivette® was discarded, and the separated saliva aliquots of 200 uL type in Eppendorf tubes for quantitation of the Aß-peptide and tau protein by ELISA.

Results: In the graph showing the concentrations of T-tau expressed in the saliva of healthy patients and patients with AD, we found that the T-Tau expression in patients (86.7 ng / ml) is significantly higher compared to patients without oF (134.4 ng / ml), confirming the hypothesis that t-tau can be used as biomarker for AD. In the graph that shows the concentration of Ab42 in the saliva of patients without AD and DA, it was observed that the variation, although small, points to higher concentrations of Ab42 in AD patients (11.47 pg / ml).

Conclusion: The experimental results and their respective validation by the literature search allowed to take as a possible outcome the following points. • The reduction in T-Tau expression and increased tau-p salivary occurred in the same group of patients with probable AD, there demonstrating viability for the use of these substances as biomarcadores.Novos are needed, involving the assessment of salivary expression substances such as beta amyloid peptide and tau protein to demonstrate the involvement of these components in patients with AD.

Poster Title: Evaluation of chemotherapy-related medication errors intervened

Primary Author: Donghak Lee, Catholic University of Daegu, Korea; **Email:** reimeyui@gmail.com

Additional Author (s):

Daeeun Lee

Jimin Ra

Bokyung Moon

Purpose: Chemotherapy is for treating cancer with anti-cancer agents. Chemotherapy may differ in dose or administration schedule based on the body surface area (BSA) and laboratory results of the individual patient, and the regimen is complicated by the variety of drug kinds, dosages and usages. In addition, the therapeutic index is narrow. So, if a medication error has occurred, it could have a serious effect on the patient, including death. The purpose of this study is to analyze the type and incidence of chemotherapy-related medication errors (ME), and to find very frequent or critical errors to prevent their potential occurrence.

Methods: Medication errors can occur at any time of the prescribing stage, the dispensing stage, and the administering stage respectively. Among them, we conducted the study with only ME found before preparation, in other words at the prescribing stage. We screened 11,244 chemotherapy-related prescriptions for outpatients and inpatients at Daegu catholic university medical center (DCUMC) from 1 October 2014 to 31 October 2015. Of these prescriptions, we reviewed the cases that had potential to harm patients and violate the process to decrease efficiency at the preparing stage. For this period, 437 ME cases occurred, resulting in interventions by pharmacists during their daily routine practice in the chemotherapy preparation room, they were submitted in error reports in the Electronic medical record (EMR). These interventions were based on patients data available on the EMR and drug-specific information, and investigated by two research pharmacists retrospectively. The analysis was classified by 9 categories: (the diluent, the dose, the administration schedule, the drug code of DCUMC, the omission of medication order to be scheduled, the prescription route, the mix group, the economics of anti-cancer agents, and others), and their type and frequency were analyzed. In general, the diluent category covered the drug adequacy, concentration, stability,

and the volume of diluents. This study was performed by detecting the prescriptions actually modified, excluding those modified by the needs of physicians.

Results: During the study period, the total number of ME was 437. Prescription route errors were the most common at 123 cases (28.1%). These involved cases in that general drugs were prescribed to the chemotherapy preparation room or anti-cancer agents that are required to be mixed were prescribed to the inpatient pharmacy. The following 110 cases (25.2%) consisted of an incorrect diluent including serious mistakes confusing dextrose in water with normal saline. Next, incorrect dosage of drug category (52 cases, 11.9%) contained cases prescribed with doses calculated by the individual BSA of the wrong patient, doses beyond the safety range of the drug, doses written in grams instead of milligrams, and doses reduced incorrectly. And a mix group designated incorrectly (61 cases, 14.0%) were next, as well as many administration schedule errors contrary to regimens reflecting the type of tumor (15 cases, 3.4%) and uneconomic drug prescriptions (14 cases, 3.2%). Other than that, there were drug code errors (6 cases, 1.3%), medication order omissions (5 cases, 1.1%), and other errors (51 cases). Some of the other errors included fatal administration route errors such as a change from intrathecal injection to intravenous injection or from intravenous injection to subcutaneous injection.

Conclusion: Pharmacy interventions among the staff could reduce the number of ME before the dispensing stage and the administering stage. In order to reduce ME, both pharmacists and other staff need to be encouraged to report ME. Besides, It is necessary to develop a chemotherapy assistant program to find and prevent the incorrect route or the incorrect diluent errors that occur frequently, instructing pharmacists to know before preparation. And appropriate education training for prescribers as well as pharmacists should be delivered.

Poster Title: Efficacy of fish oil-based versus soybean oil-based fat emulsion in the occurrence of parenteral nutrition-associated liver disease in premature infants

Primary Author: Ji-eun Kwon, the Catholic University of Korea, Korea; **Email:** csoko83@cmcnu.or.kr

Additional Author (s):
Ae-Ryoung Park
Soon-Joo Kim
Shin-Yi Hwangbo
Hyen-O La

Purpose: Administration of parenteral nutrition (PN) is critical for growth and effect of therapy in premature infants. However, in many of these infants, long term PN is associated with development of PN associated liver disease (PNALD). Recent reports show that omega-6 fatty acid in the soybean oil fat emulsion may be responsible for promoting PNALD. Fiish oil fat emulsion have been used in preterm infants for their reduction effect of PNALD. The aim of this study was to evaluate the effect of fish oil fat emulsion and soybean oil fat emulsion on the occurrence of PNALD in PN dependent preterm infants.

Methods: This study was designed for the premature infants who administered PN with lipid emulsion for at least 4 weeks at Seoul St. Mary's hospital's neonatal intensive care unit. Between September 2013 and February 2014, preterm infants who received PN with soybean oil fat emulsion were classified as SO group. And between September 2014 and August 2015, preterm infants who received PN with fish oil fat emulsion were classified as FO group. To evaluate the liver toxicity, we investigated the change of aspartate transaminase (AST), alanine transaminase (ALT) and direct bilirubin (DB) on the first day and the final day of PN. Also, to evaluate the nutritional status, we investigated the change of weight, total protein, albumin and triglyceride (TG) on the first day and the final day of PN.

Results: 74 patients were included in the study. 32 premature infants were included FO group. And 42 premature were included SO group. The change of AST was decreased 0.5 IU/L in FO group. But the change of AST was increased 8.5 IU/L in SO group. This result showed statistically

significant difference (P=0.02). The change of ALT and DB were increased 13 IU/L, 0.18 mg/dL in FO group and 27.5 IU/L, 0.53 mg/dL in SO group. These results showed no statistically significant difference. The change of weight, total protein were no significant difference. But the change of albumin level in FO group was significant greater than in SO group (0.74 mg/dL versus 0.46 mg/dL, P=0.01). Also, the change of TG level was decreased 90 mg/dL in FO group and increased 4.5 mg/dL in SO group (P=0.03).

Conclusion: Compared with the two groups, there was a significant decrease in AST of FO group. And the increase of albumin, TG level in FO group were significantly greater than SO group. In conclusion, this study suggests that fish oil fat emulsion may give the result for the effective decrease of the risk of PNALD. Also, fish oil fat emulsion was effective in the improvement of nutritional status in preterm infants.

Poster Title: Efficacy and safety evaluation of pegfilgrastim in patients with non-Hodgkin's lymphoma

Primary Author: Da Som Jung, The Catholic University of Koreaa, Korea; **Email:** sadadazio@gmail.com

Additional Author (s):
Hyun Jun Gu
Ok Youn Han
Hyen Oh La

Purpose: Myelosuppressive chemotherapy-induced neutropenia must be considered as an extremely serious condition, because it makes the body vulnerable to bacterial and fungal infection and can lead to life-threatening complications including sepsis. Pegfilgrastim(Neulasta®) is a PEGylated form of the recombinant human granulocyte colony-stimulating factor (G-CSF) analog filgrastim. Compared to other G-CSFs, pegfilgrastim is approved for prophylactic use in patients with nonmyeloid malignancies receiving myelosuppressive anti-cancer drugs associated with a clinically significant incidence of febrile neutropenia.
In this study, we aimed to assess the efficacy and safety evaluation of pegfilgrastim in 'real world' patients receiving chemotherapy regimens associated with a high neutropenia risk.

Methods: This retrospective study utilized data from patients who received first cycle of CHOP(cyclophosphamide, doxorubicin, vincristine, prednisolone or dexamethasone), R-CHOP(rituximab-CHOP), ICE(ifosfamide, carboplatin, etoposide), DHAP(cisplatin, cytarabine, dexamethasone), ESHAP(etoposide, methylprednisolone, cisplatin, cytarabine) chemotherapy for Non-Hodgkin's lymphoma(NHL) at Seoul St. Mary's hospital from March 2014 to August 2014. Subjects using pegfilgrastim(Pegfilgrastim group) were compared with those not using pegfilgrastim(Control group).

Results: A total of 56 patients, 29 patients were pegfilgrastim group and 27 patients were control group. The incidence of chemotherapy-induced neutropenia was significantly lower in the pegfilgrastim group than in the control group(37.93% vs. 81.48%, p=0.0009). Even though

the incidence of chemotherapy-induced febrile neutropenia was lower in pegfilgrastim group than in the control group(10.34% vs. 25.93%, p=0.171), there was no statistically significant difference between two groups. Adverse event occurred in only 1 patient in the pegfilgrastim group.

Conclusion: In NHL patients receiving myelosuppressive chemotherapy regimens associated with a high neutropenia risk, pegfilgrastim prophylaxis significantly reduced the incidence of chemotherapy-induced neutropenia. Therefore, prophylactic use of pegfilgrastim is considered as a suitable treatment for these patients. Further investigation is needed to evaluate the safety and cost-effectiveness of pegfilgrastim in NHL patients with febrile neutropenia.

Submission Category: Pain Management

Submission Type: Evaluative Study

Poster Title: Under optimized multimodal analgesia after major joint replacement surgeries in Korean national sample: focusing on the utilization of acetaminophen

Primary Author: Ji Hyun Park, College of Pharmacy, Seoul National University, Korea; **Email:** pharmerpark@snu.ac.kr

Purpose: Best available evidence on perioperative pain management recommends the use of multimodal analgesic therapy for all postsurgical cases. Component therapies of multimodal analgesia remain widely variable, however, the use of acetaminophen in postsurgical patients is consistently recommended by practice guidelines. The main goal of this study was to assess the use of postsurgical acetaminophen to predict national-level utilization of multimodal analgesia after major joint surgeries in Korea.

Methods: Using the Health Insurance Review & Assessment Service-National Patient Sample (HIRA-NPS) extracted from the entire population of the Korean National Health Security System (2014) applying a stratified randomized sampling method. Subjects were those who underwent knee replacement or total hip replacement surgeries. All available dosage forms of acetaminophen in Korea, such as extended-release tablet, syrup, or sterile injection solution of propacetamol were considered. Patients were regarded to have acetaminophen for their acute postoperative pain if they received acetaminophen dose more than 3,000 mg per day over two consecutive days.

Results: Among 10,771 patients of total knee and hip replacement surgeries in 2014, the average total caring periods related to the surgeries including discharge medications in 1,450 acetaminophen users were 41.8 days (minimum 0 day, maximum 161 days). For 9,321 patients who were not received acetaminophen, the average total caring periods were 35.9 days (minimum 0 day, maximum 208 days). The use of acetaminophen for acute postsurgical pain management was 13.5% (N= 1,450), which was fairly conservative compared to that of in the United States. The mean usage period of acetaminophen was 11.3 days (minimum 2 days, maximum 91 days), and the mean dose of acetaminophen per person per day was 1,942.4 mg (minimum 640 mg/d. maximum 8,000 mg/d).

Conclusion: According to the results of the analysis, the use of acetaminophen for postsurgical pain management is under optimized in major joint replacement surgeries in South Korea. It indicates limited utilization of multimodal analgesia for postsurgical patients in South Korea.

Poster Title: Management of surgical pain with dexketoprofen on pediatric patients of a Mexican Hospital

Primary Author: Jorge Jimenez Niebla, Universidad Autonoma de Baja California, Mexico; **Email:** ljimenez27@uabc.edu.mx

Additional Author (s):
Alan Pacheco Aguilar
Azucena Guadalupe Luna Arreola
Elvira Nieto Elicerio
Hermelinda De la Cruz Duran

Purpose: Dexketoprofen is the dextro-rotatory enantiomer of ketoprofen, an NSAID derived from the propionic acid. Is documented its efficacy in the management of postsurgical pain in patients after 12 years with usual doses of 50 mg every 8 or 12 hours, and maximum of 150 mg per day. At the Hospital Infantil de las Californias (HIC), dexketoprofen is used since the year 2008, usually in combination with other analgesics. Through the review of files, we show the prevalence and management of this drug in patients treated in the Ambulatory Surgery Center (CCA) of this hospital and the utility in pediatrics patients.

Methods: A retrospective study was conducted with the information contained in the files of the patients who had a surgical procedure during the year 2015, selecting a random sample of 300 files of a total of 859 corresponding to that period. A format was developed to collect the necessary information about the patients and the procedures performed. The documented variables were -file number, age, weight, sex, surgery(s) practiced(s), date, implementation and results of the scale for the measurement of pain (VAS and/or BPS), concomitant drugs (differentiating narcotics of other analgesics and drugs for other purposes), dose, route of administration, dosing interval, moment(s) of administration (pre-surgical, trans-surgical and post-surgical) and number of doses. The analysis of the information was carried out using the statistical program Statistical Package for Social Sciences® (SPSS®) version 21.0, for Windows.

Results: 300 files of patients that had some surgical procedure were reviewed: 185 men (62%) and 115 women (38%). Their ages were between 20 days and 18 years. The medical specialties in which surgical procedures were undertaken were -pediatric surgery (40%), orthopedics (18%), Ophthalmology (17%), Pneumology (8%), lip and palate (6.3%), otorhinolaryngology (5%), gastroenterology (3.7%), plastic surgery (1%), and 1 per cent other surgeries. In 118 patients (39%) dexketoprofen was administered; doses handled were 0.13-1.79 mg/Kg, with an average±SD 0.89±0.23 mg/kg intravenously. The concomitant analgesics were metamizole, fentanyl, nalbuphine and morphine and in only 16 patients the treatment of the pain was just with dexketoprofen. In 84% of the patients was applied the scale of Visual Analog Scale for assessment of pain.

Conclusion: Besides the fact that there is currently controversy about the use of dexketoprofen in individuals under the age of 12 and that in Mexico is not recognized its use in Pediatrics, the Hospital Infantil de las Californias has used this analgesic without showing adverse reactions. The analysis of 300 files of patients with some surgical procedure in the ASC of HIC showed that 39 per cent of them were administered this analgesic with an average effective dose of 0.89 mg/kg intravenously. These results help us to create a protocol for further efficacy and safety analyses.

Poster Title: Incorporation of pharmacy services at an advanced plastic surgery center in Tijuana, Mexico.

Primary Author: Itzel Del Real, Autonomous University of Baja California, Mexico; **Email:** farmaciatjplast@gmail.com

Additional Author (s):
SAUL CASTANEDA|
HECTOR MILLA
Ruth Milla

Purpose: The hospital TjPlast is an institution that specializes in procedures of plastic, aesthetic and reconstructive surgery performed in a professional manner and with high technology, which is why it took the initiative to incorporate a pharmacy specialist to the group of quality professionals that are already working in the institution beginning with activities focused on optimizing the distribution and dispensing of medicines and health products.
Assess the impact of the incorporation of the pharmacist in the area of plastic surgery in activities related to management medication use.

Methods: An space was settle for the pharmacy and we modified manuals and formats of distribution activities and dispensing medicines and medical supplies was organized.
The impact assessment was carried out by statistics that illustrate the type of procedures performed, the amount of dispensed medicines and the therapeutic group that they belong to, efficient use of drugs as well as internal reports of perceived improvements after incorporation of the pharmacist.

Results: During the period May 2016 to July 2016, we managed to implement a hospital pharmacy in TjPlast, which meets the requirements set by current regulations. Medication use was assessed and process improvements medication stages were performed. Health personnel reported that delays or cancellations of surgeries due to lack of drugs decreased by 80%. Pharmaceutical care in 116 patients was achieved. The main therapeutic groups dispensed were: Antibiotics (32%), anti-inflammatories (26%), anesthetics (19%).

Significantly, most plastic surgery clinics in Mexico do not have pharmacists for the proper use of medication. For this reason we consider important the inclusion of the pharmacist in this type of service.

Conclusion: The incorporation of the pharmacist had a positive impact as it provides knowledge towards continuous improvement for the safety of patients, but there are even more activities that can be develop to promote the correct use of medication, which is to implement later.

Poster Title: Design and Development of a Modular Compounding Starter-Kit

Primary Author: Beatriz Jimenez-Mangual, Nova Southeastern University, College of Pharmacy, Puerto Rico; **Email:** bj417@nova.edu

Additional Author (s):
Javier Carmona-Morales
Mercedes Dorado-Rodriguez

Suheily Padilla-Quiros

Purpose: Pharmacists are authorized by law to perform compounding through a validated prescription or order issued by a licensed prescriber. The practice of compounding consists on the mixing, combination, and alteration of drug ingredients, which enables the pharmacist to provide medications and novel dosage forms tailored to meet individual patient's needs. Nowadays, compounding is re-emerging as a pharmacy specialty with a tremendous potential for professional development and financial opportunities for retail pharmacists. The aim of our proposal was to design an innovative modular compounding starter-kit for non-sterile compounding in community pharmacies in Puerto Rico, and encourage pharmacists to venture into compounding.

Methods: A comprehensive literature review was conducted to scope the need and market opportunities for pharmaceutical compounding globally, and to assess the existence of a modular compounding kit similar to our proposed unit. In addition, a group of ten independent community pharmacy owners were interviewed to inquire about their willingness to incorporate compounding services in their pharmacies using our proposed modular unit. Selected pharmacies were identified from strategic locations in Puerto Rico with representation from all cardinal points of the island. Investigators contacted pharmacy owners via phone or personal visit and requested their consent to give a brief orientation about the product. After the orientation, the pharmacy owner was given a brochure describing our proposed modular compounding starter-kit, and was also requested to complete an 8-item questionnaire in order to assess their receptiveness to our novel unit.

Results: Findings from our literature review revealed a trend of stable growth of the pharmaceutical compounding market globally due to rising demand for personalized medicines to meet individual patient needs. However, no modular compounding units intended for use in community pharmacies were identified from our search. Among surveyed pharmacy owners, only 70% were engaged in compounding activities and reported an average of 16 compounding prescriptions per month. Eighty-percent of participants agreed that the compounding market in Puerto Rico has a potential for growth, and 50% were willing to invest in compounding. Regarding the pharmacy owner's receptiveness to the modular compounding starting kit, 90% agreed it is an innovative and interesting concept, and 80% reported their willingness to acquire the unit if available in the market.

Conclusion: Based on the feedback received from interviewees, a prototype of the compounding starter kit was built following the minimum legal requirements for non-sterile compounding stated by the Pharmacy Law of Puerto Rico and Regulation 156. Our novel Starter-Kit was designed to meet the required standards to help pharmacies engage in compounding in a fashionable, simple, professional, and affordable way. If performed professionally and following the highest standards, pharmaceutical compounding throughout a portable modular unit offers the the independent community pharmacists an opportunity to increase its profits, but most important, it will increase pharmacist's and patient's satisfaction with individualized therapeutic care.

Poster Title: Antibiotic dispensing patterns in community pharmacies in Minia, Egypt : a simulated patient study

Primary Author: Abdallah Abdelaziz, Faculty of Pharmacy, Minia University, Egypt; **Email:** abdullahismail095@gmail.com

Additional Author (s):
Abdel-Rahman Tawfik
Khaled Abdel-Rahman
Mohamad Omran
Al-Shaimaa Ahmed

Purpose: Although antibiotics saved countless number of lives since their discovery, recent reports have confirmed that we are rapidly approaching a time when minor curable infections will become deadly. Being the first point of contact with patients, community pharmacies play a crucial role in the regulation of antibiotics self-medication in developing countries. This is evident in Egypt, where lack of antibiotic dispensing regulations made rational use of antibiotics totally dependent on the attitude and knowledge of pharmacy staff. Thus, the aim of our study is to evaluate the quality of community pharmacies' practices toward self-medication with antibiotics in Minia governorate, Egypt.

Methods: Patient simulation methodology was employed as a tool for evaluation. Four trained undergraduate pharmacy students acted as simulated clients who visited randomly selected community pharmacies in Minia Governorate, Egypt (n=100) asking for amoxicillin. The simulated patent was a 40 year-old male with low grade fever and productive cough with purulent green sputum and malaise that was persistent for 3 days. The diagnosis should be made as a case of acute bronchitis. The SP is allergic to penicillin. SP has no prescription and has not been diagnosed by a GP. No information was provided to the pharmacy staff until being requested. The visits were recorded and filled in a standard data collection form by the SP, after completion of each visit immediately with the aid of a co-observer in order to minimize recall bias. The measured variables were: pharmacy demographics, service provider, asking about patient characteristics and dispensing patterns. The visits were done in different times to assure variability. The service provider profession (either being a pharmacist or not) was estimated by

one SP and confirmed with a second visit from another simulated patient in which the SP asked for the pharmacist directly.

Results: In 100 community pharmacies, 52.63% of service providers were pharmacists, 18.95% were pharmacy assistants, 3.16% were pharmacy assistants who referred the case to a pharmacist, 17.89% were sellers and 1.05% were pharmacy students. Generally, 95.7% dispensed amoxicillin (AMX) for the SP. Sixty nine percent of community pharmacies dispensed AMX to the SP without even knowing the reason of the request or checking symptoms. AMX was dispensed in 28.57 % of pharmacies after asking about symptoms. Only one percent abstained from dispensing AMX after knowing the symptoms and 1.09% did not ask about symptoms and did not dispense AMX. 95.6% of community pharmacies dispensed AMX without asking to see a prescription and 94.5% dispensed AMX without asking about previous diagnosis with bacterial infection. 5.61 % of pharmacies asked about previous diagnosis or a prescription before dispensing. 80% of pharmacies dispensed AMX after knowing that the SP has neither a prescription nor a previous diagnosis with bacterial infection. Surprisingly, 96.7% of pharmacies did not ask about penicillin allergy. Only 1.09% asked about allergy and dispensed cefadroxil as alternative while 1.09% abstained from dispensing AMX after asking about drug allergy. 100% of community pharmacies provided no counselling about the adverse reactions of AMX.

Conclusion: Although the majority of service providers were pharmacists, patient simulation shows a dangerously low level of community pharmacies' practices toward dispensing antibiotics. The current attitude and knowledge of pharmacy staff in Minia, Egypt toward dealing with acute bronchitis infections or dispensing antibiotics particularly are highly incompetent in facing the phenomenon of self-medication with antibiotics.

Submission Category: Small and Rural Pharmacy Practice

Submission Type: Evaluative Study

Session-Board Number: 5b-147

Poster Title: Evaluating the potential overuse of short acting inhalers in patients with chronic obstructive pulmonary disease (COPD) in a community pharmacy

Primary Author: Victoria Minton, Lipscomb University College of Pharmacy, Tennessee; **Email:** vlminton@mail.lipscomb.edu

Additional Author (s):
Justin Kirby
Benjamin Gross

Purpose: The purpose of this study is to assess the potential overuse of short acting inhalers in patients with chronic obstructive pulmonary disease (COPD) in a community pharmacy setting and make necessary interventions if needed. People with COPD are often using their short acting inhaler multiple times per day, indicating they are currently uncontrolled. These people may need additional therapy or counseling on proper inhaler technique. It is at this point pharmacists can provide the necessary intervention by recommending additional treatment to a physician, counseling on proper inhaler technique and use, or counseling on smoking cessation.

Methods: Subjects were recruited from a community pharmacy's prescription records and were included using predetermined criteria. Fill history data was collected on all prescriptions of albuterol HFA inhalers: ProAir©, ProAir Respiclick©, Ventolin©, and Proventil© filled from 01/01/2016 to 08/15/2016. Daily reviews of all short acting inhaler prescriptions were conducted. Subjects who could be contacted in person were asked if they would consent to complete a standardized, validated questionnaire to determine their COPD Assessment Test (CAT) and Modified Medical Research Council (mMRC) dyspnea scale scores. An alert note was placed with the inhaler for any subjects refilling a prescription. If the subject could not be contacted in person, a phone call was made and the same procedure was performed telephonically. Based on their scores, subjects were categorized according to the Global Initiative for Chronic Obstructive Lung Disease (GOLD) guidelines and their current medications were assessed. If it was determined that the subject was uncontrolled, a recommendation along with its evidence was sent to their physician. Subjects were asked how they were using their inhalers and counseled on technique if necessary. If the subjects admitted to smoking they

were counseled on smoking cessation. If patients could not be contacted while in the store or telephonically, a second phone call was attempted. Subjects were excluded if no contact was made on the second attempt.

Results: Qualified interventions included counseling on smoking cessation, counseling on proper inhaler technique, counseling on proper inhaler utilization, and contacting the provider with a recommendation if the subject was not on the appropriate therapy based on the GOLD guidelines. A total of 118 subjects were identified based upon the inclusion criteria. A total of 41 subjects were excluded based upon the exclusion criteria. A total of 38 subjects were unable to be contacted on a second attempt, leaving a total of 39 subjects that gave consent and completed the questionnaire. A total of 10 of the 39 (25.6%) did not require any interventions, 15 of the 39 (38.46%) required counseling on proper inhaler technique, and 11 of the 39 (28.21%) required counseling on proper use of their inhaler. A total of 12 of the 39 (28.21%) subjects admitted to continued cigarette use and were counseled on smoking cessation. Of the 39 subjects, 8 (15.38%) were identified as needing a change in therapy and a recommendation was faxed to the subject's prescriber. Out of the 8 recommendations made, the provider accepted 6. A total of 50 interventions were made during the study period.

Conclusion: As indicated by these results, there is great opportunity for pharmacists to make interventions on behalf of COPD patients. Since pharmacists are easily accessible to these patients, they have the ability to assist patients in receiving optimal benefit from their medications. This data indicates that many patients are experiencing unnecessary symptoms, most of which could be avoided with additional counseling. By providing these interventions to patients, we are able to demonstrate the vital role that we play in patient care.

Poster Title: Trimethoprim/sulfamethoxazole induced liver injury in the treatment of pneumocystis jiroveci pneumonia in an oncology patient

Primary Author: Caitlin Waldroup, Bill Gatton College of Pharmacy, Tennessee; **Email:** waldroup@goldmail.etsu.edu

Additional Author (s):
John Bossaer

Purpose: Hepatic injuries caused by trimethoprim/sulfamethoxazole are considered to be very rare and unpredictable however of all the antibiotics that has been studied to cause drug induced liver injury it is the fourth most common to do so. There is limited evidence that exist on the risk factors of drug induced liver injury however it has been shown that drugs given in higher doses of 50 mg daily are more likely to lead to drug induced liver injury than lower doses. In this case trimethoprim/sulfamethoxazole was used in the treatment of pneumocystis jiroveci pneumonia. PCP can be a life threatening acute lung disease in a patient who is severely immunocompromised and is treated with a dose of 15 to 20 mg of trimethoprim/kg/day divided every 6 or 8 hours per manufacture labeling. A 55 year old woman receiving chemotherapy for primary CNS lymphoma with a regimen of day one Rituximab 500 mg/m2, day two Vincristine 1.4 mg/m2 and Methotrexate 3.5 mg/m2 then on odd cycles Procarbazine 100 mg/m2 (days 1-8). The patient received cycle four 10 days prior to presenting to the emergency room with profound shortness of breath and fever. The CT chest scan showed small pleural effusion/multifocal consolidations confirming pneumonia. After several days of not improving on broad spectrum antibiotics it was suspected that the patient may have PCP so trimethoprim/sulfamethoxazole was started at 2 tablets every 8 hours for 21 days (12.3 mg/kg/day of trimethoprim) . The patient improved rapidly and was discharged days later to a nursing home facility close to home. After a total of five days of being on the antibiotic the patient was readmitted to the hospital with elevated liver enzymes. The nursing facility had stopped the trimethoprim/sulfamethoxazole two nights prior to being admitted to the hospital. The patient presented with jaundice eyes and itching all over along with a rash that had improved since trimethoprim/sulfamethoxazole had been discontinued. The liver enzymes upon arrival were as follows, ALK 1156, AST 258, and ALT 496. On day two of the admission the liver enzymes continued to be elevated at ALK 1176, AST 174, and ALT 394. At this point it had

been 23 days since her last administration of chemotherapy concluding that the chemo was not the causative agent. Extensive research was then performed on all medications that had been administered in the past few weeks and other than the trimethoprim/sulfamethoxazole no identifiable causative agents were discovered. Trimethoprim/sulfamethoxazole induced liver injury is classified as either unpredictable or idiosyncratic type of reaction with the most common pattern of injury (60 percent) being cholestasis. The onset of cholestasis typically occurs within 7 days after the initial administration of trimethoprim/sulfamethoxazole which fits the time frame in which this patient's liver injury occurred. Given the relationship between the trimethoprim/sulfamethoxazole and the time of onset along with an increased risk of drug induced liver injury due to the high dose used, it is apparent that trimethoprim/sulfamethoxazole is the mostly likely cause of this patient's liver injury.

Poster Title: Evaluation of outcomes pre and post implementation of a standardized pathway in pediatric posterior spinal fusion patients

Primary Author: Kembral Nelson, University of Tennessee College of Pharmacy, Tennessee;
Email: knelso15@uthsc.edu

Additional Author (s):
Leslie Rhodes
Lindsey Locke
William Mabry
Kelly Bobo

Purpose: Prior to 2011, the care of the post-operative posterior spinal fusion (PSF) patient was based on individual physician preference. A comprehensive review of the literature determined the importance of standardization of post-operative care. The purpose of this study was to evaluate patient outcomes pre and post implementation of a standardized pathway in PSF patients. Outcomes analyzed include length of stay, pain control, narcotic usage, time to ambulation, and time to regular diet.

Methods: Institutional Review Board approval was obtained to conduct a retrospective review of 64 patients with adolescent idiopathic scoliosis (AIS) treated with a PSF. All patients between 10-21 years of age with a diagnosis code of AIS and a procedure code for PSF admitted to the hospital from April 1, 2010-March 30, 2011 (n equals 27) were included in the pre-standardization group and those admitted April 1, 2014-March 30, 2015 (n equals 37) were included in the post-standardization group. Patients were excluded if they had a chronic condition including renal disease/dysfunction, seizures, and/or neurologic disorders.

Results: Data were analyzed using generalized estimating equations and the Wilcoxon Signed Rank test. With matched analyses comparing patient and clinical characteristics based on sex, race, age, and BMI, n equals 25 in both the pre and post standardization groups. The alpha equals 0.001. Although not statistically significant (p equals 0.0166), the median length of stay was 5.3 days [Interquartile Range (IQR) 5.2-5.4] and 4.4 days [IQR 4.3-4.6] in the pre and post standardization groups, respectively. Time to ambulation in the hall was significantly different

between the groups with the pre-standardization group ambulating on median post-operative day (POD) 3 [IQR 3.0-3.0] and the post-standardization group ambulating on median POD 2 [IQR 2.0-2.0] (p less than 0.0001). There was less usage of the patient controlled analgesia (PCA) with a median of 2.3 mg/kg [IQR 1.2-2.7] and 1.1 mg/kg [0.9-1.6] in the pre and post standardization groups, respectively (p less than 0.0001). The median morphine equivalent usage was 13 [IQR 0.0-160.5] and 3 [IQR 0.0-16.0] in the pre and post standardization groups, respectively. Also statistically significant, a regular diet was resumed on POD 4 [IQR 3.0-4.0] in the pre-standardization group and POD 2 [IQR 2.0-2.0] in the post-standardization group (p less than 0.0001).

Conclusion: Standardization of care for pediatric patients undergoing a PSF showed improved outcomes in our patient population. This was associated with less overall patient controlled analgesia and morphine equivalent usage along with decreased time to regular diet and mobilization in the hall, resulting in a shorter length of stay.

Poster Title: In his corner: the ongoing impact of patient-centered care on a high-utilizing patient with complicated chronic illness

Primary Author: Elizabeth Berryman, Lipscomb University College of Pharmacy, Tennessee; **Email:** egberryman@mail.lipscomb.edu

Additional Author (s):
Haden Geiger
Heather Davidson

Purpose: Healthcare Hotspotting is defined as applying resources to target patients, dubbed "super-utilizers", who are using a high percentage of healthcare resources and incurring excessive costs. As part of a minigrant project through the Camden Coalition of Healthcare Providers, Primary Care Progress, and the Association of American Medical Colleges; an interprofessional team of students sought to address issues surrounding a super-utilizing patient with sickle cell disease.

Methods: Primary outcomes for this project were frequency of emergency department (ED) visits and incurred costs over a 30-day period. A secondary outcome was hydroxyurea adherence as measured by mean corpuscular volume (MCV), which is known to increase during hydroxyurea therapy. The team was comprised of pharmacy, medical, nursing, and social work students. Some patient-specific strategies to improve outcomes included: family involvement, persistent support of medication adherence and education, advocacy, care coordination, connection to the sickle cell community, and restoring attention to patient-identified goals.

Results: A downward trend was observed in both measures of utilization that were employed. Average ED visits decreased from 3.35 to 2.16 in a 30-day period. Average costs incurred per a 30-day period also decreased from $65,700 to $35,600. MCV values increased from an average of 87 fL to 92 fL demonstrating improved hydroxyurea adherence.

Conclusion: Super-utilizing patients account for a large majority of healthcare dollars spent and resources used. By targeting super-utilizing patient through interprofessional team based

medical and social interventions, healthcare utilization and costs can be decreased and quality of life improved.

Poster Title: Gnaphalin has preferential cytotoxic effects towards breast cancer MCF-7 and prostate androgen-dependent LnCaP cancer cell lines

Primary Author: Danny Pate, ETSU Bill Gatton College of Pharmacy, Tennessee; **Email:** drpate0715@yahoo.com

Additional Author (s):
Jordan Claborn
Matthew Abbott
Victoria Palau
Ruben Torrenegra

Purpose: Gnaphalin is a flavonoid extracted from a bioactive fraction of Gnaphalium gracile, a species that belongs to the family Asteraceae. Many species of the Gnaphalium genus are commonly used in the treatment of several different diseases, such as, skin infections, bronchial disorders, and cancer. These healing properties may be attributed to flavonoids, secondary metabolites in plants, with various bioactive properties including antioxidant, anti-inflammatory, antiviral, antimicrobial, and antineoplastic effects. Gnaphalin, was tested for antineoplastic activity on breast cancer cell lines MCF7, MDA-MB-231, and prostate cancer androgen-dependent LnCaP, and androgen-independent PC3 cell lines.

Methods: Cells were seeded on a 48 well plate with the appropriate media and were allowed to reach approximately 70 percent confluency, followed by treatment of Gnaphalin in concentrations of 5, 10, 20, 40, and 80 micromolar, or DMSO (dimethyl sulfoxide), the vehicle of dissolution at a final maximum concentration of 0.3 percent. Cells treated with DMSO were used as a control. After treatment, the cells were incubated for 24 hours and MTT (3-(4, 5-methyl-thiazol-2-yl)-2, 5-diphenyl-tetrazolium bromide) was used to determine cellular viability by adding it at a concentration of 100 microgram per well followed by incubation for 3 hours at 37 degrees Celcius. Purple crystal formation indicated cell survival. Formazan crystals were dissolved with acidulated isopropanol and a measurement of optical density was obtained by spectrophotometry at a wavelength of 590 nanometers.

Results: When determining potential anti-neoplastic agents, it is preferred to achieve desired effects at concentrations of less than 100 micromolar. Gnaphalin was tested on MDA-MB231 breast cancer cells and showed an IC-50 of greater than 80 micromolar. Gnaphalin lacked efficacy in the estrogen-independent MDA-MB231 cancer cell line. Gnaphalin was also tested on MCF 7 breast cancer cells and showed an estimated IC-50 of 40 micromolar. These results suggest an increased efficacy by Gnapahlin in the estrogen dependent MCF 7 cancer cell line. Testing of Gnaphalin on PC3 prostate cancer cells, never truly reached an IC-50 within the parameters studied. Thus, it demonstrated lack of efficacy in the androgen-independent PC3 cancer cell line. Gnaphalin was tested on LnCaP prostate cancer cells, with an estimated IC-50 of 60 micromolar. Gnaphalin showed a cytotoxic effect on androgen-dependent LnCaP cancer cell line.

Conclusion: Analysis of the data reveals a cytotoxic effect of Gnaphalin on cell lines MCF-7 (breast) and LnCaP (prostate). Both cell lines had acceptable IC-50s. MDA-MB-231 (breast) and PC3 (prostate) did not exhibit cytotoxic effects due to high IC-50 levels among the drug concentrations utilized. MDA-MB-231 is more tumorigenic and less differentiated than MCF7. MCF7 preferentially forms tumors in the presence of oestrogen. LnCaP is androgen dependent for cell growth and proliferation. Both MDA-MB-231 and PC3 exhibit a lack of hormonal dependency. These results may indicate that Gnaphalin has structural/functional characteristics that are detrimental to cancer cells with hormone dependency.

Poster Title: Intralipid sequestration of lipophilic compounds

Primary Author: Luke Bolin, Lipscomb University College of Pharmacy, Tennessee; **Email:** lbolin@mail.lipscomb.edu

Additional Author (s):
Matt Vergne
Michael Fowler
Wendell Akers

Purpose: Research in animal models and human case studies has shown the effectiveness of Intralipid Emulsion (ILE) in reducing toxic levels of lipophilic drug that are encountered in overdose situations. This study looks at the ability of ILE to sequester amitriptyline and verapamil along with their active metabolites to facilitate their elimination from the body. The goal was to develop and validate an in vitro assay that would accurately quantify concentrations of drug to confirm ILE sequestration in serum. This study will prove useful in estimating drug concentration levels in a patient presenting with overdose symptoms after receiving ILE treatment.

Methods: An assay was developed and standards were prepared to cover a range from therapeutic to toxic drug concentrations. The method was validated by preparing quality controls that were compared to known drug concentrations and then quantitated using LC/MS/MS analysis. These controls were then used throughout the study to ensure precision and accuracy. An in vitro model was developed using Rapid Equilibrium Dialysis (RED) devices which allow free drug to dialyze across a semipermeable membrane and equilibrate similarly to free drug in human serum across tissue compartments. Total and free drug serum concentrations were determined in the absence and presence of ILE at equilibrium and quantified using high performance liquid chromatography coupled with tandem mass spectrometry (LC/MS/MS).

Results: Equilibrium dialysis experiments showed there was an overall reduction in free drug concentrations with the addition of ILE for both amitriptyline and verapamil as well as their metabolites. Data showed that as serum drug and metabolite concentrations increased, the

percent reduction in free drug serum concentrations by ILE also increased. In both cases, free drug concentrations were reduced by ILE to a greater extent for the parent drug than its associated metabolite. The reduction in free drug concentrations by ILE were greater for amitriptyline than verapamil. Physiochemical factors that affected ILE sequestration include: Log P, Log D, protein binding, and percent drug ionized in serum.

Conclusion: Overall, these in vitro studies support the hypothesis that the administration of ILE enhances drug sequestration in the serum compartment and reduces free drug concentrations available for diffusion into peripheral compartments for both drugs and their metabolites. Characterizing the degree of intralipid drug sequestration based on the physiochemical properties of various compounds will aid in estimating the reduction in free drug concentrations encountered in an overdose patient after receiving intravenous ILE treatment.

Poster Title: Beta blocker use in hospitalized heart failure patients: Does target dose equal target heart rate control?

Primary Author: Abdulrahman Alshaya, The University of Tennessee Health Science Center, College of Pharmacy, Tennessee; **Email:** phd.abdulrahman@gmail.com

Additional Author (s):
Carlvin Metra
Timothy Self
Carrie Oliphant
Ryan Owens

Purpose: Beta blockers are recommended in heart failure with reduced ejection fraction (HFrEF) patients to reduce mortality and mortality, with a goal to titrate to a maximum dose. However, it can be problematic to attain these high doses in clinical practice secondary to the adverse event occurrence. Newer evidence has indicated that heart rate reduction, rather than beta blocker dose achieved, may be a better predictor of prognosis given the negative cardiovascular consequences of longstanding elevated heart rate. The purpose of this study was to describe discharge heart rate as a function of beta blocker dose in hospitalized HFrEF patients.

Methods: HFrEF patients admitted between September 2013 and September 2015 were reviewed. Inclusion criteria: at least 18 years of age, ejection fraction less than 40 percent, use of a HFrEF guideline recommended beta blocker for at least 48 hours' duration and appropriate concomitant standard heart failure regimen at discharge, which consisted of an angiotensin-converting enzyme inhibitor or angiotensin receptor blocker, a HFrEF guideline recommended beta blocker, and a diuretic. Exclusion criteria: ICU admission, dobutamine administration, administration of additional rate controlling agents, atrial fibrillation history, implantable pacemaker and documented noncompliance. Target beta blocker doses were defined as: bisoprolol 10 mg daily, carvedilol 25 mg twice daily, and metoprolol succinate 200 mg once daily. Optimal heart rate control was defined as a heart rate less than 70 beats per minute (bpm) and determined based upon the last heart rate captured in the medical record prior to discharge. Patients were divided into groups based upon the percentage of target beta blocker

dose achieved. The primary subgroup analysis was the achievement of optimal heart rate control in patients receiving less than 50 percent target beta blocker dose compared to ≥ 50 percent target beta blocker dose. Secondary analysis included describing the hemodynamic adverse effects experienced during index hospitalization secondary to beta blockade.

Results: Of the 3378 patients screened, 225 met inclusion criteria with 88 patients receiving less than 25 percent target dose, 58 receiving 25-49 percent target dose, 40 receiving 50-99 percent target dose, and 39 receiving 100 percent target dose. Mean discharge heart rate was 84 ±17 bpm for patients on less than 25 percent target dose, 84 ±13 bpm on 25-49 percent target dose, 80 ±13 bpm on 50-99 percent target dose, and 76 ±12 bpm on 100 percent target dose. Overall 20 percent of the total population achieved optimal heart rate control prior to discharge (n=46 heart rate less than 70bpm; n=179 heart rate greater than or equal to 70bpm). Similar rates of achievement were observed regardless of target beta blocker dose achieved (25 percent in the ≥50 percent target dose group vs. 18 percent in the less than 50 percent target dose group;p=0.23). Rates of bradycardia (28 percent in the ≥ 50 percent target dose group vs. 19 percent in the less than 50 percent target dose group;p=0.18) and hypotension (52 percent in the ≥ 50 percent target dose group vs. 50 percent in the less than 50 percent target dose group;p=0.89) were similar between groups.

Conclusion: Optimal heart rate control achievement was similar whether hospitalized HFrEF patients were receiving at least 50 percent target beta blocker dose or less. Despite lower average heart rates observed on 100 percent target dose, a low portion of the overall population achieved optimal heart rate control secondary to beta blockade. Inpatient beta blockade remains suboptimal compared to guideline recommended target doses despite no significant differences in adverse effects with higher beta blocker doses. Opportunities exist for inpatient beta blocker optimization prior to discharge to improve both suboptimal heart rate control and suboptimal beta blocker dosing relative to guideline recommendations.

Session-Board Number: 5b-154

Poster Title: Antiproliferative and chemosensitizing effects of metformin in neuroblastoma cell lines

Primary Author: Allison Karst, Belmont University College of Pharmacy, Tennessee; **Email:** allison.karst@pop.belmont.edu

Additional Author (s):
Cassaundra Boils
Kelley Kiningham

Purpose: Metformin is a medication commonly used as first-line treatment in type II diabetes mellitus. Established studies have demonstrated potential use of metformin in decreasing proliferation in various solid tumor cancer cell lines, including, but not limited to, breast, prostate, and lung. Neuroblastoma is known to be an extreme challenge for therapeutic intervention, and increasingly higher doses of chemotherapy are required due to resistance in many patients. Subsequently, this causes increasing toxicities. Validating metformin's effect on cell proliferation and chemosensitivity would add to existing data regarding its potential use in the prevention and treatment of neuroblastoma.

Methods: Human neuroblastoma cell lines SK-N-SH and SK-N-MC were maintained in Minimum Essential Media at 37 degrees Celsius in 5 percent carbon dioxide. To optimize experimentation cell density, a concentration range of cells were plated (SK-N-SH 2 x 103 to 7 x 103); (SK-N-MC 2 x 104 to 1 x 105)) in a 96-well plate. Following a 24-hour incubation, cells were treated with 5mg/mL MTT solution and incubated an additional 2 hours at 37 degrees Celsius. MTT solution was then removed, and cells were treated with DMSO. Absorbance was measured at 570 nanometers to determine proliferation of cells.
Optimal cell concentrations were selected and plated. Following an additional 24-hour incubation, three plates of each cell line were treated with increasing metformin concentrations (0-10 millimolar) in isolated rows. Proliferation of cells was determined following treatment for 24, 48, and 72 hours. A fourth plate of SK-N-SH cells was treated with metformin (5 and 7.5 millimolar) and cisplatin (2.5 micromolar) both individually and in combination. Absorbance was measured by aforementioned process to determine cisplatin toxicity in combination with metformin compared to control.

Results: Data was collected and graphed. Regarding SK-N-SH cell line, proliferation of samples exposed to metformin succeeding 24-hour incubation was slightly greater than control. SK-N-SH samples exposed to metformin for 48 and 72-hour time intervals showed both a time-dependent and concentration-dependent decrease in proliferation compared to control ($p < 0.05$). Treatment with 1.25 and 2.5 millimolar metformin concentrations resulted in similar proliferation in regards to control, while 5, 7.5, and 10 millimolar metformin concentrations resulted in a significant decrease in SK-N-SH proliferation compared to control ($p < 0.05$).

Similarly, SK-N-MC cell line samples exhibited both a time-dependent and concentration-dependent decrease in proliferation compared to control ($p < 0.05$).

Cisplatin 2.5 micromolar alone decreased the cellular concentration following exposure to SK-N-SH cell samples for 24 hours. However, compared to treatment with cisplatin alone, SK-N-SH cells treated with a combination of cisplatin and metformin had much lower cellular proliferation ($p < 0.05$).

Conclusion: Demand for an alternative therapeutic intervention when treating neuroblastoma is vital to improve prognosis for such patients. Metformin's exceptional therapeutic index and mild side effect profile allows it to be a favorable agent for potential use in neuroblastoma. This study identifies both a time-dependent and concentration-dependent decrease in proliferation of SK-N-SH and SK-N-MC cell lines following treatment with metformin, and establishes metformin's ability to increase sensitivity of cells to cisplatin chemotherapy in SK-N-SH cells. Further studies should focus efforts on determining the mechanism of metformin's effects in SK-N-SH and SK-N-MC cell lines.

Poster Title: Employment of a Cost Savings Calculator to Enhance Physician Acceptance of an Initiative to Encourage the Cost-conscious use of Glycoprotein IIb/IIIa Inhibitors

Primary Author: Kaylyn Dougherty, University of Tennessee College of Pharmacy, Tennessee; **Email:** kaylyndougherty@gmail.com

Additional Author (s):
Heather Weese
Robley Bartholomew

Purpose: High-bolus dose tirofiban and double-bolus eptifibatide have equal recommendation in current practice guidelines for non-ST segment elevation acute coronary syndrome. However, some physicians prefer eptifibatide for this indication due to previous study with tirofiban at an inferior dose and consider it to be a more cost effective agent. This assertion is particularly challenging due to the multiple presentations of the two medications and the lack of equivalence in terms of infusion times. We aim to create a calculator capable of generating a cost of therapy estimate which will assist in encouraging physician acceptance of the most cost effective agent.

Methods: A cost calculator was devised for tirofiban and eptifibatide to illustrate anticipated drug costs associated with a calculated dose for a given patient weight. For each drug, the dose administered was defined based on recommendations found in current literature for percutaneous coronary intervention (PCI). Both drugs require weight-based dosing administered by infusion with at least one bolus dose. Set variables included recommended dose, available drug presentations, and the various drug presentation costs. A range of formulas were built into Excel which defined the amount of drug a given patient is expected to receive at a given point during infusion. Some patients, depending upon their weight and infusion time, required more than one package to satisfy the full dose required; in these instances, a combination of package sizes was used. Our calculator utilized a function in Excel Visual Basic capable of populating the best combination of available package sizes to achieve the lowest total cost for a defined infusion. Of note, after the infusion is stopped, remaining drug is wasted. Combination selection is relatively independent from the amount of drug needed as the smallest amount of necessary waste does not always correlate with the most

cost effective option. Three patient weight models (70kg, 100kg, 120kg) were run to compare the cost savings benefit defined by each group.

Results: For each drug, the most favorable package combination was chosen based on lowest total cost as determined by programmed excel functions, rather than estimated drug waste. The minimum infusion time of eptifibatide is 12 hours following two bolus doses. Tirofiban infusion may run for up to 18 hours following a single high dose bolus, however, an infusion time of 12 hours is commonly employed. For three patient weight models (70kg, 100kg, and 120kg) evaluated at a 12 hour infusion time, total costs were $944, $944, and $1,236 for eptifibatide versus $350, $525, and $541 for tirofiban, respectively. These data demonstrate cost-savings associated with tirofiban administration, specifically: $594 in the 70kg patient, $419 in the 100 kg patient, and $695 in the 120kg patient. Further illustration of this benefit is seen when eptifibatide at its minimum infusion time is compared to tirofiban at its maximum suggested infusion time. For the 70kg, 100kg and 120kg patients, the respective costs were $525, $700, and $716 for tirofiban at 18 hours versus $944, $944, and $1,236 for eptifibatide at 12 hours. The associated cost savings per patient are $419 for the 70kg patient, $244 for the 100kg patient and $520 for the 120kg patient.

Conclusion: The results of this model demonstrate a cost savings benefit associated with the use of tirofiban over eptifibatide. The employment of a cost savings calculator may help visualize anticipated savings and enhance physician acceptance of tirofiban over eptifibatide. Future implications of this tool include adjustment to evaluate other therapeutic alternatives and expanded utilization to other stakeholders as well as potential evaluation to determine efficacy in demonstrating cost-effectiveness of given therapies.

Poster Title: Analysis of Prescription Drug Labeling Changes from January 2014 to January 2016

Primary Author: Anjaly Vellian, South College School of Pharmacy, Tennessee; **Email:** anjalyvellian92@gmail.com

Additional Author (s):
Gamal Hussein

Purpose: This analysis was conducted to evaluate labeling changes communicated by the FDA in 2014 and 2015.

Methods: Data were initially collected from the FDA MedWatch safety archives. The labeling changes were categorized, tabulated in a database, and cross-referenced with Multum Medisource Lexicon's drug tables and Meyler's Side Effects of Drugs. Analysis of drugs recently approved and parameters related to labeling changes was completed.

Results: The FDA issued a total of 1089 press releases with multiple labeling changes in the past 2 years. These included black box warnings (59, 5.4%), contraindications (100, 9.2%), warnings (747, 61.3%), precautions (747, 68.6%), adverse reactions (446, 41.0%), and package inserts/medication guides notes (456, 41.9%). Most common black box warnings were drug abuse (20.3%), cardiovascular (13.6%), tumor (8.5%), and CNS events (3.4%). Most common adverse reactions addressed the skin (20.2%), sensory (12.8%), cardiovascular (12.1%), musculoskeletal (10.8%), central nervous (9.2%), endocrine (9.2%), and hematologic systems (7.2%). Of the 420 drugs approved from 2000 to 2015, labeling changes impacted 24.4%. A total of 11 drugs (26%) of the 42 drugs that were approved in 2014 received labeling changes. Drug classes with most labeling changes were CNS/Psychiatric agents (20.8.5%), anti-infective agents (13.5%), antineoplastic agents (12.6%), and cardiovascular agents (12.3%).

Conclusion: A significant number of communications with drug labeling changes have been analyzed with up to 17 labeling changes per drug. Education to health care providers is essential to improve reporting of adverse drug events for optimal assessment and analysis.

Poster Title: Evaluation of Hypoglycemia Protocol at a Tertiary Teaching Hospital

Primary Author: Caroline Flint, The University of Tennessee College of Pharmacy, Tennessee;
Email: caroline.flint321@gmail.com

Additional Author (s):
Samarth Shah
Megan Van Berkel

Purpose: Hypoglycemia can occur due to multiple etiologies including medications, liver failure, and secondary to critical illness. Due to the increased mortality risk associated with hypoglycemia, appropriate treatment of hypoglycemic episodes is crucial. Literature is available describing protocol implementation for prevention of hypoglycemia, however there is a paucity of data regarding treatment and management of hypoglycemia in the inpatient setting. At our institution, the hypoglycemia protocol is automatically ordered when insulin is prescribed. For other etiologies of hypoglycemia the nurse is required to contact the provider. The purpose of this study was to review hypoglycemia treatment at our institution.

Methods: Hypoglycemic episodes at a 650-bed academic medical center were retrospectively reviewed for events occurring during two weeks in August 2015. The methodology was approved by the University of Tennessee institutional review board. Adult patients were included for analysis if they had a blood glucose (BG) value of less than 60mg/dL on chemistry labs or point of care testing. Patients undergoing cardiopulmonary resuscitation or on an insulin infusion were excluded from this review. Secondary episodes of hypoglycemia within a single admission were also excluded. The primary outcome was percentage of times hypoglycemic episodes were treated. Secondary outcomes measured were time to treatment of hypoglycemia, time after treatment to repeat blood glucose reading, if hypoglycemia reoccurred within a 24-hour period, and etiology of hypoglycemia

Results: One-hundred and four episodes of hypoglycemia were included. Most episodes occurred in the general ward (n equals 58), followed by 24 episodes in the intensive care unit (ICU), four in a stepdown unit and 15 in the emergency department (ED). Medications were found to contribute to 45 (43 percent) hypoglycemic episodes, while liver disease accounted for

6 (6 percent), and 53 (51 percent) were due to other or unknown causes. Initial BG was a median of 52 mg/dL (IQR 42-57). For the primary outcome, only 50 (48 percent) of these hypoglycemic episodes were treated with oral or intravenous glucose. When divided by hospital unit, ICU patients had the highest treatment rate (86.6 percent), compared to the ED (53.3 percent), general wards (43 percent), and stepdown (25 percent). There was no difference in treatment rates if the protocol was previously ordered (n equals 63) compared to patients without the protocol (n equals 41), 52.3 percent versus 34.1 percent, p equals 0.32. Of the 50 episodes treated, the median time to initial treatment was 27 minutes (IQR 5-143). Time to treatment was greater than one hour in 20 episodes. The time to repeat BG was a median of 37 minutes (IQR 11-78).

Conclusion: In this retrospective analysis, the hypoglycemia protocol in this tertiary teaching hospital is underutilized. Of the episodes that were treated, the time to treat hypoglycemia was prolonged and greatly varied, as was the time to repeat BG after treatment. Based on these results of this study, we plan to design an electronic form to provide proper documentation of nursing actions taken when a hypoglycemic event occurs in addition to structured nursing education.

Poster Title: Efficacy of intravenous acetaminophen in post bariatric surgical patients

Primary Author: Thomas Neal, Lipscomb University School of Pharmacy, Tennessee; **Email:** nealtc@mail.lipscomb.edu

Additional Author (s):
Elizabeth Rahm
Alexandria Fagan

Purpose: Intravenous (IV) acetaminophen (APAP) has historically been used for pain management in bariatric surgery. The rationale is that this regimen would provide scheduled analgesia, and may eliminate the need for post-surgical pain management with opioids. Recent studies into the efficacy of this approach have yielded conflicting results. These incongruous results, along with a price increase in IV APAP, have placed extra emphasis on appropriate use of this medication. The purpose of this study was to determine the optimal duration and frequency of IV APAP needed to decrease the use of opioids for pain control after bariatric surgery.

Methods: Prior to beginning data collection, exempt status was approved by the institutional review board. Patients included in the study were at least eighteen years of age, received bariatric surgery, and had at least one order for IV APAP. Taking into account the dependent variable we used a significance level of 5 percent and 85 percent power, and determined that 102 patients would need to be included. As there were two regression lines to be fit, that number was doubled to 204. The final number of patients included was 220. Data collection points included total IV morphine equivalents (mg), total doses of IV APAP, body mass index (BMI), type of surgery, secondary perioperative procedures, and laparoscopic or open surgery. Data was collected for the determined timeframe of 7/1/12 through 7/1/15 using the electronic medical record. The collected data was then evaluated to determine the point at which an increase in IV APAP does not decrease the use of morphine.

Results: The dependent variable was the total IV morphine equivalents (mg) per patient. The independent variables included total doses of IV APAP per patient, BMI, sleeve surgery (77.27 percent), lysis of adhesion (1.36 percent), hernia repair (4.55 percent), and laparoscopic procedure (98.18 percent). Linear regression lines of the dependent variable and independent variables were overlapped analyzing for a decrease in morphine equivalents. The Davies' test was used to detect a change in the slope which determined how many doses of IV APAP were used before there was a change in morphine equivalents. There was a significant change in the trend of morphine equivalents before and after three doses of IV APAP (p=0.029) with a stronger negative trend before three doses.

Conclusion: The results of this evaluation help to identify opportunities for improvement of TriStar Centennial's utilization of IV APAP. The formulary for IV APAP limits dosing to 1,000 mg IV dosed every 8 hours and this data would suggest that 3 doses of IV APAP is sufficient for decreasing the use of opioids after bariatric surgery. Intravenous acetaminophen is a high-cost medication that is frequently used at TriStar Centennial Medical Center, particularly in bariatric surgery patients. Pharmacists have the opportunity, through increased monitoring and diligence, to reduce the use of IV APAP without compromising patient safety and care.

Submission Type: Descriptive Report

Session-Board Number: 5b-159

Poster Title: Implementation of acute care pharmacist coverage on weekends in a non-teaching community hospital

Primary Author: Molly Hunt, University of Tennessee Health Science Center College of Pharmacy, Tennessee; **Email:** mhunt12@uthsc.edu

Additional Author (s):
Jamie Chapman
Kyle Allmond

Purpose: Numerous studies in the past few years have proven the benefit of clinical pharmacy services in acute care settings, including intensive care units (ICU) and emergency departments (ED). While many hospitals have added at least partial coverage during the week, the percentage of hospitals offering weekend acute coverage by residency-trained clinical pharmacists remains low, especially in non-academic, community hospitals. The purpose of this study is to show the impact of providing weekend acute care coverage with a novel hybrid position in a community hospital.

Methods: Beginning January 2, 2016, a rotation of 4 clinical pharmacists was initiated during the weekend to provide "acute care" coverage to the emergency department and intensive care units. Prior to initiation of this program, pharmacists provided ED coverage on weekends and critical care patients were assessed only if they were on a consultation medication (i.e. Coumadin, vancomycin, etc). This hybrid shift allowed for 2 hours of designated time in the morning to round with the ICU team and evaluate each patient. Retrospective observational analysis was completed on all pharmacist-documented medication interventions during the weekends from January 2 to August 28, 2016. Intervention reports were run for each weekend and sorted by both type of intervention and identification of the acute care pharmacist on duty. Further sorting was done to manually separate interventions made for patients in the ICU from patients in the ED. The following data was compared between the ICU and ED during the hybrid weekend shift: intervention type (based on hospital-specific intervention codes), response to intervention (patient assessed, recommendation followed, and recommendation not followed), and financial implication/cost avoidance of intervention determined by Truven Analytics software.

Results: During the study period from January 2-August 28, 2016, 318 interventions were recorded by the four pharmacists rotating through the hybrid acute care weekend shift. Of the total number of interventions in both the ED and ICU, 66.5% of interventions were marked as recommendation followed, 31.7% of interventions were patient assessment only, and 6% of interventions were recommendation not followed. Interventions related to patient care in the ICU comprised 178 of the total 318 (~56%), while the ED interventions were 140 (~44%). The financial implication of these interventions for the ED and ICU was $119,992.00 and $126,434.00, respectively. This implies a savings of $3,444.58 on average for each shift worked during the study time period. New therapy recommendations, antibiotic and culture recommendations, ICU monitoring, and adverse event prevention comprised 73% of the total interventions in the ICU. In the ED, antibiotic and culture recommendations, questionable dose, medication history, and new therapy recommendations comprised 58.5% of the total interventions.

Conclusion: By designating 2 hours out of an established 10 hour weekend ED shift to ICU coverage, 178 interventions were recorded that otherwise would not have been completed. Addition of ICU coverage to the ED weekend shift prevents a 48 hour delay in appropriate treatment and avoidance of adverse events that are both clinically and financially significant.

Poster Title: Evaluation of the sepsis protocol in the emergency department.

Primary Author: Kristina York, University of Tennessee College of Pharmacy, Tennessee; **Email:** kyorkyor@uthsc.edu

Additional Author (s):
Justin Griner
Marilyn Lee

Purpose: The Center for Medicare and Medicaid Services released a quality measure in 2015 to improve outcomes in septic patients. In February 2016, our institution instituted a sepsis protocol and order set in the emergency department based on this quality measure. This protocol has led to a doubling of the use of broad spectrum antibiotics vancomycin and/or piperacillin/tazobactam in the emergency department. The purpose of this study is to follow the hospital course of patients who were initially selected for treatment with the sepsis protocol in the emergency department to determine if the use of early broad spectrum antibiotics was necessary.

Methods: The study was retrospective and has been submitted to the Institutional Review Board for exemption from final review. One aspect of the quality measure requires patients with a suspected source of infection who also met two or more criteria for Systemic Inflammatory Response Syndrome (SIRS) to be treated with broad spectrum antibiotics within three hours of presentation. Patients were included if they presented to the emergency department from February 2016 to July 2016 and received piperacillin/tazobactam and/or vancomycin as part of the emergency department sepsis order set. Patients who left against medical advice or who were transferred to or from an outside medical facility were excluded. Baseline demographics, SIRS criteria, admission diagnosis, continued antibiotics, blood cultures and discharge diagnosis were collected from institutional electronic medical records. The primary outcome was to determine how many patients initially treated with broad spectrum antibiotics for sepsis were ultimately diagnosed with sepsis.

Results: 184 patients were included in this study (n=184). Of patients meeting the sepsis criteria who were initially treated in the emergency department with empiric antibiotics, only 71% (131/184) were admitted to the hospital. The remaining 29% (53/184) were discharged from the emergency department. Of the patients admitted, 44% (57/131) had an admission diagnosis of sepsis, and 48% (62/131) had a discharge diagnosis of sepsis. Positive blood cultures returned on 13% (17/131) of patients who were admitted. At discharge, 66% (121/184) of patients who initially met sepsis criteria in the emergency department were not diagnosed with sepsis at any point during their hospital course.

Conclusion: Almost two-thirds of patients who met sepsis criteria and were empirically treated with protocol vancomycin and/or piperacillin/tazobactam upon presentation at our institution did not have a diagnosis of sepsis at any time during their hospital course. This protocol appropriately treats septic patients. However, many patients without sepsis received antibiotics unnecessarily due to the lack of specificity in identifying septic patients. This led to a sharp increase in the unnecessary use of broad-spectrum antibiotics in patients without sepsis. This increased use of unnecessary antibiotics complicates antibiotic stewardship efforts and could potentially lead to more drug-resistant strains of bacteria.

Poster Title: Cost-effectiveness of extended-release levodopa-carbidopa versus controlled-release levodopa-carbidopa in patients with advanced Parkinson's disease

Primary Author: Anderson Whitfield, Lipscomb University College of Pharmacy, Tennessee;
Email: whitfielac@mail.lipscomb.edu

Additional Author (s):
Jeff Lee

Purpose: Parkinson's disease is a progressive, neurodegenerative disease affecting dopamine levels in the mesencephalon. Parkinson's disease therapy centers on levodopa-carbidopa for symptom alleviation; however, prolonged use of levodopa-carbidopa is associated with a diminishing effect over time, requiring higher doses and, consequentially, higher risks of adverse events. Newer formulations of levodopa-carbidopa have focused on increasing the dosing interval to increase effectiveness and decrease adverse events. We sought to determine the relative cost-effectiveness of Rytary, an extended-release formulation of levodopa-carbidopa, in comparison to Sinemet CR, a controlled-release formulation of levodopa-carbidopa, and the generic equivalent of Sinemet CR in patients with advanced Parkinson's disease.

Methods: From the perspective of a U.S. health payer, we evaluated advanced Parkinson's disease patients. We developed a decision model to simulate the direct costs and outcomes associated with each levodopa-carbidopa formulation. Outcomes associated with each treatment alternative were comprised of therapy non-responders, therapy responders with no adverse events, and therapy responders with adverse events. Adverse events were characterized by type and were related to healthcare resource utilization. All clinical effectiveness data, including probability of therapeutic response and adverse event prevalence, were based on clinical trial data. We assumed no difference in clinical effectiveness between Sinemet CR and its generic equivalent. Medication costs were determined using RED BOOK. All other cost data were derived from previously published literature. We evaluated costs over a one-year time horizon and all costs were standardized to March 2016 dollars using the medical component of the Consumer Price Index (CPI). The model calculated the incremental cost-effectiveness ratio (ICER) in dollars per amount of "off" time reduced in hours for our base case

scenario. Univariate sensitivity analyses were conducted to assess the effects of input variability on the base case result. In addition, probabilistic sensitivity analysis (PSA) was conducted to assess the robustness of our base case analysis. As this was a modeling study based solely on published literature, the analysis was exempt from Institutional Review Board review.

Results: Base case analyses suggest that Rytary dominates brand name Sinemet CR. In comparison to generic CR formulations, Rytary was expected to have an ICER of $3808.40 per additional hour of "off" time reduced. PSA showed large variability in the model. Sinemet CR was dominated by both Rytary and generic controlled-release levodopa-carbidopa. The cost-effectiveness acceptability curve suggests that at a willingness to pay threshold of greater than $3800 per additional "off" hour reduced, Rytary would have a greater probability of cost-effectiveness than generic controlled-release levodopa-carbidopa. One-way sensitivity analyses suggest that our base case result was especially sensitive to changes in the efficacy of Rytary.

Conclusion: Our study determined that Rytary would be considered cost-effective if the willingness to pay threshold was greater than $3800 per additional "off" hours reduced. Standard U.S. cost-effectiveness thresholds are not helpful in evaluating the results of this model, since outcomes are not reported as quality-adjusted life years (QALY). The lack of a standard threshold to evaluate non-QALY analyses complicates the interpretation of this analysis. Future economic models of Parkinson's disease would benefit from the development of a clinically-relevant threshold for reduction in "off" hours.

Poster Title: Evaluation of Dosing Alert Parameter Customization in a Pediatric Hospital

Primary Author: John Haller, John Tyler Haller, Tennessee; **Email:** jhaller1@uthsc.edu

Additional Author (s):
Kelly Bobo
Lauchland Roberts

Purpose: An interdisciplinary team of physicians, pharmacists, and IT staff was created to review and adjust medication error alerts. A biweekly report covering the top 10 alerts over a selected time period, typically 1-2 weeks, was composed and presented to the committee. Medications were selected for review by the committee and modifications to alert parameters were adjusted if deemed necessary. This content was reviewed and modified based on primary and tertiary resources and standard practice of care was taken into consideration. The primary focus of this committee was to decrease the number of alerts without negatively impacting patient safety.

Methods: For this evaluation, the top 10 medications that triggered the greatest number of alerts were selected. These medications included ondansetron, dexamethasone, polyethylene glycol, diphenhydramine, fentanyl, diazepam, cefazolin, levetirecetam, furosemide, and ketorolac. The total number of alerts triggered by our computer system was evaluated before and after alert customization using the Students t-test. Additionally, errors reported in the Safeguard error reporting system and were compared before and after alert modifications occurred.

Results: In the group of medications evaluated, total alerts were lowered from an average of 2.37 percent in the period prior to the change to 0.78 percent in the period after the change (mean 1.58 percent, 95 percent CI 0.6801-2.4939, p value equals 0.0017). During the time periods studied there were 20 medication errors reported. Comparative safety evaluation is ongoing.

Conclusion: Careful and judicious adjustment to dosing alert parameters resulted in fewer overall alerts and decreased errors in the group of medications that were evaluated. A limitation of this evaluation is that error data was obtained from a voluntary reporting system and may not accurately reflect the actual number of events. Ongoing comparative safety data will continue to validate our findings.

Poster Title: Metformin ameliorates myofibroblast differentiation in idiopathic pulmonary fibrosis

Primary Author: Sade Jones, South College School of Pharmacy, Tennessee; **Email:** sjonestn@my.southcollegetn.edu

Additional Author (s):
Victoria Akobundu
Tyler Covington
Triet Nguyen
Maha Abdalla

Purpose: Idiopathic pulmonary fibrosis (IPF) is a chronic, progressive lung disease with poor prognosis. Management options are limited to two approved pharmacological agents. A hallmark of IPF pathogenesis is myofibroblast differentiation, characterized by de novo alpha smooth muscle actin (αSMA) stress fibers assembly. Transforming growth factor beta (TGFβ) is an established trigger of cell differentiation and matrix assembly in fibrosis. Interestingly, metformin has been shown to modulate TGFβ signaling and reduce fibrosis in preclinical diabetes models. However, its therapeutic benefits in IPF remain unclear. Thus, we investigate the efficacy of metformin as an option in the treatment of IPF.

Methods: Normal and fibrotic Human lung fibroblasts (NHLF and FHLF, respectively; FHLFs isolated from an IPF patient), and human epithelial cells were used in vitro. Western analysis: After reaching 70% confluence, cells were serum starved and subjected to TGFβ1 for 48 h and concomitant metformin for 24 h (total 72 h). Relative expression of αSMA and GAPDH were assessed using ImageJ software. Immunofluorescence: Cells were plated on a four well chamber, in the absence or presence of TGFβ1 for 48 h and concomitant metformin for 24 h (total 72 h). The fixed cells were incubated with primary anti-αSMA (Sigma-Aldrich). The immuno-fluorescence staining images were obtained using Zeiss fluorescent microscope and analysis conducted using ImageJ software.

Results: We first determined optimal TGFβ1-induced MF differentiation to occur at 72 h as evident by marked increase in αSMA. Interestingly, the stimulatory effects of TGFβ1 were decreased with metformin as evident by decreased αSMA expression and assembly in all three cell-lines. Additionally, the anti-fibrotic effect of metformin is dose dependent as evident by decreased αSMA assembly at metformin 5 mM and 10 mM.

Conclusion: Our results demonstrate that metformin has beneficial anti-fibrotic effects as it ameliorates myofibroblast differentiation. Metformin could potentially be a pharmacologic option in IPF management.

Poster Title: Incidence of hypotension in atrial fibrillation patients treated with intravenous amiodarone versus intravenous metoprolol versus intravenous diltiazem

Primary Author: Elizabeth Rahm, Lipscomb University College of Pharmacy, Tennessee; **Email:** ekrahm@mail.lipscomb.edu

Additional Author (s):
Allison Dixon
Julie Stephens

Purpose: Current intravenous (IV) therapies used to treat atrial fibrillation include amiodarone, metoprolol, and diltiazem. Since these agents can reduce blood pressure, hypotension is of concern. Previous studies conducted to determine rate-lowering effects of medications in the treatment of atrial fibrillation have observed a higher incidence in hypotension in patients receiving diltiazem compared to amiodarone. The purpose of this study was to evaluate the incidence of hypotension in hospitalized patients with atrial fibrillation receiving IV amiodarone, metoprolol, or diltiazem.

Methods: This retrospective chart review was exempt from approval by the institutional review board. Adult patients (greater than 18 years of age) with at least one order for IV amiodarone, metoprolol, or diltiazem during the timeframe of April 1, 2016 to July 1, 2016 were identified using the electronic medical record at Centennial Medical Center. Patients were not eligible if they received medications from each group (IV amiodarone, metoprolol, and diltiazem) simultaneously. For each group, fifteen patients meeting the above criteria were randomly selected and evaluated. Data points included hypotension, defined as systolic blood pressure less than 90 mmHg, time of hypotension in relation to infusion, and recorded blood pressure if hypotension occurred. Additional data points included heart rate, the time to hear rate less than 120 beats per minute in relation to infusion, and the duration of heart rate less than 120 beats per minute. Comorbidities such as heart failure, diabetes, chronic obstructive pulmonary disease, and hypertension were also evaluated.

Results: Of the three groups evaluated, IV amiodarone had the lowest incidence of hypotension with 13.3 percent of patients experiencing hypotension after administration. IV metoprolol caused hypotension in 20 percent of patients. Furthermore, IV diltiazem had the highest incidence of hypotension with 33.3 percent of patients experiencing hypotension with an average time to hypotension was 211 minutes after administration. The average time to hypotension was 158.5 minutes and 41.3 minutes for amiodarone and metoprolol, respectively. Additionally, IV diltiazem had less heart rate control between the three groups with 33.3 percent of patients experiencing a heart rate greater than 120 beats per minute after being controlled with a heart rate less than 120 beats per minute. Conversely, 6.67 percent of patients in the amiodarone group and 13.3 percent of patients in the metoprolol group did not maintain heart rate control after IV administration.

Conclusion: In this retrospective study of hospitalized patients with atrial fibrillation, IV diltiazem resulted in more frequent hypotension and had less control of heart rate compared to IV amiodarone and IV metoprolol. Amiodarone caused the least amount of hypotension. These results support the findings of previous studies when looking at rates of hypotension in the treatment of atrial fibrillation. Pharmacists have a critical role in identifying patients at higher risk for hypotension and suggesting another therapy, if necessary. Future studies are needed to investigate a pharmacist-led intervention to determine the appropriate intravenous agent to control atrial fibrillation and avoid hypotension.

Poster Title: Implementation of a continuous glucose monitor system in a diabetes education program

Primary Author: Marina Yasnogorodsky, Lipscomb University College of Pharmacy, Tennessee; **Email:** myasnogorodsky@mail.lipscomb.edu

Additional Author (s):
Garrett Crothers
Benjamin Gross

Purpose: Continuous glucose monitor systems (CGMS) provide real time readings that can be used by clinicians to determine a blood glucose pattern to enhance therapy for diabetic patients. Many patients can benefit from CGMS including uncontrolled type 1 and type 2 diabetics, patients that don't show symptoms of hypoglycemia, or are not at an optimal hemoglobin A1c goal, children with type 1 diabetes. The utilization of CGMS as a diabetes educational tool is limited and could enhance concepts of how dietary intake impacts blood glucose.

Methods: Patients were referred to the pharmacist for diabetes education in a primary practice clinic. Each patient was given appropriate counseling on diet, activity, and goals of therapy based on American Diabetes Association practice guidelines. The length of the visit was standardized to one hour. Upon consent, patients were fitted with a continuous glucose monitor (CGM) to wear for 7 days. Patients were given a food log and instructed to record all dietary intake including liquids. The patients were asked to check blood glucose a minimum of twice daily. Patients returned to the the clinic after 7 days in order for the CGM data to be downloaded. A laptop with the CGM data was shown to each patient to discuss data and compare fluctuations in blood glucose to the food log. Based on the data, patients were given additional meal planning instructions. Patients were surveyed regarding the information provided and the impact that added data had on their understanding of diabetes. Patients were monitored with follow-up in clinic three months after baseline visit for compliance with medications and improvement in A1c from baseline. Data was also presented to the primary care physician for future follow-up with patient.

Results: Currently ten patients have consented into the study. Eight patients had Type 2 Diabetes Mellitus (DM) and 2 patients had Type 1 DM. The average baseline A1c for the study group was 9.4%. The average A1c after 3 months was 7.4%. Patients in follow-up sessions demonstrated a better understanding of their disease including the impact of diet on blood glucose readings and the importance of adhering to the meal plan. Disease improvement appeared to improve patient's quality of life. In the Type 1 diabetic patients, CGM technology also allowed improved insulin utilization and both patients reported less hypoglycemia.

Conclusion: Although only a small sample, the impact of CGM technology along with standardized diabetes education provided significant reductions in A1c, improved patient satisfaction, and better understanding of the disease. Continuation of the study in order to increase the sample size may provide additional insight on how beneficial CGM may be in a diabetes education program.

Poster Title: Impact of polymerase chain reaction (PCR) blood culture identification technology on antimicrobial stewardship

Primary Author: Alexander Kreimer, Belmont University College of Pharmacy, Tennessee; **Email:** alex.kreimer@pop.belmont.edu

Additional Author (s):
Charlie Upton
Montgomery Williams

Purpose: Polymerase chain reaction (PCR) technology can be used for rapid identification of microorganisms and detect if certain resistant genes are present following a positive blood culture. PCR technology can decrease the time to organism identification which aids in more timely adjustment to appropriate antimicrobial therapy (escalation or de-escalation) or reinforces treatment decisions when treating a patient empirically. The laboratory at this community hospital utilizes a PCR blood culture identification panel for all positive blood cultures. The purpose of this study is to determine the impact of this PCR technology on antimicrobial therapy.

Methods: Existing pharmacists' documentation and patient chart information were reviewed retrospectively for the period of January 1 – April 30, 2016. Antimicrobial therapy was evaluated for 115 patients who had a positive blood culture and PCR organism-identification performed. Evaluation of the impact of organism identification via PCR was completed through patient chart review, pharmacists' documentation, and date/time of antibiotic administration. The impact of the PCR test was determined by the effect on antimicrobial therapy and classified in one of 8 categories including narrowed therapy, no change in therapy, infectious disease (ID) consult, addition of antibiotic, antibiotic discontinued, confirmed therapy, patient expired/transferred, and prevented antibiotic. Secondary analysis included the microorganisms identified by the PCR.

Results: During the four month evaluation period, 122 interventions were identified for 115 positive blood culture results. The most common interventions were narrowing therapy (20.5 percent), consulting Infectious Disease (17.2 percent), and adding (12.3 percent) or

discontinuing (11.5 percent) antimicrobials. PCR results that resulted in "no change in therapy" were primarily due to contamination (86.9 percent); however, the PCR result confirmed appropriate current antimicrobial therapy for the remainder of the results that were classified in this category. Of the 115 positive blood cultures, gram positive bacteria made up the majority at 66.1 percent (n equals 76) verses gram negative at 30.4 percent (n equals 35). Additionally, 2 samples were recorded as "none detected" (as the PCR test did not have the organism on the identification panel), and 2 samples were positive for Candida glabrata.

Conclusion: PCR rapid organism identification lead to an intervention (or multiple interventions) in 63.1percent of the cases reviewed over the four month evaluation period. As PCR results are available more rapidly than traditional blood cultures, interventions made based on these results likely improved time to appropriate antimicrobial therapy. Obtaining further data, with a more standardized documentation process (including exact time to appropriate therapy) would contribute to a better in-depth understanding of laboratory-based PCR technology significance in this hospital setting.

Poster Title: Medication utilization in a non-profit pharmacy distribution network

Primary Author: David Trinh, Lipscomb University College of Pharmacy, Tennessee; **Email:** dtrinh@mail.lipscomb.edu

Additional Author (s):
Christopher Palombo
Josh Kravitz
Edward Woo

Purpose: According to the Centers for Medicare and Medicaid Services, medication non-adherence can negatively impact patient outcomes and increase overall healthcare costs. The Dispensary of Hope addresses this issue by procuring surplus medications via donations that otherwise would have been destroyed and make them accessible to charitable pharmacies and clinics. With these medications, underserved patients who are low income and uninsured are able to continue their prescribed medication therapy. In detailing how the Dispensary of Hope manages the movement of medications, we aim to identify efficiencies in the organization's processes and how the addition of pharmacists can further enhance current operations.

Methods: Medication movement at the Dispensary of Hope begins at the point of medication donation and ends at medication delivery to charitable pharmacies and clinics. Within this framework, the Dispensary of Hope utilizes a medication list called the Target List which specify medications the organization aims to keep from medications that have been donated by manufacturers or physician practices. The Target List is updated quarterly and each update takes into consideration the addition or removal of medications based on data supporting its demand and clinical utility. Placing pharmacists in charge of updating the Target List provides benefit to the organization due to the pharmacist's extensive medication knowledge. Donations that arrive at the Dispensary of Hope and match medications designated by the Target List, are received and then entered into the organization's inventory system. Inventory updates, provided in real time, can be viewed by charitable pharmacies and clinics who are then able to order, receive, and dispense the medications to underserved patient populations across the United States. To ensure that the organization's current processes align with its operational goals, the Dispensary of Hope utilizes an independent third party to collect and analyze drug

utilization information and site satisfaction surveys. In doing so, the Dispensary of Hope aims to improve upon itself to better reflect the needs of the communities it serves.

Results: The Dispensary of Hope is operationally designed for ease of intake and distribution of donated medications to access sites, thereby increasing its charitable power to the community. In the 2015 fiscal year, the Dispensary of Hope dispensed quantities of medication equal to 359,878 thirty-day fill prescriptions. Per fiscal quarter, this translated to an average of 89,970 thirty-day fills. In the first fiscal quarter of 2016, the Dispensary of Hope dispensed a total of 124,071 thirty-day fills.

Conclusion: There has been great success with the inclusion of pharmacists at the Dispensary of Hope in helping drive formulary and medication procurement decisions. The organization still possesses a supply limitation that must be overcome in order to achieve its goal of providing medication access to the underserved population. The organization provides 225 of its 405 target list medications in consistent supply and aims to expand consistency. To do so, the organization requires increased partnership with medication donors to provide larger volumes to support demand and ensure supply stability. This step will allow for a greater impact on health improvement outcomes.

Poster Title: Impact of knowledge and job values on the career interests of student pharmacists

Primary Author: Lance Lineberger, University of Tennessee Health Science Center College of Pharmacy, Tennessee; **Email:** llineber@uthsc.edu

Additional Author (s):
Joseph Swanson
Justin Gatwood

Purpose: The profession of pharmacy is experiencing a trend of employment saturation in many avenues of the job market. This calls for further analysis of the factors affecting the perspective of student pharmacists' interest in different areas of pharmacy. The purpose of this study was to investigate the extent to which knowledge of a career path and the importance of job values impact career interests among first and second year student pharmacists.

Methods: All first and second year student pharmacists of the University of Tennessee College of Pharmacy were surveyed to evaluate their current career plans. The instrument included both established and study-derived items and focused on self-assessed knowledge of pharmacy career paths, job-related values, interest in industry-specific jobs, and basic demographics. Correlation analysis was conducted using SPSS (version 22) to determine if a relationship existed between career interest and knowledge as well as between career interest and job values. Additionally, a multinomial logistic regression was conducted using STATA (version 14) to evaluate the likelihood of choosing a specific pharmacy career path (community, hospital, non-traditional, ambulatory care, or academia) based on the relative importance of students' job values while controlling for select demographics.

Results: Three hundred and thirty-one student pharmacists were surveyed, and a positive correlation was observed between a higher interest in chain pharmacy and the importance of salary, benefits, and knowledge of chain pharmacy as a profession (p less than 0.05). Also, a positive correlation was observed between a higher interest in hospital pharmacy and the importance of advancement opportunities, work environment, and knowledge of specialist, generalist, and ambulatory career fields (p less than 0.05). A positive correlation was observed between interest in academia and the importance of advancement opportunities and

knowledge of all facets of pharmacy, except managed care and community (p less than 0.05). Controlling for gender, grade point average, and relationship status, relative risk ratios of 2.02 and 0.44 (both p less than 0.05) were observed for advancement opportunities and the importance of salary for hospital pharmacy when adjusted for the job values assessed. In addition, adjusted relative risk ratios of 0.17 and 9.5 (both p less than 0.05) were observed for the importance of salary and advancement opportunities for an academic position. In addition, adjusted relative risk ratios of 4.6 and 0.56 for advancement opportunities and salary (both p less than 0.05), were observed for non-traditional pharmacy.

Conclusion: First and second year student pharmacists who value salary and benefits are more likely to seek employment in community pharmacy practice. However, students who value advancement opportunities are more likely to seek employment opportunities within hospital, academia, and non-traditional areas of pharmacy practice.

Poster Title: Assessing the frequency of electrocardiogram (ECG) monitoring and evaluating contributing factors on the incidence of QTc-prolongation in pediatric hematology-oncology patients receiving methadone

Primary Author: Kristen Hughes, University of Tennessee College of Pharmacy, Tennessee;
Email: kristen.hughes@stjude.org

Additional Author (s):
Calvin Daniels
Jennifer Robertson
Cyrine Haidar
James Hoffman

Purpose: Methadone has a boxed warning for QTc prolongation and serious arrhythmias, such as torsades de pointes. The package insert advises that patients receive baseline and follow up ECGs when initiating and increasing methadone dosing. No studies have assessed QTc prolongation risk in pediatric patients receiving methadone. As part of a quality improvement (QI) effort, this retrospective chart review was designed to evaluate the frequency of electrocardiogram monitoring and collect data on potential risk factors for QTc prolongation in pediatric hematology/oncology patients receiving methadone therapy.

Methods: A retrospective chart review of patients who were prescribed methadone at St. Jude Children's Research Hospital between January 2014 and June 2016 was performed. The following patient data were collected from the electronic health record for each course of therapy: patient demographics, initial methadone dose, methadone titration doses, related comorbidities, relevant cardiac history, and prior history of anthracycline use. Serum concentrations for potassium, magnesium, calcium, and creatinine on the day the ECG was performed were recorded. Baseline and follow-up QTc intervals was recorded. QTc prolongation was defined as a QTc interval greater than 460 milliseconds (msec) for patients ages 0-15 years, greater than 450 msec for males greater than 15 years, and greater than 470 msec for females greater than 15 years old. Borderline QTc prolongation was defined as a QTc interval of 440-460 msec for patients ages 0-15 years, 430-450 msec for males greater than 15 years and 450-470 msec for females greater than 15 years old. Medications administered

during the week prior to ECG monitoring that could affect electrolytes (angiotensin converting enzyme inhibitors, angiotensin receptor blockers, beta blockers, and loop diuretics) or prolong the QTc interval (amitriptyline, arsenic trioxide, azithromycin, ciprofloxacin, citalopram, crizotinib, escitalopram, fluoxetine, granisetron, haloperidol, methadone, mirtazapine, olanzapine, ondansetron, pentamidine, promethazine, risperidone, sertraline, sorafenib, and trazodone) were recorded.

Results: Seventy-five methadone initiations in 52 patients were evaluated. Baseline ECGs were obtained at initiation for 57.3 percent (43/75) of methadone therapies. Normal baseline QTc interval was reported in all but one patient. This patient had a prolonged baseline QTc interval while receiving three concurrent QTc prolonging medications prior to methadone initiation. ECG monitoring after therapy initiation was performed in 70 percent (30/43) of the cases where a baseline ECG was obtained. During follow-up monitoring, borderline QTc prolongation was observed in four patients, and prolonged QTc interval was observed in one patient. Follow-up ECGs after methadone dose increases were performed in 59 percent (10/17) of patients. In patients monitored after a dose increase, one patient developed a borderline QTc prolongation, and two developed a prolonged QTc interval. Doses were decreased in all patients with a prolonged QTc interval, and QTc intervals returned to normal for two of three patients. All patients with abnormal QTc intervals during methadone therapy were receiving at least two other QTc prolonging medications. Serum electrolytes were normal in all patients at the time of the abnormal QTc intervals except for one patient with hypokalemia and hypomagnesaemia at follow-up and one patient with hypocalcemia after a dose increase.

Conclusion: In approximately half of methadone therapy initiations analyzed, a baseline ECG was obtained prior to initiation. Follow-up ECGs were obtained after therapy initiation for 70 percent of patients who had received baseline ECGs. Abnormal QTc intervals were observed during ECG follow-up monitoring after both methadone therapy initiation and dose increases. All patients with abnormal QTc intervals were also receiving at least two medications with a QTc prolongation risk. Based on the results of this project, process improvement efforts to increase QTc monitoring in patients receiving methadone will be implemented.

Poster Title: Steven-Johnson syndrome associated with the use of lisdexamfetamine in a pediatric patient

Primary Author: Megan Whitten, The University of Tennessee Health Science Center, Tennessee; **Email:** mwhitte1@uthsc.edu

Additional Author (s):
Chasity Shelton

Purpose: This case report is a retrospective case study examining a drug-induced adverse event in a pediatric patient after taking lisdexamfetamine. The 15-year old male presented from an outside hospital with a five-day history of fever and mucosal changes. After one day of fever, the patient was self-treated with one dose of ibuprofen and acetaminophen. He continued to spike fevers over the next few days, and his guardian began to notice cracking of his oral mucosa. The cracking and erythema continued to worsen, so his guardian brought him to an outside institution. Cultures were obtained, and prophylactic antibiotics and antivirals were started for suspected Stevens-Johnson syndrome (SJS). His facial swelling worsened and progressed to severe stomatitis, prompting subsequent transfer to Le Bonheur Children's Hospital. The patient had been on lisdexamfetamine 30 mg once daily for attention deficit hyperactivity disorder for an unknown amount of time, but it was noted that his last dose was one week prior to symptom onset. His oral exam revealed full-thickness desquamation and exudates on both his upper and lower lips, along with the buccal mucosa, tongue, and hard palate. The glans penis showed multiple small, full-thickness vesicles. His skin was positive for Nikolsky sign. A skin biopsy sample was taken from three separate blisters. Ophthalmic examination showed bilateral conjunctival erythema with yellow exudates. Numerous 3 to 5 millimeter vesicles were noted bilaterally on the dorsal hands and wrists. Bilateral palms and the left plantar foot contained intact bullae. Lab studies were significant for alkaline phosphatase 448 IU/L, aspartate aminotransferase 331 IU/L, and total bilirubin 5.7 mg/dL. All other labs were within normal limits. Prophylactic antibiotics and antivirals were discontinued due to the fact that they are not routinely recommended in the treatment of SJS. He was treated with lacri-lube and prednisone ophthalmic and mupirocin for his penile lesions. The patient was kept in the critical care unit as his skin condition continued to worsen developing into whitish and erythematous ulcers in the oral area, glans of penis, and throughout his

extremities. A peripherally inserted central catheter was placed in order to start total parenteral nutrition. Intravenous immunoglobulin was given for three days. He developed pancytopenia and continued to have rising liver function tests and hyperbilirubinemia. He remained febrile for seven days after admission, but all blood cultures remained negative, including cultures for herpes simplex, Epstein-Barr, coxsackie, and parvo B19. His lips became bloody and raw, and it led to them adhering together. The bullae on his hands became exposed, which required more extensive wound care. Twelve days after admission, dermatology was able to confirm the biopsy as being SJS. He continued to have persistent labial edema, and he developed a new yellow, mucopurulent drainage from his mouth. He complained of increasing pain to his tongue and lips and was only able to respond by shaking his head. Around day 16 of admission, he began to show improvement in his labial and buccal appearance and started feeling well enough for ambulation. Twenty-one days after admission, he was improved enough to be discharged and instructed to follow up with dermatology in a week. Based on the Naranjo algorithm score of 4, the probability of this being an adverse drug reaction caused by lisdexamfetamine is possible; however, there are a few case reports of amphetamines causing SJS, so the possibility should be included as part of the differential and may warrant the inclusion of monitoring for this adverse reaction as a part of routine counseling.

Poster Title: Resolution of macrocytosis with the addition of folic acid despite normal laboratory markers

Primary Author: Lauren Hoth, University of Tennessee Health Science Center College of Pharmacy, Tennessee; **Email:** lhoth@uthsc.edu

Additional Author (s):
Rex Brown
Roland Dickerson

Purpose: Anemia is commonly differentiated as microcytic or macrocytic based on the mean corpuscular volume (MCV). When MCV is elevated in the presence of concurrent low hemoglobin, macrocytic anemia is diagnosed. This is commonly associated with etiologies such as alcoholism, liver disease, or malnutrition and commonly manifests with deficiencies in cobalamin (B12) or folic acid (B9). To test for these deficiencies, laboratory values for serum methylmalonic acid (MMA) and serum homocysteine are often obtained. An increased result of either or both would indicate a nutritional deficiency. This case report suggests nutritional deficiencies to be present despite normal laboratory markers. A 37 year-old male (58.6 kg, 91 percent ideal body weight) was admitted to Regional One Health status post motor vehicle accident. He had extensive full body injuries, including a subarachnoid hemorrhage and extensive facial, rib, and extremity fractures. His social history was positive for alcohol and tobacco use. The patient was admitted to the trauma intensive care unit (TICU) and, due to his alcohol history, empirically started on folic acid 1 mg daily, thiamine 100 mg daily, and multivitamins. On hospital day 3 (HD3), the Nutrition Support Service (NSS) was consulted to provide enteral nutrition for the patient. At this time, he had a hemoglobin of 8.5 g/dL with a slightly elevated MCV of 100.7 fL indicative of a macrocytic anemia. It was noted that his MCV was elevated during prior hospital days, ranging from 99.9 to 106. Impact Peptide 1.5 with supplementary glutamine and protein was initiated and serum homocysteine and MMA levels were ordered to determine the origin of the macrocytosis. NSS continued folic acid 1 mg daily, as this deficiency is common in patients with an alcohol history. The MCV on HD4 to HD6 remained elevated between 101.9 and 102.4. On HD5, the laboratory reported values for homocysteine and MMA of less than 3 mcmol/L and 214 nmol/L, respectively. The decision was made to continue folic acid due to the patient's clinical picture and the benign nature of the

supplement. The patient also had a mandible fixation on HD5. Pyridoxine 25 mg daily was initiated on HD7 in case the patient had an underlying B6 deficiency. On HD8, the MCV peaked at 105.2 fL with a concomitant hemoglobin of 7.9 g/dL. During subsequent days, the MCV and hemoglobin continued to decline. By HD14 the macrocytosis had resolved and the MCV remained normal throughout the remainder of the hospital stay. Due to a declining hemoglobin (6.5 g/dL) and hematocrit (20.4 percent), on HD17 the patient required a transfusion of 700 mL of packed red blood cells. This raised the hemoglobin to 9.6 g/dL and this value was maintained throughout the hospital stay. On HD18, the patient was switched to Replete with Fiber and NSS signed-off allowing the medical nutrition team to take over the patient's nutrition. A follow-up homocysteine and MMA were ordered, which resulted with normal values for both homocysteine (7.1 mcmol/L) and MMA (343 nmol/L). The remaining course was largely unremarkable with the patient being transitioned to a liquid pureed diet with supplementary Boost Plus on HD31. It is notable that the patient received folic acid until discharge. He was discharged on HD35 with hemoglobin of 9.7 g/dL and MCV of 89.4 fL. It is important to take multiple factors into account when making decisions on therapy, including past histories, laboratory values, disease state knowledge, and the general clinical appearance of the patient.

Poster Title: Initiation of a pharmacy-assisted discharge counseling program in a pediatric hospital

Primary Author: David Skinner, University of Tennessee Health Science Center, College of Pharmacy, Tennessee; **Email:** dskinne3@uthsc.edu

Additional Author (s):
Wesley Arrison
William Mabry
Sadie Cox

Purpose: Discharge is a critical juncture in a patient's medication therapy and, by extension, the transition of care process as a whole. Far too often, mistakes are incurred and opportunities to optimize therapy are missed. Pharmacy involvement in discharge education and evaluation has the potential to improve outcomes and patient satisfaction while optimizing nursing staff time. This study assessed interventions resulting from a pharmacist-assisted discharge counseling program in a pediatric hospital.

Methods: A non-randomized, single-center cohort study was conducted December 13, 2015 to May 18, 2016 in a Medical Surgical Nursing Unit of a tertiary care, 255-bed pediatric hospital. Patients targeted for counseling were those discharged with home medications or new prescriptions during pharmacy discharge service hours (weekdays; 0800-1630). The clinical pharmacist was contacted by the nursing unit when discharge orders were entered in the chart. On qualifying patients, pharmacists conducted chart reviews to evaluate clinical appropriateness, potential for insurance problems, provided patient education on all medications, and notified the medical team with recommendations when appropriate. Study data were collected via weekly computerized reports that detailed information on date and time patient discharge orders were entered into the electronic medical record, actual time of discharge, and the length of time between the order and actual discharge. Data collection sheets were provided to clinical pharmacists on which to document all patients on whom they counseled. The pharmacist would record date and time, patient identifiers, medications, and total time spent on the session. Documented interventions were recorded and categorized, as well as any reason that counseling did not occur. Additional study information, including

demographics and 30-day readmission, were also recorded. Pharmacist interventions were the primary outcome evaluated, while secondary outcomes examined time requirements, reasons for missed counseling opportunities, 30-day readmission, and predicted hospital savings resulting from the program.

Results: A total of 998 patients were discharged from the nursing unit during the study period. Of the 566 patients that met inclusion criteria, 195 (34% of opportunities) were counseled. 30 interventions were made (one for every 6.5 counseling sessions or 15%) with the most common interventions being Clarification of Orders and Dosing Changes. 30-day readmission was 15% for counseled patients and 17% for documented, uncounseled, qualifying patients. A total of 3,440 minutes (57.3 hours) were spent; minimum, maximum, and average time spent was 5, 120, and 18 minutes respectively. On average, one intervention was made for every 115 minutes of pharmacist time invested. Approximate pharmacist labor cost was $3,039, while projected savings from the counseling program were $22,815; a net saving of $19,776. Reasons for not counseling the remaining 371 qualifying patients included Not Available/No Time (18%), Pharmacist Not Paged (48%), Patient Already Discharged (6%), Other (8%), and Missed Opportunity (22%).

Conclusion: A pharmacist-assisted discharge counseling program showed potential in aiding the transition of care in a pediatric hospital through interventions in both clinical and practical aspects of planned outpatient therapy. Optimization of treatment, selection of medications covered by the patient's insurance, and prevention of avertible prescription errors helped reduce discontinuity of care and showed a slight improvement in 30-day readmission. Logistical data on time and staffing requirements demonstrated a disproportionate ratio of current pharmacist availability to need. This reflects the limited resources available prior to expansion, but anticipated hospital savings are expected to aid the fiscal viability of the program.

Poster Title: Frequency, severity, and medication utilization of brown recluse envenomation in pediatric outpatients

Primary Author: Sara Neil, University of Tennessee College of Pharmacy, Tennessee; **Email:** sneil1@uthsc.edu

Additional Author (s):
Chasity Shelton
Rebecca Chhim
John DeVincenzo

Purpose: Brown recluse spiders (Loxosceles reclusa) are venomous spiders endemic to certain areas of the United States. Loxosceles envenomation is associated with a wide range of clinical symptoms. A previous comprehensive analysis performed at this hospital evaluated the incidence, clinical presentation, complications, therapies, and patient outcomes in children admitted with suspected brown recluse envenomation. Our objective was to describe the incidence, presentation, antibiotic therapy, and pain management in children presenting to the emergency department (ED) with suspected brown recluse envenomation that did not require hospital admission, with future plans to compare our findings with those patients admitted to the hospital.

Methods: The institutional review board approved the retrospective review of the medical records of patients less than or equal to 18 years of age who presented to a Southeastern regional freestanding pediatric hospital ED who had suspected brown recluse spider bite between January 1, 2008 and December 31, 2013. Patients were excluded if they were admitted to the hospital and if the probability of a brown recluse spider bite was unlikely based upon review of the electronic medical record, including ED, admission and/or discharge progress notes. Patient demographics, chief complaint, associated clinical symptoms, vital signs, lesion description, pertinent laboratory values, complications, and treatment modalities were recorded. Cases were categorized as proven, probable or possible brown recluse envenomation based on published suggested reporting standards for loxoscelism. Standard statistical tools were used for data analysis.

Results: Preliminary analyses of 594 patient charts revealed 50 patients (8 percent) classified as possible brown recluse envenomation. Out of these 50 patients, 30 (60 percent) presented with a chief complaint of spider bite and 16 (32 percent) with an abscess or lesion. Cultures were obtained on 10 patients, with 50 percent resulting positive; four patients tested positive for methicillin-resistant Staphylococcus aureus (MRSA), and 1 patient tested positive for methicillin-susceptible Staphylococcus aureus (MSSA). However, 31 patients (62 percent) were given at least one antibiotic at discharge. The antibiotics that were most often prescribed were clindamycin (74 percent) and sulfamethoxazole/trimethoprim (13 percent). Interestingly, the patient with a positive wound culture for MSSA was not prescribed an antibiotic; all 4 patients with MRSA received antibiotic therapy. For pain management, 7 patients (14 percent) were given a non-steroidal anti-inflammatory drug (NSAID), 13 (26 percent) were given an opioid, 8 (16 percent) received lidocaine, and 1 patient (2 percent) was given acetaminophen. Further symptom management included 6 patients (12 percent) receiving an antihistamine, 2 patients (4 percent) receiving steroids, and 3 patients (6 percent) receiving epinephrine. Comparison to previous admission data is ongoing.

Conclusion: While the overall incidence of possible brown recluse envenomation in patients presenting to the ED was small, the majority presented with spider bite as the chief complaint. Nonetheless, 62 percent of these patients were discharged with antibiotics, even though only 5 patients had a documented, concomitant bacterial infection. A variety of pain medications were also commonly administered for symptomatic management. These patients experienced minimal systemic effects at the time of ED presentation and did not require hospital admission for treatment. Further analysis is needed to compare inpatient and outpatient treatment of brown recluse envenomation.

Poster Title: Characteristic Traits in Pharmacy Residents: Residency Program Directors' Perceptions of Residents Who Scrambled Compared to Residents Who Matched to a Post-Graduate Year One Program

Primary Author: Danijela Stefanovic, East Tennessee State University Bill Gatton College of Pharmacy, Tennessee; **Email:** stefanovic@etsu.edu

Additional Author (s):
Sean Smithgall
Katelyn Alexander
Jessica Burchette
Rajkumar Sevak

Purpose: Research suggests that pharmacy residency programs find certain characteristic traits desirable in candidates competing for a post-graduate year one (PGY1) residency position. However, no study has compared these individual characteristic traits in pharmacy residents to determine if differences exist between those candidates that have matched and those who were left to vie for remaining openings during the post-match scramble. Select traits may be advantageous to a candidate and preferred by a program, which may strategically impact the search process. We aimed to address this comparison by evaluating perceptions of PGY1 residency program directors (RPDs).

Methods: This study was approved by the East Tennessee State University Institutional Review Board. A quantitative web-based survey using Dillman's Tailored Design Method was distributed via email to RPDs within the US on four separate occasions between January and March of 2016, Program directors were identified using the American Society of Health-System Pharmacists (ASHP) public online residency directory. RPDs that participated in the 5-minute survey answered basic demographic information and questions involving characteristics of previous residents who scrambled and matched. Informed consent was obtained by all survey participants. The 13 individual characteristic traits assessed were based on previous studies identifying desirable pharmacy resident traits by residency programs. Only responses pertaining to PGY1 residents were included in this study. Resident characteristics were evaluated using a 5-point Likert scale, from strongly agree to strongly disagree. The primary outcome was the

difference between residents that scrambled versus residents that matched to a PGY1 program and their associated personality traits. Differences in mean scores between residents who scrambled and residents who matched were compared using the Student's t-test and categorical variables were compared using the Chi-square test Values of p less than 0.05 were considered statistically significant.

Results: A total of 232 PGY1 RPDs completed the survey. Several RPDs completed matched and scrambled survey sections, resulting in a total 315 data sets. Although responses came mainly from RPDs in a Pharmacotherapy program (N = 203), there was no relationship found between type of PGY1 program and RPDs that have matched versus scrambled residents (P equals 0.97). In addition, there was no relationship found between number of residents per program and RPDs that have matched versus scrambled residents (P equals 0.71). Cronbach's alpha was calculated at 0.949, showing consistency and reliability between personality traits and allowing for a combined mean score. Overall, there was no difference in the primary outcome of combined 13 personality trait mean scores between residents who matched (mean equals 4.32, SD equals 0.48) and residents who scrambled (mean equals 4.36, SD equals 0.62) (P equals 0.54).

Conclusion: Mixed opinions and perceptions of the scramble process and scrambled resident exist. Based on the results of this research, there is no difference in perceptions between pharmacy residents that scramble and those who match to a PGY1 program from RPDs. Both groups are believed to possess the traits that are found to be desirable in pharmacy residents.

Poster Title: Cholesterol medications and breast cancer: Unraveling the potential value of statins in breast cancer treatment

Primary Author: Brittany Hayes, Belmont University College of Pharmacy, Tennessee; **Email:** brittany.hayes@pop.belmont.edu

Additional Author (s):
Edgar Diaz-Cruz

Purpose: Breast cancer is the most common female invasive cancer. Women with hormone receptor-negative breast cancer generally have a poorer prognosis as it is more aggressive and difficult to treat with current treatment. Recent evidence suggests that 3-hydroxy-3-methyglutaryl-coenzyme A (HMG-CoA) reductase inhibitors, or "statins", may play a role in cancer prevention. The purpose of this study is to test if statins decrease cell proliferation and determine their effect on anti-proliferative and pro-apoptotic signaling pathways. Furthermore, this study investigates whether these effects are dependent on estrogen receptor status.

Methods: Two breast cell lines (MDA-MB-231 and MCF-7) were used in this study. Cytotoxicity assays were performed to assess cell proliferation after 24 and 48-hour treatment using the WST-1 reagent. Cell lines were also treated for 24 hours at subconfluency with the following agents: DMSO (dimethyl sulfoxide) as a control, 20 M lovastatin, 20 M simvastatin, 10 mM metformin, 5mM aspirin, 20 M lovastatin + 10 mM metformin, 20 M simvastatin + 10 mM metformin, 20 M lovastatin + 5mM aspirin, and 20 M simvastatin + 5 mM aspirin. Following treatment, cells were lysed and protein content quantified. Changes in protein expression were analyzed using Western Blotting for a variety of pro-apoptotic, pro-survival, cell cycle regulation, and cell growth markers. Cytotoxicity assays were also performed to assess cell viability after a 24-hour treatment using the WST-1 reagent.

Results: Our results showed morphological changes and visible signs of cellular stress in cells treated for 48 hours with statins. The more evident morphological changes were observed with statins in combination with metformin or aspirin. While these changes were observed with statin treatment alone, lovastatin and simvastatin treatment resulted in a decrease in cell proliferation in MDA-MB-231 cells after 24-and48-hour treatment but not in MCF-7 cells. On

the other hand, treatment with metformin, aspirin, and the combination of a statin with metformin or aspirin resulted in cell toxicity after 48-hours in both cell lines. In an effort to study the pathways involved in these changes in cell proliferation, cells were treated for 24 hours with the different agents and protein lysates collected. Western blot analysis of MDA-MB-231 cells treated with statin drugs resulted in decreased expression of proliferative proteins (p-Akt, p-mTOR, GⓁL, and AMPKⓁ), and increased expression of the pro-apoptotic proteins (p21, p27, and cleaved-PARP). MCF-7 cells treatment with statin drugs resulted in decreased expression of proliferative proteins (p-Akt, p-mTOR, GⓁL, and c-Raf), and increased expression of the tumor suppressor p27. Furthermore, MCF-7 cells treated with metformin and aspirin showed decreased levels of pMEK1/2 and Rictor protein expression.

Conclusion: Our results support further investigation of statins as potential agents for use in breast cancer. Morphological changes in statin-treated MDA-MB-231 and MCF-7 cells were evident, suggesting that cells were undergoing stress. Protein analysis results yielded promising data in regards to anti-proliferation and apoptosis. Preliminary data suggests that both apoptosis and impaired cell survival may contribute to statin's effects on tumor growth. Our results direct our attention to the mTOR/Akt signaling pathway as a possible mechanism of action. Additional research is underway to better develop an understanding of the effectiveness of statins and if combination treatment may yield improved results.

Poster Title: Evaluation of epidural corticosteroid use and associated adverse effects

Primary Author: Kristin Flanagan, Union University School of Pharmacy, Tennessee; **Email:** kristin.flanagan@my.uu.edu

Additional Author (s):
Andrew Martin
Jodi Taylor

Purpose: Neck and low back pain are commonly treated with epidural corticosteroid injections (ESI). Serious adverse events such as paraplegia, stroke, spinal cord injury, blindness, and even death have been associated with the administration of steroids into the epidural space. In April 2014, the United States Food and Drug Administration issued a Safety Announcement requiring the labeling of injectable corticosteroids to include a warning describing these risks. The purpose of this study aims to characterize the use of epidural corticosteroid injections, describe the patients who received epidural corticosteroid injections, and attempt to identify adverse drug events associated with their use.

Methods: For this medication-use evaluation, Institutional review board approval and a waiver were obtained form Union University and West Tennessee Healthcare, respectively. Eligible subjects included any adult patient who received an epidural steroid injection starting January 1, 2012 to May 31, 2016. Informed consent was waived; only preexisting data were abstracted from the medical record. No patients who received an epidural steroid injection were excluded. Subjects were identified utilizing a search for medication orders, charges, procedure codes, ICD-9CM codes, and ICD-10 codes in West Tennessee Healthcare databases. Information Systems and Pharmacy Department employees of Jackson-Madison County General Hospital completed the search. A review of the medical record was completed to identify patient, procedural, and medication characteristics. Adverse events were identified by reviewing records from future encounters that occurred within 30 days of an epidural steroid injection. Cardiovascular and neurologic adverse events such as paraplegia, stroke, spinal cord injury, blindness, hyperglycemia, and hypertension were recorded. Basic descriptive statistics were used to describe medication utilization and safety outcomes.

Results: Between January 1, 2012 to May 31, 2016, 1,823 orders for an ESI were identified. A convenience sample of 70 patients was reviewed to establish use characteristics associated with their most recent ESI. Eighteen (26%) patients had a previous ESI. Thirty-seven (52.8%) patients were female, and 61 (87.1%) were Caucasian. The most common single indications for ESI included low back pain (41.4%), lumbosacral radiculopathy (15.7%), and spinal stenosis (14.3%). Five of six cervical ESIs were administered above the recommended C7 to T1 location (one at C5-6, four at C6-7), and 21 (30%) injection approaches were described as intralaminar. No transforaminal injections were identified. Betamethasone was the most commonly administered steroid (88.6%); no orders for dexamethasone were identified. All ESIs were administered with a local anesthetic, and 68 procedures were performed with radiologic contrast medium and fluoroscopy. Comorbidities that were present at the time of ESI and related to potential adverse events included hypertension (58.6%), diabetes (77.1%), stroke (2.9%), and seizure (4.3%). One patient was diagnosed with transient ischemic attack in the emergency department 12 days after betamethasone ESI at L4 using fluoroscopy. This adverse event was possibly related to the ESI based on a Naranjo Scale of two.

Conclusion: From this initial assessment of ESIs, providers seem to be following the recommendations of the FDA Safe Use Initiative Working Group in respect to real-time fluoroscopy and limited use of sedation but are administering particulate steroids over dexamethasone. This study was limited by the accuracy and completeness of clinical documentation and selection bias. In addition, an outpatient provider not part of West Tennessee Healthcare may have treated ESI-related adverse events. Medical records of many more patients will need to be evaluated to better characterize utilization and understand adverse events occurring in this patient population due to the low frequency.

Poster Title: Sulfamethoxazole-trimethoprim induced drug reaction with eosinophilia and systemic symptoms (DRESS) syndrome: A case report

Primary Author: Lauren Smiley, University of Tennessee Health Science Center College of Pharmacy, Tennessee; **Email:** lsmiley1@uthsc.edu

Additional Author (s):
Chasity Shelton

Purpose: This case report illustrates the potential risk of drug reaction with eosinophilia and systemic symptoms (DRESS) syndrome associated with sulfamethoxazole-trimethoprim (SMX/TMP). The patient is a 16-year-old Caucasian female who presented to the emergency department (ED) with a chief complaint of a left lower leg lesion. She had visited Puerto Rico 6 weeks prior, during which time she obtained a mosquito bite. The bite progressed to an abscess, which was initially treated with oral SMX-TMP. After 6 days of treatment, oral ciprofloxacin was added to her antibiotic regimen due to the lack of improvement. Despite dual antibiotic therapy, the patient's clinical condition worsened. Upon presentation to the ED, the patient complained of general malaise, decreased appetite, fever, and had developed an erythematous maculopapular rash covering a large percentage of her back, chest, and upper trunk. Erythema of the face and bilateral conjunctivae were also noted. The patient was hypotensive with a blood pressure of 89/62 mmHg and tachycardic with a heart rate of 118 beats per minute. Laboratory work performed in the ED was significant for white blood cell count (WBC) 1,000/mcL, hemoglobin 12.4 g/dL, hematocrit 37 percent, and platelet count 74,000/mcL. Aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were also mildly elevated at 77 IU/L and 48 IU/L, respectively. Due to concerns for sepsis, the patient was admitted to the pediatric intensive care unit (PICU) for further evaluation and management. The infectious diseases, dermatology, and hematology services were consulted. Ciprofloxacin and SMX/TMP were discontinued, and vancomycin, ceftriaxone, and doxycycline were initiated to cover for potential sources of infection. Daily complete metabolic panels (CMP), complete blood counts (CBC), and liver function tests (LFT) were ordered in addition to blood cultures. Based upon the patient's history and presenting symptoms, tick borne illness, toxic shock syndrome, and DRESS syndrome were all high on the differential diagnosis. By day 2 of hospitalization, the patient's hemodynamics stabilized, appetite improved, and the rash had

significantly faded; however, her LFTs continued to rise. The patient's WBC count and platelets trended up towards normal limits and she continued to clinically improve throughout the remainder of her hospital stay despite steadily increasing LFTs. Broad spectrum coverage with vancomycin and ceftriaxone was discontinued after 48 hours due to negative blood cultures, doxycycline was continued due to the inability to rule out a potential tick borne illness, and treatment with prednisone was initiated to prevent rebound of DRESS syndrome. The patient was discharged 3 days after admission with instructions to follow up outpatient with the dermatology clinic for monitoring of all pertinent labs including LFTs, cell counts, and thyroid function, and to adjust the steroid taper. She was seen 3 times in clinic after discharge. Her cell counts and thyroid function tests were within normal limits and her LFTs returned to baseline approximately one month following hospitalization. The patient's physical exam, history, and lab findings all supported a diagnosis of DRESS syndrome, including more specifically, fever, rash, facial erythema, elevated LFTs, elevated eosinophils, atypical lymphocytes, leukopenia, and thrombocytopenia. In addition, the timing between the initiation of SMX/TMP and the development of symptoms was also consistent with the presentation of DRESS syndrome. Based on the Naranjo score of 4, the probability of this being an adverse drug reaction caused by SMX/TMP is possible. In summary, while the probability of developing DRESS syndrome from SMX/TMP is low, it is not unheard of. This case report illustrates the importance of recognizing the signs and symptoms of DRESS syndrome, promptly identifying and discontinuing the offending agent, and knowing how to properly monitor and manage the sequelae that commonly occur with this syndrome.

Poster Title: Evaluation of potential barriers to use of sacubitril-valsartan in patients with heart failure

Primary Author: Sebastian Skordallos, Lipscomb University College of Pharmacy, Tennessee; **Email:** sskordallos@mail.lipscomb.edu

Additional Author (s):
Elizabeth Rahm
Zachary Cox

Purpose: Sacubitril-valsartan decreased mortality in patients with heart failure (HF) with reduced ejection fraction (EF) compared to enalapril in the PARADIGM-HF trial. The American Heart Association and American College of Cardiology (AHA/ACC) Guideline for the Management of HF recommends replacement of an angiotensin-converting-enzyme inhibitor (ACEI) or angiotensin II receptor blocker (ARB) with sacubitril-valsartan (Class I) in persistently symptomatic HF patients. Measuring the potential population that could benefit from sacubitril-valsartan is the first step to optimizing guideline compliance. The purpose of this study was to identify and quantify potential barriers to sacubitril-valsartan use at outpatient appointments in patients with recent HF hospitalizations.

Methods: The institutional review board approved this retrospective electronic chart review of all decompensated HF admissions to Vanderbilt University Medical Center (VUMC) from 09/01/2015 to 06/15/2016. HF admissions were identified using an automatic algorithm within the electronic medical record. Inclusion required meeting 3 of the following algorithm criteria: International Classification of Disease 9 or 10 code history of HF at admission, inpatient order for an intravenous loop diuretic, HF admitting diagnosis, or specific B-type natriuretic peptide (BNP) level based on body-mass index (BMI); BNP greater than 400 pg/mL if BMI less than 26; BNP greater than 100 pg/mL if BMI 26 to 35; BNP greater than 50 pg/mL if BMI greater than 35. Patients meeting any of the following criteria were excluded: EF greater than 40 percent, lack of chronic cardiology or primary care outpatient appointments at VUMC, or classification of New York Heart Association Class I HF at time of follow up. The primary objective was to categorize and quantify the barriers to sacubitril-valsartan therapy at the time of post-discharge follow up. Potential barriers to therapy, defined according to the package insert and PARADIGM-HF

criteria, included hyperkalemia (potassium greater than 5.2 mEq/L), renal dysfunction based on estimated glomerular filtration rate (eGFR), hepatic dysfunction (Child-Pugh class C), hypotension (systolic blood pressure less than 95 mmHg), pregnancy, lack of insurance, and documented ACEI-induced cough or angioedema.

Results: Of the 389 admissions identified, a total of 124 patients met study criteria (mean age 64 years, 58 percent male, median EF 25 percent). Only 9 patients (7 percent) received sacubitril-valsartan therapy. Of those not receiving sacubitril-valsartan, 49 patients (40 percent) were identified as having at least one potential barrier to the use of sacubitril-valsartan, and 66 patients (53 percent) lacked identifiable barriers. Patients without barriers had a higher systolic blood pressure (mean 121 vs 106 mmHg, P less than 0.001), lower serum creatinine (mean 1.3 vs 2.0 mg/dL, P less than 0.001), and increased use of ACEI or ARB therapy (67 vs 38 percent, P equals 0.003) but did not differ in age (P equals 0.5). Identified absolute barriers included hypotension (n=21, 43 percent), hyperkalemia (n=5, 10 percent), and eGFR less than 15 mL/min/1.73 square meters (n=4, 8 percent). Relative barriers included cough (n=8, 16 percent), eGFR 15 to 29 mL/min/1.73 square meters (n=16, 33 percent), and no insurance (n=3, 6 percent). Angioedema, hepatic dysfunction, and pregnancy were not observed. Of the 5 patients with hyperkalemia, 2 were receiving potassium supplementation or an ARB, and 9 of the patients with hypotension were tolerating ACEI, ARB, or hydralazine therapy.

Conclusion: In this retrospective study of patients meeting guideline criteria for sacubitril-valsartan therapy, only 7 percent of patients were prescribed sacubitril-valsartan. However, 53 percent of the total patient population lacked an identifiable barrier to use of sacubitril-valsartan. Common barriers to sacubitril-valsartan therapy included hypotension, hyperkalemia, and renal dysfunction. Pharmacists have the opportunity to play a key role in identifying patients that could benefit from sacubitril-valsartan therapy in accordance with the AHA/ACC guidelines. Future studies are needed to measure the impact a pharmacist-led sacubitril-valsartan optimization intervention could have on heart failure outcomes.

Poster Title: Development of a pneumonia severity index (PSI) calculator through a third year pharmacy student informatics internship in an academic medical center

Primary Author: Garrett Crothers, Lipscomb University College of Pharmacy and Health Sciences, Tennessee; **Email:** crothersga@mail.lipscomb.edu

Additional Author (s):
Ben Moore
Wing Liu
David Mulherin
Elizabeth Breeden

Purpose: Physicians at Vanderbilt University Medical Center (VUMC) requested development of a clinical decision support (CDS) tool for the computerized physician order entry (CPOE) system that would calculate a Pneumonia Severity Index (PSI) score upon patient presentation to the emergency department (ED), with the primary diagnosis of community acquired pneumonia (CAP). The PSI score was developed by the Pneumonia Patient Outcomes Research Team (PORT) project to create a tool for assessing short-term mortality rate in CAP patients and for guiding physician triage of patients to either inpatient or outpatient treatment.

Methods: Flowcharts were constructed which detailed the current CPOE workflow for CAP patients, the desired CPOE workflow, and the proposed PSI calculator. Communication occurred between the informatics pharmacists and providers in order to obtain feedback from the providers for specific functionality desired in the calculator. The pharmacy interns created the dynamic PSI calculator using hypertext markup language (HTML), JavaScript, cascading style sheet (CSS), and CDS rule logic coding language that updates the PSI Score, risk class, and treatment recommendation upon demand. A CDS logic file was constructed in order to implement the HTML file for the PSI calculator into the computerized ordering system. Continuous quality assurance and testing was also performed to ensure that the calculator computed values correctly and functioned as intended.

Results: The calculator computes the PSI Score and risk class based on the patient's age, gender, nursing home status, coexisting illnesses, physical findings, and lab and radiographic findings. Various point values are attributed to these options selected by the user while interacting with the tool. Alerts display if a user does not input required fields, and attributes such as age and gender prepopulate on the page through integration with the patient's record. Recent lab values such as blood urea nitrogen (BUN), sodium, and glucose also display on the calculator to aide the user in completion of the form.

Conclusion: The robustness of the PSI calculator will be validated by vigorous back-end testing before implementation into the CPOE. Back-end testing will ensure the overall quality of the webpage and help mitigate the risk of end-user error. A dynamic PSI calculator, such as this tool, aims to assist providers in determining appropriate treatment for CAP patients while improving efficiency in calculating PSI scores. In the future, data extracted from the calculator could aid in research pertaining to CAP patients. Designing and constructing a PSI calculator gave pharmacy interns experience writing code with HTML, JavaScript, and CSS.

Poster Title: Findings and implementation of the multiplex polymerase chain reaction meningitis/encephalitis panel in a community hospital.

Primary Author: Kathryn Litten, BELMONT UNIVERSITY COLLEGE OF PHARMACY, Tennessee; **Email:** kathryn.litten@pop.belmont.edu

Additional Author (s):
MONTGOMERY WILLIAMS
SHAEFER SPIRES

Purpose: Meningitis and encephalitis can lead to serious complications such as mental disabilities, sensory loss, or death if not treated swiftly and appropriately. Unfortunately, diagnosis through conventional approaches can take several days to identify the pathogen and optimize therapy. The meningitis/encephalitis (ME) multiplex polymerase chain reaction (PCR) panel identifies the most common microorganisms involved in infections of the central nervous system in roughly one hour. The purpose of this study was to to examine the implementation parameters of this novel panel at a community hospital and determine if early recognition of specific pathogens altered prescribers' antimicrobial choices to affect patient outcomes.

Methods: This retrospective analysis was conducted in a single community hospital in which 29 ME PCR panels were performed. Twenty-seven eligible participants aged 1 day to 74 years old were identified. Participants were included if the ME PCR panel was performed during their hospitalization between May 1-September 12, 2016. Testing was performed automatically on cerebrospinal fluid (CSF) with greater than 5 cells/microliter white blood cells (WBC) or at the request of the physician. There were no exclusion criteria due to the nature of the study. A manual, retrospective review of the panel findings, patient chart information, and clinical decisions of the prescribers was conducted. CSF WBC counts were recorded to aid in testing parameter decisions. Outcomes including test accuracy, antibiotic choice and duration, and length of stay were analyzed.

Results: WBC counts of positive tests ranged from 16 to 3326 cells/microliter. The ME PCR panel identified 12 positive and 17 negative results. Positive identifications included 7 enterovirus, 3 herpes simplex virus-2 (HSV2), 1 varicella zoster virus (VZV), and 1 S. agalactiae. The test was 100 percent accurate when compared to final CSF culture results. Of the enterovirus identifications, 28.6 percent of patients did not receive antimicrobials due to ME PCR panel results while 42.8 percent received one empiric dose before results were available. Acyclovir was appropriately started in 50 percent of the cases it was indicated for. The antibiotic spectrum was narrowed after the panel confirming S. agalactiae returned. Of the 17 cases negative for CNS infection, 57 percent of patients that were prescribed antimicrobials received less than or equal to 48 hours of empiric therapy. Inappropriate therapy was avoided in 20.7 percent of patients. The total average length of stay of all patients was 106.6 hours (71.8 hours for positive tests vs. 139.6 hours for negative tests). The average length of stay when antimicrobials were altered due to the ME PCR results was 88.6 hours.

Conclusion: Implementing the ME PCR panel in a community hospital allowed prescribers to deescalate antimicrobial therapy and begin acyclovir for HSV2 and VZV etiologies. This positively affects patient outcomes by reducing the risk of complications and antibiotic resistance from unnecessary antibiotic exposure. Based on the lowest CSF WBC count of this evaluation, increasing the WBC count to automatically test from 5 to 10 cells/microliter may be considered, however further study will be needed to conclude this decision.

Submission Type: Evaluative Study

Session-Board Number: 5b-181

Poster Title: Data mining in the electronic medical record to reduce alert fatigue

Primary Author: Robert Bruno, University of Tennessee College of Pharmacy, Tennessee; **Email:** rbruno@uthsc.edu

Additional Author (s):
Charisse Madlock-Brown
Muzammel Rizvi
Larry Caton

Purpose: Alert fatigue is a well-documented phenomenon whereby clinicians become desensitized to safety alerts, especially alerts within the electronic medical record. Dose range alerts are of particular importance to pharmacists as they have the potential to avert medication errors. In a single year at Methodist LeBonheur Healthcare there were 174,944 dose range alerts, 80 percent of which were overridden further highlighting the scope of the alert fatigue problem. This research seeks to predict which dose range alerts would be successful in an attempt to ameliorate alert fatigue and make dose range alerts more meaningful.

Methods: A dose range checker report was used to collect the dose range checking alerts within the Methodist LeBonhuer Healthcare System from August 1, 2015 to July 31, 2016. Patient identifiers were removed from the dataset, and eleven features were selected during preprocessing which included the drug, dose, dosage form, patient age, and others. Due to an imbalance in the number of successful and overridden alerts, the dataset was randomly reduced to 20,000 entries with an equal distribution of successes and overrides. The dataset was then used to create a decision tree within the Waikato Environment for Knowledge Analysis (WEKA) Explorer version 3.8.0. A decision tree is a predictive tool commonly used in data science and was used to build a model with our dataset which predicts whether a dosage alert will be successful or overridden. 10-fold cross validation, a robust method to estimate a predictive model's true error rate, was used to validate the decision tree. 10-fold cross validation partitions the data into ten equal subsets and uses those partitions for training and testing. For ten iterations, nine partitions are used to build a decision tree, and the subset held out at each experiment is used for testing.

Results: For the purposes of this analysis, successes were considered a positive result while overrides were considered a negative result. 17,841 alerts (89 percent) were correctly classified and 2,159 alerts (11 percent) were misclassified. 8,883 entries were labeled as a success and would have resulted in an alert being presented to the prescriber. 94 percent (8,362) of alerts labelled success were true positives, while only 6 percent (512) of alerts labelled success were false positives. 11,117 entries were labeled as an override; 85 percent (9,470) of alerts labelled override were true negatives, while 15 percent (1,638) of alerts labelled override were false negatives. The sensitivity and specificity were 84 percent and 95 percent respectively.

Conclusion: Based on the results of the 10-fold cross validation, 94 percent of alerts presented to the prescriber were successful. Thus, if this decision tree was implemented within an electronic medical record, it could greatly reduce the number of overridden alerts. This would help to reduce alert fatigue which can be detrimental to providing patient care. This analysis has confirmed the plausibility of using decision trees to reduce overridden alerts thereby making dose range alerts more meaningful. Future work will involve continuing to improve the sensitivity of the model.

Submission Type: Descriptive Report

Session-Board Number: 5b-182

Poster Title: Interdisciplinary anesthesia tray revision project: Reducing the opportunity for human error

Primary Author: Elizabeth Smith, The University of Tennessee College of Pharmacy, Tennessee; **Email:** esmit114@uthsc.edu

Additional Author (s):
Gerald Phillips
Lebron Cooper
Chris Sharp
Matt Curry

Purpose: Contrary to medication errors in other areas, anesthesia errors are poorly defined and are only recently being recognized. The administration of these medications lacks safety checks used in many areas, such as barcoding and scanning and double checks by pharmacists. There is a shortage of documentation and extensive research needed to identify and resolve problems in this unique environment. The most common anesthesia errors include mistakes in drug dose and drug substitution: both caused by human error. The purpose of this project was to implement anesthesia tray improvements to decrease the opportunity for human error.

Methods: An interdisciplinary initiative with anesthesia and pharmacy lead by the chief of anesthesia was launched to reexamine trays used in four different operating rooms. The contents were evaluated by frequency of use, par levels, location of look-alike/sound-alike medications, potential for stocking premixing, and presence of unnecessary high alert drugs. The interdisciplinary team removed medications and reconfigured trays to enhance safety.

Results: Medications that were stocked in trays but rarely used and those available in automated medication dispensing cabinets were removed, averaging ten unique medication removals per tray. Medications that previously had to be mixed and drawn up during a procedure were replaced with admixtures, averaging four unique medication replacements per tray. Also, an average of two medications were replaced per tray to allow for safer unit of use products. An average of three medications per tray were added that were previously needed, but not available. The greatest amount of changes was seen in the trauma tray with a total of

twenty-seven removals, replacements, and additions. The least amount of changes was slightly less at a total of seventeen. If look-alike/sound-alike medications could not be removed, they were strategically placed in opposite sides of the tray. By decreasing the amount of medications in each tray, previously cluttered trays became more organized. With less medications to choose from, there were less opportunities to choose the wrong drug. With pre filled syringes replacing ready mix ampules and vials, there were less opportunities to draw up the wrong dose or inadvertently administer undiluted medications.

Conclusion: Multiple opportunities were identified to enhance anesthesia medication safety in the operating room. The only costs associated with this initiative were labor. Reorganizing anesthesia medication trays was effective in decreasing the opportunity for human error and may be a simple way to lower the amount of administration errors in the operating room.

Poster Title: Pembrolizumab-induced myasthenia gravis: A fatal case report

Primary Author: Daniel Neu, University of Tennessee College of Pharmacy, Tennessee; **Email:** dneu@uthsc.edu

Additional Author (s):
Katherine March
Michael Samarin
Amik Sodhi
Ryan Owens

Purpose: Pembrolizumab is a novel monoclonal antibody that enhances anti-tumor responses by inhibiting the programmed cell-death 1 receptor. While efficacious in different metastatic cancers, pembrolizumab has also been associated with numerous life-threatening immune related adverse events. Myasthenia gravis, a neuromuscular autoimmune disorder characterized by muscle weakness secondary to antibodies targeting the acetylcholine receptor, is one such immune related adverse event that has been associated with pembrolizumab use. Although rare, it has mainly been associated with the development of exacerbations in patients with pre-existing myasthenia gravis. We present a fatal case of myasthenia gravis following an infusion of pembrolizumab in a patient with no prior myasthenia gravis history. A 63-year-old Caucasian male weighing 135 kilograms presented to the emergency department following right eyelid drooping, puffiness, blurred vision, and shortness of breath upon ambulation for two days. Past medical history was significant for hypertension, osteoarthritis, benign prostatic hypertrophy, nephrolithiasis, and stage IV malignant melanoma of the right scalp with metastases to the liver and brain. Home medications included losartan 100 mg, meloxicam 15 mg, and tamsulosin 0.4 mg all taken once daily. Per patient interview, he also underwent radiation therapy six weeks prior to admission and received the first infusion of pembrolizumab two weeks prior to his symptom onset. Physical exam was significant for mild right ptosis secondary to periorbital edema and mild erythema. A magnetic resonance angiography of the head and neck and a magnetic resonance image of the brain and brainstem were unremarkable for new findings. Abnormal admission lab results included creatinine phosphokinase 10,386 units/L, aspartate aminotransferase 409 unit/L, alanine aminotransferase 179 unit/L, troponin 1.280 ng/mL, and white blood cell count 18.5 thou/mcl.

The patient was started on pyridostigmine 120 mg orally every six hours and prednisone 60 mg orally daily for myositis, and ceftriaxone 1 gram every 24 hours for presumed infection. The patient developed facial muscle weakness, bilateral ptosis, and worsening respiratory failure on day two of hospitalization and was transferred to the intensive care unit where noninvasive positive-pressure ventilation was initiated. Intravenous immunoglobulin 40 grams daily was started on day two and continued until day six for five total doses. On day six of hospitalization the steroid regimen was changed to methylprednisolone 1 gram IV daily for seven total doses. After approximately one week of hospitalization, serologic testing results returned positive for acetylcholine receptor modulator antibody at 61 percent and negative for anti-muscarinic antibodies. These laboratory findings, coupled with the recent initiation of pembrolizumab led the medical team to diagnose the patient with PD-1 induced autoimmune myasthenia gravis with myositis. Subsequently, daily plasmapheresis was initiated days seven through nine of hospitalization and on day 11. On day nine the patient developed hypercapnic respiratory distress and became increasingly drowsy requiring mechanical ventilation. Despite aggressive medical treatment, the patient showed no signs of improvement. Per the wishes of the patient and his family, aggressive care was withdrawn and comfort measures pursued on day 12 with expiration shortly thereafter. While this immune related adverse event is rare, one previous report of new onset myasthenia gravis has been identified, though the patient was seronegative. Compared with patients experiencing a myasthenia gravis exacerbation secondary to pembrolizumab, new onset myasthenia gravis appears to be more resistant to myasthenia gravis treatment regimens. Clinicians should be aware of this rare potential adverse event and remain aggressive in treatment strategies. As our case highlights, obtaining an accurate and thorough medication history is vitally important to help differentiate a drug-induced cause and aide in determining the best treatment strategy. Rapid recognition and discontinuation of pembrolizumab therapy is imperative to prevent further worsening symptoms and improve prognosis.

Poster Title: Metronidazole-induced cerebellar toxicity following prolonged course of therapy

Primary Author: Kelsie Graham, Belmont University College of Pharmacy, Tennessee; **Email:** kelsie.graham@pop.belmont.edu

Additional Author (s):
Angel Johnson
Kristy Wahaib

Purpose: Purpose: To report a case of metronidazole-induced cerebellar toxicity noted on a magnetic resonance imaging (MRI) scan following a prolonged course of therapy. Summary: A 53-year old female, with a past medical history of Hepatitis C cirrhosis and Type 2 Diabetes Mellitus, presented to the emergency department with worsening altered mental status, dysarthria, and possible urinary tract infection (UTI). Following a thorough history and physical, it was noted that the patient had been on triple antibiotic therapy with vancomycin, ceftriaxone, and metronidazole 500mg three times daily for 6 weeks for bilateral submandibular abscesses. After ruling out a UTI, an MRI scan was completed and was notable for T2 hyperintense signal within the splenium with no definite abnormal T2 signal within the internal capsules, and symmetric abnormal T2 hyperintense signal within the cerebellum dentate nuclei, without restricted diffusion, mass effect, volume loss, or abnormal enhancement. This change is a classic sign for metronidazole toxicity, and although the MRI findings were consistent with possible metronidazole toxicity, the patient's lactulose was up-titrated to rule out hepatic encephalopathy. Conclusion: Review of the literature reveals inconsistencies regarding risk factors (i.e. dose, duration of therapy, and susceptible patient characteristics) for development of metronidazole-induced cerebellar toxicity; however MRI findings of abnormal signal intensity, involving the dentate nuclei of the cerebellum bilaterally and symmetrically, are consistent among all published case reports. Therefore, despite unknown etiology, it is likely that this patient represents a case of cerebellar toxicity due to metronidazole administration.

Poster Title: Prolongation of wound healing secondary to dexmethylphenidate: case report

Primary Author: Robert Crawley, The University of Tennessee Health Science Center College of Pharmacy, Tennessee; **Email:** rcrawle2@uthsc.edu

Additional Author (s):
David Holmes
William Mabry

Purpose: Introduction: In many disease states, such as diabetes mellitus, peripheral vasculopathies have been associated with prolonged healing times of superficial injuries and infections. Centrally-acting, psychostimulant medications are associated with peripheral vasculopathies such as Raynaud's Phenomenon. In the pediatric population, psychostimulant medications such as methylphenidate, dexmethylphenidate, dextroamphetamine, and lisdexamfetamine are commonly prescribed for treatment of Attention Deficit/Hyperactivity Disorder (ADHD). According to the Centers for Disease Control and Prevention, there are over 6 million children and adolescents in the United States diagnosed with ADHD. The aim of this report is to characterize the association of dexmethylphenidate with prolonged wound healing secondary to peripheral vasculopathy.

Case Presentation: A 14-year-old, Caucasian male presented to pediatric emergency department with bilateral lower extremity pain with accompanying inflammation. Upon x-ray, patient was found to have early exostoses involving the left first distal phalangeal tuft with mild soft tissue swelling around the nail bed. The patient had been suffering with the pain for 10 months, consulted with a podiatrist, completed two rounds of antibiotic therapy with clindamycin, and had both toenails removed. Throughout the symptomatic period, the patient had been adherent to dexmethylphenidate previously prescribed for ADHD. The patient was discharged on a twenty-eight-day course of oral clindamycin and recommendations to temporarily discontinue dexmethylphenidate.

Discussion: Given the abnormal persistence of the patient's wound, the absence of comorbid conditions, and the absence of concomitant medications, dexmethylphenidate was identified as the likely etiology of prolonged wound healing by the medical team. Evaluation with the Naranjo algorithm indicated a "possible" adverse drug reaction. One previous study, Yu et al, 2010, reported the development of peripheral vasculopathy upon initiation of methylphenidate

and dexmethylphenidate therapy in four pediatric patients. The authors demonstrated concern for adverse effects in the peripheral vascular system of children and adolescents associated with psychostimulant treatment. Upon conducting a literature search, an absence of published cases demonstrating prolonged wound healing were found.

Conclusion: Psychostimulant-induced peripheral vasculopathy can have significant impacts on wound/infection healing in pediatric patients. Given the prevalence of ADHD and psychostimulant use, current lack of case report publication indicates that adverse drug reactions, such as presented here, are often overlooked. Therefore, patients receiving centrally-acting psychostimulant medications with persistent wounds/infections should be evaluated for the presence of psychostimulant-induced peripheral vasculopathy.

Poster Title: Comparing methods of measuring adherence to glaucoma medication: self-report versus electronic monitoring

Primary Author: Jordan Johnson, University of Tennessee College of Pharmacy, Tennessee;
Email: jjohn309@uthsc.edu

Additional Author (s):
Brian Jerkins
Justin Gatwood

Purpose: Poor adherence remains problematic for many glaucoma patients. This is concerning as damage may be ongoing even though symptoms may not worsen immediately without therapy. Medication adherence is quantified through self-report, physician report, pharmacy records, and electronic monitors; however, patients and physicians often poorly estimate adherence, and pharmacy records lack verification of proper technique. Electronic monitoring could potentially become the gold standard to measure adherence as it records the exact time and number of drops instilled. This pilot study assessed and compared patient adherence and self-efficacy using adherence tools and a new electronic monitoring device, Kali Drop.

Methods: The University of Tennessee Health Science Center Institutional Review Board approved this pilot study. Patients were recruited from a group ophthalmology practice in Memphis, TN. Patients receiving treatment indicated for glaucoma were asked to participate by completing a survey at baseline and at follow-up at 60 days. Patients were further required to use Kali Drop, a new 3G wireless medication monitor, to administer all eye drops during the 60-day period. Kali Drop records and wirelessly transmits topical medication use in real-time; the resulting data can then be viewed by patients, providers, and other caretakers. The baseline survey focused on patient demographics, mobile phone usage, medication adherence, and glaucoma-related self-efficacy. Self-reported adherence was assessed using the Morisky Medication Adherence Scale and Medication Adherence Reasons Scale (MAR-Scale). Adherence was tracked using the Kali Drop web-based interface over two, 30-day intervals and across the entire study period.

Results: A total of 30 patients were recruited with complete data available for 27 at completion of the study. The majority of patients were white (70.4 percent), female (70.1 percent), and over age 65 (55.6 percent). At baseline, self-reported adherence was high according to both the Morisky Scale (high adherence equals 0; 63 percent) and MAR-Scale (7 out of 7 days; 89 percent). Adherence, according to the Morisky Scale, declined over the course of 60 days (p equals 0.01) with 56 percent remaining highly adherent. Kali Drop recorded decreasing rates of adherence from the first month (63 percent) to the second month (48 percent; p equals 0.018). No change in adherence was observed according to MAR-Scale. Many patients reported high self-efficacy at baseline (53 percent), but results showed a decline in patient's self-efficacy across the study (48 percent; p equals 0.037). Furthermore, those reporting high self-efficacy decreased in adherence according to Kali Drop (p equals 0.049). There was not a decrease in self-efficacy observed by Morisky Scale or MAR-Scale. Kali Drop observed high adherence in patients who were highly adherent according to MAR-Scale (56.5 percent; p equals 0.602) and highly adherent according to Morisky Scale (56.5 percent; p equals 0.593).

Conclusion: Self-reported adherence to glaucoma medication is typically poorly estimated and different adherence tools may show different levels of adherence. Kali Drop is an effective tool to accurately measure adherence and may be more effective at relating patient self-efficacy to adherence. Further trials are needed to assess the utility of Kali Drop at providing interventions in this population where adherence to medication is of utmost importance.

Poster Title: Evaluation of aminoglycoside dosing protocol for adults in a community hospital

Primary Author: Kwabena Nimarko, University of Maryland, School of Pharmacy, Maryland;
Email: knimarko@umaryland.edu

Additional Author (s):
Amber Chiplinski
Shawn Boland

Purpose: Aminoglycosides are an important therapy in the treatment of life-threatening gram-negative infections. They also act synergistically with beta lactams to treat gram-positive pathogens. Aminoglycosides have limited tissue distribution, are renally eliminated, and have a narrow therapeutic index. Therefore, dosing of these antibiotics is tailored to patient's indication, weight, age, and renal function. Meritus Medical Center has a protocol to guide pharmacists in selecting treatment dose and frequency. The purpose of this study is to assess adherence of pharmacists to the current protocol, frequency of extended and traditional dosing schedule, and the incidence of drug-induced nephrotoxicity.

Methods: A retrospective chart review of adults (18 years and above) who received at least one dose of gentamicin or tobramycin, spanning August 01, 2015 to July 31, 2016, were performed. Patients were excluded if they received pre or post-operative prophylaxis, were treated with a topical aminoglycoside, and or used aminoglycoside for less than 48 hours. Patients who received amikacin were excluded from this study due to lack of in-hospital monitoring and low use of medication. Eight hundred and forty patients were identified and were sieved to 109. Extended dosing was defined by 5-7 mg/kg of gentamicin or tobramycin. Traditional dosing was 1-3 mg/kg of gentamicin or tobramycin. Drug induced nephrotoxicity was identified using Acute Kidney Injury Network criteria: increase in serum creatinine more than or equal to 0.3 mg/dL or a 50% increase in SCr within 48 hours.

Results: Ninety-two orders (84.4%) were adherent to the protocol for both dose and frequency. Deviations from the protocol (5.5%) occurred when the physician did not consult the pharmacist and patients were treated in an outpatient setting. Pharmacists increased or decreased initial dose or frequency (10.1%) in response to patients' age, creatine clearance, and

disease state. Deviations occurred in the treatment of community acquired pneumonia, urinary tract infection, pelvic inflammatory disease, and endocarditis. There were two cases of inappropriate use of the extended interval regimen. Patients were on synergistic regimens, which warranted use of traditional dosing. Most patients (63.3%) were on an extended interval dosing frequency of every 24-hours. The average 6-hour serum levels were within 24-hour range on the Hartford nomogram. There was one case of extended interval of every 72 hours. The patient's supratherapeutic trough necessitated an extension of the interval. Traditional dosing occurred in 19.2% of the orders. Drug-induced nephrotoxicity occurred in 2.8% of the patients. Two of the three cases of nephrotoxicity resulted from use of tobramycin. One patient receiving gentamicin, with a serum creatinine of 1 mg/dL, experienced acute kidney injury at an initial dose and frequency of 5 mg/kg every 48 hours.

Conclusion: The application of the protocol in the majority of orders resulted in therapeutic trough levels for both drugs. Since most patients were placed in extended interval dosing, they received high peak concentrations and experienced low rates of nephrotoxicity. The incidence of drug-induced nephrotoxicity observed is less than the reported incidences of 6% in extended dosing and 15.4% in traditional dosing. Additionally, patients on extended interval dosing had a lesser need for therapeutic drug monitoring and frequent dose adjustments.

Poster Title: Observational survey-based study of healthcare access following the Maryland Health Progress Act of 2013 in homeless women of My Sister's Place

Primary Author: Amanda Nguyen, Notre Dame of Maryland University, School of Pharmacy, Maryland; **Email:** anguyen2@live.ndm.edu

Additional Author (s):
Jacek Domagala
Shayne Wharton
Megan Cook

Purpose: To evaluate access to healthcare following former Mayor Martin O'Malley's implementation of the Maryland Health Progress Act in 2013 which included an expansion of Medicaid to include a wider age range and an increase of the income cap. Currently, it is unknown how many Baltimore City residents are aware of this expansion and their possible eligibility for Medicaid coverage. The ultimate goal of this study is to determine if the Maryland Health Progress Act has made a positive impact on healthcare coverage.

Methods: My Sister's Place is a day shelter located in Baltimore, Maryland that provides resources and support to homeless women in the area. The majority of these women rely heavily on government funded healthcare programs for their health insurance. The women are given an abridged version of the Consumer Assessment of Healthcare Providers and Systems (CAHPS) survey. This survey obtains data regarding the women's access to healthcare, health insurance, fiscal status, and basic demographic information which will help categorize the population of interest. Descriptive statistics will be used to describe the My Sister's Place population's healthcare. Chi-squared analysis will be used to describe the demographic data. Inferential statistics will be used to make the comparison between healthcare access from the study population to national data.

Results: The current investigation includes data that may not represent the entire study population based on the current status of data collection. The population consists of African American females which are predominantly over the age of 35. All of the women in the study fall well below the poverty line all making a self-reported annual income of less than $10,000.

Everyone surveyed had some form of insurance which varied and all the women reported having access to a primary care provider which they have visited within the past 12 months. The average length of time between appointment scheduling and the actual visit were split among the groups. Half of the women reported making a visit within one day and the other half reported waiting from at least two weeks to two months to see their primary care provider. In addition, the majority of the women reported making at least 3 emergency room visits in the past 12 months which was not correlated to the lack of a primary care provider but seemed to trend with the travel distance from each of the women's providers. Most of the participants reported no difficulty traveling to their providers with the exception of one participant.

Conclusion: Despite the resources and assistance programs available, our team realized that a very large proportion of the participants still use the emergency department for care more than once in the past 12 months. This may be attributed to the circumstances that existed upon presentation of the illness, however it is an interesting speculation which may require further observation. The following results pose a question to the investigating team about whether or not the care and access our population of women can be compared to the average American and whether this expansion made a tangible difference in these women's lives.

Submission Type: Descriptive Report

Session-Board Number: 5b-189

Poster Title: Service description and descriptive analysis for an interprofessional discharge clinic (IDC) within a primary care practice

Primary Author: Joyce Yu, University of Maryland Baltimore School of Pharmacy, Maryland; **Email:** joyce.yu@umaryland.edu

Additional Author (s):
Kathleen Pincus
Joey Mattingly

Purpose: Transitions of care (TOC) is a focus of interest from patients, providers, and policymakers. For two years, the University of Maryland Department of Family and Community Medicine (DCFM) piloted two practice-wide initiatives to improve TOC. The first initiative consisted of 2-4 days post-discharge telephone calls according to Medicare Transitional Care Management Services. The second was an interprofessional discharge clinic (IDC) staffed by a clinical pharmacist, social worker, care management nurse and attending physician.
The purpose of this study is to describe the services and the impact on patient care, including the 30 day readmission rate, medication errors, and interventions documented.

Methods: A daily list of patients admitted to any hospital in the region was received by DCFM through a regional health information exchange. The first initiative, post-discharge telephone calls from a social worker, offered patients an appointment with a practice physician. Patients were also asked about issues regarding self-care, ability to attend appointments (e.g. transportation), and changes in medication during these phone calls. The second initiative, an interdisciplinary clinic, was held for a half-day per week. During these visits each health care professional would conduct rounds to meet with the patient individually and document their interaction in the electronic medical record (EMR).
A retrospective chart review was performed for each patient identified. Data collected included: patient age, gender, race, comorbidities, cause of index admission, readmission within 30 days and 1 year, and documented medication errors and interventions at first visit. The primary outcome was 30 day readmission. Secondary outcomes included documented medication errors and interventions at first follow-up. Data were collected retrospectively using an electronic medical record and analyzed using SAS data system.

Results: Among 167 patients, 154 patients were seen by a physician only (PO), and 13 patients were seen in the IDC. Readmission within 30 days of discharge occurred for 41 patients (26.6%) seen for follow-up by a PO and one patient (7.7%) in the IDC group (p = 0.19). Seventy patients (45.5%) in the PO group and 11 patients (84.6%) in the IDC group (p = 0.0082) were found to have at least one medication error at the first follow-up visit. All patients seen at the IDC had an intervention made at first follow-up, while 68 (44.2%) seen by a PO received no intervention (p = 0.0009).

Conclusion: Sample size was a major limitation in comparing the two groups. A statistically significant increase in medication error and intervention documentation was found in the IDC group. It is critical that health care systems continue to develop new strategies such as IDCs to reduce unnecessary hospital readmissions.

Poster Title: Applying the Theory of Planned Behavior to Inhaler Use for Patients with Chronic Obstructive Pulmonary Disease

Primary Author: Erika Pineda, University of Maryland, School of Pharmacy, Maryland; **Email:** empineda@umaryland.edu

Additional Author (s):
Kathleen Pincus
Sue Lee
Adrienne A. Williams

Purpose: Studies investigating behavioral influences on inhaler use in patients with Chronic Obstructive Pulmonary Disease (COPD) are limited. These beliefs may lead to noncompliance and non-adherence, which has the potential to increase the risk of adverse outcomes including exacerbations, worsening breathing symptoms, and possibly death. The Theory of Planned Behavior is a theoretical framework that has been used to investigate the motivations behind a variety of health behaviors. This study evaluates how patients' attitudes and beliefs toward COPD management influence their behaviors and decisions to use or not to use their inhalers as prescribed.

Methods: Patients with outpatient visits for COPD at a single primary care center over a 12-month time period were identified based on ICD-9 codes. A survey instrument characterizing patient's motivations, behavioral influences, and perceived ability relating to the use of controller inhalers had previously been developed and used for a study of patients with persistent asthma. The survey was refined to address domains for the management of COPD using a check-list and 5-point Likert-type scale questions. This was administered as a voluntary telephone survey to identified patients. For those who did not answer the initial call, a voicemail was left that included a call-back number. Three attempts were made if the participant did not answer during the first or second call. De-identified survey responses were recorded and analyzed using descriptive statistics. Chi-squared and Fisher's Exact Tests were used for subgroup analyses.

Results: Of 107 patients identified, 25 completed the survey (23% response rate). All 25 participants reported picking up a prescribed inhaler within the past year. 72% (n=18) of participants reported using their inhaler daily, or 30 out of the last 30 days, while 28% (n=7) of participants reported using their inhalers on 15-25 of 30 days. Barriers to daily use reported by patients included cost (n=8, 32%) and transportation to the pharmacy (n=9, 36%). Perception of disease severity and benefit from inhaler were also identified as potential behavior determinants with 16% (n=4) reporting other illnesses more important than COPD, feeling fine without using an inhaler, or not believing COPD diagnosis. Of those participants who rated 5/5 in importance of inhaler use, 4 were inconsistently using their inhaler within the last 30 days. These participants could not afford their prescriptions, did not believe to have COPD, and did not know how to use their inhaler. The participants who rated less than 5 on the importance of inhaler use reported feeling fine without using their inhaler or believed to have other important illnesses than COPD.

Conclusion: While most patients in this study reported purchasing inhaler medications in the last year, not all reported consistent use. Perceptions related to symptom improvement and importance of COPD identified as potential motivators for non-adherence. Cost and access to pharmacies were also identified as physical barriers to optimal medication use. These results indicate that a combination of psychosocial and external factors influence patients' decisions to use or not to use an inhaler for COPD management. Future research on perceived risk and physical barriers of medication non-adherence among patients with COPD may help clinicians better target medication education and adherence interventions.

Poster Title: Quality analysis of high-dose versus low-dose parenteral thiamine use in hospitalized patients

Primary Author: Priya Rajendran, University of Maryland School of Pharmacy, Maryland; **Email:** prajendran@umaryland.edu

Additional Author (s):
Brian Spoelhof
JIll Lowman
Simon Bae

Purpose: Chronic alcohol use can lead to thiamine deficiency with severe deficiency resulting in Wernicke's encephalopathy (WE). The Royal College of Physicians guidelines for managing WE recommends IV thiamine 500 milligrams every eight hours for three days. For WE prophylaxis, 100 milligrams daily has been widely used. The objective of this medication use evaluation was to evaluate the appropriate utilization of high-dose (greater than 100 milligrams daily) vs low-dose thiamine in patients in order to assess the need for implementation of a standardized protocol to ensure appropriate use of thiamine and for cost savings.

Methods: This retrospective study was completed at a 527-bed academic teaching hospital located in Baltimore, Maryland. The study cohort received IV thiamine between March 30, 2016 to April 30, 2016 and were analyzed for: age, sex, weight, chief complaint, initial neurologic symptoms (confusion, ataxia, delirium tremens, hallucinations, ocular symptoms, language problems, seizures), primary diagnosis, diagnosis of Wernicke's encephalopathy, current alcohol use, active withdrawal and/or history of withdrawal, pancreatitis and/or history of pancreatitis, initial parenteral thiamine regimen, number of doses of thiamine administered, length of stay, and inpatient mortality. All symptoms and history were obtained from physicians' notes through each patient's electronic medical record. Medication costs were also evaluated in our study. All of the data was analyzed using the Fisher's exact test.

Results: A total of 73 patients were included in this evaluation with 41 patients receiving high-dose thiamine (greater than 100 milligrams daily) and 32 patients receiving low-dose thiamine. Of all the patients, two had a confirmed diagnosis of Wernicke's encephalopathy and one patient with a "possible" Wernicke's encephalopathy diagnosis. The remaining 38 patients who received high-dose thiamine did not have documented WE. These patients did, however, have a greater severity of symptoms upon admission with: 15 patients who presented with confusion, 5 with delusions or hallucinations, 18 with altered mental status, and 4 with ataxia versus 0, 1, 1, and 3 patients who received low-dose thiamine, respectively. Additionally, patients with high-dose thiamine had a longer length of stay of seven days versus three days in patients that received low-dose thiamine. The total cost for the first three days of therapy for all patients was $8,523.33. If all patients without suspected or documented WE had received low-dose therapy, the cost for first three days of therapy for all patients would have been $871.50. Throughout the analysis, it was also evident that many other regimens were prescribed such as thiamine 500 milligrams daily and 100 milligrams every 8 hours.

Conclusion: Overall, high-dose thiamine regimens were used in patients presenting with a higher severity of alcohol withdrawal. Current evidence suggests that low-dose thiamine is sufficient for patients without clinical suspicion or documented WE. A standardized order panel could be implemented to give only two options for parenteral thiamine that includes 100 milligrams daily or 500 milligrams every 8 hours that automatically discontinues after nine doses. Implementation of this order panel would allow for more accurate dosing of thiamine and allow for more cost savings. Limitations of this study include its retrospective nature, sample size, and short time frame of study.

Poster Title: Investigation of pharmacologic and non-pharmacologic treatment of youth with developmental and coexisting mental health disorders classified by school grade level status

Primary Author: Christine McCulley, University of Maryland School of Pharmacy, Maryland; **Email:** ctobin@umaryland.edu

Additional Author (s):
Melissa Ross
Susan dosReis

Purpose: The aim of this study was to investigate pharmacologic and non-pharmacologic treatment of youth with developmental and coexisting mental health disorders and to identify patterns in psychiatric diagnoses and mental health treatments to ultimately describe pediatric clinical profiles and care needs.

Methods: Demographic and clinical care information was self-reported by caregivers of youth with chronic mental health conditions via an online survey that was approved by the institutional review board. Primary caregivers of children and young adults with a developmental delay and a mental health condition were recruited online from parent advocacy groups in the United States to complete the online questionnaire. Caregivers were eligible to participate in the survey if (1) their child was 21 years old or younger; (2) a doctor had ever told them that their child has a delay in development such as: behavioral, communication, social or emotional; (3) one of the following was true: the child has been diagnosed with autism spectrum disorder, the child has been diagnosed with a learning disability, the child has problems with social skills, or it is difficult for the child to have a conversation when talking with people; and (4) a doctor had ever told them that their child has Attention Deficit Hyperactivity Disorder (ADHD) or Attention Deficit Disorder (ADD), anxiety, a mood disorder, or depression. A total of 237 participants completed the questionnaire. Information on current grade and age at the time of the survey was used to determine grade status, which assessed whether youth were at or below grade level. Use of pharmacologic and non-pharmacologic treatments was investigated based on this grade status classification.

Results: 69 (29.1 percent) of the 237 participants were determined to be at grade level for age and 168 (70.9 percent) were not at grade level for age. Youth who were at grade level were significantly more likely to have caregiver-reported ADHD (P equals 0.0026) or a caregiver-reported anxiety disorder (P equals 0.0034) and were less likely to have aggression (P equals 0.0002). Youth who were not at grade level were significantly more likely to have caregiver-reported depression (P equals 0.0053) and aggression toward others (P equals 0.0018). A higher proportion of youth at grade level had caregiver-reported communication disorders (P equals 0.0803) and a higher proportion of youth not at grade level had caregiver-reported intellectual disabilities (P equals 0.1609), but these differences were not statistically significant. Youth at grade level were more likely to use benzodiazepines (P equals 0.0468) and engage in speech therapy (P equals 0.0321). Youth who were not at grade level were more likely to engage in individual psychotherapy (P equals 0.0004) and family therapy (P less than 0.0001). A higher proportion of youth at grade level used any ADHD medication (any stimulant, clonidine, or atomoxetine; P equals 0.0628), but this difference was not statistically significant.

Conclusion: Differences in developmental and mental health disorder diagnoses as well as pharmacologic and non-pharmacologic treatments were found based on grade status classification. This suggests a role for grade status in the identification of youth with certain care needs to direct interventions and provide optimal care. Youth who are at grade level may have different clinical concerns, such as ensuring progression in school by targeting anxiety, ADHD, and communication issues using evidence-based treatment. Based on this analysis, youth who are not at grade level may have conditions requiring intensive treatment such as aggression, depression, and intellectual disabilities.

Poster Title: The effect of clevidipine vs. nicardipine on blood pressure lability in acute intracranial hemorrhage

Primary Author: Theresa Chea, University of Maryland School of Pharmacy, Maryland; **Email:** tchea@umaryland.edu

Additional Author (s):
Michael Armahizer
Neeraj Badjatia

Purpose: Clevidipine is a novel ultrashort-acting dihydropyridine calcium channel blocker that is FDA-approved for rapid reduction of blood pressure when oral therapy is neither feasible nor desirable. It has been studied in the setting of subarachnoid hemorrhage, intracranial hemorrhage, perioperative hypertension, and hypertensive crises. It is administered intravenously, like nicardipine, but it has a faster onset of action and shorter duration of effect. The aim of this study is to compare the effect of clevidipine or nicardipine on blood pressure lability in patients requiring emergent blood pressure control in the Neurocritical Care Unit (NCCU) at a large academic medical center.

Methods: A retrospective case-control study was performed via chart review on all patients with hemorrhagic stroke admitted to the NCCU requiring blood pressure management with either continuous or intermittent infusions or injections of clevidipine and/or nicardipine. Patients older than 18 years of age diagnosed with hemorrhagic stroke between December 2012 to September 2016 were eligible for inclusion. Baseline characteristics such as age, gender, past medical history, initial Glasgow Coma Score, and hemorrhagic stroke severity were collected from the electronic medical record. Patients receiving clevidipine (intervention group) were matched with patients receiving only nicardipine (control group) based on diagnosis and baseline characteristics. Continuous vital signs data were collected via BedMaster (Excel Medical Electronics, Jupiter, FL), which allows for recording of all core physiological data at 240Hz for waveforms and 0.5Hz for trend data. This program allowed us to review continuous blood pressure readings, as opposed to electronically charted vital signs, which are dependent on nurse documentation. The time to reach a goal blood pressure of 160mmHg after the first exposure to the antihypertensive drug and the number of times and duration of blood pressure

deviations above 160mmHg and below 110mmHg were evaluated. Statistical tests were two-tailed, and a p value of less than 0.05 was considered to be statistically significant.

Results: A total of 20 patients were included in the intervention group. They were matched with 40 patients in the control group. The mean blood pressure prior to initiation of clevidipine in the intervention group and nicardipine in the control group did not differ. The blood pressure lability throughout the duration of the antihypertensive drug infusions also did not differ between the two groups. A statistically significant difference was found in the mean time to reach goal blood pressure (19.1 minutes vs. 48.5 minutes, p equals 0.0495).

Conclusion: This retrospective case-control study demonstrated that compared with nicardipine, clevidipine did not impact blood pressure lability. However, use of clevidipine was associated with a significantly shorter time to goal blood pressure, which may be clinically meaningful. Larger prospective studies are needed to confirm our findings, as this study had many limitations. We overcame the issue of charting inaccuracy by using a comprehensive system for data collection, which was a common limitation in previous studies. This study provided useful insight to the institution, and may encourage continued use of clevidipine in the NCCU.

Poster Title: Evaluating the impact of an oral chemotherapy standardized process improvement tool on patient-perceived ability to adhere to oral chemotherapy treatment plans

Primary Author: Katarina Stelzer, University of Maryland School of Pharmacy, Maryland; **Email:** kgstelzer@gmail.com

Additional Author (s):
Alison Duffy
Steven Gilmore

Purpose: Recent progress in the treatment of cancer has seen an increasing number of patients receiving oral chemotherapy, as well as the accelerated development of new oral antineoplastic agents. Oral chemotherapy offers certain benefits to patients including ease of administration and autonomy over treatment. However, the lack of practice-level systems to ensure the safe management of oral chemotherapy poses a challenge to patients and practitioners. The purpose of this study is to describe the effect of a standardized education process on patient-perceived ability to adhere to oral chemotherapy treatment plans and handle medication safely, and to identify patient-reported barriers to adherence.

Methods: The current study is a prospective, single center, patient survey-based study conducted at The University of Maryland Greenebaum Comprehensive Cancer Center (UMGCCC) including all oncology patients 18 years and older who were newly started on an oral chemotherapy agent from November 1st, 2015-November 1st 2016. The institutional review board approved this study. Subjects who met inclusion criteria and provided informed consent were asked to complete two versions of the same survey, once before administration of an Oral Chemotherapy Standardized Process Education Improvement Tool, and once after. The survey was devised to assess patient-perceived understanding of a myriad of factors related to oral chemotherapy treatment plans and to identify patient-perceived barriers to adherence. The Oral Chemotherapy Standardized Process Improvement Tool was administered by a study investigator and consisted of components related to drug procurement and patient education, including medication administration, food/drug interactions, side effects, storage and handling. Subjects completed the Post-Survey by telephone within 2 weeks after discharge. The primary outcome was the mean composite value of patient-perceived understanding before and after

administration of the standardized process tool, based on a scale of 1-5 (1 indicating "Not confident at all," 5 indicating "Very confident"). Secondary outcomes included: the change in frequency of identification of barriers to adherence, and the mode level of adherence determined by the Morisky Medication Adherence Scale-8 (low, medium, or high) after discharge.

Results: Ten patients were enrolled over the course of 15 weeks. Eight out of 10 patients completed the study, while 2 were unable to be reached within the designated follow-up period. At enrollment, only 8 out of 10 patients reported receiving some baseline medication education upon initiation of a new oral chemotherapy agent. The mean composite value of patient-reported understanding at baseline was 4.03 out of 5.0, with individual means ranging from 1.06 to 5.0. The mean composite value of patient-reported understanding collected in the Post-Survey period was 4.71 out of 5.0, with individual means ranging from 4.17 to 5.0. Utilization of a standardized education process demonstrated a 16.8% mean overall increase in patient-perceived ability to adhere to oral chemotherapy treatment plans and handle medication safely. Patients were 54.5% less likely to identify barriers to adherence after administration of the standardized education process tool than they were at baseline (n=5 vs. n=11) . Six out of 8 patients (75%) completing the study demonstrated high adherence within the follow-up period, while 2 out of 8 patients (25%) demonstrated moderate adherence.

Conclusion: This study has shown that implementation of a standardized education process can demonstrate a meaningful improvement in patient-perceived ability to adhere to oral chemotherapy treatment plans and handle medication safely, reduce patient-perceived barriers to adherence, and serve as a model for the development of more effective procedures at oral chemotherapy transitions of care.

Poster Title: Daptomycin utilization in a community hospital setting

Primary Author: Monica Tong, University of Maryland School of Pharmacy, Maryland; **Email:** monicatong@umaryland.edu

Additional Author (s):
Emil Sidawy

Purpose: Daptomycin (Cubicin), a broad spectrum cyclic lipopeptide antibiotic, binds to the bacterial membrane causing a depolarization of membrane potential leading to bacterial death. Daptomycin's spectrum of coverage includes gram positive bacteria commonly found in infections such as bacteremia, complicated skin and soft tissue infections (SSTI), bone/joint infections, and urinary tract infections. At this community hospital, prescribing of daptomycin is restricted to infectious disease specialists due to its broad spectrum of activity and high cost. The purpose of this study was to assess the appropriateness of daptomycin usage, perform a cost-analysis, and assess monitoring for adverse effects.

Methods: A retrospective descriptive chart review was performed. The inclusion criteria were patients who received daptomycin in the inpatient setting from January to June of 2016. Exclusion criteria were patients receiving daptomycin in the outpatient setting and those who received one time doses of daptomycin. Variables assessed included infectious disease consult in place, allergies, weight, renal function, dosing, indication, cultures and sensitivities, use of SSRIs, previous antibiotic therapies, and adverse effect monitoring (creatinine kinase (CK) levels). This drug use evaluation (DUE) is IRB approved.

Results: Daptomycin was prescribed for 39 different cases during the study period. Of the 39 cases, a total of 172 doses (230 vials) of daptomycin were administered costing a total of about $115,000. Overall, 12 cases (31%) were treated for SSTI, 12 cases (31%) for bone/joint infections, 10 cases (25%) for sepsis/bacteremia, 5 cases (13%) for urinary tract infections. Common reasons for the use of daptomycin included coverage for vancomycin resistant enterococci (VRE) until sensitivities were finalized, allergies to vancomycin, failure of vancomycin therapy, and impaired renal function. Overall, 81% of the doses of daptomycin were administered appropriately. Inappropriate usage was due to high doses, low doses, and

renally unadjusted doses. In addition, doses were assessed to determine if an alternative antibiotic could have been used first line such as vancomycin or linezolid. There were 80 vials ($40,000) of daptomycin that could have been substituted for another antibiotic based on final culture sensitivities and the patient's profile. With regards to adverse event monitoring, 18 patients (46%) had CK levels to monitor for rhabdomyolysis.

Conclusion: Retrospective analysis of appropriate daptomycin use at this community hospital revealed the need for further interventions in the usage of daptomycin from a cost and proper usage perspective. Based on the results of this analysis, a recommendation is to develop a medication usage guidelines to facilitate appropriate daptomycin prescribing and assess the need for other antibiotic usage. In addition, the guidelines should include details on monitoring for daptomycin.

Session-Board Number: 5b-196

Poster Title: Evaluation of the appropriateness of initial antibiotic therapy in sepsis

Primary Author: Alexandra Phan, Notre Dame of Maryland University School of Pharmacy, Maryland; **Email:** alexa.phan4@gmail.com

Additional Author (s):
Kimberly Couch

Purpose: Appropriate initial antibiotic therapy in sepsis has been shown to significantly reduce mortality. Although diagnostic testing for pathogens has improved dramatically, small community hospitals may not have access to these tools. Periodic re-evaluation of the epidemiology of sepsis and the susceptibilities of pathogens is necessary to provide appropriate initial therapy. The objective of the study was to evaluate the local incidence of pathogens in sepsis and compare the selection of initial antibiotic therapy for sepsis with the recovered pathogen sensitivities.

Methods: All clinical research represented in the abstract was approved by the appropriate ethics committee or institutional review board. A computer-generated list of all patients from a small community hospital with a discharge diagnosis of sepsis between March and August 2016 was completed. The source of sepsis was identified from the electronic medical record. Initial antibiotic therapy was compared to local recommendations as well as the susceptibilities of recovered pathogens. Appropriateness was determined for local recommendations and for pathogen sensitivities. Appropriate therapy for local recommendations was defined as administered therapy consistent with therapy based on local recommendations. Inappropriate therapy for local recommendations was defined as therapy anything other than the local recommendations. Appropriate therapy for pathogen sensitivities was defined as administered therapy sensitive for pathogens identified. Inappropriate therapy for pathogen sensitivities was defined as administered therapy intermediately sensitive or resistant for the pathogens identified. The percentage of appropriate therapy was calculated for the entire time period as well as for each month for local recommendations and for pathogen sensitivities.

Results: The computer system identified 245 patients with sepsis. Of those 245, only 28 (11%) patients met the Surviving Sepsis definition of sepsis and had cultures with organisms identified and sensitivities performed. Of the 28 patients, the types of infections were 13 (46%) skin and soft tissue infections, 7 (25%) urinary tract infections, 5 (18%) bacteremia, 1 (4%) intraabdominal, and 1 (4%) pneumonia. Overall the organisms recovered included 7 (25%) Escherichia coli, 6 (21%) streptococci, 6 (21%) methicillin resistant Staphylococcus aureus, 3 (11%) Pseudomonas aeruginosa, 2 (7%) Enterococcus faecalis, 2 (7%) methicillin susceptible Staphylococcus aureus, 2 (7%) Proteus mirabilis, 1 (4%) Actinetobacter baumannii, 1 (4%) coagulase-negative staphylococci, 1 (4%) Klebsiella pneumoniae, 1 (4%) Serratia marcescens, 1 (4%) Streptococcus parasanguinis and 1 (4%) viridans group streptococci. Twenty-seven (96%) patients received appropriate initial antibiotics. Vancomycin (n=20) was most frequently used, followed by piperacillin/tazobactam (n=8), cefepime (n=5), ceftriaxone (n=4), levofloxacin (n=4), clindamycin (n=2), ertapenem (n=2), linezolid (n=1), metronidazole (n=1), cefazolin (n=1), and aztreonam (n=1). Single antibiotic therapy was frequently used (n=20), then dual therapy (n=10), triple therapy (n=4), and quadruple therapy (n=1).

Conclusion: Appropriate antimicrobial therapy was successfully achieved for patients diagnosed with sepsis most of the time, which should have a positive impact on mortality and morbidity. Single antibiotic therapy was most frequently used although broad spectrum therapy was most frequently prescribed. Continued surveillance of appropriateness of therapy will allow for changes to be made to empiric therapy if necessary.

Poster Title: Effect of implementation of a residency preparation course on residency match rates at large pharmacy school

Primary Author: Alan Chen, University of Maryland School of Pharmacy, Maryland; **Email:** alan.chen@som.umaryland.edu

Additional Author (s):
David Procaccini
Toyin Tofade
Mark Brueckl

Purpose: To compare ASHP residency match rates at the University of Maryland School of Pharmacy (UMSOP) prior to and after implementation of a Residency Preparation Elective Course (RPEC), amongst students who completed the RPEC versus those who did not, amongst students who were a part of a major student organization or not, and also to identify the perceived value of RPEC by students who completed the course.

Methods: This project was approved by the University of Maryland IRB. Match rates amongst the graduating classes from 2013 to 2016 were obtained via review of university graduate and class records. RPEC was first offered to third-year pharmacy students (P-III) during the Fall semester of 2013. The pre-implementation group consists of the graduating classes of 2013 and 2014. The post-implementation group consists of the graduating classes of 2015 and 2016, for whom would have taken the course during the Fall semesters of 2013 and 2014.
Match rates amongst students in the post-implementation group who completed RPEC versus those who did not were then compared. Match rates between students who had Rho Chi (RX) and/or Phi Lambda Sigma (PLS) appointments, and who completed the residency preparation course, were compared to those who did not. Enrollment into a fellowship position is considered matched in this study. Statistical analysis for all comparisons was performed using a two-tailed fisher exact test. A P value of 0.05 was set a prior.
A survey was emailed to all previous students who pursued a residency after graduation, in order to obtain insight on how well prepared students felt they were prior to applying for residency. The results from those who completed RPEC were then compared to those who did not.

Results: The post-implementation group had a significant higher match rate compared to the pre-implementation group (75.9 percent versus 62.7 percent; P 0.031). Match rates amongst students who took RPEC were not statistically different compared to those who did not (78.4 percent versus 74.7 percent; P 0.82). Of students who completed RPEC, those who were part of a major student organization had significantly higher match rates compared to those who were not (90.3 percent versus 69.8 percent; P 0.046). Match rates comparing all students who were part of a major student organization regardless of completion of RPEC were significantly higher than those who were not (88.1 percent versus 68.9 percent; P 0.0013).
Three hundred and twenty students were provided with the survey. Twenty-eight students responded, six (21.4 percent) whom completed RPEC. All 6 students reported that they felt significantly better prepared for the application process because of this elective. Many students who did not take the elective indicated that had the class been offered at a time that better fit into their schedule they would have taken the course despite his or her confidence.

Conclusion: ASHP match rates were significantly higher amongst the graduating classes for which RPEC was offered. Match rates amongst students who completed RPEC versus those who did not were not statistically significant. Students who were part of a major student organization had significantly higher match rates compared to those who were not, irrespective of completion of RPEC. Further investigation with a larger group, accounting for additional variables that may contribute to obtaining a residency is warranted.

Session-Board Number: 5b-198

Poster Title: Evaluation of levalbuterol utilization at a community hospital

Primary Author: Ene Omakwu, University of Maryland School of Pharmacy, Maryland; **Email:** eomakwu@umaryland.edu

Additional Author (s):
Brian Stump

Purpose: There has been a long debate on whether levalbuterol provides any therapeutic advantage over albuterol in the treatment of obstructive airway diseases as acquisition costs for levalbuterol are notably higher than those of albuterol. Concerns of the deleterious effects of albuterol led to the discovery and marketing of levalbuterol although clinical literature has failed to show these adverse effects to be clinically significant. The objective of this medication use evaluation is to assess compliance to the Frederick Memorial Hospital levalbuterol use criteria.

Methods: Patients were retrospectively identified by searching the pharmacy records for levalbuterol orders between January 2016 and June 2016. The following information was collected: patient account number, age, cardiac past medical history, hospital floor where admitted, dose conversion of levalbuterol to albuterol, heart rate, home medication list, number of levalbuterol and albuterol administrations, prescribing doctor, number of days on albuterol before the switch to levalbuterol. Measures of central tendency were used for analysis. Levalbuterol criteria for use (must meet at least one): patients who report tachycardia (20 beats per minute over baseline) following administration of albuterol, pediatrics or adults who are currently on levalbuterol treatment as an outpatient, patients with cardiac diseases that could potentially worsen with tachycardia (poorly controlled arrhythmias, decompensated heart failure, and valvular disease).

Results: Two-hundred and twenty five patients with levalbuterol orders were exported from the electronic medical record between January 2016 and June 2016. Sixty randomly identified patients were included in the analysis. Of those patients 56.67% met the criteria for levalbuterol use and 43.33% did not meet criteria. The majority of patients that met use criteria did so due to the presence of preexisting cardiac disease that could potentially worsen with

tachycardia. Only one patient had documented tachycardia post albuterol administration. There were a high number of patients that did not meet criteria for levalbuterol. This resulted in two hundred and seventy three inappropriate administrations of levalbuterol which translated into $567.84 in excess cost.

Conclusion: There is currently poor compliance to the use criteria for levalbuterol at Frederick Memorial Hospital. The majority of appropriate use was due to patient's pre-existing cardiac disease. Current clinical data suggests that levalbuterol offers no clinical advantage compared to albuterol from a cardiac standpoint. Based these data and the significant cost difference between the two agents; it is recommended that the use criteria be altered to reflect current clinical evidence. Further additional efforts should be made to ensure proper utilization of restriction criteria within the hospital.

Poster Title: Appropriateness of initial antibiotic therapy for urinary tract infection (UTI) in a small community hospital

Primary Author: Barbara Obot, Notre Dame of Maryland University, Maryland; **Email:** bobot1@live.ndm.edu

Additional Author (s):
Kimberly Couch

Purpose: Urinary tract infections (UTI) are among the most common bacterial infections acquired in the hospital and community. Annual total cost of UTI in 2010 was estimated to be equivalent to $2.3 billion. Delayed antibiotic therapy may lead to progression of infection and complications such as recurrent infections, kidney damage, and sepsis. Appropriate initial therapy is important to combat progression of infection. The purpose of this study is to evaluate the appropriateness of initial antibiotic therapy for UTI in a small, community hospital.

Methods: This evaluation was approved by the appropriate ethics committee or institutional review board. Patients who were diagnosed with a UTI during March-August 2016 who had a positive urine culture were identified. Susceptibilities for the organism identified as the etiology of the UTI were examined and compared with the antibiotics the patient received. Appropriate initial therapy was defined as the initial antibiotic was susceptible for the organism identified. Inappropriate initial therapy included any instance where the organism was intermediately susceptible or resistant to the initial antibiotic therapy administered. The percentage of each pathogen was calculated. The percentage of appropriate and inappropriate therapy were calculated.

Results: Of 312 pts, 30 pts (10 percent) were randomly selected. Overall, the most prevalent organism isolated was E. coli (33 percent) followed by Klebsiella pneumoniae (13 percent). In March, P. aeruginosa (50%) incidence was equal to E. coli . In June, Klebsiella pneumoniae and E. coli made up more than half of the organisms isolated (57 percent). Twenty-two pts (73 percent) were appropriately treated with antibiotics. March had a 100 percent appropriate treatment rate. Treatment was appropriate in April through August for 83, 67, 71, 50 and 75 percent of pts respectively. The empiric antibiotic therapy used varied. Ceftriaxone was the

most frequently used antibiotic (42 percent) overall, and the most frequent monotherapy (60 percent). Ceftriaxone monotherapy was mostly appropriate (83 percent). Vancomycin (13 percent) and piperacillin/tazobactam (13 percent) were the next most frequently used antibiotics. Piperacillin/tazobactam was used appropriately every time (100 percent), while vancomycin was mostly used appropriately (80 percent).

Conclusion: Empiric antibiotics used during the treatment of UTI was appropriate for 73 percent of the patients in this study. Since the goal is to have appropriate treatment for 90 percent of patients, revision of empiric antimicrobial therapy for UTI may be necessary. Review of additional patients with a larger sample size may reveal patterns of inappropriate therapy to be addressed.

Submission Type: Descriptive Report

Session-Board Number: 5b-200

Poster Title: Relative value unit development for the evaluation of pharmacist interventions in Sentri7

Primary Author: Caleb Goodrich, University of Maryland School of Pharmacy, Maryland; **Email:** caleb.goodrich@umaryland.edu

Additional Author (s):
Michael Staley
Shawn Boland

Purpose: To develop a Relative Value Unit (RVU) for each intervention performed by a pharmacist at Meritus Medical Center(MMC).
Interventions that pharmacists make in the hospital vary greatly in patient benefit, complexity and cost. To maximize a pharmacist's time, it is essential to focus on interventions that bring clinical benefit to both the patient and highest cost savings. Evaluation of pharmacists solely on the number of interventions performed is therefore ineffective.
Understanding the gravity of each intervention a pharmacist accomplishes would become more apparent if each intervention had a relative value that correlated to its complexity, cost and patient benefit.

Methods: Sentri7 is software used by MMC to track interventions by pharmacists. Information on time taken to complete for each intervention is tracked by Sentri7. Hard cost savings were previously determine based on drug product costs and average lengths of therapy while soft cost savings were determined by literature review. Hard and soft costs were determined prior to the start of the project.
The following algorithm was developed to assign an RVU to each intervention.
$\text{Log}\_10 \llbracket (0.25(hr)) \times (0.25(cost)) \times \text{Patient Benefit} \rrbracket)$
In this equation time taken represents the complexity of the intervention the pharmacist is completing. Cost represents what dollar amount the pharmacist is saving the institution. Patient Benefit was given the most weight in the equation so that other factors do not overshadow the well-being of the patient. The Patient Benefit Rating (1-5) was assigned to each intervention by two experienced pharmacists.

Results: An RVU of 1-5 was assigned to each primary intervention listed in Sentri7, using the algorithm in the previous section. The development of the RVU is not to compare one pharmacist to another, but rather to maximize the overall effort of the pharmacist in areas that are of most benefit to the patient. This can be done with the average RVU per intervention. The larger the resulting number is, the more value each intervention has for the patient and the hospital.

7 pharmacists were evaluated based on the total RVUs associated with the interventions they had completed in the month of July. Three pharmacists evaluated had a similar number of interventions completed which were 116, 112, and 115. While the pharmacists had a similar number of interventions, their average RVUs for the month were 2.6, 2.3 and 2.5 respectively. Two other pharmacists completed 20 and 29 interventions. The corresponding RVUs were 78 and 58 respectively. While, the latter pharmacist had 29 interventions, the pharmacist with 20 intervention offered more value to the patients and hospital.

Conclusion: The development of the RVU was successful in adding value to the interventions of pharmacists at MMC. This will lead to a better understanding of interventions performed by pharmacists.

Poster Title: Incidence and trends in anticoagulants used in a small community hospital

Primary Author: Olivia Weiss, Notre Dame of Maryland University, Maryland; **Email:** oweiss1@live.ndm.edu

Additional Author (s):
Miral Patel
Kimberly Couch

Purpose: Novel oral anticoagulants (NOACs) were approved in 2010 and were the first additions to oral anticoagulation since the approval of warfarin. NOACs may provide a more predictable level of anticoagulation for patients at risk of embolism, removing the necessity of monitoring. In theory, this class of medications should provide a more favorable treatment compared with warfarin, however, differences in cost of medication may make utilization difficult. The purpose of this study is to determine the incidence of use of anticoagulants in a small community hospital and identify any trends over time.

Methods: All clinical research represented in the abstract was approved by the appropriate ethics committee or institutional review board. A retrospective review of patients receiving anticoagulation in a small community hospital was completed. All patients who received warfarin, heparin, enoxaparin, fondaparinux, apixaban, rivaroxaban, or dabigatran during January 2010-August 2016 were identified from a computer-generated list. Any dose of anticoagulant administered was counted as an episode. Only one episode per anticoagulant per admission was recorded, allowing for recording of episodes of different anticoagulants per admission. The number of episodes of each anticoagulant used was determined by month. Trends in use were identified.

Results: Fondaparinux and warfarin were the most frequently used anticoagulants in 2010-2016. The overall use of fondaparinux trended down over the 6 years. Similarly, the use of warfarin also trended down over the time span. In March 2011, dabigatran use started and the overall use increased through 2016. In March 2012, rivaroxaban use started, peaked in June 2014 and then gradually decreased. Apixaban use started in August 2014, peaked in June 2015, and gradually decreased thereafter. With the addition of more oral anticoagulants the use of

warfarin dropped significantly by as much as 50 percent. Overall, the use of heparin continuous infusion was fairly consistent during 2010-2016 and was unaffected by other agents.

Conclusion: In conclusion, the use of injectable anticoagulation agents (except heparin) and warfarin has been affected by the approval of the NOACs. Not only did the use of warfarin decrease, but the use of each NOAC rose very quickly after drug approval, only to the decrease slightly and level off after each subsequent NOAC was approved. The use of continuous infusion heparin seemed to be independent and did not appear to be affected by any other anticoagulant.

Poster Title: Adherence to guidelines for transitioning patients between anticoagulants in a small community hospital setting

Primary Author: David Lewis, Notre Dame of Maryland University School of Pharmacy, Maryland; **Email:** dlewis6@live.ndm.edu

Additional Author (s):
Miral Patel
Kimberly Couch

Purpose: Anticoagulants are used to prevent the formation/extension of blood clots related to atrial fibrillation, venous thromboembolisms (VTE) and other causes. When transitioning between anticoagulants, appropriate timing of administration is essential to prevent increased risks of bleeding from excessive anticoagulation and increased the risk of thrombosis from inadequate anticoagulation. Pharmacokinetic (PK) properties of each agent indicate the estimated onset and duration of action giving practitioners a guide for the timing of administration when transitioning between agents. The purpose of this study is to determine if the transition time between anticoagulants was appropriate.

Methods: All clinical research represented in the abstract was approved by the appropriate ethics committee or institutional review board. A retrospective review of patients receiving anticoagulation in a small community hospital was completed. All patients who received heparin, enoxaparin, fondaparinux, apixaban, rivaroxaban, or dabigatran during January 2010-August 2016 were identified from a computer-generated list. Patients were excluded if there was no start and stop date available, or there was only one agent used. The time between agents was calculated and compared to established transition times. The average transition time for each pair of anticoagulants was calculated. Transition time was acceptable if it was within 1 hour before to 1 hour after the accepted transition time to allow for the variance in nursing administration. The percentage acceptable transition time was calculated overall and for each transition pair.

Results: Overall transition-time was 66.3 percent unacceptable between anticoagulants based on guidelines. Transition-time from enoxaparin to dabigatran, enoxaparin, apixaban, heparin, or fondaparinux were 100 percent unacceptable, with average times of 7.88, 0.58, 4.83, 1.06, 9.15 hours. Transition-time from apixaban to enoxaparin, dabigatran, or heparin were 100 percent unacceptable, with average times of 16.85, 4.70, 1.53, 1.06 hours. Transition-time from dabigatran to apixaban or dabigatran were 100 percent unacceptable, heparin with a 66.7 percent unacceptable transition time, and fondaparinux with a 66.7 percent unacceptable transition time. Average times were 9.43, 10.07, 32.03, 10.25 hours. Transition-time from heparin to rivaroxaban was 75 percent unacceptable, enoxaparin was 55.6 percent unacceptable, heparin and dabigatran were 66.7 percent acceptable, apixaban was 58.8 percent unacceptable, and fondaparinux was 60.5 percent acceptable. Average times were 25.01, 15.97, 3.50, 6.81, 7.50, 5.25 hours. Transition-time from rivaroxaban to heparin or dabigatran were 100 percent unacceptable, and fondaparinux was 50 percent acceptable, with average times of 17.5, 0.30, and 11.62 respectively. Transition-time from fondaparinux to apixaban or rivaroxaban were 100 percent unacceptable, to enoxaparin or dabigatran were 75 percent unacceptable, and to heparin was 76.3 percent unacceptable. Average times were 26.95, 20.86, 21.46, 9.16, 14.38 hours.

Conclusion: There is a consistently high percentage of episodes of transitioning between anticoagulants where there isn't adequate transition time from one anticoagulant to another. The clinical significance of these occasions remains unknown, however, education of prescribers and pharmacists may increase the consistency of adherence to recommended transition times.

Submission Type: Evaluative Study

Session-Board Number: 5b-203

Poster Title: Evaluation of tutees' self-perception of the value and satisfaction of peer tutoring

Primary Author: Mary Li, University of Maryland School of Pharmacy, Maryland; **Email:** maryli@umaryland.edu

Additional Author (s):
Sheheryar Muhammad
Naim Haque
Cherokee Layson-Wolf

Purpose: Peer-tutoring programs in pharmacy schools have become more prevalent in the United States and could benefit both the peer-tutor and tutee. The peer-tutoring program at the University of Maryland School of Pharmacy was designed to assist the learning of PharmD students who may have some difficulty in a course. The purpose of this research study was to investigate the impact of peer-tutoring on tutees' self-perception of the value and their satisfaction of peer tutoring. The results from this study will be used to further enhance the peer-tutoring program at the University of Maryland School of Pharmacy.

Methods: A satisfaction survey consisting of 14 questions was distributed to 117 pharmacy students at the University of Maryland School of Pharmacy. The survey was sent by the Office of Student Affairs to tutees who received tutoring services during the 2014-2015 and 2015-2016 academic years. This voluntary survey was distributed and administered electronically through SurveyMonkey and participants were allotted 14 days to complete the survey during a single sitting with 3 reminder emails. 13 closed-ended questions evaluating tutees' self-perceptions were based on a Likert Scale of 1 to 5. An open-ended question allowed participants to elaborate on their perceptions of improvements that could be made to the peer-tutoring program, which created further insight into their satisfaction levels about the program.

Results: A total of 20 students completed the survey out of 117 enrolled (17 percent). 70 percent of students were peer-tutored 1-5 times over the course of one academic semester. Students generally agreed that peer-tutoring increased their confidence going into the exam (mean value equals 3.9) and felt that it improved their performance on the exam (mean value equals 3.7). Out of the students who reviewed materials before receiving peer-tutoring in the

specified course (n equals 17), a slight majority felt that peer-tutoring enabled them to learn and apply new study strategies (mean value equals 3.35), as well as felt that peer-tutoring reinforced their understanding of challenging concepts and materials from the course (mean value equals 3.41). In contrast, the students who did not review materials before receiving peer-tutoring in the course (n equals 3) found that peer-tutoring enabled them to learn and apply new strategies (mean value equals 4.33), as well as reinforced their understanding of challenging concepts and materials from the course (mean value equals 4.67).

Conclusion: Students generally benefited from the peer-tutoring program provided by the University of Maryland School of Pharmacy in that it helped them to ask questions they would have been reluctant to ask a professor, reinforced their understanding of challenging concepts and materials from the course, and increased their confidence going into the exam. From student comments, the program could be improved by mandating that peer-tutors and students meet at least once in person and that peer-tutors should take more initiative in understanding the tutees' learning needs.

Submission Type: Descriptive Report

Session-Board Number: 5b-204

Poster Title: Incidence and reasons for readmission within 30 days for patients with chronic obstructive pulmonary disease (COPD) and COPD related illness

Primary Author: Bryan Ahlstrand, Notre Dame of Maryland School of Pharmacy, Maryland;
Email: bahlstrand1@live.ndm.edu

Additional Author (s):
Alexis Berk
Kimberly Couch

Purpose: With the advent of the Affordable Care Act, the Centers for Medicare and Medicaid Services (CMS) are required to reduce payments to inpatient prospective payment system (IPPS) hospitals for excess readmissions, defined as any readmission within 30 days regardless of reason. Chronic Obstructive Pulmonary Disease (COPD) is identified by CMS as associated with a high risk for readmission, resulting in potential penalties to IPPS hospitals. The overall purpose of this study is to identify risk factors for COPD readmissions which may identify areas for healthcare provider intervention, thereby reducing the number of COPD readmissions and preventing loss of funds.

Methods: All clinical research represented in the abstract was approved by the appropriate ethics committee or institutional review board. At a small community hospital, the number of patients admitted between February and July 2016 with a primary discharge diagnosis of COPD was identified as a baseline potential number of 30-day-readmissions. Of these, patients who were readmitted within 30 days between March and August 2016 with a primary diagnosis of COPD were identified. Risk factors for COPD 30-day-readmission were identified. The incidence of literature-identified risk factors (including tobacco use, exposure to passive tobacco use, environmental pollution presence, weather changes, three or more emergency visits/readmissions within previous year, no immunization for influenza/pneumococcus, medication nonadherence, low physical activity, acute respiratory illness, and no pulmonologist management) was determined. Thirty-day readmission rate was determined by month and the presence of risk factors was determined for each month.

Results: There were 633 admissions with COPD diagnosis. Of these, 13 (2%) led to 1 or more readmissions within 30 days. 2 (0.3%) led to 2 readmissions within 30 days. The most prevalent risk factor for readmission was environmental pollution, with all patients (100% of readmissions) claiming exposure to pollution. Other risk factors present included tobacco use, non-adherence to yearly influenza vaccine, and acute respiratory illness. Each of these risk factors were claimed by 10 patients (66.7% of readmissions). There were 8 (53.3%) incidences without the pneumococcal vaccine. Four (26.7%) were non-adherent or did not understand proper medication technique. Two (13.3%) did not have access to a pulmonologist, and there were 0 (0%) risk factors for patients who could not afford their medications or readmissions related to weather change.

Of the 2 patients that had 3 COPD-related admissions within 30 days, each had a similar risk factor profile of environmental pollution, tobacco use, non-adherent to influenza or pneumococcal vaccine, and they were the only patients listed without access to a pulmonologist.

Conclusion: Five of ten risk factors identified were modifiable. Order of prevalence of modifiable risk factors: tobacco use, non-adherence to the influenza or pneumococcal vaccines, medication non-adherence, and lack of pulmonologist intervention. This data identifies areas of improving COPD-related readmission, which is a patient and hospital concern. Educational programs for non-adherence issues are easily implemented. Smoking cessation has a lesser success rate according to the Centers for Disease Control. Outpatient pulmonologist access can be arranged before discharge. According to the Global Initiative for Chronic Obstructive Lung Disease guidelines, these programs could reduce future readmissions.

Submission Type: Descriptive Report

Session-Board Number: 5b-205

Poster Title: Implementation of a simulated hospital medication reconciliation policy to teach medication reconciliation upon admission in a pharmacist care laboratory

Primary Author: Rachel Dewberry, Notre Dame of Maryland University School of Pharmacy, Maryland; **Email:** rdewberry1@live.ndm.edu

Additional Author (s):
Naveen Samuel
Min Kwon
Lindsey Crist

Purpose: Pharmacists play an important role in medication reconciliation to reduce the risk of medication errors. However, few studies describe strategies for the education of the process or measure the effectiveness of the education in the pharmacy curriculum. The purpose of this study is to describe a systematic method and process of teaching medication reconciliation upon admission in the hospital setting based on a simulated medication reconciliation policy and patient case in the Pharmacist Care Laboratory to second year pharmacy students.

Methods: This is a retrospective study describing the instructional method for teaching a systematic medication reconciliation process to second year pharmacy students in the Pharmacist Care Laboratory course from January 2016 to May 2016. Students are educated on a six step medication reconciliation process; in which the objectives of the lab experience is for students to be able to effectively reconcile patient's medications, identify medication reconciliation discrepancies, and document appropriate recommendations based on the simulated medication reconciliation policy and patient case. Second year pharmacy student's response on pre and post medication reconciliation assessment questions and confidence levels were collected along with student's performance on medication reconciliation on the final examination. Turning Point technologies, Exam Soft, and submission of student's medication reconciliation documentation in Joule were queried from the Pharmacist Care Laboratory course from January 2016 to May 2016 specific to medication reconciliation

Results: Fifty-six second year pharmacy students completed the Pharmacist Care Laboratory medication reconciliation course. Based on student performance, there was an increase from pre to post assessment scores, indicating student understanding of how to perform a medication reconciliation. (Pre-assessment median score 67% (IQR 76-83%) and Post-assessment median score 83% (67-100%). 82% of students reported feeling either extremely confident, very confident, or moderately confident in conducting medication reconciliation by the end of lab, compared to 48% prior to completing lab.

Conclusion: Utilization of a systematic medication reconciliation process and simulated policy is an effective way to teach 2nd year pharmacy students how to conduct medication reconciliation. Preceptors on IPPE and APPE rotations can also utilize the process to ensure appropriate medication reconciliation and it can also help to define how pharmacists approach medication reconciliation compared to other health care professionals.

Poster Title: Appropriateness of initial antibiotic therapy for community-acquired pneumonia in a small, community hospital

Primary Author: Erica Moran, Notre Dame of Maryland University School of Pharmacy, Maryland; **Email:** emoran1@live.ndm.edu

Additional Author (s):
Kimberly Couch

Purpose: Previous research has shown that utilization of guidelines for antibiotic treatment of community-acquired pneumonia (CAP) is beneficial. Guideline utilization for CAP therapy reduces 30-day mortality, length of hospital stay, and readmission rate. Additionally, there is an economic benefit associated with utilization of CAP guidelines. To provide the best care for patients, providers should follow guidelines and local antibiograms to appropriately select initial antibiotic therapy when treating patients with CAP. The purpose of this study is to assess the appropriateness of initial antibiotic therapy for CAP in a small, community hospital.

Methods: All clinical research represented in the abstract was approved by the appropriate ethics committee or institutional review board. An electronic list of patients aged 18 years or greater with a discharge diagnosis of CAP between March 1 and August 31, 2016 was generated. The Infectious Diseases Society of America/American Thoracic Society (IDSA/ATS) 2007 CAP guidelines were used to identify initial appropriate antibiotic therapy. The initial antibiotic therapy administered to the patient was compared with the guidelines. Appropriate therapy was defined as therapy consistent with the guidelines. The rate of appropriate therapy was calculated per month and for the 6-month data period.

Results: There were 257 patients identified with CAP. Of those patients, 19 (7.39%) patients had organisms that were identified. The organisms identified included Methicillin-resistant Staphylococcus aureus (n=6; 31.6%), Escherichia coli (n=3; 15.8%), Klebsiella pneumoniae (n=3; 15.8%), Pseudomonas (n=2; 10.5%), other aerobic gram-negative bacteria (n=2; 10.5%), Haemophilus influenzae (n=1; 6.67%), Methicillin-susceptible Staphylococcus aureus (n=1; 6.67%), and Streptococcus pneumoniae (n=1; 6.67%). Of those 19 patients, 16 patients (84.2%) were treated with appropriate antibiotic therapy.

Conclusion: According to the IDSA/ATS CAP guidelines, an acceptable rate of appropriate initial antibiotic therapy is between 80-95%. The rate of appropriate antibiotic therapy is acceptable, however further data collection may reveal some risk factors for alterations to therapy to increase the initial appropriate antibiotic therapy rate.

Poster Title: Is It Time to Replace Warfarin with Novel Oral Anticoagulants (NOACs) for Treating Thrombotic Disorders?

Primary Author: Charles Ng, University of Maryland School of Pharmacy, Maryland; **Email:** charlesng58@gmail.com

Additional Author (s):
C. Daniel Mullins

Purpose: To determine whether NOACs should be considered first-line treatments alongside warfarin for both VTE treatment and stroke/systemic embolism prophylaxis in patients with NVAF from a clinical and cost-effective viewpoint.

Methods: A decision tree was constructed for each of the indications: VTE treatment and stroke/systemic embolism prophylaxis in NVAF patients. Each tree compared five therapies: edoxaban, apixaban, rivaroxaban, dabigatran, and warfarin. The transition probabilities were derived from their respective phase 3 clinical trials. Costs were derived from various literature sources with a one-year time frame.

Results: In the VTE treatment analysis, apixaban was found to have the lowest average yearly cost of $7,755.91, followed by warfarin ($7,864.46), dabigatran ($8,903.02), edoxaban ($9,557.37), and rivaroxaban ($10,630.41). Effectiveness was measured by treatment response without a major bleeding or clinically relevant non-major bleeding event. Warfarin had the lowest efficacy of 0.87, followed by rivaroxaban (0.88), edoxaban (0.89), dabigatran (0.91), and apixaban (0.94). Apixaban is the most cost-effective option due to its superior price and efficacy profile.

For the analysis of prophylaxis in NVAF patients, warfarin was found to have the lowest average yearly cost of $1,119.71, followed by edoxaban ($3,596.70), dabigatran ($4,110.33), apixaban ($4,385.71), and rivaroxaban ($4,438.61). Effectiveness was measured by treatment response without a major bleeding event. Warfarin and Edoxaban had the lowest efficacy of 0.90, followed by rivaroxaban (0.91), dabigatran (0.92), and apixaban (0.94). Apixaban is the most efficacious option, but warfarin is the cheapest option. The incremental cost-effectiveness ratio

of dabigatran versus warfarin and apixaban versus dabigatran was $175,918.82 and $12,517.27 per additional treatment response without a major bleeding event, respectively.

Conclusion: From a clinical viewpoint, the NOACs are non-inferior to warfarin but are currently less utilized in practice. When cost-effectiveness analyses are integrated into clinical decision making, a need for change in the clinical guidelines is established due to the greater cost effectiveness of the NOACs compared to warfarin.

Poster Title: Ethanol lock therapy, a protocol for the prevention of catheter-related bloodstream infections in pediatrics.

Primary Author: Dhakrit Jesse Rungkitwattanakul, University of Maryland School of Pharmacy, Maryland; **Email:** dhakrit.r@umaryland.edu

Additional Author (s):
Jill Morgan
Allison Lardieri

Purpose: Central venous access devices (CVADs) are frequently used for patients requiring long term venous access. Infections caused by biofilm formation on the inner surface of the catheter are responsible for significant morbidity and mortality in pediatric patients. Infections are a major complication for these patients with long-term indwelling catheters such as patients who require total parenteral nutrition (TPN) or chemotherapy. The objectives of this study are to evaluate the evidence regarding the use of ethanol lock therapy (ELT) for prevention of catheter-related bloodstream infection and to develop a protocol for use in a pediatric children's hospital.

Methods: A literature search was conducted using PubMed (January 2009-March 2016) with search terms: ethanol lock, ethanol locks, ethanol lock therapy, prophylaxis, prevention, catheter infection, line infection, catheter-related bloodstream infection, catheter-related infection, pediatrics and children. All English-language human studies included more than one patient and a primary outcome of rates of infection, rate of catheter removal or line salvage were included and evaluated. Review articles, in vitro studies, studies where ethanol lock therapy was not used for prevention of catheter-related bloodstream infection or the main outcome was not primarily focused on rates of infection were excluded. Data were obtained and reviewed. Strengths and weaknesses of each included study were discussed and noted. The primary outcome of the review is to establish a standardized ethanol lock therapy protocol to prevent the catheter-related bloodstream infections.

Results: A total of 12 studies with 140 pediatric patients were included. Two studies were conducted prospectively; nine studies were categorized as retrospective and one as case report. Studies reported a decreased rate of infection with ethanol lock therapy with a concentration of 70% in patients requiring an indwelling catheter who have experienced more than one episode of infection of their intravascular devices. Silicone was the most compatible material when ethanol lock solution was placed. Studies were consistent with a significant decrease in the rate of infection when the minimum of a 4-hour dwell time was used with the maximum of 24 hours. No serious adverse events were found. The protocol allows use of ethanol locks in patients over 6 months of age and receiving long-term TPN. Patients are excluded if they are allergic to ethanol or have a catheter that contains an antibiotic or polyurethane. The protocol includes lock administration procedure and required volumes based on catheter diameter sizes.

Conclusion: An evidenced-based protocol for the use of ethanol lock therapy to prevent catheter infections was created using 70% ethanol lock therapy for at least 4 hours with the maximum of 24 hours daily.

Poster Title: Safety culture among Egyptian healthcare providers at a pediatric cancer center

Primary Author: Sarah El-gendi, University of Maryland Baltimore, School of Pharmacy, Maryland; **Email:** sarah.el-gendi@umaryland.edu

Additional Author (s):
Amy Howard
Sarah Mohammed
Hyunuk Seung
Agnes Feemster

Purpose: A limited amount of data exists from developing and underdeveloped nations related to patient safety. The Safety Attitudes Questionnaire (SAQ) is the most widely used, self-administered, validated questionnaire measuring patient safety. To date, one Egyptian hospital has published results from the SAQ administered to nurses. The study revealed that nurses were neutral regarding the safety of the work environment. Job satisfaction, team work climate, and stress recognition rated highest on the survey. Perceptions of management and working conditions rated lowest. Baseline assessment of patient safety culture from other members of the healthcare team is lacking.

Methods: A total of 250 employees consisting of physicians, pharmacists, nurses, physical therapists, administration, assistants, and secretaries at two medical centers in Egypt voluntarily completed the 36-questioned SAQ over a 14-day period. Participants were given the choice to complete the survey on paper or online. All paper responses were then recorded online. To detect any differences from other cultures, the safety scores of Egyptian healthcare professionals were compared with international benchmark safety domains in SAQ. In addition, associations of mean scores of each SAQ safety domain were analyzed. For comparisons of mean scores between the safety scores of Egyptian healthcare professionals and international benchmark safety domains in SAQ, 95% confidence intervals were produced to detect whether two confidence intervals overlapped. Independent t-test and one-way analysis of variance (ANOVA) were performed to detect any differences between the mean scores of each safety domain according to demographic characteristics. Tukey's multiple comparison tests were produced for each level of the main effect if the result of ANOVA was significant for each

characteristic. In addition, Pearson's correlation coefficient was used to detect any correlation between the safety culture dimensions. Analyses were performed with SAS version 9.4 (SAS Institute, Cary, NC).

Results: The scores of Egyptian healthcare professional in all domains were significantly higher than the international benchmark. There was significantly positive correlations between each safety domain scores that were detected except stress recognition versus teamwork climate and stress recognition versus safety culture. Attending/Staff physicians (90.7) had a significantly higher mean score for job satisfaction than the study population (81.1). Additionally, participants who worked less than 6 months (87.5) had significantly higher mean score on their perception of safety culture in the hospital than the study population (75.5). Participants who worked 11-20 years in the hospital (91.7) had a significantly higher mean score in terms of their perception on sufficient hospital staffing than the study population (82.2). In contrast, nurses (75.4) had a significantly lower mean score than the study population (82.2) on this item. Resident physicians (67.3) had significantly higher mean score on their opinion on the availability of resources in the hospital to make therapeutic decisions than the study population (42.9). Finally, there was no significant difference among the mean scores for individual positions in job satisfaction, but the mean score of Attending/Staff physician (90.7) was significantly different from the mean score (81.1) of job satisfaction for the study population.

Conclusion: Overall, the scores of Egyptian healthcare professionals in each domain were higher than the international benchmark. Additionally, the correlations between the safety domains were mostly positive and the same was true for safety attitudes. The results show that the hospital staff in Egypt had a positive perception of patient safety. However, there can be bias in the results due to the employer's fear of repercussion for giving a negative image of the hospital. Additionally, most of the staff members who agreed to take the survey were ones that were supportive of the hospital and its administration.

Poster Title: Novel oral anticoagulants and risk of gastrointestinal bleeding: A systematic review

Primary Author: Manal Ziadeh, University of Maryland Baltimore, Maryland; **Email:** mziadeh@umaryland.edu

Additional Author (s):
Mehmet Burcu
Elisabeth Oehrlein
Lars Björnebo
Eleanor Perfetto

Purpose: In recent years, a new class of anticoagulants, novel oral anticoagulants (NOACs) (e.g., dabigatran, rivaroxaban, edoxaban, apixaban), has been approved for treatment of atrial fibrillation (AF), providing advantages (e.g., no monitoring requirement) over warfarin treatment. However, recent post-marketing case reports and other observational data suggest NOACs may be associated with greater risk of gastrointestinal (GI) bleeding compared with warfarin. The purpose of this systematic review is to evaluate the risk of GI bleeding associated with NOACs compared with the warfarin treatment by examining published data from randomized controlled trials (RCTs).

Methods: Following a specific protocol, a systematic review of PubMed, EMBASE, and the Cochrane Registry of Clinical Trials was conducted to identify RCTs (in English) comparing NOACs to warfarin among non-valvular AF patients. Abstracts were triaged and independently reviewed by two researchers with a third reviewer providing input when necessary. Selected articles were reviewed in full.

Results: Out of 9 RCTs identified, rivaroxaban was each assessed in 3, edoxaban and apixaban were each assessed in 2, and dabigatran was assessed in 1. In one trial, high-dose edoxaban [1.51% vs. 1.23%, RR=1.23 (95% CI 1.02-1.50)], but not low-dose [0.82% vs. 1.23%, RR=0.67 (95% CI 0.53-0.83)], was associated with higher GI bleeding risk compared to warfarin. A phase 2 study of edoxaban showed that warfarin was associated with GI bleeding (1.33%) and no patients in the edoxaban treatment arm (both, high- and low-dose) had GI bleeding. In 2 rivaroxaban studies, major GI bleeding was more common in rivaroxaban-treated patients

compared with warfarin-treated patients (4.5% vs. 0.6%; 3.2% vs. 2.2%). By contrast, one study did not find higher risk of GI bleeding with rivaroxaban treatment. Compared to warfarin, dabigatran was also associated with higher risk [1.51% vs. 1.15%, RR=1.50 (95% CI 1.19-1.89)]. A phase 2 study demonstrated a higher risk of GI bleeding associated with apixaban 5mg (1.41% vs 0%). However, the phase 3 trial did not indicate a significantly higher risk of GI bleeding when compared to warfarin [0.76% vs 0.86%, HR=0.89 (95% CI 0.70-1.15)].

Conclusion: In this systematic review of RCTs among AF patients, rivaroxaban, edoxaban, and dabigatran appear to be associated with a greater risk of GI bleeding compared with warfarin. However, apixaban does not appear to be associated with a greater risk for GI bleeding. The risk may be dose-related, but that warrants further investigation.

Poster Title: Prophylaxis of thromboembolism in multiple myeloma patients receiving lenalidomide therapy at Peninsula Regional Medical Center

Primary Author: Michael Smith, University of Maryland Eastern Shore School of Pharmacy, Maryland; **Email:** mrsmith@umes.edu

Additional Author (s):
Sarah Lee
Marie-Therese Oyalowo

Purpose: Lenalidomide is an immune modulating drug (iMD) used in treatment of multiple myeloma (MM). Cancer patients with MM receiving lenalidomide therapy are at elevated risk of thromboembolic events including venous thromboembolism (VTE). The pathophysiology of increased risk is unclear, but several factors have been implicated such as increased von Willebrand factor, fibrinogen, endothelial stress markers, and impaired fibrinolysis. National Comprehensive Cancer Network (NCCN) guidelines recommend thromboprophylaxis in all diagnosed MM patients receiving lenalidomide and other iMD therapy. This study assessed adherence to NCCN guidelines for VTE prophylaxis in MM patients on lenalidomide therapy at Peninsula Regional Medical Center (PRMC).

Methods: This study was approved by the PRMC research comittee. All MM patients entering the PRMC outpatient infusion center from January 1, 2016 through August 31, 2016 were screened. The inclusion criteria were patients ages 18 and older and history of treatment with lenalidomide for MM. Exclusion criteria included patients with absolute contraindication to VTE prophylaxis including true aspirin, warfarin, or enoxaparin allergy, active bleeding, recent major surgery, or documentation of other contraindication by prescriber. Patients meeting criteria were then assessed for risk of thromboembolism using the risk factors specified by NCCN: obesity (BMI greater than or equal to 30 kg per m2), prior VTE, central venous access device or pacemaker, cardiac disease, chronic kidney disease (CKD), diabetes, acute infection, immobilization, surgery, use of erythropoietin, blood clotting disorders, diagnosis of myeloma, or hyperviscosity. Patients with one or fewer risk factors would require aspirin (81–325 mg) prophylaxis, while those with two or more risk factors as well as using lenalidomide in combination with high dose dexamethasone (greater than 480 mg per month), doxorubicin, or

multi-agent chemotherapy would require anticoagulation with warfarin or a low molecular weight heparin (LMWH). All patients were then assessed to determine whether they received any thromboprophylaxis and if prophylaxis was appropriate according to NCCN guidelines. Record of VTE while on lenalidomide therapy was also documented. Descriptive statistics were used to analyze results.

Results: Of the 56 MM patients screened, 40 patients received lenalidomide therapy. Four of these patients were excluded because lenalidomide was withdrawn due to allergy or intolerance. VTE prophylaxis with any recommended agent was used in 55.6 percent of patients. The appropriate VTE prophylaxis according to NCCN guidelines was used in 19.4 percent of patients. The most common anti-thrombotic agent prescribed was aspirin used in 65 percent of patients receiving prophylaxis. Prophylaxis with warfarin and LMWH was lower, with an incidence of 25 percent and 5 percent respectively. The average number of risk factors identified in the 36 patients meeting criteria was 2.8. Other than diagnosis of MM, the most commonly identified risk factor was obesity occurring in 44.7 percent of patients. Risk factors including cardiac disease, diabetes, prior VTE, and CKD were identified in 31.6, 31.6, 26.3, and 21.1 percent of patients respectively. Other risk factors (immobilization, pacemaker, erythropoietin use) were also identified in 18.4 percent of patients. Five cases of VTE occurring during lenalidomide therapy were identified. Four of these patients received inappropriate VTE prophylaxis according to NCCN guidelines, while one did receive any prophylaxis.

Conclusion: Many MM patients on lenalidomide are not receiving appropriate thromboembolism prophylaxis. The use of warfarin and LMWH was low in MM patients receiving lenalidomide, indicating the need for routine risk assessment. There was minimal documentation of thromboprophylaxis assessment by prescribers at PRMC, and all risk assessments may not have been found if they were not documented. Prescribers should be prompted automatically to add prophylaxis when prescribing lenalidomide to MM patients and required to document rational for withholding prophylaxis. These recommendations should be implemented rapidly considering five patients at PRMC developed a VTE without proper prophylaxis.

Poster Title: Effect of socioeconomic factors on patient beliefs of treatment and control of hypertension in elderly US adults

Primary Author: Sara Higa, University of Maryland Baltimore School of Pharmacy, Maryland; **Email:** sara.higa@umaryland.edu

Additional Author (s):
Sarah Tom
Bruce Stuart
Ebere Onukwugha

Purpose: Patient perceptions of personal health issues, self-efficacy, and perceived barriers to action, are all factors in the Health Belief Model to explain engagement in health-promoting behavior. However, there is a lack of understanding on the barriers to adherence for the elderly population regarding hypertension and how socioeconomic factors influence their beliefs on blood pressure control. The objective of this study is to evaluate potential disparities due to income and education on the confidence levels of older patients in hypertension management and their ability to pay for antihypertensives.

Methods: The institutional review board approved this cross-sectional study. Data from the Medicare Current Beneficiary Survey (MCBS) were used to study hypertensive adults from 2007 to 2011. Eligibility criteria for this study were community-dwelling beneficiaries with hypertension aged over 65 years. Institutionalized beneficiaries were excluded from this study due to the lack of questions on drug coverage in the MCBS Cost and Use files from 2007 to 2010. The primary explanatory variables were income and education levels, and the key dependent variables were answers to MCBS survey questions regarding confidence in blood pressure control and ability to pay for antihypertensive medications. Covariates included age, sex, race, geographic residence, and marital status. All data manipulation, tables, figures, listings, and analyses were documented and performed using SAS® Software v9.2. Chi-square and Fisher's Exact tests on demographic characteristics of beneficiaries showed differences between our population of interest versus beneficiaries without hypertension. Pearson's correlation coefficient was determined for income and education to test for potential multicollinearity. A proportional-odds cumulative logit model and a binary logistic regression

were used to assess differences in outcomes for each exposure variable, depending on the nature of the outcome.

Results: 4,054 beneficiaries fit our criteria. There was a positive, moderate correlation between income and education levels (Pearson coefficient: 0.4). Beneficiaries with an annual income of 10,000 to 24,999 dollars were most affected by hypertension, with 40 percent of all newly diagnosed beneficiaries falling into this income category. 64 percent of newly diagnosed beneficiaries had the equivalent of a high school diploma or lower levels of education. The results showed a statistically significant association between income and education levels on patients' confidence in blood pressure control. Beneficiaries in the highest income category were 1.42 times more likely to have higher confidence compared to those with an annual income of less than 10,000 dollars (95 percent confidence interval 1.08 to 1.86), and odds of greater confidence significantly increased with each rise in education level (OR: 1.26 and 1.64, respectively). Patients were less likely to report having difficulty paying for medications as income levels increased, with odds of reporting difficulty cut in half when annual income increased to 25,000 to 49,999 dollars (OR: 0.45, 95 percent confidence interval 0.29 to 0.71), and decreased even further with income greater than or equal to 50,000 dollars (OR: 0.2, 95 percent confidence interval 0.1 to 0.39).

Conclusion: Income and education levels affected both the patients' perception of blood pressure control and ability to pay. While many barriers to adherence and proper control have been identified in the general hypertensive cohort, the poorly understood mechanism affecting hypertension management remains a debilitating concern for a large proportion of elderly Americans. By identifying socioeconomic differences in patients' health perceptions, this study provides new insight to further examine what patient-centered barriers exist in effective blood pressure management in the elderly.

Poster Title: Pharmacists' and pediatricians' knowledge of codeine use in children

Primary Author: Ting He, University of Maryland Baltimore, Maryland; **Email:** ting.he@umaryland.edu

Additional Author (s):
Allison Lardieri
Jill Morgan

Purpose: In 2011, approximately 1.7 million pediatric patients had a codeine containing prescription filled at US retail pharmacies. Numerous cases involving serious adverse effects or fatalities have been reported in children who have been prescribed codeine. In 2013, the FDA added a black box warning to avoid codeine in children after a tonsillectomy. However, it is unknown how the current warnings surrounding codeine have impacted practice. Therefore, the purpose of this study is to determine pharmacists' and pediatricians' knowledge of the black box warning for codeine in children.

Methods: A 16-item survey was administered via survey monkey to community pharmacists in Maryland. A separate 12-item survey was administered via survey monkey to pediatricians and pediatric residents at a single institution in Maryland. Both surveys consisted of questions regarding the knowledge of the black box warning for codeine in children and which conditions would be appropriate for codeine use. Participants were recruited using emails and professional meetings.

Results: There were 105 pharmacists and 82 pediatricians who responded to the survey and of those, 85 pharmacists and 67 pediatricians completed the full survey. The pharmacists worked in a variety of settings, including independent stores (22.9%), chains (39%), hospital outpatient (22.9%), hospital inpatient (9.5%) and other settings (11.4%). Of the 82 pediatricians, 43 were attending physicians (52%) and 37 (45%) were residents. There was no difference in the awareness of the black box warning between pharmacists (43 of 88 (48.9%)) and pediatricians (41 of 80 (51.3%), p=0.88). More pharmacists knew that ultra-rapid metabolizers have greater risk for increased adverse events from codeine (40.7% pharmacists vs. 20% pediatricians, p=0.01). Only 17% of pharmacists (15/89) and pediatricians (14/80) were able to correctly

describe the black box warning in an open ended question. Also, 36% of pharmacists and 33% of pediatricians noted it was never appropriate to use codeine in a child, p=0.73.

Conclusion: The knowledge of the codeine black box warning was similar in pharmacists and pediatricians, with approximately half of the respondents stating they were aware of the warning. Also, only one third of pharmacists and pediatricians in this study would never use codeine in a child as recently reinforced by the American Academy of Pediatrics. Therefore, more education is needed for pharmacists and pediatricians regarding the dangers of using codeine in children.

Submission Type: Evaluative Study

Session-Board Number: 5b-214

Poster Title: Incidence of denosumab induced hypocalcemia in patients with bone metastases of solid tumor

Primary Author: Julia Brocato, University of Maryland Eastern Shore School of Pharmacy and Health Professions, Maryland; **Email:** jbrocato@umes.edu

Additional Author (s):
Michael Smith
Marie-Therese Oyalowo

Purpose: Denosumab is a human monoclonal antibody used to prevent skeletal related events (SREs) in patients with bone metastases from solid tumors. It inhibits receptor activator of nuclear factor kappa B ligand, which decreases osteoclast activity and bone resorption. Denosumab has been shown to cause hypocalcemia, and renal insufficiency has been proposed as a contributory factor. The objective of this study was to determine the incidence of hypocalcemia in patients receiving denosumab for prevention of SREs in bone metastases from solid tumors and the relationship to kidney function. This study also aimed to determine potential risk factors for denosumab induced hypocalcemia.

Methods: This retrospective analysis, approved by the institution's research committee, was conducted at Peninsula Regional Medical Center. A list of all patients receiving denosumab from January 2016 to August 2016 was obtained, and those charts were reviewed. Patients were included if they were 18 years of age or older, had been diagnosed with bone metastasis from a solid tumor, and had received denosumab for the prevention of SREs. Exclusion criteria were hypocalcemia at baseline and use of denosumab for treatment of hypercalcemia of malignancy, giant cell tumor of bone, or osteoporosis. Patient demographics and lab values were documented, and these included age, gender, type of tumor, serum calcium, albumin, magnesium, vitamin D, serum creatinine, and eGFR. Hypocalcemia was defined as ionized calcium less than 1.3 mmol per liter or corrected calcium less than 8.5 mg per dL. Severity of hypocalcemia was graded based on Common Terminology Criteria for Adverse Events (CTCAE). Patients were assessed for renal insufficiency, which was defined as eGFR less than 60 mL per minute per 1.73 m2. Supplementation with calcium and vitamin D during denosumab therapy

was also recorded. Descriptive statistics and logistic binary regression were used to analyze the data.

Results: A total of 135 patients received denosumab between January 2016 and August 2016. Of those, 75 patients were excluded based on established criteria, therefore 60 patients were included in the analysis. Hypocalcemia was observed in 10 patients (16.7 percent). Age range for the patients that developed hypocalcemia was 52-91 years, with 60 percent of these patients being age 70 and older. Of the patients with hypocalcemia, 5 were diagnosed with prostate cancer, 3 with lung cancer, 1 with breast cancer, and 1 with neuroendocrine cancer. A total of 25 patients had renal insufficiency during denosumab therapy, and 7 of these patients developed hypocalcemia (OR 3.81; 95 percent CI 0.88 to 16.53). Supplementation with both calcium and vitamin D was seen in 30 patients, and 5 of those patients developed hypocalcemia (OR 1.00; 95 percent CI 0.26 to 3.89). Thirty percent of patients received no supplementation, while 5 percent received only calcium and 15 percent received only vitamin D. Four of the 10 patients with hypocalcemia were hospitalized with an average length of stay of 8.25 days. Treatment of hypocalcemia consisted of oral therapy (4 patients) or both oral and IV therapy (2 patients). Hypocalcemia resolved without treatment in 4 patients.

Conclusion: Denosumab has been shown to cause hypocalcemia leading to hospitalizations, but the risk factors for developing hypocalcemia are not yet clear. Therefore, it is important to closely monitor both vitamin D and calcium levels before and during therapy in all patients. This study did not find a significant difference in the development of hypocalcemia based on renal function or supplementation, but this may be due to the small sample size. Tumor type and age may be important variables to consider in future research. Additional research is needed to determine other predisposing factors for denosumab induced hypocalcemia.

Poster Title: Assessing the impact of substance abuse education on student pharmacists' perspective of addiction: Utilization of a survey

Primary Author: Tejas Patel, Notre Dame of Maryland University, Maryland; **Email:** tpatel1@live.ndm.edu

Additional Author (s):
Shayne Wharton
Mamta Parikh
Stacey Williams
Simone Weiner

Purpose: As the country faces a prescription drug abuse epidemic along with an increase in heroin abuse and other substances of abuse, the United States Department of Health and Human Services has emphasized that training healthcare providers, such as pharmacists, is important to combat this problem. Pharmacy schools are looking to incorporate a comprehensive education on substance abuse into their curriculum. Therefore, this study assesses the changes in pharmacy students' perspective on various aspects of addiction after completing an elective course titled "Topics in Drugs of Abuse."

Methods: "Topics in Drugs of Abuse" is a 2-credit elective course offered to pharmacy students in their professional year two and three (P2 and P3). This course utilizes a lecture and presentation approach to explore the science behind drug abuse and addiction and various other areas involved in the neurobiology of addiction. It also explores the behavioral and neurobiological mechanism of action for common classes of drugs of abuse; opiates, sedative-hypnotics, anxiolytics, psychostimulants, marijuana, nicotine, and caffeine. This course was designed to expose students to the harmful consequences of drug use, focusing on the physiological, psychological, social, and economical impacts.
A survey was developed to assess the changes in (1) pharmacy students' perspective on addiction, (2) pharmacy students' perspective on addiction in a healthcare professional versus a patient, and (3) pharmacy students' motivation and ability to identify and treat a patient with addiction. The survey was administered to pharmacy students on the first day of the elective course, wherein responses were collected via TurningPoint clickers. On the last day of the

course, a paper copy of the survey was given, allowing written feedback to be added. Data were reported in quantitative (e.g., Likert scale) outcomes using narratives.

This study was approved by the Institutional Review Board for Research with Human Subjects at the Notre Dame of Maryland University.

Results: Overall, 31 responses were recorded in the 15-question post-survey results. 26 students agreed that their level of understanding of addiction would impact how they would practice as a pharmacist. 28 students agreed that a pharmacist plays a vital role in the care of addicted patients. 23 students disagreed that they would be likely to avoid a patient with addiction. 27 students responded that they disagreed that a patient with addiction can stop using drugs whenever they want. A majority of students also stated they were more comfortable in their ability to identify a patient with addiction after taking the course, compared to pre-survey results.

Conclusion: Based on the results of the survey, the course design and content altered pharmacy students' perspective about addiction and impacted how the students will identify, interact, and treat a patient with addiction. Thus, various aspects of this course could be used by other schools of pharmacy who are implementing substance abuse electives. The developed survey could serve as a useful tool for measuring the effectiveness of such courses in altering pharmacy students' perspective on various aspects of addiction.

Poster Title: Assessing adherence to the heparin protocol for the treatment of venous thromboembolism and acute coronary syndrome at a community teaching hospital

Primary Author: An Nguyen, University of Maryland School of Pharmacy, Maryland; **Email:** an.nguyen@umaryland.edu

Additional Author (s):
Julie Gould
Pan Wong
E. Loveta Epie

Purpose: Unfractionated heparin (UFH) is used in the treatment of venous thromboembolism (VTE) and acute coronary syndrome (ACS). The CHEST (2012) and AHA/ACC (2014) guidelines recommended no maximum bolus dose for VTE treatment and a maximum bolus dose of 4,000 units for treatment of definite ACS. This has led institutions to develop a heparin protocol, ensuring its safe and appropriate use. The primary objective of this study was to assess adherence to the Prince George's Hospital Center (PGHC) Heparin Protocol for UFH bolus dose administration. The secondary objective was to determine if nonadherence resulted in supratherapeutic aPTT, and clinically significant bleeding.

Methods: A list of patients was obtained from the pharmacy dispensing database for any unfractionated heparin administration between January 1, 2015 and May 31, 2016. Patients were then randomized using Microsoft Excel. Patients included in this study must have received both bolus and infusion heparin doses for one of the three approved indications per protocol: VTE, ACS without fibrinolytic and ACS with thrombolytic. Additionally, patients must also have received UFH for at least 12 hours, and must have had at least 2 aPTT values measured. Patients were excluded if they received UFH for other indications such as surgery prophylaxis or hemodialysis. Other excluded patients were those whose orders were discontinued before administration or patients on heparin for less than 12 hours. Per PGHC protocol, VTE treatment bolus is 80 units/kg with a maximum of 10,000 units, ACS (without fibrolytics) treatment as a bolus of 70 units/kg with a maximum of 5,000 units, and ACS (with thrombolytics) treatment as a bolus 60 units/kg with a maximum of 4,000 units. Adherence to the heparin bolus dose protocol was determined by evaluating the bolus dose administered to patients using the

medication administration records. Measured aPTT was then evaluated to determine whether it was therapeutic (70-110 seconds), supratherapeutic (greater than 110 seconds), or subtherapeutic (less than 70 seconds). Physician and nursing progress notes were reviewed for any documented bleeding.

Results: A list of 1,005 patients were obtained and randomized, 277 patients were reviewed and 50 patients were included in this study. 31 patients received UFH for VTE treatment, 18 for ACS without thrombolytic, and 1 ACS with thrombolytics. In all three groups, 6 (12 percent) patients received a total UFH bolus that was higher than max recommended for each indication: one VTE (3.2 percent) and 5 ACS without thrombolytic (27.8 percent). Of these 6 patients, 4 achieved supratherapeutic first aPTT and 3 continued to have sustained supratherapeutic second aPTT. When looking at compliance to protocol based on the number of UFH units given per kg for bolus doses, a total of 5 patients (10 percent) got higher than 80 units/kg (VTE treatment) and 70 units/kg (ACS without thrombolytic). Of these 5 patients, 2 achieved sustained supratherapeutic aPTT despite of adjustment. Of all cases, 2 adverse events were recorded: one hematuria and one bruising on upper extremity. Both patients received UFH bolus under maximum recommended doses per protocol for VTE treatment. No documented bleeding events were found among patients who received above maximum heparin bolus dose.

Conclusion: Twelve percent of patients received higher than maximum bolus dose of UFH per institution protocol. Although there was no adverse event reported in these patients, this study revealed the need for provider education and an alert system to ensure patient's safety. It also showed that supratherapeutic aPTT did not translate into major bleeding. Future studies with larger sample size looking at the clinical significance of sustained supratherapeutic aPTT are suggested.

Poster Title: Utilization of a validated opioid overdose knowledge and attitudes scale to assess education on opioid overdose training for pharmacists

Primary Author: Megan Cook, Notre Dame of Maryland University, Maryland; **Email:** mcook3@live.ndm.edu

Additional Author (s):
Julia Wood
Rafael Otero De Santiago
Hanna Fenta
Keila Rentas Centeno

Purpose: In the state of Maryland, drug overdoses have become a serious public health challenge. In 2015 almost 86% of all overdose related deaths were opioid-related. The need to implement an overdose response program (ORP) focusing on educating pharmacists is apparent. Pharmacy faculty members and 4th year pharmacy students are working with a local ORP agency, Baltimore Student Harm Reduction Coalition, to develop an ORP focused on educating healthcare professionals. The purpose of this study is to describe the instructional design and evaluation of the training session on opioid overdose and naloxone distribution to pharmacists in the community and hospital setting.

Methods: Pharmacy faculty members and 4th year pharmacy students modified the Baltimore Student Harm Reduction Coalition presentation to include more active learning strategies to engage learners. Instructional design modifications to the ORP training consisted of the following: two placebo product instructional stations, simulated patient counseling case scenarios, assessment rubrics on appropriate counseling technique, and content on important dispensing information directed to pharmacists specifically. During the two-hour training session validated Opioid Overdose Knowledge (OOKS) and Attitudes (OOAS) Scales were administered before and after the training to measure training effectiveness. The OOKS score ranges from 0-45 points and the OOAS score ranges from 28 to 140 points. Learning outcomes included recognition of opioid overdose, assembly of naloxone delivery devices, and administration of naloxone. Formal presentation, video demonstrations, practical exercises on how to assemble and administer naloxone, Q&A discussion, and assessment and feedback were

used to educate the participants. Evaluation of education was assessed based on changes in knowledge and attitudes. The OOKS and OOAS scales were used to help instructors to assess the effectiveness of the modified ORP education training session for pharmacists.

Results: Sixteen pharmacists working in community and health-systems pharmacy settings participated in the ORP training. 43.8 percent of pharmacists were within the age range of 25-34 years and 50 percent of pharmacists have been practicing pharmacy for 6-10 years in various counties within Maryland. 62.5 percent of pharmacists reported that they had not previously provided counseling on opioid overdose and the use of naloxone to patients. The OOKS median pre-training score was 36 (IQR 32.5 - 39), while the median post-training score was 42 (IQR 39 - 42). The median OOKS scores improved by 6 points between pre and post-training surveys. The OOAS median pre-training total score was 104 (IQR 117.75 - 90.25) and the median post-training score was 122 (IQR 99-140). The median OOAS scores improved by 18 points between pre and post-training surveys.

Conclusion: Utilization of the OOKS and OOAS results provided insight on the effectiveness of the opioid overdose and naloxone administration educational program. The pharmacists who participated in the program demonstrated an overall score improvement on both the OOAS and OOKS. Improvement in OOAS scores from pre to post-training, can be correlated to an increase in pharmacists' readiness and willingness to intervene in an overdose situation, as well as confidence to counsel patients on overdose response. Results of this ORP program will provide insight on what changes should be made in future programming tailored towards pharmacists and healthcare professionals.

Poster Title: National trends in the diagnosis and treatment of asthma in US youth by race and ethnicity before and after clinical guidelines changes

Primary Author: Jillian Aquino, University of Maryland, Baltimore, Maryland; **Email:** jillian.aquino@umaryland.edu

Additional Author (s):
Mehmet Burcu
Kenneth Doan
Julie Zito

Purpose: In 2014, approximately 8.6% of children in the United States were diagnosed with asthma. Previous literature in children shows there is racial disparity in asthma outcomes, requiring targeted intervention. In 2007, Expert Panel Report (EPR-3) guidelines have been updated to improve management of asthma. However, little is known about the impact of the guideline changes on diagnosis and treatment of asthma in US youth. The objective of this study was to examine national trends of asthma diagnosis and treatment by race/ethnicity in U.S. youth from 2001 through 2012.

Methods: The study was conducted using National Ambulatory Care Survey (NAMCS) and National Hospital Ambulatory Care Survey (NHAMCS), which are nationally representative surveys of office-based physician visits. First, we assessed asthma diagnosed visits as a proportion of total outpatient visits by race/ethnicity in three time periods (2001-2006, 2007, 2008-2012). Second, we assessed asthma medication prescribing in these asthma diagnosed visits by race/ethnicity across 12 years. The anti-asthmatic medication classes included long-acting beta-agonists (LABAs), fixed-dose LABAs, short-acting beta agonists (SABAs), leukotriene receptor antagonists (LTRAs), inhaled corticosteroids (ICS), oral corticosteroids (OCS) and other asthma medications. All analyses were population weighted to produce nationally representative findings.

Results: From 2001 to 2012, the percentage of outpatient visits with a diagnosis of asthma remained stable (from 4.5% to 4.6%). However, there were significant changes in treatment patterns in these asthma diagnosed visits. Overall, from 2001 to 2012, the proportion of asthma diagnosed visits with anti-asthmatic prescriptions increased from 70.2% to 83.1%. This growth occurred at a significantly greater rate for African Americans (from 58.7% to 83.8%) and Hispanic youth (from 66.9% to 84.5%) than white youth (from 73.9% to 82.0%). In terms of anti-asthmatic medication subclasses, there was an increase in prescribing of SABAs (54.5% vs. 65.9%), ICS (31.7% vs. 40.8%), and OCS (12.7% vs. 17.4%) –but not for other anti-asthmatic medication classes –in the 2008-2012 period compared with the 2001-2006 period.

Conclusion: Following the publication of expert panel guidelines for the management of asthma in 2007, there was a substantial increase in anti-asthmatic prescribing in nationally representative outpatient youth visits. This expansion was largely attributed to increased prescribing of anti-asthmatics, particularly for short acting beta agonists, in outpatient visits by African American and Hispanic youth.

Submission Type: Evaluative Study

Session-Board Number: 5b-219

Poster Title: Weight-based heparin dosing and time to therapeutic partial thromboplastin time: A comparison between Cardiac Heparin Protocol and Acute Coronary Syndrome Heparin Protocol at Hanover Hospital

Primary Author: Brandon Biggs, University of Maryland School of Pharmacy, Maryland; **Email:** brandonjbiggs@gmail.com

Additional Author (s):
Mark Heisey

Purpose: Weight-based dosing of unfractionated heparin is the standard of care in the treatment of acute coronary syndrome. At Hanover Hospital, a 93-bed community institution located in Hanover, Pennsylvania, the heparin protocol was modified in April 2016 to reflect the updated guidance from American College of Cardiology/American Heart Association, which recommends a lower initial weight-based heparin bolus and infusion rate. Because attaining therapeutic partial thromboplastin time has been associated with improved outcomes in these patients, this analysis examines if the updated heparin protocol would result in a longer time to achieve therapeutic partial thromboplastin time.

Methods: The Cardiac Heparin Protocol used before the updated recommendations called for a max initial bolus of 65 units/kilogram intravenously (max 6800 units) and a 13 units/kilogram/hour infusion rate (max 1400 units/hour). The Acute Coronary Syndrome Heparin Protocol employs a max initial bolus of 60 units/kilogram intravenously (max 4000 units) and a 12 units/kilogram/hour infusion rate (max 1000 units/hour). Patients hospitalized in Hanover Hospital between May 2014-July 2014 or May 2016-July 2016 who were ordered a heparin protocol for a cardiac indication were selected in the analysis. Exclusion criteria included those who did not achieve a therapeutic partial thromboplastin time due to discharge from the hospital or discontinuation of heparin prior to attainment of a therapeutic level. The time to therapeutic partial thromboplastin time was observed for 67 patients who were ordered the Cardiac Heparin Protocol (active between May 2014-July 2014) and for 81 patients ordered the Acute Coronary Syndrome Heparin Protocol (active between May 2016-July 2016). In addition, gender, age, and weight were collected for each patient. Microsoft Excel (2010) was used to calculate the mean and median time to therapeutic partial thromboplastin time in each

group. Mean values were statistically compared with a t-test and the presence of a p value less than 0.05 was considered statistically significant. IRB approval was not required at this institution due to the retrospective nature of this study.

Results: Gender distribution was not found to be significantly different between the two protocols, chi square (1, N equal 148) equals 5.98, p value less than 0.014. There was also no significant difference in mean age between the two protocol groups (p greater than 0.05). In addition, weight did differ significantly between the two treatment groups (Cardiac Heparin Protocol equals 82.1 kg. Acute Coronary Syndrome Heparin Protocol equals 92.1 kg: p values less than 0.05). However, the proportion of patients who would have received the initial max dose of either protocol was numerically similar when normalized for those exceeding the maximum recommended initial weight-based dose in the Acute Coronary Syndrome Heparin Protocol based on a weight of 82 kilograms or greater. The mean time to a therapeutic partial thromboplastin time was 18.5 hours for the Cardiac Heparin Protocol group and 14.5 hours for the Acute Coronary Syndrome Heparin Protocol group (t stat equal 1.63, p value greater than 0.05) indicating that the difference in the time to achievement of a therapeutic partial thromboplastin time value between the two groups was not statistically significant.

Conclusion: The numerical difference in time to achievement of a therapeutic partial thromboplastin time between the two protocols was not statistically significant. While the Acute Coronary Syndrome Heparin Protocol employs a lower initial weight-based bolus dose and infusion rate, the time to achievement of a therapeutic partial thromboplastin time was shorter for patients placed on Acute Coronary Syndrome Heparin Protocol than in those placed on Cardiac Heparin Protocol.

Poster Title: Evaluation of the use of tirofiban in a community hospital

Primary Author: Songe Baek, University of Maryland School of Pharmacy, Maryland; **Email:** sbaek@umaryland.edu

Additional Author (s):
Emil Sidawy
Elham Hekmat

Purpose: Tirofiban is a glycoprotein (GP) IIb/IIIa inhibitor that inhibits platelet aggregation by preventing fibrinogen from binding to the GP IIb/IIIa receptors. It is used for the treatment of unstable angina, NSTEMI, and in patients undergoing PCI in stable ischemic heart disease or STEMI (off-label). Recently, tirofiban replaced another GP IIa/IIIa inhibitor, eptifibatide, as the formulary agent at Adventist Healthcare Shady Grove Medical Center. The purpose of this study was to characterize tirofiban prescribing patterns, observe dosing and adjustments patterns, assess for adverse events and determine total cost savings from the formulary switch.

Methods: In this analysis, a total of seventeen adult patients admitted to this community hospital were placed on tirofiban from January 2016 to June 2016. Variables that were assessed include dosing, indication, infusion duration, adverse effects, renal function, appropriateness of medications administered with tirofiban, and cost of tirofiban. The equivalent dosing of eptifibatide was determined based on the indication, patient's weight, renal function, and duration of continuous infusion. The cost saving was then estimated based on eptifibatide's equivalent dosing.

Results: The mean age of the observed patients was 58.6 years and 78 percent of the patients were male. Patients on tirofiban during the six month period from January 2016 to June 2016 were admitted to the progressive care unit (PCU), intensive care unit (ICU) and the medical/surgical unit. A majority of 64.7 percent were patients admitted to the ICU. Patients experiencing STEMI who underwent a PCI was the most frequent indication for tirofiban (71 percent). Prescribing patterns have been appropriate in use, which was shown through co-administration with heparin or bivalirudin. In addition, dosing have generally been appropriate, except for one case where the continuous infusion dosing was not renally adjusted. In another

case, the dose was adjusted after the pharmacist's intervention. Other indications that were used within this patient population were use in unstable angina (5.9 percent) and NSTEMI (17.6 percent). No cases of serious side effects occurred, although a few mild side effects were observed in this patient population. Since the formulary switch from eptifibatide to tirofiban, this institution saved 4240 dollars and 18 cents in medication costs from the seventeen patients who received therapy throughout the six month period.

Conclusion: Overall, tirofiban use has been appropriately prescribed and administered at this community hospital. Tirofaban use was more cost effective than eptifibatide.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Descriptive Report

Session-Board Number: 5b-221

Poster Title: Assessment of the impact of medication history technicians on admission medication reconciliation workflow in a community-based hospital: a descriptive quality assurance/medication safety study

Primary Author: Sophie Soo, University of Maryland School of Phamacy, Maryland; **Email:** sophie.soo@umaryland.edu

Additional Author (s):
Gina Bazemore
Patrick Grove
Denise Kingsbury
Deborah Rhee

Purpose: In January 2016, a medication history technician role was established to collect home medication lists from 11 am to 11 pm for patients admitted through the Emergency Department. The role supports inpatient admission nurses, who were previously solely responsible for collecting medication lists, in an effort to provide physicians more immediate access to home medication lists for admission orders. The purpose of this review is to evaluate medication history technician impact by assessing overall medication list completion rate, and completion rate prior to input of admission orders, and medication list collection turn-around time after decision to admit.

Methods: Data was collected from the medical record for all patients admitted though the Emergency Department in June 2016. For the review of overall medication list completion rate, the percent of medication histories collected during medication history technician working hours and during technician-off hours (nursing-only hours) was evaluated. To assess turn-around time, the time difference between the decision to admit and the medication history list completion was evaluated for both the technicians and nurses. The number of medication lists collected by technicians and by nurses prior to physicians inputting admission orders was also evaluated.

Results: In June 2016, the medication history technicians collected __percent of medication lists from patients admitted during their shift. Similarly, nurses collected __percent of medication lists from patients admitted during technician off-hours. Technicians completed __percent of medication histories within 60 minutes of decision to admit and nurses completed __percent of medication histories within the same time period. The average turn-around time for technicians and nurses was __ minutes and __ minutes, respectively. The medication history technicians were able to collect __percent of medication histories prior to physicians inputting admission orders while nurses were able to collect __percent.

Conclusion: Establishing the medication history technician role has positively impacted the inpatient admission medication reconciliation process. Compared to the time when they are not staffed, medication history technicians collected __percent more home medication lists overall and __percent more lists prior to input of admission order. The average turn-around time of medication list collection following decision to admit time has also decreased by __ minutes. The addition of medication history technicians has improved workflow and provides physicians access to up-to-date medication histories, facilitating admission orders and reduces the potential for medication errors, ultimately creating a safer environment for patients.

Poster Title: Assessment of a multi-discipline implemented pegfilgrastim cost-minimization guideline: knowledge, adherence, safety, and patient-reported satisfaction

Primary Author: Susie Park, University of Maryland School of Pharmacy, Maryland; **Email:** s.park@umaryland.edu

Additional Author (s):
Joey Mattingly
Alison Duffy
Steven Gilmore

Purpose: National Comprehensive Cancer Network (NCCN) recommends use of granulocyte colony stimulating factors (G-CSFs) for use with chemotherapy regimens that are high risk, defined as greater than 20 percent, for febrile neutropenia. University of Maryland Medical Center (UMMC) recently developed a pegfilgrastim use guideline in January 2015 to identify patients who are candidates for self-administration at home via outpatient prescription sent to University of Maryland Medical System (UMMS) Ambulatory Pharmacy. This study was designed as a pilot evaluation of patient-reported knowledge, adherence, safety, and satisfaction of pegfilgrastim administration at home or administration at UMMC's outpatient infusion center (OIC).

Methods: This pilot study was prospective in design and included adult patients (18 years and older) prescribed pegfilgrastim at the University of Maryland Marlene and Stewart Greenebaum Cancer Center (UMGCC) between March and July 2016. Through the use of a recently developed pegfilgrastim prescribing guideline created at UMMC, patients were divided into two groups: those who would receive a prescription through UMMS outpatient pharmacy service to be administered at home and those who would be administered pegfilgrastim at OIC between 24 and 72 hours after chemotherapy per the guideline. For patients administered pegfilgrastim at OIC, a telephone survey was conducted within 3 days post-pegfilgrastim administration. Patients who were prescribed to self-administer pegfilgrastim at home, utilizing the UMMS Ambulatory Pharmacy Service (APS), two telephone surveys were conducted: an initial telephone survey within 3 days after scheduled delivery and a follow-up survey within 3 days after scheduled chemotherapy. The components of the survey included questions

regarding confidence in the knowledge of various factors related to pegfilgrastim, including timing of pegfilgrastim administration and side effects, as well as satisfaction with pharmacy services. The two primary outcomes evaluated were overall patient satisfaction with OIC's and UMMS APS's pharmacy services as well as time of pegfilgrastim administration in respect to chemotherapy administration.

Results: Twenty patients were included in the final analysis: twelve patients with administration from OIC and 8 patients utilizing the UMMC APS. Satisfaction with the pharmacy service was rated as 10 on a scale of 0 to 10, 9 (75 percent) of patients from the OIC arm and 5 (71 percent) patients from the UMMS APS arm. Seven (58 percent) patients experienced side effects from pegfilgrastim in the OIC arm, and all of these patients experienced bone pain, while 3 (43 percent) patients with side effects experienced both bone pain and left upper abdominal or shoulder pain. Two (40 percent) patients who completed the follow-up survey in UMMC APS arm reported experiencing side effects, all reporting bone pain. The number of patients reporting very confident on all knowledge questions was 4 (33 percent) and 4 (50 percent) in the OIC and APS arms, respectively. Pegfilgrastim administration occurred in 5 (100 percent) of the home administration arm within the recommended 24-72 hours after chemotherapy compared to 11 (92 percent) in the OIC administration arm.

Conclusion: UMMS APS was utilized to dispense pegfilgrastim for prevention of neutropenic fever in patients who met guideline criteria. Patients administered all planned doses of the prescribed injections without problems other than the most commonly reported adverse effects. Patient self-administration of pegfilgrastim at home is a viable option for patients with intermediate to high risk of febrile neutropenia after treatment with chemotherapy.

Session-Board Number: 5b-223

Poster Title: Comparison of medication palatability and flavoring knowledge of healthcare professional students

Primary Author: David Tran, University of Maryland School of Pharmacy, Maryland; **Email:** david.tran@umaryland.edu

Additional Author (s):
Elaine Pranski
Brandon Biggs
Allison Lardieri
Jill Morgan

Purpose: Medication palatability is a significant factor impacting medication adherence in children. Studies suggest 79 percent of children complain about poor tasting medication, leading to difficulty administering medications. Medication flavoring may increase compliance from 53 to over 90 percent. Currently, there is no literature documenting healthcare professional and students' knowledge of medication palatability. The primary objective of this study is to compare medication palatability and flavoring knowledge of different healthcare professional students. Secondary objectives seek to determine if current curriculums devote appropriate time covering these topics and to compare the confidence level of students in making recommendations to improve palatability.

Methods: The University of Maryland institutional review board approved this convenience sample survey study. Pharmacy, medical, dental, and graduate nursing students in the final year of their programs at one University were emailed to participate in an anonymous online survey about their knowledge of medication taste and flavoring. Exclusion criteria included inability to read English and age under 18 years. Demographic data collected from each subject included age, gender, ethnicity, years of work experience in healthcare field, and employment setting. Subjects were asked to rate their familiarity with medication taste and their confidence in suggesting medication flavoring using a Likert scale (1 indicating no familiarity/confidence and 5 indicating extremely familiar/confident). Participants were asked to rate the taste of twelve medications as "good," "bad," or "I don't know," as well as choose the best and worst tasting medication from the twelve selected medications. Additional questions were asked about

where they obtained their knowledge of medication taste and number of content hours covering medication palatability in their curriculum. Results from previous taste studies were used to predetermine answers related to these twelve medications. Mean familiarity and confidence levels were compared using student T-tests and correct answers for medication tastes were compared using chi-squared. A p-value less than 0.05 was considered significant.

Results: Seventy-seven students completed the survey (22 pharmacy, 22 medicine, 16 dental, and 17 graduate nursing). The mean Likert scale score was 2.09 for medication palatability familiarity and 1.68 for confidence in suggesting flavoring. No lecture hours on medication palatability were in required (55 percent) and elective curriculums (51 percent). Knowledge was primarily acquired from work experience as reported by 25 percent.
Twenty-nine percent of questions concerning specific medication palatability were correctly answered with the remainder of responses either incorrect or "I don't know." Pharmacy students were most likely to correctly identify the taste of a medication. Pharmacy, medical, dental, and graduate nursing students answered 41, 31, 10, and 31 percent correctly, respectively. A chi-squared test of independence was performed and revealed a significant relationship between field of study and correct taste identification, chi-squared (6, N equals 780) equals 60.5, p less than 0.001. The correct identifications of the best and worst tasting medications were as follows: 52.6 and 57.9 percent for pharmacy, 47.1 and 41.2 percent for medical, 26.7 and 53.4 percent for dental, and 50.0 and 57.1 percent for graduate nursing.

Conclusion: Pharmacy students had more knowledge regarding the palatability of individual medications as well as determining the best and worst tasting medications. A significant correlation was found between field of study and correct answers for the more commonly used medications. All health professional schools should consider providing curriculum content on adherence related to medication palatability.

Poster Title: Impact of inservice education on pharmacist competency to identify medication fall risk in patients of a rural community hospital

Primary Author: Zemen Habtemariam, University of Maryland Baltimore School of Pharmacy, Maryland; **Email:** zhabtemariam@umaryland.edu

Additional Author (s):
Julie Caler

Purpose: Patient falls are a major safety concern in the acute care setting, particularly in a rural community with a significant elderly population. Falls lead to greater length of stay and increased risk of injuries and mortality. New Joint Commission recommendations encourage medication safety assessments in patient post-fall reviews, although to date they are not always incorporated in falls prevention programs. We have established tools to assess medications, but they still require the clinical evaluation of pharmacists to investigate patient cases. The intent of this study is to assess pharmacist competency and success in assessing patients for medication-induced fall risk.

Methods: A student pharmacist developed a case scenario competency examination on medication fall risk, along with an inservice education on the topic. The inservice education highlighted common drug classes associated with falls and an established medication fall risk scoring tool intended to use in conjunction with the Morse Fall Scale. The post test examination comprised of the original pretest examination, but also included an additional section asking to perform two fall risk calculations using the available fall risk scoring tool (100 percent required to pass). The calculations section was held independent of the subject's post test competency score. All materials were reviewed by a clinical pharmacy specialist with advanced training in medication safety and geriatric pharmacotherapy.
The pretest examination was administered to eight staff pharmacists of varying experience in a rural community hospital, followed by the inservice education and post test examination one to two days later. Pharmacists needed to score at least 80 percent or higher on the post test examination to pass the competency assessment. The primary outcome measure is the percentage of pharmacists who passed the competency assessment following the post test. Secondary outcome measures include percentage of pharmacists whose scores improved

following the inservice, and percentage of pharmacists who passed the calculation section with 100 percent. Statistical analysis was performed on score improvement measure by using the Wilcoxon Rank Sum Test.

Results: Seven of the eight staff pharmacists passed the post test assessment with an average of 88 percent and a standard deviation of 10 percent, which is well over the 80 percent minimum. This is in large contrast to the pretest assessment, which reported an average of 66.8 percent and a standard deviation of 7 percent.

All of the eight staff pharmacists showed significant improvement in their post test score with an average improvement score of 21.09 percent from baseline (p value less than 0.5).

Four of the eight pharmacists were able to pass the fall risk calculation section (two out of two calculations correct). The other four pharmacists all had 50 percent (one out of two calculations) correct, and none of the pharmacists received a score of zero correct.

Conclusion: The results of this study show the unit pharmacists of the hospital demonstrated competency on potential medication fall risk. This is important to first establish, since it gives credibility toward our pharmacists' capability to consult and evaluate on patient falls on the units. It is true not all falls are necessarily medication-related, but using medication assessments can also help to rule out a potential fall risk patient or to investigate the potential risk factors leading to a patient fall. This is not a highly studied pharmacy topic, but it is a critical safety issue that deserves pharmacy to implement interventions.

Poster Title: Development and implementation of medication cards highlighting purpose and side effects to nursing units in an academic medical center

Primary Author: Brian Lindner, University of Maryland, Baltimore, Maryland; **Email:** blindner1@umaryland.edu

Additional Author (s):
Rachel Lumish
Emily Pherson
Lauren McBride

Purpose: The purpose of this project was to develop and implement unit-specific medication cards for use by nurses for patient education during medication administration. Medication education is vital to patient care. The Center for Medicare and Medicaid includes specific questions about both purpose and side effects in their Hospital Consumer Assessment of Healthcare Providers and Systems Survey (HCAHPS). All members of the healthcare team play an important role in patient education, however, the pharmacist's medication knowledge and the nurse's relationship and time spent with the patient make these two members of the team uniquely suited to assist in medication teaching.

Methods: Medication orders were assessed for each of the nursing units and the emergency department at The Johns Hopkins Hospital. The top 100 medications from each unit were gathered and combined into a "Medication Database". The database was further developed by 5 pharmacists from different specialties to include the purpose and side effects of each identified medication. Pharmacists from each respective nursing unit utilized the Medication Database to develop medication cards that contained the most appropriate and most frequently ordered medications on that unit. Following final edits, the medication cards were then printed and distributed to each hospital unit. One card was hung in each patient room adjacent to the computer where the nurse would document medication administration. The pharmacist for their respective unit worked with nursing leadership to educate the nursing staff to use the newly developed medication card to educate patients on the purpose and potential side effects of their medications at the time of administration.

Results: A comprehensive medication database was compiled containing the name, purpose, and potential side effects of the top 356 medications ordered at The Johns Hopkins Hospital. From this database, a total of 47 unique medication cards were developed containing a welcome statement as well as the information from the medication database. Each medication card includes the 57 most appropriate and frequently used medications from each hospital unit and the adult emergency department. A total of 941 medication cards were printed and placed in patient rooms.

Conclusion: Medication education is critical to patient satisfaction. Pharmacists are uniquely trained to have the medication knowledge to complete this education, and nurses are in an ideal role to partner with pharmacists to deliver this education. By working as a multidisciplinary team, The Johns Hopkins Hospital has developed a patient education model that could potentially improve both HCAHPS scores and staff satisfaction. The methods and model presented can be utilized as a framework within which to implement the expansion of medication education within a hospital system.

Poster Title: Clustered Regularly Interspaced Short Palindromic Repeats with associated Cas genes (CRISPR-Cas) system and insurance coverage if it obtains orphan drug or humanitarian use device status

Primary Author: Sarah Lee, University of Maryland Eastern Shore School of Pharmacy, Maryland; **Email:** lee.sarah033@gmail.com

Additional Author (s):
Robert Freeman

Purpose: There is no doubt that technology as a whole has continued and will continue to advance in the coming years with medicine advancing alongside it. One of the biggest advances in medicine is genome editing, with the newest being the CRISPR-Cas system. CRISPR-Cas is going through its first clinical trial in augmenting cancer therapies that involve a patient's T-cells. Once all the trials, safety testing, approval, and classification by the Food and Drug Administration (FDA), there is the question: will insurance cover this?
CRISPR-Cas is a gene-editing tool that can target and modify parts of specific deoxyribonucleic acid (DNA) sequences. It is based on a system used by bacteria to protect themselves from viral infections. To use the CRISPR-Cas system, scientists input a small part of pre-designed ribonucleic acid (RNA) sequence into the single guide RNA which bind to DNA and guide the Cas9 enzyme to the correct site. Cas9 then cuts both strands of DNA, triggering DNA repair. However, mutations can occur during the DNA repair process. This system may have a large impact on medical conditions that involve a genetic component, such as cancer, hepatitis B, or high cholesterol. There would be two ways that the system would work: 1) by silencing or disrupting the gene using the cell's natural but imperfect DNA repair mechanism causing a mutation or 2) by including a repair template with a specific change.
The Orphan Drug Act provides orphan status to drugs and biologics for those intended to treat, diagnose, or prevent rare diseases or disorders that affect less than 200,000 people or affect more than 200,000 people but are not expected to recover the cost of development and marketing. The Humanitarian Use Device (HUD) program creates another approval pathway for "medical devices intended to benefit patients in the treatment or diagnosis of a disease or condition that affects or is manifested in fewer than 4,000 individuals in the United States per year".

Each insurance prescription drug plan has its own formulary that can be placed in three to five tiers. Medicare Part D's SilverScript Plus plan has five tiers: Tier 1 (preferred generic, low cost preferred generic drugs), Tier 2 (generic, includes preferred generic and some preferred brand drugs), Tier 3 (preferred brand, includes preferred brand and non-preferred generic drugs), Tier 4 (non-preferred brand and non-preferred generic drugs), and Tier 5 (specialty tier, including high cost generic and brand drugs). CRISPR-Cas will likely fall into the specialty tier of formularies: Tier 5 in 5 tier plans and Tier 4 in 4 tier plans. Medicare Part D's SilverScript Plus plan has a coinsurance of 33 percent for up to a 30-day supply9 for its specialty tier. Kaiser Permanente's Point-of-Service Plan has two payment options: 1) 20 percent coinsurance up to 150 dollars at the Kaiser Permanente pharmacy or 2) 30 percent coinsurance up to 200 dollars for preferred specialty drugs or 30 percent coinsurance for non-preferred specialty drugs at MedImpact pharmacy. Medicare coverage and claims for HUD utilization is determined by local Medicare Administrative Contractors, resulting in variation in reviewing and processing claims. However, the pharmacy benefits manager that assist in developing an insurance plan's formulary and managing drug benefits by negotiating with pharmacy networks and analyzing medication data. Some issues addressed include quality-of-life improvement, cost-benefit analysis, and supporting evidence deficiencies.

CRISPR-Cas can potentially revolutionize treatments of disease states, however, access to these novel technologies is somewhat uncertain due to payers' actions in the areas of prior authorization, patient cost-sharing and dollar limits on coverage.

Poster Title: Role of the pharmacist in reducing 30-day hospital readmission rates: a literature review

Primary Author: Sara Zifa, University of Maryland, School of Pharmacy, Maryland; **Email:** szifa@umaryland.edu

Additional Author (s):
Tim Rocafort

Purpose: Because the majority of medication errors occur while transitioning patients from one setting of care to another, hospitals have been working diligently to develop new programs that assure these transitions run as efficiently as possible. As the medication experts of hospital teams, pharmacists have become increasingly involved in the effort to reduce the medication errors leading to early readmissions. This review explores pharmacist involvement in different TOC programs aimed at reducing 30 day readmissions.

Methods: This literature review was completed using the PubMed, Web of Science, Embase and Scopus databases. The MESH terms "pharmacy", "reduce" and "30-day hospital readmissions" were all used along with Boolean terms in order to conduct this search. Inclusion criteria consisted of human clinical trials or case studies published in English on or after the year 2009. Studies that did not use 30-day readmission rate as one of the endpoints and or examine the pharmacists' role in the TOC process were excluded from the review.

Results: A total of 26 studies were found to fit the criteria for this literature review. Almost all programs offered bundled packages of TOC services, making it difficult to identify the direct impact of each individual intervention. However, analysis of the data revealed that bundled services requiring more patient involvement were only capable of significantly reducing 30-day readmissions for the minority of patients able to complete the programs. Patients appeared less likely to drop out of programs that required less commitment from them.

Conclusion: While many TOC programs proved to be efficacious under ideal circumstances, a closer look at study dropout rates reveals that a large percentage of patients may not have the motivation or ability to complete these programs. This is very important when considering which interventions will yield results widespread enough to reduce overall 30-day readmission rates and avoid financial penalties for hospitals. Future studies should examine whether TOC programs designed to operate regardless of patient-specific factors can potentially result in more universal reductions in 30-day readmissions.

Poster Title: Use of topiramate for the treatment of substance abuse: a systematic review

Primary Author: Shayne Wharton, Notre Dame of Maryland University

School of Pharmacy, Maryland; **Email:** swharton2@live.ndm.edu

Additional Author (s):
Sharon Park
Reine Lienou

Purpose: Substance use disorders (SUD) are a rising issue in the United States, costing approximately 700 billion dollars annually; the most common substances abused include alcohol, tobacco, cannabis, stimulants, and opioids. Topiramate, an antiepileptic also indicated for migraine prophylaxis, has been used in treating SUD because of its potential to increase GABAergic activity, possibly reducing reward and craving sensations, thus making users less likely to abuse their substance of choice. However, its efficacy and safety for treating SUD have not been clear. The purpose of this systematic review is to comprehensively review the evidence for topiramate use in SUD.

Methods: A systematic review was conducted with a comprehensive literature search in PubMed (keyword and MeSH), Medline, PsychInfo, CINHAL, Embase, and Google Scholar. A combination of the following keywords were searched in each database: "topiramate," "substance abuse," "dependence," "dependency," "addiction," "drugs of abuse," "street drugs," "cocaine," "alcohol," "methamphetamine," "opiate," and "tobacco." Studies were included in the review if they (1) used topiramate as a main or singular treatment for substance abuse, (2) were published as clinical trials, either observational or controlled trials, (3) reported patient outcomes, and (4) were written in English. Studies were excluded if (1) their focus was to explore the pharmacogenomics of topiramate use, (2) they used topiramate as adjunctive therapy, or (3) they used topiramate as treatment for psychiatric disorders. Four investigators independently searched, reviewed, and extracted data from the studies for their quality, appropriateness, and description of methods and results. Based on consensus, one investigator compiled the final articles selected for this review. The outcomes of the review included (1) cessation or quit rates, (2) a decrease in positive use-days or craving intensity, or (3) duration or

frequency reduction compared with placebo or standard therapy. Data were reported in either quantitative data using descriptive statistics or qualitative data using narratives.

Results: After screening for titles and abstracts, 168 studies were retrieved and reviewed. Studies were excluded because they were not a clinical trial (n=109), focused on pharmacogenomics of topiramate or substance use (nequals8), used topiramate as adjunctive therapy (nequals4), and used topiramate to treat psychiatric disorders (nequals12). The remaining 35 articles comprised of 7 studies on cocaine, 15 on alcohol, 4 on methamphetamines, 3 on tobacco, and 6 on other substances. The studies reported objective measurements such as urine drug screenings, serum drug levels, and subjective measurements such as cognitive performance, withdrawal symptoms, or patient-reported abstinence, cravings (intensity, frequency, duration), and behavioral changes. Overall, topiramate was shown to (1) reduce craving duration (pequals0.018) and intensity (pequals0.012) in cocaine-dependent individuals, without affecting the frequency of abuse, (2) reduce the amount of cigarettes smoked (pless0.01) in alcoholic individuals, and (3) enhance nicotine withdrawal and reward in non-alcoholic individuals (pless0.01). Compared with placebo, topiramate-treated patients had 2.88 fewer drinks per day (pless0.01) and 27.6 percent fewer heavy drinking days (pless0.01). However, topiramate did not (1) increase abstinence from methamphetamine (pequals0.13) or cocaine (pequals0.23), (2) reduce cocaine use or cravings in alcoholic individuals (pgreater0.19), or (3) reduce alcohol use in cocaine users (pequals0.19).

Conclusion: Topiramate was effective in reducing the amount of drinks per day and heavy drinking days in alcoholic individuals, and reduced craving duration and intensity in cocaine-dependent individuals. It also enhanced nicotine withdrawal and reward in tobacco-dependent individuals. However, topiramate did not reduce the amount of methamphetamine or cocaine abuse. When an individual is dependent on more than one substance, topiramate was not effective in reducing substance use, with the exception of treating tobacco dependence in alcoholic individuals. More research is necessary for prescribing topiramate to treat SUD with methamphetamine, cocaine, or tobacco, and for finding effective therapeutic dosages for SUD.

Poster Title: Evaluation of pharmacist-driven dosing guidelines for Staphylococcus aureus bloodstream infections

Primary Author: Michelle Maddox, Wayne State University Eugene Applebaum College of Pharmacy and Health Sciences, Michigan; **Email:** mmaddox@wayne.edu

Additional Author (s):
Jessyca Mourani
Lauren Flynt
Rachel Kenney
Susan Davis

Purpose: Bacteremia caused by Staphylococcus aureus is a serious infection that is associated with high morbidity and mortality. Dose optimization of vancomycin by pharmacists using the recently updated Henry Ford Health System vancomycin dosing guidelines is essential in the successful treatment of patients presenting with Staphylococcus aureus bacteremia. This study was designed to evaluate the appropriate use and safety of these guidelines in patients with Staphylococcus aureus bacteremia at our health-system.

Methods: This retrospective chart review was IRB approved at Henry Ford Health System. Patients included were greater than or equal to 18 years of age, with a positive Staphylococcus aureus blood culture from April 2016 to August 2016, receiving vancomycin with a trough level drawn, and without pre-existing renal dysfunction. Upon initiation of vancomycin, a pharmacist will perform dosing and document in the medical record all the details used to calculate the initial dosing regimen. The primary endpoint was to identify whether an appropriate initial vancomycin regimen was selected and was assessed through a composite outcome of appropriate trough goal selected, accurate calculation of creatinine clearance, and consideration of a patient's individual history of vancomycin use. The secondary endpoints included safety of vancomycin use evaluated by incidence of nephrotoxicity and incidence of supratherapeutic and subtherapeutic troughs. The incidence of nephrotoxicity was defined as an increase in serum creatinine (SCr) by 0.5 mg/dL in 48 hours or by 50 percent from baseline. Descriptive statistics were utilized.

Results: Of the 130 patients who were screened, 30 patients met all inclusion criteria. Of those excluded, 33 were excluded due to inappropriate monitoring of first steady state trough level. Of the patients included, 21/30 (70 percent) were initiated on an appropriate vancomycin regimen. 22/30 (73 percent) had an appropriate selection of trough goal of 15-20 mcg/ml and 20/30 (66 percent) had an appropriate creatinine clearance calculation. Of the 12 patients with a history of vancomycin use within the last 2 years 10/12 (83 percent) had documentation and consideration of a patients' previous vancomycin use. 6/30 (20 percent) of patients experienced nephrotoxicity while on vancomycin therapy. Incidence of supratherapeutic troughs was 7/30 (23 percent) and subtherapeutic was 17/30 (56 percent).

Conclusion: Through this evaluation of appropriate use and safety we were able to identify areas of success and areas for improvement in our pharmacists' vancomycin dosing strategies. Areas of success included evaluation of prior vancomycin use and selection of appropriate trough goal. Areas identified for future education include timing of appropriate troughs and calculation of appropriate creatinine clearance with selection of appropriate weight.

Session-Board Number: 5b-230

Poster Title: Identifying key stakeholders and their roles in the implementation of a learning healthcare system

Primary Author: Edward Neuberger, University of Maryland School of Pharmacy, Maryland; **Email:** eneuberg@umaryland.edu

Additional Author (s):
Hillary Edwards
C. Daniel Mullins

Purpose: The current healthcare system is often criticized as riddled with inefficiencies. Information does not always flow completely through the translational stages between science, evidence, care, and ultimately, patient outcomes and quality of life. The continuously learning healthcare system (LHS) model integrates research and patient care to develop a positive feedback loop in which research both informs and relies on patient care. This project was designed to determine how to implement an innovative LHS model by identifying key stakeholders and their roles. This will provide a structure of outlined responsibilities for organizations that are ready to pursue a LHS.

Methods: A literature review of PubMed was performed to identify articles 1) elucidating specific stakeholders and their roles in LHS development or implementation, whether conceptual or in practice; and 2) identifying requirements for the development and implementation of learning healthcare systems.

Results: Key stakeholders include healthcare delivery organizations, clinicians, patients and families, patient advocacy organizations, health professional education programs, public and private insurers, health care product manufacturers, standards organizations, digital technology developers, research funding agencies, health economists, health service researchers, and governing boards of health care delivery organizations. Roles span the full spectrum of healthcare including adjusting payment models, capturing data at the point of care delivery, and reworking ethical and practical frameworks currently segregating research and clinical care.

Conclusion: Roles were identified for virtually all members involved in the patient care process, from research and education to the delivery of care. Great change is necessary in the culture and practice of data collection, sharing, and utilization. Key roles revolve around creating a digital infrastructure to harness and translate data, dedicating care toward patient-centricity, and providing incentives at all levels to reward value and improvement. Stakeholders must align goals to overcome barriers such as technical complexity, integrating research and clinical care, potential lack of patient-engagement, and funding.

Poster Title: Improving Communication about Medication HCAHPS Scores: A Collaboration of Pharmacists and Nurses on Patient Education at a Community Teaching Hospital

Primary Author: Vala Behbahani, Notre Dame of Maryland University School of Pharmacy, Maryland; **Email:** vbehbahani1@live.ndm.edu

Additional Author (s):
Rhiannon Marselli
William Charles
Andrea L'Heureux
Katelyn Smith Quartuccio

Purpose: The Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) is a standardized, nationwide survey that measures the quality of a patient's hospital stay. Administered to patients after discharge, HCAHPS scores have been increasingly used for the evaluation of patient experiences and healthcare reimbursement. At Sinai Hospital (Baltimore, MD), the "Communication about Medication" survey responses had been suboptimal despite multiple attempts to improve HCAHPS scores. The purpose of this study was to determine whether the implementation of a medication education protocol by nurses who have been trained by pharmacists improve medication-related HCAHPS scores in a community teaching hospital.

Methods: The institutional review board approved this prospective observational study, which consisted of two phases. In Phase 1, pharmacists trained nurses to provide medication education. All nurses on the Pulmonary/Infectious Disease Unit received group training and educational materials, including side effect information sheets for commonly administered medications. Day shift nurses subsequently received individual training by pharmacists. Night shift nurses were excluded from individual training due to pharmacist staffing limitations during these hours. Nurses completed a pre- and post-survey that assessed the outcome of the intervention on nursing perceptions and practice. In Phase 2, the sustainability of the intervention in Phase 1 was assessed by standardized patient interview and direct observation. Fifteen patients were randomly selected each week; data was collected for two, five-week blocks. Patients with altered mental status and/or those receiving mechanical ventilation were

excluded. Between the two blocks, a sign-off sheet that included nurse and patient signatures was introduced to improve accountability and adherence to the study protocol. The primary outcome measure compared HCAHPS medication communication responses prior to the intervention to HCAHPS responses at 3 months after the intervention. Secondary outcomes include the change in HCAHPS responses at 6, 9, and 12 months post-intervention, the results of nursing pre- and post-surveys, and patient responses to interview questions posed during Phase 2. All data was compared using descriptive statistics.

Results: Three months after the intervention, there was no change in HCAHPS medication communication responses compared to baseline (P equals 0.9345). Data for 6, 9, and 12 months post-intervention are pending. Twenty-three nurses completed the pre-survey and seventeen nurses completed the post-survey. Following the intervention, nurses reported a greater responsibility for providing medication education (median Likert 4 pre- vs. 5 post-, P equals 0.0383) and improved confidence with performing this task independently (median Likert 4 pre- vs. 5 post-, P equals 0.0284). Nurses also reported using the "teach-back method" more frequently to assess patient understanding about their medications (median Likert 3.5 pre- vs. 5 post-, P equals 0.0034). Nursing satisfaction with the medication education process at the hospital improved (median Likert 4 pre -vs. 5 post-, P equals 0.0009). The sign-off sheet increased the number of patients who reported learning about their medications from nurses (72% vs. 97.3%, P equals 0.0001). The sign-off sheet was also associated with the presence of more side effect information sheets in patient rooms (37.3% vs. 81.3%, P equals 0.0001) and an increase in the number of patients who reported learning about medication side effects (33.3% vs. 77.3%, P equals 0.0001).

Conclusion: The process of pharmacists training nurses to provide medication education did not significantly impact HCAHPS scores at 3 months post-intervention. However, there were favorable effects on nursing perception and practice as well as improvements in patient reports of education received. HCAHPS scores for 6, 9, and 12 months post-intervention are pending.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Poster Title: Evaluation of conversions between direct oral anticoagulants and subcutaneous anticoagulants in hospitalized patients

Primary Author: Ava-Dawn Hammond, University of Maryland, School of Pharmacy, Maryland; **Email:** ahammond@umaryland.edu

Additional Author (s):
Colby Miller
Mary Taylor

Purpose: The development of the new direct oral anticoagulants (DOACs) has expanded venous thromboembolism treatment and prophylaxis options. The addition of this new class has increased the opportunity for medication errors especially for patients transitioning through various levels of hospitalized care. Surgical procedures, medication failure, change in kidney function, change in patient preference or NPO status, or emergence of a new thrombus are all reasons for transitioning agents. Inappropriate medication administration times place a patient at increased risk of bleeding or clotting which may result in significant morbidity or mortality.

Methods: A retrospective analysis was conducted in patients converting between a DOAC (rivaroxaban, edoxaban, dabigatran, apixaban) and a subcutaneous anticoagulant (enoxaparin, heparin) on a single calendar day of hospitalization. These transitions occurred from January 2015 to July 2016 at Sinai Hospital and from January 2016 to June 2016 at Northwest Hospital. Basic data collection included medical service, medications, doses, month of conversion, type of conversion and number of days of medication overlap. The appropriateness of anticoagulant transition was assessed using a package insert recommendations. The conversion was considered in error if the patient was placed at increased risk of bleeding or clotting based on time of administration. For patients transitioned incorrectly, a degree of risk was assigned to the patient. The risk was classified as high risk (two active orders for 2 different anticoagulants given together), medium risk (incorrect overlap of two anticoagulants at full therapeutic doses), low risk (incorrect overlap of two anticoagulants at prophylactic doses) and clotting risk (lapse of any anticoagulation therapy for period of time during conversion). Patients on heparin drips, patients receiving fondaparinux or patients switching to warfarin were excluded from the study.

Results: Two hundred and four patients at Sinai Hospital and 40 patients at Northwest Hospital were converted between anticoagulants during the study period. All (n equals 36) of the patients at Northwest and 74 percent (n equals 150) of the patients at Sinai were on the medicine service. The most common anticoagulant transitions were between enoxaparin and apixaban at Sinai, and between enoxaparin and rivaroxaban at Northwest. Ninety patients (44 percent) were correctly and 114 patients (56 percent) were incorrectly converted between agents at Sinai Hospital. At Northwest, 15 patients (37.5 percent) were correctly converted and 25 patients (62.5 percent) were incorrectly converted between agents. Of the 114 incorrect conversions at Sinai, 42 patients (37 percent) were assigned to the high risk category, 7 patients (6 percent) to the medium risk category, 32 patients (28 percent) to the low risk category and 33 patients (29 percent) to the clotting risk category. At Northwest, 6 patients (24 percent) were assigned to the high risk category, 9 patients (36 percent) were assigned to the medium risk category, 6 patients (24 percent) were assigned to the low risk category and 4 patients (16 percent) were assigned to the clotting risk category.

Conclusion: Fifty to sixty-three percent of patients were placed at increased risk of bleeding or clotting when converting from one anticoagulant medication to another. The number of incorrect transitions continued to occur at the same frequency although educational interventions were deployed in the middle of the study period. Forty-eight patients were placed at high risk of bleeding. An action plan utilizing clinical decision support during anticoagulant ordering, verification and administration, anticoagulant education and standardizing anticoagulant medication administration times is in development. Education will be ongoing and a prospective audit will be conducted to assure safer anticoagulant transitions for our patients.

Submission Category: Cardiology/ Anticoagulation

Submission Type: Evaluative Study

Session-Board Number: 5b-233

Poster Title: Evaluation of quality and safety of anticoagulation services of a Veterans Affairs community living center

Primary Author: Elaine Pranski, University of Maryland School of Pharmacy, Maryland; **Email:** elaine.pranski@umaryland.edu

Additional Author (s):
Stephanie Callinan

Purpose: Management of warfarin therapy is complex due to its narrow therapeutic index and many drug-drug and drug-food interactions. The purpose of this study was to evaluate the efficacy and safety of warfarin treatment in an inpatient Veterans Affairs (VA) community living center in order to compare to other settings described in the literature. Additionally, this study was performed to identify methods to improve the outcomes rendered by the anticoagulation service at this facility.

Methods: This retrospective investigation was deemed to be exempt from IRB approval and that informed consent was unnecessary. Subjects were included if they had documented BCMA administration of warfarin between May 1, 2015 and January 31, 2016 at the VA Loch Raven community living center. International normalized ratio (INR) was measured by blood draw or portable INR monitoring device. The interval between INR values for all subjects did not exceed fifty-six days.
For medication efficacy, three main measures were used: percentage of INR readings within range, percentage of time in therapeutic range (TTR), and INR variability. Therapeutic range was determined from the patient's medical record. TTR was used to extrapolate the number of days within range using the Rosendaal method. The percentage of days with an INR value within therapeutic range was calculated. INR variability was assessed by calculating the average INR reading and its associated standard deviation. Subjects were subdivided into three groups for both percentage of INR readings within range and TTR as follows: poor control was under 60 percent, good control was between 60 and 75 percent, and excellent control was over 75 percent.
Documented cases of venous thrombus embolism (VTE) (which was used to encompass thromboembolic events such as stroke, systemic embolus, and VTE), bleeding (major and minor

hemorrhage), and anticoagulation-related hospitalizations in patient's medical records were used to assess medication safety.

Results: Similarities were observed between different efficacy measures of warfarin. 43 percent of INRs and 53 percent of days were within therapeutic range. The majority of patients were deemed poor responders according to both INR reading and TTR. There was a positive correlation between percentage of INR readings within range and percentage of days within range (R2 equals 0.67). Nursing home and rehab patients had similar efficacy results, as well as different age groups. Interestingly, patients on warfarin with indications for anticoagulation of atrial fibrillation or atrial flutter seemed to become less efficacious over the observed time frame, while prophylaxis for DVT and pulmonary embolism became more efficacious in the same time frame.

Most of the subjects did not have any safety event occurrences. The majority of safety events were related to bleeding. There were no VTE events or anticoagulation-related hospitalizations. Bleeding events did not correlate with the degree of control. Occurrence of safety events was not correlated to anticoagulation indication. More bleeding events occurred in nursing home patients rather than rehab patients. A larger amount of safety events occurred during warfarin therapy between May 1, 2015 and July 31, 2015 when compared to the other three month time periods.

Conclusion: Warfarin, a narrow therapeutic window drug, has complex associated management that can lead to great harm with both excessive and insufficient anticoagulation. The TTR found in this study was within the range observed in the VA healthcare system but was below the level associated with beneficial outcomes. However, minimal numbers of safety events were observed but this may be due to the low number of subjects. Strategies that could be implemented to achieve a higher TTR include decreasing time to next INR reading, identification of therapy barriers, and use of an algorithm to manage sub- and supra-therapeutic INR values.

Poster Title: Analyzing oncology product medication waste in a regional medical center

Primary Author: Megan Cox, University of Maryland Eastern Shore School of Pharmacy, Maryland; **Email:** macox@umes.edu

Purpose: Reducing specialty drug product waste is a top priority for institutional pharmacy departments. This project was designed to estimate the amount of oncology product waste saved by the use of the Gri-Fill 3.0 (Grifols, SA) system and implementing protocol-driven dose rounding system. Specifically, overall pharmacy drug costs pre- and post-implementation, adjusted for patient volume, were recorded along with breakdowns by specific chemotherapeutic agent.

Methods: The Gri-Fill 3.0 system uses a 0.22-micron filter to sterilize medication waste and extend their shelf life. The pharmacy department recorded weekly data for drugs that were saved through the Gri-Fill 3.0 system. The product volumes saved per week were calculated into cost savings. The pharmacy department also developed dose-rounding protocols in which practitioners round to the nearest vial size to eliminate waste completely or decrease waste from partial vials as much as possible. Data was collected from the partial vial waste log and was analyzed to see if there was a correlation between the start of the dose-rounding protocols and a decrease in waste.

Results: From July 2015 to August 2016 the Gri-Fill 3.0 system saved a total cost of $77,055.36. Due to implementing dose-rounding protocols on chemotherapeutic agents and other expensive products, three drug products decreased to zero waste, three drug products continue to decrease in waste, and three drug products are fluctuating but have decreased from January 2014.

Conclusion: Oncology product medication waste can be decreased in a regional medical center by using the Gri-Fill 3.0 system and implementing dose-rounding protocols.

Submission Category: Critical Care

Submission Type: Evaluative Study

Poster Title: Evaluating the appropriateness of stress ulcer prophylaxis in the adult intensive care unit at a community teaching hospital

Primary Author: Elissa Lechtenstein, University of Maryland School of Pharmacy, Maryland; **Email:** elechtenstein@umaryland.edu

Additional Author (s):
Pan Pan Wong

Purpose: Stress ulcer prophylaxis (SUP) is commonly administered to critically ill patients for the prevention of stress-related mucosal bleeding and clinically important gastrointestinal bleeding. However, SUP is often over utilized in the intensive care unit (ICU). The decision to initiate and continue acid suppressive therapy should be carefully considered as it has been associated with Clostridium difficile infection and hospital-acquired pneumonia. The purpose of this study is to evaluate the appropriateness of stress ulcer prophylaxis in the adult intensive care unit (ICU) at Prince George's Hospital Center.

Methods: This single center, retrospective observational study was exempt from review by the institutional review board as it was considered as a quality improvement project. Patients were identified using the pharmacy dispensing database. Patients aged 18 and older who were admitted to the ICU between May 1, 2016 and June 30, 2016, and had at least one SUP medication were included in this study. Patients with an active upper gastrointestinal bleed, active peptic ulcer disease, or receiving dual antiplatelet therapy or concurrent antiplatelet/anticoagulation therapy were excluded. Patients with acid suppressive therapy on medication reconciliation were also excluded. The primary objective of this study was to evaluate the frequency of the appropriate indication for SUP. The secondary objectives were to identify the proportion of appropriate SUP discontinuation when the risk factor resolved and upon transfer out of the ICU. Appropriateness of SUP was assessed based on the 1999 American Society of Health‑System Pharmacists Therapeutic Guidelines on Stress Ulcer Prophylaxis.

Results: Of the 183 patients initially reviewed, 105 patients were included in this study. The majority of patients were excluded due to having an antiplatelet/anticoagulant, dual anticoagulants, or acid suppressive therapy prior to admission. SUP was indicated in 78 percent (82 of 105) of patients. Mechanical ventilation for more than 48 hours was the most common indication for SUP (48 percent of patients). When the initial risk factor requiring SUP had resolved, only 10 percent (10 of 105) of patients were appropriately discontinued. Additionally, upon transfer out of the ICU, SUP was appropriately discontinued in only 14 percent (15 of 105) of patients.

Conclusion: Stress ulcer prophylaxis is over utilized in the adult intensive care unit of Prince George's Hospital Center. While the majority of SUP indications were appropriate, a significant proportion of SUP was inappropriately continued in patients when the initial risk factor resolved and upon transfer out of the ICU. Both an institutional guideline and physician education need to be implemented in order to reduce inappropriate use of SUP.

Submission Category: General Clinical Practice

Submission Type: Descriptive Report

Poster Title: Let's talk about it. Can palliative care clinical pharmacists impact family satisfaction by attending goals of care conversations?

Primary Author: Ashley Fan, The University of Maryland School of Pharmacy, Maryland; **Email:** ashley.fan@umaryland.edu

Additional Author (s):
Joshua Fabie
Kathryn Walker

Purpose: A palliative care clinical pharmacist is known as a valuable team member in managing symptoms but is not always recognized for their role in supporting goals of care discussions. Many goals of care conversations include breaking bad news about the lack of effective treatment options, discussing transitions in care involving significant medication changes, strategizing the risks and benefits of further treatments, and the options for symptom management. The objective of this study was to compare families' satisfaction with communication after a palliative team goals of care meeting with and without a trained palliative care clinical pharmacist.

Methods: After approval from our Institutional Review Board, a convenience sample of 28 patients receiving an initial palliative care family meeting at MedStar Union Memorial Hospital between June 23- July 24, 2015 were approached for inclusion in this study. Families consenting to participate were surveyed using an electronic tablet after the goals of care meeting regarding their satisfaction of communication, listening, trust, meeting needs, explaining or understanding, and courtesy or respect. Clinicians involved in the meeting were also surveyed to record perceptions of family and topics discussed during the meeting. No more than 5 family members and 5 clinicians were asked to complete the survey per meeting. Responses were rated via a Likert scale and a net promoter scores (NPS, range negative 100 to positive 100) was calculated to use in comparisons between groups. Data was analyzed using descriptive statistics.

Results: Twenty-eight families with fifty-eight representatives (n=58 respondents) participated this study. Most were the patient's primary spokesperson (58 percent). The most common topics discussed in the goals of care meetings were prognosis and overall goals of care. In the meetings with a clinical pharmacist involved, pain and symptom management was discussed more often than in meetings without a clinical pharmacist (88 percent vs 30 percent). The goals of care meetings with pharmacists showed improvement in family satisfaction in the following areas: trust (delta 35), listening (delta 17), explaining or understanding (delta 13), met needs (delta 13), and courtesy or respect (delta 3).

Conclusion: Families reported high levels of satisfaction in goals of care meetings with palliative care clinical pharmacists present. Areas of greatest impact included trust, listening, explaining/understanding and meeting families' needs. Courtesy and respect were high in both groups. Future research should further describe the role of clinical pharmacists in participating in family meetings and the impact of care.

Submission Category: Leadership

Submission Type: Evaluative Study

Session-Board Number: 5b-237

Poster Title: Evaluating the availability of leadership positions at different PharmD programs with main and satellite campuses.

Primary Author: Ha Phan, University of Maryland, Baltimore, Maryland; **Email:** ha.phan@umaryland.edu

Additional Author (s):
Kacie Whitty
Patrick Rocafort
Lisa Lebovitz
Jill Morgan

Purpose: To compare the leadership opportunities that are accessible for PharmD students at the main and satellite campuses.

Methods: Schools listed on the ACPE website with branch campuses were classified into two general models: "sequential" where all PharmD students start on the main campus and finish at a branch campus, and "mothership/ satellite" where one large cohort and smaller cohort(s) complete their entire education at their assigned campus. School websites were used to determine the number of student organizations. Descriptive statistics was used to analyze the results.

Results: There are 33 schools of pharmacies that have at least one branch campus [24 have one branch campus, 5 have two branch campuses, 4 have three branch campuses]. Of these, 22 (69%) use the "mothership/satellite" model. There are slightly more opportunities for student involvement in pharmacy student organizations at main campuses: average of 11.5 student organizations (range 6-20) at main campuses, average of 10.7 student organizations (range 4-19) at branch campuses. Despite having similar opportunities, anecdotal feedback was that satellite students are less active in organizations.

Conclusion: ACPE mandates that schools with branch campuses provide comparable educational and extracurricular opportunities, and leadership experiences are emphasized for

well-rounded residency applicants. Schools should encourage satellite students to take advantage of leadership opportunities as part of career preparation.

Session-Board Number: 5b-238

Poster Title: Evaluation of medication use among inpatients discharged to home hospice: Potential for deprescribing?

Primary Author: Kevin Lei, University of Maryland, Baltimore - School of Pharmacy, Maryland;
Email: kevin.lei@umaryland.edu

Additional Author (s):
Angeo Rey Belen
Nina Bemben

Purpose: As goals of care change, therapies should be evaluated to ensure they are consistent with patient preferences and appropriate given the patient's clinical status. While medications used to manage chronic diseases have potential benefits of slowing disease progression, at some point the burdens of therapy may outweigh these potential benefits. Deprescribing is a process of stopping medication therapy whose potential harms outweigh potential benefits. The purpose of this study is to determine whether patients discharged from the University of Maryland Medical Center to home hospice care are receiving medications that could potentially be deprescribed.

Methods: A retrospective chart review was performed for inpatients discharged from the University of Maryland Medical Center to home hospice care between 7/1/2015 and 12/31/2015. A list of medications that can potentially be deprescribed was developed based on a review of current literature related to deprescribing. Patient medical records were screened for the medications on this list. Medications classified as those that could potentially be deprescribed included: aspirin, histamine blockers, pentoxifylline, proton pump inhibitors, statins, metformin, sulfonylureas, angiotensin converting enzyme (ACE) inhibitors, alpha blockers, angiotensin receptor blockers, beta blockers, calcium channel blockers, diuretics, and nitrates. The frequency of patients being discharged on IV fluids, supplements, and vitamins were also documented.

Results: A total of 23 patients discharged to home hospice between 7/1/2015 and 12/15/2015 were included. The frequency of patients discharged to home hospice on aspirin, proton pump inhibitors, statins, and sulfonylureas were 4 (17.4 percent), 4 (17.4 percent), 5 (21.7 percent)

and 2 (8.7 percent), respectively. No patients were discharged on metformin. Histamine blockers were prescribed to 2 patients (8.7 percent) and pentoxifylline was prescribed to 1 patient (4.3 percent). The number of patients being discharged on angiotensin converting enzyme (ACE) inhibitors, alpha blockers, angiotensin receptor blockers, calcium channel blockers, diuretics, and nitrates was 2 (8.7 percent), 1 (4.3 percent), 2 (8.7 percent), 4 (17.4 percent), 5 (21.7 percent), and 2 (8.7 percent) times, respectively. In addition, 11 patients (47.8 percent) were discharged to home hospice on beta blockers (with one patient receiving 2 beta blockers). Five patients (21.7 percent) were discharged with zero potentially-deprescribable medications.

Conclusion: Despite the growing body of literature regarding deprescribing, a significant amount of patients (78.3 percent) are discharged to home hospice on medications that may have little benefit and may have increased burden. Individual clinical judgment plays a role in which medications are deprescribed; however, these results suggest a need for more education of healthcare providers to improve medication use at the end of life.

Submission Type: Evaluative Study

Session-Board Number: 5b-239

Poster Title: Evaluation of inpatient medication use and its potential in increasing fall risk

Primary Author: Stephanie Huang, University of Maryland Baltimore School of Pharmacy, Maryland; **Email:** shuang@umaryland.edu

Purpose: Falls can result in serious injury such as fractures, broken bones, head injuries, and even death. It is particularly important to assess fall risk in the hospital setting as the patient is in a more fragile state. Fall risk is based on factors such as age, history of falls, medications, and chronic conditions. Medications may increase fall risk through side effects like dizziness. The purpose of this study is to determine which medication classes may contribute to an increased risk of fall in a patient within 24 hours of use.

Methods: This study is a descriptive, retrospective chart review of quarterly documented falls in patients admitted to inpatient unit from July 2015 to March 2016 within a small community hospital. Documented falls were reported in the following intervals: July to September 2015, October to December 2015, and January to March 2016. The AGS Updated Beers Criteria for Potentially Inappropriate Medication Use in Older Adults was used to help target medications that increase patients' fall risk. Although the AGS Beers Criteria is focused on older adults, the resource is generally still applicable to patients of all ages. Data collection included the medication name, dose, and time and frequency of administration within the 24-hour period following medication administration. Patients were admitted if they were admitted to the inpatient unit and had a documented fall after the use of a medication under the AGS Beers Criteria. Patients were excluded if they were seen in outpatient clinics, had documented falls that followed the use of medications not under the AGS Beers Criteria, or had documented falls with no medication-related cause.

Results: From July to September 2015, there were 50 medication-related falls. The medication administration frequencies showed the following: opioids 27.85%, benzodiazepines 24.05%, cardiovascular agents 17.72%, antihistamines 16.46%, antipsychotics 6.33%, and nonbenzodiazepine hypnotics 2.53%
From October to December 2015, there were 20 medication-related falls. The medication administration frequencies showed the following: opioids 26.32%, cardiovascular agents

21.05%, benzodiazepines and antihistamines 15.79%, antipsychotics 13.16%, and nonbenzodiazepine hypnotics 5.26%.

From January to March 2016, there were 22 medication-related falls. Of these falls, cardiovascular agents had the highest administration frequency of 29.03%. Benzodiazepines were 19.35%, opioids were 16.13%, antipsychotics and antihistamines were 12.90%, and antidepressants were 9.68%.

The overall results from July 2015 to March 2016 showed a total of 92 medication-related falls with the following medication administration frequencies: opioids 25%, benzodiazepines and cardiovascular agents 20.95%, antihistamines 15.54%, antipsychotics 9.46%, antidepressants 6.08%, and nonbenzodiazepine hypnotics 2.03%. Over time, there was a decreasing trend in the use of opioids and an increasing trend in the use of cardiovascular agents. With regards to the cardiovascular agents, it was noted that the falls were possibly linked to a dose increase.

Conclusion: Analysis of chart reviews from July 2015 to March 2016 showed that 2/3 of the documented falls occurred after the administration of medications from 3 main drug classes: opioids, benzodiazepines, and cardiovascular agents. These results suggest that use of opioid, benzodiazepine, or cardiovascular agents are associated with increased risk of falls. Based on this analysis, it is recommended that a medication evaluation component, focusing on the aforementioned drug classes, be incorporated into the current fall risk scoring tool to help reduce the patients' fall risk.

Submission Category: Infectious Diseases

Submission Type: Evaluative Study

Session-Board Number: 5b-240

Poster Title: Real life medication adherence with newer hepatitis C treatments and their effect on sustained virologic response (SVR)

Primary Author: Farrah Tavakoli, University of Maryland School of Pharmacy, Maryland; **Email:** ftavakoli@umaryland.edu

Additional Author (s):
Joey Mattingly
Neha Sheth Pandit

Purpose: It is known that older hepatitis C virus (HCV) regimens including interferon and ribavirin required greater than 80% adherence in order to achieve 50-70% cure rates. Newer HCV treatments such as ledipasvir/sofosbuvir (LDV/SOF) and paritaprevir/ritonavir/ombitasvir plus dasabuvir (PrOD) have shown sustained virologic response rates at 12 months after treatment cessation (SVR12) of about 95%. What is unknown is the amount of adherence needed for newer HCV therapies to achieve optimal outcomes such as SVR12. This study aims to assess real-life adherence rates to newer HCV regimens to determine its effect on patient's ability to achieve SVR12.

Methods: The institutional review board approved this observational study. Patients were identified by having either LDV/SOF or PrOD filled by the University of Maryland Medical System Pharmacy between October 2014 and September 2015. Patients were excluded if they did not have any HCV viral load results, if they did not begin and complete their therapy between the dates above and if their charts did not state their exact start and stop date of the medication. Medication refill data was provided by the pharmacy. Adherence rates were calculated based on the start and stop date of the medication states in the medical chart and the number of refills provided by the pharmacy. The primary outcome was to assess real-life adherence rates to newer HCV treatment. The secondary outcome was to assess how adherence rates effect achievement of SVR12.

Results: One hundred and two patients met the inclusion criteria with 95 having been prescribed LDV/SOF and 7 prescribed PrOD. The overall mean adherence rate was 92%, with 94% adherence for LDV/SOF and 86% for PrOD. Seventy-nine patients achieved an SVR12 with 73 in the LDV/SOF group and 6 in the PrOD group. Twenty patients in the LDV/SOF group could not be assessed for SVR12 because they did not have a viral load drawn. Twelve patients had adherence rates of less than 80%. Of those, fifty-eight percent achieved SVR12 and only 1 did not. The other 4 patients did not have a viral load drawn to assess SVR12.

Conclusion: New HCV treatments such as LDV/SOF and PrOD show SVR12 rates of 77% with real-life adherence. This study found that real-life adherence is greater than 85% with LDV/SOF and PrOD. Even in cases with low adherence of less than 80%, high rates of SVR12 are still seen. Use of the newer HCV medications requires the patient to have a viral load level drawn 12 weeks after the end of therapy, an area that data was missing. The clinical significance of these effects must be determined in larger clinical trials.

Poster Title: Why are specialty pharmaceuticals so special?

Primary Author: Alexander Joachim, University of Maryland School of Pharmacy, Maryland;
Email: alex.joachim@umaryland.edu

Additional Author (s):
Judith Kim
Kathryn Vranek
Todd Mattingly

Purpose: Specialty pharmacy has experienced rapid growth compared to traditional drug utilization in 2015. Despite significant growth there is no industry consensus on the definition of specialty drugs. Pharmacy benefit managers use certain characteristics in their definitions, including: special handling and administration requirements or intensive clinical monitoring, intensive patient training, limited distribution, cost, and biologics as a whole. The purpose of this study was to compare prescriptions dispensed from a closed door mail-order specialty pharmacy and traditional community pharmacy based on financial and operational characteristics.

Methods: A retrospective cross-sectional study was conducted by collecting dispensing records from a community pharmacy and closed door mail-order specialty pharmacy owned by the same academic medical center from May 1, 2016 – May 31, 2016. Variables collected included total revenue, total prescriptions dispensed, National Drug Code (NDC), day supply, therapeutic category, and dosage form. Projected margins were calculated as a percentage of revenue per prescription using various estimated gross margin percentages. Prescriptions were identified as specialty if revenue per 30-day supply met the Centers for Medicare and Medicaid Services' Specialty Tier criteria of greater than 600 dollars per 30-day supply. Prescriptions were categorized as requiring Risk Evaluation and Mitigation Strategies by their inclusion in the United States Federal Drug Administration's Approved Risk Evaluation and Mitigation Strategies (REMS) website. Statistical analysis was done in SAS Version 9.4 (Cary, NC) to determine differences by pharmacy type. Continuous variables were assessed using Student t-tests and categorical variables were assessed using Chi-Square.

Results: A total of 4,808 and 5,583 prescriptions were identified at the community and specialty pharmacies, respectively, for total revenues of 1,596,977 and 4,181,550 dollars. Mean revenues per prescription were 332 dollars (SD 1915) and 749 dollars (SD 3,277), (p-value less than 0.0001). Specialty pharmacy median revenues per prescription were approximately three fold greater, 42 vs 13 dollars. Projected margins at 10, 15, and 20 percent between the community and specialty pharmacies were 159,698 and 418,155 dollars (p-value less than 0.0001), 239,547 dollars and 627,233 dollars (p-value less than 0.0001), and 319,395 and 836,310 dollars (p-value less than 0.0001) respectively. The community pharmacy filled a greater percentage of prescriptions requiring REMS (4.8 vs 3.62 percent, p-value of 0.0035). There was no difference in proportion of dosage forms other than oral tablets or capsules between the types of pharmacy (p-value of 0.18). The specialty pharmacy had a greater number of prescriptions that met the CMS' Specialty Tier criteria of greater than 600 dollars per 30-day supply, 1026 (18 percent) vs 528 (11 percent), (p-value less than 0.0001).

Conclusion: Dispensing specialty pharmaceuticals significantly increases overall revenue, revenue per prescription and median revenue. Mean revenues and median revenues per prescription were approximately 2.25 and 3 times greater at the specialty pharmacy. Additionally, the specialty pharmacy filled only 775 more prescriptions yet its' revenue exceeded the retail pharmacy's by 2.5 million dollars. The difference in the revenue can be accounted for by the 7 percent increase in the number of prescriptions meeting the specialty by cost criteria filled by the specialty pharmacy.

Poster Title: Probiotic protocol utilization in an inpatient geriatrics unit

Primary Author: Hanna Fenta, Notre Dame of Maryland University, Maryland; **Email:** hfenta1@live.ndm.edu

Additional Author (s):
Monique Mounce

Purpose: Clostridium difficile (C. difficile) is an infection resulting in severe diarrhea commonly associated with antibiotic use in healthcare facilities. Hospital acquired C. difficile can increase length of stay and healthcare costs. Recently, data has shown decreases in C. difficile associated diarrhea in patients using antibiotics and probiotics concomitantly. Anne Arundel Medical Center has incorporated a protocol in which pharmacists initiate probiotics in patients indicated for antibiotic use greater than 48 hours. The purpose of this study is to evaluate the use of probiotics initiated by the pharmacy probiotic protocol and investigate the continued use of probiotics at discharge.

Methods: This study is a retrospective observational study of patients that were given lactobacillus acidophilus probiotics (administered three times a day) during an inpatient stay at Anne Arundel Medical Center as a part of the Pharmacy Protocol: Probiotics Ordering in Select Adult Patients Receiving Antibiotics. This pharmacy protocol facilitates provision of probiotics to certain adult inpatients on systemic antibiotics in order to reduce the incidence of C. difficile. To evaluate the use of the probiotic protocol, medication charge data during August 1st to 31st, 2016 was utilized to identify patients exposed to probiotics, and the electronic health record was examined for patient demographics and outcomes with the use of probiotics. Specifically, the probiotic use in patients from the geriatrics unit was analyzed and descriptive statistics were employed.

Results: There were 7,500 doses of probiotics administered to 874 patients during the month of August 2016. Ninety-two patients were admitted to the acute care/elderly unit. Only 15 (16 percent) patients had probiotics initiated by the pharmacy protocol. The average age was 78 years, 50 percent male, and 1 (0.067 percent) patient had a previous C. difficile infection. Among the 15 patients, 7 (47 percent) patients were discharged on antibiotics but 4 (27

percent) were also discharged on probiotics, both with the set end dates. Two patients (0.13 percent) experienced diarrhea after antibiotic initiation and all the patients tested for C. difficile were negative. The remaining 73 patients received probiotics that were initiated by the prescriber or automatically initiated via infection order sets which included both antibiotics and probiotics.

Conclusion: This preliminary study shows the importance of probiotic use in patients receiving antibiotics. Of the patients in this data set, all were negative for the development of C. difficile. In addition, 27 percent of patients were discharged on probiotics however all were also discharged on antibiotics. It is unknown whether the probiotics were stopped once the antibiotic treatment was completed. Since probiotics are available over the counter, discharge on probiotics unnecessarily can result in improper administration and avoidable costs. Further studies are needed to evaluate the proper use and discontinuation of probiotics after discharge and its effects on medication costs.

Submission Type: Evaluative Study

Session-Board Number: 5b-243

Poster Title: Bioanalytical approaches to determine the variability in physiochemical properties and stability between brand and generic colloidal iron products

Primary Author: Sameh Abdelmalak, University of Maryland,School of Pharmacy, Maryland;
Email: sameh.abdelmalak@umaryland.edu

Additional Author (s):
Sarah Michel
Heather Neu

Purpose: Recent studies have questioned the equivalency between brand and generic iron colloidal complexes. Iron nanoparticles are known to have a large variation in particle size that may attribute to the assembly of the ferric iron core and the type of carbohydrate used in the core. If the physiochemical properties of Nulecit differ from those of Ferrlecit, there will be cellular consequences such as iron uptake and iron related toxicity. A more detailed investigation is warranted to ensure the comparability of the physiochemical properties between all generic and brand iron products.

Methods: The assembled research team will collect marketed brand and generic sodium ferric gluconate products and compare them in terms of potency, impurity, and other drug product quality attributes. Molecular weight and stability of each drug will be determined using high performance gel permeation chromatography method (HP-GPC), dynamic light scattering (DLS), colloid osmomerty, inductive coupled ray powder diffraction (XPD) and atomic force microscopy (AFM). The core components of iron will be characterized using various methods such as inductively coupled plasma mass spectrometry (ICP-MS) and UV-visible spectroscopy. ICP-MS high sensitivity will enable one to measure the periodic table of transition metal ions (including iron) at ng/l concentrations. Secondly, the team will develop bio-analytical methods to determine plasma iron components such as labile iron, non-transferrin bound iron (NTBI), total iron (TI) and transferring bound iron (TBI).

Results: The primary outcome tested was the assessment of non-inferiority of the generic colloid product against the reference colloid product with respect to non-transferrin bound iron (NTBI). NTBI can be measured using various methods including a chelation-ultrafiltration-

detection approach that uses nitrilotriacetate to chelate with iron. The chelated NTBI can then be detected by colorimetry or high performance liquid chromatography. NTBI can also be measured using bleomycin that forms a complex with DNA and a redox active ferrous iron. The secondary outcomes include the comparison of generic colloid product against the reference colloid product with respect to TI and TBI by employing novel analysis methods. TBI requires a separation and exclusion from free iron and drug-derived iron. It can then be separated through a Spectrophotometric analysis and later quantified through colorimetric procedures.

Conclusion: Many novel methods have been proven reproducible in comparing the plasma iron components such as labile iron, non-transferrin bound iron, total iron and transferring bound iron. Further research is necessary to develop more robust methods to successfully compare colloidal complexes and other nanoparticles.

Poster Title: Patient characteristics and post epinephrine management of anaphylaxis when treating allergic reactions according to a statewide school based emergency treatment protocol

Primary Author: Emily Powell, University of Maryland School of Pharmacy, Maryland; **Email:** e.powell@umaryland.edu

Additional Author (s):
Mary Beth Bollinger
Cheryl DePinto
Alicia Mezu
Mona Tsoukleris

Purpose: Anaphylaxis is a life-threatening allergic reaction requiring immediate recognition and management. Although rare, anaphylactic fatalities worldwide have been associated with medical care gaps. Further emergency medical care is required to monitor for delayed reactions and side effects following epinephrine administration. In 2012, Maryland passed legislation mandating that schools stock epinephrine and follow an anaphylaxis treatment protocol that includes transport to the Emergency Department (ED) post epinephrine administration. Our objective was to determine differences between patients transported to EDs following epinephrine administration versus those who were not transported per the protocol.

Methods: Data were obtained from reports of epinephrine administration submitted from schools throughout Maryland over four academic years (2012 - 2016). Data included demographics, patient and reaction characteristics and transportation to a medical facility. Patient and reaction data included presenting symptoms, outcomes, history of allergies, time of onset and treatment. Form data was entered into an Access database. Highly skewed continuous data were reported as mean plus/minus interquartile range (IQR) and analyzed using Wilcoxon rank-sum test. Normally distributed continuous data were analyzed using Student's t-test. Categorical data were analyzed using Chi-Square or Fisher's exact test. Significance was set at p less than 0.05.

Results: Of 799 epinephrine administration reports, 759 (95 percent) were for students. Median sample age was 12 (plus/minus 6) years. Patients experienced median 4 (plus/minus 3) symptoms of anaphylaxis, including respiratory, gastrointestinal, cardiovascular, skin or other anaphylaxis symptoms (range: 0-19).

ED transport post epinephrine was not completed per protocol in 74 (9.3 percent) patients. The most common reasons included parent refusal (78.6 percent) and EMS recommendation after assessment post-treatment (16.1 percent). Transported patients had more symptoms (p equals 0.0016), but did not differ in age (p equals 0.1091), gender (p equals 0.4569), race (p equals 0.6054) or Latino ethnicity (p equals 0.1304). Physiologic characteristics of diastolic blood pressure (p equals 0.8806), systolic blood pressure (p equals 0.9694), respiration (p equals 0.1091) or pulse (p equals 0.5256), did not differ by group.

No between-group differences in documented allergy history (p equals 0.1292), having healthcare provider emergency action plan (p equals 0.8085), asthma history (p equals 0.9709), anaphylaxis history (p equals 0.4266) or prior epinephrine use (p equals 0.4273) were detected. Of patients transported, 36.7 percent had an epinephrine order versus 63.3 percent with no healthcare provider epinephrine order (p equals 0.0274).

Conclusion: There were no statistically significant differences in demographics between patients transported to EDs post epinephrine administration versus those not transported. Although physiologic characteristics did not differ between groups, the number of patient symptoms was statistically significant. Caregiver and healthcare provider education regarding post epinephrine treatment is an important component of anaphylaxis management. A limitation of this study is that our analysis only uses information that is available on the submitted anaphylaxis report form. Additional analysis is required to confirm patients receiving epinephrine had true anaphylactic reactions.

Poster Title: Effects of glucagon-like peptide-1 receptor agonists in patients with type 2 diabetes mellitus at the Veterans Affairs Maryland Health Care System

Primary Author: Joshua Chou, University of Maryland School of Pharmacy, Maryland; **Email:** joshua.chou@umaryland.edu

Additional Author (s):
Amy Chung
Sarah Pierce

Purpose: Glucagon-like peptide-1 (GLP-1) receptor agonists are a newer class of medications that are increasingly being utilized for diabetes management, as they are associated with weight loss and low hypoglycemia risk. At the Veterans Affairs Maryland Health Care System (VAMHCS), they are classified as non-formulary, with exenatide being a preferred non-formulary agent within the class. Literature evaluating the efficacy of GLP-1 receptor agonists within the Veteran population is limited. The purpose of this study is to describe the effects of exenatide on diabetes control, weight, and blood pressure in patients with Type 2 Diabetes Mellitus at the VAMHCS.

Methods: This descriptive, retrospective study has been approved by the University of Maryland Institutional Review Board and the VAMHCS Research and Development Committee. Data was collected from electronic medical records for patients who had a diagnosis of type 2 diabetes mellitus and an index prescription for exenatide between April 1, 2005 and September 1, 2015. Patients were excluded from the study if they had a diagnosis of type 1 diabetes, initiated insulin therapy or other diabetes medications during the study period, initiated or discontinued use of medications that cause clinically significant changes in weight and/or glycemic control during the study period, discontinued exenatide during the study period, or had a history of bariatric surgery. The primary outcome measure was the change in A1c from baseline after 3 and 6 months of treatment. Secondary outcomes included changes in weight, body mass index (BMI), and blood pressure from baseline after 3 and 6 months of treatment. Descriptive statistics, t-test, and chi-square analysis were performed in Microsoft Excel 2010 to analyze collected data.

Results: The medical record review identified 41 patients meeting criteria for selection. The mean change in A1c from baseline at 3 and 6 months was -0.82±1.18% (p= < 0.05) and -0.52±1.67% (p>0.05), respectively. The mean change in weight from baseline at 3 and 6 months was -6.98±7.69 lbs (p= < 0.05) and -7.02±10.74 lbs (p= < 0.05), respectively. The mean change in BMI from baseline at 3 and 6 months was -1.01±1.25 (p= < 0.05) and -1.03±1.51 (p= < 0.05), respectively. Finally, at 3 and 6 months from baseline, the mean change in systolic blood pressure was 1±15 mmHg (p>0.05) and 2±18 mmHg (p>0.05), respectively. On the other hand, at 3 and 6 months from baseline, the mean change in diastolic blood pressure was 4±10 mmHg (p= < 0.05) and 3±9 mmHg (p>0.05), respectively.

Conclusion: Use of exenatide in patients at the VAMHCS resulted in statistically significant decreases in A1c at 3 months, weight at 3 and 6 months, and BMI at 3 and 6 months. As there was no statistically significant change in glycemic control observed at 6 months, this patient population may benefit from continued interventions to improve adherence and optimization of their diabetes regimen after initiation of exenatide.

Poster Title: Driving practice changes by utilizing quantitative analysis of available Health-System pharmacy data

Primary Author: Patrick Mensah, University of Maryland School of Pharmacy, Maryland; **Email:** pmensah@umaryland.edu

Additional Author (s):
Justin Penzenstadler
Kikelola Gbadamosi

Purpose: The explosion in the availability of "big data" has created a unique opportunity for the administrative pharmacist. Pharmacy data can be methodologically gathered and analyzed to drive administrative practice decisions, which could improve outcomes or reduce cost. Two specific use-cases where acquisition, physician ordering, compounding, and dispensing electronic medical record data are presented to show how data can be used to elucidate problems and provide a solution.

Methods: Using Microsoft Excel and the "R" programming language, several sources of data were analyzed, and visualized, including de-identified electronic health records (EHR) from Holy Cross Hospital, a 443 bed hospital. A medication "dashboard" was built to reproducibly visualize spending trends and identify cost-saving targets. Based on the results, intravenous immunoglobulin (IVIG) and epoetin were identified as drugs of interest and were further investigated using these sources of raw data, including Dose-Edge, Quality Compass, Clarity, and Cerner. Potential cost savings by switching from an actual body weight (ABW) to ideal body weight (IBW) dosing approach for IVIG were evaluated. Utilizing dispensing data and the National Health and Nutrition Examination Survey (NHANES) demographic dataset, artificial patients and administration intervals were generated which reflect settings similar to our hospital. Cost savings over time were simulated using Monte-Carlo methods. For both dosing regimens, 95, 50 and 5 percent utilization intervals were generated non-parametrically and compared. Several sources of data were used to identify the compounding, dispensing, and administration trends of epoetin in patients and in adjunct outpatient settings. Trends amongst prescribers, wards, and patient populations were analyzed to find potential targeted opportunities, and potentials for savings.

Results: Our dashboard identified two drugs, epoetin and IVIG, to have the largest potential for cost savings using criteria of total expenditure and proportional increase from the prior year. Using EHR data, there were no trends suggesting changes in prescribing habits in inpatient due to relatively low utilization in this sector, but suggested increase in use in adjunct facilities. The same analysis provided a list of providers who prescribed the most, allowing for a targeted audit and chart review. Dosing protocol change from ABW to IBW resulted in a reduction in utilization of IVIG. Based on the analysis, the multi-dose epoetin approach significantly reduced cost as compared to individualized vial dosing.

Conclusion: By identifying the strongest contributors to the pharmacy budget, and being backed by robust, quantitative analysis, practice changes were proposed and implemented to minimize the overall cost of care for the patients that require these agents, while maintaining the delivery of quality care. Such strategies included protocol changes to reflect IBW dosing for IVIG and pharmacy to dose epoetin from multi-dose vials.

Poster Title: Evaluation of medication usage after revisions to non-formulary medication policies

Primary Author: Bob Pang, University of Maryland School of Pharmacy, Maryland; **Email:** bob.pang@umaryland.edu

Additional Author (s):
Kevin Lei
Brian Pinto
Celia Proctor

Purpose: Formulary management is one of the cornerstones in the safe, efficacious, and cost-efficient usage of drug therapies. The primary purpose of this study was to determine how major revisions to an academic medical center's policies on the usage of non-formulary therapies affected medication use through the analysis of purchasing data. The revisions included changes to non-formulary approval, modification to non-formulary inventory management, and overall reorganization of the formulary. The secondary purpose was to develop workflow and tools to quantify and monitor future non-formulary drug spend.

Methods: The hospital policy revisions that impacted non-formulary medications occurred in the first and second quarter of 2016. Monthly purchase invoices were collected from all satellite pharmacies at the hospital and compiled into a database ranging back to the first quarter of 2015. This range was to allow sufficient run-in time to establish baseline drug spend trends prior to changes in policy. This purchasing data was run through an automated computer script against a formulary index to classify each medication purchase as formulary, formulary with restrictions, and non-formulary. Descriptive analysis was completed on this data set using business intelligence analytic tools to generate non-formulary purchasing trends.

Results: Since the implementation of the revisions to the non-formulary medication policy, the data shows a significant decrease in the purchase of non-formulary items throughout all divisions of the hospital. In addition, subgroup analysis of high cost medications such as biologics, chemotherapy, antivirals, and single-source generics show decreases in their purchase as usage restrictions were placed on individual medications in these drug classes or

when the medications were classified as non-formulary. Results from the data analysis correlate well temporally with the changes and implementation of changes to hospital policy. Overall the data does well to highlight the importance of proper formulary management by demonstrating that while formulary medication purchases make up the bulk of the quantity amount purchased, non-formulary medication purchases greatly eclipse formulary purchases in dollar cost on a monthly basis.

Conclusion: Revisions made to hospital non-formulary medication policies showed significant impact in decreasing non-formulary medication purchases after implementation. As a result, the data establishes the importance of formulary management in controlling drug expense. The tools and processes used to complete data analysis can be employed to monitor future drug utilization and to identify medications in the formulary that require management. Since medication purchasing data is a surrogate for medication usage, medication administration data generated from computerized order entry systems should be analyzed as follow-up to validate these results.

Submission Category: General Clinical Practice

Submission Type: Descriptive Report

Session-Board Number: 5b-248

Poster Title: Assessment of a statistics review for third year pharmacy students

Primary Author: Travis Van Ede, South Dakota State Univeristy, South Dakota; **Email:** travis.vanede@jacks.sdstate.edu

Additional Author (s):
Jenna Welu
Zachariah Iverson
Anthony Wacholz

Purpose: The purpose was to evaluate the improvement in comprehension and interpretation of clinical statistics from the beginning of the third year of pharmacy school to the end of the year after exposure to multiple statistics reviews. Our hope was to provide third year pharmacy students with practice interpreting different aspects of statistical analysis to improve their ability to evaluate the statistical components of medical research.

Methods: To measure the outcomes of this study, student-led journal club sessions were held throughout the school year. At least once a month, a statistics session was held concurrently with the journal club session to review key statistics information from the journal articles. A 14-question, multiple-choice, pre-test examining students' knowledge of statistics was given at the first journal club session and then, a post-test with the same questions was given at the last session. The average score of correctly answered questions was calculated for each test. Participation in the tests was voluntary and topics tested included confidence intervals, hazard ratios, absolute risk reduction, relative risk reduction, number needed to treat, number needed to harm, internal/external validity, various trial designs (case crossover, cohort, randomized control trials, etc.), composite endpoints, surrogate endpoints, clinical vs. statistical significance, and non-inferiority vs superiority trials. The study population was made up of South Dakota State University third-year pharmacy students during the 2015-2016 academic year. The primary endpoint was the difference in average scores between the pre-test and post-test in the total population. A secondary endpoints included the difference in average test scores among a population subset of students who participated in both the pre-test and post-test (determined by matching student identification numbers).

Results: During the fall semester, 30 third year professional students completed the pre-test assessment in the fall semester compared with 35 students that completed the post-test in the spring semester. The average percent correct increased by 11.4% from the pre-test to the post-test from an average of 51.4% on the pre-test to an average of 62.7% on the post-test. A total of 12 students were identified as completing both the pre-test in the fall semester and the post-test in the spring semester. The average percent correct for this subset of students also increased by 11.4% from 56.5% on the pre-test to 67.9% on the post-test. Out of the 12 students participating in both assessments, 58.3% (n=7) of students received a higher score for the post-test, 33.3% (n=4) of students received the same score on the pre-test and post-test, and 8% (n=1) of students received a higher score on the pre-test.

Conclusion: There was a numerical increase in the average percent correct on the statistics assessment from the beginning of the third year of the professional program to the end of the year. This increase suggests that third year students in the professional program benefit from statistics reviews throughout the year. Further analysis is required to determine more effective methods to increase student understanding of the statistical components of medical research.

Poster Title: Impact of metformin on ROS and inflammatory signaling in breast cancer

Primary Author: Chandler Schexnayder, Xavier University of Louisiana College of Pharmacy, Louisiana; **Email:** cschexn2@xula.edu

Additional Author (s):
Christopher Williams
Shawn Lopis

Purpose: The first line anti-diabetic drug metformin has been under intense investigation recently for its ability to prevent or treat numerous neoplastic diseases including breast cancer. Various mechanisms have been postulated for metformin's effect in tumorigenesis, including induction of apoptosis. Here, we propose that at low concentrations, metformin fails to induce apoptosis or proliferative arrest, but instead functions by repressing the production of reactive oxygen species and dampening inflammatory signaling in breast cancer/ breast cancer microenvironment.

Methods: The impact of metformin on cell viability was ascertained by DNA content analysis, fluorescent vital dye exclusion, and dye-dilution proliferation assays. In order to determine the effects of metformin at sub-apoptotic concentrations, migration and invasion assays were performed using BCFA (Boyden chamber-Flow Cytometry Assay). NF kappa B activity was determined using a MDA-MB-231-derived, RELA responsive luciferase reporter cell line. The expression of the inflammatory, NF Kappa B-target proteins COX2 (cyclooxygenase 2) and ICAM (intercellular adhesion molecule 1) were determined by immunostaining and flow cytometry. Reactive oxygen, a major regulator of NF kappa B activity, was determined in the presence and absence of metformin using CELLROX assay, followed by flow cytometry.

Results: In the milliMolar (mM) concentration range, metformin caused decreased cell viability and G2 cell cycle arrest. At 100 microMolar (µM) however, metformin failed to induce apoptosis. However, metformin exposure was associated with a greater that 60% reduction in migration, and approximately 40% invasiveness in breast cancer cells. Metformin's ability to disrupt invasions and migration was correlated with a suppression of induced and constitutive NF kappa B transcriptional activity. Additionally we observed 60% and 30% decrease in the

expression of the NF-Kappa B target genes ICAM and COX2, supporting the contention that metformin inhibited NF-kappa B transcriptional activity. Reactive oxygen, a primary regulator of NF-kappa B activity, was also suppressed by metformin, suggesting that metformin reduced NF-kappa B transactivation by repressing endogenous production of reactive oxygen species.

Conclusion: At sub-apoptotic concentrations, metformin inhibits ROS and NF Kappa B signaling in breast cancer cells, resulting in decreased migration and invasiveness. These findings suggest that the anti-neoplastic effects of metformin in the breast may be a result of its ability to prevent invasiveness and metastasis, as opposed to the induction apoptosis which occurs at arguably supra-pharmacologic concentrations.

Poster Title: Pilot study to assess the dose accuracy of compounded electrolyte intravenous (IV) admixture solutions

Primary Author: Seda Donmez, St. John Fisher College Wegmans School of Pharmacy, New York; **Email:** sd08263@sjfc.edu

Additional Author (s):
Maria Caraballo
Kimberly Chichester
Irene Kimaru
Fang Zhao

Purpose: IV admixtures are commonly compounded by pharmacists in various healthcare settings. In recent years, there have been serious concerns about the quality of compounded sterile preparations (CSPs), ranging from sterility to dose accuracy. At the authors' institution, St. John Fisher College, pharmacy students receive rigorous training on aseptic techniques to ensure the sterility of CSPs. However, they are not exposed to any analytical methods for assessing dose accuracy. The purpose of this project was to develop a sterile compounding training module with an analytical component to increase the awareness of CSPs quality assurance among pharmacy students.

Methods: Practice prescriptions were created for 79 second year pharmacy students to prepare a 1 gram calcium gluconate or magnesium sulfate IV bag in 50 mL 0.9 percent sodium chloride injection. Once the compounding activities were completed, ten bags each of calcium gluconate and magnesium sulfate were randomly selected for analysis by two fourth year pharmacy students. Due to the variability of IV bag overfill and additive volume, each bag was first cut open, and the entire content was transferred to a graduated cylinder for accurate measurement of the total volume. Three aliquots from each sample were then analyzed for electrolyte concentration using the titration methods described in the United States Pharmacopeia (USP) monographs. Ethylenediaminetetraacetic acid disodium salt (EDTA) was used as the titrant for both electrolytes. Hydroxynaphthol blue and eriochrom black T were used as the indicators for calcium gluconate and magnesium sulfate, respectively. The concentrations of the three aliquots were calculated and averaged for each bag. The final

strength (dose) of the bag was calculated by multiplying the concentration and the total bag volume.

Results: All 79 students completed the calculations and compounding activities according to the practice prescriptions. The calculations were checked by teaching assistants prior to compounding. Out of the ten randomly selected bags, the volume ranged from 65 to 67 mL for calcium gluconate bags and 56 to 59 mL for magnesium sulfate bags. The titration of the calcium gluconate bags was carried out smoothly, and the final strengths of the ten bags ranged from 0.953 to 0.988 grams, 95.3 to 98.8 percent label claim. The titration end point of magnesium sulfate was more difficult to observe than that of calcium gluconate, which resulted in more data variability. The final strengths of the ten magnesium sulfate bags ranged from 0.941 to 1.015 grams. Nevertheless, they were all within the standard acceptance range of 90 to 110 percent label claim as specified in USP 797 general chapter for CSPs.

Conclusion: A new training module on sterile compounding has been successfully developed. The module includes the calculation and preparation of calcium gluconate and magnesium sulfate IV admixtures followed by the USP titration analysis to confirm the dose accuracy. This module will be incorporated in future compounding training for second year pharmacy students at the authors' institution with an intention to increase the students' awareness on quality assurance of compounded sterile preparations.

Poster Title: Deciphering Pharmacy Students' Attitudes, Comfort Level, and Knowledge of Substance Use Disorders

Primary Author: Sandy Lerner, St. John's University, New York; **Email:** sandylern7@gmail.com

Additional Author (s):
Jenna Butner
Ebtesam Ahmed

Purpose: To date, there is minimal research on pharmacy students' attitudes, comfort level, and knowledge of substance use disorders (SUD). Pharmacists play a crucial role in screening and treating SUDs as they are on the front-lines in the community. There is a shortage of addiction-related curricula in most pharmacy programs throughout the United States, and pharmacy students' comfort level and attitudes on SUD topics remain largely unknown. Learning Objectives:
1. To understand pharmacy students' attitudes and comfort level discussing addiction.
2. To assess pharmacy students' knowledge of SUD
3. To evaluate pharmacy students' preparedness in screening, recognizing, and treating SUDs.

Methods: A 15 question survey utilizing Survey Monkey technology will be administered to 5th and 6th year pharmacy students at St. John's University School of Pharmacy. Questions will be in the following multiple choice format: 5 questions on students' comfort level with addiction, 5 questions on students' knowledge base of addiction, 5 patient cases further exploring students' knowledge of SUDs.

Results: Results will be collected in an ongoing fashion as results from the survey are acquired.

Conclusion: Pharmacy students' comfort level and attitude towards addiction-related topics is deficient. The frequency of screening for SUDs in the community is lacking. More research is needed on this topic as pharmacists can play an important role in screening and treating patients with SUDs. Instituting curricula on addiction in pharmacy programs is fundamental to producing pharmacists knowledgeable on SUD assessment and pharmacotherapy.

Submission Type: Case Report

Session-Board Number: 5b-252

Poster Title: Meropenem-induced hypoglycemia: a case report

Primary Author: Hina Ghani, St. John's University College of Pharmacy and Health Sciences, New York; **Email:** ghani.hina@gmail.com

Additional Author (s):
Gerianne Hurney

Purpose: This case report discusses the importance of drug-induced hypoglycemia and the relevance of reporting adverse drug events. More specifically, the report will go over in detail the uncommon side effect of a commonly prescribed antibiotic: Meropenem.
A 77-year-old Caucasian male is presented to the emergency department with a gastrointestinal bleed. His past medical history includes atrial fibrillation, prostate cancer, gastroesophageal reflux disease (GERD), insomnia, thiamine/ vitamin C deficiency, recent case of aspiration pneumonia, recurrent Clostridium Difficile (c.diff) infections, respiratory failure, and cardiogenic shock. Medications prior to admission include: acetaminophen 325mg every four hours as needed for pain, albuterol sulfate 2.5mg/3ml every four hours as needed for shortness of breath, apixaban 5mg twice a day, ascorbic acid 500mg daily, atorvastatin 40mg daily, bisacodyl 10mg daily as needed for constipation, cholestryamine 4g daily, cilostazol 100mg daily, digoxin 250mcg daily, enalapril maleate 5mg daily, folic acid 1mg daily, Lactobacillus Acidophilus twice a day, metoprolol tartrate 100mg twice a day, omeprazole 20mg daily, quetiapine sulfate 25mg daily, magnesium hydroxide 500mg/5ml 30ml as needed for constipation, quetiapine sulfate 12.5 mg twice a day, thiamine 100mg daily, and trazadone 25mg daily.
There were no known drug allergies. On admission, the patient was 5'8" and weighed 68.4 kg. Vital signs at the time of admission were: oral temperature of 98.9 °F, blood pressure of 119/53 mmHg, heart rate at 57 beats/min, respiratory rate of 29 breaths/min, and oxygen saturation of 100% on two liters oxygen via nasal cannula. Physical examination revealed unresponsive mental status at bedside. The patient lab results were consistent with increased lactate levels indicative of sepsis. His white blood count was 16.9x103/μL, platelets 81x103/μL, hemoglobin 9.5g/dL, and hematocrit of 29.4%. His basic metabolic panel was sodium 139 mEq/L, potassium 2.6 mEq/L, blood urea nitrogen 41 mg/dL, serum creatinine 1.03 mg/dL, and blood glucose was 30 mg/dL. He was admitted to the intensive care unit and received IV fluids, thiamine 100mg IV,

famotidine 20mg IV, meropenem 1g, dextrose 10% in water, albuterol sulfate 0.083%, midazolam 1mg IV, dextrose 50% syringe 50ml as needed, and acetaminophen 650mg rectally. Upon administration of meropenem on day 1, the patient's blood glucose was reported to be 50 mg/dL at 8pm, two hours after the initial dose. The patient was given bolus dose of dextrose D50W, which elevated the blood glucose to 77 mg/dL at 10:45pm. On day 2, the patient was given another dose of meropenem at 2 pm, and the blood glucose dropped to 28 mg/dL. The blood sugar was checked 3 minutes later and found to be 24 mg/dL. The patient was administered D50W, which brought the blood glucose back to 96 mg/dL. The patient continued to receive his medications, including meropenem, and four hours later the blood sugar was 27 mg/dL. At this point, it was suspected that meropenem caused the hypoglycemia. The decision was made to discontinue meropenem and start ertapenem 1g IV.

It is unlikely that the hypoglycemia was caused by any other concomitant drugs or due to the patient's dietary restrictions because the adverse effect was resolved upon discontinuation of the meropenem. There are only a few reports of meropenem-induced hypoglycemia identified in the literature. However; meropenem-induced hypoglycemia appears to occur more often than reported in post-marketing clinical trials. This case study shows the importance of reporting adverse drug events. It demonstrates how conscientious health care providers can make a difference in the safety of a drug after it has been approved as well as serve to protect the public's health. Therefore, reporting adverse events in clinical practice are invaluable.

Poster Title: Dose management of dolutegravir in those who are concurrently being treated with rifapentine

Primary Author: Omar Rahman, Saint John's University, New York; **Email:** omar.rahman10@gmail.com

Additional Author (s):
Bruce Hirsch
Loyce Mol
Megan Lam
Suzan Chin

Purpose: 51 year-old-male with a history of Acquired Immunodeficiency Syndrome (AIDS) is recently diagnosed with latent tuberculosis (TB). According to the University of Liverpool guidelines, the patient's scheduled therapy with rifapentine will compromise the bioavailability of his current antiretroviral (ARV) drug regimen. The University guidelines suggest administering dolutegravir (50 milligrams) twice daily instead of once daily in efforts to maintain therapeutic drug concentrations.

An obese 51 year-old-male has a history of AIDS, hypertension and pre-diabetes. He returns to the clinic following his recent diagnosis of latent tuberculosis via Quanteferon TB-Gold Test wishing to start Directly Observed Therapy (D.O.T) with rifapentine, isoniazid, and vitamin B6. The patient's original ARV drug regimen included Triumeq (Abacavir/Dolutegravir/Lamivudine) once daily. An additional dose of dolutegravir (50 milligrams) was given to neutralize the suspected induction of enzymes - responsible for decreasing plasma levels of dolutegravir - caused by rifapentine. Along with his adjusted dolutegravir regimen, the patient began his therapy with rifapentine on 2/29/16. The patient's viral load was undetectable at the start of his therapy with rifapentine. The patient's viral load was tested every four weeks throughout the course of his therapy with rifapentine, which served as a clinical marker for the management of his AIDS infection in the wake of his newly adjusted dolutegravir dose. The patient's viral load remained undetectable with each subsequent visit. Additional monitoring parameters included a complete metabolic panel, complete blood count and chest X-ray - all of which were within normal limits at baseline and throughout the course of D.O.T.

The patient started D.O.T for TB on 2/29/16. The D.O.T regimen lasted twelve weeks. The patient received 900 milligrams of rifapentine, 900 milligrams of isoniazid, and 50 milligrams of vitamin B6 every Monday until the end of treatment on 5/16/16. The patient was provided daily doses of vitamin B6 (50 milligrams) in pill trays for the remainder of each week. His ARV drug regimen was adjusted due to potential drug interactions between rifapentine and dolutegravir. The supplementary dose of dolutegravir (50 milligrams) was added on at bedtime in efforts to compensate for the heightened metabolism - of dolutegravir - induced by rifapentine. Aside from mild episodes of joint pain and headache, the medications were well tolerated by the patient. The patient completed 12 weeks of D.O.T with no missed doses. Following the completion of D.O.T, the patient returned to taking Triumeq once daily and discontinued the bedtime dose of dolutegravir.

Treatment of both TB and Human Immunodeficiency Virus (HIV) among coinfected patients is now the standard of care. The metabolism of dolutegravir is expected to increase when coadministered with potent metabolic inducers such as rifapentine. The pharmacokinetic profiles highlight the risk of subtherapeutic levels of dolutegravir when administered with rifapentine. Subtherapeutic plasma levels may encourage the risk of virologic failure and resistance development in the management of HIV. The current literature highlights clinically significant interactions between dolutegravir and various antimycobacterials such as rifampin, rifampicin, and rifabutin; But fails to address the clinical relevance of coadministering dolutegravir with rifapentine. The University of Liverpool's suggestions stem from dolutegravir interaction studies with rifabutin and rifampicin, rather than with rifapentine. This case demonstrates the therapeutic value of an additional dose of dolutegravir (50 milligrams) when coadministering rifapentine. Our case shows that virologic maintenance of HIV/AIDS can be accomplished - without signs of toxicity - when administering an additional dose of dolutegravir. Our case study addresses an important void in the literature surrounding dose management of dolutegravir in those who are concurrently being treated with rifapentine.

Poster Title: Cost-Analysis of Pharmacologic Management of Gastroparesis-Related Symptoms

Primary Author: Pavit Singh, St. John's University College of Pharmacy and Health Sciences, New York; **Email:** pavitsing@gmail.com

Additional Author (s):
Erica Gray

Purpose: Gastroparesis is a syndrome characterized by delayed gastric emptying and is associated with early satiety, postprandial fullness, nausea, vomiting, bloating, and upper abdominal pain. Diabetic gastroparesis has one FDA-approved medication for its management, metoclopramide. A number of prescription and over-the-counter medications are used intermittently by patients for treatable symptoms including prokinetic agents (e.g., domperidone and erythromycin), anti-emetic agents (e.g., prochlorperazine, promethazine, ondansetron, aprepitant, dronabinol, and transdermal scopolamine), intrapyloric botulinum toxin injections, and nutritional supplements. The economic burden of gastroparesis is notable and increasing in the United States. This study quantified medications' costs used for management of gastroparesis symptoms.

Methods: Key gastroparesis-related symptoms and recommended medications (metoclopramide, domperidone erythromycin, prochlorperazine, promethazine, ondansetron, aprepitant, dronabinol, transdermal scopolamine, intrapyloric botulinum toxin, and multivitamins) used for symptom control were found in the American College of Gastroenterology's 2013 Management of Gastroparesis guidelines. Micromedex RedBook was used to determine the average wholesale price (AWP) of each drug. Healthcare Bluebook was used to find the injection fee of botulinum toxin. Package inserts were utilized to determine the daily frequency and maximum possible duration of treatment. Since there is no current symptom severity scale for gastroparesis, two hypothetical patient cases were created to provide an understanding of how patients may present with symptoms, their potential treatment courses, and the yearly medication costs associated with symptom control. When creating patient cases, a literature search was conducted to determine the prevalence of each gastroparesis-related symptom. A minimum and maximum analysis was used to determine the potential costs of treatment based on treatment failure and persistent symptoms.

Results: Since patients with gastroparesis can experience a wide range of frequencies and severities of gastroparesis-related symptoms, their medication pathways can vary. Medications often used to treat the symptoms associated with gastroparesis include prokinetic agents (e.g., metoclopramide, domperidone and erythromycin), anti-emetics (e.g., prochlorperazine, promethazine, ondansetron, aprepitant, dronabinol, and transdermal scopolamine), intrapyloric botulinum toxin, and multivitamins. A patient with mild abdominal pain, post-prandial fullness, three to four bouts of nausea per week, and one vomiting episode per week had an average a cost of $1,424.79 based on AWP. A patient with abdominal pain, post-prandial fullness, decreased appetite, weight loss, nausea after each meal, and three episodes of vomiting had a cost of $8,708.13. Depending on the medication, duration, frequency of medication use, anti-emetics can cost from $8.58 to $40,203.07 per year, prokinetics can cost $17.94 to $325.49, and intrapyloric botulinum toxin injections can cost $1.450.60 to $2,901.20. This study shows a conservative societal cost of the medication burden in patients with gastroparesis.

Conclusion: Gastroparesis is an understudied disease state with primary pharmacologic treatment options that have limited duration of use (metoclopramide and domperidone) and availability (domperidone). Additionally, depending on the patient's gastroparesis-symptoms, this disease state can result in a significant financial burden of pharmacologic treatment. After evaluating the symptomology and the frequency of these symptoms, we attempted to provide an understanding of the disease state, as well as calculate the potential medication costs. While this study highlights the potential financial burden of the medications used to treat gastroparesis symptoms, the financial effects of gastroparesis on quality of life should be further explored.

Poster Title: Quantifying the minimum adherence threshold associated with the development of reverse transcriptase resistance mutations among HIV-infected Veterans' Affairs patients receiving antiretroviral therapy

Primary Author: Jenna Yager, Albany College of Pharmacy and Health Sciences, New York; Email: jenna.yager@acphs.edu

Additional Author (s):
John Faragon
Nimish Patel

Purpose: Poor adherence (ADH) to antiretroviral therapy (ART) can lead to deleterious patient outcomes including development of resistance among patients infected with human immunodeficiency virus (HIV). The primary objective of this study was to quantify the minimum ADH threshold associated with development of reverse transcriptase (RT) resistance mutations among Veterans' Affairs patients receiving combination ART. The secondary objective was to determine if the minimum adherence threshold was independently associated with development of RT resistance mutations after adjustment for confounding variables.

Methods: A retrospective cohort study, utilizing repeated subject sampling strategies, was conducted among patients receiving care at the Upstate New York Veterans' Healthcare Administration (VISN-2) between 2000 and 2013. Inclusion criteria were: 1) age ≥ 18 years, 2) diagnosis of HIV infection, 3) receipt of ≥ 3 ART medications for ≥ 3 months, 4) availability of pre-treatment resistance tests, and 5) availability of post-treatment resistance tests. Patients' ART regimens must have included ≥ 2 classes. Data were obtained from patients' medical records and the following variables were collected: demographics, history of HIV infection, antiretroviral history, genotypic test results and dispensing records. Medication ADH was captured using pharmacy refill records in order to calculate medication possession ratios as a percentage. Times in which patients were in possession of < 3 ART medications were considered periods of non-adherence. The outcome of interest in this study was new mutations in RT as indicated by genotypic test results. Classification and regression tree (CART) analysis was performed to identify the minimum ADH threshold associated with development of

incident RT mutations. Logistic regression was used to determine if the minimum ADH threshold was independently associated with development of RT resistance mutations.

Results: Among the 65 included subjects, mean ± standard deviation (SD) age was 49.2 ± 8.7 years. Subjects were primarily male (98.5%). Distribution of ART regimens was: protease inhibitor-based (40.0%), followed by mixed class (≥ 3 ART classes, 30.8%), non-nucleoside reverse transcriptase inhibitor-based (26.2%) and integrase strand transfer inhibitor-based regimens (3.1%). The median (IQR) ART ADH was 70.0 (47.1 – 83.6%). Mutations in RT were observed in 25 (38.5%) patients with the most common being K103N (36.4%), M184V (27.3%), T215Y (13.6%) and L74V (9.1%). Only 1 (4.5%) patient had a 69 insertion complex. The CART-derived ADH threshold associated with development of RT mutations was 80.5%. Patients above this threshold were less likely to develop RT mutations than those below (13.6% versus 51.2%, p=0.003). Among treatment-naïve individuals, patients above the CART-derived threshold were less likely to develop RT mutations than those below (0% versus 69.2%, p=0.002). Among treatment-experienced individuals, development of RT mutations did not differ for those above/below the CART thresholds (23.1% versus 43.3%, p=0.31). In multivariate analyses, ART ADH ≥ 80% (adjusted odds ratio: 0.15, 95% confidence interval: 0.04–0.60, p=0.007) was independently associated with development of RT mutations after adjustment for regimen type and number of non-ART medications.

Conclusion: ART ADH continues to be an important predictor of clinical outcomes among patients with HIV infection. Patients with an ART ADH threshold of ≥ 80% were significantly less likely to develop RT resistance mutations than patients below this threshold. After adjustment of confounding factors, ART ADH ≥ 80% was independently protective against developing RT resistance mutations. Clinicians should advocate strong ART ADH among patients receiving combination ART. These data need to be incorporated with the ART ADH thresholds associated with virologic suppression and other important HIV outcomes.

Poster Title: Risk of using mislabeled and unregulated cannabidiol products for pain management.

Primary Author: Zachary Piracha, St. John's University College of Pharmacy and Health Sciences, New York; **Email:** zachary.piracha11@stjohns.edu

Purpose: On 06/21/16, the Consumer Complaint Coordinator division of the Food and Drug Administration (FDA) received a report from a consumer that had discovered an online seller of dietary supplement, www.hemplife.com, and purchased the product CannazAll. CannazAll is a hemp cannabidiol (CBD) tincture, 250 mg, liquid that is used widely for its pain relieving claims and minimal side effects. CannazAll is labeled to contain negligible levels of THC, the main psychoactive compound found in marijuana. The consumer was taking the tincture and stated that one bottle would last for approximately one month. His dose was 2-3 drops of the liquid orally, 2-3 times a day, and has been doing so for approximately 6 months. The consumer was taking this product because of his chronic back pain, to which he was taking hydrocodone. The opioid medication would blunt his pain, but also give uncomfortable adverse effects such as GI disturbances and day time drowsiness. The consumer claimed the tincture relieved his pain and made him comfortable enough to carry out his activities of daily living.
In April 2016, he had been referred to a back specialist, who prior to treating any patient, requires a complete blood and urine panel checking routine lab values and a drug screen. The consumer submitted to the doctors requirements, submitted a blood and urine sample and disclosed his prescribed opioid pain medications to the doctor.
When he met with the doctor to discuss his analysis, he was shocked to learn that his blood panel showed that he had 83 ng/ml of THC within his blood. According to the complainant the standard cut off is 50 ng/ml which, the doctor explained to him that because of this level of THC, the consumer met criteria to be classified as a "drug addict". This now means the doctor cannot prescribe any medications to him for pain because of the possibility he will continue his "addict" habits. This was a very troublesome time for the consumer who had stopped talking the CannazAll and is unable to receive supplemental pain medication which he needs. The doctor had to refer him to a Pain Management Treatment Center for drug addicts for further treatment. The consumer stated that he does not smoke or eat marijuana, he does not use other hemp product, and he has not been around other people smoking it or using it. He was

very shocked to find out that the CannazAll would contain such high levels of THC, since according to his doctor, his levels showed that he was a very active cannabis user. The patient exclaimed that if he would have gotten into a car accident and was screened for drugs he would have been charged with driving under the influence.

CBD products are considered dietary supplements and are not regulated by the FDA. Since there is no regulation, it is uncertain what is actually going into the products that are shipped out to those who purchase them. It is legal to purchase CBD in all 50 states, as long as there is a minimal THC content. The mislabeling and no regulation of this product has uprooted an individual's life and has the potential to do the same if there is no action taken to either regulate the product to ensure its contents or removal from the market.

Poster Title: Evaluation of tamsulosin use for urolithiasis at an academic teaching hospital

Primary Author: Ilana Shemaev, St. John's University, New York; **Email:** ilana.shemaev11@stjohns.edu

Additional Author (s):
Brian Cheng
Ahrang Lee
Maha Saad
Nicole Maisch

Purpose: The American Urological Association recommends the use of alpha-blockers, particularly tamsulosin, for patients with distal ureteral stones measuring 10mm or less. Ideal candidates for medical expulsive therapy include those with optimized pain control and without renal insufficiency. Patients with compromised renal function are recommended to undergo immediate surgical intervention, since awaiting spontaneous stone expulsion with tamsulosin may further worsen their kidney function. The purpose of this study was to assess the utilization of tamsulosin in treating urolithiasis at Long Island Jewish Medical Center (LIJMC).

Methods: Following Institutional Review Board approval, a retrospective chart review of patients who were prescribed tamsulosin for suspected urolithiasis in LIJMC from December 2015 to May 2016 was performed. Data was accessed through electronic medical records and patients were identified with the ICD 10 code "urolithiasis." Inclusion criteria consisted of adult patients, aged 18 to 89 years, with an identified stone in the urinary tract who received tamsulosin. Data collection included: patient age, gender, race, BMI, the number of stones present, the size and location of the stones, estimated glomerular filtration rates (eGFR), previous history of urolithiasis, dose and frequency of tamsulosin administered, the type of imaging received, the amount of pain medications received and the need for surgical intervention. Descriptive statistics were used to analyze the data. After data collection was completed, it was de-identified in order to maintain patient confidentiality at all times.

Results: The charts of 134 patients were reviewed (69.4 percent male, mean age 51.8 years). Sixty-five patients (48.5 percent) had a history of urolithiasis in the past, whereas 69 patients (51.5 percent) were newly diagnosed with urinary tract stones. The mean stone size and number of stones was 6.2mm and 1.6, respectively. The mean eGFR was 73.6mL/min/1.73 m2. The majority of patients had stones localized to the ureter (77.6 percent) and most had unilateral stones (74.6 percent). Eighteen patients (13.4 percent) were offered tamsulosin for stones measuring greater than 10mm. Additionally, 17 patients (12.7 percent) were offered tamsulosin for stones located in the kidney and bladder, without evidence of ureteral stones. There were 45 patients (33.6 percent) identified with an eGFR of less than 60.0ml/min/1.73 m2 who had received tamsulosin during their acute episode. The mean number of pain medications administered was 3.9. Thirty-five patients (26.2 percent) were admitted for surgical intervention, while 108 patients (80.6 percent) were discharged with a prescription for tamsulosin for a mean duration of 16.1 days.

Conclusion: Despite the current American Urological Association guidelines, a subset of patients was offered tamsulosin for stones measuring greater than 10mm in size. A small subset of patients was offered tamsulosin for non-ureteral stones. Finally, we identified a substantial amount of patients with renal insufficiency that was prescribed tamsulosin for urolithiasis. We recommend stronger adherence to current guidelines and a more established protocol for tamsulosin use at our medical center.

Session-Board Number: 5b-258

Poster Title: Post-hoc evaluation of drug-allergy alert reduction strategies and prescriber override rate through of suppression of inactive ingredient match: One year later

Primary Author: Vinh Luong, Wegmans School of Pharmacy, New York; **Email:** vql07086@sjfc.edu

Additional Author (s):
Vladimir Poplavskiy
Justin Foster
Lisa Nelson

Purpose: Clinical decision support systems (CDSS) with interruptive drug-allergy alerts has become an integral part of most healthcare systems utilizing electronic medical records (EMR). While CDSS are thought to be helpful to prescribers, clinical data shows that override rates of drug-allergy alerts have been steadily increasing overtime. There are currently no novel reduction strategies of drug-allergy alerts. Initial data-mining at our site, identified a significant amount of drug-allergy alerts triggered due to inactive ingredients. The purpose of this project was to evaluate prescriber override rates one-year after the suppression of drug-allergy alerts identified secondary to inactive ingredients.

Methods: Drug allergy alert data was extracted from a report encompassing all medication order via the EMR at affiliated inpatient and ambulatory practice settings within the University of Rochester Medical Center (URMC). Allergy alerts consisted of three severities: cross-sensitive class match, drug class match, and ingredient match. For the purposes of this review drug ingredient allergens were classified as active or inactive ingredient via the FDA ingredient database. Inactive ingredients characterized as dye based or non-dye based ingredient. All data were filtered by warning showed to user, warning status, severity of alert, drug-allergy matching reason, and number of alerts. Initial data was collected from June 2015 through July 2015 to serve as a benchmark to quantify prescriber override patterns and percentage of allergy alerts due to the type of drug ingredient match (active or inactive). Alert reduction strategies were implemented through custom suppression of inactive drug ingredients within Medi-span drug database of all drug allergen. Inactive ingredients triggering drug-allergy alerts were identified through initial data collection process. Reduction strategies were implemented

gradually from August 2015 until June 2016. Medication order alerts and prescriber override patterns from URMC were collected one year after initial baseline data from June through July 2016 to validate alert reduction strategies.

Results: Alert sample data before and after intervention yielded a total of 95,853 alerts and 94,053 alerts. Initial data samples prior to intervention indicated inactive ingredients contributed to 20.8 percent of all drug allergy alerts, of which dyes contributed 12.9 percent. Data sampled one year after the implementation of the intervention showed that inactive ingredients contributed to 4.5 percent of all drug-allergy alert and dyes contributed 1.6 percent. Muting inactive ingredients as a possible drug-allergen match contributed to a 16 percent reduction in related alerts. Initial data analysis of allergy severity revealed that drug-allergy alert due to drug class matches had highest override rate of 80.8 percent followed by cross-sensitive class matches and ingredient matches with override rate of 76.7 percent and 76.4 percent. Post-deployment, drug-class matches had the highest override rate of 82.3 percent, followed by cross-sensitive class match and ingredient match with override rate of 76.2 percent and 67.8 percent. Override rates of drug-allergy severity did not achieve statistical significance with the exception of the ingredient match, which saw an 8.9 percent reduction in override rate. Sub-analysis revealed inactive ingredients contributed to 20.8 percent of all ingredient matches initially and 2.2 percent after the reduction strategy was implemented.

Conclusion: Implementation of drug-allergy suppression intervention resulted in significantly less total number of overall allergy alerts being displayed to ordering providers during the study period. This suppression also provided provider with more meaningful drug-allergy alert. Post-hoc analyses one year of implementation revealed the benefits of alert reduction strategies and provided further insight into provider override patterns.

Poster Title: Continuation of outpatient medications upon admission to a general medicine unit at a community teaching hospital

Primary Author: Samantha Leistman, Wegmans School of Pharmacy, New York; **Email:** scl05732@sjfc.edu

Additional Author (s):
Melanie Symoniak

Purpose: Completing accurate and thorough medication reconciliations, in a timely manner, is crucial to providing high-quality patient care in the inpatient setting. When a complete list of outpatient medications is not available upon admission to the hospital, this information gap leaves patients at risk for multiple medication-related errors. The purpose of this evaluation was to determine the average percentage of patients' outpatient medications that are restarted/continued within two business days of being admitted to a general medicine unit at Rochester General Hospital (RGH). RGH is a 531-bed, community hospital with a general medicine residency program.

Methods: The Institutional Review Board at RGH approved this prospective, observational review. One hundred unique, adult patients, admitted to the same general medicine unit at RGH between June 1, 2016 and September 1, 2016, were randomly selected based on a convenience-sample model. Patients must have had a medication-reconciliation completed within two business days of being admitted. Patients who were transferred to the unit from an intensive care unit or step-down unit were excluded. Investigators used a random number generator to identify which patient's data would be collected each day. All data was collected from the electronic medical record, so no direct patient contact occurred. Data collected included demographic information, admission related data, the type of health care professional that completed the medication reconciliation, the time between admission and the completion of the medication reconciliation, specific medications each patient was taking as an outpatient, and specific medications each patient was taking within two days of admission. Data was logged into a secured spreadsheet. The primary outcome was the average percentage of patients' outpatient medications that were restarted within two business days of being admitted. Secondary outcomes were to observe whether or not the primary outcome was impacted by

factors such as patient population, type of health care professional completing the medication reconciliation, or admission via a specific interdisciplinary admission service in the emergency department.

Results: The median age of included patients was 69 years; 58 percent were male. The primary spoken language was English for 95 percent of patients. The average percentage of patients' outpatient medications that were restarted/continued within two business days of being admitted was 60 percent. The average number of outpatient medications was 10.9 and average time to complete medication reconciliation was 7.2 hours. The highest average percentage of restarted medications, 70 percent, was seen in patients who were admitted via a specific admission team; these patients had medication reconciliation completed by a pharmacist. Interestingly, patients with fewer comorbidities and fewer than five outpatient medications experienced the lowest average percentage of continued medications (55 percent and 33 percent, respectively), while patients with greater than five comorbidities and at least ten outpatient medications had relatively higher average percentages of continued medications (67 percent and 65 percent, respectively).

Conclusion: Overall, the average percentage of medications continued in this observational evaluation seems low at 60 percent. Trends seen suggest that patients who are admitted via interdisciplinary admission teams and have medication reconciliation completed by a pharmacist, experience the highest percentage of continued medications. It is unclear why patients with minimal comorbidities, who are taking fewer medications as an outpatient, experienced lower average percentages. Results of this evaluation warrant larger, more in-depth study to determine how the medication-reconciliation process during hospital admission can be further improved.

Poster Title: Evaluating Variation in Pharmacy Student Learning Styles Using H-PILS

Primary Author: Zachary Lawrence, University of Louisiana at Monroe School of Pharmacy, Louisiana; **Email:** zachlawrence09@gmail.com

Additional Author (s):
Adam Pate
Kristen Meier
Dharti Desai

Purpose: To determine student preferred learning style utilizing the Health Professional Inventory of Learning Scale (HPILS). The research will hopefully identify learning style preferences that can be used to create learning environments to enhance student learning.

Methods: An electronic survey was emailed to all ULM pharmacy students using their school email addresses. Participation was strictly voluntary and no additional incentives were given for completing the survey. This research study was approved by the institutional review board at ULM. The Health Professionals' Inventory of Learning Styles (H-PILS) was used to allow students to think about a few situations where they had to learn something new to solve a problem. The situations include but not limited to: while they were taking course at school, learning to use new software, or figuring out how to assemble a barbecue. The survey contained 17 questions with 4 answer choices – A, B, C, or D (A=Accommodator, B=Assimilator, C=Converger, D=Diverger) which characterizes the students preferred learning style. The students were given approximately two months to anonymously complete the survey and submit their responses. The data was collected from the completed survey, compiled, and analyzed.

Results: A total of 67% of students from the University of Louisiana at Monroe School of Pharmacy completed the survey. Analyzing the data for dominant and secondary learning styles revealed a dominant style of assimilator and secondary learning style of converger. The cumulative results indicate that 67% of students dominant method of learning is assimilator; they prefer working by themselves, at their own pace and time, or with small groups of like-minded people. The secondary learning style was Converger, which indicates that 43% of

students are focused, practical, and to the point. These 112 students usually find themselves in a leadership role and enjoy the challenges.

Conclusion: These results indicate that although students have a variety of learning styles, there may be a "majority" preferred learning style that is prevalent among pharmacy students i.e. Assimilator. This may be due to the selection process for pharmacy school or possibly due to generational differences in learning. This information may provide opportunities to faculty members to best enhance their learning activities to appeal to these learning styles.

Poster Title: Impact and feasibility of prospective medication review in the emergency department

Primary Author: Kwong Lau, Arnold and Marie Schwartz College of Pharmacy,

Long Island University, New York; **Email:** kwong.lau@my.liu.edu

Additional Author (s):
Richard Tong
Billy Sin
Josel Ruiz
Kimberly Sarosky

Purpose: Clinicians in the Emergency Department (ED) often find themselves working in a crowded, fast-paced and stressful environment that is typically defined by high patient volume, complex patient acuity, and staff shortages. These factors have been attributed to the cause of frequent medication errors in EDs. Prospective medication review (PMR) allows a pharmacist to capture medication errors prior to reaching the patient. However, the necessity and practicality of PMR is constantly questioned due to concerns of delays to patient care and increased length of stay. The purpose of this study was to evaluate the feasibility of PMR in the ED.

Methods: This was a retrospective study designed to evaluate the feasibility and impact of prospective medication review in the ED. Electronic medical records (EMR) of patients who presented to the ED at any time from September 2014 to September 2015 were reviewed. Adult and pediatric non-admitted ED patients who were prescribed medication orders by ED clinicians were included in the study. All medication orders that were evaluated had to be dispensed from an automated dispensing cabinets (ADC) located within the ED.
The primary outcome was the time interval from medication order entry by ED clinician to order verification by the pharmacist. The secondary outcomes included: time interval from order verification to dispense of medication from an ADC, time interval from dispense of medication from an ADC to time of administration as documented in the EMR, the total time interval for the entire medication use process, the number of interventions conducted by the pharmacist that were accepted, and cost-avoidance accrued with the accepted interventions.

Results: A total of 834 medication orders were included for evaluation. The median time for order verification, order verification to dispense, and dispense to administration were 3 mins (interquartile range [IQR]= 1-7 mins), 20 mins [IQR= 7-45 mins], and 10 mins [IQR= 6-16 mins]. The median time interval for order verification to dispense was longer during the overnight pharmacy shift (median=5 mins, IQR=2-9 mins) compared to the day and evening shifts (median=3 mins, IQR=1-6mins) A total of 563 interventions were recommended by the pharmacists and accepted by ED clinicians. These interventions equated to $47,585 worth of cost-avoidance.

Conclusion: Our data suggested that PMR is a feasible process which positioned pharmacists to make positive impacts on patient safety and therapeutic efficacy without causing delays to patient care. We found that the time intervals from medication dispense after verification of order and from medication dispense to administration composed of the majority of total time needed to complete the medication use process.

Poster Title: Significance of new metformin renal dosing recommendations: a retrospective study comparing previous and updated guidelines

Primary Author: Aswin Mathew, St. John's University, New York; **Email:** aswin.mathew10@stjohns.edu

Additional Author (s):
Amy Yang
Nicole Maisch
Maha Saad

Purpose: Metformin, a first-line antidiabetic agent, requires monitoring to avoid toxicity in patients with impaired renal function. Traditionally, serum creatinine (SCr) was used for eligibility; however, Scr is an imprecise measure when used alone. These criteria have prevented many otherwise eligible patients from receiving metformin. The U.S. Food and Drug Administration released new recommendations using estimated glomerular filtration rate (eGFR), citing that data indicate metformin has been safely used in patients with mild-moderate renal impairment and practitioners often use it despite SCr criteria. This study was conducted to determine whether a clinical difference exists in metformin eligibility using the different methods.

Methods: The institutional review board approved this retrospective chart review. Adult patients aged 18-89 were eligible for this study. Patients were included if an active order for metformin was entered while admitted at Long Island Jewish Medical Center (LIJMC) from April 8th to August 12th 2016. Patient information was de-identified prior to exporting to a Microsoft Excel spreadsheet. A data collection sheet was created and collected the following: age, sex, race, and SCr as well as eGFR as calculated by the hospital laboratory department using the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation. Patients were excluded if any one of the four parameters were not reported. The patient parameters were used to calculate eGFR for each patient via the Modification of Diet in Renal Disease-4 (MDRD-4) equation. Patients with a SCr of at least 1.5 mg/dL (males) or 1.4 mg/dL (females) or an eGFR of less than 30 mL/min/1.73m2 (calculated using both CKD-EPI and MDRD-4 equations) were considered contraindications for metformin therapy. The primary outcome of the study was

difference between number of patients contraindicated based on SCr criteria and eGFR criteria as calculated by MDRD-4. In addition, discrepancies between outcomes with MDRD-4 and reported CKD-EPI will be explored.

Results: Of 261 patients screened, 250 patients met inclusion criteria. Eleven were excluded because one or more parameters were not reported. Sixty percent were female, 30 percent were African American and the mean age was 60 years. The mean SCr and eGFR, as calculated using both MDRD-4 and CKD-EPI equations, were 0.90 mg/dL, 85 mL/min/1.73m2 and 86 mL/min/1.73m2, respectively. Metformin use was contraindicated in 11/250 (4.4 percent) of patients using SCr criteria compared to 1/250 0.4 percent patients using eGFR recommendations. No differences were detected between eGFR reported using CKD-EPI and MDRD-4. Seven and eight patients had reported eGFR between 30 and 45 mL/min/1.73m2, as reported using the CKD-EPI and MDRD-4 equations, respectively. Of these patients in the reported eGFR range, 85.7 percent and 87.5 percent patients were contraindicated based on SCr cutoffs but were eligible to continue with close monitoring based on eGFR recommendations calculated using CKD-EPI and MDRD-4, respectively.

Conclusion: The use of eGFR criteria for metformin eligibility allowed more patients to continue therapy with metformin compared to using SCr alone as a marker for renal function. However, limitations such as including patients with an active sickness may have reflected an acute reduction in renal function. Additional long-term studies with larger study populations are required to determine the true difference between renal function estimating methods with respect to increased eligibility and the incidence of lactic acidosis.

Session-Board Number: 5b-263

Poster Title: The use of sub-dissociative dose ketamine (SDDK) for the management of sickle cell crisis: a case series

Primary Author: Michelle Liu, Arnold and Marie Schwartz College of Pharmacy, New York;
Email: mliu0417@gmail.com

Purpose: Sickle cell crises or vaso-occlusive crises (VOC) are the most common and urgent complication of sickle cell disease, as well as the primary reason for emergency room visitations. Opioids had been traditionally recommended for the management of acute pain. However, there are growing concerns with the abuse and misuse of opioids. Ketamine has been used for acute pain, with limited literature suggesting its use for VOC. The purpose of this study was to explore whether the utilization of sub-dissociative dose ketamine (SDDK) as an adjunct to standard opioid therapy would result in satisfactory pain control while decreasing subsequent opioid consumption.

Methods: A 5 month retrospective chart review was conducted in a 350-bed urban community teaching hospital. Adult sickle cell patients that presented to the ED with acute pain secondary to vaso-occlusive crisis (VOC) who received intravenous sub-dissociative ketamine (SDDK) as identified by the pharmacy record were included. Exclusions included any incomplete documentation of data, and past medical history of malignancy or recreational drug usage. The data was reviewed from the electronic medical record (EMR) and extracted onto a standardized collection form. Pain control was measured using the Numerical Rating Scale (NRS), subsequent opioid consumption was measured by repeat doses of opioids and adverse events were identified. Data were analyzed descriptively.

Results: A total of 14 patients were identified to have received an intravenous ketamine infusion of 0.1mg/kg/hr. The use of SDDK in conjunction with standard opioid therapy decreased 85.7% (12/14) of the patient's perception of pain as measured by the Numerical Rating Scale (NRS). The mean pain reduction was 2.2 points with 78.6% (11/14) of the patients who had a pain score reduction of >2 points and 42.9% (6/14) with >3 points. One patient had no change in pain from baseline and another had increased 2 points in pain score. Half of the patients (7/14) received rescue doses of opioids after a mean of 119 minutes into the ketamine

infusion. Adverse drug events experienced were mild and infrequent. The most common occurrence was headache (14.2%), agitation (7.1%) and nausea (7.1%).

Conclusion: SDDK provided effective pain relief with a tolerable side effect profile of no reported emergence phenomena in patients who presented with VOC.

Poster Title: Association between dialysate calcium concentration and parameters of chronic kidney disease- mineral and bone disorder in hemodialysis patients

Primary Author: Jeffrey Bettinger, Albany College of Pharmacy and Health Sciences, New York; **Email:** jeffrey.bettinger@acphs.edu

Additional Author (s):
Andrea Glogowski
Amy Murdico
Kovesdy Csaba
Elvira Gosmanova

Purpose: Hemodialysis (HD) is a life-saving procedure for patients with end-stage renal disease (ESRD) and it is performed to restore electrolyte and fluid balance. Abnormalities in chronic kidney disease-mineral and bone disorder (CKD-MBD) such as calcium (Ca), phosphorus (Pi) and parathyroid hormone (PTH) are common in patients with ESRD. Ca concentration in dialysate fluid can be adjusted during HD. Therefore, we investigated effects of two dialysate Ca concentrations ("a standard" 2.5 mEq/L and "a higher" 3 mEq/L dialysate Ca concentrations) on serum Ca, Pi, and PTH in HD patients.

Methods: This was a retrospective study that included 72 veterans undergoing chronic HD for ESRD at the Stratton VA Medical Center, Albany, NY. Patients were included into analysis if they received HD between January 1, 2013 and June 30, 2016 and underwent 3-times weekly HD for at least 6 months using two different Ca dialysate concentrations of 2.5 and 3.0 mEq/L for at least 3 months. Time-averaged total serum Ca, albumin-adjusted Ca (adjCa), phosphorus (Pi), and intact PTH (iPTH) were analyzed during the use of 2.5 and 3.0 mEq/L Ca dialysate concentrations. Linear regression analysis was used to examine the strength of association between iPTH and time-averaged adjusted total serum Ca, adjCa, and Pi.

Results: The mean (SD) age for the total cohort was 62.9 (9.3) years, 97.4% were men, 18.4% and 81.6% were African-American and White, respectively, and 52.5% had diabetes as a cause of ESRD. Total Ca and adjCa were higher on lower Ca concentration dialysate: total Ca was 8.8 and 8.6 mg/dL, while patients were dialyzed on 2.5 versus 3 mEq/L Ca dialysate, respectively

(p=0.009 for difference), and adjCa was 9.3 and 9.2mg/dL, respectively (p=0.03 for difference). There was no difference in Pi concentration with different Ca dialysate concentrations (4.9 and 4.7 mg/dL on 2.5 and 3 mEq/L Ca dialysate, respectively, p=0.5); while, iPTH concentration was lower on 2.5 mEq/L Ca dialysate as compared with 3 mEq/L Ca dialysate (460.2 and 364.9 pg/mL, respectively, p=0.009). In linear regression analysis, iPTH did not correlate with total Ca or adjCa (p was not significant), and was weakly negatively correlated with Ca dialysate concentration (r=-0.16, 95% Confidence interval (CI) -0.27- -0.05, p=0.007) and positively correlated with serum Pi concentration (r=0.32, 95% CI 0.21-0.42, p < 0.001).

Conclusion: In this retrospective analysis we found that the use of higher 3 mEq/L Ca dialysate resulted in lower levels of iPTH without raising total and albumin-adjusted serum calcium levels and phosphorus levels. Elevated serum Pi positively correlated with iPTH, therefore control of Pi is paramount in achieving control of secondary hyperparathyroidism in ESRD patients.

Session-Board Number: 5b-265

Poster Title: Vitamin D Supplementation in Cancer Patients: Safety and Benefits

Primary Author: Kristin Yin, University at Buffalo, School of Pharmacy and Pharmaceutical Sciences, New York; **Email:** qyin@buffalo.edu

Additional Author (s):
George Nimako
Zachary Wintrob
Alice Ceacareanu

Purpose: The roles of vitamin D in the pathogenesis and progression of cancer and many chronic conditions have been studied in in-vitro, animal and epidemiologic studies. Potential health benefits of vitamin D are receiving increased attention in medical research as well as social media. Due to the conflict in evidence, there is currently no consensus regarding vitamin D recommendations beyond dosages recommended by the Institute of Medicine (IOM), especially in cancer patients. This article reviews both prospective and retrospective studies with supplementation of Vitamin D in cancer populations for efficacy and toxicity.

Methods: Literature search was performed on vitamin D supplements by using PubMed. We selected key terms to capture vitamin D supplementation and cancer outcome. Terms selected included vitamin D and cancer, vitamin D supplementation. We restricted the search to articles published in English, studies of humans, and randomized controlled trials published in the last 10 years. We also manually searched reference list of some retrieved articles for additional studies relevant to the review.

Results: A total of 12 studies were selected for analysis (8 prospective, 3 retrospective, 1 epidemiologic). There are no inherent toxicities observed with supplementing Vitamin D up to greater than 10,000 International Units (IU) daily, but with benefits especially in breast, prostate, and colorectal cancer. Ten of the studies showed inverse association between vitamin D status and risk of cancer occurrence or progression. Five of the studies showed that vitamin D supplementation at doses higher than the current recommended dose by IOM were successful at reaching the primary outcomes. Two studies observed no effect of vitamin D supplementation on cancer outcomes, but concluded that the dose was too low. The most

common expected adverse effects of hypercalcemia and hypercalciuria were rare and precipitated by other co-existing conditions.

Conclusion: The literature shows that supplementing vitamin D at a higher than currently recommended dose has been shown to be safe and without significant related toxicities. Because of its prevalence, ease of detection, array of associated adverse events, and the ease to which it can be supplemented, vitamin D insufficiency should be of concern to all oncologists and proper supplementation to an adequate level should be first priority to better outcomes.

Poster Title: Evaluation of pharmacists' and student pharmacists' perception of the use of a medication therapy management based medication falls risk assessment tool

Primary Author: Collin Clark, The University at Buffalo School of Pharmacy and Pharmaceutical Sciences, New York; **Email:** collincl@buffalo.edu

Additional Author (s):
Scott Monte
Robert Wahler

Purpose: The Medication Falls Risk Assessment Tool (MFRAT) is a prototype clinical decision support tool designed to be integrated into a medication therapy management (MTM) encounter. This tool has been used by students at the University at Buffalo (UB) School of Pharmacy and Pharmaceutical Sciences (SPPS) and by practicing pharmacists in the community. The purpose of this study is to assess users' perceptions of the MFRAT in terms of its usability in workflow, clinical utility, patient usability of the generated reports and technical difficulties encountered. Differences in perceptions of respondents based on users' experience with the tool was also of interest.

Methods: In this UB IRB approved cross-sectional study, a survey of pharmacists and student pharmacists with relevant experience using the MFRAT captured demographic information, number of uses of the MFRAT for each respondent, and a series of Likert scale questions investigating the tools perceived performance in workflow, clinical utility, and patient usability from. Workflow items assessed the compatibility with established pharmacy MTM operations. The clinical utility domain evaluated the tools ability to provide an assessment of a patient's fall risk. The patient usability items probed patients' reaction and ability to use information provided by the tool. Additionally, analysis included grouping respondents into "educational" and "clinical" group based upon the MFRAT application and number of uses. The educational group consisted of third year students who used the tool solely as part of coursework (n=88, mean uses = 1.1) and a combined group with clinical application of the tool (n=26, mean uses = 7.8) which included third year student users as part of a MTM clinic (n=19), fourth year student users completing advanced pharmacy practice experiences (n=3), pharmacists with a Bachelor of Science in Pharmacy degree (n=2), and pharmacists with Doctor of Pharmacy training (n=2).

Differences in positive (strongly agree/agree) and non-positive (strongly disagree/disagree/neutral) responses between groups were analyzed using Minitab 17.0 with the chi-squared and Fisher's exact tests as appropriate.

Results: A total of 131 surveys were sent out during the study period and 114 surveys were submitted for a response rate of 87 percent. Positive responses were the most frequent responses across all three survey domains. Overall, all uses provided positive responses to workflow, clinical utility, patient usability domains which ranged between 65.8% to 82.3%, 52.1% to 85.8% and 73.3% to 86.6%, respectively. When the clinical and educational groups were compared, only two items differed. One workflow item found that the clinical group perceived the rate of data entry improved with more uses of the MFRAT versus the educational group (66.67% vs. 33.33%, p=0.0046). The clinical group also responded more positively when asked about the patient's ability to understand their medication action plans (85.7% vs. 33.3%, p=0.0203). The lowest positive response rate of 51.1% in the clinical utility domain was an item that probed the speed of medication list evaluation and utility to the user. User comments for this domain included that dose and patient comorbidities were not incorporated into the MFRAT. Qualitative feedback on technical difficulties included inability to use the tool with specific operating systems and problems with information input and formatting.

Conclusion: Participants responded positively about the MFRAT's utility in workflow, clinical utility and patient usability. Clinical users of the MFRAT with multiple patient encounters perceived an improved rate of data entry as well as increased patient comprehension of their action plan compared to educational only users. Few significant differences were identified based on grouping with the MFRAT suggesting that the aggregate response data is not skewed by the larger student group. Barriers with this prototype such as incompatibility with certain operating systems were identified. Continued development of the MFRAT is reasonable based on these findings to improve provider and patient satisfaction.

Poster Title: Effects of fructose advanced glycation end products (AGEs) on microglia and neuronal cell lines

Primary Author: Susan DeNapoli, St. John Fisher College, New York; **Email:** smd02656@sjfc.edu

Additional Author (s):
Drew Seidel
Brigit Kirwan
Joy Snyder
Melinda Lull

Purpose: Microglia are innate immune cells in the brain that are responsible for maintaining a healthy environment for neurons. Microglia can become chronically activated which may lead to neuronal damage. Research has shown that sugars can activate microglia. In addition to direct sugar effects, glucose and fructose produce advanced glycation end products (AGEs) during the catabolic process which are known to be damaging to the body. Due to its high reactivity and increasing presence in the American diet, fructose is the focus of this research. The effects of fructose AGEs on microglia and neuronal cell lines in vitro was evaluated.

Methods: Experiments were conducted in rat HAPI microglia and rat B35 neuroblastoma cell lines. Varying concentrations of fructose AGEs were used as treatments for all experiments as follows: 0.8, 0.4, 0.2, 0.1 mcg/mcl. After a specified treatment period (3 or 24 hours), the cells were analyzed using one or more of the following methods: MTT assay for cell death, protein expression via Western Blot, or reverse transcription polymerase chain reaction (RT-PCR) to measure gene expression. The protein of interest for the western blot analysis was the receptor for AGEs (RAGE). The following genes were measured using RT-PCR: RAGE, sweet taste receptor (Tas1R3), nuclear factor kappa B (NFkB), and enolase 2 (ENO2). Microglia and neurons were analyzed after direct treatment. To assess the impact of microglial activation on neuronal function and survival, HAPI microglia were treated first and incubated for varying time intervals (3 to 24 hours). After the desired time, the cell culture media was removed from the HAPI cells and placed onto the B35 cells for 24 hours to examine the effects of soluble factors released by microglia (a surrogate co-culture method) using the methods listed above.

Results: Direct treatment of neurons with fructose AGEs showed variable effects on cell survival, with the 0.2 mcg/mcl dose significantly decreasing cell survival, and higher doses having no significant change in survival. However, the co-culture of neurons and microglia soluble factors showed improved survival, up to a 17% increase in the 0.4 mcg/mcl treatment. Next, gene expression was examined to look for changes in neuronal function. Direct fructose AGE treatment on neurons increased RAGE expression by up to 15%, while decreasing ENO2 by up to 37%. Expression of NFkB remained largely unchanged. Co-culture treatment of neurons and microglia soluble factors decreased expression of RAGE (up to 39%) and NFkB (up to 29%). Expression of ENO2 in this experiment was decreased by 12% and 26% in the 0.8 mcg/mcl and 0.1 mcg/mcl doses, respectively, but was unchanged at medium concentration doses. In microglia treated directly with fructose AGEs, protein expression of RAGE was also measured. Results showed a decrease in levels of glycosylated (mature) RAGE by up to 59%, of unglycosylated RAGE by up to 39%, and of degraded RAGE by up to 52%.

Conclusion: Normal fructose metabolism produces AGEs, which can be harmful to the body. It is hypothesized that accumulation of these AGEs plays a role in neurodegenerative diseases. The results of this research were conflicting. Certain markers, NFkB and RAGE, revealed there was damage to the neurons. On the other hand, ENO2 results implied there was an increase in survival. These results suggest that microglia may be releasing molecules that are harming neurons or causing cellular dysfunction, but not causing them to undergo apoptosis. Further studies will elucidate the exact mechanisms that altered cell function.

Poster Title: Use of intravenous lidocaine for ankle fracture and dislocation

Primary Author: Kimberly Koop, Long Island University, Arnold & Marie Schwartz College of Pharmacy and Health Sciences, New York; **Email:** kimberly.koop@my.liu.edu

Additional Author (s):
Grace Tam
Billy Sin
Diana Gritsenko
Eva Mok

Purpose: This case report illustrates the safe and effective use of intravenous lidocaine in a patient with acute pain secondary to ankle fracture. A 17-year-old Asian male (100kg, 188cm) presented to the Emergency Department (ED) from school with a chief complaint of severe pain and distress secondary to left ankle and foot deformity. The patient was playing volleyball at school and injured his ankle from an awkward landing. In the field, the ankle was immobilized and an ice pack was applied. Upon arrival to the ED, patient was crying in acute distress, tachypneic, and reported a pain score of 10/10. His past medical history was not significant. Upon physical examination, all parameters were within normal limits with positive findings of a deformed left ankle. Upon further examination of the ankle, there was severe swelling, limited range of motion, and intact skin with soft tissue tenderness. The dorsalis pedis pulse was felt with sensation intact. No other injuries were noted on the left leg. After the physical examination, the ED clinical pharmacist conducted an extensive bedside medication reconciliation and allergy review. There were no known drug allergies and the patient was not on any medications at home. No use of herbal supplements or over-the-counter medications was reported. Initial X-ray imaging of the ankle noted a possible fracture through the body of the talus and a complete medial subtalar dislocation. Morphine 4mg intravenous push (IVP) was immediately administered for pain control. Fifteen minutes after morphine, SK was still diaphoretic, crying in severe distress, and reported a numeric pain score (NRS) of 10/10. Since SK did not respond to initial therapy, a decision was made to initiate lidocaine at 1mg/kg/dose (total dose 100mg) IV piggyback over 15 minutes for pain. Prior to administration of lidocaine, the pain score was 10/10. Five minutes after lidocaine was administered, the pain decreased to 6/10. At 20 minutes, the pain score was 3/10 and remained 3/10 until 75 minutes after

initiation of drug (IOR). His blood pressure and respiratory rate decreased to normal limits and no arrhythmia was noted on the monitor. No adverse events were reported. Patient appeared comfortable and manipulation of his ankle for examination by podiatry was performed. At 90 minutes post-infusion, his pain was 9/10 and he required rescue analgesia with morphine 4mg IVP and ketorolac 30mg IVP. Shortly after, podiatry performed closed reduction of ankle under conscious sedation with fentanyl and midazolam. Posterior splint was applied and patient was discharge home with follow-up to clinic. In this case, the utilization of intravenous lidocaine was safe and effective for the management of acute pain secondary to trauma. Our case report adds to the limited available literature and highlights the importance of bedside patient care from pharmacists to identify and alternative agents to provide safe and effective analgesia in the ED.

Poster Title: Poly lactide-co-glycolide (PLGA) microcapsules for controlled delivery of buprenorphine

Primary Author: DeMaurian Mitchner, Xavier University of Louisiana, Louisiana; **Email:** dmitchne@xula.edu

Additional Author (s):
Richard Graves
Grace Ledet
Levon Bostanian
Tarun Mandal

Purpose: Buprenorphine hydrochloride is an opioid medication used in the treatment of opioid addiction. A controlled release formulation of buprenorphine may improve the effectiveness of the compound by reducing the potential for abuse and reducing variations in efficacy. The purpose of this study was to investigate the applicably of utilizing our patented microencapsulation technique to prepare a 30-day sustained release microcapsule injectable formulation.

Methods: In this study, a modified double emulsion solvent evaporation technique was utilized to produce poly lactide-co-glycolide (PLGA) loaded microcapsules with buprenorphine hydrochloride intended for an extended 30-day release formulation. Two ester-terminated PLGA polymers, a 7,000-17,000 molecular weight polymer and a 54,000-69,000 molecular weight polymer, and an acid-terminated 7,000-17,000 molecular weight PLGA polymer were formulated with three drug loadings (5 percent, 10 percent, and 20 percent weight/weight) of buprenorphine hydrochloride. The freeze-dried formulations were evaluated for their physical properties (morphology, particle size distribution, and thermal properties), and drug loading and drug release profiles were determined.

Results: All ester-terminated formulations resulted in particles which were smooth and spherical, but some contained a small percentage of broken particles. The acid-terminated formulations had only a small number of smooth spherical particles with the bulk containing small, irregularly shaped particles and porous spheroids. Encapsulation efficiency ranged from

49 percent, for the high molecular weight ester-terminated PLGA particles with 10 percent drug loading, to a high of 73 percent, for the high molecular weight ester-terminated PLGA particles with 20 percent drug loading. Both ester-terminated polymers exhibited a delayed drug release with the bulk of drug release occurring after 8 days. The acid-terminated polymer, however, displayed a much more rapid release with the bulk of release drug occurring in the first 12 days. The total drug released from the acid-terminated polymer was low with no more than 25 percent drug release in the 30-day study period. The total drug release from the ester-terminated polymers ranged from 40 percent to 95 percent.

Conclusion: This patented formulation technique appears well-suited for the preparation of controlled release buprenorphine microcapsules. The optimal polymer for further study as a controlled release buprenorphine microcapsule formulation is the low molecular weight ester-terminated PLGA polymer, while a combination of the low molecular weight ester-terminated and the acid-terminated PLGA may result in a more sustained release over the entire 30-day study period.

Poster Title: The identification of estrogen active chemicals in a pharmaceutical database using a novel pharmacophore paired docking search method

Primary Author: Gerald Guirard, Xavier University of Louisiana College of Pharmacy, Louisiana; **Email:** gguirard@xula.edu

Additional Author (s):
Tamara Mitchell
Peng Ma
Thomas Wiese

Purpose: The application of virtual screening methods to identify estrogenic chemicals in databases of commercially available chemicals continues to be a challenge. We test the hypothesis that pharmacophore models coupled with ligand-receptor docking can identify estrogen active substances in a database of pharmaceutical chemicals.

Methods: Of the many Estrogen Receptor alpha Ligand Binding Domain (ERLBD) crystal structure complexes in the RCSB Protein Databank, most contain novel ligands. Taken together, all of these ERLBD ligand complexes represent a wide range of ligand-receptor interactions and binding pocket configurations. Thus, there is the potential to use each ERLBD complex as a unique pharmacophore model along with docking for virtual screening. Such a method should have higher reliability than docking alone since all of the experimentally determined ER ligand binding modes would be described from both ligand and receptor points of view in the screening process. In this study, multiple ERLBD crystal structure complexes containing novel ligands were each used to generate pharmacophore models that were then coupled sequentially with docking to the corresponding crystal structure in a virtual screening method. The NCGC Pharmaceutical Database (NCP) from the NIH NCATS was filtered by size and washed to remove counter ions using MOE (Chemical Computing Group). Reasonable 3D structures were then generated with Corina (Molecular Networks) and optimized in MOE (MMFF94). Screening of the NCP subset database with the Pharmacophore-Dock method using MOE produced hits that were then sorted by score.

Results: The highest scoring hits from the screen were selected for estrogen potential. These were then sorted and prioritized by relevance (current use pharmaceuticals or components) and obtained (when available) for validation testing in a cell-based estrogen responsive reporter gene bioassay. Compounds in the database with weak or previously uncharacterized estrogen activity were identified along with known estrogen agonist and antagonist drugs (positive controls). The database hits obtained for validation testing that induced estrogen agonist activity included propylparaben, ethylparaben, hexylresorcinol, genistein, resveratrol and monobenzone. Risocaine and tiabendazole did not produce agonist activity on their own, but induced synergistic effects once combined with estradiol. Methylparaben and dapsone were found to have antagonist activity.

Conclusion: The virtual screening process applied in this study appears to have utility in identifying estrogenic chemicals in large databases. This method has revealed compounds in current use pharmaceuticals or in clinical testing that have endocrine disrupting potential. Endocrine disrupting chemicals have been reported to cause birth defects, developmental disorders and may be related to the progression of hormone dependent cancer. Pharmacotherapies including the compounds identified in this study should likely be evaluated for hormonal disrupting impact on patients.

Poster Title: Framing a pharmacy student congress from the pharmacy students' perspective

Primary Author: Michael Aiello, St. John's University, New York; **Email:** michael_aiello@outlook.com

Additional Author (s):
Donna Sym
Anthony Marziliano
Marc Gillespie

Purpose: Student governments are essential components to the development of leadership skills and work toward driving student involvement in, and responsibility for, their own education. In this study we surveyed pharmacy students to identify the key aspects of pharmacy student government that impact student participation. Our aim was to identify a student government framework that students envision to identify an optimal model for a College of Pharmacy.

Methods: An online survey, focused on communication, inclusion, structure and function of a pharmacy student government, was developed and distributed to the acting pharmacy student presidents of The Rho Chi Society (pilot survey) and the current pharmacy students of St. John's University (follow-up survey). The pilot survey was distributed to 105 acting pharmacy student presidents of the Rho Chi Society, resulting in 33 responses. The follow-up survey was later distributed to 1139 current SJU pharmacy students, enrolled in years P3 through P6, resulting in 166 responses. SJU student responses were also compared to student presidents of The Rho Chi Society responses. Survey results have been anonymized and date reported aggregately. This study was reviewed by the SJU Institutional Review Board and was approved receiving exempt status.

Results: Over 85% of pharmacy students surveyed supported a pharmacy-specific student congress independent of a campus wide student government body. The majority of students indicated that a pharmacy student congress should include students in years P1 through P4 for membership, with an executive board consisting of a President, Vice President, Secretary, Treasurer and Student Class Representatives. Students selected a 3.0 minimum GPA required

for eligibility to be a member or to hold an executive board position. Elections for executive board positions would be held yearly. Students were also asked if a pharmacy student congress should develop a mentor/mentee program. An overwhelming 96% said yes and P3 students were identified as ideal mentors, with P1 students selected as benefitting the most from mentorship. The survey also asked the preferred process (i.e. appointment vs. election) in selecting students to serve on college committees. The majority of students (69%) preferred the election process and for students, faculty, and student, advisors to participate in this election. Improving communication between faculty and pharmacy students was cited as the most important factor in improving communication within a college of pharmacy. Email and text messaging were identified as most preferred for communicating high priority information to pharmacy students.

Conclusion: Our findings indicate that SJU pharmacy students want a dedicated and separate pharmacy student congress. Designing a pharmacy student congress based on the recommendations of these students may encourage them to participate in this congress fostering an environment to learn, develop and reveal leadership skills.

Poster Title: Cost effectiveness of lenalidomide maintenance after autologous stem cell transplant in patients diagnosed with multiple myeloma

Primary Author: Mary Allison, University of Louisiana at Monroe School of Pharmacy, Louisiana; **Email:** marygrace.allison13@gmail.com

Additional Author (s):
Elizabeth Stephenson
Jill Comeau
Scott Baggarly

Purpose: Lenalidomide, an immunomodulatory agent, is a common medication utilized in induction therapy for the treatment of multiple myeloma in both transplant and non-transplant candidates. In addition, single agent lenalidomide is a category 1 preferred recommendation per NCCN guidelines for maintenance therapy to delay relapse and prolong remission. To our knowledge, no current pharmacoeconomic studies have assessed the cost effectiveness of maintenance lenalidomide after autologous stem cell transplant. Also, overall survival outcomes vary amongst clinical trials. Lenalidomide maintenance remains a controversial topic due to outcomes, side effects including an increased risk of malignancies, and long-term cost.

Methods: The project was approved by the University Institutional Review Board. Our study analyzed two randomized control trials, Attal et al. and McCarthy et al., investigating efficacy of maintenance lenalidomide after autologous stem cell transplantation. We modeled cost-effectiveness analyses on previous studies of lenalidomide maintenance in non-transplant candidates. Using drug costs, office visit expenses, and lab costs, the average cumulative cost per progression free survivor (ACCPFS) was assessed. Medication costs from Redbook were used to determine total cost of lenalidomide capsules. Medicare and Medicaid HCPC (healthcare common procedure coding) and corresponding pricing were used to determine physician office visit and lab monitoring costs. Though the length of multiple myeloma maintenance is dependent on a patient's individualized disease course, we used a duration of three years in order to compare outcomes of the two studies. Prescription drug and physician service expenses were adjusted from 2011 to 2015 dollars using the consumer price index (CPI). The primary outcome for the analysis was incremental cost-effectiveness ratio (ICER)

comparing the maintenance lenalidomide versus placebo. ICER was computed for two similar clinical trials utilizing treatment costs for three years and progression free survival (PFS) at three years.

Results: Data from Attal et al. and McCarthy et al. allowed separate economic analyses of ACCPFS and ICER. For Attal et al., total costs per progression free survivor for 3 years in terms of drug, office visits, and labs were $694,500.09, $1091.11, and $1474.34, respectively. For McCarthy et al., total costs per progression free survivor for 3 years in terms of drug, office visits, and labs were $703,510.58, $1091.11, and $993.86, respectively. The ACCPFS combined these expenses for maintenance lenalidomide patients: $697,065.54 (Attal et al.) and $705,604.55 (McCarthy et al.). Drug expenses were omitted to determine the ACCPFS for the placebo group. Placebo costs per progression free survivor totaled $2565.45 (Attal et al.) and $2084.97 (McCarthy et al.). For Attal et al. and McCarthy et al., PFS at 3 years for lenalidomide maintenance (0.59 and 0.66) and placebo groups (0.35 and 0.39) was the outcome used to calculate the ICER for each study. Calculated ICER values were $2,893,750.38 (Attal et al.) and $2,605,628.07 (McCarthy et al.) per additional progression free survivor at 3 years.

Conclusion: This analysis highlighted the costs and improved PFS associated with maintenance lenalidomide compared to placebo. ICER values were large and positive, indicating that lenalidomide was more effective but with exorbitant costs for each additional progression free survivor at 3 years. Limitations noted in this analysis were the following: no analysis of adverse effects or quality of life, inconsistency of drug strengths and anticoagulation, and assumptions about treatment protocol. Future research to determine willingness to pay, allowing incremental net benefit analyses, would provide additional insight into the use of lenalidomide in multiple myeloma maintenance.

Poster Title: Oral anticoagulants in subjects eligible for bariatric surgery

Primary Author: KwanNok Leung, State University of New York at Buffalo, New York; **Email:** kwannokl@buffalo.edu

Additional Author (s):
Qing Ma
Joseph Caruana
Scott Monte

Purpose: Novel oral-anticoagulants (NOACs) have come into favor due to lack of monitoring requirements and favorable drug interaction profile versus warfarin. While many have benefited knowledge gap exists for safety and efficacy in people undergoing bariatric surgery. NOAC manufacturers note up to 60% reduction in AUC when delivered to the distal small intestine. Given anatomic and physiologic changes of the gastrointestinal tract after Roux-en-Y gastric bypass (RYGB) and Sleeve Gastrectomy (SG) potential exists for altered absorption. The purpose of this study was to characterize anticoagulation treatments of subjects presenting for bariatric surgery and to follow medication use and outcomes after surgery.

Methods: The protocol was approved by the State University of New York at Buffalo Institutional Review Board. A retrospective review was performed of patients presenting for bariatric surgery from 2014-2016. Subjects were included if they met age, body mass index and/or co-morbidity criteria for surgery. The primary outcome was prevalence of warfarin and NOACs at initial surgery evaluation. Secondary outcomes were post-surgical use of warfarin and NOACs including the percentage of patients that remained on warfarin or NOAC, converted from warfarin to NOAC or NOAC to warfarin and those that discontinued therapy. Safety and efficacy measures included major bleed requiring hospitalization, venous thromboembolus (VTE), stroke and mortality with a minimum follow-up period of 30-days.

Results: A total of 1298 patients met criteria for review. Twenty-seven subjects presented on oral anticoagulants at initial evaluation, 17 (63 percent) presented on warfarin and 10 (37 percent) on NOACs. NOACs included rivaroxaban (50 percent), apixiban (40 percent) and dabigatran (10 percent). Among the 27 patients, 11 (41percent) presenting for initial evaluation

did not proceed to surgery and the remaining 16 subjects underwent SG. Nine subjects (90 percent) remained on warfarin while one discontinued therapy after surgery. Two subjects (33 percent) remained on NOAC while two (33 percent) converted from warfarin to NOAC, one converted from NOAC to warfarin and one discontinued after surgery. No subjects had major bleed requiring hospitalization, VTE or stroke. No subjects died. Median follow-up duration was 237 days (range 43-456).

Conclusion: NOACs represented one-third of anticoagulant use in subjects presenting for bariatric surgery. After surgery treatment plans for subjects on NOACs were variable with an equal number maintaining pre-surgery NOAC and converting to warfarin. No bleeding or thrombotic outcomes were observed for subjects maintained on warfarin, NOAC, those therapeutically interchanged or discontinuing therapy. Efforts to combine data from high volume bariatric centers should be made to confirm the preliminary suggestion from this study that NOACs may be safe and effective after SG. RYGB was not represented and should be targeted given expectation that medication delivery is more distal than Sleeve Gastretomy..

Poster Title: Weight and metabolic outcomes of patients managed through gastric bypass and traditional care in a patient-centered medical home

Primary Author: Courtney Cardinal, University at Buffalo School of Pharmacy and Pharmaceutical Sciences - SUNY, New York; **Email:** cmcardin@buffalo.edu

Additional Author (s):
David Jacobs
Joseph Caruana
Scott Monte

Purpose: Gastric bypass (GB) has been widely studied and reproducibly provides profound benefits on weight loss, blood pressure, cholesterol, blood glucose, cardiovascular events and medication requirements. Mortality is less than 0.5%. Paradoxically, less than 1% of obese adults seek consultation. This information should be of great interest to providers in health care models where disease prevention, outcomes and cost are paramount. While there is little need to add to an already substantial evidence base for disease modifying effects of GB, this study aims to bring awareness by presenting usual care and GB outcomes through the lens of a patient-centered medical home.

Methods: The protocol was approved by the State University of New York at Buffalo Institutional Review Board. A retrospective review was conducted by combining data from one patient-centered medical home and one bariatric surgery center in Buffalo, NY. Subjects that had gastric bypass were matched 1:1 with controls not undergoing surgery on the basis of gender, age ± 5-years and BMI ± 5 kg/m2. The primary outcome was the difference in excess body weight loss over 5-years of follow-up. EBWL is defined as the percentage of excess weight lost where excess weight is calculated as the total pounds above ideal body weight. Secondary outcomes included changes in T2DM, HTN and HLD disease status and medication use. Interim analysis of 1-year weight and medication outcomes are presented. Categorical variables were analyzed using Chi-square tests and continuous variables were compared with the Student's t-test. A $p < 0.05$ was considered significant.

Results: 162 RYGB and obese control subjects were included in the 1-year analysis. RYGB subjects had significantly greater EBWL at 1-year than their matched counterparts (41.0±8.7 vs. -0.95 ±9.5; p < 0.0001). RYGB subjects lost an average of 97.4 ± 30.0 pounds whereas obese controls gained 1.0±20.0 pounds (p < 0.0001). RYGB subjects on ACEI/ARB reduced use by 14%, statin by 10% and both basal and bolus insulin by 14%. Obese controls increased ACEI/ARB use by 1%, statin by 4%, basal insulin by 7% and bolus insulin by 3%.

Conclusion: This is the first study to report real-world comparative long-term outcomes of obese control and RYGB subjects managed in a patient-centered medical home. Primary care providers can expect that obese subjects in their population will not lose weight or gain slightly over a 1-year period whereas those undergoing GB will lose over 40% their excess body weight. Obese subjects will continue to maintain or require addition of ACEI/ARB, statin and insulin medications whereas RYGB subjects will have a reduction in these medication requirements.

Poster Title: Impact of a novel digital education process on hospital readmissions in kidney transplantation

Primary Author: Kimberly Lapierre, St. John's University College of Pharmacy and Health Sciences, New York; **Email:** kimberlylapierre1@gmail.com

Additional Author (s):
Demetra Tsapepas
Nicholas Jandovitz
Sara Hammad
David Salerno

Purpose: Early hospital readmissions within the first 30 days of discharge from the index admission for kidney transplantation are common. Furthermore, these episodes may be costly and are associated with morbidity and mortality. The most common reasons for readmission include rejection, infection, and failure to thrive. Poor health literacy and knowledge about medicines has been shown to be a predictor of hospital readmission. Through integration of technology into patient medication teaching, pharmacists have the unique ability to positively affect readmission rates. The impact of a digital medication teaching tool on readmission rates and related outcomes was evaluated.

Methods: Single-center, retrospective analysis of 312 adult (greater than 18 years) patients who received a kidney transplant only from January 2015 through July 2016. Medical charts were reviewed for demographic and transplant characteristics, hospital readmissions from the time of transplant through August 2016, and reason for readmission. Patients were stratified into two groups: intervention group, those who received digital tablet medication teaching in combination with in-person follow-up (n equals 189) and control group, those who received standard in-person medication teaching (n equals 123). Groups were examined for differences between readmission rates, time to first readmission after transplant, reasons for readmission, and patient and allograft outcomes.

Results: The study population consisted of primarily Caucasian (42.9 percent), male (61.9 percent) recipients with the majority of patients receiving dual maintenance immunosuppression with tacrolimus and mycophenolate sodium. The average length of stay for the index hospitalization was 9 days and 12 days for the intervention and control groups, respectively. Patients were more likely to have at least one early hospital readmission in the control group vs. the intervention group (35.8 percent vs. 27.5 percent). The average time to readmission was 58 days for the intervention group and 99 days for the control group. The control group was readmitted for GI disturbances, fever, elevated serum creatinine, and urinary tract infection more frequently than the group who received digital tablet education. During a mean follow-up of 287 days, 95.2 percent of patients of the intervention group had functioning grafts as compared to 93.5 percent of the control group. At the end of the study period survival rates were comparable between the intervention and control groups (97.9 percent vs. 96.8 percent).

Conclusion: Our novel digital medication teaching regimen tool provided a consistent message, enabled repeat sessions, and included knowledge assessment. The rate of rehospitalization in kidney transplant recipients was reduced in patients who received digital medication teaching. These results suggest that the use of digital technology to educate patients may reduce early hospital readmission, although more data is necessary to form concrete associations.

Poster Title: Olanzapine-induced seizure: a case report

Primary Author: Gretchen Marcelino, Touro College of Pharmacy, New York; **Email:** gmarceli@student.touro.edu

Additional Author (s):
Talin Mehranian
William Olsufka
Mary Choy
Martha Rumore

Purpose: Olanzapine is an atypical antipsychotic commonly used to treat schizophrenia and/or bipolar disorder. This case report describes a 19-year-old male who developed a new-onset seizure after starting olanzapine. The patient had no history of seizures prior to admission. He presented to the psychiatric unit with a diagnosis of unspecified psychosis versus schizophrenia versus schizoaffective disorder. His past medical history includes glucose-6-phosphate-dehydrogenase deficiency (G6PD), eczema, and thyroid dysfunction. His past psychiatric history consists of schizophrenia and autistic spectrum disorder. A number of different antipsychotics have been used in his treatment including haloperidol, chlorpromazine, risperidone, quetiapine, ziprasidone, and fluphenazine. The patient was only able to tolerate olanzapine but stated he was non-adherent and could not recall when he had stopped the medication. For the past five months, he was also taking clonazepam 1 mg three times daily, which he had stopped four days prior to admission. On admission, the patient was re-initiated on olanzapine 5 mg every 12 hours and daily folic acid supplementation. The olanzapine dose was increased to 15 mg daily (5 mg in the morning and 10 mg at bedtime). Four days after the increased dose, the patient had a generalized tonic-clonic seizure lasting about 1.5 minutes with a bitten tongue. The patient's vital signs were: blood pressure 124 mmHg / 68 mmHg, heart rate 136 bpm, fasting sugars 106 mg/dL, 98% oxygen on room air, and respiratory rate 16 bpm. The patient's initial rhythm was sinus tachycardia. When the rapid response team arrived, he had an altered state of consciousness, but was no longer seizing. Subsequently, two doses of intravenous (IV) lorazepam 2 mg and a 1 liter bolus of normal saline were given. He was then transferred to the medical floor for a neurological work-up. Labs drawn post-seizure showed elevated lactic acid (13.3 mmol/L) and bicarbonate (7 mmol/L) likely secondary to seizure activities. His arterial

blood gas and lactic acid level (1.9 mmol/L) improved with normal saline. A magnetic resonance imaging (MRI) performed one day post-seizure showed unremarkable findings; however, there were no baseline MRIs. An electroencephalogram (EEG) was performed two days after the seizure occurred and did not show any seizure or epileptiform features. Due to the patient's unstill behavior, a computerized tomography (CT) scan was not performed. The neurology team recommended the patient to continue olanzapine due to history of intolerance with other antipsychotics. The recommendation was accepted and clonazepam 1 mg every 12 hours was initiated three days post-seizure. However, the patient showed continued agitation, which led to a discontinuation of clonazepam and initiation of valproic acid 500 mg and chlorpromazine 50 mg twice daily for impulsivity and agitation. Upon review of the medication reconciliation the patient did not receive any new medications that could have induced the seizure. He had been consistently receiving folic acid and olanzapine while last receiving an "as needed" dose of haloperidol 5 mg and lorazepam 2 mg five days prior to the seizure. The urine toxicology and alcohol level were negative upon admission. The patient had no recurrence of seizures with this combination. One month later, the patient's most current medications consist of chlorpromazine 100 mg twice daily, valproic acid 750 mg every 12 hours, propranolol 10 mg three times daily, olanzapine 5 mg in the morning, 5 mg at 2:00 pm and 10 mg at night. A Naranjo adverse drug reaction probability score of 5 was obtained, indicating olanzapine as a probable cause of his seizure. Although more study is needed to further strengthen this potential causal relationship, it is important for healthcare providers to inquire about this risk with olanzapine therapy in the adolescent/adult population.

Poster Title: Prevalence of influenza vaccination and awareness of influenza on a college campus

Primary Author: Meghin Cocca, D'Youville College School of Pharmacy, New York; **Email:** meghincocca02@gmail.com

Additional Author (s):
Lauren Donohue
Devlynn Chlebowy
Nicole Cieri
Stephanie Brian

Purpose: The close-living quarters and volume of students present on college campuses creates an ideal environment for the spread of the influenza virus. The objective of this project was to investigate the prevalence and awareness of influenza vaccinations among students, faculty and staff on the D'Youville College campus, in Buffalo, NY. D'Youville College is unique in that it educates a variety of health professions including chiropractic, dietetics, nursing, occupational therapy, pharmacy, physician assistant, and physical therapy. The primary outcome was to identify factors that are associated with an increased likelihood that an individual will receive an annual influenza vaccination.

Methods: An anonymous, electronic survey was created with questions regarding demographic information, influenza vaccination information, and influenza awareness. This survey was sent to all students, faculty and staff at D'Youville College using an automated emailing system. The system reaches 2494 students, 860 faculty members and 366 staff members, for a total of 3,721 people. The survey was available from October 26, 2015 until November 23, 2015. The data was collected and analyzed using QualtricsTM software. Data were reported utilizing descriptive statistics for awareness of influenza vaccinations and associations between factors that may increase the likelihood of an individual to receive a vaccination. Several demographic factors were analyzed (age, ethnicity, academic standing, etc). Awareness questions included, "Per CDC guidelines, what age group is eligible to receive the influenza vaccine," "How many people are hospitalized each year with complications from influenza," "How long is an individual contagious after signs and symptoms of the flu have appeared," and "If someone does not have

any signs and symptoms of the flu, it is possible to infect other individuals." The factors analyzed for faculty and staff were similar to those analyzed for students, but looked at the department with which they were associated instead of major or academic standing.

Results: The primary outcome was identification of factors associated with an increase in the likelihood of an individual to receive an influenza vaccination. Out of 3,721 people that received the survey, 426 people responded; response rate of 11.4%. It was found that graduate students and upperclassmen were more likely to receive the influenza vaccination (67%) compared to lower class standings (7%). Those that received the vaccine for the 2015-2016 season, were more likely to have received the vaccine for the previous season (2014-2015), 87% vs. 41%. Several responses regarding why a participant chose not to be vaccinated were found to be common misconceptions; "makes me sick," "don't know why I need it," or "not effective." Participants who received the influenza vaccination were able to answer the awareness questions correctly more often than those who did not receive the vaccine. For example, 79% of people who received the vaccine knew the recommended age to receive the vaccine, while only 63% of people who did not receive the vaccine answered correctly. Encouragingly, it was found that 94% of participants knew they could receive their influenza vaccine at a community pharmacy and 50% of participants received their vaccination in a community pharmacy.

Conclusion: Influenza awareness is an important topic on college campuses. It was identified that older class standing may be associated with an increased likelihood of an individual to receive an influenza vaccination. In addition, a large number of participants knew they could receive an influenza vaccination in a pharmacy. This alludes to a positive awareness among patients that influenza vaccinations are available in community pharmacies. Further research may be warranted to elucidate other factors associated with an increased likelihood of an individual to be vaccinated. In addition, research into pharmacist's association with vaccine awareness in the community may also be beneficial.

Poster Title: Vancomycin-induced drug reaction with eosinophilia and systemic syndrome (DRESS): A case report

Primary Author: Halie Verret, University of Louisiana at Monroe - School of Pharmacy, Louisiana; **Email:** verrethe@warhawks.ulm.edu

Additional Author (s):
Shelby Cranfield
Liz Lafitte

Purpose: The authors report a possible case of vancomycin-induced drug reaction with eosinophilia and systemic symptoms (DRESS). DRESS, although a rare occurrence, is a severe adverse drug reaction associated with fever, skin rash, eosinophilia, enlarged lymph nodes, and organ involvement. The patient is a 64-year-old female with a past medical history of diabetes, hypertension, chronic obstructive pulmonary disease, and hyperlipidemia who underwent a right total knee arthroplasty in April 2016 and was discharged three days later. She presented to the emergency department twenty-three days later with complaints of drainage at the surgical site and was started on empiric treatment with vancomycin and piperacillin/tazobactam pending culture and sensitivity results. Her antibiotic regimen was de-escalated on day 2 to vancomycin and ceftazidime when her blood cultures showed methicillin-resistant Staphylococcus aureus. The patient underwent irrigation and debridement of the site on days 3 and 10 of admission, where removal of the implant and placement of a non-biodegradable temporary tobramycin and vancomycin cement was placed on day 10. After placement of a PICC line, the patient was discharged on day 13 with intravenous vancomycin to be given for six weeks. After twenty-six days of vancomycin therapy the patient developed a red macular/morbilliform, erythematous, blanching rash on her groin, abdomen, and arm. On day thirty-six she was instructed to stop taking the vancomycin and received a new regimen for clindamycin, minocycline, and sulfamethoxazole/trimethoprim DS for which she only took two doses before returning to the emergency department with the rash now spread to all four extremities and her face. In addition to the full-body rash, the patient reported small blisters to her legs and lips that resolved prior to presentation. Labs were collected to assess hematologic abnormalities and signs of organ dysfunction. Pertinent findings that are consistent with the diagnosis of DRESS include slightly elevated temperatures ranging from 98.9°F to 101°F,

creatinine of 2.10 mg/dL (baseline 0.5-0.6), BUN 29 (baseline 7), CRP 6.4 mg/dL, and WBC of 24.6 K/μL with eosinophilic predominance of 15,000 K/μL. In contrast to typical DRESS findings, the patient did not have any elevations in liver enzymes. The more recently prescribed antibiotics were ruled out as a potential cause for DRESS due to their short duration of use and the patients report that her rash had progressed 2-3 days prior to their ingestion. The patient was placed on high-dose oral steroids (methylprednisolone 60 mg twice daily) with close blood sugar monitoring and discharged seven days later with a six-week taper and orders for follow-up. At her clinic appointment in July 2016 she had complete resolution of symptoms. As this case report suggests, vancomycin is the likely culprit for DRESS and recognition of these adverse effects should be sought early-on to prevent permanent organ dysfunction, patient decline, and associated mortality.

Poster Title: Prolonged asymptomatic Mycobacterium avium-intracellulare Complex (MAC) infection and potential reactivation disease in an HIV-negative patient

Primary Author: Sara Elsayed, Xavier University of Louisiana, Louisiana; **Email:** selsayed@xula.edu

Additional Author (s):
Alaina DeKerlegand
Anthony Poche
Ifeanyi Onor

Purpose: Non-tuberculous mycobacterial (NTM) infections such as Mycobacterium avium-intracellulare (MAC) are most common among immunocompromised HIV-positive patients. Infections are uncommon among HIV-negative/immunocompetent patients, but recent evidence shows an increasing prevalence. Unlike Mycobacterium tuberculosis (TB), NTM transmission occurs through environmental sources, and NTM organisms do not enter a latent stage (with subsequent reactivation disease) as seen in TB. Current evidence shows that cavitary MAC lung disease is typically a fast-progressing infection, leading to destruction of lung tissue and eventual respiratory failure within two years if left untreated. We present a case of prolonged asymptomatic Mycobacterium avium-intracellulare Complex (MAC) infection in an HIV-negative patient. The patient was a 53-year-old homeless male who presented with a chief complaint of shortness of breath for three weeks. He also reported night sweats, poor appetite, and subjective fevers without hemoptysis. Upon hospital admission, the patient had three positive Systemic Inflammatory Response Syndrome (SIRS) criteria and two positive quick Sepsis-Related Organ Failure Assessment (qSOFA) criteria. Although some SOFA criteria were unavailable, the patient still had a score of 3 indicating potential sepsis using this scale as well. The patient was administered NaCl 0.9% 1000 mL intravenous bolus on admission for fluid resuscitation due to sepsis and hypotension. Vancomycin, piperacillin-tazobactam, and ciprofloxacin were initiated as empiric therapy for suspected bacterial pneumonia-induced sepsis. Patient chart review showed a past medical history of chronic obstructive pulmonary disease (COPD) and a diagnosis of MAC three years prior without completion of appropriate therapy. During a previous hospital admission one-month prior, a chest CT was performed which showed a cavitary focus within the left upper lobe with surrounding regions of airspace

disease and diffuse pleural thickening. After discovering his past medical history, new radiographs and laboratory tests were obtained to diagnose continued MAC infection. Current chest X-Ray showed pleural-parenchymal opacities in the left apex, which were concerning for mycobacterial disease. Two induced-sputum acid-fast bacilli smears were collected and culture results were positive for Mycobacterium avium-intracellulare Complex. After X-Ray and culture results confirmed continued MAC infection, empiric pneumonia therapy was discontinued. He was then initiated on azithromycin 250 milligrams (mg) intravenously, ethambutol 1,200 mg (15mg/kilogram) by mouth, and rifampin 600 mg by mouth daily. After two days of inpatient treatment, the patient was discharged with prescriptions for these medications as daily oral therapy to be continued for at least 12 months after the first negative induced-sputum culture. Our team counseled him on the severity of his infection, importance of compliance with medications, and referred him to an outpatient clinic for follow-up. Our patient's current homeless status potentially created a greater risk of exposure to environmental contaminants, and COPD made him more vulnerable to development of MAC pulmonary disease. This patient had an untreated MAC infection for at least three years, with radiographic evidence of cavitation. Against typical expectation for progression in cavitary MAC infection, this patient did not present with evidence of severe lung destruction or respiratory failure. Although latency would not be expected with MAC, due to preservation of lung function, it is possible that the MAC infection in this patient became latent, delaying progression to respiratory failure. After discontinuation of COPD maintenance medications a few months prior to admission, the increase in COPD symptoms could have contributed to the reactivation of a potentially latent MAC infection. Studies indicate that NTM infections occur anywhere from 1 to 14.1 times in 100,000 person-years. Although they are relatively rare in immunocompetent patients, it is important for clinicians to understand that prevalence is rising, especially among individuals with chronic lung disease or those without access to purified drinking water.

Poster Title: Barriers to metformin usage amongst type 2 diabetic patients in a rural Hispanic population

Primary Author: Alaina DeKerlegand, Xavier University of Louisiana College of Pharmacy, Louisiana; **Email:** adekerle@xula.edu

Additional Author (s):
Donyika Joseph
Hannah Naquin
Lovie Rodgers

Purpose: The American Diabetes Association (ADA) and the Latin American Diabetes Association (LADA) recommend Metformin use, along with lifestyle modifications, as first-line treatment for type 2 diabetes mellitus (T2DM). During a medical service trip to Puerto Penasco, Mexico in 2015, many patients with T2DM reported not using metformin for diabetes management due to associated side effects. A survey was developed to determine utilization and barriers to metformin use among type 2 diabetics in rural Mexico.

Methods: A team of six pharmacy students from Xavier University College of Pharmacy and one clinical pharmacist participated in a medical service trip to Puerto Penasco, Mexico. The trip was facilitated by International Service Learning (ISL), a company that coordinates international interdisciplinary medical mission trips and internships for health professionals and students. Each student participated in a week long service program and provided various services that included residential health screenings, diabetes education and a "pop up health clinic" in one of the community centers. Basic health screenings including blood pressure and blood glucose checks were offered and provided to patients the group encountered. A survey was created in order to determine the utilization and potential barriers to metformin use among type 2 diabetics in the community. Self-reported diabetic patients were offered the opportunity to participate in the survey and assured them that their level of care was not dependent on their decision. Patients were given the option to read and answer the survey questions on their own or allow a volunteer and translator discuss the questions. The surveys and informed consent forms were available in English and Spanish translations. Patient identifiers were not obtained or documented in the survey responses and each questionnaire

was assessed after the trip. All methods, the survey, and informed consent received approval from the Xavier University of LA Institutional Review Board.

Results: Survey responses from 16 patients were received; no self-reported diabetic patients declined participation. Overall, 11 of 16 patients (68.8 percent) reported current use of metformin, while 2 of 16 (12.5 percent) reported being past users. Among patients with a history of metformin use, 7 of 13 (53.8 percent) had experienced associated side effects, but only 4 of 13 (30.8 percent) reported side effects as a barrier for use (p=0.0699). Cost was a barrier to use in 6 of 16 (37.5 percent) of patients, and 5 of 16 (31.3 percent) reported stopping metformin when they run out of pills and do not have access to more. The results of the survey were shared with ISL, the company that works closely with the community in order to ensure health services are accessible. ISL was grateful to receive the information and has committed to obtaining resources in order to address these concerns.

Conclusion: In order to provide optimal care to patients, healthcare providers must overcome treatment barriers. ADA guidelines recommend metformin as the cornerstone of treatment for patients with T2DM. Among areas visited in 2016, a higher percentage of patients were using metformin than predicted. Many patients reported cost or running out of medication as their main barrier to usage. The survey results suggest that there is a disparity in access to metformin in this community. Identifying a method of providing free or discounted metformin to these patients would increase medication adherence, decrease diabetic complications, and improve overall health in Puerto Penasco.

Poster Title: Pharmacy students' reflections on an oral targeted agents lecture and recitation quiz in an oncology drugs and diseases course

Primary Author: Julia Kamuda, St. John's University College of Pharmacy and Health Sciences, New York; **Email:** julia.kamuda10@stjohns.edu

Additional Author (s):
Tina Kanmaz

Purpose: The first time students are introduced to chemotherapy agents in our curriculum is during the third professional year in the content-rich, intensive Oncology Drugs and Diseases course. Students attend class two hours per day, five days per week over six weeks and complete two assessments, a midterm and final exam. The purpose of this study was to evaluate student learning in the therapeutics lecture on oral targeted agents and to determine if additional assessments (i.e. quizzes) would help with student learning, attendance and performance in the course.

Methods: The institutional review board approved this study as exempt. Students in attendance during the Fall 2015 oral targeted agents therapeutics lecture were asked to write an anonymous one-minute reflection paper towards the end of the lecture reflecting on: what topic(s) were most clear to them during the lecture and what topic(s) were still confusing. The papers were analyzed to determine which lecture topics were well understood and which need to be explained differently in future presentations. The same students were asked to complete an anonymous SurveyMonkey as fourth professional year students during Summer 2016, reflecting on the quizzes that were administered during recitation on the day before the midterm and final exams.

Results: Of 275 students, 142 completed the reflection. Students listed 218 topics they learned best during the lecture and 139 topics that were still confusing. The clearest topics were multikinase inhibitor-induced hand-foot syndrome (32.4 percent), chronic myelogenous leukemia (27.5 percent), epidermal growth factor receptor inhibitor-induced acneiform rash (20.4 percent), side effects (12.7 percent), drug interactions (12.7 percent), and administration of epidermal growth factor receptor inhibitors (12 percent). Drug names, mechanisms of action

or drug targets, and choosing the best first line option were still confusing to 14, 12, and 10.6 percent, respectively. Another 10.6 percent noted nothing in the lecture confused them. The survey on quizzes administered during recitation was completed by 165 students. Overall, 44 percent found quizzes helpful, 23 percent found them not very helpful, 7 percent felt quizzes negatively affected learning, and 26 percent were neutral. Approximately 57 percent indicated that quizzes should continue to be given in the course. Nearly 59 percent of students attended recitation only because the quiz was being administered. In comparison to their exam grades, 38 percent of students stated their quiz scores were within 10 points, 15 percent scored higher, 22 percent scored lower, and 25 percent did not remember.

Conclusion: The topics students understood the most were those that contained visual aids, while most students struggled to take away knowledge of content requiring pure memorization, such as drug names. Student surveys indicated that most students found quizzes helpful or were impartial to the quizzes. The quizzes were an incentive for more than half of the class to attend recitation. Quizzes increased student attendance and more than half of the class believed quizzes should be continued in the course.

Submission Type: Evaluative Study

Session-Board Number: 5b-282

Poster Title: Evaluation of curricular stress in doctor of pharmacy students and its impact on residency application

Primary Author: Ciera Cammilleri, D'Youville College School of Pharmacy, New York; **Email:** cammic13@dyc.edu

Additional Author (s):
Timothy Hutcherson
Amany Hassan

Purpose: Pharmacy students are required to complete three to four years of didactic and experiential coursework before they are eligible to complete US practice licensure examinations. The Accreditation Council for Pharmacy Education requires programs to provide student services that facilitate the attainment of programmatic objectives, including services that address student stress and mental health. The purpose of this study was to investigate the relationship between pharmacy students' perceptions of stress during their didactic education and their desire to seek a postgraduate pharmacy residency.

Methods: Current first-year through fourth-year students at D'Youville College School of Pharmacy completed an anonymous online questionnaire that collected demographic information and assessed their perceived degree of stress before, during, and after didactic curricular assessments such as quizzes, examinations, projects, and presentations. Student demographic data included age, gender, duration of post-secondary education, and degree of interest in pursuing a post-graduate pharmacy residency. Students' degree of stress was rated on a continuous scale ranging from zero to 100, with zero being the minimum and 100 being the maximum level of stress experienced. Data was collected for each type of curricular assessment. Approval was granted by the D'Youville College Institutional Review Board prior to the commencement of this research and informed consent was obtained for all participants.

Results: Of 279 possible participants, 250 students completed the questionnaire, yielding a 90 percent response rate. Higher student-reported grade point averages were associated with a significantly higher degree of interest in pursuing a post-graduate pharmacy residency (P equals 0.019). Students reported their mean baseline degree of stress as 60.7 for any given time

during the academic year. The mean degree of stress one week before a scheduled exam, project, or presentation was 59.0. The mean time prior to quizzes, examinations, and projects or presentations that students reported feeling stressed was approximately two days, five days, and four days, respectively. The mean degree of stress when presented with quizzes, examinations, and projects or presentations was 49.8, 74.1, and 60.1, respectively. The mean degree of stress from the time of completing a curricular assessment and subsequently receiving a grade for that assessment was 42.9 for quizzes, 59.0 for examinations, and 37.6 for projects and presentations. Didactic course coordinators reported disseminating assessment scores to students approximately seven days following assessment completion regardless of assessment type. Preliminary analyses did not demonstrate any statistically significant correlations between student- reported curricular stress and degree of interest in pursuing a post-graduate pharmacy residency.

Conclusion: Students who reported higher grade point averages during their didactic pharmacy education reported a higher degree of interest in pursuing post-graduate pharmacy residencies. No significant differences were found upon comparison of the mean degree of student stress and the degree of interest in pursuing a post-graduate pharmacy residency. Further analyses should be conducted to identify subgroups within the population to determine if multiple factors may elucidate other significant relationships. Limitations of this study include self-reported data points; exclusion of assessments conducted during introductory and advanced pharmacy practice experiences; exclusion of longitudinal assessments; and exclusion of assessments conducted during elective coursework.

Submission Type: Evaluative Study

Session-Board Number: 5b-283

Poster Title: Impact of vacations on professional pharmacy students' perceived stress levels

Primary Author: Aaron Head, University of Louisiana at Monroe School of Pharmacy, Louisiana;
Email: headaa@warhawks.ulm.edu

Additional Author (s):
Trista LeBeouf
Chelsie Morein
Tibb Jacobs
Jamie Terrell

Purpose: Pharmacy and other health professions claim some of the highest potential stressors in the current job market. Students in professional schools across the United States face stressors every week inside and outside of the classroom. The primary endpoint of this study is to examine if taking a vacation positively impacts professional pharmacy students by reducing their overall perceived stress level during the professional pharmacy rigor. Secondary endpoints include determining if the number of vacations or the distance away from their current residence has any bearing on perceived stress, as well as if the students were 'unplugged' while on their vacation.

Methods: This survey was approved by the university's Institutional Review Board. A link to an anonymous questionnaire evaluating the perceived stress levels of professional pharmacy students and vacations taken was emailed to all currently enrolled students (n=377) in the School of Pharmacy (SOP). The first 10 questions of the questionnaire were the Perceived Stress Scale-10 (PSS-10), a questionnaire designed to place a numerical score associated with a person's stress level at the time of questioning. 15 other questions were asked to assess if students had taken a vacation or traveled to a professional pharmacy meeting in the previous year. If the students did go on either trip, they were prompted to answer questions evaluating the number of trips taken, anxiety level during their trip, distance away from their current residence, and if they checked their emails, calendar, or grades while on their trip. Each students' PSS-10 score was calculated and t-tests were used to determine statistical significance.

Results: 115 students completed the survey during the two-week open window. The perceived stress levels of students who did not take a vacation was not statistically higher than those that did take a trip during the previous year (p = 0.1448). Students who went on two or more vacations reported less stress than those students who only took one vacation (p = 0.00056). The distance away during the vacation and 'unplugging' while away did not demonstrate less perceived stress in the professional pharmacy students (p = 0.3625 and p = 0.4556, respectively).

Conclusion: Taking vacations during a professional pharmacy program, including trips to professional pharmacy meetings, may help to alleviate stress in pharmacy students. Taking more than one trip per year was shown to significantly reduce stress levels in pharmacy students at the SOP. Further studies could be done to include correlations with grade point averages, work outside of school, or family stressors.

Poster Title: Prolonged hypocalcemia in a patient with reduced renal function post denosumab injection

Primary Author: Andrea Glogowski, Albany College of Pharmacy & Health Sciences, New York;
Email: a.glogowski@hotmail.com

Additional Author (s):
Jeffrey Bettinger
Paul Der Mesropian

Purpose: Denosumab (Xgeva), a RANKL inhibitor, is FDA-approved for the prevention of skeletal-related events in patients with bone metastases from solid tumors. Hypocalcemia is a well-known adverse effect of denosumab therapy, and appears to be of greater risk for patients with renal impairment. However, there are currently no dosage reductions recommended for patients with reduced renal function. This report describes the case of a 57-year-old female with a history of stage IV breast cancer (ER/PR positive, HER2 positive) with bone metastases who developed prolonged, denosumab-induced hypocalcemia.

Upon diagnosis of bone metastases, the patient had reduced renal function, with a creatinine clearance ranging from 50-60mL/min. She was initially started on zoledronic acid, but one month later her renal function further declined, and she was switched to denosumab 120mg subcutaneously every month. Thirty days post injection, the patient developed prolonged hypocalcemia with total serum calcium concentrations reaching 6.5mg/dL and ionized calcium reaching 0.94mmol/L. Clinical manifestations included facial tingling and a slightly prolonged QTc interval. The hypocalcemia persisted for over 3 months despite aggressive vitamin D and oral/IV calcium supplementation (35g of IV calcium gluconate required in total).

Growing literature demonstrates an increased incidence, duration, and severity of hypocalcemia in patients with renal impairment. Although the manufacturer recognizes that an increased risk exists in patients with renal dysfunction, only close monitoring of calcium and vitamin D levels and consideration for preemptive treatment is suggested. Dose reductions of denosumab are not currently recommended.

We recommend that all patients receiving denosumab obtain adequate treatment with calcium and vitamin D supplements throughout the duration of treatment to prevent the development of prolonged, severe hypocalcemia. Clinicians should consider that denosumab therapy poses

an increased risk of hypocalcemia in patients with reduced renal function. However, further studies are required to determine whether dose reductions mitigate this risk.

Poster Title: Characterization of stress management methods of doctor of pharmacy students

Primary Author: Qasim Abdulle, D'Youville College School of Pharmacy, New York; **Email:** abdulq03@dyc.edu

Additional Author (s):
Michael Zheng
Emmanuel Oduro
Nicole Cieri
Stephanie Brian

Purpose: It may be beneficial that students learn how to cope with stress in order to perform successfully in pharmacy school, and ultimately in their future careers. The course load in a Doctor of Pharmacy program may be more intense than most students have previously experienced. With the addition of experiential training, pharmacy students are under extra pressure to efficiently manage their time and achieve balance between social life, family time, and academic performance. This study aims to identify the most common stressors experienced by student pharmacists and the methods they use to manage stress.

Methods: The institutional review board approved an email containing a link to an electronic survey that was presented to first-, second-, and third-professional year pharmacy students (total of 218 pharmacy students) at D'Youville College School of Pharmacy. The survey contained a range of both Likert-type and free response questions to assess demographic information, sources of stress, and stress management methods. At the end of the survey, students were also asked to answer questions based on the Cohen Perceived Stress Scale (PSS), an established and accepted form of gauging psychological stress. All data analysis was performed utilizing descriptive statistics with Qualtrics Survey Solutions and Microsoft Excel.

Results: A total of 86 students responded to the survey, giving a response rate of 39.45 percent. However, 3 respondents did not complete the survey (96.51 percent completion rate). Cohen PSS scores were similar between professional years and genders, with an overall mean of 21.01 out of a possible total of 36. For reference purposes, normative data gathered in 2009 shows a US average PSS of 15.21. The majority of respondents felt what they experienced was either

average stress (30/83; 36.1 percent) or above-average stress (38/83; 47.8 percent). When asked if they were comfortable at their current level of stress, 40 percent of respondents replied 'yes', while another 40 percent replied 'no' and the remaining 20 percent were unsure. The most common stressors observed were related to academics, such as exams (mean stress on scale of 1-5: 4.48) or grades (mean stress: 4.14), with financial concerns (mean stress: 3.72) also ranking quite high amongst respondents. The highest-ranked stress management methods were sleeping (mean ranking: 3.27), eating (mean ranking: 4.02), socializing (mean ranking: 4.07), and music (mean ranking: 4.30). Furthermore, when comparing between different variables such as professional year or gender, the top stressors and coping mechanisms remained consistent.

Conclusion: The results of our study suggest that student pharmacists may work under greater than average levels of stress based on a comparison of their Cohen scores to normative US data. While we were unable to compare actual academic performance to perceived stress, the most prevalent stressors seen in the survey results were related to academic performance. These results show that, as a whole, the students in this pharmacy program may have consistently elevated stress due to increased academic demands, and that only 40 percent of respondents felt comfortable at their current stress level.

Poster Title: Assessing the perceived efficacy of an elective (PHRD 5065 Clinical Pharmacy Career Development) on the success of pharmacy students pursuing post-graduate residency training

Primary Author: Dharti Desai, University of Louisiana at Monroe School of Pharmacy, Louisiana; **Email:** dmdesai14@gmail.com

Additional Author (s):
Hannah Halbrook
Tibb Jacobs
Jamie Terrell

Purpose: Attaining a post-graduate residency position is becoming more difficult due to an increasing number of applicants versus residency positions. Our School of Pharmacy (SOP) offers an elective course to expose students to various clinical careers available after completing a residency. This course guides students on how to become a competitive candidate by writing CVs, letters of intent, and also guiding students through the Midyear experience and interviewing processes. The purpose of this study was to assess students' perceived preparedness toward post-graduate residency training after taking this elective and the likelihood of obtaining a residency position.

Methods: This survey was approved by the university's Institutional Review Board. A survey of 18 questions was emailed to a total of 63 alumni who participated in the elective course from 2011 to 2014. The survey was emailed using each student's personal email address that was provided to the SOP for post-graduate contact. The survey asked multiple choice and open-ended questions pertaining to feelings of preparedness on topics such as writing a CV, letter of intent, and the residency application process, as well as their success in the PGY1 application process, including number of applications submitted and interviews attained. The multiple choice portion used a Likert scale with 1 corresponding to not at all helpful and 5 being extremely helpful. Students were given approximately 1.5 weeks to complete the survey. The data were collected from the completed survey, compiled, and analyzed.

Results: The data collected were reported using descriptive statistics. Among the 63 students that were emailed the survey, 40 students voluntarily participated in the survey, two of the emails were undeliverable, and 21 students did not respond to the request. Of the 40 students that participated in the survey, 24 students (60%) applied for a PGY1 residency and of those students 20 (83.3%) were successful in the first match. A total of 22 (62.50%) students that applied for a PGY1 position felt very prepared or extremely prepared in composing CV after the lecture and feedback provided. 83% of students felt the mock interview exercise improved their interviewing skills, and 70% of those felt very confident during the interviewing process. Approximately 67% of all students who applied for a residency would recommend this class to others who are interested in obtaining a residency position. According the National Match website, the match rate from 2012 to 2015 is approximately 64%, while students that complete this course have a match rate of 83%.

Conclusion: Overall, it appears that students feel the PHRD 5065 elective course has positively impacted their experience in the residency application process. Students that applied for a residency felt the course benefited them in preparing their CVs, letters of intent, as well as for the interview process. Although this is a small sample size, alumni that complete this elective feel they have a competitive advantage in the application process and have a higher match rate than the national average. It is possible that other schools of pharmacy could benefit from a similar elective course.

Poster Title: Appropriate use of ondansetron in the emergency department

Primary Author: Shelby Cranfield, University of Louisiana at Monroe School of Pharmacy, Louisiana; **Email:** wellssl@warhawks.ulm.edu

Additional Author (s):
Savannah Posey

Purpose: Several randomized controlled trials show that the incidence of nausea and vomiting (N/V) following opioid administration is very low, however, prophylactic ondansetron administration immediately preceding an opioid continues to be common practice in the emergency department (ED). Indications for the use of ondansetron include prevention of N/V associated with chemotherapy or radiation, and post-operative N/V; however, no indication exists for the prophylaxis of opioid-induced nausea and vomiting (OINV). Due to lack of an approved FDA indication for OINV the appropriate strength is also unclear. The purpose of this study was to evaluate the use of ondansetron in the ED.

Methods: Between December 1st and December 31st of 2015, all patients that received ondansetron were reviewed retrospectively to determine appropriate use. Appropriate use was defined as chart documentation of N/V during ED admission before administration of ondansetron, receipt of ondansetron at least an hour after opioid administration, or ondansetron administration after patient received an opioid and became nauseated. Patient's that had inappropriate use of ondansetron were those with no known documentation of N/V while receiving both an opioid and ondansetron during ED admission. Other outcomes explored included: differences in prescribing habits of ondansetron among four physicians, the strength of ondansetron administered to the improper use group, and the differences in hospital costs among different strengths of ondansetron.

Results: Of the 506 patients reviewed in the study, 261 (52%) received ondansetron appropriately while improper use occurred in the other 245 (48%) patients. There were a total of eight instances where patients did not meet the criteria for either category, five of which were given ondansetron with ketorolac and three of which had no documentation of N/V or narcotic administration. These eight patients were therefore placed in the improper use group.

Upon examination of the strength of ondansetron administered to the improper use group, 44% of patients received a 4 milligram dose whereas 56% received an 8 milligram dose. The difference in hospital cost for both groups was analyzed and found to be greater in the patients that received the larger ondansetron dose, with intravenous administration costing more than oral.

Conclusion: This study found that improper use of ondansetron is common in our department and leads to increased hospital costs. Further education will be done in our ED to ensure that physicians have a higher regard for pharmacovigilance. In addition, the role for ondansetron and the appropriate dose when used in this setting requires further safety and efficacy studies before our department establishes a protocol for its use.

Poster Title: Dobutamine-induced rash in a critically ill full-term neonate: A case report

Primary Author: Hailey Lipinski, Albany College of Pharmacy and Health Sciences, New York;
Email: hailey.lipinski@acphs.edu

Additional Author (s):
Brian Cowles
Leslie Young

Purpose: A full-term, male neonate weighing 2970g was admitted to the neonatal intensive care unit (NICU) from the delivery room for respiratory distress, dysmorphic features, and possible cardiac malformation. At delivery, the infant was noticed to have elongated fingers and toes, pigeon chest, and low-set ears. A chest x-ray performed in the NICU revealed cardiomegaly and an echocardiogram revealed ductal-dependent pulmonary blood flow through a small patent ductus arteriosus as well as regurgitation at both the mitral and tricuspid valves. Shortly after birth, the infant was intubated for respiratory support. Around 14 hours of life, a continuous infusion of dobutamine prepared in dextrose was initiated at 3mcg/kg/min for mean arterial pressure (MAP) measurements of 30-36mmHg. Approximately 30 minutes after the start of the infusion, nursing staff reported the emergence of skin irritation starting on the face, which rapidly progressed to a centrally-clearing erythematous rash with serpiginous borders on the infant's neck, head, trunk, and back. Accompanying the rash was an elevation in heart rate from 130-140 bpm to 160-170 bpm. The dobutamine infusion was infused for approximately 2.5 hours and then discontinued. Approximately 45 minutes after discontinuation, the rash cleared. Other medications given around the time of the rash included ampicillin and gentamicin, an alprostadil infusion to maintain the ductus arteriosus, and a fentanyl infusion with intermittent vecuronium doses for sedation and paralysis. One hour after discontinuation, the dobutamine infusion was resumed at 3mcg/kg/min for MAP measurements around 34mmHg. No increase in MAP or was observed after one hour, so the dobutamine infusion was increased to 5mcg/kg/min. At this time the rash returned and the infant's MAP continued to decrease. The dobutamine infusion was stopped and two boluses of normal saline were given, followed by a continuous infusion of dopamine at 5mcg/kg/min. The infant's MAP improved and the rash again resolved upon discontinuation of the dobutamine

infusion. The infant was not re-challenged with dobutamine again and the rash did not return for the remainder of his NICU stay.

This appears to be a case of a medication allergy to an intravenous dobutamine infusion prepared in dextrose in a full-term neonate. Although rare, cases of rash following dobutamine infusions have been reported. These reactions are usually accompanied by eosinophilia and bronchospasm and are thought to be caused by sulfite preservatives contained in the formulation. However, to our knowledge, observation of this type of reaction has been limited to the adult population and has not been reported in neonates. Unlike previous reports, the patient in question did not present with eosinophilia at the time the rash was observed. There were also no signs of bronchospasm reported at the time of the rash, however due to his intubation and mechanical ventilation, this may have been difficult to observe. Other potential causes of the observed rash were considered including other medications, as several medications were given around the time of the initial rash, as well as the possibility that the rash was rather a vasomotor reaction resulting from his critical illness. However, the fact that the rash first appeared and dissipated within one hour of initiation and discontinuation of the first infusion and subsequently re-emerged and dissipated with initiation and discontinuation when the patient was re-challenged with the medication strongly suggests dobutamine to the be cause. This case displays a unique case of what appears to be a drug-induced reaction to a medication in a population where allergic drug reactions are rare events.

Poster Title: Pharmacy students' perception of taking Drug-induced Diseases course before versus after advanced pharmacy practice experience rotations

Primary Author: Tamara Yunusova, St. John's University College of Pharmacy and Health Sciences, New York; **Email:** tyunusova93@gmail.com

Additional Author (s):
Caitlyn Cummings
Sum Lam

Purpose: Our college has recently revised the Doctor of Pharmacy (Pharm.D.) curriculum which requires pharmacy students to complete all didactic courses before starting Advanced Pharmacy Practice Experience (APPE) rotations. In Spring 2016, 460 students were enrolled in Drug-induced Diseases (DID) course: cohort A (n equals 218) took the course BEFORE starting rotations and cohort B (n equals 242) took the course AFTER completing rotations. Cohort C (n equals 91) were at APPE rotations and took the course in Spring 2015 BEFORE starting rotations. This study evaluated students' perception of taking the course before starting or after completing APPE rotations.

Methods: A standardized survey, with language specific to each cohort, was sent out to 551 students via SurveyMonkey after the final exam for voluntary participation. Students rated course difficulty using a scale of 1 to 10 [1 – Easiest, 10 – Hardest] and their perception based on taking the course the way it was assigned to them, either before starting or after completing rotations using a scale of 1 to 10 [1 – Hated it, 10 – Loved it]. Self-reported course grades and factors contributing to course grades were also collected. Additional comments related to the study objective were recorded. Finalized course grades for cohorts A and B were provided by the course coordinator, and were used as an indicator of actual academic performance. Student's t-test was used for data analysis for rating scores and course grades.

Results: Of 551 students, 12 percent completed the survey (cohort A equals 35, cohort B equals 24, cohort C equals 7). Students preferred to take the course before starting rotations [(9 plus minus 1.3) cohort C versus (7.0 plus minus 2.1) cohort B; P equals 0.007]. Cohort A reported the preference score as (7.9 plus minus 2.0). Students who took the course after completing

rotations rated the course to be easier [(4.4 plus minus 1.9) cohort B versus (5.4 plus minus 1.9) cohort A; P equals 0.03]. Cohort C reported the course difficulty score as (5.4 plus minus 2.6). Based on self-reported course grades, cohort B anticipated higher course grades than cohort A; [(86.5 plus minus 4.1) versus (83.6 plus minus 5.5), respectively; P equals 0.01]. However, there is no significant difference in actual academic performance regardless whether the students took the course before or after the rotations [(82 plus minus 7.0) cohort A versus (83 plus minus 7.3) cohort B; P greater than 0.05]. The most beneficial topics to review were drug-induced cardiovascular disorders (cohorts A and C) and drug-induced fluids and electrolyte disorders (cohort B).

Conclusion: Doctor of pharmacy students prefer taking the DID course before starting APPE rotations; however students found the course easier after completing rotations. There is no significant difference in actual academic performance in the two cohorts that completed Spring 2016 course.

Poster Title: The Necessity for Pharmacists to Review Patient Cases That Involve Patients on Multiple Medications

Primary Author: Eesha Khan, St. John's University, New York; **Email:** eesha.khan09@stjohns.edu

Purpose: This case report demonstrates the need for pharmacists to review patient cases that involve patients on multiple medications. GG is a 71 year old female who presented to the ED with a chief complaint of abdominal pain radiating to her back. She states that she had similar pain eight months ago, for which she was admitted to the hospital with gallstone-induced pancreatitis. During her prior stay, a cholecystectomy was postponed when the patient's stone passed and her symptoms resolved. Her past medical history is significant for: Asthma, rheumatoid arthritis (status-post total right shoulder replacement), breast cancer status-post lumpectomy (1997), gallstone-induced pancreatitis, bilateral cataracts, dilated cardiomyopathy, gastroesophageal reflux disease, cervical herniated disk, hypothyroidism, hyperlipidemia, hypertension, myocarditis, urinary incontinence, and insomnia. Her home medications include: docusate, levothyroxine, fexofenadine, captopril, montelukast, singulair, flovent, verapamil, simvastatin, colchicine, hydroxychloroquine, spironolactone, omeprazole, folic acid, movantik and temazepam. In the hospital, captopril, verapamil, spironolactone, and movantik were held. The patient was placed on a regimen of ursodiol 300 mg twice daily with meals. All other medications or an equivalent that was on the formulary were continued. Her heart rate varied from 74-88 bpm, and blood pressure fluctuates from 106-115/65-68. The patient was normotensive, which is consistent with her captopril, verapamil, and spironolactone being held. In the ED, she was immediately made NPO and labs were taken. Labs were significant for elevated ALT and AST as well as an elevated serum lipase level of 5920 U/L. All other medications or an equivalent that was on the formulary were continued. The patient's abdominal and pelvic CT were consistent in displaying cholelithiasis with mild nonspecific gallbladder distention significant for pancreatitis, while the hepatobiliary scan ruled out acute cholecystitis. During this admission, the general surgeon determined that the patient required a cholecystectomy which the patient refused, claiming she had not yet healed from her shoulder replacement and thus, her body was not ready to handle another procedure. The patient also refused ERCP (endoscopic retrograde cholangiopancreatography). Her serum lipase level

significantly decreased to 131 U/L within two days in the hospital, and she was scheduled for a cholecystectomy for a date she agreed to. The patient was told she could re-start all her medications that she hadn't been taking in the hospital. The patient's medication regimen was reviewed by pharmacy, with a couple of problems being immediately noted. After a series of questions that were presented to the patient, several interventions were made. The patient did not have an outpatient cardiologist; her medication regimen was made primarily by her primary care physician. The patient did not have an indication for the following medications: verapamil, colchicine, and movantik. The patient did not any concomitant atrial fibrillation or angina, and her history of dilated cardiomyopathy and possible left ventricular dysfunction was also contraindicated with the use of verapamil, which was then discontinued. According to the patient, her colchicine was being used for her rheumatoid arthritis. After researching the possible off-label indication, the results were weak supporting its use in rheumatoid arthritis, and was thus discontinued. Also, the patient was not taking any opiates, thus the movantik was deemed unnecessary. Furthermore, the use of ace-inhibitors is implicated in the onset of acute pancreatitis, with the highest incidence being tied to captopril and enalapril. The patient was switched from captopril to an equivalent dose of lisinopril, and carvedilol was initiated for dilated cardiomyopathy. The spironolactone was held due to the patient's blood pressure, and a cardiologist follow-up was made for one week after discharge. Through medication therapy management, pharmacists have the ability to identify potential problems in therapy and intervene to allow for optimal patient outcomes.

Poster Title: Hypertonic saline for the treatment of bronchiolitis in infants and children: The saga continues

Primary Author: Vincent Tao, St John's University College of Pharmacy and Health Sciences, New York; **Email:** vincent.tao11@stjohns.edu

Additional Author (s):
Tom Hashimoto
Gladys El-Chaar

Purpose: Bronchiolitis is the leading cause of hospitalizations in children. The American Academy of Pediatrics (AAP) recommends nebulized hypertonic saline (HS) as the sole therapy in bronchiolitis. In 2016, an extensive review of 22 studies (2682 children) detailed the role of HS. In these trials, HS resulted in improvement in clinical severity score (CSS) and reduced rates of admissions from the emergency department, while data on length of stay (LOS) reduction were equivocal. Since then, new data and analyses have questioned the role of HS in bronchiolitis. This paper will assess whether hypertonic saline's niche in bronchiolitis has changed.

Methods: Extensive literature searches using PubMed were conducted to gather the most recent studies (January 1, 2016 – December 31, 2016) that included the use of hypertonic saline for the treatment of bronchiolitis in children. We excluded studies that were previously analyzed by the review published in 2016. Articles that were determined to be valid and well supported by evidence were chosen for further evaluation. Our aim was to examine whether the benefits of HS, including its impact on LOS, efficacy, and safety continue to be supported by these new data. Two pharmacy students conducted the literature searches and one clinical pharmacist with advanced training in pediatric pharmacotherapy evaluated the literature for validity and content. Nine articles were initially selected to examine the role of HS in children with bronchiolitis. After careful review, five articles were excluded due to doubtful methodology, lack of evidence and limitations. The four remaining articles had proper methodology to evaluate the evidence for efficacy and adverse effects of hypertonic saline in bronchiolitis.

Results: Three of four studies tested the impact of HS on CSS. Study 1, examining Indian children, showed a significant decrease in CSS for patients treated with 3 percent HS vs. normal saline (NS) (p equals 0.001). Study 2 treated young children with 3 percent, 7 percent HS or NS in combination with salbumatol. All saline preparations reduced CSS from baseline to 24 hours (p equals 0.001) with no differences between them (p greater than 0.16). Study 3 found no reduction in CSS at 3 days between 3 percent HS and NS (p equals 0.86) (Baseline data omitted). LOS was examined in all studies. Study 1 showed a 1.5-day reduction in LOS in children less than 25 months of age (p equals 0.001). Study 2 found no reduction in LOS in children less than two years (p equals 0.76). Studies 3 and 4 found no significant reduction in LOS in infants less than one year of age (p equals 0.73 and 0.747, respectively). Study 2 deemed 3 percent HS and NS safe, with the exception of two cases of temporary bronchospasms associated with 7 percent HS. Study 3 found a higher incidence of cough and rhinorrhea with 3 percent HS.

Conclusion: Based on our review, two studies continue to support the efficacy of HS in bronchiolitis, while one that failed to show improvement lacked baseline data. LOS was reduced in one study, but not in two studies that restricted enrollment to children less than one year of age. We question whether a prolonged LOS in this age group relates more to severity of illness rather than ineffectiveness of HS. Overall, HS is safe. Therefore, the role of HS in bronchiolitis remains unchanged. Its use is beneficial in reducing bronchiolitis severity scores; however, its ability to reduce LOS remains unclear.

Poster Title: Protecting the elderly: Assessment of community pharmacists' application of the 2015-updated Beers Criteria in underserved neighborhoods of New York, New York

Primary Author: Elisheva Friedman, Touro College of Pharmacy, New York; **Email:** eswartz@student.touro.edu

Additional Author (s):
Tu-Anh Tran
Maria Sorbera

Purpose: The American Geriatrics Society (AGS) Beers Criteria for Potentially Inappropriate Medication Use in Older Adults is a list of recommendations intended to guide healthcare practitioners in providing safe medications in the elderly population. The purpose of this study was to assess community pharmacists' application of the 2015 updated Beers Criteria in the underserved minority neighborhoods of Central Harlem and Washington Heights/Inwood in New York, New York. The secondary objective was to compare the application of the 2015 updated Beers List among chain and independent community pharmacies.

Methods: Questionnaires were designed to gather relevant pharmacist and pharmacy characteristics, and to assess the pharmacists' exposure to and application of the 2015-updated Beers Criteria. Background information collected included pharmacy classification (chain or independent), pharmacist title, average prescription volume, and percentage of patients over 65 years of age. Application of the Beers List was assessed by asking whether the pharmacist read the 2015 updates, used an automated computer system to identify drug errors, and/or utilized drug information resources in addition to those provided by the pharmacy. Data on the frequency of contacting prescribers to make age-related interventions, and frequency of referring to Beers Criteria or similar resources were also compiled. Investigators approached pharmacists in Central Harlem and Washington Heights community pharmacies to complete the questionnaire. The questionnaire took each pharmacist approximately two minutes to complete. If multiple pharmacists were on duty at one pharmacy, both pharmacists were asked to complete a separate copy of the questionnaire. Pharmacists were excluded from the study if they exhibited reluctance to participate due to reasons such as time constraints. All statistics

used were for descriptive purposes only. This study was approved by the institutional review board.

Results: Questionnaires were collected from a total of 26 pharmacists working at 22 different pharmacies (12 at chain pharmacies and 14 at independent pharmacies). The majority of participating pharmacists (57 percent) had not read the 2015 updated Beers Criteria, and 50 percent claimed to never refer to the Beers Criteria or similar references in order to make age-related interventions. All pharmacies employed an automated computer system which flagged potential drug-drug or age-drug interactions, and 76.9 percent of pharmacists reported use of an additional drug information resources. There are no recognizable differences of Beers Criteria awareness existing between the chain and independent pharmacies; however, it appears that pharmacists at independent pharmacies contact prescribers more frequently to perform age-related interventions than pharmacists at chain pharmacies (91.6 percent perform 0-5 calls daily, 8.3 percent perform 6 or more calls daily vs 57.1 percent perform 0-5 calls daily, 42.9 percent perform 6 or more calls daily). There were no discernible patterns in Beers Criteria awareness and application based on the factors of pharmacist title, average prescription volume, and percentage of patients over 65 years of age.

Conclusion: The elderly population is at an increased risk of medication-related adverse events. Among community pharmacists, a knowledge gap seems to be present regarding the 2015-updated Beers Criteria. An increased need for pharmacist education is warranted in order to provide optimal medication safety to the elderly population.

Poster Title: Pharmacist participation on pediatric emergency response teams

Primary Author: Andrea Goettel, Albany College of Pharmacy and Health Sciences, New York;
Email: andrea.goettel@acphs.edu

Additional Author (s):
Sierra Stauber
Nicole Acquisto
Meghan Baldo

Purpose: Pharmacists play a crucial role on the pediatric emergency response team by providing medication recommendations, obtaining requested medications, determining proper medication doses, and preparing medications for use. Pharmacist involvement on pediatric emergency response teams may result in fewer adverse drug reactions and medication errors along with increased compliance with advanced cardiac life support guidelines. This study intended to characterize the pediatric pharmacist's role on the pediatric emergency response team at an academic medical center.

Methods: Pediatric pharmacists at Golisano Children's Hospital at Strong Memorial Hospital routinely document their participation in pediatric medical and traumatic emergencies for quality improvement purposes. Data from standardized code documentation sheets for the years 2012-2016 were interpreted to characterize the pharmacist's role in pediatric emergency response teams using descriptive statistics. Information included on code documentation sheets were as follows: date, time, age, sex, location of emergency, number of pharmacists responding, patient diagnosis prompting the code, diagnosis corresponding to medication administration, medication name, total number of medications prepared, and total time spent by the pharmacist.

Results: Pediatric pharmacists at Golisano Children's Hospital at Strong Memorial Hospital documented 390 code responses for the years 2012-2016. The majority occurred during the day shift (54.6 percent) compared to the evening (41.8 percent) and overnight shifts (3.6 percent). The mean age was 120 days in those less than 1 year old and 8 years in those greater than or equal to 1 year old. The most common locations were the pediatric emergency (41.8

percent), trauma (24.8 percent), and intensive care units (12.3 percent). One or two pharmacists responded to a code 88.1 percent of the time. The most frequent diagnoses prompting a code were pain/sedation (29.5 percent), respiratory arrest requiring rapid sequence intubation (28.5 percent), and cardiac arrest (24.5 percent). Medications were administered 77.7 percent of the time, most commonly for pain/sedation (37.6 percent), respiratory arrest requiring rapid sequence intubation (35.0 percent) and cardiac arrest (30.7 percent). Benzodiazepines (34.9 percent), opioids (33.3 percent), and epinephrine (32.2 percent) were administered the most frequently. Four or less medications were given 83.8 percent of the time, with two medications being most common at 29.4 percent of the time. The average time spent by a pharmacist at each code was 40 minutes.

Conclusion: Pediatric pharmacists at Golisano Children's Hospital at Strong Memorial Hospital responded to 390 documented codes during the five year period. Medications were required a majority of the time, which may provide significant opportunities for pediatric pharmacists to have an impact on direct patient care during code situations.

Poster Title: Y-Site Compatibility of N-acetylcysteine and Amiodarone

Primary Author: Julie Zeng, Arnold and Marie Schwartz College of Pharmacy and Health Sciences at Long Island University, New York; **Email:** julie.zeng@my.liu.edu

Additional Author (s):
Mark Klang

Purpose: The combination N-acetylcysteine and amiodarone was used in an institutional review board (IRB) protocol for the prevention of atrial fibrillation after thoracic surgery. However, studies evaluating stability were not conducted. The purpose of this study was to determine the Y-site compatibility of amiodarone 1.8mg/ml and N-acetylcysteine (NAC) 2.5 mg/ml (NAC 50mg/kg/day up to max dose 5 gm added to 200ml D5W). Both are continuous infusions.

Methods: Prior to assessing particle changes, the apparatus was calibrated using dispersions of spherical particles of known sizes between 10 μm and 25 μm. These standard particles were dispersed in particle-free water. The USP reference standard was a particle count suspension that contains 15 μm polystyrene spheres in aqueous suspension. The acceptable value for counts at 10 μm is between 3330 and 4110 counts/mL. The measured value was 3758 counts/mL. USP < 788> 39NF3 Method 1 was utilized to check that the environment is suitable for test, that the glassware is properly cleaned, and that the water to be used is particle-free. The particulate matter in five samples of particle-free water, each of 5 mL should be less than 25 for the number of particles of 10 mm or greater size for the combined 25 mL. This indicates that the precautions taken for the test were sufficient. Amiodarone Hydrochloride Injection (900mg/ 18 mL) was diluted with 5% dextrose in water (D5W) to a final concentration of 1.8 mg/mL. Acetylcysteine Injection (6g/ 30mL) was diluted with D5W to a final concentration of 2.5 mg/mL. Initial solution appearances such as color, clarity, and particulates were observed and documented. Diluted solutions were mixed together in a PAB Mixing container (B Braun) and evaluated using visual eye and particle-counting assessment upon mixing and again at 2 and 4 hours after mixing.

Results: Initial combination of acetylcysteine and amiodarone resulted in an immediate effervescent and foam adherence to the side of the vessel. The cumulative counts did not exceed 6000 per container equal to or greater than 10 mm and 600 per container equal to or greater than 25 mm for pre-test, amiodarone in D5W, and NAC in D5W. However amiodarone 1.8mg/ml + NAC 2.5 mg/ml (in D5W) exceeded the limits at baseline, 2 hours and 4 hours. An additional sample of Amiodarone 1.8 mg/ml and NAC 25 mg/ml, an increase in 10-fold concentration, was analyzed and exceeded the limits at baseline, 2 hours, and 4 hours. Thus, co-infusion of amiodarone and acetylcysteine via Y-site is considered incompatible.

Conclusion: Acetylcysteine and amiodarone was placed in D5W to determine the size and number of particles at 0, 2 and 4 hours, respectively. The combination of amiodarone 1.8 mg/ml and acetylcysteine (2.5 mg/ml and 25 mg/ml) in D5W exceeded the limits of particles during baseline, 2 hours and 4 hours of the test. Thus, co-infusion of amiodarone and acetylcysteine via Y-site is considered incompatible.

Submission Category: Emergency Medicine/ Emergency Department/ Emergency Preparedness

Submission Type: Evaluative Study

Session-Board Number: 5b-295

Poster Title: A single-center retrospective analysis of the effect of emergency department pharmacists on the time to first dose of antibiotics in sepsis.

Primary Author: Dylan LeBlanc, The University of Louisiana at Monroe School of Pharmacy, Louisiana; **Email:** dylan.joseph.leblanc@gmail.com

Additional Author (s):
Kelsie Stark
Elizabeth Lafitte
Ashley Sadowy

Purpose: The primary endpoint was to determine the impact of an emergency department (ED) pharmacist on the time from physician assignment to administration of the first dose of piperacillin-tazobactam in patients admitted through the emergency department with a diagnosis of sepsis or systemic inflammatory response syndrome (SIRS). Secondary endpoints included assessing the impact of adding an emergency department pharmacist on the time between order placement and verification, the impact of adding piperacillin-tazobactam to the emergency department automated medication dispensing system (AMDS) on the time to administration of piperacillin-tazobactam, and the impact of these interventions on the patients' length of stay.

Methods: This quality improvement project was a retrospective chart review examining three distinct time periods: prior to addition of an ED pharmacist and addition of piperacillin-tazobactam to the AMDS (April-June 2014); after the addition of an ED pharmacist, but before addition of piperacillin-tazobactam to the AMDS (October-December 2015); and after the addition of an ED pharmacist and addition of piperacillin-tazobactam to the AMDS (May-July 2016). The following data were collected for patients admitted with a diagnosis of sepsis or SIRS who received a dose of piperacillin-tazobactam in the ED: age, sex, admit date, discharge date, time physician assigned to patient, time of initial piperacillin-tazobactam order placement, time of order verification, time of dispense, time of administration, acuity of admission.

Results: The number of charts meeting inclusion criteria from each of the selected date ranges were 26, 34, and 13 from 2014, 2015, and 2016, respectively. The average age and sex distribution for each group were as follows: 52 and 46.15% male (2014), 49 and 44.12% male (2015), 43 and 46.15% male (2016). The average time in minutes from physician assignment to administration trended up from 236.7 in 2014, to 259.2 in 2015, to 269.7 in 2016. The average time in minutes from order placement to verification trended down from 21.5 to 7.2 to 6.15 minutes from 2014 to 2015 to 2016, respectively. The average time between order verification and administration decreased from 97 to 80 minutes with the addition of piperacillin-tazobactam to the ADMS. The average length of stay trended down from 8.34 days in 2014, to 6.64 days in 2015, to 5.15 days in 2016.

Conclusion: The average time from physician assignment to administration trended up despite a downward trend in the time between order placement and verification, and the time between verification and administration. The pharmacy factors that influence time to first dose of antibiotic administration improved after the addition of a clinical pharmacist in the ED and the addition of piperacillin-tazobactam, a common antibiotic used empirically in sepsis, to the ADMS in the ED.

Poster Title: Pharmacists' attitudes and practices regarding the tetanus, diptheria, and pertussis vaccination in pregnancy and surrounding newborns

Primary Author: Christine Echtenkamp, D'Youville College School of Pharmacy, New York; **Email:** echtec31@dyc.edu

Additional Author (s):
Stacie Lampkin
Amany Hassan

Purpose: The objective of this study was to evaluate pharmacists' understanding, attitudes, and practices surrounding the recommendations of the Advisory Committee on Immunization Practices (ACIP) regarding vaccination of pregnant females or individuals planning to come into close contact with infants with Tetanus, Diphtheria, Acellular Pertussis (Tdap), updated in 2013. In addition, we sought to identify barriers to implementing these recommendations in pregnant females.

Methods: The survey for this study was distributed electronically via Qualtrics® on April 12, 2016 to a random sample of 10,000 pharmacists across the United States and was closed on April 26, 2016.
The survey questions were modeled after a previously published study evaluating pharmacists' knowledge, attitudes, and practices regarding influenza vaccination in pregnant women. The modified survey had 27 questions that assessed three major areas; the role of the pharmacist in Tdap vaccination, perceived barriers to vaccination, and understanding of the Advisory Committee on Immunization Practices (ACIP) recommendation. The original survey was validated by authors of the previous study using convenience sampling. Our survey was similarly piloted among pharmacists in Buffalo, NY selected via convenience sampling, to check for face validity.
Survey participation was voluntary and anonymous and no personal identifiers were collected. As an incentive to complete the survey, participants were given the opportunity to provide their name and email address in order to be entered in a drawing for a 100 dollar VISA gift card. The D'Youville College Institutional Review Board approved the study.

Demographic characteristics were summarized using frequencies and percentages. Chi-square tests were used to test differences in responses by gender, year of graduation, and role in the pharmacy. McNemar's tests were used to measure the level of agreement in responses to outcomes of interest.

Results: A total of 225 pharmacists responded to the survey. Most respondents agreed that pharmacists should have a role vaccinating the public and individuals expecting to come into contact with a newborn against Tetanus, Diptheria, and Pertussis (88.5 percent and 86.9 percent) respectively, but only 77 percent agreed that pharmacists should have a role vaccinating pregnant women against Tdap (p equals less than 0.001). Numerous barriers to vaccinating pregnant women against Tdap were identified, with the highest number of respondents recognizing lack of insurance coverage, lack of interest in vaccination by patients, advice from patient's physicians, and liability concerns as barriers. Only 80.2 percent of respondents agreed that the Tdap vaccination is safe during pregnancy. When asked to respond to two case scenarios of pregnant women eligible for vaccination in their 29th and 31st weeks of pregnancy, only 22.5 percent and 30.6 percent respectively stated they would offer the vaccination. When asked to respond to a case scenario of a woman in her 21st week of pregnancy for whom the vaccination is not recommended, 17.3 percent said they would offer the vaccination.

Conclusion: Our survey suggests that while most pharmacists feel they should have a role in vaccinating pregnant women and those expecting to come into contact with a newborn against tetanus, diptheria, and pertussis, there are barriers to implementing this practice. Future efforts should focus on further evaluating identified gaps and developing programs for pharmacists emphasizing the significance of vaccinating these patients to reduce the burden of pertussis in infants.

Poster Title: Vancomycin vs. vancomycin-rifampin for the treatment of MRSA-associated acute pulmonary exacerbations of cystic fibrosis

Primary Author: Corey Wells, University at Buffalo School of Pharmacy and Pharmaceutical Sciences, New York; **Email:** coreywel@buffalo.edu

Additional Author (s):
Nicholas Fusco
Calvin Meaney
Richard Francisconi
William Prescott

Purpose: Patients with cystic fibrosis (CF) experience recurrent acute pulmonary exacerbations (APEs). Methicillin-resistant Staphylococcus aureus (MRSA) colonization, a common cause of APEs, has increased from 9.2% in 2002 to 25.9% in 2014. Although the CF pulmonary guidelines do not make a recommendation regarding treatment of MRSA, vancomycin with and without rifampin has been used in this population, despite a lack of evidence. The purpose of this study was to compare the change in pulmonary function in patients having CF and MRSA colonization treated with either vancomycin monotherapy or vancomycin plus rifampin for an APE.

Methods: This retrospective cohort study analyzed patients with CF hospitalized for an APE between 5/1/2012 and 4/30/2014. Inclusion criteria were: aged 6-20 years; diagnosis of CF; admission diagnosis of an APE; colonization with MRSA in sputum; at least 3 sequential doses of vancomycin; at least 1 correct vancomycin trough; and, baseline and follow-up pulmonary function tests. Patients with multiple hospital admissions were included as separate patient encounters. Patients were divided into two cohorts: vancomycin monotherapy ("monotherapy group") and vancomycin plus rifampin ("dual therapy group"). The primary endpoint was the change in forced expiratory volume in 1 second (FEV1), and secondary endpoints were the change in forced vital capacity (FVC) and hospital length of stay (LOS). Statistical analysis was completed using SAS version 9.4. Continuous variables were compared using Student's t-test or Wilcoxon rank-sum test as appropriate, and categorical data were compared using the Fisher's exact or Chi-squared tests as appropriate. A p-value less than 0.05 was considered to be

statistically significant for all analyses. Normally distributed data was reported as mean +/- SD, and non-normally distributed data was reported as median (IQR).

Results: A total of 40 patient encounters met inclusion criteria: 25 patients received monotherapy and 15 patients received dual therapy. No statistically significant difference in demographics was found between the groups. Mean vancomycin dose (14.9 +/- 4.8 vs. 13.5 +/- 3 mg/kg; p = 0.3) and mean trough level (12.3 +/- 2.2 vs. 13.6 +/- 5 mg/L; p = 0.8) were similar between the monotherapy and dual therapy groups, respectively. Rifampin was dosed as 600 mg/day in one or two doses with a mean of 13.8 +/- 4.7 mg/kg/day. There was no difference in mean change in FEV1 (32.0 +/- 28.4 vs. 21.0 +/- 12.1%; p = 0.1) nor FVC (21.9 +/- 25.5 vs. 14.0 +/- 9.3%; p = 0.2) between the monotherapy and dual therapy groups, respectively. Median LOS [13 (11 − 14) vs. 13 (9 − 14) days; p = 0.6] and median time to readmission [82 (43 − 129) vs. 147 (78 − 219) day; p = 0.2] were similar between the monotherapy and dual therapy groups, respectively. No difference existed between mean change in minimum inhibitory concentration (MIC) between the monotherapy (0.4 +/- 0.9) and dual therapy (0.2 +/- 0.6) groups (p = 0.9).

Conclusion: The addition of rifampin to vancomycin for the treatment of an APE of CF had no significant impact on improvement in pulmonary function or LOS in this small, single-center study. This study was limited by a small sample size at a single center. Until further data is published regarding the role of combination vancomycin and rifampin for treatment of an APE of CF it's use should be discouraged.

Poster Title: Pharmacy interpretation and translation refugee services in the city of Buffalo

Primary Author: Angela Pieprzak, University at Buffalo School of Pharmacy and Pharmaceutical Sciences (SUNY), New York; **Email:** anpieprz@buffalo.edu

Additional Author (s):
Sarah Dascanio
Gina Prescott

Purpose: Refugees accessing the United States healthcare system have limited English language skills and health literacy. Refugee healthcare needs requires proper navigation and utilization of the healthcare system. Community pharmacies are the most accessible health service available to service them and can serve to treat medical conditions as well as refer to the proper healthcare professional. The purpose of this study is to evaluate the presence and utilization of interpretation and translation services available to refugee populations accessing community pharmacies in the Buffalo area and to assess the appropriateness of these services and identify any deficiencies and areas for improvement.

Methods: Pharmacies serving refugees were identified based on geographic areas (zip codes) where refugees reside. A 30-question survey consisting of both free response and multiple choice questions was developed. Content included pharmacy and refugee service demographics, types of interpreting and translation services, and the interest in and/or availability of other resources. The survey was administered prospectively to a pharmacist or technician via an on-site interview. Any questions about the survey or content being asked were answered and clarified on-site during the survey administration. The survey was administered from March 2, 2016 to March 18, 2016. Frequency data was analyzed with Microsoft Office Excel and SAS. Results were further categorized into the following sections: Demographics, Pharmacists Competency and Interest, Translation Services, and Interpretation Services.

Results: A total of 15 pharmacies were identified and administered surveys. One pharmacy that did not service refugees was excluded. The most common pharmacy was a large community chain (50 percent) or independent (43 percent). The majority of the pharmacies know some of their refugees' country of origin (93 percent). Most pharmacists thought their staff was knowledgeable about their translation/ interpretation services offered (86 percent); however, less than half were knowledgeable on finding outside resources (43 percent versus 57 percent). Pharmacists believe they moderately understand who refugees are and their differences (71 percent), but fewer had a moderate/lesser understanding of a refugee view of United States healthcare (57 percent). The translation services were through computer software, non-pharmacy software, and on-site personnel (79 percent, 71 percent, and 57 percent, respectively). Interpretation services were similar. Translation and interpretation services were described as adequate (71 percent and 82 percent, respectively), however most were 'rarely' used (87 percent and 71 percent, respectively).

Conclusion: While the availability of translation and interpretation services at pharmacies with a high refugee population may be sufficient, the utilization of these services may be lacking. Pharmacists could benefit from additional refugee healthcare training. There are multiple opportunities to improve upon current services to not only provide sufficient and correct medical information, but to aide in improved refugee healthcare.

Session-Board Number: 5b-299

Poster Title: Symptomatic intracerebral hemorrhage after thrombolysis with tissue plasminogen activator in minor stroke: A case report

Primary Author: Kim Hoang, Xavier University College of Pharmacy, Louisiana; **Email:** khoang2@xula.edu

Additional Author (s):
Jessica Johnson
Toni Rougeou
Ahmed Zaki

Purpose: Current data supports the safety of intravenous tissue plasminogen activator (tPA) in patients with minor stroke symptoms, categorized as a National Institutes of Health Stroke Scale (NIHSS) score between 1 to 4 before thrombolytic therapy. In the RESUVAL Stroke Network study in France, a total of 1,043 patients had received tPA, and 170 of those patients had a NIHSS score of less than or equal to 4. Overall, no patient had experienced symptomatic intracerebral hemorrhage (SICH) in this study. Thus, the authors concluded that there is evidence of safety and potential benefit of tPA administration in minor stroke patients. However, we present a case of a 48 year-old male with comorbidities of hypertension, hyperlipidemia, heart failure, type II diabetes mellitus, and stage 3 chronic kidney disease (CKD) who presented to the emergency department for hypertensive emergency with decompensated heart failure with preserved ejection fraction (HFpEF) and was admitted to intensive care for intravenous vasodilator therapy. Late on the first night of his admission, a bedside nurse noticed signs of left facial droop. The patient was still able to follow commands, responded to questions, and demonstrated strong and equal grip in both upper extremities and strong and equal resistance in both lower extremities. A neurology assessment was performed with a CT head scan, found no signs of hemorrhage, and the patient was determined to have an NIHSS score of 2. The neurologist discussed with the patient the benefits and risks of tPA and received patient consent to begin tPA administration. The patient then received a tPA bolus of 9 mg given over one minute, followed by a one-hour tPA 81 mg infusion. Approximately four hours after the start of tPA, a bedside nurse noticed bleeding around his foley catheter. One hour later, the patient appeared to be disoriented and had symptoms of slight weakness in grip of the left upper extremity and a more pronounced left facial droop. The patient later had

intermittent episodes of vomiting and became aphasic, but was still able to follow commands. Follow-up CT scans were performed, which showed intracerebral hemorrhage with midline shift requiring external ventricular drain (EVD) and monitoring of intracerebral pressure. The patient was treated and monitored for approximately 7 weeks throughout his admission before being discharged to a nursing facility due to new disabilities. Assessment just before discharge reported improved alertness with intermittent orientation, dysarthria and dysphagia, minimal spontaneous speech, normal grip strength in upper extremities, and requirement of assistance to move to the edge of his bed. It should be noted that, previously, the patient was living independently without assistance before his hospital admission. Four days after discharge, the patient was readmitted to the hospital with acute kidney injury (AKI) and urosepsis, for which the patient received appropriate antibiotics based on culture results. Two days after his readmission, the patient developed significant decline in mental status, unarousable to voice or pain, with frequent episodes of apnea. His family was notified of his declining condition, and the patient expired the third day following. As this case report suggests, the benefit of tPA in minor stroke patients with an NIHSS score of 4 or less versus the risk for intracerebral hemorrhage (ICH) should be assessed very closely. Considering this patient's comorbidities, his history of hypertension and CKD with elevated serum creatinine were potential risk factors for ICH. Although previous studies support the safety of tPA in minor stroke patients, providers should carefully consider ICH risk factors in minor stroke patients before administering tPA.

Poster Title: Evaluation of serum calcium differences between hypertensive crises and control patients: a case-control study

Primary Author: Hannah Naquin, Xavier University of Louisiana College of Pharmacy, Louisiana; **Email:** hnaquin@xula.edu

Additional Author (s):
DeMaurian Mitchner
Mariah White
Amber Faciane
Emmanuel kouagou

Purpose: Serum calcium is an important cation involved in cardiovascular and kidney processes, smooth muscle contractions, and other physiologic functions. Parathyroid hormone, vitamin D and calcitonin regulate serum calcium levels. Previous studies analyzing serum calcium and blood pressure are conflicting; some report a positive correlation while others report no association. There are no previous studies assessing the serum calcium levels in patients presenting with hypertensive crisis. The purpose of this study is to evaluate serum calcium levels in hypertensive crisis patients and a control group without hypertensive crises.

Methods: This is a retrospective, case-control, single-center study. This study has been approved by Xavier University of Louisiana College of Pharmacy Institutional Review Board and the University Medical Center New Orleans Research Review Committee. Patients' electronic charts were reviewed from August 2013 through August 2015. Calcium levels in patients presenting with hypertensive crises were compared to all patients admitted to the hospital who met the inclusion criteria during the study duration. Patients were included if they were 18 years old, with either a diagnosis of hypertensive crisis – case group or without diagnosis of hypertensive crisis – control group. Exclusion criteria consisted of a diagnosis of primary or secondary hyperparathyroidism, CKD (stages 3, 4 or 5), calcium or vitamin D supplementation prior to serum calcium level or vasopressor administration prior to documented blood pressure. The primary objective of this study was to determine differences in serum calcium between hypertensive crises patients (cases) and those without hypertensive crises (controls). Secondary objectives included exploring correlation between serum calcium and systolic blood pressure

(SBP) and diastolic blood pressure (DBP) at the time of hypertensive crisis and determining the effects of covariates (age, race, sex, BMI and history of diabetes) on blood pressure in hypertensive crisis patients. Student's t-test and simple linear/multiple linear regression analyses were performed using IBM SPSS Statistics 19.

Results: There were 234 patients in the control group and 212 patients in the control group. Our study population was majority African American (71.4 percent cases; 58 percent controls) and males (65.8 percent cases; 75 percent controls). Patients in the case cohort had a mean BMI of 30.26 kg/m2 compared to 26.81 kg/m2 in the control group (p < 0.001). The mean calcium level was not significantly different between the cases and controls (8.9 mg/dL vs. 8.9 mg/dL, respectively; p equals 0.960). Serum calcium and SBP during hypertensive crises were positively correlated (r equals 0.103 and R2 equals 0.011; p equals 0.058). Of all the covariates assessed, none had a significant association with SBP during crises. With regards to DBP during hypertensive crises, age, BMI, and history of diabetes were all negatively correlated.

Conclusion: We did not observe a significant difference in serum calcium levels between patients with hypertensive crisis and compared controls. There was however, a small but significant positive correlation between serum calcium and SBP at the time of crises; with calcium accounting for 1.1 percent of the variability in the systolic blood pressure. Our findings suggest a potential role for serum calcium altering (specifically calcium depleting therapies) in the care of hypertensive crises patients. Further studies should evaluate the possible role of age, BMI, and history of diabetes in hypertensive crises patients.

Poster Title: Utilizing a medication synchronization program in improving adherence and overall health outcomes.

Primary Author: Pejman Farrokh, St. John Fisher College (Wegmans School of Pharmacy), New York; **Email:** pf06292@sjfc.edu

Additional Author (s):
MacKenzie Crist
Angela Nagel
Nabila Ahmed-Sarwar
Danielle Webster

Purpose: Medication synchronization programs have the ability to align patients' multiple medications to once monthly deliveries. The purpose of this program was to assess patient interest in a medication synchronization program located at a pharmacy within the same health-care system as the PCP/CCP office.

Methods: Patients were identified using Home Health Care Managers at clinics in the same health-care system as the medication synchronization pharmacy. Patients were selected based on the following criteria; contact with PCP/CCP in last 6 months, >/= 4 medications on their active profile, and followed by care manager. Then, patients were screened on willingness to switch pharmacies and enroll in the medication synchronization program.

Results: A total of 213 patients were identified as utilizing a Home Health Care Manager, of these patients 46 were already utilizing the in-system pharmacy services. After screening by the managers and pharmacy interns, 102 patients were further reviewed by the clinic pharmacist for appropriateness. A total of 60 patients fit the criteria for switching to the medication synchronization program. Of these patients meeting criteria, 8 were willing to change pharmacies.

Conclusion: Several barriers were identified during this pilot program. These included patients not actively engaged in health care, as identified by no show to appointments, preference for previous pharmacy services, and proximity to in-system pharmacy. Of the patients that accepted transfer to the program, future efforts will be made to evaluate health outcomes; blood pressure, blood glucose, and hemoglobin A1C. This will help to determine the impact of the medication synchronization program.

Poster Title: Association of serum magnesium on blood pressures in hypertensive crises patients: a case-control study

Primary Author: Emily Johnston, Xavier University of Louisiana College of Pharmacy, Louisiana; **Email:** ejohnsto@xula.edu

Additional Author (s):
Nicole Little
Rosanna Dastoori
Devinn Rolland
Jasmine Kinnard

Purpose: Magnesium, an essential cofactor, plays a vital role in various physiologic processes including cardiac excitability, neuromuscular transmission, and glycolysis. Observational and clinical trials have shown conflicting evidence on the relationship between blood pressure and serum magnesium levels; some show no association, while others show a negative association. The primary objective of this study is to determine differences in serum magnesium between hypertensive crises patients and a control group. The goal of the study is to determine the relationship between serum magnesium and blood pressure to inform and advise healthcare providers' decision to supplement (or not supplement) magnesium in hypertensive crises.

Methods: The study is a single-center, retrospective, chart review, case-control study conducted at University Medical Center New Orleans (UMCNO) in Louisiana. This study is Institutional Review Board (IRB) approved by Xavier University of Louisiana. Patient cases from August 2013 to August 2015 who were greater than or equal to 18 years old with hypertensive crises and ICD-9 code of 401.9 and patient controls without ICD-9 code of 401.9 were included. Only patients with documented magnesium levels on their electronic medical record were included. Patients with chronic kidney disease stages 3, 4, or 5, end stage renal disease, hepatic cirrhosis, pheochromocytoma, alcoholism, chronic diarrhea, or hyperaldosteronism were excluded. Patients who received magnesium supplementation (oral or IV) at home or during the encounter before magnesium levels were drawn were also excluded. Additionally, patients who received vasopressors or inotropes prior to measurement of blood pressure were excluded. The primary objective of the study is to compare mean serum magnesium levels between

hypertensive crises patients and a control group. Secondary objectives of the study includes assessing the association between serum magnesium on systolic and diastolic blood pressure (SBP and DBP) and the effect of covariates (age, sex, race, Body Mass Index (BMI), and history of diabetes mellitus) on SBP and DBP in hypertensive crises patients. Student's t-Test and simple/multiple linear regression analyses were performed using IBM SPSS Statistics version 19.

Results: A total of 218 hypertensive crises patients and 749 control patients were included in the data collection. Gender distribution was 54 percent males and 46 percent females in the case group and 64 percent males and 36 percent females in the control group. There was no statistical significant difference in the mean serum magnesium levels in patients with hypertensive crises compared to the control group (1.88 mg/dL versus 1.91 mg/dL; p=0.66). Serum magnesium was not a statistically significant factor in determining systolic (r=0.059; p=0.382) or diastolic blood pressure (r=-0.04; p=0.544) in hypertensive crises patients. Of the four electrolytes measured, only calcium was significantly correlated with SBP at time of crises (r=0.181; p=0.007). Also, potassium was the only electrolyte (among four) that significantly correlated with DBP at time of crises (r= 0.133; p=0.049). A statistically significant difference was seen in BMI between cases and controls (30.5 kg/m2 versus 26.4 kg/m2 respectively; p < 0.001). Among the covariates assessed, age was a significant predictor variable of DBP at time of crises and BMI was a significant predictor of both SBP and DBP at the time of crises (p < 0.05 for all).

Conclusion: We found no significant difference in serum magnesium levels between hypertensive crises patients and our control group. Also, there was no significant association between magnesium and either systolic or diastolic blood pressure the hypertensive crises patients. Unexpectedly, calcium was directly correlated with systolic blood pressure. The relationship between calcium and blood pressures in hypertensive crises patients represents an area of future research exploration.

Poster Title: Breast cancer mobile applications designed for patients: An assessment of quality

Primary Author: Zethan Koch, D'Youville College School of Pharmacy, New York; **Email:** kochz11@dyc.edu

Additional Author (s):
Qasim Abdulle
Stacie Lampkin
Amany Hassan

Purpose: Breast cancer diagnosis is of increasing concern among women in the United States. For this reason, proper education about breast cancer prevention and maintenance is important. With the increase of smartphone and smartphone application (app) use, healthcare professionals may be able to recommend apps to patients as a reference for breast cancer education. The purpose of this study is to assess the quality of breast cancer apps for patient use based on app engagement, functionality, aesthetics, and information. A secondary objective is to provide a list of apps that may be recommended by health care professionals, such as clinical pharmacists.

Methods: Two major app stores, Google Play for the Android platform and Apple App Store for the iOS platform, were searched using terms for the most commonly associated breast cancer diseases and symptoms. Apps were included in the study if they were available in United States on Google Play Store or Apple App Store, free of charge, were written in the English language, had a main focus on breast cancer, and were for patient oriented education. Relevant apps were evaluated by two reviewers on April 2016, using the Mobile App Rating Scale (MARS) tool. The MARS tool is a verified mobile app rating tool which collects information about an app to classify and rate it based on four categories: engagement, functionality, aesthetics and information quality. Each category has a subset of Likert scale questions, which were averaged to provide an overall category score. Scores of 1 to 1.99 were rated as inadequate, 2 to 2.99 as poor, 3 to 3.99 as acceptable, and 4 to 5 as good. It was determined by the reviewers that a score of 4-5 (good) across each of the categories would allow for an app recommendation for patient use.

Results: A total of 101 apps were included in the study. Of those apps, 28 (27.7 percent) were available strictly on the Google Play Store, 41 (40.6 percent) on the Apple App Store and 32 (31.7 percent) were available through both stores. Amongst all the apps evaluated, 26 (25.7 percent) in the information category, 14 (13.9 percent) in the engagement category, 42 (41.6 percent) in the functionality category, and 37 (36.6 percent) in the aesthetics category received a score of good (4-5) via the MARS tool. Overall, 9 (8.9 percent) apps received a score of good in each of the app categories. Of the 9 apps, 3 (33.3 percent) were from Android platform, 4 (44.4 percent) were from the iOS platform, and 2 (22.2 percent) were rated individually but were from both platforms.

Conclusion: In conclusion, a minority of the apps within the Google Play Store and Apple App Store received a score of 4-5 (good) across all four categories. Therefore, few apps on either of the markets are suitable to recommend by healthcare professionals, to patients for breast cancer prevention and maintenance.

Poster Title: Evaluation of the need for pharmacologic venous thromboembolism (VTE) prophylaxis in patients with cirrhotic coagulopathy

Primary Author: William Michaels, University at Buffalo School of Pharmacy and Pharmaceutical Sciences, New York; **Email:** wcmichae@buffalo.edu

Additional Author (s):
Sarah Issa
Ashley Woodruff

Purpose: Due to decreased synthetic capabilities of clotting factors in cirrhotic patients, the International Normalized Ratio (INR) is commonly elevated. Clinicians often translate this as being 'auto-anticoagulated', therefore not requiring inpatient prophylaxis with an anticoagulant. In contrast, a new hemostatic balance is achieved in these patients, similar to the normal patient but more fragile, leaving them concurrently prone to emboli formation and bleeding. The fine line that exists in these patients between risk of bleeding and clotting requires exploration. The objective of this study was to identify the impact of prophylactic VTE anti-coagulation in hospitalized patients with cirrhosis.

Methods: This was an institutional review board approved, single-center, retrospective cohort study evaluating the impact of pharmacologic VTE prophylaxis in patients with cirrhotic coagulopathy. Patients with an ICD-9 code pertaining to chronic liver disease or cirrhosis who were admitted to Buffalo General Medical Center between April 2011 – April 2015 were evaluated for inclusion. Inclusion criteria were age 18 years or greater with an International Normalized Ratio (INR) greater than or equal to 1.5 not due to anticoagulant use. Patients were excluded if they presented with acute VTE or active bleeding. The primary endpoint of this study was to compare the rate of nosocomial acquired venous thromboembolism in cirrhotic hospitalized patients treated with a conventional VTE prophylaxis dose of either subcutaneous unfractionated heparin (UFH) 5000 units every 8 hours, UFH 5000 units every 12 hours, subcutaneous enoxaparin 30 or 40mg every 12 hours, or fondaparinux 2.5mg every 24 hours versus cirrhotic hospitalized patients not treated with any pharmacologic VTE prophylaxis. Nosocomial VTE was defined as a VTE acquired during hospitalization or within 30 days of prior hospitalization. The secondary outcome of this study was to compare bleeding rates between

the pharmacologic and non-pharmacologically treated groups. Bleeding related to heparin use was defined as bleeding which occurred 24 hours after heparin initiation that was not present at the time of admission.

Results: There was no statistically significant difference in regard to both primary and secondary outcomes. The rate of VTE in the non-pharmacologic arm was 2.4% versus 0.6% in the pharmacologic arm (p = 0.32). Bleeding was experienced in 4.12% of patients in the pharmacologic treatment arm versus 1.59% in the non-pharmacologic arm (p = 0.31).

Conclusion: Although a numerical reduction in nosocomial VTE was achieved with the use of pharmacologic VTE prophylaxis this difference was not statistically significant. With this reduction in nosocomial VTE also came an increased risk of bleeding. The balance between thromboembolism risk and bleeding risk should be weighed when deciding whether or not to use pharmacologic VTE prophylaxis in this population.

Poster Title: Evaluation of the use of phytonadione for the management of an elevated INR in patients who have not received vitamin K antagonists

Primary Author: H Andrew Wilsey, University at Buffalo School of Pharmacy and Pharmaceutical Sciences, New York; **Email:** handreww@buffalo.edu

Additional Author (s):
James Fenner
Cynthia Lackie
Kimberly Zammit

Purpose: The administration of vitamin K for the treatment of an elevated International Normalized Ratio (INR) in the presence of a vitamin K antagonist or malnutrition is well established. However, there is a lack of evidence supporting the benefit of vitamin K administered in the attempt to correct the coagulopathy associated with impaired synthetic function typical of liver cirrhosis. The purpose of this study was to evaluate INR changes in cirrhotic patients who received vitamin K to reverse coagulopathy not associated with systemic use of a vitamin K antagonist.

Methods: A retrospective observational study was performed via electronic chart review on adult patients greater than or equal to 18 years of age admitted to Buffalo General Medical Center and Millard Fillmore Suburban Hospital who received vitamin K. Records were reviewed and any patient with a history of vitamin K antagonist use within 7 days were excluded from analysis. The cohort was divided into two groups corresponding to receipt of fresh frozen plasma. The primary objective was to compare the degree of change in patient INR levels before and 48 hours after vitamin K administration. The mean change decrease in INR was determined by comparing the baseline INR pre vitamin K with the INR at 48 hours. Additional endpoints collected include change in prothrombin time and platelet count at 48 hours.

Results: The mean INR was 2.62 in patients prior to receiving vitamin K, with "liver impairment" as the most commonly cited reason for an elevated INR by prescribers. Vitamin K had no significant impact 48 hours after administration, as INR levels dropped to an average of 2.33 in patient who had not received fresh frozen plasma (n=63, P=0.11). An individualized patient

review found an average INR decrease of 0.31, with the largest drop of 2.52 and, in some patients, an increase in INR by 3.79. These results demonstrate the lack of clinical benefit of vitamin K administration in order to correct an elevated INR typical of cirrhotic patients. Prothrombin time was minimally improved, decreasing from 27.14 to 27.03 seconds, but was found to be neither statistically nor clinically relevant (P=0.07). Platelet count was also found to decrease 48 hours after vitamin K administration, from an average of 127 to 100 x 10^9 per liter (P=0.027).

Conclusion: This retrospective chart review demonstrated the lack of benefit in administering vitamin K to correct the coagulopathy typical of liver cirrhosis. These results align with previous studies that discuss the inability of INR to represent the new hemostatic balance achieved in cirrhotic patients. This evaluation will assist in the creation of prescriber education programs and the development of a guideline to establish best practice for the utilization of vitamin K agent in this patient population.

Poster Title: The Role of C1- Esterase Inhibitors in the Management of Hereditary Angioedema Exacerbation

Primary Author: Mariah White, Xavier University of Louisiana, Louisiana; **Email:** mwhite10@xula.edu

Additional Author (s):
Candice Burke
Ellen McKnight
Jessica Johnson

Purpose: C1- esterase inhibitor is a blood protein that regulates the body's ability to fight infections, coagulate and complement inflammatory response. Patients with hereditary angioedema (HAE) have a defect in the gene that controls this protein and as a result have either inadequate or non-functioning C1- esterase inhibitor. The biochemical imbalance of C1-esterase inhibitor causes unwanted peptides to induce capillaries to release fluids into surrounding tissues causing edema. There are three types of HAE: type I HAE is caused by inefficient production of the C1- esterase inhibitor while in type II, the production of C1-esterase is sufficient, however the function is inadequate. Type III is an extremely rare form where the C1- esterase protein level and function are normal while the patient still exhibits symptoms. It is most common in women usually exacerbated by hormonal irregularities (i.e. pregnancy, oral contraceptives). Based on pharmacokinetics and pharmacodynamics, the therapeutic profile of C1- esterase inhibitor provides an onset of 15-minutes with a complete resolution of symptoms within 30-minutes. This case report describes the potential use of C1-esterase inhibitor therapy in exacerbations of suspected hereditary angioedema. Our patient is a 26 year old female with multiple presentations to a medical intensive care unit with life-threatening oropharyngeal swelling. The patient's angioedema exacerbations began after pregnancy and were unassociated with ACE Inhibitor use. Multiple blood tests resulted with normal C1- esterase level. The patient's, age, symptoms, normal C1- esterase level, and multiple angioedema exacerbations occurring post-pregnancy give us reason to suspect type III HAE. Current standard therapy for HAE exacerbation consists of corticosteroid and antihistamine administration, despite the lack of obvious pathophysiological benefit. However with the use of C1- esterase inhibitor, HAE patients experience fewer angioedema-associated

complications and improved symptom relief. Furthermore, given the high cost of C1- esterase therapies, an opportunity exists for pharmacists to improve overall health effectiveness and outcomes in patients with this rare condition.

Poster Title: Drug interaction between methadone and fluconazole

Primary Author: Negin Alizadeh, Touro College of Pharmacy, New York; **Email:** nalizade@student.touro.edu

Additional Author (s):
Keith Veltri

Purpose: Purpose: This case report illustrates the increase in serum concentrations of methadone when co-administrated with fluconazole. DO, a 58 year old male, presented to the emergency department (ED) with progressive difficulty and pain in swallowing for 3 weeks. Past medical history includes Human Immunodeficiency Virus (HIV) with a CD4 23, VL 867878, non-compliance to antiretroviral therapy secondary to depression and active poly-substance abuse issues on methadone maintenance, and chronic obstructive pulmonary disease (COPD). Upon admission, according to the gastrointestinal team's recommendation, the patient was treated for presumed esophageal candidiasis with fluconazole 100mg PO daily for 14 days, and was considered for an esophagogastroduodenoscopy if symptoms persisted. The maintenance dose of methadone, 100mg PO daily, according to the patient's treatment program was continued. Infectious Disease team was also consulted and suggested 100mg IV fluconazole daily, which began on hospital day 2. The dysphagia continued to improve, and the patient was switched back after 3 days of IV to fluconazole 400mg oral suspension daily as his swallowing improved and he felt less retrosternal pain.

On hospital day 8, the patient developed an acutely altered mental status, with alternating agitation and somnolence as well as confusion, on a non-focal neurological exam. The patient was disoriented and restless throughout the day. A stat head computerized tomography revealed no acute intracranial pathology. It was reported that the clinical pharmacist noted on rounds that fluconazole, a known cytochrome P450 inhibitor, suppresses the metabolism of methadone in liver. Therefore, fluconazole increases the serum level of methadone and potentiates its effect. The patient was referred to Addiction Psychiatry who subsequently recommended decreasing the methadone dose, to 30mg daily as he was deescalated incorrectly from IV to PO antifungal therapy. On hospital day 9, the patient also presented with seizures requiring a total dose of 4mg lorazepam, with subsequent improvement. A magnetic resonance imaging of the brain later revealed patchy white matter hypo-densities and

periventricular matter, confirming the altered mentation was likely secondary to methadone toxicity in the setting of a drug-drug interaction with concomitant HIV encephalitis.
The patient became asymptomatic for several days, after discontinuing fluconazole and his mental status slowly improved as the drug concentrations were gradually eliminated after a 7-10 day wash out period. No ECG changes were noted throughout the admission. He was eventually discharged on hospital day 20 to a nursing home.

Poster Title: Aprepitant use evaluation in the prevention of postoperative nausea and vomiting in bariatric patients at Huntington Hospital

Primary Author: Stephanie Lim, St. John's University, New York; **Email:** stephanie.lim11@stjohns.edu

Additional Author (s):
Agnieszka Pasternak

Purpose: Nausea and vomiting is a common postoperative complication, with an incidence reaching as high as 70-80% in general surgery. While there are prior studies of aprepitant in preventing postoperative nausea and vomiting (PONV), there is conflicting and inconclusive data over the relationship between body mass index (BMI) and the incidence of PONV in the obese bariatric surgery patient population. Therefore, the purpose of this study was to evaluate the use and efficacy of aprepitant in preventing PONV 24-hours post-surgery, specifically in this population.

Methods: This is an IRB approved retrospective drug use evaluation study of aprepitant conducted at Huntington Hospital (HH). The use of aprepitant 40 mg one-time dose was approved for the prevention of PONV by Northwell Health Pharmacy and Therapeutics Committee on October 5, 2011. A report from an automated dispensing cabinet from HH was generated for patients on aprepitant 40 mg between May through August 2016. Electronic medical records were reviewed and data was collected on the following: patients' demographics (gender, age, BMI), drug allergies, home medications, admitting diagnosis, surgery performed, duration of surgery, preoperative and 24-hours postoperative medication administration records. Primary outcome studied was the incidence of nausea and vomiting, defined as the number of rescue antiemetics doses given 24-hours postoperatively. Secondary outcomes included: concomitant home medications with greater than or equal to 10% risk of nausea and vomiting, confirmed by two drug information resources, and the number of opioid doses given 24-hours postoperatively.

Results: The report generated 90 patients and data was collected on 84 (58 females, 26 males, average age of 45 years). Six patients were excluded either for surgery other than bariatric or aprepitant use outside the recommended 3-hour time frame prior to anesthesia induction. All laparoscopic bariatric surgeries, which lasted approximately 2 hours, were performed by the same surgeon. Twenty eight (33%) patients were obese, 48 (57%) were morbidly obese, and 8 (10%) were severely obese, as per BMI classification. No standardized preoperative medication protocol existed. Thirty three (40%) patients did not receive antiemetics 24-hours postoperatively and 51 (60%) received 1 or more. Of the 33 patients who did not receive antiemetics, 23 (70%) had no concomitant home medications that had greater than 10% risk of nausea and vomiting and 10 (30%) had 1 or more. Of the 51 who received more than 1 antiemetic, 32 (63%) patients had no concomitant home medications and 19 (37%) had 1 or more. Out of 33 patients who had no antiemetics, 28 (85%) were given opioids 24-hours postoperatively and 5 (15%) had none. Out of the 51 who had 1 or more antiemetics, 43 (84%) received opioids 24-hours postoperatively and 8 (16%) received none.

Conclusion: The majority of patients were not taking concomitant medications that had a high-risk for nausea and vomiting prior to surgery, but we observed no reduction in the number of antiemetics given 24-hours postoperatively. The use of opioids 24-hours postoperatively was high (84.5%) and 51 patients needed rescue antiemetics, which shows that postoperative opioids play a role in the incidence of PONV. Literature shows that medications can potentiate the incidence of PONV, but further studies in bariatric surgery patients are needed with a larger sample size to confirm these results.

Poster Title: Ketorolac-induced acute kidney injury associated with hearing loss

Primary Author: Phoebe Wong, Touro College of Pharmacy, New York; **Email:** pwong2@student.touro.edu

Additional Author (s):
Kelly Moore
Robert Wessolock

Purpose: We present a probable case of ketorolac-induced acute kidney injury associated with acute hearing loss. According to the Kidney Disease: Impacting Global Outcomes (KDIGO) guidelines, acute kidney injury (AKI) is defined as an increase in serum creatinine by 0.3 mg/L or greater within 48 hours, an increase in serum creatinine to 1.5 times baseline, which is known or presumed to have occurred within the prior 7 days or urine volume of 0.5 mL/kg/h for 6 hours. Evaluation of hearing loss can be either audiometric which includes standard pure tone thresholds, speech discrimination scores, otoacoustic emission and psychophysical measurements or nonaudiometric data which includes self-reported hearing loss via survey results.

Non-steroidal anti-inflammatories (NSAIDs), specifically ketorolac, are associated with acute kidney injuries. Signs and symptoms of an acute kidney injury include increase serum creatinine, elevated BUN, weight gain and hyperkalemia. The mechanism of NSAID- induced kidney injury is typically caused by hypoperfusion to the kidney cause by inhibition of prostacyclin synthesis. It is has been suggested the mechanism of NSAIDs induced hearing loss is similar to salicylates. Suggested mechanism of ototoxicity is an increase in norepinephrine, a decrease in prostacyclin, and decrease cochlear blood flow.

A 57-year-old male (165.1 cm, 142 kg) with a primary diagnosis of osteoarthritis of bilateral knees and receiving a left total knee revision (TKR) for recurrent prosthetic joint infections and severe progressive pain and instability in the left knee. His past medical history includes anxiety, arthritis, borderline diabetes, gout, herpes simplex virus, hypertension, infection of ankle joint, infection of prosthetic left and right knee joints, morbid obesity, bilateral feet neuropathy, obstructive sleep apnea, renal failure, spinal stenosis, and venous insufficiency of lower extremities. Immediately post-operatively, the patient was started on ketorolac 15 mg IV push every 6 hours. He received 5 doses of ketorolac on post-op day 1 and 1 dose of ketorolac

and 1 dose meloxicam 15 mg on post-op day 2. The patient was also started on aspirin 325 mg by mouth twice daily for deep vein thrombosis (DVT) prophylaxis, hydromorphone PCA, docusate, senna, pantoprazole, and morphine immediate release on post-op day 1. The patient renal function was normal and his serum creatinine was 0.8 mg/dL at baseline and following, the administration of ketorolac his serum creatinine increased to a maximum of 3.5 mg/dL on POD 3. The ketorolac was discontinued and the patient serum creatinine returned to 1.0 mg/dL on POD 5. The patient also became hyperkalemic with potassium of 5.6 mmol/L. Compared to his baseline of 5.0 mmol/L. Upon physical exam, the patient also reported hearing loss in both ears on POD 2, which started to resolve on POD 5 and fully resolved at discharge. It was determined that ketorolac, a nephrotoxic agent, was the probable cause. The Naranjo probability score was five, indicative of probable ketorolac induced acute kidney injury. Interestingly, the patient reported hearing loss at the same time as the acute kidney injury and the hearing loss resolved a few days following the resolution of the acute kidney injury.

Poster Title: Assessing the appropriateness of sugammadex use in accordance with pre-established Pharmacy and Therapeutics Committee approved criteria.

Primary Author: Kortney Morrell, Albany College of Pharmacy and Health Sciences, New York; **Email:** kortney.morrell@acphs.edu

Additional Author (s):
Kassandra Marsh
Carley Luker
Lauren Gimlin
Thomas Lombardi

Purpose: Sugammadex is FDA approved for routine reversal of the neuromuscular blocking agents vecuronium and rocuronium. In May of 2016, our institution approved sugammadex for the reversal of vecuronium and rocuronium by anesthesia during surgery when response to neostigmine is not adequate or surgery is unexpectedly aborted. It was additionally approved for use in the emergency department when emergent intubation is aborted. The purpose of this study was to evaluate sugammadex use to determine compliance with pre-specified guidelines set by the Pharmacy and Therapeutics Committee (P&T).

Methods: The institutional review board approved this open-label, observational study. All patients who received sugammadex between June 16, 2016 and September 7, 2016 were included in the study. There were no exclusion criteria. Patients were identified as having received sugammadex via a central search of medical records using a Drug Utilization Review Report through the Pharmacy Information System. Patients receiving sugammadex were assessed by a review of anesthesia records, progress notes, and physician orders. Data collected included the type of neuromuscular blocking agent used, department where sugammadex was administered, whether neostigmine was given prior to sugammadex, documentation of the time of administration of neostigmine and sugammadex, and documented reasons for sugammadex use. Thresholds of 100% were set for use of vecuronium or rocuronium, 90% for prescribing by an anesthesiologist or ED physician, 90% for inadequate response to neostigmine, surgery unexpectedly aborted, or emergent intubation aborted. The primary endpoint of this study was the percentage of time that sugammadex was used in

accordance with the criteria for use set forth by the P&T. Secondary endpoints included documented reasons for sugammadex use, documentation of administration times, and the incidence of use over the three-month period.

Results: In a three-month period, sugammadex was used in 30 patients (mean = 10/month). Expected use was estimated at 4 cases per month. Rocuronium was used prior to administration of sugammadex in 100% patients (30/30). In the 30 cases, 100% (30/30) were ordered by anesthesiologists, and 0% (0/30) were ordered by the emergency department. Sugammadex was not used for emergent abortion of surgery (0/30) or emergent abortion of intubation (0/30). Sugammadex was administered after inadequate response to neostigmine in 76.7% cases (23/30). Reasons for sugammadex use when neostigmine was inadequate were breathing difficulties (7/23) and weakness (4/23). The remaining cases (12/23) did not have a reason documented. Reasons for sugammadex use without prior use of neostigmine included train of four of 0 out of 4 (2/7), for patient assessment in PACU (1/7), and unknown secondary to no documentation (4/7). Documentation of the time administered was reported for neostigmine only in 34.8% (8/23), sugammadex only in 13% (3/23), both medications in 34.8% (8/23), and neither medication in 17.4% (4/23) of cases. P&T criteria for sugammadex use were not met in 23.3% of cases (7/30).

Conclusion: The number of times sugammadex was administered was higher than the expected use of 4 per month. Goals of 100% and 90% were achieved for use of correct neuromuscular blocking agent and prescribing by allowed physicians, respectively. The goal of 90% adherence to P&T protocol was not met due to seven cases where neostigmine was not used prior to sugammadex administration. Education of physicians, anesthesiologists, and nursing staff regarding sugammadex and the guidelines for its use will be implemented in order to ensure appropriate future use of sugammadex.

Poster Title: Pharmacodynamic relationship between PCSK9, alirocumab concentration, and LDL-C lowering in four Phase 3 ODYSSEY trials with or without statin background therapy

Primary Author: Alvina Abramova, Long Island University

Arnold & Marie Schwartz College of Pharmacy and Health Sciences, New York; **Email:** alvina.abramova@my.liu.edu

Additional Author (s):
Angela Khodzhayev
Guillaume Lecorps
Jennifer Robinson

Purpose: Proprotein convertase subtilisin/kexin type 9 (PCSK9) protease, a key regulator of cholesterol homeostasis, promotes degradation of low-density lipoprotein (LDL) receptors in the liver, leading to increase of LDL cholesterol (LDL-C). Alirocumab, a human monoclonal antibody, binds and inhibits PCSK9, and decreases LDL-C levels. It is indicated as an adjunct to diet and maximally tolerated statin therapy in heterozygous familial hypercholesterolemia (HeFH) or clinical atherosclerotic cardiovascular disease for patients requiring additional LDL-C lowering. Clinical trials suggest the pharmacokinetic profile (concentration-dependent and non-linear kinetics), PCSK9 production rate, and LDL-C reduction differs amongst alirocumab dosing strategies, with statin therapy, and compared to ezetimibe.

Methods: In this analysis we used data from four ODYSSEY Phase 3 randomized trials, MONO, FH I, COMBO II, and LONG TERM in which pharmacokinetic samples were collected, to identify the relationship between the pharmacokinetic profile of alirocumab and pharmacodynamic profiles of PCSK9 and LDL-C. Patients in the MONO trial were on alirocumab monotherapy, and the other three trials enrolled patients on maximally tolerated statin therapy. MONO and COMBO II compared alirocumab with ezetimibe, and FH I and LONG TERM compared alirocumab with placebo. In MONO, COMBO II, and FH I patients were initiated on alirocumab 75 mg every 2 weeks (Q2W) and dose-escalated to 150 mg Q2W at Week 12 if their LDL-C was still greater than or equal to 70 mg/dL. In the LONG TERM study, patients received 150 mg Q2W for the entire study. The study durations were 24 (MONO), 78 (FH I and LONG TERM), and 104 (COMBO II) weeks. Concentrations of alirocumab, free and total PCSK9 were measured at

Weeks 4, 12, 16 and 24, along with LDL-C levels at Weeks 4, 8, 12, 16 and 24. Alirocumab pharmacokinetic parameters included trough concentration that was assessed 8 to 21 days after previous injection.

Results: In total, 2407 patients were randomized to receive alirocumab. The mean trough concentration (standard deviation) of alirocumab at Week 24 for FH I, MONO and COMBO II was 12,148.1 (8,914.0), 14,772.2 (10,201.7), 8,384.3 (10,942.8) ng/mL in patients who required dose adjustment, versus trough concentration of 4,465.1 (2,467.3), 6,991.4 (4,418.4), 3,945.8 (2,728.1) ng/mL in patients who did not, respectively. LDL-C reduction in the alirocumab arms was apparent by Week 4 and was sustained until the end of treatment. Mean percentage changes in LDL-C concentrations from baseline to Week 24 ranged from minus 47.2 percent to minus 61.0 percent with alirocumab compared to minus 15.6 to minus 20.7 percent with ezetimibe and 0.8 to 9.1 percent increase with placebo (P less than 0.0001). Although mean concentrations of free PCSK9 at Week 12 in MONO, COMBO II and FH I were somewhat higher in patients who required dose adjustment than those who did not (MONO: 59.3 versus 40.4 ng/mL; COMBO II: 211.9 versus 141.5 ng/mL; FH I: 188.9 versus 185.5 ng/mL), an additional decrease in mean free PCSK9 concentrations was observed after alirocumab dose adjustment to 150 mg Q2W (MONO: 14.3 ng/mL; COMBO II: 131.3 ng/mL; FH I: 80.5 ng/mL, at Week 24).

Conclusion: Treatment with alirocumab resulted in an increase in serum alirocumab concentrations, leading to a decrease in free PCSK9 and significant reduction in LDL-C levels in all Phase 3 ODYSSEY trials evaluated. LDL-C followed the same pharmacodynamics pattern as free PCSK9. Free PCSK9 levels were higher in statin-treated patients and remained consistently higher throughout the study, supporting existing evidence that statins increase PCSK9 production. Free and total PCSK9 levels at baseline were higher in patients who received alirocumab dose adjustment, likely due to greater PCSK9 production and therefore need for higher doses to achieve required LDL-C thresholds.

Poster Title: Evaluating the effectiveness of an unfractionated heparin protocol that uses anti-factor Xa monitoring

Primary Author: Joseph Graber, D'Youville College School of Pharmacy, New York; **Email:** grabej05@dyc.edu

Additional Author (s):
Stacie Lampkin
Amany Hassan

Purpose: Intravenous unfractionated heparin offers rapid anticoagulation, but also requires continuous monitoring and frequent administration rate adjustments. Hospitals use heparin protocols to aid in the determination of initial infusion and subsequent adjustment rates. This study evaluated the effectiveness of an existing weight based heparin protocol used at a large community teaching hospital. The existing weight based protocol has established maximum heparin doses to be administered at both initial dosing and subsequent rate adjustments. This study will also evaluate the appropriateness of the maximum doses by comparing time to achieve therapeutic anticoagulation in obese and non-obese patients.

Methods: This single center, observational, retrospective cohort study was conducted using data from patients who were treated with intravenous unfractionated heparin infusions at a large community teaching hospital from May 2015 to April 2016. The heparin protocol utilized antifactor Xa (anti-Xa) monitoring. For the primary endpoint, patients' anit-Xa levels were collected to determine percentage of patients achieving therapeutic anticoagulation at 24, 48, and 72 hours post initial infusion. Additional secondary outcome measures assessed were the average percentage of time spent by patients in the therapeutic window over the course of their treatment, as well as difference in time to achieve therapeutic anticoagulation between obese and non-obese patients. Therapeutic anticoagulation was defined as two consecutive therapeutic levels, with anti-Xa levels defined as 0.3 to 0.5 units/mL for patients placed on low heparin protocol and 0.5 to 0.7 units/mL for patients placed on high heparin protocol. Frequencies and percentages were used to summarize the proportion of patients achieving therapeutic levels at 24, 48, and 72 hours, and to determine the average percentage of time patients maintain therapeutic anti-Xa levels during the course of treatment. Kaplan-meier

estimates and log-rank tests compared the difference in time to achieve therapeutic levels between obese and non-obese patients from initial infusion to 72 hours.

Results: Anti-Xa levels were analyzed from 191 patients meeting inclusion criteria for this study. At 24 hours post initial heparin infusion 32.98% of the 191 patients had achieved therapeutic Anti-Xa levels. Of the 191 patients studied, 110 patients remained on heparin infusions after 48 hours of therapy. At 48 hours post initial infusion 62.73% of the 110 patients had achieved therapeutic Anti-Xa levels. At 72 hours post initial heparin infusion 62 of the original 191 patients remained on heparin therapy. 61.29% of these 62 patients achieved therapeutic Anti-Xa levels at 72 hours post initial infusion. On average patients spent a time of 57 hours on a heparin infusion. 38.94% of the average time spent by patients on heparin infusions was spent in the therapeutic range as defined by the studied protocol. There was no difference in time to achieve therapeutic levels between obese and non-obese patients (log-rank test p-value=0.104).

Conclusion: The results of this study suggest the existing heparin protocol needs to be re-evaluated. A high percentage of patients had not achieved therapeutic anticoagulation at 24, 48, and 72 hours post initial heparin infusion. Furthermore, the results indicate that over the course of heparin treatment, patients spend, on average, a higher percentage of time non-therapeutic than therapeutic. No difference was found in time to achieve therapeutic Anti-Xa levels between obese and non-obese patients. This suggests the current protocol's maximum initial and subsequent adjustment dosing does not contribute to differences between obese and non-obese patients in time to achieve therapeutic anticoagulation.

Session-Board Number: 5b-313

Poster Title: Preferred First-line Add-on Therapy to Metformin in Non-Insulin Dependent Diabetic Patients in an Outpatient Urban Setting

Primary Author: Tatyana Bazarova, Touro College of Pharmacy, New York; **Email:** tbazarov@student.touro.edu

Additional Author (s):
Rebecca Cope

Purpose: In 2015, the Comprehensive Type 2 Diabetes Management Algorithm published by the American Association of Clinical Endocrinologists (AACE) and American College of Endocrinology (ACE) updated the Glycemic Control Algorithm to provide a suggested hierarchy of use for the preferred, first-line add-on therapy to metformin. This algorithm now lists glucagon-like peptide-1 receptor agonists (GLP-1RAs) and sodium glucose co-transporter 2 (SGLT2) inhibitors as the top two agents to consider following metformin. The purpose of this study is to determine whether antihyperglycemic medication prescribing in an urban, outpatient setting reflects the changes in the Glycemic Control Algorithm set forth by the AACE/ACE.

Methods: The institutional review board at The Brooklyn Hospital Center in Brooklyn, NY approved this retrospective cohort study, which utilized chart review of patients identified from a password protected site where pharmacist interventions regarding chronic care management are logged. Data from three outpatient clinics was reviewed to identify an eligible patient cohort. The patient population extracted in the present study satisfied the following conditions: (i) diagnosis of Type 2 Diabetes Mellitus; (ii) age ≥18 years old; (iii) seen by a clinical pharmacist between April 2015 to August 2016; (iv) medication therapy of metformin + at least one other antidiabetic agent. Inclusion period was chosen based on the date of publication of the first AACE/ACE algorithm (2015) to make the previously described changes to the suggested hierarchy of antihyperglycemic use. Exclusion criteria was: (i) presence of chronic kidney disease, ≥ stage 4; (ii) Estimated glomerular filtration rate (eGFR) of < 30 mL/min; (iii) treatment with insulin therapy; (iv) A1C of ≥ 9%. Eligible patients' charts were analyzed to determine which diabetes therapy were utilized in addition to metformin for patients who do not require

insulin therapy. Demographics, vitals, laboratory values, and other baseline characteristics were collected for each eligible patient. Descriptive statistics were used to summarize the data.

Results: Out of 319 patients screened, 22 met eligibility criteria. Of the 22 included patients, 32% were African-American, 64% had Medicaid, and the mean age was 59 years old. The preferred add-on therapy to metformin in this patient population and practice setting appears to be dipeptidyl peptidase-4 (DDP4) inhibitors, with 64% of regimens containing one of these medications. Although sulfunylureas (SUs) are now considered to be last-line therapy as per the AACE/ACE Glycemic Control Algorithm, 45% of regimens still contained a SU. Although 64% of patients had a diagnosis of hypertension and 55% had a BMI ≥ 30 kg/m2, only 5% were on SGLT2 inhibitors and 0% were on GLP-1RAs.

Conclusion: Although the AACE/ACE Glycemic Control Algorithm recommends GLP-1RAs, followed by SGLT2 inhibitors, as the preferred, first-line add-on therapies to consider after metformin, these agents are being minimally utilized in our patient population despite the additional benefits these medications may confer. Future studies are needed to determine potential barriers leading to underuse of these agents in practice.

Poster Title: Anaphylaxis to rocuronium during anesthetic induction

Primary Author: Amy Yu, St. John's University, New York; **Email:** amy.yu11@stjohns.edu

Additional Author (s):
Candace Smith

Purpose: Anaphylaxis during anesthesia is considered a rare phenomenon, but it poses life threatening complications if not managed quickly and appropriately. Neuromuscular blockers (NMBs) are commonly used as paralytic agents during surgical induction and have been associated with anaphylactic reactions. One of the agents highly implicated is rocuronium. This case report illustrates how the use of one NMB may be associated with anaphylaxis while another class of NMBs may be safe. This is a 73-year-old African American man who developed anaphylactic reactions to rocuronium on two separate occasions during induction for a left popliteal aneurysm repair. During the first induction, fentanyl, etomidate, sevoflurane, and rocuronium were administered over a few minutes. Within thirty minutes after administration of these agents, his systolic blood pressure dropped to 35 mmHg from 160 mmHg. The patient averaged systolic pressures in the 50-60 mmHg range for ten minutes. Vitals returned back to baseline with the use of phenylephrine, vasopressin, and epinephrine. Given the patient's acute on chronic kidney disease and hypotensive episode, the surgery was postponed. Approximately two weeks later, the patient returned to the OR for a second attempt for left lower extremity revascularization. This time, induction was completed using sevoflurane, propofol, and rocuronium. Again his systolic blood pressure dropped to 35 mmHg from 170 mmHg, averaging in the 40-50 mmHg range. Resuscitative measures included phenylephrine, norepinephrine, epinephrine, vasopressin, hydrocortisone, and two units of PRBC's. The procedure was once again cancelled. At this time, there was a strong suspicion that the patient may be allergic to rocuronium which was supported by a positive serum tryptase level of 48.8 ng/mL measured approximately 30 minutes after onset of the hypotensive episode. The patient returned to the OR the following day and cisatracurium was used instead of rocuronium. The surgery was successful and the patient was brought to ICU for further observation and was eventually discharged. The quaternary ammonium ion structure of NMBs is the main contributing factor in the development of allergic reactions. Therefore, it is not surprising to see that most cases of anaphylaxis are associated with the use of succinylcholine, due to its molecular flexibility. The

ability to vary the distance between its quaternary ammonium ion structure favors binding to IgE antibodies, and thus cause a subsequent reaction. Rocuronium, belonging to the aminosteroidal drug class, has a slightly less mobile structure, but may bind to IgE in a similar fashion. Benzylisoquoliniums, such as mivacurium and atracurium, induce histamine release. Cisatracurium, an isomer of atracurium, has a lesser tendency to produce mast cell degranulation, even though it shares the same benzylisoquolinium structure. Cross reactivity relates with the structure of the molecule, its flexibility, and the way an allergic response is initiated. It is thus essential to understand the cross reactivity between the different NMBs, and their associated risk for having an anaphylactic reaction.

Poster Title: Assessing knowledge and level of concern regarding Zika virus in Nuevo Cuscatlan, El Salvador

Primary Author: Alexandra Mancuso, St. John Fisher College Wegmans School of Pharmacy, New York; **Email:** amm03505@sjfc.edu

Additional Author (s):
Lauren Bowers
Alexander DeLucenay

Purpose: Zika Virus has recently become an area of great concern because of its continuing spread throughout the world. It is especially concerning for pregnant women and people of childbearing age, as it may cause microcephaly and severe fetal brain defects. Although it is not yet common in the United States, education and prevention tips are being discussed all over the news. This project was designed to assess knowledge of Zika virus and transmission in subjects in the endemic country of El Salvador.

Methods: One hundred adults patients (>18 years old) in attendance at a Global Health Outreach clinic located in Nuevo Cuscatlan, El Salvador from July 30, 2016 to August 7,2016 were asked to complete a survey. The survey consisted of basic demographic questions, questions regarding knowledge and transmission of Zika virus, and level of concern regarding the virus. The interviewer presented the survey verbally to the subject with the use of a Spanish interpreter.

Results: Of the 100 patients surveyed in Nuevo Cuscatlan, El Salvador 32 patients were male and 68 patients were female. The majority of the patients were greater than 40 years of age. In total 91% of patients had heard of Zika virus, 60% stated they knew how Zika was transmitted, 39% had received information from a healthcare professional and 85% were concerned about Zika virus in their country. Regarding the risk between Zika and pregnancy 53% were aware such a risk existed stating consequences such as "microcephaly, baby malformations, and babies can die". Regarding knowledge of transmission 39% of patients did not know or inaccurately defined the mode of Zika transmission.

Conclusion: This study evaluated the knowledge of patients in El Salvador regarding Zika virus and its modes of transmission. Although prevalent in El Salvador, only 1 in 2 people knew the importance of Zika in regards to birth defects and many people did not understand how the virus was spread. Healthcare professionals, including pharmacists, need to further educate patients in developing nations on both long- and short-term mission work in order to prevent the spread of this disease.

Bhumi Pandhi

Purpose: The recent surge of antibiotic resistance has resulted in an increased awareness of antibiotic stewardship programs. At Huntington Hospital (HH), we developed a guideline for the treatment of symptomatic uncomplicated urinary tract infections (UTIs). The purpose of this study is to assess if patients in our Emergency Department (ED) are being appropriately treated according to an internally developed guideline for UTI following 2010 IDSA recommendations.

Methods: A retrospective chart review was conducted at HH to assess the treatment of ED patients discharged home who were diagnosed with acute urinary cystitis after implementation of internally developed guidelines for the Treatment of UTI in the ED for patients discharged home. Exclusion criteria included: males, pregnant females, children < 16 years of age, patients diagnosed with complicated UTIs, pyelonephritis, contaminated urine samples or admitted patients. Eligible patients received empiric treatment with antibiotics in our ED in conjunction with a urinalysis and a urine culture. Assessment of antibiotic selection and duration was further evaluated against urine culture results and documented in the HH "ED laboratory call back" by Physician Assistants (PAs). . Through our medical electronic record system, we extracted patients who received a urinalysis in the ED and identified patients diagnosed with UTIs from January 1 - 31, 2016 (Controlled group) and March 1 - 31, 2016 (Intervention group). The primary outcome was to determine if patients who were diagnosed with symptomatic uncomplicated UTIs and who had positive urinalysis and urine culture were treated according to the guidelines. The secondary outcome was to evaluate whether patients who obtained negative cultures were stopped or continued on their antibiotic treatment.

Results: There were 39 patients in the Control group and 40 patients in the Intervention group. Nine (36%) patients in the Control group received appropriate antibiotic therapy vs. 18 (78%) patients in the Intervention group. Out of 9 patients in the Control group, one patient received the appropriate dose of antibiotic and duration of the therapy as compared to 5 out of 18 patients in the Intervention group. There were 11 (100%) patients in the Control group who obtained a negative urine culture and were continued on antibiotic treatment at home vs. 6 (60%) patients in the Intervention group.

Conclusion: The implementation of the uncomplicated UTI guidelines in our ED has led to a positive shift in the selection of empiric treatment of antibiotics for patients being discharged home. Limitations of our study include a small sample size, high ED physician turnover and difficulty in ensuring continued education of the guideline. The next step is the creation of an inter-disciplinary team between pharmacy, physicians and PAs to review susceptibility of urine cultures and to continually assess for appropriate selection and duration of antibiotics. This will optimally lead to the prevention of inappropriate antibiotic treatment in patients diagnosed with uncomplicated UTIs.

Poster Title: Pharmacists' Attitude Towards Pharmacogenomic Testing

Primary Author: Mina Awad, Saint John's University, New York; **Email:** awadmina08@gmail.com

Additional Author (s):
Gabrielle Guancione
Billy Ning
Pavit Singh

Purpose: Pharmacogenomics is a growing field with great potential that involves utilizing a patient's genetic information to optimize therapeutic outcomes and minimize adverse events. It is important for pharmacist's to be equipped with the knowledge and basic understanding of this field. The new 2016 ACPE standards include pharmacogenomics as one of it's required elements of the pharmacy curricula. The purpose of this study was to assess how knowledgeable pharmacists are with available pharmacogenomic resources. Additionally, pharmacists' level of comfort and potential barriers their participation in pharmacogenomics will be studied.

Methods: This study has been approved by the institutional review board. A survey was created using Survey Monkey and distributed to New York State pharmacists via various social media outlets. Those who are participating provided consent. The anonymous survey asked a series of questions centered on pharmacists' knowledge and utilization of pharmacogenomics to guide patient therapy. The following data was collected: years as a licensed pharmacist, gender, area of practice, specialty, level of education, specialized training, understanding of pharmacogenomics, education received in pharmacogenomics, level of comfort of ordering pharmacogenomic tests, frequency of accessing pharmacogenomics resources, resources used, knowledge of drugs for which pharamcogenomic markers are relevant, frequency of recommending pharmacogenomic testing, liability and responsibility associated with pharmacogenomic tests, importance of pharmacogenomic testing, etc. Data determined the frequency, comfort level, and importance associated with the pharmacist's role in the utilization of pharamcogenomic testing to guide patient therapy. The survey took approximately 5-10 minutes and all questions did not require a response.

Results: Seventy-five pharmacists were surveyed, 64.8 percent being female. The majority of respondents had either less than 5 years (41.4 percent) or greater than 15 years (28.6 percent) of experience. Most practiced in general inpatient care (45.5 percent) followed by general community practice (30.9 percent). A total of 69.7 percent of respondents reported understanding concepts of pharmacogenomic testing but only 15.4 percent said they felt qualified recommending testing. Only 19 percent were able to accurately identify how many drugs had pharmacogenomic statements issued by the FDA. Additionally, 71.4 percent said they did not receive any training at all in pharmacogenomics and 82.3 percent felt it is crucial to introduce pharmacogenomics as a topic taught in pharmacy and continuing education curricula. Only 35.5 percent of surveyed pharmacists provided a response on resources that contain information related to pharmacogenomics. Furthermore, 54.1 percent of respondents have never accessed pharmacogenomic-specific resources. Of note, 58 percent reported feeling responsible to ensure proper pharmacogenomic testing when needed in optimizing drug therapy, while 90 percent of respondents report having not having recommended pharmacogenomic in the past 6 months. Also, 96.6 percent report never having encountered a patient who has brought pharmacogenomic tests for interpretation or guidance.

Conclusion: The use of pharmacogenomics in the profession of pharmacy has grown from a supplemental reference to an integral knowledge set over the past few years. This is shown by mandating the incorporation of pharmacogenomics into the pharmacy curriculum by ACPE. However, practicing pharmacists are reporting feeling unqualified and unprepared to utilize this information on a day to day basis. Pharmacists want and need additional training to feel fully equipped in making pharmacogenomic recommendations.

Poster Title: An interprofessional educational outreach program by pharmacy and public health students in a community based organization servicing patients with sickle cell disease

Primary Author: Ashley John, Long Island University Arnold & Marie Schwartz College of Pharmacy and Health Sciences, New York; **Email:** ashley.john@my.liu.edu

Additional Author (s):
Daria Smith
Aicha Diallo
Jadwiga Najib
Fraidy Maltz

Purpose: Team based care is important in providing patient education on chronic disease states in a public setting and empowering patients with knowledge to help manage their health conditions. The aim of this project was to evaluate the impact of pharmacy and public health students' educational outreach initiatives in raising awareness of the importance of immunizations in patients with sickle cell disease. Also to provide public awareness of the condition during Sickle Cell World Day 2016 at a local community based organization in an underserved community.

Methods: Study participants provided informed consent prior to the surveys. A Center for Disease Control and Prevention (CDC) questionnaire was used to assess the respondent's baseline knowledge of sickle cell disease. Additionally, patient baseline demographic data, including health beliefs was collected prior to any educational informational session.
Based on the results of the CDC questionnaire, two pharmacy and two public health students provided educational materials (e.g. brochures, flyers) in support of providing accurate evidence-based information to the respondents individually and provided clarification to any discrepancies as noted in the patient specific responses. Additionally, a 30-minute interprofessional student developed and directed informational interactive session was delivered to the audience to enhance the patient's comprehension of the health related topics. Afterwards, a post survey was administered to the participants for their feedback and to assess their knowledge of material presented.

Results: Study participants provided informed consent prior to the surveys. A Center for Disease Control and Prevention (CDC) questionnaire was used to assess the respondent's baseline knowledge of sickle cell disease. Additionally, patient baseline demographic data, including health beliefs was collected prior to any educational informational session. Based on the results of the CDC questionnaire, two pharmacy and two public health students provided educational materials (e.g. brochures, flyers) in support of providing accurate evidence-based information to the respondents individually and provided clarification to any discrepancies as noted in the patient specific responses. Additionally, a 30-minute interprofessional student developed and directed informational interactive session was delivered to the audience to enhance the patient's comprehension of the health related topics. Afterwards, a post survey was administered to the participants for their feedback and to assess their knowledge of material presented.

Conclusion: Interactive sessions led by pharmacy and public health students had a positive impact on health literacy and providing an educational outreach session on World Sickle Cell Day in the community. Open discussion format with patients was a valuable learning experience as noted by patients on their evaluations. Outreach to community-based organizations should be encouraged among students from various disciplines as part of the interprofessional educational experience in professional health programs.

Purpose: The Brazil Scientific Mobility Program (BSMP) provides one-year scholarships to undergraduate students for studies in the Science, Technology, Engineering and Mathematics fields in United States colleges and universities. The program intends to foster academic and research exchange. In 2013, St. John's University (SJU) College of Pharmacy and Health Sciences started accepting BSMP students. The purpose of this project was to survey past and current students to assess satisfaction with their curriculum and overall experience in this exchange program and to identify areas that need improvement.

Methods: Past and current BSMP students were invited to participate. A list of email addresses of 98 candidates was obtained and a self-administered electronic survey instrument was utilized. The purpose, anonymity, and voluntary nature of the survey was disclosed and return of a completed survey implied consent. Majority of the survey questions assessed satisfaction with the curriculum and participants were also given the opportunity to provide additional comments. Additional survey questions assessed satisfaction with housing and the overall experience. Curriculum questions evaluated pharmacy classes and their application to the practice of pharmacy in Brazil and the advantage, if any, of English language classes. This project was submitted to the SJU Institutional Review Board and received exempt status.

Results: Fifty two candidates responded. Majority (≥90%) took English language classes prior to starting the program and deemed them beneficial. More than 96% of the Brazilian students were housed in one residence hall and more than 92% were satisfied with this residence. They did feel however, they would prefer to be more integrated into other facilities that housed American students. This would allow a more extensive submersion into American student

culture and strengthen their conversational English speaking. Majority of students were satisfied with the courses they completed. The courses with the most satisfaction (>80%) were Pharmaceutical Marketing, Pharmacoeconomics, Public Health, Leadership Development, Pharmacy Practice and the US Healthcare Environment. Courses of least satisfaction were courses with a content focus in clinical pharmacy practice and basic science. This was due to the vast difference in the practice of pharmacy in Brazil vs. the US.

Conclusion: BSMP students were very satisfied with their overall US experience. However, a more focused curriculum would specifically improve their pharmacy learning experience and would be more applicable to their interests and the practice of pharmacy in Brazil. This survey has acknowledged that the practice of pharmacy can be vastly different in other countries and that a curriculum should be customized to have a greater impact and satisfaction on the curriculum experience.

Poster Title: Analogues of resveratrol as novel cis-stilbene antiestrogens

Primary Author: Tamara Mitchell, Xavier University of Louisiana College of Pharmacy, Louisiana; **Email:** tjmitche7@gmail.com

Additional Author (s):
Peng Ma
Thomas Wiese

Purpose: While the synthetic stilbene diethylstilbestrol is well known as an estrogen agonist with toxic effects after developmental exposure, natural trans-stilbenes such as resveratrol, piceatannol and pterostilbene found in grapes, blueberries and other plants have been shown to have antineoplastic and other medicinal properties. In this report, we test the hypothesis that stilbene analogues and isomers of resveratrol have estrogen agonist or antagonist activity.

Methods: Presented is the in vitro estrogen activity of 29 stilbene analogues and isomers obtained from Dr. Agnes Rimando of the USDA Natural Products Utilization Research Unit in Mississippi. The estrogen-dependent breast cancer cell T47DkbLuc reporter gene assay and the MCF-7 proliferation assay were both utilized to determine estrogen agonist and antagonist activity. For those with activity at high dose, data was obtained over the range of 1 nM to 10 uM. In an effort to explain estrogen agonist or antagonist activity observed, computer stimulations were performed using MOE software to dock the 29 stilbenes to the crystal-structure of the Estrogen Receptor alpha Ligand Binding Domain (ERLBD). These crystal-structures contained diethylstilbestrol or tamoxifen bound within representing agonist and antagonist binding modes. Multiple configurations of potential poses for each stilbene were generated using MOE and the poses were ranked in ascending order by delta-G.

Results: No significant estrogen agonist activity of the stilbene analogues was observed using the reporter gene and cell proliferation assays. At the same time, stilbenes 4 and 9 were found to have dose dependent estrogen antagonist activity. Stilbenes 4 and 9 are both cis-isomers with meta-methoxys on one phenyl ring, where resveratrol is a trans-isomer with meta-hydroxyls. The hydroxyl group on the styryl-ring of resveratrol is replaced by a nitro-group in stilbene 4 and an ethoxy-group in stilbene 9. The MOE docking stimulations of the stilbenes

with ERLBD generated ligand binding poses that suggest reasonable antiestrogen binding modes for stilbenes 4 and 9 bound to ER. Thus, the cis-stilbenes 4 and 9 fit well into the tamoxifen binding pocket of the antagonist form of the ERLBD. These cis-stilbenes can mimic tamoxifen binding that occupies a channel to the outside of the ER, mechanically blocks helix-12 and receptor mediated transcription is inhibited. This antagonist stilbene binding mode is only possible for cis stilbenes.

Conclusion: Data obtained from this study can be used to suggest the potential of stilbene analogues as antihormones that could be used in estrogen dependent breast cancer. Previous studies involving these stilbene analogues reported that the methoxyl compounds had the most antitumor activity in hormone independent cells. These earlier studies determined that increasing the number of methoxy groups will result in greater antiproliferative effects and that the cis-isomers exhibited greater antagonist activity than the trans-isomers. Our study of the estrogen activity of the stilbenes analogues describes a similar structure activity relationship for the antiestrogen activity in breast cancer cells.

Poster Title: Evaluation of Clinical vs. Administrative Barriers in Prior Authorization Requests for Hepatitis C Therapy in the HIV/AIDS Medicaid Population

Primary Author: Kenny Ng, St. John's University, New York; **Email:** kenny.ng11@stjohns.edu

Additional Author (s):
Nabil Umer

Purpose: To evaluate the (clinical vs. administrative) factors in the decision-making process related to the Prior Authorization requests by providers for HCV medications in a HIV/AIDS Medicaid Managed Care Organization (MCO) for patients presenting with HIV/HCV co-morbidities.

Methods: A retrospective, cross-sectional analysis was performed using both administrative and clinical data for Hepatitis C Prior Authorization (PA) requests in a Medicaid HIV/AIDs Special Needs Health Plan with over 6,000 Medicaid HIV/AIDS positive members in New York for the year of 2015. The reasons for HCV PA denials and approvals were then categorized as either clinical or administrative factors.

Results: The initial Hepatitis C drug PA denial rate was 8.9% or 40 denials out of 450. After an appeal (second request attempt), 22 were later approved resulting in 432 overall approvals or 96% overall approvals for 2015. The denial reasons in descending order of frequency for the initial requests (n=40) included alternative regimen recommended by health plan's clinical pharmacist to provider (42.5%), member has unsuppressed HIV Viral Load per the health plan's prior authorization policy (37.5%), insufficient evidence per AASLD to support drug effectiveness in certain patients (12.5%), and incomplete lab data from providers (7.5%) (Table 1). 92.5% of the denials were based on clinical factors compared to 7.5% of denials based on administrative reasons. Of the 40 denied cases, 22 were later approved after an appeal. Of the denials that were eventually approved, 90.9% were based on clinical factors compared to 9.1% which were based on administrative factors. Further analysis was done related to the outcomes for the remaining 5% of members who requested for Hepatitis C during the 2015 calendar year for which their requests were denied completely. 66.7% of the denials were based on clinical factors compared to 33.2% of denials based on administrative reasons.

Conclusion: Clinical factors played a major contributing factor for patients being denied or approved Hepatitis C therapy in the health plan compared to administrative factors. Based on this evaluation, evaluating the clinical factors may prove to be in the best interest of the patient population by the health plan to address if certain barriers should be modified or improved upon to ensure best clinical practices are followed. Further analysis should also be done in accessing the health outcomes of patients that have completed their respective HCV therapy.

Submission Type: Descriptive Report

Session-Board Number: 5b-323

Poster Title: Effect of proton pump inhibitor use on infection rates in kidney transplant recipients

Primary Author: Christina Benenati, Long Island University - Arnold & Marie Schwartz College of Pharmacy, New York; **Email:** christina.benenati@my.liu.edu

Additional Author (s):
Christina Guerra

Purpose: Following transplantation, patients receive maintenance immunosuppressant medications, such as mycophenolate mofetil and steroids, which can cause gastrointestinal upset upon initiation. Thus, medications such as proton pump inhibitors (PPIs) are often prescribed for the first month. The inherent acidity of the stomach prevents bacterial growth, however, PPIs inhibit gastric acid secretion, creating an environment susceptible to bacterial colonization. Infections can be fatal for these patients due to immune system limitations as a result of immunosuppressants. The risk-benefit balance of utilizing PPIs post-transplant remains controversial. This study aims to evaluate the relationship between PPI use and infection incidence in kidney transplant recipients.

Methods: This single center, retrospective chart review included all adult patients who received a kidney transplant between January 2014 and December 2015. Data was collected on patient demographics, details of PPI use, and the incidence and type of any infections experienced. The time the patient developed these infections in relation to the time of transplant was also taken into consideration. The data collected was analyzed utilizing descriptive statistics.

Results: Fifty percent of the patients that were prescribed a PPI post-transplant developed infections within the first three months of the procedure. During this time frame, the number of infections that each patient developed varied, with 73 percent of patients developing multiple infections. Out of the 26 patients who had at least one infection, 96 percent were on a PPI for at least two months post-transplant and the remaining patient was on this therapy for less than one month. Eighty percent of the infections were urinary tract infections and only one patient developed Clostridium difficile diarrhea.

Conclusion: Although half of the patients developed at least one infection within three months of transplant, with majority on daily PPI therapy for more than two months, the infections experienced by patients mainly included urinary tract infections. Patients treated with PPIs have traditionally been thought to be at an increased risk for enteric infections such as Clostridium difficile, Campylobacter and Salmonella, but only one patient had an infection of this nature. Thus, it does not appear that PPI use has increased the risk for infections in kidney transplant recipients. However, randomized placebo-controlled studies are needed to further clarify this relationship.

Poster Title: Evaluating patient knowledge of outpatient proton-pump inhibitor use in a transitional care setting

Primary Author: Seth Amidon, St. John Fisher College Wegmans School of Pharmacy, New York; **Email:** sma02491@sjfc.edu

Additional Author (s):
Mary Staicu
Christine Hamby

Purpose: Proton-Pump inhibitors (PPIs) are among the most frequently prescribed classes of medications. Many patients take PPIs longer than recommended in the package insert. Since studies have shown an association between PPIs and an increased risk of bone fracture, pneumonia and Clostridium difficile infection, long-term use has consequences associated with cost and safety. We sought to evaluate patient knowledge of their outpatient PPI use in a transitional care setting.

Methods: Adult patients admitted to the internal medicine service with a PPI listed as an outpatient medication were prospectively interviewed by a pharmacy student using a PPI questionnaire. The questionnaire assessed PPI indication, duration and administration as well as patients' knowledge of PPI side effects and alternative medications prescribed. Patients unable to answer questions and who did not have a caregiver present were excluded. Interviews were conducted over a 4-week period in August and September 2016 with responses recorded in a central database. This project was approved by the Institutional Review Board.

Results: A total of 30 patients consented to participate in the study. The average age of the patients interviewed was 71.3 years. The PPIs consisted of either pantoprazole (15, 50%) or omeprazole (15, 50%). Acid reflux (15, 50%) was the most frequent indication patients gave for taking a PPI followed by a response of "I don't know" (11, 36.7%). An antacid was the most commonly reported alternative therapy (12, 40%). The most common response patients gave for their duration of therapy was "longer than 1 year" (15, 50%). Patients most often replied

"none" (13, 43.3%) or "I don't know" (14, 46.7%) when asked about their awareness of PPI side effects.

Conclusion: Our survey is an effective tool to assess patient knowledge about outpatient PPI use in a transitional care setting. Acid reflux was the most common outpatient indication; however, more than 36% of patients did not know why they were taking the medication. Half of the patients described a duration of therapy greater than one year, whereas the majority of patients were either unable to name side effects or felt there were none. Larger studies are needed to further validate our results.

Poster Title: Content, curriculum, and design of clinical pharmacokinetics courses in Accreditation Council for Pharmacy Education (ACPE)-accredited colleges of pharmacy

Primary Author: Ruby Lee, St. John's University College of Pharmacy and Health Sciences, New York; **Email:** ruby.lee11@stjohns.edu

Additional Author (s):
Vassilia Sideras
Gregory Hughes
Candace Smith

Purpose: Clinical pharmacokinetics is a necessary and vital part of every pharmacist's education to ensure the proper use of medication. At this time, the methods of structuring and delivering this material across pharmacy schools is unknown. To determine the current content, curriculum, and design of clinical pharmacokinetics courses in all Accreditation Council for Pharmacy Education (ACPE)-accredited schools, a survey was distributed to each school. This enables us to assess the current focus and trend in clinical pharmacokinetic education.

Methods: Each ACPE-accredited college of pharmacy was individually contacted to determine the individual that could best answer questions regarding their respective school's pharmacokinetics curriculum. That individual then received an online survey and all the answers were compiled and analyzed. The respective colleges of pharmacy and respondents' names were anonymous through the survey. The survey was organized into four categories; (1) the curriculum portion included how the material is distributed throughout the degree; (2) the design portion included teaching and assessment methods; (3) the course content portion identified specific medications, classes, and mathematical models used; and (4) the last section identified other teaching methods that were not previously mentioned. Responses were analyzed using descriptive statistics.

Results: A voluntary survey recipient was acquired from 108 colleges of pharmacy. Of these, 76% (82/108) completed the full survey. Biopharmaceutics and basic pharmacokinetics preceded the clinical pharmacokinetics course in 54% and 66%, respectively. Fifty-nine percent delivered clinical pharmacokinetics as a stand-alone course, and 41% integrated the topics

within other courses. Classroom instruction averaged 15 hours when integrated within other courses. Clinical/applied pharmacokinetics is mostly taught within the P2 and P3 years (70% and 53%, respectively). The top three classes of medications, aminoglycosides, vancomycin, and phenytoin are taught in 96%, 94%, and 91% of schools, respectively. Although most students were provided the pharmacokinetic equations to use on exams (84%), they were mostly restricted to only use a scientific calculator (88%). The most utilized teaching methods included lecturing, using actual pharmacokinetic cases, and practice quizzes/exams (for no credit), 95%, 85% and 58%, respectively.

Conclusion: This survey returned a large response rate of ACPE-accredited pharmacy schools. Results indicated a variation of teaching methods, content, and curriculum throughout the schools as expected. Seeing these results in aggregate may be useful as a reference for schools that are redesigning their curriculum or are considering doing so.

Poster Title: Assessment of obesity trends and nutrition knowledge in first through third year pharmacy students

Primary Author: Nicole Little, Xavier University of Louisiana College of Pharmacy, Louisiana; **Email:** nlittle@xula.edu

Additional Author (s):
Emily Johnston
Stephanie Hymel
Alaina Dekerlegand

Purpose: Obesity can be directly linked to many chronic health problems. Therapeutic lifestyle changes based on diet and exercise have proven to be preventative in many disease states. Although some information about nutritional tools and guidelines is available for pharmacy students, there could be additional student training in this area. The purpose of this study was to identify the need for additional education in regards to obesity and nutrition for pharmacy students in order to promote preventative patient care.

Methods: The institutional review board approved our study. A comprehensive survey was issued to first through third year pharmacy students at the local college of pharmacy. The survey consisted of ten multiple-choice questions regarding obesity trends in the United States, nutrition, and lifestyle modifications. Pre-tests and post-tests were administered to students on a voluntary basis. In between the surveys, students were encouraged, but not required to attend educational presentations regarding the subject. Surveys with 100 percent of questions correct were considered adequate prerequisite knowledge.

Results: Thirty-three pharmacy students completed the pre-test. One student answered nine survey questions correctly. Eight students answered seven to eight questions correctly. Seventeen students answered four to six questions correctly. Seven students answered one to three questions correctly. Based on these results the average score was calculated to be 5.12 out of 10 correct answers on the pre-survey. Twenty-three pharmacy students completed the post-test. One student answered all ten survey questions correctly. Eight students answered eight to nine questions correctly. Twelve students answered six to seven questions correctly.

Only two students answered four to five questions correctly. Based on these results the average score was calculated to be 7.21 out of 10 correct answers on the post-survey.

Conclusion: The results showed that pharmacy students benefit from educational sessions regarding obesity and nutrition. Pharmacy students lacked sufficient knowledge about the topics in the pre-survey. There was approximately a two-question increase in scores from the pre-survey to the post-survey. We can conclude that there was a positive shift in student knowledge provided by the educational presentations. This tool may be useful in the future for assessing deficiencies in other fields of pharmacy to identify areas of educational opportunity in preventative patient care.

Stephanie Ramirez

Purpose: As part of the Affordable Care Act, Centers of Medicare and Medicaid Services (CMS) began financially penalizing hospitals with higher than average 30-day readmission rates starting in October 2012. Currently, CMS looks specifically at readmission data for core measures, which include acute myocardial infarction, heart failure, pneumonia, chronic obstructive pulmonary disease exacerbation, and total hip/knee arthroplasty. In the Medicare population, adverse drug events make up 20 percent of readmissions within the first three weeks after discharge. The transition of care between inpatient and outpatient services is vital for positive patient outcomes and prevention of readmissions.

Methods: To improve the transition of care, disease state education, medication reviews and discharge counselings were completed from June 7, 2016 until September 27, 2016 by the transition of care pharmacist and fourth year pharmacy interns at a 383 bed community/teaching hospital. Customized patient lists were generated through the electronic health record, Epic, to identify patients who had a targeted disease state in their problem list and those who had discharge orders submitted by their physician. Targeted disease states included acute coronary syndrome (ACS), congestive heart failure (CHF), chronic obstructive pulmonary disease (COPD), cerebrovascular accident (CVA), atrial fibrillation (AF), deep venous thrombosis (DVT) prophylaxis, and thromboembolism (PE). In June and July, the process was to identify the selected patients and coordinate with their nurse to complete discharge counseling together. As difficulties in coordination arose, the process was changed in August and September to obtain the discharge summaries from the nurse and complete the counseling independently. Patients were counseled prior to discharge according to their reason for

admission and discharge medication list. There was also a focus on patients being discharged on an anticoagulant. If there was a need for intervention, the pharmacist/pharmacy intern provided corrected medication administration instructions or collaboratively worked with the provider to make the necessary changes. Education documentation was kept within the patient chart and in a spreadsheet.

Results: In total, 176 patients were encountered. Disease state counseling and medication education was provided to all patients. A full medication review was completed with 147 patients and 81 patients received discharge counseling. There were 180 disease state educations delivered/provided to patients with the following diagnoses: CHF, COPD, ACS, AF, PE, DVT, CVA, hip and knee replacements and unspecified conditions. Medication education for anticoagulation was provided to 97 patients; 33 on Coumadin, 32 on Xarelto, 19 on Eliquis, 11 on Lovenox, 1 on Pradaxa, and 1 on both Coumadin and Lovenox. There were a total of 20 interventions made and documented in 63 patients. Interventions included correction of prescribing errors, optimization of pharmacotherapy, correction of drug administration, and implementation of adherence methods.

Conclusion: Pharmacy involvement in the discharge process greatly improves patient care. Patients who are knowledgeable about their medications are more likely to be adherent and take their doses correctly and appropriately. We positively impacted each patient encountered by making necessary interventions prior to discharge and providing disease state medication counseling. We believe continuation and expansion of this pharmacy-driven service will result in decreased readmissions, improved patient outcomes, and reduce overall healthcare costs.

Poster Title: Quality assessment of post-graduate readiness workshop series during the fourth year of pharmacy school

Primary Author: Allan Batalier, St. John Fisher College Wegmans School of Pharmacy, New York; **Email:** agb01598@sjfc.edu

Additional Author (s):
Kaleigh Gregory
Jennifer Mappus
Angelica Wisniewski
Deirdre Pierce

Purpose: The purpose of this workshop series is to expand the content of a postgraduate preparation workshop series for fourth year pharmacy students (P4). Previously, this series solely addressed residency preparation, including the application process, interviewing skills, and integration of an evaluated mock interview/case presentation scenario. It did not address other concerning areas for P4 students, such as answering insurance questions, managing student loans, and ideas for attaining professional practice at the top of a pharmacist's license. Therefore, student leaders of the P4 class collaborated with the Wegmans School of Pharmacy (WSoP) faculty to further develop the workshop series.

Methods: P4 student leaders pre-screened the P4 class for interest in a postgraduate student developmental workshop series. As there was positive interest in the series, P4 student leaders collaborated with pharmacy faculty to build upon an established series that focused on residency preparation. Inclusive of topics more relevant to community practice, financial health and overall job satisfaction, the new workshop series included: The Good, The Bad and The Ugly: Interview Gaffes and Strokes of Genius; How to Navigate ASHP Midyear and the Residency Application Process; 2 in 10 If Your Prior Auth is Approved, Net 30: All You Could Ever Know About Insurance; Shut Up and Take My Money: How to Achieve Your Financial Goals; and Life After Pharmacy School and Residency: Survival Tips and Tricks. Coinciding with various community- and residency-associated deadlines, these workshops were set to launch in September 2016. To better gauge the relevance of this series, P4 student leaders developed an 11 question Likert Scale survey with 10 questions directed at assessing readiness for life after

pharmacy school. One open-ended question was also included, allowing for expression of further areas of concern. The survey was distributed via email as a Google form to 82 students comprising the WSoP Class of 2017. Students were allotted one week to respond.

Results: A total of 36 out of 82 P4 pharmacy students responded to the survey. Students reported feeling unprepared to manage post-graduate finances (50%), write a letter of intent and curriculum vitae (47% and 49% respectively), apply for post-graduate careers (36%), answer questions regarding insurance (37%), and transition to an entry-level pharmacy position (42%). Students also expressed a general lack of familiarity with the residency application process and its major deadlines (64%). Although an optional educational session focusing on creating portfolios was offered during the 2015-2016 academic year, most students felt that they were not knowledgeable about portfolio components (72%). Lastly, 39% of students felt unprepared to attend the American Society of Health-System Pharmacists Midyear clinical meeting and exhibition in 2016. Concerns regarding post-graduate pharmacy professions were also expressed in the results of the open-ended question.

Conclusion: Pharmacy students indicated that there are many facets of post-graduate preparation that they are ill-equipped to manage and, thus, are areas for concern. These include various aspects surrounding the community practice and residency application process; the explanation of common, often complex, adjudication problems; and the achievement of personal and professional goals following graduation. These results have shown that providing educational workshops geared towards these topics may be beneficial in enabling and empowering our P4 students to be more successful and prepared upon graduation. These results will be used to emphasize those aspects during the future workshop series.

Submission Type: Case Report

Session-Board Number: 5b-329

Poster Title: Hypertriglyceridemic pancreatitis: a case report

Primary Author: Andy Nguyen, Touro College of Pharmacy, New York; **Email:** anguyen20@student.touro.edu

Additional Author (s):
Roksolyana Filipchak
Keith Veltri

Purpose: It is well documented that the risk of hypertriglyceridemic pancreatitis (HTGP) is markedly increased when serum triglyceride levels exceed 1000 mg/dL. This case report describes R.M, a 26 year old male with a past medical history of pancreatitis, obesity, asthma, hyperlipidemia, hypertriglyceridemia, hypertension, uncontrolled Type 2 diabetes (HbA1c 13.1%) secondary to medication non-compliance (off insulin for 3 weeks) and diabetic ketoacidosis (DKA), who presented to the emergency department (ED) with acute onset abdominal pain, elevated lipase (432 U/L), amylase (159 U/L), triglyceride levels of 3449 mg/dL and a pseudohyponatremia (Na = 133 mEq/L) secondary to excess triglycerides which displace water-containing sodium. The pain was described as a constant "stabbing" event that began around his epigastric area and was reported a 2/10 at onset but quickly progressed to a 10/10 with radiation to the back and was later associated with nausea and emesis. A computerized tomography (CT) was performed and revealed findings consistent with acute pancreatitis. In the setting of R.M.'s elevated triglycerides with no past medical history of gallstones, abdominal trauma, newly prescribed medication or non-prescription herbal supplementation nor unusual food intake or alcohol consumption, hypertriglyceridemia was the most likely etiology. No other systemic findings or organ failure complications were noted. On admission, the patient was given several doses of hydromorphone 1 mg for pain and ondansetron 4 mg for nausea as well as a continuous intravenous D5W maintenance infusion at 200 ml/hour. On hospital day 2, R.M was initiated on an insulin drip at 8 units per hour after an endocrine consult. Given that the patient's fasting blood glucose (FSBG) level was reported around 200 mg/dL, he also required a D5W intravenous infusion at 300 ml/hour simultaneously with the insulin drip to avoid a hypoglycemic episode. Titration of the D5W to maintain a FSBG between 150-200 mg/dL was also documented while maintaining the insulin drip between 8-6 units per hour. Potassium chloride (KCl) 20 meq/L in D5W at 300 ml/hr was substituted if potassium levels fell below 3.5

mEq/L. By hospital day 3, the triglyceride levels decreased to 1383 mg/dL and the patient's overall pain began to resolve. On hospital day 4, the triglycerides decreased even further to 831 mg/dL by that morning. Discontinuation of the insulin drip was recommended by the endocrine team after the triglyceride levels dropped below 500 mg/dL which was achieved by day 5 of the hospital stay. Upon resolution of the acute pancreatitis, the patient was started on clear liquids and was advanced as tolerated after clinical improvement by day 6. The patient was eventually transitioned to an adjusted detemir and lispro insulin regimen along with low dose metformin. A low fat diet was encouraged upon discharge in addition to a combination gemfibrozil 600 mg twice daily and omega-3 fatty acids 4 grams daily regimen with close follow up of lipid and glucose monitoring in the outpatient diabetic clinic.

Poster Title: Retrospective analysis on the incidence of falls in patients taking medications associated with fall risk

Primary Author: Ansue Koshy, St. John's University, College of Pharmacy and Health Sciences, New York; **Email:** ansue.koshy11@stjohns.edu

Additional Author (s):
Ridha Hassoun
Marina Barsoum
Nicole Maisch
Maha Saad

Purpose: Falls are a significant public health problem, especially among the elderly. Falls are not only associated with morbidity and mortality in patients but can lead to a decrease in independence and early admission to long-term care facilities. There are numerous risk factors associated with falls, including age, comorbidities and medications. Medications are a modifiable risk factor that pharmacists can play a role in addressing, both in inpatient and community settings. The purpose of this study was to determine whether there is an association between the medication(s) a patient is taking and the occurrence of falls in that patient.

Methods: The institutional review board approved this retrospective chart review. Adult patients were included if they were admitted to Long Island Jewish Medical Center from January to December 2015, experienced one or more reported falls during admission, and were given a medication known to be associated with falls. A list of medications associated with falls was compiled after consulting the 2015 Beer's Criteria and a literature search. Patients who were under the age of 18, experienced a fall in the emergency department or outpatient clinic, or were not given a medication from the compiled list were excluded from the chart review. Information such as patient age, comorbidities, medication therapy regimens, documentation of fall assessment and reported falls were analyzed from patient electronic medical records. Assessment of therapy based on patient comorbidities and age was performed to determine whether medications administered during their inpatient stay contributed to their risk of falls. During review of patient charts, medications that were given within 48 hours of the reported

fall event were stratified, and the duration between medication administration and fall events were recorded. The primary outcome was to identify specific drug classes from the compiled list that resulted in the highest rate of falls in admitted patients. In addition, the timing of medication administration to fall was explored.

Results: Two hundred and thirty-six patient charts were reviewed, and 150 patients met the inclusion criteria. The average age was 66 years (19 to 95). Most patients were female (51 percent). The majority of patients only had one fall during their admission (99 percent), with two patients (1 percent) had two falls. A fall risk assessment was performed on 99 percent of patients, and from those patients 96 percent were at risk for a fall. We focused on nine different drug classes, with anti-hypertensives, anticoagulants and narcotics being the most used. Out of 150 patients, 33 percent were on one anti-hypertensive drug, and 25 percent were on two or more. Thirty-seven percent of patients were on one anticoagulant. Lastly, 32 percent of patients were on one narcotic, and 3 percent were on two or more. Mean time to fall, in hours, for the top 3 drug classes are as follows: anti-hypertensives 3.7, anticoagulants 4.2 and narcotics 4.1.

Conclusion: Following analysis of the reported falls in one year of admissions, anti-hypertensives, anticoagulants, and narcotics caused the most number of falls. Although administration route and patient comorbidities influence onset of action, certain drug classes are attributed to increased fall-risk shortly after administration of a class medication. This study reflects the increasing need for inpatient fall assessment and careful consideration of patients taking medications known to cause falls. Long-term studies analyzing drug interactions and patient adherence will provide further insight into fall prevention during admissions.

Submission Type: Descriptive Report

Session-Board Number: 5b-331

Poster Title: Community pharmacy survey regarding naloxone education, access, and distribution

Primary Author: Mara Garfinkel, Albany College of Pharmacy and Health Sciences, New York;
Email: mara.garfinkel@acphs.edu

Additional Author (s):
Lisa Dragic
Jeffrey Bettinger
Jeffrey Fudin
Jacqueline Cleary

Purpose: In 2013 New York State (NYS) logged 1,589 opioid related deaths. Naloxone is a non-scheduled opioid antagonist that has been proven to rapidly reverse life-threatening opioid induced respiratory depression (OIRD). Pharmacist initiated naloxone prescriptive authority varies by state. NYS requires either a provider-initiated prescription or a collaborative practice agreement, and registration "as an opioid overdose prevention program to furnish naloxone under a non-patient specific prescription (standing order)". The objective of this study was to ascertain the availability of naloxone from community pharmacies and identify barriers, if any, for accessing naloxone within the Albany, NY capital district.

Methods: Study personnel approached pharmacies in Albany County and three surrounding Counties (Rensselaer, Saratoga, and Schenectady) to ascertain availability of naloxone and potential pharmacist distribution barriers. Contact was made by Student Pharmacists and Pharmacy Residents by phone or in person. Predetermined questions were posed to pharmacists and were documented on a de-identified spreadsheet. Participants were asked if the pharmacy currently had any form of naloxone on the shelf, if they had a collaborative practice agreement to prescribe naloxone, how many prescriptions they filled weekly for naloxone, who the pharmacist believed would be an appropriate person for in-home naloxone, and if they would be willing to use an available risk-assessment tool that accurately quantified percent risk for opioid-induced respiratory depression in order to qualify patients for a naloxone prescription. Participation was voluntary and responses were kept anonymous.

Results: One-hundred and forty-six (146) pharmacies were contacted in total, of which 93 agreed to participate. Out of 93 participants, 58 reported having a collaborative practice agreement to prescribe naloxone. Nevertheless, 71 percent of pharmacies (66 out of 93) had no naloxone in stock. Reported reasons for not stocking naloxone included high cost (22 percent), low demand (24 percent), tight inventory (32 percent), and unknown reason (13 percent). Out of all the participants, 96 percent reported receiving an average of zero prescriptions per week for any form of naloxone. When asked if it would be appropriate for patients with an opioid abuse disorder or patients on chronic opioid therapy to have naloxone, 88 percent and 80 percent respectively responded yes. When participants were asked if having a quick tool for assessing OIRD would be beneficial, 86 percent responded yes, 10 percent responded no, and 4 percent were unsure.

Conclusion: Naloxone procurement and distribution by pharmacists is fragmented. This survey demonstrates that almost every pharmacy is not receiving naloxone prescriptions and therefore not stocking naloxone due to inventory and cost restrictions, regardless of regulation that allows pharmacist distribution of naloxone without an external prescription. Pharmacists could play a key role in reducing these barriers by increasing prescriber and patient knowledge about OIRD, assessing risk, educating patients and caregivers on available products, and distributing naloxone. To assist pharmacists in identifying and qualifying patients, a tool for determining OIRD could be beneficial.

Poster Title: Retrospective evaluation of post market data regarding GLP-1 agonists and DPP-4 inhibitors incidence rates of pancreatitis

Primary Author: Derrick Wong, St. John's University College of Pharmacy and Health Sciences, New York; **Email:** derrick.wong11@stjohns.edu

Additional Author (s):
Nicole Maisch
Maha Saad
Kenneth Wu
Rohan Ramnarain

Purpose: Dipeptidyl peptidase 4 inhibitors (DPP-4) and glucagon-like peptide 1 (GLP-1) agonists are anti-diabetic medications that target incretin, a hormone that stimulates the pancreas to create more insulin and lower blood glucose levels. The benefit of choosing these therapies over insulin and insulin secretagogues is due to a lower risk of hypoglycemia. However, an FDA safety communication was issued in order to raise awareness that incretin based therapies have an increased risk of pancreatitis. The purpose of this study is to compare the risk profiles of pancreatitis between the GLP-1 agonist and DPP-4 inhibitors.

Methods: The institutional review board has approved this retrospective study. The FDA Adverse Event Reporting System (FAERS) consists of thousands of de-identified anonymous reports that is publicly available and extracted into excel files from 2004-2015. A subset of data from the database consisted of patients either on a GLP-1 agonist (exenatide and liraglutide) or a DPP-4 inhibitor (sitagliptin, saxagliptin, linagliptin, and alogliptin) from 2011 to 2015. Subsequently, incidence of pancreatitis within each medication was recorded. Patients were excluded if they were on a combination therapy involving one of these agents. Two proportions was calculated for each class of medication and compared against the other using a proportional t-test. A 95 percent confidence interval was used to establish differences. The first proportion is the ratio of patients who were on a GLP-1 agonist and had pancreatitis over every patient on a GLP-1 agonist. The second proportion is the ratio of patients on a DPP-4 inhibitor that had pancreatitis over all patients on a DPP-4 inhibitor.

Results: A total of 75,679 patients who were on a GLP-1 and DPP-4 inhibitor were extracted from the database from 2011 to 2015. Extracted data from the FAERS database consisted of 34,507 reports of patients taking a DPP-4 inhibitor. Of those, 5,020 reports had an episode of pancreatitis that warranted documentation in the database. On the other hand, 41,172 reports were withdrawn from the database who was taking a GLP-1 agonist. Of those, 7,206 patients who were on a GLP-1 agonist experienced pancreatitis. Patients that received a GLP-1 agonist had a higher incidence of pancreatitis when compared to DPP-4 inhibitors, however this was nonsignificant (17.5 percent versus 14.5 percent; p greater than 0.05).

Conclusion: Looking at the reports of GLP-1 agonists and DPP-4 inhibitors spanning from 2011-2015 shows that the incidence rates of pancreatitis is similar between the two classes of medications and therefore a significant difference in the risk profiles does not exist. The FAERS database consists of mandatory reports from drug manufacturers or voluntary reports that are serious enough to document, therefore, all the adverse events may not reflect the entirety of the population. As a result all conclusions with significance from the study must be evaluated in the context of these reports.

Submission Type: Evaluative Study

Session-Board Number: 5b-333

Poster Title: Anti-Tumor Necrosis Factor alpha safety in inflammatory-mediated diseases using FAERS

Primary Author: Rohan Ramnarain, St. John's University College of Pharmacy and Health Sciences, New York; **Email:** rohan.ramnarain11@stjohns.edu

Additional Author (s):
Maha Saad
Nicole Maisch
Kenneth Wu
Derrick Wong

Purpose: Biologic therapy, notably the anti-tumor necrosis factor alpha agents, are known for their efficacy against inflammatory and immune mediated diseases such a psoriasis and rheumatoid arthritis. Injection site reactions (ISR), upper respiratory infections (URI), and death are three relevant adverse events of anti-tumor necrosis factor alpha agents such as etanercept (Enbrel) and adalimumab (Humira). This retrospective study will determine whether a significant difference exists between the incidence of adverse events such as ISR, URI, and death for the above mentioned indications.

Methods: This retrospective study was approved by the institutional review board. The FDA Adverse Event Reporting System (FAERS), a publicly available database containing thousands of de-identified anonymous adverse event reports was analyzed from 2004-2015. All FAERS reports on etanercept and adalimumab indicated for psoriasis and rheumatoid arthritis were extracted. The database was mined for the adverse effects, ISR, URI, and death and were recorded within each indication. A comparison of adverse events was performed by drug and indication. The proportion of each adverse event over the total number of adverse events for each indication was calculated and compared. A proportional t-test was used to compare the ratios of the adverse events of the medications within the indications. A 95 percent confidence interval was calculated.

Results: A total of 197,208 etanercept and 110,948 adalimumab reports were generated from adverse events common to both drugs severe enough to warrant reporting to the FAERS database from 2004-2015. There were 67,162 etanercept reports were indicated for psoriasis and 130,046 were for rheumatoid arthritis. In the adalimumab population, 53,106 were indicated for psoriasis and 57,842 for rheumatoid arthritis. In psoriasis-indicated etanercept versus adalimumab, etanercept demonstrated a higher rate of ISR (29.8 percent versus 14.1 percent; p less than 0.05). Similarly, the ISR rates for the rheumatoid arthritis-indicated reports, etanercept had a significantly higher incidence (27.5 percent versus 11.1 percent; p less than 0.05). However etanercept showed a non-significant lower rate of URI incidence in the psoriasis-indicated reports (13.5 percent vs 20.1 percent; p greater than 0.05). Lastly, the URI incidence for rheumatoid arthritis patients showed a significantly higher rate in the etanercept versus adalimumab reports (41.8 percent versus 15.1 percent; p less than 0.05).

Conclusion: There was not a significant difference between etanercept and adalimumab in the incidence rate of URI in psoriasis patients. However, there was a significant difference in the incidence of ISR and URI in patients with rheumatoid arthritis as well as ISI in the psoriasis population. All of the adverse events reported to FAERS may not reflect the entire population since all reports are voluntarily reported. As a result all conclusions drawn must be evaluated in the context of these reports.

Submission Type: Evaluative Study

Session-Board Number: 5b-334

Poster Title: Incidence and risk factors of acute kidney injury (AKI) in hospitalized children receiving combination vancomycin and piperacillin/tazobactam

Primary Author: Maya Holsen, University at Buffalo School of Pharmacy and Pharmaceutical Sciences, New York; **Email:** mayahols@buffalo.edu

Additional Author (s):
Nicholas Fusco
Calvin Meaney
Amanda Hassinger

Purpose: Vancomycin is commonly used for treatment of Methicillin-resistant Staphylococcus aureus (MRSA) infection in children. Several studies have identified that adult patients treated with combination vancomycin plus piperacillin/tazobactam experienced more episodes of acute kidney injury (AKI). A recent study identified that significantly more children with late AKI received combination vancomycin plus piperacillin/tazobactam (61.9% vs 38.4%; p = 0.04). The primary objective of this study was to determine the rate of AKI in critically ill children treated with vancomycin and piperacillin/tazobactam. Secondary objectives were to describe and compare the characteristics of patients that developed AKI versus those that did not.

Methods: This retrospective cohort study analyzed children admitted to the pediatric intensive care unit (PICU) at Women and Children's Hospital of Buffalo between 01/01/14 and 12/31/15. Inclusion criteria were: admission to the PICU; age great than 2 months; treatment with concurrent vancomycin and piperacillin/tazobactam for at least 48 hours; serum creatinine (SCr) level within 24 hours of antibiotic initiation and throughout therapy; and at least one appropriately drawn vancomycin trough value. Subjects with underlying renal dysfunction, defined as glomerular filtration rate (GFR) less than 90 mL/min/1.72 m2 as calculated by the Schwartz equation, were excluded. AKI was defined as an increase in SCr by greater than or equal to 0.3 mg/dL within 48 hours, and increase in SCr to 1.5x baseline within the prior seven days or urine volume less than or equal to 0.5 mL/kg/hour for six hours, according to the Kidney Disease Improving Global Outcomes AKI Consensus Conference. The primary endpoint was the rate of AKI. Statistical analysis was completed using SAS version 9.4. Continuous variables were compared using Student's t-test or Wilcoxon rank-sum test as appropriate, and categorical data

were compared using the Fisher's exact or Chi-squared tests as appropriate. A p-value < 0.05 was considered to be statistically significant for all analyses. Normally distributed data was reported as mean and SD, and non-normally distributed data was reported as median (IQR).

Results: A total of 63 patients met the inclusion criteria. AKI occurred in 18 (28.1%) of patients. Demographic data were similar between AKI and non-AKI groups, including median Pediatric Index of Mortality II (PIM II) score [4.4 (3.2 – 4.7) vs. 4.2 (3.1 – 4.6); p =0.77] respectively. Median vancomycin dose [15 (7.6 – 16.3) mg/kg/dose vs. 14.9 (10 – 15) mg/kg/dose; p = 0.44] and duration of vancomycin treatment [3.5 (2.3 – 6) days vs. 3 (2 – 4) days; p =0.36] were similar between the AKI and the non-AKI group, respectively. Initial vancomycin trough levels were similar between the AKI group [10 (7.6 – 16.3 mg/dL) and the non-AKI groups [9.5 (7.6 – 14.2) mg/dL; p = 0.59]. Piperacillin/tazobactam doses were similar for the AKI group [95.6 (76.08 – 95.61) mg/kg/day] compared to the non-AKI group [90.51 (66.1 – 100) mg/kg/day; p = 0.58]. Duration of piperacillin/tazobactam was similar [3 (2.3 – 3.8) days vs. 3 (2 – 4) days; p = 0.87] between the AKI and non-AKI groups, respectively. Thirty-three percent (n = 6) of patients in the AKI group were on a concurrent nephrotoxin compared to 21.3% (n = 10) in the non-AKI group (p = 0.93).

Conclusion: Over one-quarter of critically ill pediatric patients treated with combination vancomycin and piperacillin/tazobactam developed AKI. No difference existed between vancomycin dose, initial trough level, and duration; nor in piperacillin/tazobactam dose and duration in the AKI and non-AKI groups. As AKI occurred in at a high rate in this heterogeneous and complex population, further research should seek to identify risk factors for developing AKI when combination vancomycin and piperacillin/tazobactam is used.

Session-Board Number: 5b-335

Poster Title: Measuring the impact of pharmacist interventions to smart infusion pump drug library parameters for the high alert medication dexmedetomidine

Primary Author: Victoria Polla, St. John's University College of Pharmacy and Health Sciences, New York; **Email:** victoriapolla@optonline.net

Additional Author (s):
Laura Gianni
Barbara Kandel

Purpose: Dexmedetomidine, a high alert medication, is prone to decimal point errors when being programmed in a smart infusion pump for administration. Smart infusion technology provides the ability to either deliver medication as a Basic Infusion without benefit of dosage/rate protection, or through a drug library, which acts as a second-check. Alerts are generated when an infusion's entered parameters fall outside of the hospital's pre-determined limits. In this study, we analyzed alerts generated by the Guardrails, Alaris System to evaluate interventions made, identify potential areas for improvement, and increase medication safety.

Methods: After reviewing drug information resources and looking at data derived from the smart infusion technology, it was decided to change the drug library parameters for dexmedetomidine. The changes were: (1) lower soft maximum continuous dose (CD) from 1 to 0.7 mcg/kg/hour; (2) add a hard maximum CD of 1 mcg/kg/hour; (3) lower soft minimum bolus dose (BD) from 0.9 to 0.5 mcg/kg; (4) lower our soft maximum BD from 1.1 to 1 mcg/kg; (5) lower our hard maximum BD from 1.2 to 1.05 mcg/kg; (6) lower our soft minimum bolus dose administration rate (BDAR) from 0.09 to 0.05 mcg/kg/min; (7) lower soft maximum BDAR from 0.11 to 0.1 mcg/kg/min; (8) add a hard maximum BDAR of 0.11 mcg/kg/min. These changes were implemented on July 21st 2014. We collected 1 year of alert data prior to the changes and 1 year of alert data post-changes to measure the impact of the library changes. Infusion alerts can be overridden, reprogrammed, or cancelled. Overrides or reprograms can occur when a soft alert is generated. Hard alerts require either a reprogram or cancellation.

Results: As a result of library update on July 21st 2014, the number of CD alerts for overrides above the drug's soft maximum decreased from 460 to 207 (55 percent). The number of all CD reprograms above the maximum increased by more than four-fold from 63 to 271 (430 percent). The number of CD cancellations decreased from 45 to 2. The number of overrides below the newly instituted soft minimum for BD and BDAR were 131 and 7, respectively. The total number of reprograms increased significantly after instituting new CD parameters, indicating that users agreed with and complied with the alerts generated; doses were reprogrammed within the allowed limits. The number of CD alert overrides decreased significantly, as expected with the addition of a hard maximum CD. The number of cancellations did not increase, as one would expect when instituting a hard maximum CD. This suggests that the users did not cancel out the infusion to go to Basic Infusion and thus the drug remained protected by Guardrails. The data suggests that a reevaluation and possible further decrease of our soft minimum BD and BDAR limits may be necessary to minimize alert fatigue in smart infusion pump users.

Conclusion: Safety software is important for minimizing intravenous medication errors, improving patient care, and measuring system performances; it is essential for patient safety and preventing adverse outcomes resulting from programming errors. Due to the addition of a hard maximum CD, we were able to see an increase in reprograms, decrease in cancellations, and decrease in overrides. Providing the infusion user with an alert can prevent the administration of a potentially dangerous medication dose to a patient.

Submission Category: Small and Rural Pharmacy Practice

Poster Title: Prevalence and knowledge of hypertension in a selected cohort in rural Haiti

Primary Author: Trang Le, Touro College of Pharmacy, New York; **Email:** trangled@gmail.com

Additional Author (s):
Phoebe Wong
Roopali Sharma

Purpose: The global burden of hypertension is increasing, with a projected increase in prevalence to 29.2%, or 1.56 billion, by the year 2025. Uncontrolled hypertension can cause serious morbidity. Haitians consume excessive amount of salt. It is estimated that they consume 30 to 35 grams of sodium daily whereas the WHO recommends 4 grams of salt intake daily. There is little information about the enormity of the problem of hypertension in Haiti. This project was designed to determine the prevalence of hypertension, assess the basic knowledge of Haitians regarding high blood pressure and heighten awareness in the seriousness of this condition.

Methods: A survey was designed to collect information about hypertension. Verbal consent from the patient was obtained prior to administering the questionnaire. The survey was translated from English to Haitian Creole and patients over the age of 18 with hypertension were included. Data on age, gender, height, weight, blood pressure measurement at the time of clinic visit was collected. Assessment on the basic knowledge of hypertension, diet, perception of seriousness of the disease and barriers to seeking health care in rural Haiti was also documented. Creole translators helped with data collection. Patients were prescribed antihypertensive medications and were given at least a 30-day supply. They were also counseled on the disease state and the medication that were prescribed.

Results: One hundred and thirty four patients completed the survey. All patients surveyed were adults. The blood pressure ranged from 129/80 mmHg to 225/140 mmHg. Only 42% of patients reported they knew they had high blood pressure for more than 3 years. Over 12% of patients had no knowledge of having hypertension. Of the patients that knew that they had hypertension 89% of patients reported they have been treated with antihypertensive medications in the past, but most do not have continuing treatment. Approximately, 66% of

patients reported that they considered hypertension to be a serious condition. Majority of the patients' diet consisted of vegetables, rice, beans, meat and fish. Assessment of salt-intake was difficult to measure. Sixty four percent of patients reported that their main barrier to health care and treatment of hypertension was mainly due to limited income and health care resources.

Conclusion: Many participants who were surveyed didn't know they had hypertension and were unaware of the seriousness of the disease. There are many barriers in preventing patients from having access to health care, including medications especially when living in rural areas of Haiti. It is unclear whether the patients with high blood pressure will be able to purchase antihypertensive medications to control their hypertension once they have exhausted their medication supply. Uncontrolled hypertension can lead to serious adverse outcomes and major interventions in rural Haiti are needed to address adequate management of hypertensive patients through chronic use of medications and follow-ups.

Poster Title: Comparison of dofetilide and sotalol in reducing atrial fibrillation related hospital re-admissions

Primary Author: Charlene Fernandez, St. John's University, College of Pharmacy and Health Sciences, New York; **Email:** charlenekim.fernandez11@stjohns.edu

Additional Author (s):
Ruby Lee
Danielle Crotty
Agnieszka Pasternak

Purpose: Dofetilide (Tikosyn®) and sotalol (Betapace AF®) are Class III antiarrhythmics indicated for the treatment of highly symptomatic atrial fibrillation or atrial flutter. Due to their QTc prolonging effects and risk for development of the life-threatening arrhythmia torsades de pointes (TdP), treatment must be initiated in the hospital so patients can have their heart rhythm, kidney function, and electrolytes monitored for a minimum of three days. Pharmacists play a crucial role in monitoring for renal dose adjustments and screening for dangerous drug-drug interactions during initiation of dofetilide or sotalol therapy.

Methods: A retrospective chart review will be conducted in patients who received dofetilide or sotalol therapy as a new start or continuation from home during any admission at our institution from September 2014 through August 2016, and included in the primary efficacy analysis if there is a 6-month period after discharge to evaluate. All data will be recorded without patient identifiers and to maintain confidentiality. The data collected from the electronic medical record (EMR) will include the patient age, comorbidities, baseline creatinine clearance (CrCl), electrolytes, and QTc values, medication doses, drug-drug interactions, and adverse reactions/events. The primary outcome will be rate of hospital re-admissions secondary to uncontrolled atrial fibrillation/flutter while on dofetilide or sotalol therapy. Secondary outcomes will be any adverse drug events due to dofetilide or sotalol requiring discontinuation, number of interventions documented by pharmacist as per our drug protocol, and number of drug-drug interactions prevented or that occurred.

Results: A total of 36 and 47 patients were prescribed dofetilide and sotalol therapy during the last 2 years, respectively. Of dofetilide patients, 32 (88.9%) were new starts, and for sotalol, 21 patients (44.7%) were new starts. The median age was 69 years old (IQR 64-78) and 72 years old (IQR 61-84) for patients on dofetilide and sotalol, respectively, with median CrCl of 74 mL/min (IQR 53-97) and 69 mL/min (IQR 39-81). For the primary outcome, 1/17 patients (5.9%) discharged on dofetilide therapy had a hospital readmission for uncontrolled atrial arrhythmia within the next 6 months, compared to 4/33 (12.1%) discharged on sotalol therapy. Of all patients on dofetilide, 7/36 (19%) required drug discontinuation during their admission; 4 due to QTc prolongation, 1 for patient complaint of headache and nausea, 1 for a severe drug-drug interaction, and 1 for risk avoidance of thrombosis if cardioverted to normal sinus rhythm. Of sotalol patients, 9/47 (19%) also required drug discontinuation; 4 for lack of efficacy in patients remaining in rapid AF, 2 for renal impairment, 2 for QTc prolongation/bradycardia, and 1 for a newly diagnosed ejection fraction < 40%.

Conclusion: Dofetilide and sotalol are efficacious when used as antiarrhythmic therapy to prevent recurrence and re-hospitalization for atrial fibrillation or flutter. However both have a high risk of QTc prolongation and significant drug-drug interactions, requiring careful monitoring and intervention. Pharmacists play an important role in monitoring dosing based on creatinine clearance, other labs values, and screening for potential drug interactions.

Poster Title: Fructose alters cell survival and gene expression in microglia and neuronal cell lines

Primary Author: Drew Seidel, St. John Fisher College Wegmans School of Pharmacy, New York; **Email:** dps02008@sjfc.edu

Additional Author (s):
Susan DeNapoli
Thomas Maciulewicz
Melinda Lull

Purpose: Microglia are macrophages that are found primarily in the CNS and play a crucial role in maintaining a healthy brain by engulfing invading microorganisms, releasing inflammatory mediators, and pruning dead cells. Microglia can become activated in response to certain stimuli which causes them to transition into a pro-inflammatory state, and can sometimes become chronically activated which can result in neuronal damage. Studies have shown a causal relationship between this activation and sugars such as fructose and glucose. We sought to understand the role of sugars in microglial activation and the subsequent effects on neuron health.

Methods: Rat microglia (HAPI) and neuronal (B35) cell lines were treated with varying concentrations of fructose (25 mM, 12.5 mM, and 6.25 mM) or glucose (25 mM and 12.5 mM) as a positive control to determine their effects on the cells. Following treatment and incubation for 3 or 24 hours, the cells were analyzed using an MTT assay to measure cell survival or real-time polymerase chain reaction (RT-PCR) to measure gene expression levels. Effects of fructose were measured in HAPI microglia after direct treatment with the sugar. The genes investigated by the RT-PCR in the HAPI cells included: glucose transporter 5 (GLUT5), and the inflammatory markers high mobility group box 1 (HMGB1), and prostaglandin E receptor 2 (Ptger2). To evaluate the effects of microglial activation on neuronal function, the B35 neurons were treated either directly with sugars or with the supernatant collected from fructose-treated HAPI microglia. This allows examination of the effects of soluble neuron-injury factors released by microglia. The genes investigated by RT-PCR in B35 neurons included nuclear factor kappa B (NFkB) and enolase 2 (Eno2).

Results: Cell survival assays showed that 24-hour direct fructose treatment increased B35 cell survival by up to 13%, while groups treated with microglia supernatant increased cell survival by up to 33%. In HAPI microglia, 3 hours of treatment with fructose caused GLUT5 expression to be suppressed by up to 32% in all treatment groups except for 6.25 mM fructose, while Ptger2 and HMGB1 expression was increased by as much as 65% and 15%, respectively. After 24-hours of treatment with fructose, the HAPI microglia showed a maximum of 80% increased expression of HMGB1, while Ptger2 expression was mostly unchanged. In B35 neurons, 3 hours of treatment with fructose caused a decrease of up to 26% in NFkB and an increase of up to 46% in Eno2 expression.

Conclusion: Cell survival results indicate that the microglia may provide a short term protective effect on the B35 neurons. However, data from the gene expression assays show evidence of cellular dysfunction in neurons and pro-inflammatory activity in microglia which may lead to neuronal death on a longer timeline. As seen in the gene expression results, microglia had increased expression of pro-inflammatory genes and B35 neuronal cells had increased expression of markers of cellular damage. Future studies will further explore the effects of fructose on expression of other genes and examine the effects on neuron survival at later time points.

Poster Title: Role of nurr1 in mediating the antineoplastic effect of fenretinide in breast cancer

Primary Author: Anthony Poché, Xavier University of Louisiana College of Pharmacy, Louisiana;
Email: apoche@xula.edu

Additional Author (s):
Kiera Broussard
Shawn Llopis
Christopher Williams

Purpose: NURR1, a member of the constitutively active NR4A nuclear receptor family, exhibits context dependent tumor suppressor or promoter effects in cancer. Our previous studies reveal that NURR1 is silenced upon neoplastic transformation of breast epithelium, and higher expression is associated with greater breast cancer patient survival. Although the receptor is not known to bind endogenous ligands, pharmacological induction of NURR1 expression has shown mediation of growth arrest and apoptosis. Fenretinide, an atypical retinoic acid derivative, has been shown to induce expression of other NR4A family receptors. Here, we investigated if fenretinide is a NURR1 regulator in breast carcinoma cells (BCCs).

Methods: Cell lines were treated with fenretinide and its ability to induce expression of NURR1 micro ribonucleic acid (miRNA) and protein in BCCs was ascertained using quantitative reverse transcriptase polymerase chain reaction (qRT-PCR) and flow cytometry, respectively. We developed stable BCC lines by stably transfecting MDA-MB-231 breast carcinoma cells with NURR1 specific CRISPR/CAS9 expression plasmid, thereby eliminating endogenous NURR1 expression (BCC-N1KO cells). Since previous studies have suggested that fenretinide induces apoptosis independently of RXR and RAR, we ascertained the capacity of fenretinide to induce transcriptional activity from retinoic acid response element (RARE) and NGF1-beta response element (NBRE) driven luciferase reporters. In order to determine if NURR1 transcriptional activity was sufficient to induce apoptosis, we transiently transfected HEK293 cells to express wild-type NURR1, a naturally-occurring dominant negative NURR1 variant (NURR1a) or the DNA binding mutant (NURR1-DBDmu), and used annexin V staining as a determinant of apoptosis.

Results: Our studies show that loss of NURR1 resulted in an increased basal proliferation, but increased sensitivity to fenretinide-mediated cell death. Our findings also show that fenretinide induces apoptosis in a dose dependent fashion with approximately 32 percent and 42 percent of the cell population staining positive for annexin V at 1 and 10 micrograms per milliliter respectively. We also saw an over 2-fold increase in the induction of NURR1 gene expression when cells were treated with 10 micromolar concentration of fenretinide. Fenretinide failed to induce RARE activity, confirming previous reports that fenretinide does not function as a potent RAR/RXR agonist. However, the NR4A-responsive (NBRE)-luciferase activity was significantly induced by fenretinide. Interestingly, all three NURR1 variants were able to induce apoptosis as determined by annexin V staining.

Conclusion: Together, these studies confirm that NURR1 has a gene-dose dependent function in cancer. At basal levels, NURR1 transcriptional function opposes proliferation and may function to help the cell survive in high stress environments such as drug therapy. Alternatively, high levels of expression result in non-transcriptional functions which induce apoptosis in breast cancer. Pharmacological targeting of NURR1 with fenretinide may be a feasible method for both chemoprevention and treatment of breast carcinoma.

Poster Title: Comparing the pro-resolving effects of fish and krill oils

Primary Author: Joseph Aladeen, Wegmans School of Pharmacy at Saint John Fisher College, New York; **Email:** jda09728@sjfc.edu

Additional Author (s):
Ramil Sapinoro

Purpose: The omega-3 fatty acids eicosapentaenoic acid and docosahexaenoic acid are often used to treat hypertriglyceridemia, but recent studies have suggested that these molecules may also be useful for the treatment of inflammatory conditions. Omega-3 fatty acids are used as building blocks in the biosynthesis of a class of molecules called specialized pro-resolving mediators (SPRMs). SPRMs execute various inflammation resolving functions throughout the body. Two common dietary supplements, which contain omega-3 fatty acids, are fish oil and krill oil capsules. The purpose of this study was to evaluate and compare the in-vitro pro-resolving effects of fish oil and krill oil.

Methods: This study was designed to test, in various ways, the inflammation resolving effects of Omega-3 fatty acids using a cell line of cultured rat microglia called highly aggressively proliferating immortalized (HAPI) cells. These cells were chosen as a model for inflammation because microglia form the basis of the active immune response in the brain and omega-3 fatty acids have shown promising activity in the central nervous system. HAPI cells were plated and treated in triplicate. One set of three wells was left untreated. Another group of wells was treated with lipopolysaccharide (LPS) in order to stimulate inflammation. A third set of wells was treated with either fish oil or krill oil to ensure that no part of the formulation resulted in an elevation of inflammatory markers. The fourth group was treated with either krill oil or fish oil and LPS. Several assays were then used to assess the level of inflammation in each group. Experimental sample supernatants were used to assess nitrite concentrations using a Griess assay. The inflammatory markers tumor necrosis factor-alpha and interleukin-6 were measured via ELISA.

Results: The cells that were activated with LPS all displayed significantly higher levels of nitrite, tumor necrosis factor-alpha and interleukin-6 than those that were not treated with LPS. The treatment groups that were activated with LPS and treated with omega-3 fatty acids showed statistically significant reductions in nitrite, interleukin-6 and tumor necrosis-alpha levels compared to the LPS only treatment group. The cells that were activated with LPS and treated with krill oil had significantly lower nitrite, tumor necrosis factor-alpha and interleukin-6 concentrations than the LPS activated cells that were treated with fish oil.

Conclusion: Treatment with both forms of omega-3 fatty acids resulted in reduced levels of nitrite, tumor necrosis factor-alpha and interleukin-6 in LPS stimulated cells. Treatment with krill oil exhibited greater pro-resolving effects than treatment with fish oil. These results suggest that further evidence should be obtained to determine whether pharmacists should preferentially recommend krill oil over fish oil.

Poster Title: Challenges and opportunities: Establishing an interprofessional education (IPE) experience in a college of pharmacy with an unaffiliated academic health center (AHC)

Primary Author: Isha Rana, Long Island University Arnold and Marie Schwartz College of Pharmacy, New York; **Email:** isha.rana@my.liu.edu

Additional Author (s):
Edwin Lam
Lyndsi Meyenburg
Akash Alexander

Purpose: This communication describes the process of establishing an inter-professional education (IPE) experience between Arnold and Marie Schwartz College of Pharmacy (AMSCOP), a school unaffiliated with an academic health center (AHC), and Weill Cornell Community Clinic (WCCC), an underinsured, primary care clinic. In 2010, the World Health Organization published an IPE and collaborative practice framework to stimulate innovation in healthcare education. Accreditation standards, including those for pharmacy education, have been instituted to incorporate IPE. This newly established collaboration between two previously unaffiliated institutions aims to further the mission of IPE in pharmacy and other healthcare fields at the experiential level.

Methods: A search for an AHC to establish a collaborative practice with AMSCOP was conducted in the metropolitan New York City area. Affiliation opportunities were restricted to the ambulatory care setting in order to facilitate inter-professional interaction between multiple health disciplines and the patient. A total of seven institutions were contacted, with responses from five. Four institutions cited malpractice concerns and spatial restrictions as the primary reasons for lack of pursuing collaboration. Weill Cornell Community Clinic was open to establishing an IPE opportunity with pharmacy involvement, and worked with AMSCOP over the course of 18 months to establish a formal memorandum of understanding between the college and the clinic. Two pharmacy students took on roles as pharmacy co-directors of this project, and met with the clinic medical student co-directors and faculty clinical director to establish goals of the collaboration, as well as a framework by which to integrate pharmacy involvement into an established clinic. Pharmacy involvement in clinic operations were aimed

to address the need for medication review for patients with high disease burden, patient education to increase adherence and safe medication use, and pharmacoeconomic considerations as related to medication reimbursement costs. In order to mirror medical student involvement at the clinic, pharmacy student co-directors established a student recruitment timeline and interview process.

Results: After an initial pilot period of 6 months with two pharmacy student co-directors, a selection process, involving a letter of intent and interview, was conducted to select students for the following academic year. Prior to establishment of this contract, medical students assisted patients with procuring high cost medications, and managing reimbursement for eligible prescriptions; however, there was no pharmacy involvement, as all matters were managed by medical students. With the establishment of this collaboration, pharmacy students have been involved more directly with patient care through collection of medication histories, formulation of a patient plan in conjunction with an interdisciplinary team, and patient education. Thus far, pharmacy students have been involved in six clinic visits resulting in 19 hours of direct patient care, addressing interventions such as omission of therapy, selection of appropriate agents, management of polypharmacy, patient education on OTC product selection, and evaluation of therapeutic equivalence for patients on foreign medications. Six volunteer pharmacy students for the 2016-17 year were selected to be involved with continuing this initiative, providing direct patient care as part of an interdisciplinary team at the clinic, student to student mentorship, pharmacotherapy presentations for medical students, and longitudinal, scholarship projects.

Conclusion: The primary purpose of this collaboration was to establish an inter-professional educational experience for pharmacy students that would improve patient care and outcomes in a student-coordinated, primary care clinic in the New York City metropolitan area. Over the course of two years, a working contract was established; pharmacy students have participated in direct patient care encounters on a regular basis while providing educational presentations to medical students, and a unique perspective on medication management. All of these activities encompass an IPE framework which guides future expansion and scope of involvement in this collaboration.

Poster Title: Acute effects of chocolate, coffee and tea constituents theobromine, caffeine, and l-theanine on cognitive function and mood: a meta-analysis

Primary Author: Kenny Chan, St. Johns University, New York; **Email:** kenny.chan11@stjohns.edu

Additional Author (s):
Cesar Lau-Cam
Rishi Dave
Zack Piracha
James Bhaidas

Purpose: Chocolate, tea and coffee are popular foods with naturally occurring stimulants consumed to enhance mood and cognitive function. Caffeine is a xanthine and the most widely consumed stimulant found in coffee and tea. l-theanine is an amino acid found in tea along with caffeine. Theobromine is a caffeine metabolite and mild stimulant found in chocolate. The purpose of this meta-analysis is to assess the individual acute effects of compounds caffeine, l-theanine and theobromine on cognitive function and mood within one and two hour post treatment time periods.

Methods: We searched PubMed, SCOPUS, and Cochrane Central from their inception to October 2016. Included randomized controlled trials (RCTs) had to be fully published. RCTs with the following criteria were included: 1) healthy adult sample, 2) oral administration of coffee, tea and chocolate with one or more of the following constituents : Caffeine, l-theanine, theobromine and 3) must measure cognitive function and mood. Mood was assessed through alertness, and calmness derived from Bond-Lader scales. Cognitive Function was assessed through rapid visual information processing and attention switching tasks. All measures of mood and cognitive function had to be used across three or more individual studies. Mean changes from baseline and post treatment outcomes were calculated using the "metafor" (version 1.9-8) package in "R". Meta-analysis for comparable outcome measures was conducted using a random-effects model in MATLAB-r2016b, with average effect size presented as average standardized mean differences (SMDs) for the first and second hours post treatment dose. SMDs between treatment and placebo were calculated by dividing the mean difference by the

pooled standard deviation. Restricted maximum-likelihood estimation was used to estimate the between-study variance (t) in a random-effects meta-analysis. A moderator analysis for dosage and effects correlation was conducted in a mixed-effect model. In cases where data necessary for calculations were not available, the original authors were contacted to obtain raw data.

Results: We screened 4352 studies and evaluated 109 full-text articles. A total of 19 RCTs (n=433 participants) met our eligibility criteria. Eleven RCTs (n=332) evaluated caffeine and l-theanine. Eight RCTs (n=101 participants) evaluated theobromine and caffeine. For the mood evaluation, first hour Bond-Lader "alert" ratings for caffeine, l-theanine and theobromine were inputted into a random effects model to obtain the average SMD of 0.653 (SE = 0.05) in favor of caffeine (t=7.87, $p < 0.01$). Second hour random effects model with an average SMD estimated to .435 (SE=0.10) favored theobromine (t=3.15, $p < 0.01$). Bond-Lader "calm" ratings after one hour using a REM with an average SMD of 0.435 (SE = 0.05) favored l-theanine (t=5.45, $p < 0.01$). Second hour calm analysis was nonsignificant ($P > 0.05$). Cognitive function accessed through accuracy in attention switching data favored caffeine (t=7.34, $p < 0.05$) for the first hour using a REM with an average SMDs estimated at .289 (SE = 0.05). Second hour accuracy data favored theobromine (t=5.34, $p < 0.01$) using a REM with an average SMDs estimated at .289 (SE = 0.03). Insufficient data was available to conduct a meta-analysis for rapid visual information processing. Moderator analysis on dosage and effect was nonsignificant ($p > 0.05$).

Conclusion: Caffeine and theobromine alone increased Bond-Lader alertness in the first hour while l-theanine did not. Caffeine achieved the highest first hour alertness SMD of .653 vs .342 (theobromine). Second hour Bond-Lader alertness favored theobromine over caffeine with an average SMD of .435 and .234 respectively. Cognitive function data defined though accuracy in attention switching tasks followed similar trends and favored caffeine in the first hour and theobromine in the second hour. Caffeine's higher alertness and accuracy in the first hour are likely attributed to its shorter half-life and higher blood brain barrier penetration compared to theobromine.

Submission Type: Case Report

Session-Board Number: 5b-343

Poster Title: Personalized pharmacotherapy in a patient with cytochrome P450 2D6 polymorphism

Primary Author: Sheeba Paul, St. John's University, New York; **Email:** sheeba.paul11@stjohns.edu

Additional Author (s):
Celia Lu
Lauren Block

Purpose: All individuals vary in their genetic makeup, and therefore standard prescribing guidelines cannot be used consistently for all patients. This case illustrates the need for personalized pharmacotherapy in a patient with a history of serotonin syndrome complicated by cytochrome P450 2D6 polymorphism. JK is a 47-year-old female with a history of depression, migraine headaches, anxiety, urticaria and eating disorders. During a follow-up visit with her primary care physician, patient reported symptoms of palpitations, night sweats, and hot flashes as well as occasional tremors. At the time of the visit, patient was taking vortioxetine 5 milligrams three times daily, duloxetine 30 milligrams three times daily, and sertraline 125 milligrams daily, which are substrates of the cytochrome P450 2D6 enzyme. An electrocardiogram showed sinus tachycardia at 101 beats per minute, which had increased from 3 months prior. Laboratory testing including blood count, thyroid function, and metabolic panel all came back normal. The patient also denied use of any stimulants or over the counter medications. Results of her genetic testing returned and indicated that patient is a poor metabolizer of cytochrome P450 2D6, increasing her risk of serotonin syndrome on these medications. Due to the concern of her emerging serotonin syndrome, tapering of vortioxetine and duloxetine were recommended after discussion between her primary care physician, pharmacist, and psychiatrist. A few days after the visit, patient reported a resting heart rate of 195 beats per minute. Her psychiatrist also noted psychomotor agitation. The patient was admitted to the hospital for worsening symptoms of serotonin syndrome. During her hospitalization, all antidepressants were discontinued and symptoms abated. The new discovery of the patient's genetic makeup and history of serotonin syndrome posed a great challenge in providing appropriate medications to treat her multiple disease states such as migraines. Beta-blockers and tricyclic antidepressants, first-line or second-line medications

recommended by guidelines for migraine prophylaxis, are affected by cytochrome P450 2D6 metabolism. Therefore, the patient can no longer receive standard therapy and must receive individualized treatment. Rather than treating her migraines prophylactically, she is now being treated symptomatically with medications to help with her nausea and pain. Also her depressive symptoms are controlled with lamotrigine which has an off label indication for depression. Studies outlining the complexities of individual genetics set the ground for the concept of personalized medicine. Due to the great deal of psychiatric medications affected by cytochrome P450 2D6, genetic testing should be considered in patients taking multiple medications that are substrates of the enzyme. The development of pharmacogenetics can help guide safe prescribing methods for individualized treatment. Increasing awareness of the importance of pharmacogenetics in personalized pharmacotherapy can improve the safe treatment of behavioral health problems and decrease potential for adverse reactions.

Poster Title: Back to the future: Systematic review of current dosing algorithms for erythropoiesis-stimulating agents in hemodialysis patients to better inform a novel, universal, and precise approach

Primary Author: Jamie Gaesser, University at Buffalo School of Pharmacy and Pharmaceutical Sciences, New York; **Email:** jamiegae@buffalo.edu

Additional Author (s):
Ben Robinson
Mandip Panesar
Gauri Rao
Calvin Meaney

Purpose: Erythropoiesis-stimulating agents (ESA) are the primary treatment of anemia in patients with end-stage renal disease on hemodialysis. Use of ESAs is problematic due to complex pharmacokinetics and a narrow pharmacodynamic target of hemoglobin 10 to 12g/dL. Overshoot of this target hemoglobin is associated with an increased risk of thromboembolic events. Lower hemoglobin increases the risk for blood transfusions, cardiac dysfunction, and decreased quality of life. There is no universal ESA dosing algorithm with strong accuracy and precision to maintain hemoglobin at the target range. The purpose of this study is to define characteristics and performance of current ESA dosing algorithms.

Methods: A systematic literature review was conducted. The following search terms were used in Pubmed and EMBASE databases from inception of the database until 08/24/2016: (epo OR erythropoietin OR erythropoiesis stimulating agent OR ESA) AND (computerized OR physician OR individualized OR decision OR monitoring OR algorithm OR protocol) AND (ESRD OR end stage renal disease OR hemodialysis). Inclusion criteria were algorithms applied to human subjects, published in English, and evaluated the use of epoetin alfa or darbepoetin alfa in patients with end-stage renal disease on hemodialysis. Literature search results were filtered based on study title and abstract with application of inclusion criteria. Full-text articles were then evaluated for inclusion. If included, a standard database was utilized to organize and characterize findings from each study. Data extraction included: study design, setting, size, inclusion/exclusion criteria, dosing software and/or algorithm, parameters included in the

dosing algorithm, laboratory values, demographic information, hemoglobin target range, hemoglobin values, type of ESA utilized, and ESA dosing. The primary endpoint was the percentage of patients at the target hemoglobin (defined by each individual study) over the study period.

Results: The literature search yielded 2,048 results. Thus far, 6 studies have met inclusion criteria. Study 1 utilized a pharmacokinetic model that targeted a hemoglobin range of 10 to 13g/dL in 1,558 patients. The median hemoglobin was 11.9 g/dL, however only 42 percent were constantly in range. Study 2 utilized a pharmacodynamic model that increased the time within target hemoglobin range (10.5 to 12.5g/dL) from 56 to 66 percent in 214 patients. Study 3 utilized a decision table to target hemoglobin 10 to 12g/dL in 49 patients. Percent within target range increased from 77.6 to 85.7 percent. Study 4 utilized Smart Anemia Manager software in 52 patients targeting hemoglobin 10 to 12g/dL. Percent within target range increased from 61.9 to 72.5 percent. Study 5 utilized Crit-Line software with AMIE computer algorithm in 44 patients to target hemoglobin 11 to12 g/dL. Results demonstrated an increase in target attainment from 28 to 39 percent. Study 6 utilized DARWIN computer decision support system in 8,941 patients to target hemoglobin 10 to 12g/dL. DARWIN was not associated with an improved on-target hemoglobin (odds ratio 1.12, 95 percent confidence interval 0.97 to 1.28) but did reduce the likelihood of hemoglobin greater than 12g/dL.

Conclusion: There are currently a variety of ESA dosing algorithms in the literature. These tools have a mild degree of success, with an improvement of on target hemoglobin ranging from 0 to 11 percent. However, there is no universally applicable algorithm with excellent accuracy and precision. Characteristics of algorithms with high success rates include monitoring hemoglobin monthly, assessing ferritin and TSAT for adequate iron dosing, and individualization through computer software. Future studies should include a large number of subjects, compare a robust dosing approach to the current standard of care, and include outcomes of hemoglobin, quality of life, and costs.

Poster Title: Duration of antibiotic therapy in septic shock patients with intra-abdominal infections

Primary Author: Rachel Abramov, St. John's University College of Pharmacy and Health Sciences, New York; **Email:** rachel.abramov11@stjohns.edu

Additional Author (s):
Lathan McCall
Wenchen Wu
Candace Smith
Rafael Barerra

Purpose: The recent study by Sawyer et al. found no difference in outcomes among patients with complicated intra-abdominal infections who received short-course antibiotic therapy (4 plus or minus 1 days), as opposed to traditional 7-14 day antibiotic therapy, given adequate anatomical source control. The objective of our study was to determine whether a shorter course of antibiotic therapy, with adequate source control, applied to septic shock patients with intra-abdominal infections.

Methods: This retrospective chart review, at a tertiary care center of adult surgical intensive care unit patients, was approved by the Institutional Review Board. Our study evaluated septic shock patients with intra-abdominal infections who were treated by adequate surgical source control and antibiotics between April 20, 2012 and May 23, 2016. Data was collected from electronic medical records, with all information documented without patient identifiers to maintain confidentiality. Severity of patients' illness was stratified using Acute Physiology and Chronic Health Evaluation II (APACHE II) and Sepsis-related Organ Failure Assessment (SOFA) scores. Patients were evaluated on the following criteria: median days to resolution of fever (less than 38 degrees Celsius for 24 hours), normalization of white blood cell count (less than or equal to 11,000 per cmm), vasopressor requirements, resolution of Systemic Inflammatory Response Syndrome (SIRS) related physiological abnormalities, 28- day mortality, recurrence of intra-abdominal infection, and development of subsequent infections. The primary outcome was duration of antibiotic therapy to achieve resolution of septic shock. The secondary

outcome was 28-day mortality. Student's t-test and Chi-square test were used to evaluate demographic data and severity of illness. Fisher's exact test was used to evaluate mortality.

Results: One hundred and two patient records were evaluated; 52 patients met criteria of septic shock with an intra-abdominal infection and adequate surgical source control. The median duration of antibiotic therapy for all patients was 7 days, whereas the median time to resolution of septic shock was 6 days. Patients were then divided into two groups based on the median time to resolution of septic shock symptoms. Twenty patients had resolution of septic shock within less than or equal to 6 days of antibiotic therapy (Group 1), while 32 patients (Group 2) had resolution of these symptoms after more than 6 days of antibiotics. Mean APACHE II scores for Group 1 and Group 2 were 22.35 plus or minus 6.2 and 7.80 plus or minus 3.3, respectively (p equals 0.07). The mean SOFA scores were 19.34 plus or minus 5.4 for Group 1 and 8.34 plus or minus 2.7 for Group 2 (p equals 0.52). Twenty-eight day mortality occurred in 6 patients (11.5 percent); 5 patients in Group 1 (25 percent) and 1 patient in Group 2 (3.13 percent) (p equals 0.026).

Conclusion: Short-course antibiotic therapy may not be sufficient in the treatment of septic shock patients with intra-abdominal infections, who had undergone an adequate source control procedure, and may lead to increased risk of 28-day mortality.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Session-Board Number: 5b-346

Poster Title: Evaluation of prescribing patterns of Quetiapine fumarate extended-release (XR) at an inpatient psychiatric facility

Primary Author: Nirvana Awad, St. John's University, New York; **Email:** awad.nirvana@gmail.com

Additional Author (s):
Farah Khorassani

Purpose: Quetiapine is a widely prescribed atypical antipsychotic that is commonly used for multiple indications including bipolar disorder, schizophrenia, and augmentation in major depressive disorder. It is currently available as an immediate-release (IR) and an extended-release (XR) tablet and both have demonstrated similar efficacy, tolerability, and pharmacokinetic profiles. Additionally, both may be dosed once daily. The extended-release formulation is significantly more expensive than the immediate-release formulation. The purpose of this retrospective drug-utilization review is to evaluate the prescribing patterns of quetiapine XR and assess potential hospital cost savings if all orders for the XR formulation were switched to quetiapine IR.

Methods: This is an institutional review board (IRB) approved, retrospective chart review. This review will include 100 patients, over the age of 18 years, who have been prescribed and were taking quetiapine XR as inpatients between January 1, 2015 and August 30, 2016. Patients who were refusing their medication were excluded from the study population. Data collected includes: patient demographics (age, sex, race, weight, height), psychiatric diagnosis, medication use information (e.g., medication name, dosage, frequency). All study data was obtained and evaluated from the confidential medical record.

Results: Out of 100 randomized patients, 16 were diagnosed with schizophrenia, 31 were diagnosed with major depressive disorder, and 39 were diagnosed with bipolar disorder. Mean doses were: 293 mg, 235 mg, and 303 mg in patients with schizophrenia, major depressive disorder, and bipolar disorder, respectively. Eighteen patients received quetiapine XR for other indications. The total amount spent on quetiapine XR on these patients was $30,285 based on

the average wholesale price. Substituting each of the orders with quetiapine IR would result in a cost of $18,044 to the hospital, and savings of $12,241.

Conclusion: Quetiapine XR is a more expensive formulation that increases hospital costs without adding any therapeutic benefit. Converting patients from quetiapine XR to quetiapine IR through use of a therapeutic interchange policy would result in cost savings for the hospital with no expected effect on patient outcomes.

Poster Title: Analysis of student research programs across pharmacy schools and hospitals

Primary Author: Lina Lin, St. John's University College of Pharmacy and Health Sciences, New York; **Email:** linalin26@gmail.com

Additional Author (s):
Karen Berger

Purpose: Clinical research is a cornerstone of a pharmacy practice, yet pharmacy students are not routinely exposed to it in their curriculums. Engaging in student research is associated with development of valuable skills and higher levels of critical thinking. Residency programs and employers increasingly seek graduates with research experience. However, there is no standardized program recommended by the ACPE. Schools that extend research opportunities often do so as an elective, while others do not offer any at all. The purpose of this analysis is to characterize various clinical research programs specifically geared towards PharmD students offered by pharmacy schools and hospitals.

Methods: An online search was initiated to identify hospitals and schools of pharmacy in the United States that offer a structured clinical research program for students. Program information was either obtained from journal articles yielded by a PubMed and Google Scholar search or published webpages on hospital/pharmacy school websites found from a general Google search. These programs were analyzed for specific predetermined variables including: duration of program, student eligibility requirements, participant selection process (i.e. open, proposal, GPA), whether it was an elective course or extracurricular, whether a mentor was assigned, if funding was provided, and if a presentation or publication was required. Programs were excluded if their descriptions did not address all of the above features on their program webpages. Programs that met inclusion criteria were further compared to identify unique features.

Results: Twenty student-focused research programs were identified from the literature search. Two were developed by hospitals and the remaining 18 by schools of pharmacy. The length of the programs varied greatly, ranging from 9 weeks to two years. The eligibility of students spanned across nearly all years of pharmacy school - from second year of pre-pharmacy to the

last professional year. Four programs targeted P1/P2 students, four targeted P3/P4 students, with the remaining being open to all students. As for the selection process, most programs required an application (n=14). The composition of the applications differed greatly however, with some requiring a minimum GPA (n=7) and letters of recommendation (n=5) and others requesting a topic proposal (n=5). One program held up to 2 rounds of interviews. In terms of program outcomes, the majority required their students to present at the respective sites' research symposiums (n=10). While most programs encompassed similar components, some implemented innovative features. One program awarded NIH grants to its participants and funded the cost of poster materials and travel to conferences. Another program had its participants present and defend their research protocols, similar to a PhD thesis presentation. One program held IRB training sessions.

Conclusion: There is a wide spectrum of student clinical research programs with differing requirements and goal outcomes amongst programs. Most programs shared similar core components, however some included innovative features such as IRB training and defending research protocols. Hospitals and schools of pharmacy looking to develop a research program can use these practices as foundation for building their program. Programs that have developed a successful research program should consider publishing their results or including them as part of their program website.

Submission Category: Pain Management

Submission Type: Descriptive Report

Session-Board Number: 5b-348

Poster Title: Improving pain management knowledge in palliative care through global education

Primary Author: Rucha Acharya, St. John's University, New York; **Email:** rucha.acharya11@stjohns.edu

Additional Author (s):
Christine Kim
Ebtesam Ahmed

Purpose: Data indicates that tens of millions of people worldwide lack access to essential pain medications causing unnecessary suffering from severe pain. There are many reasons behind this, which can include undue restrictive regulations regarding opioid prescription medications, distribution barriers, stigma, and the high cost of some medications. Many patients, including cancer and palliative care patients in Guatemala are not receiving adequate pain management due to the growing concern of abuse for these medications. The main purpose of this project was to increase awareness and improve pain management by providing much needed education on prescription opioids in the relief of pain.

Methods: A global academic service-learning component was incorporated into an Advanced Pharmacy Practice Experience (APPE) rotation in May 2016 in Guatemala City, Guatemala. During this time, a survey questionnaire and presentation for medical students and physicians at the national cancer hospital was conducted. The presentation covered topics such as the World Health Organization analgesic ladder, calculations using the equianalgesic opioid dosing chart, conversions involving methadone, and discussions on the use of adjuvant analgesic options for pain management. The survey questionnaire, which was given pre and post the in-service, focused on methods used to manage pain and was given to the students and residents before and after the presentation to assess their knowledge on pain management.

Results: Sixteen individuals including medical students and physicians from the national cancer hospital attended the educational in-service regarding opioid prescriptions medications and their use in pain management. Prior to the in-service, the overall passing rate was 63%. A score of 3 out of 5 (60%) was considered passing. The overall passing rate post in-service was 92%.

Conclusion: An educational in-service, such as ours has demonstrated benefits in improving knowledge among healthcare professionals in Guatemala regarding the use of opioid prescription medications for pain management in palliative care patients. Collaborative efforts should be made by governments, health care administrators, pharmacists and prescribers to ensure that opioids are available for the treatment of pain management.

Submission Category: General Clinical Practice

Submission Type: Case Report

Session-Board Number: 5b-349

Poster Title: Risperidone-induced hepatotoxicity in a schizophrenic patient unresolved after switching to paliperidone

Primary Author: Frances Sousonis, St. John's University, College of Pharmacy and Health Sciences, New York; **Email:** frances.sousonis11@stjohns.edu

Additional Author (s):
Farah Khorassani

Purpose: This case report describes possible risperidone- and paliperidone-induced hepatotoxicity. A 23-year-old hispanic male with a past medical history of schizophrenia was admitted to an inpatient psychiatric unit after psychiatric decompensation in the community secondary to medication non-adherence. Prior to admission, the patient's family reports he was isolated, restless, malnourished, and paranoid that his food was being poisoned. On admission, his baseline liver function tests (LFTs) were within normal limits. The patient was started on risperidone 1mg, and was titrated in 1mg increments over five days until he reached a 4mg dosage. Approximately one week after initiating risperidone 4mg, the patient experienced a significant rise in LFTs. Aspartate aminotransferase (AST) and alanine aminotransferase (ALT) peaked at 125u/L and 469u/L on the eighth consecutive day of receiving risperidone 4mg, respectively. Medical causes such as refeeding syndrome were ruled out, and it was deemed that the risperidone was the possible cause for the hepatotoxicity. One day after discontinuing risperidone, the patient's LFTs began trending down. His regimen was switched to oral paliperidone 6mg due to minimal hepatic metabolism and a lower hepatotoxicity incidence reported. The patient's LFTs consistently trended downward after three days of oral paliperidone 6mg, and he was thus bridged to the paliperidone palmitate 234mg, the long-acting injectable formulation of paliperidone, four days after initiation of oral paliperidone. The patient's labs fluctuated for six days, however his LFTs began trending upward again (AST: 80u/L and ALT: 217u/L). The second dose of paliperidone palmitate was held to assess if LFTs would continue to rise. Four days later, liver enzymes were still persistently elevated. The patient was switched to oral haloperidol. By the next day, the patient's LFTs were reduced by almost half, and reached normal range approximately three weeks after the discontinuation of paliperidone palmitate. After four weeks of receiving haloperidol, the patient's LFTs remained stable. The patient was discharged on haloperidol decanoate and normal LFTs. This case

highlights possible hepatotoxicity associated with risperidone that remained unresolved after switching to paliperidone, but resolved after switching to haloperidol. Findings of this case suggest that haloperidol may be an appropriate antipsychotic to switch to if a patient develops hepatotoxicity during risperidone or paliperidone therapy. Additionally, baseline and routine screening of liver function tests in patients initiated on risperidone may be warranted.

Poster Title: Effects of delayed rifampin administration in combination with polymyxin B against KPC-producing Klebsiella pneumoniae

Primary Author: Justin Osorio, University at Buffalo School of Pharmacy, New York; **Email:** justinos@buffalo.edu

Additional Author (s):
Nicholas Smith
Patricia Holden
Brian Tsuji
Zackery Bulman

Purpose: Infections caused by KPC-producing Klebsiella pneumoniae (KPC-Kp) are associated with unacceptably high mortality rates in the clinical setting. As a result, the need for novel combinations and dosing strategies has arisen in order to effectively combat KPC-Kp. The objective of this study was to compare the combinatorial pharmacodynamics of polymyxin B (PMB) and rifampin (RIF) administered simultaneously, versus polymyxin B with delayed rifampin administration.

Methods: Five clinical KPC-Kp strains (3 KPC-2 and 2 KPC-3) obtained from patients with bacteremia were investigated (Strain, PMB/RIF MICs: 9A, 0.5/64; 26A, 0.5/64; 27A, 1/>64; 8A, 0.5/32; 25A, 0.5/32). Combination therapies of PMB (1.5 and 3mg/L) + RIF (3.5mg/L) were evaluated versus a starting inoculum of 10^7 CFU/ml in 24h static time-kill experiments. The total bacterial population was quantified by plating serial dilutions of bacterial samples on cation adjusted Mueller-Hinton agar plates and then quantified following incubation for 24h at 37 Celsius. Bacterial log(CFU/ml) reductions from baseline were calculated at individual time points to compare the pharmacodynamic effects of RIF added 0, 2, 4, 6, or 8h after the addition of PMB.

Results: Against 9A, simultaneous administration of PMB 3mg/L and RIF displayed the greatest bactericidal activity indicated by a -7.4 log(CFU/ml) reduction in the time-kill experiment from 4-8h. Addition of RIF at 2h to PMB 1.5mg/L was superior to simultaneous administration for 9A, displaying a -7.3 log(CFU/ml) reduction from 4-6h. RIF administration at 2h was the most

effective regimen against 26A, irrespective of PMB concentration. PMB 1.5 mg/L and 3mg/L with RIF added at 2h achieved undetectable counts from 4-8h and 2-6h, respectively. Against 27A, simultaneous administration of PMB 3mg/L and RIF produced the greatest bactericidal activity with a -7.2 log(CFU/ml) reduction from 6-8h. All regimens of PMB 1.5mg/L displayed similar activity regardless of time of RIF administration. Interestingly, against 8A, PMB 3mg/L+RIF dosed at 6h displayed enhanced killing compared to other regimens, generating a -7.2 log(CFU/ml) reduction from 6-8h. PMB 1.5mg/L regimens all displayed similar activity regardless of time of RIF administration. Against 25A, eradication was detected at 24h for PMB 3mg/L+RIF administered at 2, 4, and 6h, while simultaneous and 8h delayed administration of RIF resulted in regrowth. Against PMB 1.5mg/L, complete killing of 25A throughout the experiment was seen only with administration of RIF after 6 and 8h.

Conclusion: KPC-infections have become increasingly problematic to treat in the clinical setting and as a result require innovative treatment approaches. Delaying the addition of rifampin relative to polymyxin B may be advantageous when compared to simultaneous administration by potentiating bactericidal activity of polymyxin combinations against KPC-producing K. pneumoniae. Further studies are warranted to determine if this phenomenon is dependent on the infecting strain.

Poster Title: Management of latent tuberculosis in directly observed therapy programs coordinated by clinical pharmacists

Primary Author: James Bhaidas, Saint John's University - College of Pharmacy and Health Sciences, New York; **Email:** james.bhaidas11@stjohns.edu

Additional Author (s):
Loyce Mol
Megan Lam
Suzan Chin
Omar Rahman

Purpose: Directly Observed Therapy (DOT) is a widely recommended and promoted strategy used to manage latent tuberculosis (TB). DOT among individuals at the highest risk for progression to active disease is an important strategy used to reduce drug-resistance, relapse, and further transmission. Control and elimination can be achieved with a concerted effort between healthcare practitioners and their inclusion of clinical pharmacists. A pharmacist can offer benefits including expert medicinal care and support, walk-in center convenience, and medication therapy management. This project was designed to highlight the ever-expanding role and capacity of pharmacists in the management of DOT for latent TB.

Methods: A clinical pharmacist at an infectious disease clinic was given the opportunity to manage DOT patients. Prior to the start of therapy, the pharmacy staff at the infectious disease clinic coordinates with the patient's outpatient pharmacy to determine if the medications require a prior authorization. If so, the manual process was initiated and completed by the pharmacist. The initial visit comprised of an interview which served as a priority assessment tool to address barriers to adherence and any patient concerns. A cornerstone of the initial visit was the identification, resolution and prevention of potential drug-related problems completed by the clinical pharmacist. The DOT regimen lasted 12 weeks and consisted of weekly doses of 900 milligrams of Priftin, 900 milligrams of Isoniazid, and 50 milligrams of vitamin B6. Each patient was provided daily doses of vitamin B6 (50 milligrams) in pill trays for the remainder of the week. Additional monitoring parameters included a complete metabolic panel, and a

complete blood count every 4 weeks throughout the course of DOT. The pharmacist participated in the evaluation and distribution of all DOT incentives.

Results: The DOT program has been supervised by the clinical pharmacist since 2013. Since it's inception, the program has enlisted a total of 50 patients. 42 patients have successfully completed DOT, whereas 8 patients failed to complete therapy. 4 of the 8 patients withdrew from therapy prior to completion because of severe adverse drug reactions. 2 of the 8 patients were dismissed because of poor compliance. 2 patients discontinued therapy because of miscellaneous reasons. The clinical pharmacist used a proactive approach in reducing the frequency of drug related problems, thus influencing better pharmacotherapy outcomes for the patient. For some drug interactions, the pharmacist was able to independently identify whether or not the risk outweighed the benefit. The pharmacist served as an asset for patients by obtaining and evaluating pertinent laboratory results. The pharmacist documented and discussed clinically relevant findings with the patient's physician and nurse. The pharmacist assessed any adverse effects, reinforced counseling, and reviewed education points during all encounters.

Conclusion: The critical role that medication management plays in treating latent TB suggests that the integration of clinical pharmacists into DOT teams has the potential to improve health outcomes. Our project elucidates an innovative opportunity for pharmacists to participate in all stages of DOT, including drug ordering, dispensing, administering, and monitoring.

Poster Title: Acetaminophen Stability in Polyolefin and Polyvinyl Chloride

Primary Author: Albin Mathew, Arnold & Marie Schwartz College of Pharmacy and Health Sciences,

LIU Pharmacy, New York; **Email:** amathew88@gmail.com

Additional Author (s):
Mark Klang
Debra Willner

Purpose: Acetaminophen's stability according to the manufacturer is listed as six hours, although
current literature implicates that it may be stable for longer. This literature, a specific study
conducted by Kwiatkowski et al in the American Journal of Health System Pharmacists,
evaluated the drug in syringes or glass containers and not in the intravenous bags routinely used in
pharmacy practice. Our experiment repeated this study utilizing B Braun Polyolefin and
Hospira Polyvinyl chloride intravenous-use containers.

Methods: Our stability-indicating study, was based on the current literature and modeled after the
stability study aforementioned. We created an high performance liquid chromatography
analysis and modeled it to optimize
wavelength and retention time. Our preparations bore 10 miligram per mililiter concentrations and all tests
were performed in triplicates. Our models to date indicate a linear function with respect to our
data and our results are reproducible. Analysis was conducted with the drug mixed with HCl 1
N, NaOH 1 N, H_2O_2 3 percent and heat (125 degrees centigrade for 15 minutes). The
breakdown products generated
peaks distinct from the targeted medication. The containers were kept at controlled room
temperature to maximally stress the solutions. Samples were removed from all containers at
time 0, 6 and 24 hours and at days 4, 7 and 14.

Results: Throughout the study only one peak was seen on the chromatograph. There was no decrease in concentration. The concentration was slightly elevated in the polyvinyl chloride containers. No sign of drug degradation was noted throughout the study.

Conclusion: The increase in concentration seen with long term storage in polyvinyl chloride is expected as water will evaporate through polyvinyl chloride. Therefore polyvinyl chloride is not a good option for long-term storage of any aqueous component. Acetaminophen has been found to be stable for 14 days and can be stored at room temperature. In accordance with USP 797, the optimal storage would be refrigeration,prepared in batched lots inside a 797 clean room.

Submission Type: Evaluative Study

Session-Board Number: 5b-353

Poster Title: Pigtail catheters versus traditional chest tubes and the need of pain medications in trauma patients

Primary Author: Terri Frazier, Xavier University of Louisiana, College of Pharmacy, Louisiana; **Email:** tlmcgee@xula.edu

Additional Author (s):
Sara Al-Dahir
Jennifer Mooney
Taylor Hillburn
Adele Williams

Purpose: Thoracic injury resulting in pneumothorax or hemothorax is quite common. Traditionally, large bore chest tubes (32-40F) are inserted to treat both pneumothorax and hemothorax. Recent literature has suggested that using smaller pigtail catheters (14F) is equally efficacious, with similar complication rates and fifty percent less insertion site pain when compared to larger tubes. We hypothesize that the placement of a smaller bore pigtail catheter will result in a decreased need of pain medications post pull insertions when compared to traditional chest tubes.

Methods: The institutional review board has approved this retrospective chart review with patients identified through the trauma registry as meeting the following criteria: patients admitted for trauma with a diagnosis of pneumothorax or hemothorax for which a tube thoracostomy was performed. The charts were reviewed and pertinent demographic and clinical data retrieved. Inclusion criteria were all adult trauma patients with tube thoracostomy at any time during admission. Exclusion criteria were those who died prior to tube removal, those with a pneumothorax on pre-pull chest x-ray and patients less than eighteen years of age. Pain medication need was assessed 72-hours post-tube placement. All opiate medications were converted to their morphine equivalences. Data was assessed to determine if patients receiving pigtail catheters required less pain medication when compared to patients who received larger chest tubes.

Results: Among 105 charts reviewed, 35 patients received a pigtail catheter (33 percent). The total 72-hour post-tube placement pain medication need for patients who received a smaller pigtail catheter was compared to patients who received a larger bore chest tube. The mean difference (plus or minus standard deviation) between the larger chest tube and pigtail catheter was found to be 354.36 plus or minus 227.78 milligram and 553.72 plus or minus 422.42 milligram respectively. A significant difference was not found when comparing both groups (P equals 0.66) total opioid use without fentanyl. All data was analyzed using ANOVA for mean comparison of total morphine equivalence.

Conclusion: When comparing patients who received a smaller bore pigtail catheter versus a larger bore chest tube after being diagnosed with a pneumothorax or hemothorax, there was not a significant reduction in the need for pain medication 72-hour post-tube placement. Data collected directly challenges the results of recent studies which have suggested smaller bore catheters resulting in the need of a reduction in pain medication administration. Further analysis is needed in a larger populations and further assessment of confounding constraints and procedure adverse effects are warranted.

Submission Type: Evaluative Study

Session-Board Number: 5b-354

Poster Title: Assessing real world evidence of edema in Philadelphia positive chronic myeloid leukemia patients receiving imatinib and nilotinib

Primary Author: Steven George, St. John's University College of Pharmacy and Health Sciences, New York; **Email:** steven.george11@stjohns.edu

Additional Author (s):
Rohan Ramnarain
Wenchen Wu

Purpose: Imatinib mesylate (Gleevec) and nilotinib (Tasigna) are medications in the class of BCR-ABL tyrosine kinase inhibitors and are used to treat patients with Philadelphia positive chronic myeloid leukemia (Ph+ CML). The purpose of this retrospective study is to compare the risk profile of edema between imatinib and nilotinib in patients with Ph+ CML, using the FDA Adverse Event Reporting System (FAERS) database in an attempt to illuminate a reflective method on how to help ascertain the risks and benefits of administering these particular medications in patients who are prone to developing edema.

Methods: The institutional review board has approved this retrospective study. The FAERS database comprises anonymous adverse drug events that are publicly accessible comma separated value files from 2004 to 2015. A subdivision of data from the database involves patients who were taking either imatinib or nilotinib with the indication of Ph+ CML listed during the period stretching from 2011 to 2015. These patients were split into two proportions and the rate of edema within each medication for this indication was then recorded. The most suitable statistical tool for this scenario is a two-proportion t-test, given that the researchers are comparing two probabilities of independent events happening. In order to detect a difference, a 95 percent confidence interval was used. The first proportion is the number of total edema events that occurred within the subpopulation of Ph+ CML patients who were on imatinib. The second proportion is the number of total edema events that occurred within the subpopulation of Ph+ CML patients who were on nilotinib.

Results: A total of 4,998 adverse drug reaction records with a Ph+ CML indication that met the standards for Medwatch reporting were cultivated from the FAERS database from 2011 to 2015. The data consisted of 2,330 nilotinib-associated reports. 97 of this dataset showed the occurrence of edema. On the other hand, there were 2,668 imatinib-associated reports, 84 of which exhibited edema. Using a proportional t-test, the research demonstrated a statistically significant difference in edema incidence rates between imatinib and nilotinib (3.15 percent versus 4.16 percent, respectively; p less than 0.05).

Conclusion: In the context of this type of reporting, patients receiving nilotinib were shown to have a higher incidence of edema than patients receiving imatinib. While this data may serve as a pharmacovigilance tool, future post-marketing studies involving these two medications should consider as many individualistic patient variables as possible. Assumptions made about the results of this study must be interpreted considering the manner in which these reports were voluntarily submitted by qualified personnel.

Submission Category: Practice Research/ Outcomes Research/ Pharmacoeconomics

Poster Title: Assessing the relationship between patient perceptions regarding hypertension medications, medication adherence, and blood pressure goal attainment

Primary Author: Kevin Heacock, St. John Fisher Wegmans School of Pharmacy, New York; **Email:** kjh06992@sjfc.edu

Additional Author (s):
Stacy Roche
Nabila Ahmed-Sarwar

Purpose: Monitoring patient adherence to hypertension medication remains challenging. Patient perception regarding the efficacy and importance of a medication regimen may play a large role in the degree of adherence and ultimately blood pressure goal attainment. This project was designed to target patients on antihypertensive regimens, and gain understanding regarding their needs and concerns about their antihypertensive medications in order to increase understanding the relationship between perceptions and maintaining adherent to prescribed medications.

Methods: Patients diagnosed with hypertension being treated with at least one hypertensive medication were selected for inclusion if they met the following criteria: 1 or more blood pressure medications, at least 18 years of age, and presenting to their primary care provider for a follow-up visit for hypertension. Patients were excluded if they had a psychiatric condition that impaired their ability to control their own medication adherence. Utilizing a convenience sample process, patients identified were administered an eight item questionnaire to determine their needs and concerns surrounding the use of blood pressure medications. Additionally, patients were asked requested to self-identify their level of adherence and their blood pressure value for that visit was recorded. Outcomes measured will include: Level of agreement for statements regarding needs and concerns about antihypertensive medications, self-reported rate of adherence, and number of patients at goal blood pressure.

Results: A total of 22 patients were identified that met inclusion criteria and completed the questionnaire. Twenty-seven percent of patients self-identified as being adherent to medication therapy, medication adherence was not assessed in 18 percent of patients. Goal blood pressure was achieved by all patients that self-reported as being adherent and only 40 percent of patients that self-report non-adherence. Regardless of level of medication adherence, 100 percent of patients strongly agreed with statements that assessed their need for their blood pressure medication to maintain their health. All patients that self-identified as non-adherent strongly disagreed with statements that indicated they have concerns regarding their medications, where as 80 percent of patients that self-identified as adherent to therapies, indicated a level of agreement with statements that indicated they have concerns regarding their medications.

Conclusion: The ability to achieve goal blood pressure is impacted by adherence to antihypertensive therapies. Regardless of level of adherence patients on antihypertensive medications strongly agree the medication is needed to maintain their health. Patients concerns regarding their antihypertensive therapies differs with level of adherence, those that are adherent are more concerned with the effects of their medications and medication dependency in comparison to non-adherent patients.

Submission Category: Emergency Medicine/ Emergency Department/ Emergency Preparedness

Submission Type: Descriptive Report

Poster Title: Update: description and analysis of a clinical emergency pharmacist program in a rural hospital

Primary Author: Rebecca Martin, University at Buffalo School of Pharmacy and Pharmaceutical Sciences, New York; **Email:** rmartin6@buffalo.edu

Additional Author (s):
Christina Andrade

Purpose: The acute and fast pace of the emergency department (ED) creates an environment vulnerable to preventable medication errors. The ED has one of the highest preventable medication error rates, hospital wide. The role of the ED pharmacist as a readily visible and available position has drastically evolved. ED pharmacists can improve patient outcomes through interventions including dose adjustments, drug information, patient education and reducing medication errors. In 2010, a small rural hospital in Gallup, New Mexico established a successful ED Clinical Pharmacist Program. This is an update to program establishment, and assessment of evolving responsibilities of the current program.

Methods: The data collection to justify the progression of ED pharmacist integration within the interprofessional team and exemplify intervention evolvement began on September 26th, 2016 and will conclude November 15th, 2016 by the lead ED clinical pharmacist. The study was conducted at Gallup Indian Medical Center (GIMC), a 66 bed Indian Health Service (IHS) rural hospital with a 14 bed ED. Daily pharmacist interventions performed in the ED by the pharmacist were documented on a daily log sheet. Targeted interventions included therapeutic consultation, drug research and information, antimicrobial selection or dosing, dosage calculations or adjustments, response to new lab results, renal dosing advice, promotion of evidenced based guidelines, etcetera. Furthermore, a 10-question survey was developed and deployed from ED staff including physicians, nurses and technicians to capture perspective on ED pharmacist interventions and this position's utility to ED patients, staff and hospital work flow.

Results: A daily log sheet was created to document pharmacist intervention records during weekly shifts of the ED pharmacist. During the first example week, a total of 124 interventions have been made. 21 Intervention categories were observed after the first week of the study. The top three interventions included antimicrobial selection, therapeutic consultation and provision of drug research and information. The preliminary results correspond to the first week of the project; further results are pending. The results of this study will be compared to the interventions made during the inception of the program.

Conclusion: Based off the preliminary results, pharmacist involvement in the ED has expanded significantly in comparison to such implementation in 2010. The ED pharmacist continues to be an integral and appreciated part of the interdisciplinary team caring for ED patients. Continuation and expansion of the pharmacist position in this rural hospital may be warranted, based upon possible future higher patient volumes as this program will continue to aid in decreasing medication errors, improved patient and ED staff satisfaction and continued efficiency associated with real-time interventions.

Submission Type: Evaluative Study

Session-Board Number: 5b-357

Poster Title: Compounded apixaban suspensions for enteral feeding tubes

Primary Author: Maria Caraballo, St. John Fisher College Wegmans School of Pharmacy, New York; **Email:** mlc00400@sjfc.edu

Additional Author (s):
Seda Donmez
Kobi Nathan
Fang Zhao

Purpose: Medication administration via enteral feeding tube is on the rise for critically ill patients. Apixaban is a relatively new oral factor Xa inhibitor which is available only as 2.5 and 5 mg film coated tablets. There are limited compatibility and stability data on compounded apixaban preparations for enteral feeding tubes. This study is intended to identify a suitable apixaban suspension formulation which is easy to prepare by pharmacists, is compatible with commonly used enteral feeding tubes, and has a beyond-use date of at least 48 hours.

Methods: Two types of nasogastric tubes, polyurethane (10 french, 36 inches) and polyvinyl chloride (18 french, 48 inches), were used in this study to represent the commonly used tube materials and to bracket the typical tube diameter range for adults. The tubes were mounted on a pegboard to simulate the patient position. Suspension vehicles of ORA-Plus and water mixtures were first screened for flowability through the tubes. Twenty milliliters of each vehicle were poured in a syringe and allowed to flow through the tube via gravity. All evaluations were done in triplicates, and the tube was flushed with 60 mL water and 60 mL air between runs. Once a suitable vehicle was identified, 0.25 mg/mL apixaban suspensions, were prepared from 5 mg strength tablets using mortar/pestle, Silent Knight Pill Crusher, or crushing syringe. Selected apixaban preparations were administered through each type of tubes for flowability evaluation (n equals 3 with fresh tubes). The drug concentration before and after tube administration was also analyzed by reversed phase high performance liquid chromatography (RP-HPLC). Finally, a stability study of the chosen apixaban suspension formulation was conducted. The suspension was stored in an amber polypropylene bottle at room temperature and analyzed on day-0, 1, 3, and 7 by a stability-indicating RP-HPLC method.

Results: It was observed that ORA-Plus and water mixtures, at 40:60, 50:50, and 60:40 ratios, flowed through both types of tubes at slightly varying speeds with little to no residual volume. Due to its simplicity and ease of preparation, the 50:50 ORA-Plus:water mixture was selected as the vehicle to prepare apixaban suspensions. Among the three compounding methods evaluated, the mortar/pestle approach gave the most accurate potency result of 0.247 mg/mL (99.0 percent label claim) with a relative standard deviation of 2.2 percent. Significant drug loss and variability were observed for Silent Knight Pill Crusher and crushing syringes, respectively. The apixaban suspension prepared by mortar/pestle flowed through both types of tubes with no significant residual volume. The RP-HPLC results also confirmed that more than 98 percent drug remained in the suspension after tube administration. The stability study results indicated that the chosen suspension formulation retained more than 95 percent of initial drug concentration over seven days of storage. No significant degradation products were observed.

Conclusion: A suitable apixaban suspension for enteral feeding tube administration was identified as 0.25 mg/mL drug in 50:50 ORA-Plus:water. This suspension was prepared from 5 mg strength oral tablets, and the traditional mortar/pestle compounding method was found to achieve more accurate and consistent potency results than the Silent Knight Pill Crusher or crushing syringe methods. The chosen apixaban suspension formulation exhibited satisfactory flowability via 10 to 18 french enteral feeding tubes and minimal sorption to polyurethane and polyvinyl chloride tube materials. The beyond-use date of this apixaban suspension, stored at room temperature, was established for up to seven days.

Poster Title: Management of hyperglycemic emergencies in an academic medical center: assessment of current practicies

Primary Author: Daria Zavgorodnyaya, Long Island University, New York; **Email:** daria.smith@my.liu.edu

Additional Author (s):
Alan Hui
Teresa Chan
Sandra Ude

Purpose: Diabetic ketoacidosis (DKA) and hyperosmolar hyperglycemic state (HHS) are complications of diabetes that can result in prolonged hospital admissions and mortality if they occur in the setting of multiple comorbidities, advanced age or are inappropriately managed. In this study we performed a retrospective chart review to evaluate the correlation between the treatment received in the hospital and length of stay, and to identify areas for improvement with a subsequent goal of updating the current institution protocol to improve patient outcomes.

Methods: Patients admitted with a hyperglycemic emergency event from January 1, 2016 to August 30, 2016 who received a continuous insulin infusion were identified. Exclusion criteria were age younger than 18 years old, concurrent diagnosis of cardiac arrest, myocardial infarction, stroke, rhabdomyolysis, leave against medical advice or a presentation inconsistent with either DKA or HHS.
De-identified data of 34 patients was assessed.
The primary endpoint was the effect of the initial emergency department (ED) management, defined as the time to IV fluid and insulin drip initiation, on patient disposition to medicine service versus intensive care units (ICUs). Laboratory parameters related to the hyperglycemic emergency management were collected at the baseline and at the time of patient transfer from the ED. A regression analysis was used to assess correlation between the time of IV fluid and insulin drip initiation and percent reduction in anion gap at the time of transfer.
Secondary endpoints included appropriateness of fluid management, transition to long-acting insulin, resolution of the hyperglycemic event before insulin drip discontinuation, and regular

laboratory assessment. These parameters were analyzed in the subgroups of ICU and medicine patients for correlation with the length of stay.

Results: There were 9 admissions to the medicine service and 25 admissions to the ICUs with the median length of stay of 3 and 5 days, respectively. The average decrease in anion gap from the presentation to the transfer from the ED was 49 percent for the medicine group and 35 percent for the ICU group. There was no significant correlation between the time to initiation of IV fluids and insulin drip with the percent change in anion gap (adjusted R-squared equals 0.04). In the subgroup analysis there was a trend towards a negative correlation between proper fluid management, transition to long-acting insulin, resolution of the hyperglycemic event and regular laboratory assessment with the length of stay (adjusted R-squared equals negative 0.2 in the medicine group, adjusted R-squared equals negative 0.1 in the ICU group).

Conclusion: While our analysis did not show a statistically significant correlation of appropriate management of hyperglycemic emergencies with the decision on transfer to the ICUs versus medicine service and length of stay, this can be partially attributable to study limitations such as its retrospective design and a modest sample size.
The results derived from the analysis have identified areas for improvement and will be included in the new institution protocol on the management of DKA and HHS.

Poster Title: Implementation and impact of pharmacist-led transitions of care pilot program in the emergency department

Primary Author: Laura Sedita Alaimo, Arnold and Marie Schwartz College of Pharmacy and Health Sciences

Long Island University-LIU Brooklyn, New York; **Email:** laura.seditaalaimo@my.liu.edu

Additional Author (s):
Xiao Ng
Kimberly Koop
Diana Gritsenko
Billy Sin

Purpose: Approximately 3.3 million emergency department (ED) visits every year are due to patients presented with asthma and chronic obstructive pulmonary disease (COPD). These respiratory diseases can be managed with proper use of inhalers. However, lack of consultation and inappropriate use of inhalers and lack of follow-up care has led to overcrowding in the ED. The purpose of this study is to determine if a pharmacist-led transition of care pilot program will reduce ED visit rates for patients presenting with acute asthma or COPD exacerbations.

Methods: The pilot program was implemented between November 1, 2015 and May 31, 2016 in the ED. The intervention group included patients who presented to the adult ED with a chief complaint of asthma or COPD exacerbation, subsequently discharged from the ED after treatment and willing to provide consent to be seen by a primary medical doctor (PMD) affiliated with the institution. The control group included patients with an existing private PMD. The intervention group received medication reconciliation, discharge counseling, education about their respective disease states, and follow-up with the pharmacist-led transitions of care clinics. The primary endpoint was 30-day ED revisit rates for a similar chief complaint. The secondary endpoint included ability to recall correct inhaler techniques after first counseling attempt, adherence to transition of care clinic visits, and patient satisfaction which was assessed via a Likert scale.

Results: Forty patients were enrolled in the study. All patients presented with a chief complaint of acute asthma exacerbation. The patients enrolled were divided in two groups. There was no statistically significant difference in the baseline characteristics of the patients in both groups. Control group included twenty-four patients who had a private primary medical doctor. The intervention group included sixteen patients who received discharge counseling in the ED and received appointments for follow-up with pharmacist-led transitions of care clinic. The 30-day ED revisit rates for a similar chief complaint was 37.5 percent in the control and 18.8 percent in the intervention group. This result, however, was not found to be statistically significant (p equals 0.297). A subgroup analysis of control versus patients who adhered to the scheduled clinic appointment revealed that six out of the sixteen patients counseled adhered to their clinic appointment. No statistical significant difference was observed in the subgroup analysis (control 37.5 percent versus intervention 16.7 percent; p equals 0.633). In regards to secondary endpoints, fifteen out of sixteen patients were able to correctly recall 87.6 percent of correct inhaler techniques. The mean patient satisfaction score was 4.60 out of 5. Patients expressed gratitude and enjoyed the program.

Conclusion: Discharge counseling in addition to referral appointments for follow-up with pharmacist-led transitions of care clinic reduced 30-day ED revisit rates among patients with acute asthma exacerbation. However, the result was not statistically significant. Patients who participated in the study were able to demonstrate appropriate use of inhalers and provided positive patient satisfaction scores.

Poster Title: Antihypertensive drug utilization patterns and blood pressure control in Hispanic Americans: The National Health and Nutrition Examination Survey, 2003 to 2012

Primary Author: Amy Yang, St. John's University, College of Pharmacy and Health Sciences, New York; **Email:** amy.yang11@stjohns.edu

Additional Author (s):
Hyde Zhuang
Anna Gu

Purpose: Antihypertensive pharmacotherapy effectively reduces hypertension-related morbidity and mortality. Several studies have raised the concern of suboptimal pharmacological antihypertensive treatment among Hispanic populations. While insufficient insurance coverage and poor access to healthcare are most widely accepted determinants of health disparities, the causes of racial inequalities are complex and require systematic studies in order to bridge the gap in achieving universal high-quality clinical outcomes. We aimed at evaluating antihypertensive drug utilization patterns and hypertension control among Hispanic hypertensive individuals by insurance status, age, and presence of comorbidities, especially in comparison to Caucasians and African Americans.

Methods: A serial cross-sectional study was conducted based on the latest available nationally representative data, the National Health and Nutrition Examination Survey (NHANES, 2003 to 2012). Conducted by the US National Center for Health Statistics (NCHS), the NHANES has been implemented as a continuous, cross-sectional annual survey, and data are publicly released in 2-year cycles since 1999. The surveys were reviewed and approved by the NCHS Institutional Review Board (IRB) and documented consent was obtained from participants. To be included in the study, participants must be ≥18 years old, and not pregnant at the time of survey. Hypertension was defined as systolic blood pressure (SBP) ≥140 and/or diastolic blood pressure (DBP) ≥90 mmHg and/or affirmative response to "Are you currently taking medication to lower your blood pressure?" Linear trends in the utilization patterns and control of hypertension were assessed with regression models with a 2-year period treated as a continuous variable. Logistic regressions were applied to model probability of antihypertensive treatment and hypertension control among treated and reported odds ratios (ORs) and 95% confidence intervals (CIs) of

Hispanics relative to Caucasians and African Americans. The analyses were conducted in overall sample and subgroups by insurance, age, and comorbidity, with appropriate sample weights accounting for differential probabilities of selection and the complex multistage survey design. All analyses were conducted using SAS 9.4 (SAS Institute, Inc., Cary, NC).

Results: A total of 8796 hypertensive people ≥18 years were identified. During the study period, all three racial groups (Hispanics, Caucasians and African Americans) experienced substantial increase in antihypertensive treatment and hypertension control, with the lowest rates persistently observed in Hispanics. The overall treatment rates were 60.7% (95% CI 57.0%-64.3%), 73.9% (95% CI 71.6%-76.2%), and 70.8% (95% CI 68.6%-73.0%) and hypertension control rates were 31.2% (95% CI 28.6%-33.9%), 42.9% (95% CI 40.5%-45.2%), and 36.9% (95% CI 34.7%-39.2%) for Hispanics, Whites, and African Americans, respectively. The lower treatment rates among Hispanics were particularly pronounced with regard to polytherapies: Hispanic hypertensive individuals were 23% less likely (OR, 0.77 [95% CI, 0.65-0.92]) than Caucasians and 40% less likely (OR, 0.60 [95% CI, 0.42, 0.86]) than African Americans to receive antihypertensive polytherapies, when controlling for potential confounders. When stratified by insurance status, Hispanics (odds ratios, 0.74 [95% CI, 0.60-0.91] for insured and 0.58 [95% CI, 0.36-0.94] for uninsured) persistently had lower rates of hypertension control compared with Caucasians. These disparities also persisted in subgroups stratified by age (≥60 and < 60 years) and presence of comorbidities but worsened among patients < 60 years.

Conclusion: Our study confirms positive trends in both antihypertensive therapy utilization and hypertension control in all racial groups over the 10 year study period. At the same time, we observed marked racial differences in these measures. Hispanic patients appeared to have poorer hypertension control compared to Caucasians and these differences were more pronounced in younger and uninsured patients. While African Americans received more intensive antihypertensive therapy Hispanics were undertreated. Therefore, further efforts should focus on understanding the reasons for racial inequalities in hypertension control and mounting a broader effort in addressing these reasons.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Descriptive Report

Session-Board Number: 5b-361

Poster Title: Quality assessment before and after implementation of a revised warfarin management program in a small community hospital

Primary Author: Lyla Tan, St. John Fisher College Wegmans School of Pharmacy, New York; **Email:** lt06968@sjfc.edu

Additional Author (s):
Deirdre Pierce

Purpose: The objective of this evaluation is to assess the effectiveness of warfarin management before and after new warfarin dosing guidelines and education were implemented with medical providers and pharmacists.

Methods: The warfarin policy and dosing guidelines were expanded and updated to include suggested dosing strategies in patients with low risk, average risk, and high risk for warfarin sensitivity and bleeding. Education for warfarin pharmacodynamics and pharmacokinetics, dosing, and monitoring was provided to medical providers and pharmacists.
A Medication Use Evaluation was conducted for the month of March in 2015 and 2016, which represented conditions before and after the implementation of the warfarin new management program. Patients admitted during the time period and receiving warfarin were randomly selected and included for evaluation.
Targeted parameters of the evaluation included incidence of an International Normalized Ratio (INR) assay greater than 4.0 that occurred during the admission period. INR values greater than 4 on admission were excluded from this measurement. Also measured were increase of INR greater than 1.5 points per day of therapy, presence of INR measurement at baseline, initial doses greater than 5 mg in patients not receiving warfarin prior to admission, and patients that were in therapeutic INR range at discharge.

Results: A total of 22 patients were evaluated from both time periods. Supratherapeutic INRs greater than 4.0 upon admission were greater in 2015 (14%) than in 2016 (5%) after implementation of the updated warfarin management protocol. The percentage of patients who experienced INR increases over 1.5 points at any day was greater in 2015 than in 2016 (14% vs. 5%). There were no significant differences before and after implementation of the

warfarin management guidelines in the incidence of therapeutic INRs upon discharge, with 36% therapeutic INRs in 2015 and 41% in 2016.

Conclusion: After the implementation of an updated warfarin management program there was a decrease in the incidence of INR values over 4.0 and INR value increases greater than 1.5 points on any day of therapy, however the results did not meet statistical significance. Additionally, there was no significant difference in the percentage of therapeutic INRs upon discharge.

Submission Category: Geriatrics

Submission Type: Descriptive Report

Session-Board Number: 5b-362

Poster Title: Concurrent Cholinesterase Inhibitor and Anticholinergic Therapies in Patients with Dementia

Primary Author: Chelsea Capley, Idaho State University College of Pharmacy - Meridian, Idaho; **Email:** caplchel@pharmacy.isu.edu

Additional Author (s):
Paul Black
Dane Kaster
Garret Smith
Rex Lott

Purpose: Acetylcholine (ACh) plays a significant role in cognition and memory formation, and the current mainstay of therapy for dementia are cholinesterase inhibitors (ChIs). The 2015 American Geriatrics Society (AGS) Beers Criteria recommends against the use anticholinergic medications in older adults with dementia, due to unintended memory impairment, attention deficits, and confusion. Concurrent use of these medications may outweigh the marginal benefits provided by ChIs. This evaluation sought to identify the incidence of concurrent use of anticholinergic and ChIs, assess for anticholinergic burden, and identify the discontinuation frequency of anticholinergics at the initiation of ChI therapy within the Boise Veterans Affairs.

Methods: Based on initial review of 202 patient profiles, this retrospective, descriptive, medication evaluation included 131 patients who met criteria for inclusion. Patients were included based on the following: (1) received prescribed either donepezil, rivastigmine, or galantamine for a minimum of 90-days; (2) received concurrent ChI therapy in addition to anticholinergic therapy; (3) concurrent therapy continued for a minimum of 90 days; and (4) documentation of dementia that is either Dementia, Alzheimer's, Lewy Body, or Vascular dementia.
The Computerized Patient Record System (CPRS) was used to obtain individual patient information. De-identifiable demographic data included: age, gender, race, and Boise VAMC location. Relevant medication information collected consisted of the date of initiation, and when available, the date and rationale for discontinuation of anticholinergic therapy.

Reviewal of medication histories began from one year following the original issue date of ChI treatment. If concurrent anticholinergic therapy occurred, then the primary author evaluated for the accumulative Anticholinergic Drug Scale (ADS) activity. Individual medications were scored based on their serum anticholinergic activity (SAA): Level 3 (markedly anticholinergic), Level 2 (ACh adverse events usually at excessive doses), and Level 1 (potentially anticholinergic).

Each patient evaluated for their accumulative ADS "risk burden" by summating the SAA level for each documented ACh agents and sorted into two risk groups: high/medium and low anticholinergic burden.

Results: Seventy percent (92) of Boise VAMC patients utilized concurrent therapy compared to 30% (39) with only ChIs. Of those 92 patients, 26 (28%) had an accumulative ADS level of ≥3, whereas the majority of patients (72%) had an ADS level ≤2. Concurrent therapy was common (56; 61%) with one ACh medication, with only three patients (5%) who fell into the high/medium risk group with an ADS level of ≥3. Thirty-six patients (39%) used two or more ACh agents of which 23 (64%) had an ADS level ≥3.

Fifty-one patients (55%) had at least one ACh medication discontinued at a particular point in time. Reasons included: expired prescription or rationale not found (32), reported adverse side effects (10), lack of benefit (3), or switched to another medication (3). Five patients (9%) reported adverse side effects related to cognitive function. Three patients (6%) had an ACh medication discontinued following ChI initiation. In two of these patients, the ACh medication was replaced by another ACh agent.

Patients were predominately male (93%) and white (96%) and 79 (±10) years old. Documentation of "dementia" was the most common (79%) diagnosis and donepezil (68; 74%), and galantamine (24; 26%) were the most commonly used agents.

Conclusion: Twenty-six patients (28%) had an increased risk of adverse cognitive effects and decreased the efficacy of ChI. Diagnosis documentation in the patient's problem list was inconsistent and potentially created false exclusions for patients who otherwise may have met criteria. There is not a standardized list of ACh medications known to cause adverse cognitive side effects. A list of agents found to cause adverse cognitive effects, based on evidence-based research, was generated and compared to the VA Drug Formulary. In the future, an evaluation that incorporates changes or decline in cognitive function would strengthen the value of this theoretical drug-drug interaction.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Evaluative Study

Session-Board Number: 5b-363

Poster Title: Evaluation of Opioid Reversal with Naloxone: a Single-Center Retrospective Study

Primary Author: Lada Radetic, University of Utah College of Pharmacy, Utah; **Email:** lada.radetic@gmail.com

Additional Author (s):
Michael Curcio
Shannon Inglet

Purpose: Opioid medications consistently rank among the drugs most frequently associated with adverse events. We reviewed cases of naloxone administration at our institution to assess our opioid prescribing and administration practices. Our primary measure was the rate of opioid reversal with naloxone. Secondary endpoints included demographic information, proportion of patients with at least 2 known risk factors for over-sedation, proportion of patients with opioids on their admit medication history, cumulative 24-hour opioid amount given prior to reversal, rate at which nurses followed our institution's Range Orders Procedure, and number of submissions to our institution's internal event reporting system describing opioid reversal.

Methods: We systematically reviewed all cases of naloxone administration at our institution from March 2016 through May 2016. Cases stemming from outpatient opioid use were excluded. Patients who did not receive opioids outside of the operating room were also excluded. Risk factors for over-sedation were defined as those included in the Joint Commission Sentinel Event Alert on the safe use of opioids in hospitals. Twenty-four hour cumulative morphine equivalents were determined using the Hopkins Opioid Conversion Program online calculator in order to provide consistency and prevent calculation errors.

Results: In the defined time frame, 6673 inpatients received an opioid analgesic. Naloxone for opioid reversal was administered to 39 patients (0.58%) who met inclusion criteria. Of these patients requiring opioid reversal, we found the following demographic data: mean age was 63 years, 59% were female, 59% were post-operative, median serum creatinine was 1.0 mg/dL, and the mean BMI was 29.4, though 46% of patients were obese (BMI ≥ 30). In this cohort, 79.5% had at least 2 risk factors for over-sedation. Nearly 85% did not have an opioid

documented on their admission medication history, suggesting they were potentially opioid-naïve. The mean morphine milligram equivalents given in the 24 hours preceding naloxone administration was 19.6 mg. Per our institution's policy on range orders, nurses are instructed to begin with the lowest prescribed dose of opioid; this policy was followed in 53.8% of cases. Naloxone administration has historically been used as a surrogate marker for overall event reporting. We reviewed all event reports submitted during the study period and found that only one corresponded to opioid reversal, so it may be that our event reporting rate is as low as 2%.

Conclusion: Our overall rate of opioid reversal with naloxone was 0.58%, which is comparable to similar studies. However, our secondary endpoints indicate that opioid prescribing and administration habits may not take into account patient-specific risk factors for over-sedation. These results may serve as an impetus for improvements in quality and patient safety.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Session-Board Number: 5b-364

Poster Title: Inpatient anticoagulant usage trends in a healthcare system from 2010-2016

Primary Author: Elyse Schwab-Daugherty, University of Utah College of Pharmacy, Utah; **Email:** elyse.schwab@pharm.utah.edu

Additional Author (s):
Richard Ensign

Purpose: The purpose of this investigation was to determine the usage patterns of warfarin and the direct acting oral anticoagulants (DOACs) within the Intermountain healthcare system over a six year period.

Methods: Data was extracted from the Enterprise Data Warehouse (EDW) from January 2010 to March 2016. Comparisons were made between warfarin and the different direct oral anticoagulants over time and across the Intermountain Healthcare hospitals to see the usage patterns of anticoagulants. Intermountain Healthcare switched electronic medical record systems at different hospitals starting in October 2014, the data from those hospitals were not available during this analysis.

Results: Anticoagulant usage patterns varied over the last six years. Warfarin prescribing has decreased system-wide after the introduction of DOACs to the market. Dabigatran use slightly increased when first approved but its use has decreased since the approval of rivaroxaban and apixaban. Rivaroxaban use increased over the last 5 years but has remained level since the approval of apixaban. Apixaban use has been increasing over the last year. Edoxaban was not used across the system during the time period investigated. Anticoagulant use varied by hospital and type of unit or floor.

Conclusion: Warfarin use has seen a steady decline while rivaroxaban and apixaban use have seen an increase over the last two years. Dabigatran use has been low and edoxaban has not been used over the last six years. Anticoagulant usage patterns have changed across hospitals with the introduction of DOACs and may continue to change over time. As reversal agents for DOACs are approved, usage patterns may change further.

Submission Category: General Clinical Practice

Submission Type: Evaluative Study

Session-Board Number: 5b-365

Poster Title: Acceptance of medication therapy management (MTM) recommendations: A retrospective comparison of face-to-face and telephonic delivery models

Primary Author: Brian Bell, Idaho State University College of Pharmacy, Idaho; **Email:** bellbria@pharmacy.isu.edu

Additional Author (s):
Thomas Wadsworth
Kathy Eroschenko

Purpose: The purpose of this study is to determine and compare the recommendation acceptance rates of two MTM delivery models.

Methods: An employee with PacificSource performed a search to identify patients that received MTM services from March 2015 to December 2015 and created a spreadsheet containing the de-identified data. The de-identified data was then sent to Bengal Pharmacy and securely stored on an encrypted flash drive. This was then accessed through an encrypted computer within the Bengal Pharmacy MTM offices. The data was then separated into two groups. Namely, those who participated in face-to-face (F2F) and telephonic MTM services. The number of recommendations made within each group was added up. Then the number of accepted recommendations was determined using claims data. These numbers were then used to perform statistical analysis, using 2 proportions z-test.

Results: A total of 418 F2F comprehensive medication reviews (F-CMR) and 2,846 telephonic CMRs (T-CMR) were collected. Out of those CMRs, 1,716 recommendations were made during the F2F encounters and 5,887 recommendations during the telephonic encounters. Only 32 of the F2F recommendations were accepted and resulted in a claim that made a change in accordance with the recommendation (1.8%). A sum of 1138 accepted recommendations resulted from the telephonic services (19.3%). This resulted in a Z-score of 17.6 ($p < 0.01$), thus indicating a significant difference between the two proportions and disproving my original hypothesis.

Conclusion: Telephonic CMRs produced abnormally higher acceptance rates when compared to CMRs performed face-to-face with patients. Due to the volume of CMRs completed telephonically versus face-to-face, this also suggests that T-CMRs may be more attainable. This leads us to conclude and recommend that pharmacist, insurance companies, and MTM vendors should not be required to meet with their patients face-to-face. The average number of recommendations made per CMR and the rate of acceptance are inversely related – this may indicate that providers are less likely to review more lengthy CMR results as well.

Submission Type: Evaluative Study

Session-Board Number: 5b-366

Poster Title: Analysis of perceived barriers to pharmacy-based human papillomavirus vaccination provision among practicing and student pharmacists: opportunities for education

Primary Author: Amir Piranfar, Idaho State University College of Pharmacy, Idaho; **Email:** piraamir@isu.edu

Additional Author (s):
Catherine Oliphant
Glenda Carr

Purpose: The National Immunization Survey (NIS) of 2015 found that only 35% of adolescents in the U.S. had completed the 3-dose series of HPV vaccine. Pharmacists can be a valuable resource in improving HVP vaccination rates through offering the convenience of patients not having to return to their physician's office for their 2nd or 3rd dose. However, the HPV and other adolescent vaccines are not as widely offered by community pharmacies as other vaccines. The purpose of this study was to determine areas in which foundation and continuing education can be improved to expand pharmacist provision of the HPV vaccine.

Methods: A survey was adapted from Teeter and colleagues that assesses pharmacists' beliefs and perceptions about providing the HPV vaccine in a pharmacy setting. The online questionnaire was administered via email to ISU College of Pharmacy alumni and current PharmD students using REDCap (Research Electronic Data Capture). The questionnaire included basic demographic information such as level of experience, gender and practice setting and 33 5-point Likert-type questions (1-strongly disagree to 5-strongly agree, or 1- not at all to 5-extremely). The primary endpoint was to identify correlations between the beliefs and perceived barriers and the respondents' level of experience. Secondary endpoint identified questionnaire's correlations with gender and pharmacy practice setting. Two subgroup analyses were also preformed comparing independent pharmacists against chain pharmacists as well as 1st and 2nd year students against 3rd and 4th year students. Data was and stored on REDCap and analyzed using Microsoft Excel and MIniTab Express. The Chi squared test of independence and adjusted residuals were used to analyze differences between pharmacist demographics and each question. Idaho State University's IRB deemed this study exempt from the approval process.

Results: Ninety-seven questionnaires were completed, resulting in a response rate of 7.4%. The survey groups had significantly differing opinions on 4 of the 33 questions. For the primary endpoint, students were more likely agree that the failure of some insurance companies to cover the vaccination costs was a barrier to providing the HPV vaccine(P=0.006). For the secondary endpoints, participants that worked in the community setting were more likely to strongly agree with this (P=0.005) although those in a health-system setting were more likely to only slightly agree (P=0.04). Health-system and female participants disagreed that children should be vaccinated against HPV once they are sexually active (P=0.003, 0.005), whereas community and male participants were unsure (P=0.001, 0.02). Community participants were more likely to strongly agree that there are too few patients who want the HPV vaccine compared to health-system participants (P=0.005), and health-system participants felt less strongly (P=0.004). Females were more likely to disagree to having moral or religious apprehensions about HPV vaccine (P=0.003), and men were more unsure (P=0.007). There were no statistically significant differences across the questionnaire for either of the subgroup analyses.

Conclusion: This study suggests that offering education to students in school as well as continuing education for community pharmacists on insurance reimbursement models for vaccinations may help to increase pharmacists' provision of the HPV vaccine. Barriers were more often reported by community participants compared to health-system, which shows that the barriers exist more strongly against community pharmacists. The HPV vaccine seems to still be stigmatized as a female vaccine rather than a gender-non-specific vaccine. Thus, there exist opportunity for education among all levels of experience for regarding current recommendations that HPV vaccine applies equally to both males and females.

Submission Category: Oncology

Submission Type: Descriptive Report

Session-Board Number: 5b-367

Poster Title: Assessment of minority inclusion by sponsor in select FDA oncology approvals: 2010-2015

Primary Author: Maygen Cardona, Idaho State University College of Pharmacy, Idaho; **Email:** cardmayg@pharmacy.isu.edu

Additional Author (s):
Christine Merenda

Purpose: Minority inclusion in clinical trials is important for drug development because rates of morbidity/mortality are higher in minorities in the United States (U.S.). Despite FDA and NIH guidance to sponsors for inclusion of these populations in clinical research to observe differences in safety and efficacy, overwhelmingly low minority inclusion persists, far below U.S. demographic and disease prevalence. Reliance on industry-funded trials and use of foreign trial participants guiding drug approvals may be exacerbating these patterns. This project assessed inclusion of diverse populations in clinical trials, and evaluated for inclusion trends among sponsors in recent FDA approvals of select oncology products.

Methods: Oncology products included in the assessment were identified through the Hematology/Oncology (Cancer) Approvals & Safety Notifications page of the FDA website (www.fda.gov). U.S. prevalence data were gathered from the Surveillance, Epidemiology, and End Results (SEER) program database for multiple myeloma, breast, colon, lung, and prostate cancers; cancers that are noted for disparities among African Americans. The demographics of trial participants for each new drug approved for these select cancers from the years 2010 to 2015 were obtained from the Medical Reviews through the Drugs@FDA database. The demographics of trial participants were compared by cancer type to SEER prevalence data. In addition, sponsors with two or more drug approvals during the specified time period were assessed for trends in demographic inclusion.

Results: Throughout the years 2010-2015 sponsors did not include a diverse population in their oncology clinical trials. Trial participants did not mirror disease prevalence or U.S. demographics. In addition, there was a marked trend toward greater inclusion of White/Caucasians in oncology clinical trials, and a resulting decrease in all other racial and

ethnic groups except Asians. Increased inclusion of Asian populations was noted among a select number of sponsors, likely due to their clinical trial site(s) in Asia.

Conclusion: Products approved by the FDA from 2010-2015 to treat select cancers failed to include diverse populations in their supporting clinical trials. Additionally, declining minority inclusion was seen in trials of evaluated sponsors, with the exception of Asians. This movement toward greater reliance on White/Caucasians and non-U.S. Asians to support drug approvals means knowledge gaps in safety and efficacy for minorities will persist. These ongoing gaps will fail to shed light on the role drugs play, if any, in health disparities. This project's results cast doubt on ability of providers to generalize these drugs' efficacy and safety to the U.S. population.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Descriptive Report

Session-Board Number: 5b-368

Poster Title: Pharmacy Department Standardization of Intravenous Medications

Primary Author: Roger Call, Idaho State University College of Pharmacy, Idaho; **Email:** callroge@pharmacy.isu.edu

Additional Author (s):
Michelle Steed-Ivie
Lindsey Reeder
Howard Madsen
Katy Burton

Purpose: Due to variability in IV room experience, a wide range of methods have been employed in regards to intravenous medication preparation, leading to the development of this quality improvement study. Uniformity and simplicity are two key characteristics that are necessary during the process of preparing intravenous medication drips. The Institute for Safe Medication Practices (ISMP) encourages healthcare facilities and systems to select a standard way to dose medications. This process is also likely to decrease medication errors. The purpose of this study is to establish uniformity by implementing a standardized method for preparing common intravenous medication drips.

Methods: Ten intravenous medication drips were included in the study: 1) Norepinephrine, 2) insulin, 3) nicardipine, 4) dexmedetomidine, 5) fentanyl double strength, 6) midazolam, 7) morphine, 8) furosemide, 9) vasopressin, and 10) amiodarone. Pharmacy staff members were asked to complete pre and post surveys in order to observe varying preparation methods and to then determine a standardized method before administration of the post survey. For each of the ten drips, the following were preparation options which participants could select on the survey:
A) Add volume of ordered drug.
B) Remove volume equal to amount of drug to be added, then add drug.
C) Remove overfill, then add drug.
D) Remove overfill plus volume equal to amount of drug to be added, then add drug.
E) Add amount of drug calculated to account for base fluid overfill.
F) Other, please describe_____.

After completion of the pre-survey, the method selected to be the new standard was option E) Add amount of drug calculated to account for base fluid overfill. The rationale behind this method was to decrease number of port entries.

Results: The pre-survey was completed by 32 pharmacy staff members. Using a retrospective approach, the standardized method was selected as the correct preparation method 62 times out of 320 total responses. The other 258 responses, although highly variable, were incorrect. As can be observed, less than 20 percent of survey responses reflected adherence to the standard although it was not yet implemented. The post survey was completed by 16 pharmacy staff members. Out of 160 total responses, 117 responses were correct. This reflects an adherence measure, to the newly implemented standardized method of preparation, of 73%. After performing a chi-square test, the findings are noted to be statistically significant ($P < 0.001$).

Conclusion: Although there was a decrease in number of respondents from pre-survey to post survey, findings manifest that there is a difference in method of preparation before and after implementation of the standardized method of intravenous medication admixtures. A higher degree of variability, in respect to preparation method, existed before the standard was in place. A significantly higher number of admixtures are being prepared in a uniform manner, thereby providing more precise drug concentrations from preparation to preparation. Minor alterations to the standard method of preparation will help simplify the process and lead to higher levels of standardized method compliance.

Session-Board Number: 5b-369

Poster Title: Off-label use of PD-1 inhibitors nivolumab and pembrolizumab at Huntsman Cancer Institute

Primary Author: Jenessa Lee, University of Utah, Utah; **Email:** jenessa.lee@pharm.utah.edu

Additional Author (s):
Leigh Fritz
Makala Pace

Purpose: PD-1 inhibitors improve overall survival and progression free survival in many patients with metastatic melanoma, non-small cell lung cancer (NSCLC), renal cell carcinoma (RCC) and Hodgkin's Lymphoma. Their increased use is promising for patients with metastatic disease. However, their use has been seen in non-approved metastatic disease as well. The purpose of this study was to determine the demographics and if the use of PD-1 inhibitors at Huntsman Cancer Institute was similar according to FDA labeling.

Methods: Pending approval, the institutional review board will assess this medication use evaluation. Men and women greater than 18 years old were enrolled if they had received either nivolumab or pembrolizumab at Huntsman Cancer Institute, electronically prescribed from EPIC database, from July 1, 2014 through July 31, 2016. Patients on study nivolumab or pembrolizumab were excluded. The primary outcome measure was total administrations according to FDA approval versus off-label use.

Results: Of the 255 patients enrolled; there were a total of 1,754 administrations (1,043 of pembrolizumab and 711 of nivolumab) between July 1, 2014 and July 31, 2016. The average age at diagnosis was 61, and average weight was 79 kg. 95% of all infusions were given in the outpatient setting in the infusion room. Average dose was 195 mg. 58% (1,016) of all administrations were for malignant melanoma, 15% (259) for NSCLC, 0.3% (5) for Hodgkin's Lymphoma, and 27% (474) for miscellaneous malignant neoplasms.

Conclusion: There were a total of 1,724 administrations. Of those, 27% (474) did not have a diagnosis code that correlated to an FDA approved indication. The patients without a FDA approval should have been on study medication.

Poster Title: Identifying opportunities to improve patient care by assessing knowledge of hemoglobin A1c and vaccine status in patients with type 2 diabetes

Primary Author: Anna Woods, University of Utah College of Pharmacy, Utah; **Email:** anna.woods@pharm.utah.edu

Additional Author (s):
Christine Gundersen
McKay Robinson

Purpose: Patients with diabetes are at risk for multiple complications, including immunodeficiency. Patients diagnosed with diabetes are typically educated about goal plasma glucose levels according to the American Diabetes Association Standards of Care. However, there seems to be a disconnect between the patient's understanding of the interpretation of glucose levels and the translation to their hemoglobin A1c. Additionally, the Advisory Committee on Immunization Practices (ACIP) recommends patients with diabetes receive additional vaccines due to increased risk for pneumonia and hepatitis. This project was designed to identify knowledge gaps among patients, and evaluate where a pharmacist could become involved by providing education.

Methods: This project was conducted in two separate retail pharmacies, one within a grocery store (Site A) and one embedded in a community clinic (Site B). Both pharmacies have established programs aimed at helping patients manage their diabetes in a one-on-one setting. Protocols were already in place at both pharmacies to administer vaccines in accordance with ACIP recommendations. Patients qualified for inclusion if they were picking up a medication used to treat diabetes. A short survey was conducted at the time of dispensing by either a pharmacist, pharmacy intern, or pharmacy technician. The survey consisted of three yes or no questions with a possible two additional follow-up questions to ascertain whether the patient knew their most recent A1c result, when it was checked, and an assessment of their vaccine status. Pharmacy employees were trained on the best practices to conduct this survey during workflow so as to minimize the additional time required during the check-out process. The survey included guidance for the pharmacist or intern to provide education if the patient was

interested, such as A1c goals, appropriate timing of A1c tests, and cost of point-of-care testing. The patients' protected health information was not recorded for the survey purposes.

Results: Fifty-nine patients participated in the survey. The American Diabetes Association Standards of Care were used to determine recommended time frames for A1c tests. Overall, 71% of patients knew their A1c and had gotten it tested within the appropriate time frames (73% at Site A, 69% at Site B). Per patient report, approximately 53% of patients had received all recommended vaccines (42% at Site A, 65% at Site B) and 20% of patients had received some of the recommended vaccines (15% at Site A, 27% at Site B).

Conclusion: Most of the interviewed patients knew their A1c result, but there were 29% of patients who did not or had not had it tested within the appropriate interval. While several patients had received a portion of their recommended vaccines, there were still 47% of patients that were not fully immunized. By asking patients these simple questions during the check-out process, pharmacists and other staff can identify which patients may require more education, provide point-of-care testing, and administer needed vaccines in order to cover this gap in patient care.

Submission Type: Evaluative Study

Session-Board Number: 5b-371

Poster Title: Improving patient satisfaction and safety by compounding fluorouracil continuous infusions

Primary Author: Stephanie Monaco, University of Utah College of Pharmacy, Utah; **Email:** stephanie.monaco@pharm.utah.edu

Additional Author (s):
Scott Silverstien
Jamie Doi-Slade

Purpose: Two important components of fluorouracil home infusions are patient safety and satisfaction. Huntsman physicians ordered patient's home infusions by sending them to an outside pharmacy to be compounded and delivered. Deliveries were made at the Huntsman Infusion room on the day of the patient's infusion and were hooked up by nurses. Delays in delivery caused patients to wait for up to hours in the infusion chair. This resulted in a significant decrease in patient satisfaction. The purpose of this project was to improve patient satisfaction and safety by compounding home infusion fluorouracil at Huntsman with standardized supplies and infusion education.

Methods: Huntsman Cancer Hospital management verified with regulatory compliance the feasibility of transitioning compounding from Home infusion to Huntsman Cancer Hospital. Bundling payments for the elastomeric pumps with 5-FU drug and supplies allowed hospital compounding to be a reasonable option. Nurses were already hooking up patients to be sent home on their pumps in the infusion room. The switch entailed compounding the drug at Huntsman, providing line care supplies, and coordinating of orders with home health companies. The switch improved patient care by minimizing potential errors with care coordination, reducing delays in infusion delivery, providing more patient friendly devices (elastomeric instead of electronic pumps), and reducing potential for chemotherapy spills. Pharmacy IT helped facilitated the change through Epic. To assess the impact of the switch, we surveyed infusion room nurses. They were asked to respond to the following statements using a Likert scale of strongly agree, agree, neither agree or disagree, disagree, and strongly disagree: 1. There are fewer delays in 5FU continuous infusion starts since implementation, 2. Patients receive adequate supplies to manage 5FU continuous infusions, 3. Patient satisfaction

has increased since Huntsman implementation, 4. Nursing satisfaction was increased since Huntsman implementation, 5. Patients have had less issues with their elastomeric pump, 6. Patients prefer the elastomeric pump.

Results: Of the 13 Huntsman infusion nurses surveyed, none strongly disagreed with any of the statements and only one nurse disagreed with one statement. The most positive responses were to the statement "There are fewer delays in 5FU continuous infusion starts since implementation", with 77% of nurses strongly agreeing and 23% agreeing. There was an overall positive response to the statement "Patients prefer the elastomeric pump", with 76% of nurses either agreeing or strongly agreeing, and 23% neither agreeing/disagreeing. Overall, nurses felt patients were more satisfied with the switch. The least positive response was to the statement "Patients have had less issues with their elastomeric pumps.", with 8% disagreeing, 46% neither agreeing or disagreeing, and 46% either agreeing or strongly agreeing. Comments the nurses left explained the elastomeric pumps would sometimes not fully infuse. The lower positive results could be due to a higher number of patients receiving elastomeric balls and the increased role infusion room nurses have in managing fluorouracil home infusions.

Conclusion: The nurse survey showed that the wait times for patients have decreased, a main goal in improving patient satisfaction. The nurses were more satisfied with the switch and felt patients preferred Huntsman to compound their fluorouracil home infusions. Issues with the switch were the failure of elastomeric pumps to fully infuse. The next step for this project will be to survey the patients themselves on the impact the switch had on satisfaction, safety and cost.

Submission Type: Descriptive Report

Session-Board Number: 5b-372

Poster Title: Reducing 30-day readmission rates: what is the impact of decentralized bedside delivery?

Primary Author: Valerie Tran, University of Utah College of Pharmacy, Utah; **Email:** valerie.tran@pharm.utah.edu

Additional Author (s):
Paul Wohlt
Daniel Stoddard
Michael Akagi

Purpose: The rate of hospital readmissions within 30 days is an indicator for quality of care. In addition to having a direct effect on patients, hospital readmissions represent a financial burden on the healthcare system. Not all reasons for readmission are preventable, but some medication-related ones may be. Medication non-adherence is responsible for up to two-thirds of hospital admissions. Reasons for non-adherence are multifactorial including poor communication about medications and financial burden for patients. As healthcare moves in the direction of population health and shared accountability, reducing 30-day readmission rates becomes increasingly important for patient care.

Methods: The Medication Reconciliation, Education, Adherence, and Delivery Initiative (Med READI) is the decentralized bedside delivery service offered by Intermountain Medical Center Community Pharmacy. The program aims to decrease medication non-adherence and consequently 30-day readmission rates by ensuring patients leave with their discharge medications in hand, understand their medications, and know how to contact a pharmacist with any questions. To determine the effect of the decentralized Med READI model, 30-day readmission rates from February 1, 2014 through February 1, 2015 were compared to 30-day readmission rates from October 1, 2015 through September 1, 2016. These periods correlate with the centralized Med READI model and the decentralized Med READI model implementation dates, respectively. A readmission was defined as any encounter within 30 days of discharge, including inpatient, outpatient, and emergency department visits. Readmission rates were evaluated for the following units: the cardiothoracic unit (S3 and S4), surgical unit (T10 and T11), and medicine unit (T8 and T9). These units and dates were included

based on the risk of 30-day readmission being related to medication use, and on the implementation of the decentralized Med READI model being on all units. Not all floors serviced by Med READI were represented in this study. The maternity unit, same day surgery unit, and Intermountain Surgical Center unit were excluded due to the lower probability that 30-day readmissions are medication-related.

Results: Under the centralized Med READI model (February 1, 2014 through February 1, 2015), an average of 813 patients per month received discharge medications before leaving the hospital. After implementing the decentralized Med READI model (October 1, 2015 through September 1, 2016), an average of 851 patients per month received discharge medications through the service. Transitioning to the decentralized Med READI model increased the number of patients served by 4.7 percent. Readmission rates were determined for both models. With the centralized Med READI model, a total of 33.8% of patients were readmitted during the study period. Following the implementation of the decentralized Med READI model, the 30-day readmission rate decreased to 29.5% of patients. The readmission rates from these two periods were compared using the z-test for proportions, and the difference was found to be statistically significant. Subgroup analysis for each floor found statistically significant differences on all floors, with the exception of S4 which showed no difference.

Conclusion: The rate of 30-day readmissions reduced with the implementation of a decentralized Med READI model. The results are likely due to a mixture of reasons including increasing the number of patients served and performing medication education by pharmacy. One limitation of the study is attributing the reduction in readmission rates to decentralizing Med READI as opposed to other hospital initiatives occurring simultaneously. Although the reduction in readmission rate is likely due to many efforts, we feel the impact from decentralizing Med READI is still significant based on the timing of other initiatives, target audiences, and subgroup analyses.

Poster Title: Dexmedetomidine use for extubation in mechanically ventilated patients

Primary Author: Amy Robinson, South Carolina College of Pharmacy, South Carolina; **Email:** amyes@email.sc.edu

Additional Author (s):
Douglas Furmanek
Michael Wagner

Purpose: Dexmedetomidine is a selective alpha-2-adrenergic agonist which possesses sedative, analgesic, and anesthetic properties. Although many studies have investigated dexmedetomidine for ICU sedation, limited trials have been conducted to evaluate dexmedetomidine during extubation in agitated patients. This is of particular interest as agitation increases the risk of self-extubation and leads to prolonged intubation time. Dexmedetomidine may have an advantage in extubation of agitated patients as the clinical practice guidelines state that non-benzodiazepine regimens prevent delirium more than benzodiazepine regimens. This study examines the use of dexmedetomidine in the specific patient population of agitated patients when extubation is expected within 24 hours.

Methods: This is a single center, retrospective cohort study where chart records of patients at Greenville Memorial hospital will be reviewed for inclusion criteria and eligibility for this study. Once patients are identified as meeting inclusion criteria data will be obtained from their medical chart by study investigators. Inclusion criteria include all patients receiving dexmedetomidine to assist with extubation at Greenville Memorial Hospital from July 2016 through June 2017. Exclusion criteria include: patients requiring mechanical ventilation less than 24 hours, patients less than 18 years of age, and pregnancy. The primary outcome is the percentage of successful extubations within a 24 hour period per total number of patients receiving dexmedetomidine. Secondary outcomes include: Intensive Care Unit length of stay, hospital length of stay, and cost of therapy. Safety endpoints include: Hemodynamic instability defined as hypotension (reduction in MAP less than 60 mmHg for 2 consecutive readings throughout duration of infusion or greater than 20 percent drop in systolic blood pressure for 2 consecutive readings) or bradycardia (heart rate less than 60 beats per minute for 2 consecutive readings) or incidence of respiratory depression (O2 Sat less than 88 percent,

respiratory rate less than 10, need for CPAP/BIPAP or reintubation within 24 hours of extubation).

Results: Results pending.

Conclusion: Research in progress.

Submission Category: Ambulatory Care

Poster Title: MTM Hybrid Course Improves Student Self-efficacy in Performing Medication Therapy Management Services (MTMS)

Primary Author: Mallory Moore, Presbyterian College School of Pharmacy, South Carolina; **Email:** mamoore@presby.edu

Additional Author (s):
Tara-Dawn Tootle
Tiffany Threatt
Sarah Wagner
Eileen Ward

Purpose: To determine if an integrated approach between a Medication Therapy Management elective course and an Introductory Pharmacy Practice Experience (IPPE) would improve a student's self-efficacy in providing MTM services (MTMS).

Methods: An elective course was structured so that students were initially trained through the APhA certificate program Delivering Medication Therapy Management Services. These students were then enrolled in an MTMS focused, 6-week IPPE under the supervision of a preceptor who had also completed the same certificate training program. A self-efficacy survey adapted by Dahl and Hall (University of Florida College of Pharmacy) was administered to pharmacy students in their third professional year to determine their confidence levels before and after the hybrid course. A control group of third-year pharmacy students, who participated in the same certificate program but did not have an IPPE specifically focused on MTMS, also completed the survey.

Results: Of the 26 students targeted to complete the post-survey, 21 responded (80% response). For analytical purposes, the self efficacy survey was divided into five specific categories: billing, communication, documentation, barriers, and clinical knowledge and skills. The hybrid course improved the self-efficacy of our students in the areas of communication ($p < 0.05$), and documentation ($p < 0.05$).

Conclusion: A hybrid course blending together the didactic experience with hands-on application of skills may improve a student's learning experience and skill set. Furthermore, improving a student's self-efficacy in the area of MTMS may promote the involvement and competence of future pharmacists in performing MTMS.

Submission Type: Evaluative Study

Session-Board Number: 5b-375

Poster Title: Acute kidney injury in patients treated with rasburicase for tumor lysis syndrome

Primary Author: Allison Smith, South Carolina College of Pharmacy, South Carolina; **Email:** smitha89@email.sc.edu

Additional Author (s):
LeAnn Norris
Christina Cox
Phillip Mohorn

Purpose: Tumor lysis syndrome (TLS) is an oncologic emergency that can cause multiple metabolic complications in patients undergoing chemotherapy. The occurrence of acute kidney injury (AKI) in these patients increases their risk of death and development of further complications as well as additional use of healthcare resources. The mainstays of therapy for preventing and treating this type of AKI include aggressive hydration, allopurinol, and rasburicase. Due to uncertainty of rasburicase's clinical efficacy with respect to resolution of AKI, further investigation is warranted. The purpose of this study is to assess severity of AKI after rasburicase use in patients with TLS.

Methods: Adult and pediatric patients were included in the study if they were admitted to the study site between January 1, 2010 and June 1, 2016, diagnosed with clinical or laboratory tumor lysis syndrome, and received at least one dose of rasburicase during hospitalization. Patients were excluded if they had a history of chronic kidney disease, diagnosis of sepsis, history of renal transplant, received high-dose methotrexate regimen during admission, or were pregnant. Demographic information was collected including patient age, gender, weight, height, race/ethnicity, tumor type, hospital unit, total length of stay in hospital, baseline serum creatinine, uric acid level, and baseline stage of AKI. AKI staging and severity was determined using RIFLE and P-RIFLE criteria.

Results: A total of 81 patients received rasburicase during the study period. To date, 4 patients have been evaluated. Three patients have been identified as meeting study inclusion, and one patient was excluded due to history of CKD. Two out of three patients were female and Caucasian and one out of three was male and African American. All patients presented in

clinical tumor lysis syndrome and AKI, had an average Cairo Bishop grade of 3.3, and an average age of 65 years (no pediatric patients have been evaluated at this time). The average length of hospital stay was 38 days and the average baseline SCr was 0.99 mg/dl. Malignancies represented include multiple myeloma, endometrial cancer with myelodysplasia, and B-cell lymphoma. On average, patients were admitted for 8 days before receiving rasburicase, had a pre-rasburicase SCr of 4.8 mg/dl, a uric acid level of 17.3 mg/dl, a RIFLE stage of 3 (failure), and received a 13 mg dose of rasburicase (some weight based, some standard). One patient received dialysis and saw resolution of AKI 34 days after receiving rasburicase. Two patients expired before resolution of AKI within an average rasburicase treatment duration of 11.5 days.

Conclusion: Preliminary data suggest that patients receiving rasburicase in response to TLS may not have resolution of AKI or may endure a long hospital stay to achieve resolution of AKI. As data collection is ongoing, it is difficult to draw conclusions based on a small sample of preliminary data. Additional research is needed to further evaluate the efficacy of rasburicase in resolving AKI for these patients.

Poster Title: Assessment of adherence to formulary drug restrictions after modification of criteria display

Primary Author: Meining Fu, Medical University of South Carolina, South Carolina; **Email:** fummc@musc.edu

Additional Author (s):
Christopher Wisniewski
Genevieve Hayes
James New

Purpose: Using a formulary is important for all institutions because they optimize patient care, increase safety, and decrease costs. A mechanism for formulary management is to restrict medications to certain prescribing criteria, like service, indication, or location. Despite the establishment of restriction criteria, maintaining adherence to evidence-based restrictions can be difficult. The purpose of this project was to assess if there was an improvement of adherence to formulary restriction criteria at an academic medical center after changing the presentation of formulary-restriction information. Pharmacist opinion on formulary website modification was also captured.

Methods: Modifications to formulary-restriction criteria on a formulary website improved the style and readability of the content text in July 2015. Restriction criteria were formatted with italics, bolded words, and underlined words to make the style more appealing to the reader. In order to assess improvement, adherence to formulary restrictions was collected in 2 cohorts from before (December 2014 to February 2015) and after (December 2015 to February 2016) website modification. Profiles of patients receiving formulary-restricted drugs, based on top 5% most commonly charged formulary-restricted medications during the month, were reviewed. From these medications, 20% of orders were evaluated for adherence to restriction criteria. The percentage of adherent orders from the before cohort was compared with the after cohort using descriptive statistics. A survey was sent to pharmacists to assess their opinion of the changes to formulary-restriction criteria display on the formulary website.

Results: A total of 288 and 570 samples were randomly selected and assessed in the before and after cohort, respectively. While all samples in the before cohort (n = 288/288) were able to be assessed for compliance, 38 orders in the after cohort (n = 532/570) could not be evaluated due to limitations associated with patient records. It was found that 90.28% (n = 260/288) of orders in the before cohort were compliant with restriction criteria compared with 87.03% (n = 463/532) in the after cohort, resulting in a decrease in adherence of 3.25%. This difference is approximately equivalent to 7869 orders for restricted medications not meeting appropriate criteria being approved out of an average of 242,115 total restricted medication orders that are made monthly. The drugs that increased the most in compliance were ertapenem (Invanz®), ciprofloxacin (Cipro®), and intravenous acetaminophen (Tylenol®). Medications with the largest reduction in adherence to restriction criteria were intravenous immune globulin (Privigen®), meperidine (Demerol®), and linezolid (Zyvox®).

Conclusion: The overall change in adherence to formulary restriction was not enhanced by an improved display via a formulary website, based on an observed decrease in compliance to restriction criteria when comparing time periods before and after the modification of restriction criteria display. This suggests that further enhancements to improve formulary restriction adherence are necessary beyond changes to display criteria on formulary websites. Future potential initiatives include a formulary website change, appropriateness stewardship programs, clinician education, and employee incentives for formulary restriction adherence.

Poster Title: Analyzing the Impact of Elective SCCP 757 on Students' Preparedness for Advanced Pharmacy Practice Experience (APPE)

Primary Author: Micaela Furest-Cataldo, Medical University of South Carolina College of Pharmacy, South Carolina; **Email:** furestca@musc.edu

Additional Author (s):
Taylor Peters
Stephanie Kirk
James Sterrett

Purpose: APPE rotations are designed to improve and test a pharmacy student's ability to provide pharmaceutical care, while ultimately determining if the student has achieved the competencies required to practice pharmacy. Various opportunities are available throughout the pharmacy curriculum to practice clinical skills in preparation for APPE rotations. During the spring semester of the P3 year a new course (SCCP 757) was made available to students that allowed them to interact with real patients on an inter-professional team. Our objective was to determine if completing course SCCP 757 prior to APPE rotations affected students' perception on their preparedness for APPE rotations.

Methods: An anonymous survey was sent via email to the third year class and promptly closed the evening before the initiation of APPE rotations. The survey included 11 questions; Question #1 determined participation in the course and the remaining assessed the student's confidence in various competencies. For questions #2-8, a Mann-Whitney U test was performed as the students were asked to assess their confidence using a 1-5 Likert scale. Answers to questions #9-11 were examined using the Fisher's Exact test.

Results: Survey response rate was 70%. The mean responses of the student's that participated in the SCCP 757 (group 1) tended to be higher than those of the students that did not (group2). The difference between the both groups was statistically significant for questions #2(How prepared do you feel for APPE (4th) year rotation?) and #5 (I am confident in my ability to perform a medication reconciliation for a patient), $p=0.015$ and $p=0.036$ respectively. Only one question that had a lower average response in group 1, but this difference was not significant.

Conclusion: Students that participated in this elective course seemed to feel better prepared in the competencies investigated by this survey. This course may benefit students by exposing them to direct patient care and interdisciplinary teams, ultimately better preparing students for APPE rotations.

Poster Title: Evaluating the effect of two weight-based parenteral nutrition formulations on the incidence of hyperglycemia and hypernatremia in low birth weight neonates

Primary Author: Erna Kukic, Medical University of South Carolina, South Carolina; **Email:** kukic@musc.edu

Additional Author (s):
Julie Safirstein
Toby Cox
Sarah Taylor
Sandra Garner

Purpose: At the Medical University of South Carolina (MUSC), neonates with a birth weight less than 1800 grams receive standardized parenteral nutrition (PN) formulations on their first day of life until a custom PN can be started. Initially, a single PN formulation was used; however, we noted hypernatremia requiring increased fluid rates and subsequent hyperglycemia. As a quality improvement measure, our neonatal intensive care unit (NICU) implemented a change in policy to two weight-based standard PN formulations for the first day of life PN. The purpose of this study was to evaluate the potential benefits of this policy change.

Methods: This was an observational study of the electronic medical records of low birth weight (less than 1800 grams), preterm neonates at MUSC Children's Hospital. Inclusion criteria were patients admitted to the NICU between August 2014 and May 2015 (single PN group) and May 2015 to July 2016 (weight-based PN group) who received standardized PN at less than 48 hours of life. Patients transferred from outside hospitals, born with suspected or known major congenital or chromosomal anomalies, or who did not survive to 24 hours were excluded. The single PN group received 10 percent dextrose and 4 percent amino acids initiated at 80 mL/kg/day, while the weight-based PN group received a standard formulation based on weight (greater than or equal to 1000 grams: same formulation as single PN group, or less than 1000 grams: 7.5 percent dextrose and 3 percent amino acids initiated at 100 mL/kg/day). Data collected included birth weight, gestational age, Apgar scores, appropriateness of size for gestational age, concurrent medications, serum glucoses while receiving standardized PN, and serum sodium concentrations obtained in the first 24 hours of life. Primary endpoints were

proportions of patients with hyperglycemia (glucose above 150 mg/dL) and hypernatremia (sodium concentration above 145 mmol/L). Secondary endpoints were proportions of hyperglycemia and hypernatremia in neonates less than 1000 grams. Differences between groups were analyzed by Chi-Square and t-test.

Results: During the enrollment period, 407 patients received standard PN with 170 included in the study, 92 in the single PN group and 78 in the weight-based PN group with a median birth weight of 1270 grams (range 456-1795 grams) and median gestational age of 29.7 weeks (range 23-36.7 weeks). Patient demographics were similar between the two groups. Although not statistically significant, there was a higher proportion of small for gestational age (SGA) neonates in the weight-based PN group (39 percent versus 28 percent, p equals 0.16). There was no significant difference in rates of hypernatremia between the two groups (17 percent in the single PN group versus 12 percent in the weight-based PN group, p equals 0.28). This finding was consistent in neonates less than 1000 grams (single PN: 9 of 25, 36 percent versus weight-based PN: 6 of 28, 21 percent, p equals 0.24). However, there was a significantly higher rate of hyperglycemia in the weight-based PN group (27 percent versus 11 percent, p equals 0.007) which was also seen in the subgroup analysis of neonates less than 1000 grams (weight-based PN: 16 of 28, 57 percent versus single PN: 5 of 25, 20 percent, p equals 0.006).

Conclusion: The purpose of this single-center observational study was to determine if rates of hyperglycemia and hypernatremia were decreased with weight-based PN instead of a single standard PN formulation. Surprisingly we found no difference in hypernatremia and an increased risk of hyperglycemia in the weight-based PN group. Although not significant, there were more SGA neonates in the weight-based PN group, which could have influenced the rate of hyperglycemia. Further research is necessary to determine the optimal standardized PN formulation for low birth weight neonates.

Poster Title: Evaluation of vancomycin dosing regimens and resulting trough concentrations in pediatric bone marrow transplants patients

Primary Author: Meredith Jenkins, South Carolina College of Pharmacy-Medical University of South Carolina Campus, South Carolina; **Email:** jenkims@musc.edu

Additional Author (s):
Julia Heh

Purpose: Achieving a target vancomycin trough concentration is often difficult in pediatrics due to variable pharmacokinetic profiles. There is limited data on appropriate dosing of vancomycin in pediatric bone marrow transplant patients, but proper antibiotic dosing and empiric coverage in febrile neutropenia is of vital importance in this highly immunosuppressed population. The purpose of this study was to evaluate the effectiveness of an empiric dosing regimen of vancomycin 15 mg/kg every eight hours in achieving target vancomycin trough concentrations of 10-15 mcg/ml in pediatric bone marrow transplant patients to determine if a change in the febrile neutropenia protocol was warranted.

Methods: This was a retrospective chart review that evaluated vancomycin dosing for febrile neutropenia in pediatric bone marrow transplant patients at the Medical University of South Carolina Children's Hospital from July 2014-July 2016. Both the empiric vancomycin dosing regimen with resulting trough concentration and the vancomycin dosing regimen that ultimately resulted in the target trough concentration of 10-15 mcg/ml were assessed in 25 pediatric patients that received bone marrow transplants. Subsequent dose modifications as well as trends in serum creatinine were also evaluated throughout the entire course of vancomycin.

Results: The protocol regimen of vancomycin 15 mg/kg every eight hours achieved a target vancomycin trough concentration of 10-15 mcg/ml in 12 percent of patients and resulted in a vancomycin trough concentration less than 5 mcg/ml in 65 percent of patients. One patient had a trough concentration greater than 15 mcg/ml. Eight patients that were evaluated were not included in the empiric dosing analysis due to differing regimens or not receiving vancomycin. Of the 23 patients that received vancomycin, 9 percent of patients required dosing regimens

less than 15 mg/kg every eight hours to achieve target trough concentrations and 83 percent of patients required dosing regimens greater than 15 mg/kg every eight hours. The dosing regimen that achieved a target trough concentration in the largest percentage of patients was 20 mg/kg every six hours. After achieving a target trough concentration, 48 percent of patients required subsequent dose reductions due to supratherapeutic trough concentrations.

Conclusion: The protocol dosing of vancomycin 15 mg/kg every eight hours resulted in subtherapeutic vancomycin trough concentrations in more than 82 percent of patients and more than half of the patients required a dosing regimen of at least 20 mg/kg every six hours to achieve the target vancomycin trough concentration. The outcomes of this study resulted in a change in the empiric dosing regimen of vancomycin to 15 mg/kg every six hours for febrile neutropenia in pediatric bone marrow transplant patients.

Poster Title: Evaluating the frequency of appropriate metabolic monitoring in hospital inpatients on second generation antipsychotics

Primary Author: Rachel Stelling, Presbyterian College School of Pharmacy, South Carolina; **Email:** restellin@presby.edu

Additional Author (s):
Jennifer Partelow
Ashley Abee
Brandi Sharpe
Nancy Goodbar

Purpose: In 2004 a consensus statement was published regarding metabolic monitoring for patients taking second generation antipsychotics (SGA) because of their ability to cause metabolic syndrome to include hypertension, hyperlipidemia, hyperglycemia, and obesity. These guidelines were the collaborative work of several research groups including the American Diabetes and Psychiatric Associations and suggested a schedule for appropriate monitoring. Adherence to monitoring has become relevant in clinical practice because of the increasing number of patients on SGA rather than first generation antipsychotics (FGA) due to the potential for extrapyramidal side effects (EPS) and the risk of developing cardiovascular disease from metabolic syndrome.

Methods: Following Institutional Review Board (IRB) submission and approval, a patient list from an institutional setting was generated for all medical inpatients currently on or initiating SGA therapy. Patients were randomly selected via a random number generator to compile an adequate sample size of 500 patients. Exclusion criteria included surgical admissions. Inclusion criteria included patients over 18 years old admitted to the hospital over the last 5 years on SGA therapy including clozapine (Clozaril), olanzapine (Zyprexa), risperidone (Risperdal), quetiapine (Seroquel), aripiprazole (Abilify), and ziprasidone (Geodon). Retrospective analysis over a 5 year period was conducted to gather demographics and evaluate whether appropriate monitoring was completed per guidelines during hospital stay.

Results: Adherence to metabolic monitoring was defined as completion of suggested monitoring parameters to include blood pressure, blood glucose, lipid panel, waist circumference and body mass index (BMI). Non-adherence was determined by the absence of any one parameter. In years 2010, 2011, and 2014 adherence to metabolic monitoring was 0 percent in patients on SGA prior to hospital admission and patients initiated on SGA during their hospital stay. Analysis of each parameter revealed that waist circumference was the number one parameter not measured by providers with 100 percent non-adherence. The most frequently measured parameters were blood pressure followed by blood glucose then lipid panels. Blood pressure measurements were taken in 100 percent of patients, blood glucose measurements ranged from 93 to 97 percent, and lipid panels ranged from 6 percent to 11 percent over the analyzed time period. Weights were documented for all patients allowing our research team to calculate BMI using a standard BMI calculator. Because of this we considered adherence to measuring BMI 100 percent. Data collection was prematurely ceased after analysis of only 3 years instead of 5 years since no significant difference in overall adherence rates to metabolic monitoring were observed.

Conclusion: Given the low adherence rates and negative findings, we conclude that the impact of the consensus statement was poor. This study included patients from a hospital inpatient setting which we feel was a limitation. Reasons for hospital admissions ranged from managing comorbidities to acute illnesses which likely took precedence over completing metabolic monitoring in certain cases. Further interventions are needed for improvement which should be driven by pharmacists in the form of continuing education and involvement in multi-disciplinary rounds. Also, advances in medical charting could allow for automatic prompts to remind providers of the monitoring parameters for patients on SGA.

Poster Title: Clinical Impact of Prescription Medication Quantity on Grip Strength

Primary Author: Krishnan Brown, South Carolina College of Pharmacy, South Carolina; **Email:** larkinka@email.sc.edu

Additional Author (s):
LeAnn Norris
Bryan Love

Purpose: Hand grip strength has been widely used as a practical and reliable measurement for evaluating age-related changes and alterations in biological functions. The use of specific medications, including cardiovascular agents, have been associated with reduced grip strength. Studies have also found that grip strength is inversely related to polypharmacy, the concurrent use of five or more medications. Additional research is necessary to determine whether the association between grip strength and other medication classes is generalizable.

Methods: This study examined associations between prescription medication count and grip strength among 5,197 patients, aged 18 years and older who participated in the 2011–2012 National Health and Nutrition Examination Survey (NHANES). Prescription medication use was self reported and collected by a trained interviewer. Baseline demographic information was collected and evaluated including age, gender, medications history, and prescription count. Muscle strength was assessed using the Takei digital grip strength dynamometer. Combined grip strength was calculated by totaling the best reading from each hand. Multiple linear regression models were used to examine the association between combined grip strength and the number of medications used, with and without an adjustment for gender, age, height, and arm circumference.

Results: The average age of the NHANES patients was 45.9 years. The mean height was 175.8 cm for men and 162.1 cm for women. Mean combined grip strength, measured in kilograms, was higher among men than women (89.8 kg vs. 56.4 kg; $p < 0.001$). Men and women reported an average of 1.57 and 2.06 prescriptions, respectively ($p < 0.001$). In both unadjusted and

adjusted models, there was a linear decline in combined grip strength associated with increasing number of medications (p < 0.001).

Conclusion: Increasing quantity of prescription medications is associated with reduced grip strength independent of age, gender, height, and arm circumference. Additional studies are needed to clarify if reduced grip strength is directly due to medication use or another underlying process.

Poster Title: Trends in formal diagnosis and self-acknowledgement of depression and depressive symptoms of patients with diabetes in a rural healthcare setting

Primary Author: Eileen Ward, Presbyterian College School of Pharmacy, South Carolina; **Email:** edward@presby.edu

Additional Author (s):
Zach Howard
Emily Huneycutt
Tiffaney Threatt

Purpose: Approximately 14.8 million American adults suffer from depression, and two out of three people do not seek or receive proper treatment for depression. Depression is linked to poor health behaviors such as under or overeating, physical inactivity, and lack of motivation for self-care which may negatively affect comorbid diabetes management. A diagnosis of diabetes may also negatively impact depression management. This project was designed to assess and compare trends related to depression diagnosis, self-acknowledgement, and management between privately-insured and uninsured patients with diabetes in a rural setting for the purpose of advising on screening and management behaviors in these settings.

Methods: A retrospective medical chart review of patients referred to a rural diabetes education program by local free clinics and private medical practice offices was performed. Participants with a diagnosis of diabetes or prediabetes and at least 18 years of age completed a diabetes assessment between September 2014 and December 2016. The assessment gathered information regarding whether the participant suffered from anxiety or depression and reviewed current medications; a Patient Health Questionnaire-9 (PHQ-9) was also completed to screen for depression. Referring provider notes were reviewed for a diagnosis of depression. Providers were also contacted to verify the presence or lack of a depression diagnosis. Patients were excluded if any described assessment information was missing or if the provider did not respond regarding diagnosis of depression. PHQ-9 categories consisted of those who were likely experiencing minimal or no depressive symptoms, mild, moderate, or severe depression. If a diagnosis was not specified in the available medical records, those taking selective serotonin reuptake inhibitors were considered to be treated for depression while

those on bupropion, selective norepinephrine reuptake inhibitors, tricyclic antidepressants, and trazodone had an "unknown" treatment status. Statistical and descriptive analyses were performed as appropriate to evaluate the prevalence of self-acknowledged or provider diagnosed depression, PHQ-9 scores, and presence or absence of treatment with antidepressants in the two clinic populations and describe differences in these variables between groups.

Results: Ninety-six patient charts, 58 free clinic and 38 private practice, were analyzed. No statistically significant differences existed between the groups in baseline demographics, proportion of patients self-reporting or being formally diagnosed with depression, or presence of treatment. PHQ-9 scores differed significantly between the groups at baseline with free clinic patients experiencing higher PHQ-9 scores consistent with more severe depressive symptoms. Of the free clinic patients (n equals 28) and private practice patients (n equals 18) who self-reported having depression, 61 percent of free clinic patients had a formal diagnosis of depression compared to 91.7 percent of private practice patients. Sixteen free clinic patients had symptoms of moderate or severe depression. Seven of these patients (43.7 percent) had no diagnosis of depression and seven patients (43.7 percent) were not receiving treatment for depression despite presence of moderate or severe symptoms. No private practice patients with moderate or severe depressive symptoms were undiagnosed or untreated. Six participants in the total free clinic population (approximately 10 percent) had symptoms of moderate or severe depression and lacked both a physician diagnosis of depression and treatment.

Conclusion: Compared to patients referred from primary practice offices, free clinic patients experienced higher rates of depressive symptoms but were more likely to lack formal diagnosis of depression and lack treatment for symptoms. It is possible free clinic patients are not reporting depressive symptoms to free clinic providers or providers are overlooking the diagnosis and treatment of depression due to lack of screening or resources to manage the condition. This study highlights how routine screening for depression along with timely diagnosis and treatment could benefit diabetes patients in a rural, free clinic setting. Larger studies are needed to confirm these results.

Poster Title: Identification, Prevalence, and Treatment of Painful Diabetic Neuropathy in Patients from a Free Clinic in a Rural Area in South Carolina

Primary Author: Jimmy Pruitt, Presbyterian College School of Pharmacy, South Carolina; **Email:** jlpruitt@presby.edu

Additional Author (s):
Carolina Moracho-Vilrriales
Tiffaney Threatt
Sarah Wagner
Alfonso Romero-Sandoval

Purpose: Diabetic patients in rural areas have significant disadvantages, which places this population at higher risks of developing complications and having less access to proper treatment. We studied a rural population of diabetic patients that attended a pharmacist-lead free clinic for a diabetic education program. Our objectives were: 1) Determine the prevalence of diabetic peripheral neuropathy (DPN) and painful diabetic neuropathy (p-DN) in type 2 diabetic patients. 2) Assess the proportion of patients with DPN and p-DN left undocumented upon physician referral to a pharmacist-led free clinic, and 3) Determine the appropriateness of pain medication regimen.

Methods: We performed a retrospective analysis of clinical records of patients from the Presbyterian College School of Pharmacy (PCSP) Wellness Center located in Clinton, SC. Diagnosis of DPN and/or p-DN were obtained from referral notes in the clinical records and compared with results from foot exams performed by the pharmacists in the free clinic using Weinstein-Semmes monofilament exam and clinical features. Medication regimens were obtained from these clinical records and compared using AAN treatment guidelines.

Results: Within our study population, the prevalence of DPN was 62.2%, compared to published national average of 37.2%, p-DN was 23.4% compared to published national average of 17.5%. In p-DN patients, 53.8% (n=14) had a documented diagnosis of p-DN by the referring physician, and 46.2% (n=12) were identified by the pharmacists. We uncovered that 95% (19 of 20) of the

patients treated for p-DN received sub-optimal treatment. Gabapentin was the most frequently used medication in our population with 65.4%.

Conclusion: Patients in rural South Carolina had a higher prevalence of DPN and p-DN with over 60% undocumented cases of p-DN. Greater than 95% of patients receiving pain treatment did not receive optimum therapy according to AAN guidelines. Our study also confirms the positive role of pharmacists in diabetic complication management in rural areas. Pharmacist-led diabetes education programs are in a position to reduce the percentage of uninsured diabetic patients untreated and undiagnosed with painful diabetic neuropathy in similar rural communities and demographics.

Poster Title: Induction of P-glycoprotein in Caco-2 cells and chemotherapy resistance

Primary Author: Wanai Kum, Presbyterian College School of Pharmacy, South Carolina; **Email:** skumwanai@presby.edu

Additional Author (s):
Lisa Gibbs
Catherine Blauvelt
Chris Farrell

Purpose: Multidrug resistance (MDR) is a huge barrier to cancer treatment with chemotherapy agents. Increased drug efflux due to the overexpression of the protein transporter P-glycoprotein (P-gp), encoded by ABCB1/MDR1 gene, has been shown to be a major contributor to MDR. Certain P-gp substrates, such as anticancer agents, have been shown to induce MDR in cancer cells. The purpose of this study was to evaluate if the P-gp substrates losartan and fexofenadine would induce P-gp overexpression in Caco-2 cells, a colorectal cancer cell line. In addition, assess whether these chemotherapy naïve Caco-2 cells show resistance to P-gp substrate chemotherapy agents.

Methods: Caco-2 cells were cultured in EMEM supplemented with 20 percent FBS and penicillin-streptomycin solution. Cultures were incubated at 37 degrees Celsius and 5 percent carbon dioxide in 100 millimeter dishes. The cells were grown until they were 80-90 percent confluent then subcultured following ATCC protocol. Cells were removed using trypsin-EDTA solution. New plates were inoculated with 400,000 cells. Cells were given either losartan (5, 50, 100 micromolar) or fexofenadine (25, 75 micromolar). Negative control cells were not given a drug, and positive control cells were given 10 nanomolar vinblastine. RNA was harvested once per month. Expression of ABCB1 was analyzed using the quantitative-PCR BioRad CFX96 thermocycler and normalized to eEF1 expression. A cell proliferation assay was performed according to manufacturer protocol, with the PrestoBlue Cell Proliferation Assay kit. Losartan and fexofenadine treated Caco-2 cells were seeded in a 96 well plate. Same seeding was done for the positive and negative controls. The wells were then incubated at 37 degrees Celsius for 4 days, after which a chemotherapy agent was added to each well. PrestoBlue reagent was added to the wells and then incubated for 2 hours. Absorbance was read at 595 nanometers.

Results: Real-time PCR analysis showed overexpression of P-gp in the Caco-2 cells treated with losartan and fexofenadine. Positive control cells, cells treated with losartan and cells treated with fexofenadine had an increase in the ratio of ABCB1 expression to eEF1 expression compared to the negative control. Cells treated with 100 micromolar losartan, and cells treated with 25 micromolar fexofenadine showed the most increase in the ratio of ABCB1 expression. When the chemotherapy naïve, losartan and fexofenadine treated cells were treated with a chemotherapy agent during the cell proliferation assay, the losartan and fexofenadine treated cells had higher absorbance values than the negative control cells, indicating resistance to the chemotherapy agent.

Conclusion: Chemotherapy naive Caco-2 cells increased in expression of P-gp while under continuous exposure to the P-gp substrates losartan and fexofenadine. After the increased P-gp expression was observed, the cells showed resistance to chemotherapy. Prolonged use of P-gp substrate drugs, such as losartan and fexofenadine, for the treatment of common conditions such as allergic rhinitis and hypertension could lead to increased expression of P-gp in cancer cells. Increased P-gp expression in these individuals could cause chemotherapy resistance to P-gp substrate chemotherapy. Knowledge of the potential for P-gp overexpression by common P-gp substrate drugs could lead to further personalized cancer treatment.

Session-Board Number: 5b-385

Poster Title: Induction of P-gp Expression in Colorectal Cancer Cells Following Exposure to P-gp Substrates

Primary Author: Taylor Greene, Presbyterian College School of Pharmacy, South Carolina; **Email:** tagreene@presby.edu

Additional Author (s):
Ro-Derick Middleton

Purpose: The aim of the study is to determine if colorectal cells will develop resistance to non-chemotherapy agents through induction of P-glycoprotein (P-gp) expression following chronic exposure to P-gp substrates, specifically losartan and fexofenadine.

Methods: Cell lines and culturing: The cell line used was Caco2, purchased from ATCC (Manassas, VA). Caco2 cells were cultured in EMEM with 20 percent FBS and penicillin-streptomycin solution. Cultures were incubated at 37 degrees Celsius and 5 percent CO_2 in 100mm dishes. The cells were treated with three concentrations of losartan (5, 50, and 100 micro-molar), two concentrations of fexofenadine (25 and 75 micro-molar), and 10 nano-molar vinblastine. They were grown until 80-90% confluency, then subcultured for viability analysis using American Type Culture Collection protocol. Subculture procedures were performed at approximately an 80 percent confluency observed microscopically.
RNA isolation & PCR: mRNA from the Caco-2 cells was isolated using the RNA Isolation Kit: RNasy Mini Kit (Qiagen), and concentrations measured using the NanoDrop Lite spectrophotometer. Following isolation of the mRNA, reverse transcriptase with iScript cDNA Synthesis Kit (Bio-Rad Laboratories, Hercules, CA) was used per reaction protocol to prepare samples for RT-PCR. The ABCB1 transporter expression was measured using quantitative-PCR (qPCR) BioRad CFX96 thermocycler per protocol. Expression data was normalized to the housekeeping gene EEF1A.
Accumulation: Intracellular levels of losartan and fexofenadine in the treated cells were measured using high-performance liquid chromatography (HPLC).
Resistance: Cells with increased expression of P-gp from losartan exposure were treated with higher doses of the losartan to analyze the induction of resistance. Concentrations ranged from 100-500 mM for high-dose losartan.

Results: PCR analysis demonstrated increased expression of the ABCB1 gene in comparison to the EEF1A gene for the cells treated with 100 micro-molar losartan and 25 micro-molar fexofenadine. Of the three treated samples used, two of them demonstrated increased expression of ABCB1. HPLC showed the intracellular levels to be less in the cells that had higher expression of P-gp. Intracellular levels of the drug were higher when the samples were measured with mass spectrometer. The increased activity was able to be induced by treatment with the substrates, resulting in decreased accumulation of drug in the cells. Viability testing showed that the cells previously treated with losartan were able to survive when treated with the high doses of losartan. Since the concentrations of losartan were considered toxic to the cells, this finding confirms an induced drug resistance in the cells.

Conclusion: Cells treated with losartan and fexofenadine were able to induce an overexpression on the P-gp transporter. This finding confirmed that exposure to non-chemotherapy substrates was able to cause resistance to other P-gp substrates in the cells. With this, there is reason to believe that long term use of losartan or fexofenadine may alter expression of the efflux transporter. Advances such as this could provide answers for patient care in areas that are affected by resistance to therapy. Future studies should be done to further understand the potential causes for inducible resistance.

Poster Title: Evaluation of combination treatment with a cyclin dependant kinase (CDK) 8/19 inhibitor with epidermal growth factor (EGFR) inhibitors to prevent resistance in breast cancer cells

Primary Author: Kingsavanh Philavong, South Carolina College of Pharmacy - Columbia Campus, South Carolina; **Email:** kpp@email.sc.edu

Additional Author (s):
Chuck Hennes
Gary Schools
Martina McDermott
Eugenia Broude

Purpose: Our previous data suggest that inhibition of cyclin dependent kinase 8 (CDK8) can prevent acquired resistance to lapatinib, a dual epidermal growth factor receptor/ human epidermal growth factor receptor 2 (EGFR/HER2). It is, however, unknown if this mechanism of preventing resistance is dependent on HER2 or EGFR activity, or both. The purpose of this study is to evaluate the effectiveness of Senexin B (SNXB), a CDK8/19 inhibitor in HER2 positive cancer cells to prevent resistance to epidermal growth factor receptor inhibitors.

Methods: SKBR3 cells were seeded at 125,000 cells/well and treated with pre-selected concentrations of each EGFR inhibitor monotherapy or in combination with SNXB. Controls of SKBR3 cells with medium only and SNXB monotherapy were grown and split throughout the entire experiment. Drug-containing media was replenished every 3 to 4 days and phase contrast images were used to monitor any changes and developments in cell morphology, death, and cell senescence. One duplicate flask for each treatment was stained with crystal violet and imaged to show the estimated point of maximum inhibition for each treatment (midpoint), while the other duplicate continued treatment with various end points. Once resistant cells began to show in the presence of sole EGFR inhibitor treatment, the cells were stained and a visual comparison of monotherapy and combination treated cells was conducted to determine if an EGFR and CDK8 inhibition can prevent the emergence of resistance to EGFR targeted therapy. Furthermore, these potentially resistant cells were allowed to grow to explore the mechanism of resistance. MTT assays were performed to determine the 50%

inhibitory concentration (IC50s) and a western blot was performed to qualitatively assess a difference in the amount of CDK8 and EGFR protein expression between normal and resistant SKBR3 cells.

Results: SKBR3 cells that had undergone the gefitinib monotherapy treatments at concentrations 0.25uM, 0.5uM, and 1uM exhibited minimal growth inhibition after 6 treatments. In comparison, the erlotinib monotherapy treatment group at concentrations of 3uM, 4uM, and 5uM showed promising growth inhibition with the greatest seen at 5uM. Combination treatment with gefitinib and SNXB exhibited more growth inhibition versus gefitinib monotherapy, however, there was no visual change in inhibition from midpoint to endpoint. An obvious visual rise in resistance could be seen in the combination treatment with 1uM gefitinib. Combination treatment with erlotinib and SNXB exhibited a greater amount of inhibition versus monotherapy erlotinib and combination gefitinib treatment with no visible cells in the 5uM erlotinib and SNXB combination therapy. 5uM SNXB monotherapy showed partial inhibition (50%) in monotherapy treatment. Results of the MTT assays did not show significant differences in IC50 concentrations. Western blot of non-resistant versus possibly resistant SKBR3 cells showed an increase of EGFR expression in the resistant cells by twice the amount in non-resistant. The resistant cells also showed an increase 1.5 times the non-resistant cells in phosphorylated EGFR protein expression. No difference was observed in CDK8 expression.

Conclusion: Combination therapy of SNXB and EGFR inhibitors showed promising effect in preventing resistance to EGFR monotherapy; especially at higher doses with the erlotinib combination. Calculated IC50s as well as western blotting results give quantitative data that further verifies that there is indeed a trend towards resistance that occurs in monotherapy treatment with EGFR inhibitors. These promising results demonstrate the need to further explore the use of SNXB in combination with EGFR inhibitors and possibly other chemotherapeutic drugs to prevent ongoing development of resistance in cancer cells. Ongoing research with SKBR3 and BT474 cells with SNXB are currently in progress.

Poster Title: Daptomycin in combination with ceftaroline for hematogenous osteomyelitis in an 11 month old

Primary Author: Katelyn Bull, South Carolina College of Pharmacy, South Carolina; **Email:** bullk@email.sc.edu

Additional Author (s):
Alyssa Berganini
Robert Daniels
Anna-Kathryn Burch

Purpose: A previously healthy 11 month old caucasian male with a recent history of varicella zoster presented with two weeks of fever, decreased activity, and decreased oral intake. A few days prior to admission, the patient would not ambulate on his own. On the day of admission, his abdomen was distended. Parents denied any emesis, cough, congestion, rhinorrhea, swollen joints, or cellulitis.

Baseline labs revealed a WBC 21.5, Bands 25, Polys 38, CRP 240, and a fever of 101.2˚F. Blood, urine, and CSF cultures were positive for MRSA. Vancomycin 15 mg/kg every 6 hours was initiated. The patient had a therapeutic trough drawn appropriately. On hospital day 3, the patient remained febrile, cultures were still positive, CRP was decreasing. On hospital day 4, a decision was made to change vancomycin to daptomycin 10 mg/kg IV every 24 hours + ceftaroline 15 mg/kg IV every 8 hours. A whole body MRI revealed a right proximal leg abscess, septic right hip joint, peritonitis, epidural abscess, and osteomyelitis of the right ilium, ischium, and proximal femur. A diagnosis of acute, multifocal osteomyelitis was given. The patient underwent multiple I&D throughout the next several days. Blood cultures remained positive until hospital day 9.

On hospital day 16, ceftaroline was discontinued due to the patients improving status (CRP down to 21.3 and patient afebrile for >48 hours). During the following days, CRP began to increase, so ceftaroline was restarted on day 22. On day 23, the patient was re-imaged. No new fluid collections were found and the epidural abscess had resolved.

The patient was monitored in clinic with weekly labs. On day 47, labs were within normal limits, the patient had been treated 4.5 weeks from the last afebrile day, therefore antibiotics were discontinued.

This patient presented a unique case of acute multifocal osteomyelitis that was difficult to clear. The infection resulted in septic joints, numerous deep seeded abscesses, including the peritoneal and epidural space. First line treatment for children with acute hematogenous MRSA osteomyelitis and septic arthritis is IV vancomycin while bacteremia persists. Although daptomycin is not indicated by the FDA for pediatric osteomyelitis, it is an alternate treatment option.1

Treatment failure with vancomycin is to be considered when blood cultures remain positive while a vancomycin trough is within therapeutic range (15-20 mcg/mL). In the adult literature, in the event of a vancomycin failure, daptomycin may be used in combination with a beta-lactam.1

A combination of ceftaroline plus daptomycin may speed up clearance of a staphylococcal bacteremia that has been refractory to other antibiotics due to their synergistic effects.2

A daptomycin dose of 6-10 mg/kg is recommended for pediatric patients with bacteremia.1

Ceftaroline dosing in pediatrics has not been formally established, therefore our dosing recommendations were based upon on an ongoing clinical trial evaluating ceftaroline use in children with osteomyelitis infections (NCT02335905). The dose chosen for our patient was 15 mg/kg every 8 hours infused over 120 minutes, based on safety parameters of this study.

To our knowledge, this is the first pediatric patient to be treated with this combination therapy. Our hope is that this case will demonstrate the clinical benefit of this antimicrobial combination in the pediatric population and encourage further studies to assess the success rate and safety of this combination in the treatment difficult MRSA infections in children.

Poster Title: Assessment of adherence to formulary restrictions for intravenous immunoglobulin (IVIG) in an academic medical center

Primary Author: Megan McGugan, South Carolina College of Pharmacy - Medical University of South Carolina (MUSC) Campus, South Carolina; **Email:** mcgugan@musc.edu

Additional Author (s):
Chase Brown
Christine Jiang
Melissa Kallas
Genevieve Hayes

Purpose: Intravenous immunoglobulin (IVIG) is approved by the U.S. Food and Drug Administration for the treatment of immune disorders, such as low IgG. As IVIG is a high-cost medication, it has been restricted at MUSC Health. Current formulary restrictions note that ordering must occur via an order set and reordered daily by attending physicians. The restriction also requires that the indication must be included in the diagnoses covered under the Medicare Local Coverage Determination (LCD). The goal of this medication use evaluation was to assess the compliance of prescribed orders to the MUSC formulary restriction in the inpatient setting.

Methods: Orders for IVIG for admitted patients in May, June, and August 2016 were identified via the electronic medical record, Epic. Restriction adherence was assessed for both the indication for IVIG use as well as attending physician authorization. The indication entered by the ordering provider was compared with the indications on the Medicare LCD list to determine adherence to the indication portion of the formulary restriction. Attending physician authorization was assessed via whether the attending was the ordering provider or whether the attending endorsed the use of IVIG in a progress note. The primary endpoint was the percentage of IVIG orders prescribed for indications included in the formulary restriction. The secondary endpoints included the percentage of IVIG orders placed by an attending, the percentage of IVIG orders acknowledged by the attending, and the overall restriction compliance.

Results: During the months of May, June, and August 2016, 180 orders of IVIG were administered to 121 inpatients. Overall, 63.9 percent of orders (115 orders) were placed for an indication included on the Medicare LCD list. The most common unapproved indications were encephalopathy, seizures, and hyperbilirubinemia. The percentage of orders placed by an attending was 8.3 percent (15 orders). The attending physician acknowledged the use of IVIG in the progress note in the majority of cases.

Conclusion: There is significant room for improvement in prescribing intravenous immunoglobulin (IVIG) for an appropriate indication based on formulary restrictions at MUSC Health. Following an assessment of allowed indications at other academic medical centers, proposed changes will be vetted through the Pharmacy and Therapeutics committee and implemented in the coming months.

Poster Title: Community education of personalized breast cancer therapy utilizing students of healthcare professions

Primary Author: Madison Caudle, Presbyterian College School of Pharmacy, South Carolina; **Email:** mncaudle@presby.edu

Additional Author (s):
Melanie Routhieaux
Morgan Enlow
Christopher Farrell

Purpose: Health literacy is a growing problem that can further lead to altered decision making, an amplified variety of health conditions, and decreased survival rates. This study demonstrates that by providing brief, educational seminars to medically under-served members of local communities, we could improve patients' basic knowledge of breast cancer and explain specific treatment options that are available. Through this expanded knowledge, it is expected that patients will take a more active role in their own healthcare.

Methods: The study began by developing a PowerPoint; based on a fifth grade reading level so all levels of education could be involved and understand how to respond. Topics such as breast cancer statistics, incidence rates, screening, risk factors, signs and symptoms, genetic testing and markers, and treatment were combined in order to give a diversity of subjects patients would benefit from in regards to breast cancer. Once created, pharmacy students reached out to local under-served communities to raise awareness about breast cancer and the many options patients have. Patients were given a pre-presentation survey in order to assess their basic knowledge of breast cancer. The survey consisted of a one (strongly disagree) to five (strongly agree) key to measure the patients understanding of various topics related to breast cancer. After the pre-presentation survey was completed, an educational breast cancer PowerPoint was presented. Questions were then asked and a post-survey (with the same questions as the pre-survey) was given in order to determine whether the presentation met its primary goal of elevating patient's awareness of breast cancer.

Results: Whether breast cancer naive or a survivor, the majority of the patients present reported expanded knowledge of breast cancer and felt that they were more confident in taking initiative in their healthcare. With an alpha level set at 0.05, all of the questions showed statistical significance. Three key elements that showed the greatest improvement of gained knowledge involved the causes of breast cancer (pre-score 2.9- post-score 4.6 (standard deviation 1.69)), signs and symptoms of breast cancer (pre-score 3.5-post-score 4.5 (standard deviation 0.96)), and treatment options available to the public (pre-score 3.3-post-score 4.6 (standard deviation 1.31)). This suggests that at baseline, the patients were comparatively less aware and educated on breast cancer then after the presentation, when the post-survey was given. By presenting the material with a pre- and post-presentation survey, this enables the amount of knowledge gained by participants to be measured, and helps shape future presentations to guarantee maximum awareness to the patients attending.

Conclusion: By this study, it can be concluded that pharmacists play a vital role in increasing health literacy and perhaps a subsequent improvement in survival rates by promoting breast cancer education and community outreach. By utilizing pharmacy students as presenters, this enables patients to have their medication questions answered, but also provides a platform for furthering pharmacy student's education and skills as they develop into healthcare providers. The students also serve as a reminder that pharmacists are the most accessible healthcare provider, and a valuable resource for medical information and referrals.

Submission Type: Evaluative Study

Session-Board Number: 5b-390

Poster Title: Evaluation of contracted sexually transmitted infections by state sex education mandate status

Primary Author: Marilyn Herrera-Sanchez, South University School of Pharmacy, South Carolina; **Email:** mherrera333@gmail.com

Additional Author (s):
Courtney McBroom
Kenric Ware

Purpose: The purpose of this study was to determine if a difference existed between the mandated and non-mandated sex education states as it relates to the associated number of cases of chlamydia, gonorrhea, and syphilis.

Methods: This was a retrospective study evaluating data from the 2015 State Sex and Human Immunodeficiency Virus (HIV) Education Policy presented by the Henry J. Kaiser Family Foundation and the 2013 Rates of Reportable Sexually Transmitted Infections (STIs) among Young People 15 – 24 Years of Age furnished by the Centers for Disease Control and Prevention (CDC). With respect to the 2015 State Sex and HIV Education Policy, the section of interest to the investigation was the "Mandates Sex Education" category which yielded "Yes" or "No" designations. Each listing per state, and the District of Columbia (DC), was included in the analyses. As it pertains to data from the 2013 Rates of Reportable STIs among Young People 15 – 24 Years of Age, estimates pertinent to the investigation were the number of cases of chlamydia, gonorrhea, and syphilis reported. These findings, per state and the DC, were included in the analyses. The Mann - Whitney U test was utilized to detect potential differences observed between the mandated and non-mandated sex education states, corresponding to the number of cases of chlamydia, gonorrhea, and syphilis. With regards to the statistical testing performed, P less than 0.05 was deemed to be statistically significant.

Results: States that mandated sex education (Group A) and those that lacked this mandate (Group B) were twenty four states, including the DC, and twenty six states, respectively. The median number of cases of chlamydia for Group A and Group B were 7,765 and 16,013, respectively. No statistical difference was observed between these two groups as it pertains to

the number of cases of chlamydia reported (95 percent CI, -12,555 to 869 percent, P equals 0.09). The median number of cases of gonorrhea for Group A and Group B were 1,309 and 2,857, respectively. No statistical difference was observed between these two groups as it relates to the number of cases of gonorrhea reported (95 percent CI, -2,580 to 298 percent, P equals 0.19). The median number of cases of syphilis for Group A and Group B were 30 and 59, respectively. No statistical difference was observed between these two groups with respect to the number of cases of syphilis reported (95 percent CI, -52 to 11 percent, P equals 0.22).

Conclusion: Acquisition of STIs, namely chlamydia, gonorrhea, and syphilis, was not shown to be statistically different among states with a sex education mandate versus those without this decree. The difference in the number of chlamydia cases reported between the two study groups was found to be approaching statistical significance. The utility of these findings should be viewed in the larger context of expected variance in the delivery of sex education offered among states that possess the mandate. Furthermore, it's important to account for the undisclosed sex education offerings provided by states that lack an official directive.

Submission Category: Small and Rural Pharmacy Practice

Submission Type: Evaluative Study

Poster Title: Treatment patterns of patients 80 years of age and older with diabetes in a rural primary care setting

Primary Author: Emily Huneycutt, Presbyterian College School of Pharmacy, South Carolina; **Email:** edhuneycu@presby.edu

Additional Author (s):
Chase Board
Jennifer Clements

Purpose: There is limited data on the adequate control of diabetes in patients older than 80 years of age. The aim was to evaluate the treatment patterns of patients older than 80 with diabetes, in a rural health, family medicine setting to determine if the American Diabetes Association (ADA) and American Geriatrics Society (AGS) guideline goals are being met.

Methods: The Greenville Health System Institutional Review Board approved this retrospective chart review conducted in a rural health, family medicine clinic. Charts were screened and included if the following inclusion criteria were met: a diagnosis of diabetes (type 1 or 2), age 80 years or older, and prescribed at least one blood glucose lowering agent. Data was collected from July 1, 2015 to June 30, 2016, using computerized patient records. This data includes: age, smoking status, current diabetes medications, lipid lowering medications, blood pressure medications, A1c values, blood pressure measurements, low density lipoprotein concentration, macrovascular and microvascular complications. The primary outcome was percentage of patients with controlled or uncontrolled diabetes in a rural health, family medicine clinic. Fisher's exact test was used for the statistical analysis by an independent statistician.

Results: One-hundred seventeen patient charts were analyzed. Of all patients analyzed, 49.1 percent were on metformin therapy, 31.9 percent were on basal insulin therapy, 47.1 percent were on an ACE inhibitor, 96 percent were on statin therapy, as these medications are recommended by the American Diabetes Association and American Geriatrics Society to adequately treat diabetes mellitus and other interrelated chronic conditions. Of the patients analyzed, 84.8 percent of patients (73.7 percent with A1c less than 7.5 percent and 11.1 percent with A1c between 7.5 to 8 percent) met A1c goals of less than 8 percent per AGS

guidelines. Of those not taking metformin, only 82 percent were at A1c goal of less than 8 percent. There was a statistically significance association between meeting A1c goal and number of antidiabetic medications for the management of diabetes (p equals 0.031). For other endpoints, statistical significance was found between number of medications and attained blood pressure goals, per national hypertension guidelines (p equals 0.038).

Conclusion: In a rural health, family medicine setting, patients were more likely to meet A1c goal if currently prescribed metformin, compared to using other antidiabetic therapies. In addition, patients with more antihypertensive medications were less likely to have controlled blood pressure. This study compares the framework of the American Diabetes Association and the American Geriatric Society guidelines, but more explicit studies need to be done to support these results.

Submission Category: Cardiology/ Anticoagulation

Submission Type: Evaluative Study

Session-Board Number: 5b-392

Poster Title: Low molecular weight heparin dosing and monitoring in venous thromboembolism treatment in obese patients

Primary Author: Sarah Fisher, South Carolina College of Pharmacy - Medical University of South Carolina, South Carolina; **Email:** fishersa@musc.edu

Additional Author (s):
Emmeline Tran
Ashley Duckett
Nicole Bohm

Purpose: Limited information is available regarding the dosing and clinical outcomes of low molecular weight heparin (LMWH) therapy for venous thromboembolism (VTE) in patients weighing over 150 kg. The purpose of this case series is to describe the clinical outcomes of such treatment and the observed monitoring practices using LMWH anti-Xa levels.

Methods: A retrospective chart review was performed on adult patients admitted from November 2, 2012 to July 31, 2015 who received at least one regularly scheduled dose of enoxaparin for VTE treatment. Patients with a body mass index greater than 40 kg/meter squared and weight greater than 150 kg were included. Patients were excluded if creatinine clearance could not be calculated using the Cockcroft-Gault equation due to missing values, the patient had a diagnosis of atrial fibrillation, the patient was admitted to an oncology service, or the dose was prescribed as a one-time order. Data elements to characterize the enoxaparin regimen, creatinine clearance, bleeding, and recurrent VTE events were collected for each patient. Major bleeding was defined as bleeding leading to death, requiring greater than 2 units of packed red blood cells, occurring at a critical site, or a decrease in hemoglobin by at least 2 g/dL. Descriptive statistics were applied.

Results: Thirteen patients had a BMI greater than 40 kg/meter squared and weighed greater than 150 kg (range 152-258 kg). Four patients weighed greater than 200 kg. All patients had a creatinine clearance greater than 50 mL/min calculated with the Cockcroft-Gault equation using ideal body weight. No major bleeding events or recurrent VTEs were noted during enoxaparin treatment. Enoxaparin dosing ranged from 0.7 to 1 mg/kg twice daily for a median of 5.5 doses

(range 1-17). The duration of enoxaparin treatment ranged from 1 to 10 days (median 3 days). Eight patients could have received a dose closer to 1 mg/kg without added inconvenience or exceeding 1 mg/kg of total body weight. Anti-Xa levels were checked in 7 patients, typically after 2 to 3 doses. Five levels were between 0.5 to 1.2 IU/mL (doses 0.7-1 mg/kg), 1 was subtherapeutic at 0.38 IU/mL (dose 0.8 mg/kg), and 1 supratherapeutic at 1.22 IU/mL (dose 0.7 mg/kg). Six dose adjustments in 4 patients were made in response to LMWH anti-Xa level monitoring. A transition to warfarin occurred in 10 patients and to rivaroxaban in 3 patients.

Conclusion: The role of LMWH anti-Xa monitoring to guide dose adjustments has not yet been clearly elucidated. While additional data regarding clinical outcomes is warranted to confirm these findings, it appears that dosing at or close to 1 mg/kg of total body weight is reasonable.

Session-Board Number: 5b-393

Poster Title: Sleep habits and quality among pharmacy faculty members

Primary Author: Kathryn Masincupp, Presbyterian College School of Pharmacy, South Carolina;
Email: kmmasincu@presby.edu

Additional Author (s):
Jennifer Clements

Purpose: A recent study evaluated career satisfaction, lifestyle, and stress level among pharmacy faculty members, but did not collect data or assess sleep habits and sleep quality among this population. There is a lack of published evidence regarding sleep habits and quality among pharmacy faculty members. This study was designed to determine an association between sleep habits with sleep quality among pharmacy faculty members from current schools or colleges of pharmacy in the United States.

Methods: A survey was administered to pharmacy faculty members who were current members of the American Association of College of Pharmacy. Participation in the study was voluntary. The survey contained 20 questions regarding demographics, including academia status, and the Pittsburgh Sleep Quality Index (PSQI). A link to the survey was sent on August 1, 2016 with a remainder email on August 16, 2016; the survey closed on August 31, 2016. After data collection, Wilcoxon sum rank test and Kruskal Wallis test were used, respectively, for two groups or more for global scores among patients, Chi-square analyzed proportional differences of good verses poor sleep by characteristics, and a multivariate logistic regression model calculated factors associated with poor sleepers.

Results: Of the 7043 pharmacist faculty members invited to participate, 1213 (17.82%) completed the survey. The mean component scores for the PSQI were: sleep quality 1.01, sleep latency 0.89, sleep duration 1.08, sleep efficiency 0.58, sleep disturbance 1.11, use of sleep medications 0.34, and daytime dysfunction 1.07. Of these results, a global score, a combined measurement of all components, was determined to be 6.08, indicating that 66.7% of faculty members were categorized as poor sleepers. There was a significant different in the global score between married and unmarried group (p < 0.001). There was an association between job title and global scores, (p < 0.001). The proportion of poor sleepers in unmarried group is

significantly higher than in married group (76.7% vs. 63.5%, p < 0.001). Full-time professors were noted to have a 50% reduction in being a poor sleeper as the proportions of poor sleepers are significantly difference among the respondents with different job titles (p = 0.009).

Conclusion: This survey was concluded among pharmacy faculty members in the United States, indicating a majority of this population can be categorized as poor sleepers, particularly among those who are unmarried. In addition, job title of full-time professor may be associated with a reduction in the classification of poor sleeper. Additional studies should be conducted to assess sleep habits and quality during an academic year. Strategies to improve sleep habits and quality among pharmacy faculty members should be considered.

Poster Title: Evaluating the financial burden of pre-residency preparation and assessing student financial preparedness

Primary Author: Nathaniel Russell, South Carolina College of Pharmacy, South Carolina; **Email:** russelnh@email.sc.edu

Additional Author (s):
Joshua Caballero
Sandra Garner
Nicole Davis
P. Brandon Bookstaver

Purpose: Student pharmacists embark on a time intense and rigorous process should they choose to pursue residency training. This process is frequently costly and students are often unaware of the full financial commitment. The purpose of this study is to assess applicant expenses who applied for and interviewed during the 2016 residency cycle and evaluate their financial preparedness.

Methods: Data were collected by an electronic survey (Survey Monkey) sent to 2016 residency applicants from six United States colleges of pharmacy representing various regions of the country. The survey requested information related to how much the student spent traveling to conferences, the application process itself, traveling to interviews, and how much the student spent if they participated in phase 2 or the scramble phase. Information was also collected on the number of programs applied to, both in and out of state, as well as the number of interview invitations received. The primary outcome was to determine the median amount spent by the students who responded to the survey, and identify any trends that may prove useful to future applicants. A secondary endpoint was to evaluate financial preparedness for residency expenses.

Results: The survey was completed by 159 applicants who applied to residency programs in 2016. Overall, the students applied to a median of 8 programs (IQR 5-10) and received a median of 4 interviews (IQR 2-6.5). The median amount spent for the entire process was 1,840 dollars (IQR 1,090 to 2,955 dollars), applicants participating in the phase 2 match reported

median expenditures directly related to phase 2 of 280 dollars (IQR 180 to 360 dollars). Median pre-application costs such as conferences, professional wear and printing totaled 1,000 dollars (IQR 600 to 1,500 dollars). PhORCAS expenses were 410 dollars (IQR 290 to 530 dollars), and the median spent to attend on-site interviews was 440 dollars (IQR 20 to 1,140 dollars). Median expenditures for residency bound students who attended mid-year were 2,260 dollars (IQR 1,660 to 3,365 dollars) compared to 910 dollars (IQR 621 to 1,493 dollars) for those who did not attend. Approximately 72 percent of respondents reported they either did not prepare a budget, or did not budget enough for the residency application process. Fifty respondents (31 percent) reported taking out loans to help cover the cost of the residency application process.

Conclusion: The results of the survey reveal residency candidates will likely spend approximately 1,800 dollars during the match process, and should anticipate up to 3,000 dollars. Mentors and students can utilize these data for early recognition of the importance of financial planning for the residency process.

Submission Type: Evaluative Study

Session-Board Number: 5b-395

Poster Title: Predictors of antiretroviral errors among patients in the intensive care unit

Primary Author: Shelby Merchant, South Carolina College of Pharmacy, South Carolina; **Email:** merchasl@email.sc.edu

Additional Author (s):
Taylor Foore
Tanvi Mehta
Emily Moose
Brandon Bookstaver

Purpose: South Carolina consistently ranks among the top ten nationally for newly diagnosed HIV/AIDS cases. The complexity of antiretroviral therapy (ART) puts this population at a greater risk for medication errors, which can be compounded when they are hospitalized. The complexity of ART places HIV-infected patients at a high risk for medication errors, which may be increased in the intensive care unit (ICU). The primary objective of this study is to quantify antiretroviral (ARV) medication error rates in HIV -infected patients admitted to the intensive care unit and to identify risk factor associated with these errors.

Methods: This study is an Institutional Review Board approved, single center, observational, retrospective cohort study. Eligible patients were adult HIV-infected patients admitted to the ICU for 24 hours or more between January 1, 2009 and December 31, 2014 at Palmetto Health Richland Memorial Hospital. Electronic medical records were reviewed for host and medication related data. Antiretroviral-related errors were identified and classified as follows: incomplete regimen, incorrect dosage, incorrect ARV ordered, drug-drug interactions, and dose omission. Appropriateness of crushable administration was also calculated. Descriptive statistics were used to calculate the ARV error rate and duration of errors. Patients were grouped by presence or absence of medication error for comparison using Student t-test or Chi-square as appropriate (p < 0.05).

Results: Of the 2828 patients reviewed, 225 met inclusion criteria. Patients were 50.3 years old, predominantly male (67%) and spent an average of 7.3 days in the ICU. Most patients' primary diagnosis was non-HIV related. Fifty patients (22%) did not continue ARVs during their ICU stay.

Approximately 66% of patients experienced an ARV medication error. About 52% of these patients experienced more than one medication error. The most common error was dose omission (64%), followed by incomplete regimen (34%) and dosing errors (31%). Approximately 41% of the ICU stay resulted in a dose omission. Mean creatinine clearance was significantly lower for patients who experienced a medication error (60.39mL/min vs 76.81mL/min,p=0.0062), shown in the 75% of dosing errors due to renal dysfunction.

Conclusion: A significant number of HIV-infected patients in the intensive care unit experienced an ART error. Pharmacists have the ability to make a significant impact by assessing ART for appropriate drug selection, dosing, and administration.

Poster Title: Quantitation of cytokines in human cervical mucus using proximity ligation assay

Primary Author: Jamie Hansen, Presbyterian College School of Pharmacy, South Carolina;
Email: jhansen@presby.edu

Additional Author (s):
Rebecca Foster

Purpose: Persistent human papillomavirus (HPV) infection is the primary risk factor for cervical cancer development. In order to understand clearance versus persistence of HPV infection, it is necessary to understand the immune response to the infection. Cytokines IL-12 and IL-6 contribute to the proinflammatory process responsible for mounting an effective immune response. Cytokine profile analysis offers potential as an early diagnostic tool and biomarker for personalized treatment of persistent HPV infections and directed drug therapy in the treatment of advanced disease. This project focuses on using proximity ligation assay to quantify IL-6 and IL-12 in human cervical mucus samples.

Methods: The proximity ligation assay (PLA) was completed using the Taqman Protein Assay Open Kit from Applied Biosystems. Assay probes were prepared using biotinylated affinity-purified polyclonal antibodies against human IL-6 and IL-12 purchased from R and D Systems. Each antibody was separated into two aliquots and the 3' and 5' oligonucleotides provided in the Taqman Protein Assay Open Kit were added to each aliquot separately. A standard curve was prepared for each antibody using a recombinant protein corresponding to either IL-6 or IL-12 and the PLA was performed using the protocol from Applied Biosystems. The data was analyzed on the BIORAD CFX 96 Real-time PCR system. The assay was validated using cervical mucus samples obtained from Women's Care Clinic at the University of South Carolina. Clinical data and laboratory data regarding presence and type of HPV present in the sample were also available for each cervical mucus sample. The quantity of the cytokines in the cervical mucus samples was determined by comparing the Cq values determined by the PLA to the standard curves. For the purpose of validating the PLA, these relative cytokine quantities could then be compared to cytokine quantitation data determined previously using an ELISA technique.

Results: The Taqman Protein Assay Open Kit from Applied Biosystems was used to effectively design assays for both IL-6 and IL-12. Standard curves were generated for both IL-6 and IL-12 with the minimum detection limit of both cytokines being approximately 30 picograms per microliter. A limited number of cervical mucus samples (20) were used to effectively validate the use of the PLA for the quantitation of both IL-6 and IL-12 in clinical cervical samples.

Conclusion: The PLA proved to be an effective tool in the quantitation of IL-6 and IL-12 in clinical cervical samples. Further analysis on a larger sample set is warranted and currently being pursued in order to compare the quantitation results with known immune status regarding HPV clearance. We are hopeful that the PLA will prove to be a valid technique not only in biomarker discovery but in the future in its practical application as a clinical diagnostic tool which will help direct drug therapy.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Descriptive Report

Session-Board Number: 5b-397

Poster Title: A Nicotine Replacement Therapy Medication Use Evaluation (MUE) in an Inpatient Psychiatric Hospital

Primary Author: Joshua Sanders, South University School of Pharmacy, South Carolina; **Email:** jrsander@stu.southuniversity.edu

Additional Author (s):
Tracy Dinh
Erika Tillery
Jessica Gates
Ahmad Ismail

Purpose: Cigarette smoking is a major public health issue and risk factor for many leading causes of death including heart disease, stroke, and lung cancer. Individuals with mental illness may utilize smoking to self-medicate in order to relieve psychiatric symptoms. Smoking cessation is the key to decrease the number of diseases and deaths related to smoking. Nicotine replacement therapy (NRT) is available to help individuals who are attempting to quit. The purpose of this study is to assess the appropriate use of NRT in patients with a history of tobacco use disorder in an inpatient psychiatric facility

Methods: A medication use evaluation (MUE) form was created to determine the appropriate use of nicotine replacement therapy in adult patients with psychiatric disorders. Forms were designed to determine justification of use, appropriate dosing, and adequate length of therapy. Chart reviews were conducted from October – December 2015 with goals corresponding to The Joint Commission (JTC) standards. Average compliance was calculated and results presented at the Medication Management Committee in January 2016.

Results: Justification for use, dosing, and length of treatment were recorded and analyzed for the Division of Inpatient Services. The compliance rate for justification of use was 78%, appropriate dosing was 33%, and adequate length of treatment was 25% with 0% documenting continued-NRT use beyond recommended therapy.

Conclusion: The NRT MUE of patients with a history of smoking cessation in an inpatient psychiatric hospital identified key areas of improvement. While compliance rates for justification of use could improve, compliance rates for dosing and length of therapy were dismal. Future educational interventions should target common prescribing patterns, identify best practices associated with NRT prescribing, and include pharmacists educating patients and prescribers. Evidence has shown that behavioral support and pharmacist counseling alongside NRT has a positive impact on patients' ability to quit, but it is unknown how to maintain and improve smoking cessation post discharge in inpatient psychiatric settings.

Submission Type: Descriptive Report

Session-Board Number: 5b-398

Poster Title: Feasibility of implementing NCCN clinical practice guidelines in a pharmacy based tobacco treatment program

Primary Author: Lindsay Deloney, South Carolina College of Pharmacy (Medical University of South Carolina Campus), South Carolina; **Email:** pruittl@musc.edu

Additional Author (s):
K. Micheal Cummings
Georges El Nahas
Graham Warren
Katherine Hoover

Purpose: The Clinical Practice Guidelines in Oncology for Smoking Cessation, developed by the National Comprehensive Cancer Network (NCCN) in 2015, state that smoking cessation should be an integral part of oncology treatment. The guidelines require all cancer patients to be screened for tobacco, advised to quit and provided evidence-based assistance and follow-up to promote abstinence from tobacco during and after cancer treatment. This report describes the implementation of an automated system to identify and refer current cigarette smokers to a pharmacy led tobacco treatment program in a NCI designated cancer center designed to be consistent with the NCCN Clinical Practice Guidelines.

Methods: Data was collected from 15,868 patient visit records for outpatients seen at the Hollings Cancer Center from November 1, 2015 to July 31, 2016. During this 9-month period, 1,022 current smoking oncology patients were eligible to be enrolled into our tobacco treatment program. An automated system attempted to reach eligible patients by phone within a week after their last oncology clinic visit to invite them to schedule a future appointment with a clinical pharmacist for behavioral counseling and pharmacotherapy consistent with the NCCN guidelines. Pharmacists were authorized to initiate, modify, discontinue and determine duration and dose for smoking cessation medications for enrolled patients under a collaborative drug therapy management protocol. With some exceptions (e.g., distance of the patient's residence from the cancer center), clinical pharmacists delivered 4 or more behavioral counseling sessions consistent with NCCN guidelines. The goal of the tobacco treatment program is for all patients to have both pharmacotherapy and behavioral counseling. All

patients, regardless of whether they received care from the pharmacist or not, were called back at one, three and six months to assess their tobacco use and offer follow-up assistance if needed.

Results: Of the 1,022 eligible smokers, 499 were reached by phone (49 percent). Of those patients reached by phone, 226 accepted an appointment with a pharmacist (45 percent). Patients not reached by phone or who were not ready for assistance were sent information about the tobacco treatment program. Data available on patients reached at the one-month revealed that 20% were not smoking with quit rates approximately 2 times higher in those who had seen a pharmacist.

Conclusion: It is feasible to implement a pharmacy based tobacco treatment program using the NCCN Clinical Practice Guidelines for Smoking Cessation in a large cancer center, although further refinement of these methods are needed to engage more patients in the process of quitting.

Poster Title: Impact of an annual medication use evaluation on formulary adherence of antiretroviral agents used to treat human immunodeficiency virus (HIV)

Primary Author: Elissa Baker, South Carolina College of Pharmacy - MUSC campus, South Carolina; **Email:** bakee@musc.edu

Additional Author (s):
Christopher Wisniewski

Purpose: Some drug classes present formulary management challenges based on the large number of therapeutic options and lack of active-control studies. One such class is antiretrovirals used to treat human immunodeficiency virus (HIV). In order to better manage antiretroviral medications available on the formulary of an academic medical center, an annual medication use evaluation of the class was initiated. The primary objective of this study was to analyze if an annual MUE of antiretroviral medications used to treat HIV improved overall formulary adherence with these medications.

Methods: In May 2012, an annual medication use evaluation of antiretrovirals used to treat HIV was initiated at an academic medical center. Every spring since, the Infectious Diseases specialty pharmacy resident works with a drug information specialist to review antiretroviral utilization, HIV guidelines, and drug costs to recommend formulary changes to the Anti-infective subcommittee. A retrospective review was conducted to examine baseline antiretroviral medication use from August 2008 to April 2012 prior to the implementation of this project. All inpatient orders for both formulary and nonformulary antiretroviral medications were collected from the institution's order entry systems; formulary adherence was determined based on the formulary status of the medication at the time of the order. "Annualized" evaluation periods in the before time frame were broken into three time periods of varying length based on availability of previously collected data. The primary outcome of this study was overall formulary adherence, calculated by divided nonformulary antiretroviral use by total antiretroviral use, before and after the implementation of the annual MUE. Secondary outcomes were annualized adherence of antiretroviral medications and total and annualized formulary changes, cost savings, and utilization of these medications. Institutional Review Board (IRB) approval was not necessary as this was a quality improvement project.

Results: Total formulary adherence was 10.57% (n = 1977/18697.5) in the evaluation period before the implementation of the annual MUE and 3.53% (n = 949/26913) time period after the implementation. Before examining an annual MUE of antiretroviral medications for the treatment of HIV non-formulary use was 9.88% between May 2011 to April 2012. After initating an annual MUE to evaluate antiretroviral medications used to treat HIV non-formulary use decreased to 3.14% in 2012, 2.58% in 2013, 4.07% in 2014 and 4.12% in 2015. All inpatient HIV medications were reviewed based on if at the time the patient received the medication it was formulary or non-formulary. In total, 30 formulary changes were made between August 2008 and February 2016; 17 and 13 formulary changes were performed before and after the annual MUE implementation, respectively.

Conclusion: Based on results of the study, an annual MUE increased formulary adherence of antiretroviral medications used to treat HIV. Antiretroviral medication formulary changes have decreased in recent years at this academic center since the initiation of this annual MUE. The MUE will continue to be an annual project that the Infectious Diseases specialty pharmacy resident will complete on their medication use policy rotation.

Session-Board Number: 5b-400

Poster Title: Medicinal marijuana legislation: Evidence based or not?

Primary Author: Aaron Adams, South University School of Pharmacy, South Carolina; **Email:** adadams1@stu.southuniversity.edu

Additional Author (s):
Shaqueda Jenkins-Parnell
Erin Dalton
Andrea McKeever

Purpose: The legalization of marijuana has been a highly debated topic both on a federal and state level. Even as more states move to approve legislation to legalize the use of marijuana for medical purposes, it continues to be classified as a class 1 federally controlled substance, and is therefore, considered to be illegal with no federally recognized medicinal purpose. The purpose of this project is to determine if the rationale or justification utilized by state legislatures, which have legalized marijuana use for medicinal purposes, was based on scientific evidence.

Methods: Twenty-five states, the District of Columbia, and the U.S territories of Guam and Puerto Rico were identified as having legalized marijuana use for medicinal purposes. Students in their third and final year of pharmacy school paired with a pharmacist faculty member, reviewed the state laws associated with the aforementioned legislatures for verbiage indicating that scientific evidence was a contributing factor for the pursuit of the legalization of medical marijuana use, as well as any articles or research named specifically in the legislation as evidence toward this goal.

Results: Fourteen of the twenty-eight legislatures evaluated specifically list scientific evidence as a reason for seeking legalization of medicinal marijuana. Of those fourteen, seven states list medical journals or scientific research as evidence for legalizing medical marijuana. Of note, all twenty- eight legislatures outline medical conditions, labeled as "debilitating medical conditions," within the laws for which medicinal marijuana may legally be used. Additionally, all twenty-eight legislatures outline provisions for a committee which would guide change to their individual medicinal marijuana programs as needed (e.g., changes or additions to approved medical condition lists, or legal possession limits), and most of these states required committee

membership to include medical professionals. Those states not requiring healthcare professionals on the committees require their committee membership to seek outside counsel with appropriate healthcare professionals before acting.

Conclusion: Fifty percent of the enacted medical marijuana laws in the United States are based on scientific evidence as cited in their respective legislative action, and twenty-five percent of these laws are for specific patient populations and/or indications. Therefore, an opportunity exists to educate legislatures on evaluating medical literature and potentially grading the evidence to help guide decisions related to controversial agents such as marijuana in possible legalization,monitoring of effects, as well as further research on those agents. A scientific methodical approach would help ensure appropriate use and target populations.

Poster Title: Incidence of Hypophosphatemia in Very Low Birth Weight Infants Receiving Parenteral Nutrition

Primary Author: Sona Tailor, South Carolina College of Pharmacy, South Carolina; **Email:** tailorsr@email.sc.edu

Additional Author (s):
Justin Gardo
Caroline Macpherson

Purpose: Very low birth weight (VLBW) infants are at a higher risk for nutritional and electrolyte deficits compared to infants born at normal birth weights. Administering optimal concentrations of calcium and phosphate presents a challenge due to solubility limitations in parenteral nutrition (PN). Despite an emphasis on calcium, both elements have a significant impact on bone development and mineralization. The recommended calcium to phosphate ratio during the first week of life is 1.3 to 1.7. The purpose of this study is to report the incidence of hypophosphatemia within days 4-14 of life in VLBW infants receiving PN and other nutrition sources.

Methods: This retrospective, observational study reports the incidence of hypophosphatemia, defined as a serum phosphate level less than 4.0 mg/dL, within days four to fourteen of life in VLBW infants receiving PN. Initial inclusion criteria were VLBW infants weighing less than 1500 grams who were admitted into the NICU between August 1, 2015 and March 31, 2016. Additionally, subjects must have received parenteral nutrition and had at least one renal laboratory panel between days four and fourteen of life. Eligible patients were also evaluated for impact of birth weight classification on development of hypophosphatemia. Time to resolution was measured by number of days from diagnosis of hypophosphatemia until a serum phosphate level of ≥ 4.0 mg/dL was achieved. The median time to resolution was determined by Kaplan-Meier analysis. A Cox regression analysis assessed time to resolution based on calcium to phosphate ratio as a covariant.. For each resolution time, the total phosphate and calcium intake (mmol/kg/day and mEq/kg/day, respectively) , as well as the calcium to to phosphate ratio, were measured the day prior to resolution. These values were then averaged for each respective resolution time in order to determine what amount of phosphate intake

and what calcium to phosphate ratio resulted in resolution. Also, the impact of hypophosphatemia on clinical outcomes, such as ventilator and/or CPAP use, was evaluated.

Results: Of the 136 patients admitted during the study period, 122 met inclusion criteria. Eighty-seven percent of patients (n=106) were hypophosphatemic between days four and fourteen of life (C.I. 0.80-0.92). Of the four birth weight categories, subjects with a birth weight less than 750 grams had the highest incidence of hypophosphatemia (37.7%) compared to subjects with a birth weight of 750-999 grams (27.4%), 1000-1249 grams (15.1%), and 1250-1500 grams (19.8%). The median time to resolution in subjects who were hypophosphatemic was 4 days from day of diagnosis (95% CI 0.35-0.54). The mean calcium intake the day prior to resolution for subjects who resolved after the median time to resolution of four days was 1.15 mEq/kg/day and the mean phosphate intake was 1.10 mmol/kg/day. The mean calcium to phosphate ratio the day before resolution for all patients who resolved after 4 days was 1.14:1. Additionally, one of the clinical outcomes that was measured was the odds of a hypophosphatemic VLBW infant being intubated, which was 4.36 times the same odds in a baby without hypophosphatemia (p>0.0085, C.I. 1.30-16.02).

Conclusion: The incidence of hypophosphatemia is significant in VLBW infants, especially those with a birth weight less than 750 grams, suggesting lower birth weights may be associated with increased risk of hypophosphatemia. The lower calcium to phosphate ratio intake the day before hypophosphatemia resolution, as compared to the current recommendations of 1.3 to 1.7, suggests inadequate phosphate supplementation relative to calcium intake in these infants. While attention to phosphate supplementation is recommended, additional research is warranted to establish clinical outcome correlations and to recommend a change in current electrolyte requirement practices.

Submission Type: Evaluative Study

Session-Board Number: 5b-402

Poster Title: Y-site physical compatibility of hydrocortisone infusions with intensive care unit admixtures

Primary Author: Pmichiaele Meredith, Presbyterian College School of Pharmacy, South Carolina; **Email:** pomeredit@presby.edu

Additional Author (s):
Jaime Foushee
Laura Fox

Purpose: Despite controversial evidence of survival benefits, intravenous low dose hydrocortisone is recommended by current sepsis guidelines to treat adults with septic shock who remain hemodynamically unstable after adequate fluid resuscitation and vasopressor therapies. Septic shock patients may require multiple intravenous medications and hydrocortisone to aid in restoration of hemodynamic stability. Compatibility data is imperative to safely co-infuse these medications through a y-site connector of patients with limited IV access. The purpose of this study was to examine the physical compatibility of hydrocortisone with select intravenous drugs used for critically ill patients in intensive care units through a simulated y-site infusion.

Methods: The tested drugs were metoprolol, esmolol, labetalol, albumin, levothyroxine, acetaminophen, ibuprofen, meropenem, doripenem, ciprofloxacin, levofloxacin, cefepime, epinephrine, norepinephrine, and cisatracurium. Equal volumes of either normal saline or hydrocortisone were combined with each test drug at the maximum concentrations safe for patient infusion or the commercially available concentration, as appropriate. The samples were examined visually against white and black backgrounds and also using turbidimetric analysis to determine physical compatibility. Observations and analyses were take over a one hour-period at 15-minute intervals beginning after mixing to account for contact time in a y-site connector. Each test was performed in triplicate. A difference in nephelometric turbidity units (NTU) of > 0.5 units between control and test solutions is commonly accepted as incompatible. Further statistical analysis was completed using One Way Analysis of Variance with Tukey Multiple Comparison Procedure on all groups pairwise for normally distributed data and Kruskal-Wallis

Analysis of Variance on ranks with Tukey Multiple Comparison Procedure on all groups pairwise for data that was not normally distributed.

Results: None of the admixtures demonstrated visual changes against white and black backgrounds when combined with hydrocortisone. Although less than 0.5 NTU differences were obtained when examined via nephelometer, combinations of hydrocortisone with levofloxacin, cefepime, and ciprofloxacin demonstrated statistical differences in turbidity from controls (p-value >0.05) Labetolol demonstrated physical incompatibility with a change in turbidity > 0.5 NTU compared to controls.

Conclusion: Metoprolol, esmolol, labetalol, albumin, levothyroxine, acetaminophen, ibuprofen, meropenem, doripenem, epinephrine, norepinephrine, and cisatracurium exhibited no evidence of visual or turbidimetric incompatibility, showing physical compatibility when co-infused with hydrocortisone. Chemical compatibility data should also be evaluated prior to co-infusing these medications. Labetolol displayed physical incompatibility with hydrocortisone, and the two agents should not be co-infused. Levofloxacin, cefepime, and ciprofloxacin displayed statistical differences from control solutions when combined with hydrocortisone and further testing is warranted before these agents can be safely administered through a y-site connector.

Poster Title: Host Factors Associated with Elevated Minimum Inhibitory Concentrations to Fosfomycin and Doxycycline among Vancomycin-Resistant Enterococcal Urine Isolates at a Tertiary Care Medical Center

Primary Author: Jillian Hayes, South Carolina College of Pharmacy - University of South Carolina Campus, South Carolina; **Email:** hayesje3@email.sc.edu

Additional Author (s):
Brian O'Quinn
Kevin Lu
Celeste Caulder
P. Brandon Bookstaver

Purpose: Antibiotic susceptibility patterns of vancomycin-resistant Enterococcal (VRE) urine isolates to fosfomycin and doxycycline are generally lacking. The purpose of this study is to identify factors which are predictors of fosfomycin or doxycycline non-susceptibility among VRE urine isolates. This was an observational, retrospective study completed at a tertiary care medical center in Columbia, South Carolina.

Methods: A susceptibility profile was created from non-repeat VRE urine isolates that underwent Epsilometer testing over a 14-month period to evaluate daptomycin, doxycycline and fosfomycin in vitro activity. Routine susceptibilities from automated testing (Vitek II) were collected. FDA-approved Enterococcal breakpoints were used. Isolates were divided into the following groups for evaluation: fosfomycin MIC 64mcg/mL and doxycycline 4mcg/mL. Fisher's exact and Student's t-tests were performed to compare host factors and laboratory parameters between groups (p < 0.05 for significance). Multivariate regression was performed to determine predictors of elevated MICs.

Results: Sixty-seven isolates were included in the analysis. The patients were primarily women (66%) and 61 years old. Forty-one isolates (61%) were hospital-acquired. Twenty-six (39%) isolates had an MIC 4mcg/mL). The fosfomycin MIC50 was 96mcg/mL and MIC90 128mcg/mL; doxycycline MIC50 was 12mcg/mL and MIC90 24mcg/mL. Patients with fosfomycin-susceptible isolates had poorer renal function (CrCl ≤30 ml/min) (50% vs 34%, p=0.214), and isolates were

more often hospital-acquired (69% vs 56%, p=0.315), although neither were statistically different. There were no statistical differences in host or laboratory variables detected between the fosfomycin or doxycycline susceptible vs non-susceptible isolates, respectively.

Conclusion: Available susceptibility data may substantiate expanded treatment options for multi-drug resistant urinary tract infections. Additional data are needed to conclude definitive risk factors for fosfomycin or doxycycline-resistance among VRE urine isolates.

Poster Title: Survey review of a patient-centered approach to diabetes management

Primary Author: Jesus Gracia, Rosalind Franklin University of Medicine and Science, Illinois;
Email: jesus.gracia@my.rfums.org

Additional Author (s):
Janice Gilden
Keith Riley

Purpose: Diabetes mellitus is a demanding disease that requires patient adherence to complicated medication therapy. These requirements can negatively impact patients' quality of life. Furthermore, poor glycemic control may cause macro and micro vascular complications including neuropathy, retinopathy, nephropathy, cardiovascular, and cerebrovascular disease. Prior research shows that interventions aimed at improving adherence to antidiabetic medications have not always produced significantly positive impacts on patient outcomes. There is a growing philosophy that patient-centered care may be more effective at enhancing patient outcomes. This study evaluated a patient-centered approach to treatment and its impact on life quality, glycemic control, and perceived disease progression.

Methods: This study is a retrospective chart review of 119 veteran patients over the age of 18, diagnosed with either type 1 or 2 diabetes mellitus. Patients were enrolled in the outpatient endocrine clinics located at the James A. Lovell Federal Health Care Center. Patients were offered an opportunity to participle in a survey assessing their current treatment for diabetes. Informed consent was obtained from every participant. All participants received and completed a one-sided page patient-centered questionnaire regarding their diabetes treatment in their room before seeing the physician. The survey assessed patient characteristics such as diet, frequency of exercise, number of missed doses, reasons for noncompliance, knowledge of current therapy, and whether said knowledge assisted with compliance. The survey asked patient to list any diabetes medication they were currently taking. If patient was using insulin, the question was asked if there were any extra vials of insulin around the house. Patient perceived progression was also assessed through a question that asked whether the patient felt better, the same, or worse since, and by what percentage, since their last visit. The survey inquired how the patient's blood sugars have been since their last visit, what times the patient

checks blood sugar levels, and if podiatrist and optometrist appointments were annually done. The reason for the survey was conveyed to patients before check-out.

Results: A total of 119 patients received a survey, but not every patient completed it. Unanswered or incorrectly answered questions were counted as non-applicable and unreadable responses as inconclusive. Of patients answering, about 88 percent followed a special diet and 75 percent endorsed some form of exercise. Since their last visit, 42 percent of patients reported their health remaining the same, 22 percent reported improvement, 11 percent reported worsening, and 25 percent of answered were inconclusive or non-applicable. About 55 percent of patients reported forgetting to take their medication while 44 percent denied ever missing a dose. Most patients, 90 percent, endorsed knowledge of their medication for diabetes but only about half of the patient population considered this knowledge helpful with compliance. Only about 35 percent of patients carried an updated medication list. Patients reported blood sugar control as bad 17 percent of the time and adequate 65 percent of the time. For blood sugar monitoring, 35 percent of patients endorsed checking 3 to 4 times a day, while 9 percent checked once or none times a day. Up to 16 percent of patients endorsed checking 5 or more times a day.

Conclusion: Diabetes management involves a lot of patient involvement. Patient education is an important role for a pharmacist and the study shows that most patients understand how their medication works, but there is still room for compliance improvement through different vehicles. Many survey responses were non-applicable which may have skewed results. This may necessitate a revision of the survey's language. This patient population appears active in their diabetes care. Moving forward, the next step is assessing clinical outcomes to find correlations to survey responses. These future data may lead to a focus shift for diabetes management from the patient's perspective.

Poster Title: Medication use evaluation of corticosteroids in the neonatal intensive care unit

Primary Author: Bridget Biskup, Midwestern University- Chicago College of Pharmacy, Illinois;
Email: bbiskup77@midwestern.edu

Additional Author (s):
Justin Graff
Julia Ihlenfeldt

Purpose: Corticosteroids are given to infants in neonatal intensive care units (NICU) to treat and prevent bronchopulmonary dysplasia, as well as other conditions. However, data for the bronchopulmonary dysplasia dosing of corticosteroids in neonates is limited and controversial. Recent studies have suggested that lower doses may be as effective and have fewer side effects than what has been previously recommended. The purpose of this project was to evaluate the corticosteroid dosing strategies used by our neonatologists, and identify differences between our practice and current recommendations to determine if changes needed to be made to improve patient safety and quality of care.

Methods: This medication use evaluation (MUE) was approved by the institutional review board. Medication administration records were reviewed for patients admitted to our NICU between 2013 and 2015. Patients who received hydrocortisone, dexamethasone, or budesonide for the treatment and prevention of bronchopulmonary dysplasia or to facilitate extubation were included in the evaluation. Patients who received corticosteroids for other indications, such as hypotension or adrenal insufficiency, were not included. The indication for use, initial weight-based dose, day of life therapy was started, length of therapy, and number of courses given were evaluated for each corticosteroid qualified patients received. This data was analyzed and compared to current dosing recommendations from drug information databases. Differences in dosing regimens were measured. A difference was defined as any weight-based dose or dosing interval of a prescribed dosing regimen that did not match what was recommended per the most recent literature at the time the corticosteroid was received. All-cause mortality and transfer to a children's hospital for more critical care were also measured in this evaluation to determine if there was a link between corticosteroid doses that deviated from recommendations and poor outcomes.

Results: A total of 35 patients were included in this evaluation. A wide variety of dosing regimens were seen for hydrocortisone and dexamethasone, but budesonide dosing was consistent across all patients. A total of 22 patients from the evaluation received dexamethasone. Of these patients, 63 percent were dosed within the range suggested by recent literature. Thirty-two percent of the patients who received dexamethasone were dosed above the suggested range, with 5 percent dosed below. Thirty of the evaluated patients received hydrocortisone, however only 3.3 percent of those patients were dosed according to current recommendations. The other 96.7 percent of hydrocortisone patients received doses that were significantly higher than recommended. One hundred percent of patients who received budesonide were dosed per recommendations. It was also noted that 33.3 percent of the entire patient population that received any corticosteroid either died or became so critically ill they had to be transferred to a children's hospital for further care. Ninety-one percent of these patients received corticosteroid doses that were higher than what was recommended by literature. However, due to gathering information from handwritten charts, it is unknown if the over-dosing of corticosteroids had any direct impact on these adverse outcomes.

Conclusion: There is room for improvement when it comes to the dosing of corticosteroids in our NICU. This MUE showed that a majority of corticosteroids, especially hydrocortisone and dexamethasone, were given to patients at doses other than what is recommended by current literature. In most cases, these corticosteroids were given at higher than recommended doses, which could potentially lead to adverse events and poor long-term outcomes. Future improvement strategies include physician education and updated dosing protocols.

Poster Title: Improvement in medication adherence after engagement in medication synchronization in an ambulatory care pharmacy

Primary Author: Lauren Endriukaitis, University of Illinois at Chicago, Illinois; **Email:** endriuk1@uic.edu

Additional Author (s):
Katherine Lee-Mosio
Maribelle Vasavanont
Anitha Nagelli

Purpose: Hypertension affects 1 in 3 Americans. Adherence to one's antihypertensive regimen is associated with overall reduced morbidity and mortality related to end-organ damage. UI TEAM RX is a patient care model offered through the University of Illinois at Chicago outpatient pharmacies. The goals of UI TEAM RX are to have a positive impact on safety, adherence and costs related to pharmacy care. The purpose of this study is to explore if engagement in the UI TEAM RX care model impacts adherence to prescribed antihypertensive therapy.

Methods: The project was a retrospective refill record review conducted at University Village Pharmacy (UVP) in Chicago, IL, an ambulatory care pharmacy associated with the University of Illinois Hospital and Health Sciences System. UI TEAM RX patients with hypertension and association with the pharmacy for at least three fills prior to, and three consecutive refills after engagement in UI TEAM RX were included. Patient names were collected using the UI TEAM RX calendar. Enrollment dates of each patient were obtained and documented. Using the pharmacy's prescription management software, the number of antihypertensive medications were recorded. Adherence was measured by calculating patient proportion of days covered (PDC) in the time period between three refills prior to and after engagement in UI TEAM RX. PDC was calculated as the number of days in period covered divided by the number of days in period, then multiplied by 100 to provide a percentage. The PDC of each patient before and after engagement in UI TEAM RX was compared. Upon review, the patients were then categorized into four groups: 1)non-adherent to adherent; 2) maintained adherence; 3) adherent to non-adherent; 4) maintained non-adherence. In following with current literature, 80 percent was used to categorize a patient as adherent or non-adherent.

Results: Among 42 patients enrolled in UI TEAM RX at UVP, 33 patients met the defined inclusion criteria. Overall, 8/33 (24 percent) patients improved from clinically defined non-adherent to adherent, 20/33 (60 percent) patients maintained adherence, 2/33 (6 percent) patients declined from adherent to non-adherent, and 3/33 (9 percent) patients maintained non-adherence.

Conclusion: Among patients with hypertension who are managed with the UI TEAM RX model, participation in the program appears to impact adherence to prescribed antihypertensive therapy. Overall, there was an increase in patients considered clinically adherent when compared to adherence rates prior to implementation of the care model. Further exploration of the model is needed in order to establish a potential correlation between adherence and program engagement. Pharmacists should continue to identify patients that can benefit from this program and maintain patients currently enrolled in order to maximize the benefits of their antihypertensive regimens.

Poster Title: The Impact of Genotype Testing On Clinical Outcomes in Warfarin Treated Patients Undergoing Major Orthopedic Surgery and Managed by a Pharmacist-Guided Personalized Consult Service

Primary Author: Po-Hung Lin, University of Illinois at Chicago, Illinois; **Email:** plin30@uic.edu

Additional Author (s):
Beenish Manzoor
Dan Gratie
Edith Nutescu

Purpose: The objective of this study was to evaluate whether genotype testing improves clinical outcomes in warfarin treated patients undergoing major orthopedic surgery and managed by a pharmacist-guided personalized consult service.

Methods: This was a prospective observational cohort study at UI-Health from April 2014 to April 2015. The intervention group included patients managed by the pharmacist-guided personalized consult service and who also had genotype testing ordered (genotype-guided group), while the control group included patients managed by the pharmacist-guided personalized consult service but did not have genotype testing ordered. The primary efficacy outcome was time to reach first therapeutic International Normalized Ratio (INR) and the primary safety outcome was the proportion of INRs at extreme values (INR < 1.5 or >4). Bivariate analysis was employed to identify significant factors ($p < 0.05$) associated with each outcome. Multivariate linear and survival models were used to assess the association between the genotype-guided group and each primary outcome.

Results: A total of 52 consecutive patients were enrolled. The mean age for patients receiving genotype-guided dosing was 63.1 years vs. 61.6 years for controls (p=0.47). Thirty-two percent of patients were African-American in the genotype-guided group vs 56% in controls (p=0.33). The proportion of women was 52% and 44% (p=0.59), respectively. There was no statistically significant between-group difference in the time to reach the first therapeutic INR and the proportion of INRs at extremes between the genotype-guided group and controls (mean±SD: 4.1±3.0 vs. 4.0±2.8 days, p=0.89; and 34.8%±25.0 vs. 38.7±29.4, p=0.63, respectively). The

treatment effect was not statistically significant for time to reach the first therapeutic INR or proportion of INRs at extremes (HR: 0.54, 95%CI: 0.26 -1.12; β: -0.66, 95%CI: -14.72-13.40, respectively).

Conclusion: The addition of genotype testing in orthopedic surgery patients newly initiated on warfarin when already managed by a pharmacist-guided personalized consult service did not result in significant changes in clinical outcomes.

Poster Title: Effects of Providing Medication Reconciliation Services on Pharmacy Student Knowledge and Attitudes at a Large Academic Medical Center

Primary Author: Christopher Kapolas, Midwestern University Chicago College of Pharmacy, Illinois; **Email:** ckapolas43@midwestern.edu

Additional Author (s):
Zahi Fawaz
Sally Arif
Spencer Harpe

Purpose: According to Objective 1.1 of the 2015 American Society of Health-Systems Pharmacy (ASHP) initiatives to improve pharmacy practice in health systems, pharmacists are encouraged to help hospitalized patients achieve the best use of their medications. When overseen by a pharmacist, student pharmacists participating in Advanced Pharmacy Practice Experiences (APPEs) can help achieve a positive impact on the appropriate use of medicines while improving their own learning. The purpose of this study is to assess if students have an increase in knowledge about the medication reconciliation process and changes in perceived value, skills, and attitudes after providing these services.

Methods: Subjects included 4th year student pharmacists from four colleges of pharmacy enrolled in a five to six week long APPE at a large academic medical center from June 2015 to April 2016. Students were introduced to the medication reconciliation process and were expected to complete the admission medication reconciliation within 24 hours of patient hospitalization under the supervision of a pharmacist. A 26-item electronic survey voluntary was administered at the beginning and end of the APPE. The survey gathered demographics, previous medication reconciliation experience and pharmacy work experience. Student's baseline knowledge was assessed using 10 multiple-choice questions about the medication reconciliation process. Student attitudes, perceptions, skills, and confidence related to communication, problem solving, critical thinking, patient-centered care, and ability to apply medication reconciliation concepts in a hospital setting were assessed on a Likert scale, where one indicates strongly disagree and five indicates strongly agree). The number of medications the patient is taking, medication discrepancies identified, high-risk drug discrepancies

identified, and time spent conducting the medication reconciliation were also assessed. Pre- and post-survey results were compared to determine whether student knowledge, attitudes, perceptions, and skills had increased after conducting med rec. Wilcoxon signed- rank test and paired t-test was used to compare pre-and post-medication reconciliation attitudes, perceptions, and knowledge with p-values less than 0.05 considered statistically significant.

Results: Amongst the 49 student respondents with little to no prior experience with conducting medication reconciliations, there was a statistically significant increase in mean knowledge-based scores (before APPE was seventy-seven percent, after APPE was eighty-three percent; p-value equals 0.036). Performing medication reconciliations did not show a change in students' attitudes and perceptions of cultural competency and confidence in interactions with patients. Overall, students perceived less of an improvement in their skills after completion of the APPE (mean before APPE was 4.7 [SD equals 0.4], Mean after APPE was 4.4 [SD equals 0.4]; p-value equals 0.003). Students' perceived ability to identify and assess discrepancies also decreased overall. There were 1,394 medication reconciliations and 4,473 discrepancies were identified (average 3.2 discrepancies per patient profile), of which 19 percent required a pharmacist intervention. The average time completing a medication reconciliation was 23 minutes (SD equals 10.5) which varied across significantly across hospital locations (p-value equals 0.001).

Conclusion: Pharmacy students were able to correctly identify important discrepancies within patient medication profiles and spend a significant amount of time conducting medication reconciliations during their APPEs. While students demonstrated an increase in their knowledge about the medication reconciliation process, they had an overall decrease in their perception, attitudes, and skills regarding what could be learned from the medication reconciliation process. The study results suggest more time should be spent educating students about the value of the medication reconciliation process during APPEs.

Poster Title: Four brains are better than one: Can cognitive training in an IPE clinical setting reduce processing biases in health professionals and improve patient outcomes?

Primary Author: Theresa Kodua, Rosalind Franklin University of medicine and science, Illinois; **Email:** theresa.kodua@my.rfums.org

Additional Author (s):
Michelle Shalaby
Tamzin Batteson
James Carlson

Purpose: Understanding how information processing biases heuristics, such as, decision making, cognitive shortcuts and functional fixedness interact is crucial in the education of health professionals, as it could have a differential impact on diagnostic error. The purpose of this study is to provide insight into the cognitive and affective influences occurring in both type 1 and type 2 thinkers, related to judgment, diagnostic decision-making, diagnostic success and cognitive heuristics involved in relationship with brain activity during the diagnostic process.

Methods: A protocol was specifically developed to explore whether the Emotiv could be utilized to understand and change decision making strategies in students. Research assistants first calibrated the wireless eeg and were given instructions on how to participate in a verbal protocol (talk aloud protocol).. The subjects were asked to stare at a small point on the screen for two minutes in order to capture baseline brain activity on the eeg and beta, theta, alpha and delta brain waves on the 3D model. They were given six classic problem solving tasks (The Chicken and the Fox, etc). Verbal protocol (talk aloud protocol) was used to observe cognitive process, in-line recorded brain wave activity. Recordings from the sessions were captured four times; at baseline, after each problem was given, when incorrect heuristics were used and when correct solutions were given. The verbal protocols were also transcribed.

Results: Initial results tentatively suggest that experience moderates relationship between wave form and accuracy. As resting state Alpha dissipates, the beginning of conscious processing begins as Beta becomes active. The areas cover AF3 (logical attention), Fz (working

memory) and F7 (verbal expression). Logical attention and working memory areas light up in Delta, which indicates deep, intuitive processing. This pattern was not observed when problems could not be resolved, with Alpha and Delta waves engaged in resting state, and no activity recorded in Beta.

Conclusion: Diagnostic reasoning is a crucial skill. Understanding what cognitive processes underlies decision making and problem solving can aid in the design of specific diagnostic reasoning pedagogies, that target those particular conscious processes. Data from this study will aid as indices for future diagnostic decision-making studies, measurement of diagnostic skills, and how students can be trained to develop accuracy in diagnosing.

Jozef Stec

Purpose: Development of new reactions allowing carbon-carbon and carbon-heteroatom bond formation is the essence of organic chemistry. New reactions are very often applied in synthetic medicinal chemistry to access new scaffolds possessing unique bioactivity. The purpose of this project was to investigate new reaction protocols to efficiently synthesize acylated carbamates and ureas as potential bioisosteres of a peptide bond. The use of carbamates in the development of prodrugs cannot be overemphasized. Prodrugs are frequently used to increase the bioavailability of drugs and thus improve their absorption, distribution, metabolism, and excretion (ADME) profile.

Methods: New and efficient synthetic organic chemistry methods were sought for the synthesis of acylated carbamates and ureas with the aim to apply the invented protocol to medicinal chemistry projects. The developed synthetic method includes isocyanites generated in situ from benzamide or alkyl amides by using oxalyl chloride, followed by an addition of a nucleophile such as amine, alcohol, thiol, amide, and sulfonate to give the corresponding acylated ureas or acylated carbamates. This project produced a small library of compounds that were purified via crystallization or automated flash chromatography purification system and further analyzed using proton and carbon nuclear magnetic resonance (1H, 13C NMR) spectroscopy and high-resolution mass spectrometry (HRMS) techniques. The purity of the final compounds was assessed by analytical high performance liquid chromatography (HPLC).

Results: During this project, a series of acylated ureas and acylated carbamates was synthesized by using novel synthetic methodology. The final compounds were prepared in a convenient one-pot two-step reaction sequence under relatively mild conditions and reaction time of

approximately 6 hours. The purification of final compounds required either convenient crystallization process or a little bit more laborious flash chromatography. Overall, 13 compounds were prepared which will be further evaluated in biological testing.

Conclusion: In conclusion, scoping studies were performed on a novel one-pot two-step reaction sequence to obtain acylated carbamates, ureas, and related compounds. The products were synthesized in good yield after final purification. The developed synthetic protocol is currently utilized in the synthesis of compounds suitable for further biological investigation.

Poster Title: Pharmacist implementation in independent physician offices to perform clinical pharmacy services to help Medicare patients

Primary Author: Anh Lam, Chicago College of Pharmacy at Midwestern University, Illinois;
Email: alam76@midwestern.edu

Additional Author (s):
Julian Muron
Aakash Shah

Purpose: The Centers for Medicare and Medicaid Services (CMS) is shifting reimbursement of physician offices from a fee for service model to more outcomes oriented payments. Medicare has recently provided financial incentives for physicians to apply clinical pharmacy services within their own practice. This business plan was initiated in order to explore the opportunities of establishing clinical pharmacy services to complement patient care provided by independent physician offices. This would initiate multidisciplinary team-based patient-centered care to a more local level in order to optimize health outcomes of Medicare patients.

Methods: Research was performed on multiple aspects of the market with a focus on Medicare patients. We specifically initiated our research with Chronic Care Management (CCM) and then expanded to Transitions of Care Management (TCM) and Annual Wellness Visits (AWV) in order to get a sense of how physicians were conducting these services. In order to do this we performed market research on patient-centered medical homes, physician groups and clinics, health information software, and ambulatory care clinics. We assessed how many physicians are taking advantage of these new comprehensive services, any obstacles that they are experiencing, and how CMS has responded to the data that they have received thus far. Research was also performed on the local (Chicago, Illinois) market in order to gather information and assess the possible impact of implementing pharmacists to assist in performing these services. In addition, the logistics of operations of a possible independent company to provide pharmacy clinical services were researched in order to find the optimal location of establishment.

Results: It was determined that physician offices were not implementing these comprehensive services because of the intensity of labor involved without an equal financial reimbursement. CMS has responded to the minimal implementation of the services with an expansion to CCM reimbursement to stratify the reimbursement and requirements to fulfill a larger range of Medicare patient population. The Medicare Access and Children's Health Insurance Program Reauthorization Act (MACRA) is a measure to incentivize physicians with Merit-based Incentive Payment System (MIPS) as one of the alternatives for reimbursement. This has alleviated some of the difficulties in making implementation of these services practical. Many of the services that are required in order to receive full reimbursement can be performed by a pharmacist that is partnered with a physician. We have found that other essential personnel would be a social worker, nurse, and pharmacy technician in order to optimize operations to ensure efficiency and outcomes. Another crucial component that would help to solidify these clinical services into a comprehensive and collaborative health care would be clinical software that is adaptive and flexible to make the patient experience and health care seamless.

Conclusion: There is a significant need for the improvement of health quality outcomes and Medicare has provided an opportunity for pharmacists to fulfill this need. Clinical pharmacy services can complement physician practices while taking advantage of the opportunities that CMS provides. Pharmacists have an array of clinical skills associated with medications and disease states that are underutilized and can be employed to complement physicians who are trying to adapt to the new rules and regulations. Ongoing research and implementation of pharmacists to perform these clinical services will help advance the health profession to new heights and better outcomes.

Poster Title: Patient response to intravenous valproate sodium for the treatment of status migrainosus with aura: a case report

Primary Author: Anna Xie, Midwestern University College of Pharmacy, Illinois; **Email:** axie72@midwestern.edu

Additional Author (s):
Richard Wenzel

Purpose: There is some literature suggesting the efficacy and tolerability of intravenous (IV) valproate sodium in the treatment of status migrainosus with or without aura. Existing data suggest that doses ranging from 300 milligrams to 1 gram are associated with migraine headache relief within several hours. This case report describes a patient response to IV valproate sodium used in the treatment of status migrainosus. The patient is a 23-year-old female with a past medical history of status migrainosus with aura, who was admitted to an inpatient headache clinic with refractory headache pain. Upon admission, the patient's pain score was 8 on a scale of 1 to 10. She was initiated on treatment with 9 scheduled doses of IV dihydroergotamine over 6 days and gradually improved over this time. However, on admission day 7 the patient felt subjectively worse despite the initiation of a second course of IV dihydroergotamine, reporting a pain score of 9. Other IV abortive medications were ordered for the patient as needed, including diphenhydramine, ketorolac, methylprednisolone, and orphenadrine, but these did not provide substantial pain relief. On day 11, the patient received 500 milligrams of IV valproate sodium. Within one hour of administration, the patient's pain score decreased from a score of 8 to a score of 2. The patient tolerated the medication well, and experienced a 75% decrease in her pain level over the course of four hours. This decrease in pain score demonstrates a positive response to therapy with IV valproate sodium. Due to the efficacy of this treatment for the patient, therapy with IV valproate sodium was continued; the dosage was increased to 750 milligrams every eight hours on day 12. By day 13, the patient rated the severity of headache as 1 to 2 out of 10. The following day, the patient rated the severity of headache as 0 out of 10, and was discharged on day 14. Her discharge medications included oral valproic acid as an abortive medication, among others, in the case of future attacks. This case report provides one example of a favorable patient response to IV valproate sodium. Because individual responses to valproate sodium and other abortive medications are

highly patient-specific, further study into possible predictors for positive responses would be valuable for the management of acute migraine attacks.

Poster Title: Identification of unapproved prescription drug products and the impact of the FDA's Unapproved Drugs Initiative on approval status

Primary Author: Lillian Bellfi, University of Illinois at Chicago College of Pharmacy, Illinois; **Email:** lbellf2@uic.edu

Additional Author (s):
Christopher Saffore
S. Albert Edwards
Glen Schumock

Purpose: Healthcare providers should be aware that not all medications currently on the US market have been approved by the FDA. Certain drugs entered the market prior to the Federal Food, Drug, and Cosmetic Act of 1938 and the 1962 amendment that together established safety and efficacy standards. In 2006, the FDA implemented the Unapproved Drugs Initiative to take action against these drugs. The purpose of this study was to identify these products and assess the impact of the Initiative on approval status.

Methods: To identify marketed unapproved drugs, a list from the FDA Prescription Drug Wrap-Up program of 1984, known as DESI-II, was acquired using the Freedom of Information Act. A systematic search of the DESI-II list by two independent reviewers was conducted to identify single-entity prescription drug products. Over the counter medications, combination products, and discontinued products were excluded from our search. Online FDA resources were used to determine the approval status of each drug. Resources included the FDA Orange Book, National Drug Code Directory, Drugs@FDA, and the Enforcement Activities section of the FDA website. In addition to approval status, we collected information on proprietary names, formulation, approval date (if applicable), and any FDA enforcement warnings that prompted approval. Descriptive statistics were used to characterize the approval status and other attributes of these products.

Results: Sixty-six drug products were identified from the DESI-II list. Of these, 29 drugs (44%) were marketed and remained unapproved, 16 (24%) were approved, and 21 (32%) had both approved and unapproved formulations. Of the 37 products that received approval, 16 were

sent a FDA enforcement warning as a result of the Unapproved Drugs Initiative. Examples of drug products that gained approval following FDA warnings included colchicine and pain medications such as codeine, hydrocodone, and oxycodone. Drugs that had not received a FDA enforcement warning went through the approval process voluntarily. The majority of drugs were characterized as injectable (43%) or oral (33%) formulations. Other identified formulations included ophthalmic, topical, suppository, sublingual, and inhalant products. Hospital drugs such as injectable phenobarbital and calcium gluconate continued to be marketed as unapproved products. Other common hospital drugs with both approved and unapproved formulations included oral barium sulfate and injectable epinephrine, hydromorphone, morphine, magnesium sulfate, sodium bicarbonate, phenylephrine, and vasopressin.

Conclusion: Despite efforts by the FDA to remove unapproved drugs from the market, many still remain. It is important for healthcare providers to be aware that unapproved drugs still exist and their safety and efficacy cannot be assured. The Unapproved Drugs Initiative's aim is to ensure quality standards, however, unapproved drugs that undergo the approval process regain de facto patent exclusivity which could potentially result in increased prices. Further research should be conducted to determine the impact of the FDA Unapproved Drugs Initiative on drug expenditures.

Poster Title: Impact of discharge anticoagulation education by pharmacists in the emergency department

Primary Author: Daniel Dickson, Rosalind Franklin University of Medicine and Science - College of Pharmacy, Illinois; **Email:** daniel.dickson@my.rfums.org

Additional Author (s):
Peter Nguyen
Abbie Erickson Lyden
Elizabeth Zdyb

Purpose: Significant risks are associated with new prescriptions for anticoagulation medications. While the impact of a pharmacist's role within an ambulatory care setting has been demonstrated in regard to anticoagulants, the evidence for these interventions in the emergency department (ED) are less established. Since 2013, pharmacists have been involved in discharge counseling and phone follow-up for anticoagulant medication prescriptions in the ED at Northwestern Memorial Hospital (NMH). The purpose of this study is to identify the impact of pharmacist counseling, defined by intervention on callback, versus standard of care discharge measures on patient understanding and appropriate use of anticoagulant medication

Methods: In May 2013, an initiative was set forth in the NMH ED whereby patients discharged from the ED with a new prescription for an anticoagulant (low molecular weight heparin, warfarin, or direct oral anticoagulants) received counseling by the ED pharmacist. During hours when the pharmacist was not present, patients received standard discharge counseling from physicians and/or nurses. All patients receiving anticoagulation, regardless of the counseling intervention provided, received a follow-up phone call by an ED pharmacist within 24-72 hours of discharge. This study was a retrospective chart review of all patients discharged from the ED at NMH from May 2013 to May 2016 with a new prescription for an anticoagulant. Patients were included who had documentation of an "ED Anticoagulant Counseling" note in the electronic medical record during this time frame. For those patients that received pharmacist counseling prior to discharge the following information was collected: demographics, medication, indication, prior history of anticoagulation use, noted drug-drug interactions, appropriateness of medication dosing, if the patient was able to fill the prescription, if they

were taking the medication appropriately, and any side effects experienced. Patient charts were also reviewed for documented readmission to a hospital within 90 days following their initial ED visit for worsening condition or an issue related to their anticoagulation medication.

Results: 174 patients were analyzed in a per protocol analysis. Patients who did not receive pharmacist counseling prior to discharge required an increased need for intervention during callback versus patients who received pharmacist discharge counseling (36.4% vs. 12.9%, p equals 0.0005). A few example interventions on callback included: patient administering medication inappropriately or taking concomitant medications that interact with their prescribed anticoagulant. In addition, patients who had not received counseling were more likely to return to NMH within 90 days for an anticoagulant related problem versus patients who had received counseling (12.12% versus 1.85%, p equals 0.0069). Although not statistically significant, patients who received counseling by a pharmacist were more likely to seek appropriate follow-up with their primary care provider (77.8% versus 66.7%, p equals 0.1145). There were no statistically significant differences between the two groups in gender, age, type of anticoagulant selected, nor indication for anticoagulation.

Conclusion: Discharge counseling by pharmacists in the ED leads to improved patient understanding and appropriate usage of anticoagulant medications.

Poster Title: The evaluation of opioid prescribing practices in the emergency department

Primary Author: Leena Hamadeh, University of Illinois at Chicago College of Pharmacy, Illinois;
Email: leena.hamadeh@gmail.com

Additional Author (s):
Megan Rech
Shannon Lovett
Mark Grant

Purpose: Over the past several years, opioid prescription abuse has increased significantly, resulting in serious sequelae such as overdose and death. The Center for Disease Control (CDC) released a Morbidity and Mortality Weekly Report (MMWR) detailing this epidemic in January 2016 and clinical guidelines for prescribing opioids in March 2016. The goal of this study was to characterize opioid prescribing practices at a large, academic medical center Emergency Department (ED) before and after these recommendations in order to determine if the number of opioid prescriptions or quantity of opioids has declined.

Methods: This was a retrospective cohort of patients at least 18 years of age who received at least one prescription upon discharge from the Loyola University Medical Center ED between March – June 2015 (pre-MMWR group) and March – June 2016 (post-MMWR group). Patients were not included in the study if there was incomplete medication documentation. The primary objective was determining the percentage of opioids prescriptions prescribed between the two time periods. Secondary endpoints included opioid dose, strength, relative potency, duration, and number of doses. This study also characterized the change in non-opioid analgesic medications prescribing practices.

Results: Preliminary results of this study include 303 patients (pre-MMWR group n = 178; post-MMWR group n = 125). Notable differences in baseline demographics include higher incidence of cancer (3.9 % vs. 12.0%, p < 0.01) and osteoporosis (1.1% vs. 16.0%, p < 0.01) in the post-MMWR group and higher incidence of arthritis in the pre-MMWR group (6.2% vs. 0.8%, p = 0.02). Overall, 111 (36.6%) received a prescription for an opioid upon discharge. For the pre-MMWR group of 2015 data, 71 received an opioid upon discharge (39.89%) compared to 40

(32.0%) patients in the post-MMWR group (p = 0.16). The most prescribed opioid upon discharge for both groups was hydrocodone with acetaminophen (33.7% vs 28.8% p= 0.469).

Conclusion: These preliminary results demonstrate a non-significant trend towards decreased opioid prescriptions since awareness has been directed towards the ongoing crisis of opioid abuse in the US. We plan to continue to add to this data in order to characterize the patterns of opioid prescribing methods over a longer period of time. This can help to determine if the CDC MMWR and new clinical guidelines has made a significant impact regarding opioid prescribing practices.

Poster Title: Effect and incidence of treatment with hydroxocobalamin or sodium nitrite/sodium thiosulfate in patients with inhalation injuries

Primary Author: Kali Weber Adorable, University of Illinois Chicago, Illinois; **Email:** kweber26@uic.edu

Additional Author (s):
Sarah Zavala
Megan Rech

Purpose: Smoke inhalation injuries can result in cyanide toxicity that can significantly increase the morbidity and mortality in burn patients. Cyanide prevents oxygen utilization during cellular aerobic respirations. This rapidly leads to functional tissue hypoxia if left untreated. The purpose of this study is to evaluate the incidence and effects of cyanide treatments on patients with smoke inhalation injury with possible cyanide toxicity.

Methods: The institutional review board approved this single center, retrospective cohort study. All patients age 18 years and older were enrolled if they were admitted to Loyola University Medical Center between January 1, 2008 through March 1, 2015 with possible cyanide toxicity due to smoke inhalation injury. The primary endpoint was to describe the incidence of cyanide exposure treatment and determine if receiving treatment is associated with decreased 30-day mortality in burn patients with smoke inhalation injury. Secondary endpoints included mechanical ventilation, duration of mechanical ventilation, intensive care unit and hospital length of stay, and hospital mortality.

Results: Overall 148 patients were admitted for inhalation injury, of which 134 (90.5%) were included. Twelve patients (9%) received cyanide treatment. Baseline demographics were well-matched between groups. The inhalation injury score was significantly higher in the between patients who received cyanide treatment and those who did not (median; 3 [interquartile range (IQR) 3 – 4] and 2 [IQR 1 – 2] respectively; p≤0.01). There was no difference in mortality between groups (16.7% cyanide treatment vs. 25.41% no treatment; p=0.51). Patients treated for cyanide exposure had longer median days of mechanical ventilation (24 days [IQR 18-28] vs. 11.5 days [IQR 3-28]; p= 0.03), were more likely to be continuously paralyzed in the first 24

hours after injury (75% vs. 39.3%; p=0.02), and had longer median ICU (39 days [IQR 20-65] vs. 16.5 days [IQR 7-33]; p=0.02) and hospital length of stay (40 days [IQR 19-66] vs. 19.5 days [IQR 7-35]; p=0.04).

Conclusion: The incidence of cyanide treatment for inhalation injury was low. There was a non-significant decrease in mortality in patients that were treated with cyanide antidotes, despite higher baseline severity of illness. This finding warrants further exploration in a larger trial.

Poster Title: Evaluation of effect of programmed death-1 inhibitors on coagulation markers

Primary Author: Zachary Madej, Southern Illinois University Edwardsville School of Pharmacy, Illinois; **Email:** zmadej@siue.edu

Additional Author (s):
Keith Hecht

Purpose: The programmed death-1 (PD1) inhibitors, nivolumab and pembrolizumab, represent a new therapeutic target in the treatment of cancer. They are approved for various cancers including melanoma, non-small cell lung cancer, renal cell carcinoma, head and neck cancers, and Hodgkin's lymphoma. These drugs have no known effect on coagulation. At our institution, it was observed that one patient who was receiving warfarin therapy required multiple dose modifications of warfarin upon initiation of nivolumab. The purpose of this evaluation was to determine if administration of programmed death ligand inhibitors affected coagulation markers in patients with or without concomitant administration of anticoagulants.

Methods: The institution's investigational review board approved this retrospective chart review. A database query was conducted to identify all patients who received either nivolumab or pembrolizumab from September 2014 to September 2016. Electronic medical records were utilized to determine information regarding PD1 inhibitor use including dose, indication, and administration dates. When available, coagulation markers including partial thromboplastin time (PTT), prothrombin time (PT), and international normalized ratio (INR) values were collected at baseline and throughout PD1 inhibitor therapy. The use of anticoagulants was recorded including any dose modifications of anticoagulants during PD1 inhibitor therapy. The presence of any documented bleeding events was also noted. Due to the anticipated small sample size, descriptive statistics only were used to evaluate the results.

Results: During the study period a total of 114 patient's received treatment with a programmed death-1 inhibitor, 91 patients received nivolumab and 23 patients received pembrolizumab. Only 26 of 91 of nivolumab patients (29%) and 8 of 23 pembrolizumab patients (35%) had coagulation markers reported at baseline or during PD1 inhibitor therapy. 13 of 34 (38%) total patients with coagulation markers were receiving concomitant anticoagulant therapy (7

warfarin, 2 enoxaparin, 2 rivaroxaban, 2 apixiban). Only patients receiving concomitant warfarin experienced substantial changes in coagulation markers during PD1 inhibitor therapy. Of the 7 patients receiving warfarin and PD1-inhibitor therapy, 5 required warfarin dose adjustments. Causality of need for dose adjustments could not be definitively determined. No bleeding events were reported in any of the patients evaluated.

Conclusion: This data demonstrates that in the absence of warfarin, programmed death-1 inhibitors do not affect coagulation markers. The concomitant use of nivolumab or pembrolizumab with warfarin may affect coagulation markers and require warfarin dose modification. Warfarin should be used with caution in patients receiving PD1 inhibitors and INR should be monitored carefully

Submission Category: Infectious Diseases

Submission Type: Evaluative Study

Session-Board Number: 5b-419

Poster Title: Characterization of MRSA versus MSSA prevalence based on risk factors and infection source to identify opportunities to minimize vancomycin utilization

Primary Author: Michelle Kapugi, University of Illinois at Chicago, Illinois; **Email:** mkapug2@uic.edu

Additional Author (s):
Paulina Szczepaniak
Sarah Wieczorkiewicz

Purpose: Vancomycin is routinely used for empiric broad-spectrum Gram-positive coverage despite lack of patient risk factors. Antimicrobial overuse can lead to unintended consequences (e.g., bacterial resistance, increased costs, and adverse effects). Conversely, inadequate antimicrobial coverage of pathogenic organisms can have detrimental effects. There are evidence-based risk factors helpful when determining need for empiric MRSA coverage. The CDC Core Elements of Hospital Antimicrobial Stewardship Programs lists de-escalation of empiric MRSA coverage as a syndrome-specific intervention. The purpose of this study was to characterize patient and culture-specific factors associated with MRSA versus MSSA infection to identify strategies to optimize vancomycin use.

Methods: This was a single-center, retrospective, observational study. All positive S. aureus cultures from January 2015-December 2015 were included. Cultures with incomplete susceptibility data were excluded. Culture-specific data collected included culture site, S. aureus susceptibility, and vancomycin MIC. Patient-specific data included infection source, presence of purulence if skin and soft tissue infection, vancomycin exposure, nasal MRSA PCR results, and history of S. aureus infection in the past 90 days. Descriptive statistics were performed for all continuous (mean ± SD) and categorical [N (%)] data. All normally distributed categorical variables were compared using X2. A two-tailed p-value of 0.05 was considered statistically significant.

Results: Total of 819 cultures from 643 subjects. MRSA prevalence was 34.7% (n = 285). Of subjects < 65 years (n = 432), cultures positive for S. aureus were more prevalent than the ≥65 years (551 versus 268, respectively) however, MRSA prevalence was lower in subjects < 65

years (27.2% versus 50.3%, respectively, p < 0.0001). MRSA more frequent in subjects admitted to the general floor (n = 212) versus ICU (n = 44) with MRSA prevalence of 37.8% and 26.3%, respectively (p < 0.0083). Most common sources of S. aureus included SSTI (n = 281, 34.3%), pulmonary (n = 103, 12.6%), bacteremia (n = 101, 12.3%), and unknown/multiple source (n = 87, 10.6%). MRSA was most prevalent in the genitourinary source (51%) compared to other sources, and 70% of these subjects were ≥ 65 years old. Majority of subjects with pulmonary MRSA were ≥65 years (n = 22, 61.1%). MRSA nasal PCR negative predictive value in the ICU from all sources was 98%. For 79 cultures, subjects had history of MRSA infection within < 90 days but only 37.9% had current positive MRSA culture (n = 30) versus MSSA (n = 49). 58.6% of MSSA infections were treated with ≥1 dose of vancomycin.

Conclusion: Overall low MRSA prevalence. MRSA infection within < 90 days was not predictive of current MRSA infection, contrary to existing evidence. MRSA nasal PCR has reliable negative predictive value in the ICU making this a valuable tool for early vancomycin discontinuation. Lack of MRSA nasal PCR assessment outside the ICU is a limitation. Although not a frequent genitourinary pathogen, if present, increased MRSA likelihood supports empiric vancomycin until susceptibilities finalized. These data support opportunities for reduced vancomycin use in patients < 65 and in the ICU if nasal MRSA PCR negative.

Email: imasic16@midwestern.edu

Additional Author (s):
Nancy Gorgi
Niree Kalfayan
Bryan Shaw
Milena McLaughlin

Purpose: The presence of allergies in the medical record may result in less efficient and more costly antibiotic use. Allergy services are often consulted to determine a true antibiotic allergy history when the optimal antibiotic is limited by a history of antibiotic allergy. The objective of this study was to evaluate the recommendations resulting from allergy consults and the frequency of antibiotic allergies being correctly updated in the medical record after the allergy service consult.

Methods: Consideration for study inclusion were patients 18 years or older, received an inpatient or outpatient allergy service consult, were hospitalized at Northwestern Memorial Hospital between January 2009 and July 2012, and had one or more beta-lactam allergy listed in the medical record. Additionally, the allergy reaction (if available), information regarding graded challenge or desensitization, and infectious diseases consult information was collected.

Results: A total of 156 patients were included in the study. Patients were predominantly female (n equals 84, 53.8 percent), Caucasian (n equals 104, 66.7 percent), with mean age 58.9 years (SD 17), median length of hospital stay 12 days (IQR 7-24.5), and median days to allergy service consult 5 (IQR 2-10). There were 90.4 percent of patients (n equals 141) with reported penicillin allergy, n equals 37, 23.7 percent with cephalosporin allergy, and n equals 9, 5.8 percent with reported allergy to carbapenems. A reaction was only documented in 75.6 percent of reported allergies with the most common reaction being rash/itching (n equals 57, 46.7 percent). The allergy service recommended changes in 71.6 percent (n equals 111) of cases. The allergy list

was updated post allergy service consult for 73.9 percent (n equals 82) of patients. A graded challenge was recommended in 88 (56.8 percent) of patients and a desensitization was recommended in 11 (7.1 percent) of patients. All graded challenges and desensitizations were successful. An infectious diseases service was consulted in approximately 80 percent of patients and recommendations from this service were followed in 100 percent of consults.

Conclusion: Only three quarters of medical records were appropriately updated after an allergy consult. Approximately half of patients with an allergy consult had a graded challenge in which they tolerated a beta-lactam, potentially resulting in the administration of a more appropriate antibiotic. Future studies should stress on the reinforcement of an allergy "de-labeling" intervention post allergy consult.

Poster Title: Discontinuation of antipsychotics initiated for hospital delirium

Primary Author: Sarah Wagner, Southern Illinois University Edwardsville School of Pharmacy, Illinois; **Email:** sarawag@siue.edu

Additional Author (s):
Katie Ronald
Benjamin Wunderlich

Purpose: Hospital delirium is a common issue in acutely ill patients. Although there are many strategies for the prevention of hospital delirium, many patients require pharmacologic treatment with haloperidol or atypical antipsychotics such as quetiapine and olanzapine. Similar to proton-pump inhibitors in ventilated patients, antipsychotics used for hospital delirium may be overlooked during patient discharge. The unnecessary continuation of these medications increases the risk of harmful adverse effects such as QTc prolongation and pseudoparkinsonian effects. The purpose of this study is to determine the rate at which antipsychotics initiated for hospital delirium were continued after hospital discharge.

Methods: The institutional review board approved this single-center retrospective chart review. Informed consent was not necessary. Patients aged 18-89 years old who received at least one dose of haloperidol, olanzapine, quetiapine, or ziprasidone while admitted to the medical floor or intensive care unit between May 2015 and July 2015 were included in the review. Patients were excluded if they were younger than 18 years old, pregnant, had a medical history of psychotic disorder (such as schizophrenia, bipolar disorder, and major depression with psychotic features), received a new diagnosis of psychotic disorder, received alcohol withdrawal therapy, included an antipsychotic medication on their home medication list, were treated for drug or alcohol intoxication, and/or expired during hospitalization. Data collection included demographic information including age and sex, floor status at the time of antipsychotic initiation, whether the patient was sedated, intubated, immobilized, or admitted to an intensive care unit, and if so, for what length of time, whether the patient received physical or occupational therapy, and overall hospital length of stay. Descriptive statistics were utilized.

Student Poster Abstracts

Results: Of the 290 patients who received an antipsychotic between May and July of 2015, 239 were excluded, leaving 51 patients for analysis. Of the 51 patients who met criteria, 10 (19.6 percent) patients were inappropriately discharged on an antipsychotic. Of these patients, 80 percent were male and the mean age was 60.1 years. 80 percent of patients initially received haloperidol IV for delirium and 70 percent were discharged on quetiapine oral tablets. 70 percent of patients were sedated for an average of 4.3 days, 50 percent of patients were ventilated with an average of 6.4 days and 80 percent of patients were immobilized for an average of 3.9 days. 90 percent of patients received some form of physical or occupational therapy. Only 40 percent of patients were admitted to an intensive care unit at any point during their stay. Of those patients, the average time spent in the intensive care unit was 9.25 days. Overall, the average hospital length of stay was 11.6 days.

Conclusion: Continuation of antipsychotics initiated for hospital delirium was frequent. In this short three month study, approximately 20 percent of patients were inappropriately discharged on an antipsychotic. Of those patients, 80 percent initially received haloperidol and 70 percent were discharged from the hospital with a new prescription for quetiapine. A larger study spanning over a longer period of time may better determine which patients are at a higher risk of this oversight and which medications are most commonly overlooked.

Poster Title: Assessing student pharmacist confidence in communication skills

Primary Author: Georgiana Ismail, Midwestern University Chicago College of Pharmacy, Illinois;
Email: gismail72@midwestern.edu

Additional Author (s):
Jineen Sadi
Sally Arif
Spencer Harpe
Jennifer Mazan

Purpose: Courses emphasizing communications skills (CS) have been included in many pharmacy curricula. Confidence in CS can influence communication-related behaviors. Student pharmacists may have good knowledge yet lack confidence in their CS resulting in reluctance to interact with patients or providers. Conversely, student pharmacists with high levels of confidence may downplay their actual knowledge and demonstrate less than optimal interactions with patients or providers. The primary objective of this study was to examine students' self-reported confidence in specific CS areas. A secondary objective was to examine differences by program year, general communication abilities, and academic performance.

Methods: A questionnaire was constructed where students reported their perceived confidence (from 1: No confidence to 5: Very confident) in selected CS areas: counseling geriatric patients, counseling pediatric patients, counseling patients with limited health literacy, counseling patients with unique cultural/religious beliefs, counseling patients about sensitive prescriptions, and the use of motivational interviewing during patient counseling. In addition to demographics, students provided an assessment of their overall academic performance (How would you rate yourself as a student?) and general written and verbal communication abilities. The questionnaire was administered online via REDCap to all first-, second-, and third-year students at Midwestern University's Chicago College of Pharmacy. Student confidence in the selected CS areas and demographics were described for the overall sample. Differences across program year were examined with ANOVA. Self-reported academic performance and communication abilities were collapsed into "Good" vs. "Other" groups and compared using unpaired t-tests. An overall alpha level of 0.05 was used for all analyses.

Results: Of the 611 students that the survey was distributed to, a total of 379 students completed the survey (62.0 percent response rate). The majority of respondents were either first- (51.9 percent) or third-year (36.7 percent) students. More than half of the participants were female (69.3 percent) and self-identified as Caucasian (46.2 percent) or Asian (32.7 percent). The mean (standard deviation (SD)) age of participants was 24.7 (4.4). The mean (SD) confidence for the targeted CS areas were as follows: geriatric counseling: 3.2 (1.1), pediatric counseling: 3.1 (1.1), patients with limited health literacy: 3.3 (1.0), patients with unique cultural/religious beliefs: 3.2 (1.1), sensitive prescriptions: 3.3 (1.1), and use of motivational interviewing: 3.3 (1.1). Confidence in these areas decreased across program year (p less than 0.01) with third-year students being significantly lower than first-year students. Students rating themselves good students or with good written/verbal communications had significantly higher scores in geriatric counseling and use of motivational interviewing. Students with higher self-reported verbal communication ability had significantly higher confidence in counseling about sensitive prescriptions or for cultural/religious beliefs. Confidence in counseling patients with limited health literacy was significantly higher for students with self-reported good verbal or written communication abilities.

Conclusion: In this group of student pharmacists, self-reported confidence in selected CS areas actually decreased as they progressed through the pharmacy program. It is possible that students over-estimated their confidence earlier in the program with their self-ratings becoming more realistic as they gained more experience with patient counseling. Students who rated themselves as good students or having good written or verbal communication abilities generally had higher confidence levels in the various CS areas. Future research could examine the relationship between CS confidence and CS attitudes, as well as the relationship between self-reported confidence and external observation of CS skills.

Poster Title: Hazards of computerized default medication administration times

Primary Author: Tina Chen, Midwestern University Chicago College of Pharmacy, Illinois; **Email:** tina.ruo.chen@gmail.com

Additional Author (s):
Richard Wenzel

Purpose: Electronic medical records in hospitals, e.g. Epic Systems, have become widespread and offer many benefits.1 However, the introduction of new software can create previously unrecognized risks. Faulty software issues, particularly those related to medications, are so pervasive that the Institute of Safe Medical Practices recently drafted a set of guidelines for the Safe Electronic Communication of Medication Information.2
Medication order processing remains a key, common activity of electronic medical records. Drug databases are utilized to facilitate this processing. However, if the database contains faulty information, an error may result. Herein we describe several examples.
While processing a drug order, a pharmacist discerned a discrepancy between the Epic Systems' drug database default medication administration times (0900 and 1700) and the drug's intended administration times (every 12 hours). The database's description of the drug was "diltiazem 12-hour capsule 60 mg", yet this medication defaulted to be administered every eight hours. Further investigations by the pharmacist and a Doctor of Pharmacy candidate found additional examples of "12 hour" drugs defaulting to eight hour administration times: "bupropion 12-hour tablet 100 mg", "carbamazepine 12-hour tablet 100 mg", and "pseudoephedrine 12-hour tablet 120 mg". These medications' clinical effects occur optimally with these formulations if given every twelve hours. Moreover, the carbamazepine issue was particularly concerning due to the medication's narrow therapeutic window when prescribed to treat seizures; incorrect administration intervals could affect serum drug levels and result in patient harm.
The pharmacist and candidate alerted the hospital's Informatics Support (IS) staff about these discrepancies. The IS staff then performed a comprehensive review of the "12-hour" medications in the database, updating any identified drugs' information to default from every eight hours to every twelve hours.

A PubMed literature search did not yield any articles discussing the default time medication hazards. Thus, to our knowledge this is the first report regarding this problem.

Poster Title: Impact of clinical decision support on proton pump inhibitor utilization in an acute care hospital

Primary Author: Angela Weng, University of Illinois at Chicago College of Pharmacy, Illinois;
Email: weng.angela@gmail.com

Additional Author (s):
Andrew Merker
Zahra Khudeira

Purpose: Proton pump inhibitors (PPIs) are one of the leading treatments for various gastrointestinal (GI) disorders. However, it is estimated that only one-third of PPI use is clinically appropriate. Prolonged use of PPIs has been associated with increased fracture risk, hypomagnesemia, Clostridium difficile diarrhea, and pneumonia. Although it is commonly agreed there is a need to decrease PPI prescribing, there is sparse literature discussing methods to accomplish this in the inpatient setting. This project was designed to evaluate the effect of requiring PPI indications into an existing computerized order entry (CPOE) system in a hospital setting.

Methods: This was a retrospective, chart review study. A preliminary analysis was completed over one month for inpatient orders with intravenous (IV, including IV push and infusion) and oral (PO) pantoprazole and famotidine to assess baseline usage. Additionally, all orders were assessed on the last day of the month-long time period for an indication based on prescriber documentation.
Based on the results, the CPOE screen for pantoprazole orders was modified in an effort to curb inappropriate prescribing. The indication for pantoprazole orders had to be specified by the provider from a pre-populated list: treatment of erosive esophagitis, gastroesophageal reflux disease, hypersecretory conditions, duodenal ulcers, active GI bleeds, or GI prophylaxis in ICU patients (with one or more of the following: coagulopathy, mechanical ventilation for greater than 48 hours, spinal injury or traumatic brain injury, history of GI ulcers), or in high-risk patients (with two or more of the following risk factors: sepsis, ICU stay exceeding 7 days, occult bleeding for 6 days or more, or treatment with high dose corticosteroids). There was no

famotidine indication requirement added to CPOE. The medical staff was educated on the intervention prior to implementation.

After six weeks following implementation of clinical decision support, another one-month period of pantoprazole and famotidine usage was obtained with a single day snapshot assessing appropriateness of pantoprazole and famotidine indication for comparison to pre-implementation data.

Results: Following implementation of the new pantoprazole order screen, IV and PO pantoprazole orders decreased by 38 percent and 32 percent, respectively. However, post-implementation orders for IV and PO famotidine orders increased by 5 percent and 47 percent, respectively. Overall, pantoprazole use decreased by 34 percent compared to a famotidine increase of 25 percent. When assessing the appropriateness of orders post-implementation, there was a large decrease in pantoprazole or famotidine orders with either an unknown or inappropriate indication (28 percent) compared to baseline (58 percent). Medical staff entering orders selected the appropriate pantoprazole indication in 97 percent of orders.

Conclusion: Implementing PPI clinical decision support led to an overall decrease in pantoprazole utilization plus fewer pantoprazole and famotidine orders with unknown or inappropriate indications. Famotidine utilization increased after implementation of the clinical decision support, although the percentage increase in famotidine use was not equal to the magnitude of the percentage decrease observed with pantoprazole orders. Famotidine does not currently have clinical decision support for ordering, but this may be considered if inappropriate utilization continues to increase. This study provides support for the implementation of similar clinical decision support at other institutions to promote more appropriate use of PPIs.

Poster Title: Impact of epidural standardization on the safety and efficacy of epidural management

Primary Author: Lyly Tran, Chicago State University College of Pharmacy, Illinois; **Email:** ltran21@csu.edu

Additional Author (s):
Fadumo Mire
Mary Kate Miller
David Dickerson
Randall Knoebel

Purpose: In December 2015, the University of Chicago Medical Center reviewed all epidural solutions and developed a standardized process for selecting epidural solutions. New preferred solutions contained lower concentrations of both bupivacaine and opioid than what was standardly used. The purpose of this study is to evaluate if the new process for solution selection results in changes in drug concentration utilized and if so were analgesia or adverse events altered.

Methods: This single-center retrospective study evaluated the charts of adults aged 18 and over receiving thoracic epidural analgesia from December 2014 to June 2015 (pre-implementation) and from December 2015 to June 2016 (post-implementation). This project was formally determined to be quality improvement, not human subjects research, and was therefore not overseen by the Institutional Review Board, per institutional policy. The primary endpoint of this study was to determine if lower concentration of epidural medication results in a lower incidence of critical hypotension (mean arterial pressure less than 65 mmHg) 72 hours after initiation of thoracic epidural analgesia. Secondary endpoints include intensive care unit length of stay, strength of epidural solution used, efficacy of analgesia, and number of solution changes required.

Results: The rate of vasopressor utilization 72 hours after initiation of thoracic epidural analgesia was significantly less in the post-implementation group compared to the pre-implementation group (8.45 percent vs. 32.79 percent, p-value less than 0.001). There was a

significant difference in the types of epidural solutions used between the two study groups. Approximately 66 percent of patients in the pre-implementation group received one of the two lower concentrated solutions compared to 86 percent of the patients in the post-implementation group (p-value less than 0.001). Subgroup analyses, efficacy data, and rate of hypotension will be reported at the ASHP Midyear Clinical Meeting.

Conclusion: There is a significant difference in the types of epidural solutions prescribed pre- and post-implementation that resulted in a significantly lower rate of vasopressor utilization within 72 hours after initiation of thoracic epidural analgesia.

Poster Title: Implementation of a sepsis alert system and the impact on bundle compliance and clinical outcomes in the medical intensive care unit

Primary Author: Brittany Lee, University of Illinois at Chicago College of Pharmacy, Illinois; **Email:** lee562@uic.edu

Additional Author (s):
Dawn Hyatt
Scott Benken

Purpose: Sepsis accounts for approximately 10 percent of all admissions to the intensive care unit (ICU) and the reported incidence of sepsis continues to increase. The 2012 Surviving Sepsis Campaign guidelines promote the use of time-dependent care-bundle targets. The purpose of the study was to assess bundle compliance and clinical outcomes of patients in the medical intensive care unit (MICU), before and after implementing a sepsis alert system.

Methods: This was a retrospective, institutional review board approved, analysis of de-identified adult sepsis database examining the presence, absence, and timing of the surviving sepsis campaign care-bundle targets before and after the implementation of a sepsis alert system. Consecutive patients with severe sepsis or septic shock admitted to the University of Illinois (UI) Health MICU from 3/1/2015 to 10/27/2015 were included as the before-sepsis-alert group. Patients with severe sepsis or septic shock admitted to the UI Health MICU from 3/21/2016 to 9/26/2016 were included as the after-sepsis-alert group. Inclusion criteria were patients greater than 17 years of age diagnosed with severe sepsis or septic shock requiring MICU admission; the exclusion criteria included prisoners and pregnant females. Data collection consisted of baseline characteristics including demographics, comorbidities, and infection-related variables. Care-bundle characteristics included time to first antibiotic administration, time to drawing first lactate after hypotension (mean arterial pressure less than 65 mmHg), initial fluid amount, and time to vasopressor initiation. Treatment characteristics collected included appropriateness of antibiotic selection, need for vasopressors or inotropes, and total amount of fluid administered. The clinical outcomes assessed included response to fluids, response to vasopressors, length of stay (ICU and hospital), mortality (ICU and hospital), and discharge disposition.

Results: Fifty-two patients were identified who met inclusion criteria with 27 patients included in the before-sepsis-alert group and 25 patients included as the after-sepsis-alert group. Average time to first lactate was improved after the implementation of the alert system from 3.3 hours plus or minus 4.5 hours to 1 hour plus or minus 1.8 hours (P equals 0.018). The percentage of patients who achieved time to first lactate within 3 hours of first hypotension was 92 percent after the alert system compared to 63 percent before (P equals 0.013). The percentage of patients who received antibiotics within 3 hours improved from 74.1 percent to 84 percent though this did not reach statistical significance (P equals 0.381). There were no statistically significant changes in time to first antibiotic or time to initiation of vasopressors. Clinical outcomes did not change with the implementation of this alert.

Conclusion: Implementation of a sepsis alert system in the electronic medical record improved the percentage of patients who achieved sepsis bundle goals for time to first lactate as well as the average time to drawing the initial lactate. Additionally, there was improvement in the percentage of patients receiving antibiotics within the target time. This improvement was not statistically significant but carries meaningful clinical significance. The sepsis alert system has utility in the electronic medical record in achieving care-bundle compliance but the impact on clinical outcomes yet to be determined.

Poster Title: Outcomes associated with time-to-antibiotic administration among patients with febrile neutropenia in the emergency department

Primary Author: Amanda Firmansyah, Chicago State University College of Pharmacy, Illinois; **Email:** afirmans@csu.edu

Additional Author (s):
Hanh Nguyen
Monique Bidell
Zhe Han
Natasha Pettit

Purpose: Febrile neutropenia is an oncologic emergency, associated with mortality rates as high as 58 percent in patients with multiple comorbidities. Prompt administration of empiric broad-spectrum antibiotics is essential in preventing complications and death. The purpose of this study is to determine the outcomes associated with time-to-antibiotic administration among patients with febrile neutropenia presenting to the emergency department (ED).

Methods: This was a single center, retrospective chart review including patients that presented to the ED with febrile neutropenia between January 1, 2009 and April 24, 2013. Time to broad-spectrum antibiotics was determined by comparing ED presentation time to medication administration times as documented in the medication administration record. Patients in the study were divided into those that received antibiotics within 3 hours and greater than 3 hours from time of presentation. The primary objective of the study was to compare all-cause inpatient mortality between those that received antibiotics within 3 hours versus greater than 3 hours. The secondary objective of the study was to assess length of stay (LOS). Type of malignancy, absolute neutrophil count (ANC, cells/mm3) at time of admission, and vasopressor requirement were also assessed.

Results: A total of 57 patients were included in this study. Of the included patients there were 21 patients with solid tumors, 33 patients with leukemia, and 3 patients with no known malignancy. Twenty-six patients received antibiotics within 3 hours of presentation and 31 patients received antibiotics greater than 3 hours from presentation. The overall mortality rate

was 7 percent (4 patients); 3 of the patients that expired had received antibiotics greater than 3 hours (between 6-30 hours) from presentation (P=0.376). In the four deaths reported, three of the patients received a vasopressor. There was no statistically significant difference between vasopressor use in the two groups (P=0.567).

The median LOS was 4 days. The median LOS among those patients receiving antibiotics within 3 hours was 5.62 days, while those that received antibiotics greater than 3 hours had a LOS of 7.58 days (P=0.5559). The median ANC was 130 (cells/mm3). The greater than 3-hour group had a greater ANC than the within-3 hour group (199.6 cells/mm3 vs.118.1 cells/mm3; P=0.0164).

Conclusion: Based on the analyses, the rate of mortality in patients that received antibiotics within 3 hours was lower (3.8 percent) compared to those who received antibiotics greater than 3 hours from ED presentation (9.7 percent). Additionally, patients that received antibiotics within 3 hours had a median LOS that was approximately 2 days shorter than those receiving antibiotics greater than 3 hours after presentation. The differences between groups in terms of mortality and length was not statistically significant, however potentially clinically relevant. These results suggest a benefit to receipt of antibiotics within 3 hours for patients with febrile neutropenia.

Poster Title: Outcomes of multiple site Methicillin Susceptible Staphylococcus aureus infections: Getting to the source

Primary Author: Hankyung Cho, Midwestern University Chicago College of Pharmacy, Illinois; **Email:** hcho91@midwestern.edu

Additional Author (s):
Milena McLaughlin
Ashley Gale
Elise Gilbert
Viktorija Barr

Purpose: Methicillin sensitive Staphylococcus aureus (MSSA) blood stream infections (BSIs) are often treated with oxacillin or cefazolin as first-line options (standard therapy). However, other agents with reported susceptibility may also be considered for use based on convenience of dosing, concomitant infecting organisms, or patient allergies.
Patients with MSSA BSIs often have other concomitant site infections that may change or extend treatment. The purpose of this study was to evaluate outcomes in patients with MSSA infections originating from multiple sites treated with standard therapy (ST) versus other beta-lactam therapy (OBT).

Methods: This was a retrospective, cohort study of patients with MSSA BSIs plus another positive infection site treated with beta-lactam antibiotics as definitive therapy at an academic medical center between January 2012 and December 2014. Patients 18 years of age or older at time of culture and treated with definitive beta-lactam therapy for at least 48 hours were included in two groups: ST or OBT. The primary outcome was time to microbiological cure, measured as time to negative blood cultures. Secondary outcomes included infection recurrence, hospital length of stay, intensive care unit (ICU) length of stay, and inpatient mortality. This study was approved by the Institutional Review board at Northwestern University.

Results: There were 110 patients included in this study (n equals 23 OBT, n equals 87 ST). Baseline demographic

data was similar between groups. There was no difference in modified APACHE II score (p equals 0.65). A larger percentage of patients in the ST group had a wound as a second infection source (35.6 percent vs. 17.4 percent) and urine was the most common second infection source in the OBT group (n equals 7; p equals 0.12 overall). The primary outcome of time to negative blood cultures was not statistically significantly different between groups (p equals 0.75) and all patients in both groups cleared blood cultures. Patients in the ST group had a statistically significantly shorter median hospital length of stay than patients in the OBT group (12 days vs. 23 days, p equals 0.04); however, there was no difference in the ICU length of stay between groups (4 days vs. 11 days, p equals 0.13) or infections recurrence (n equals 3 vs. n equals 0, p eqauls 0.99). There was significantly lower in-hospital mortality in the ST group with 3 deaths (3.5 percent) compared to 6 deaths (26.1 percent) in the other OBT group (p less than 0.01).

Conclusion: For patients with MSSA BSIs and another concomitant site of infection, ST and OBT had similar time to negative blood cultures. Standard therapy was associated with significantly shorter hospital length of stay and lower in-hospital mortality. Future studies should focus on the impact of specific non-ST beta-lactam agent use in multi-focal MSSA infection.

Poster Title: Prevalence of obstructive sleep apnea and related risk factors in opioid prescribed patients

Primary Author: Ashley Kim, University of Illinois Chicago, Illinois; **Email:** kim143@uic.edu

Additional Author (s):
Adam Bursua
Lisa Kumor

Purpose: Opioid-induced respiratory depression and opioid related deaths have been on the rise. Obstructive sleep apnea and concomitant benzodiazepine use are well-known risk factors for opioid induced respiratory depression. The purpose of this study was to provide an estimate of the prevalence of diagnosed obstructive sleep apnea, risk factors for obstructive sleep apnea and other related risk factors for opioid-induced respiratory depression in a cohort of subjects prescribed opioid analgesic medications. Data regarding the prevalence of these risk factors could help support implementation of interventions to decrease the harm from opioid analgesic medications.

Methods: The institutional review board approved this retrospective, medical chart review assessing the presence of obstructive sleep apnea and related risk factors for opioid induced respiratory depression at the University of Illinois Hospital and Health Sciences System. Via a computer-generated prescribing report, investigators identified 250 subjects prescribed targeted opioid analgesic medications within the past year. Male and female subjects age 18 years or older who received their care at the University of Illinois Hospital and Health Sciences System were included. Investigators collected information on obstructive sleep apnea risk factors and diagnosis, and other risks related to sleep disordered breathing and opioid use that were present at the time of the opioid analgesic prescription. Many of the risk factors collected included those described in the STOP-BANG and Berlin Questionnaire obstructive sleep apnea screening tools. Data regarding the presence of additional opioid risk factors unrelated to obstructive sleep apnea were also collected. These risk factors include a history of cardiovascular and pulmonary disease and concomitant use of benzodiazepines and other non-benzodiazepine sedative medications. Data collected was analyzed to determine the prevalence

of obstructive sleep apnea risk factors, concurrent benzodiazepine use and additional cardiovascular or pulmonary risk factors.

Results: Fifty subjects were randomly identified within each stratification of the following targeted opioid analgesic medications: fentanyl transdermal patch, hydrocodone bitartrate-acetaminophen, hydromorphone hydrochloride, morphine sulfate, and oxycodone hydrochloride. Of the 250 subjects prescribed an opioid analgesic medication, 144 subjects were women and 106 subjects were men. A diagnosis of obstructive sleep apnea was found in 14.8 percent (n=37). Just under half of the cohort, 49.2 percent (n=123), had two or more risk factors for obstructive sleep apnea without a diagnosis and 22 percent (n=55) had three or more risk factors, suggesting significant risk of obstructive sleep apnea. Among the 250 subjects reviewed, 21.6 percent (n=54) of subjects had concurrently been prescribed a benzodiazepine within the last six months from the time of prescribing an opioid analgesic medication.

Conclusion: The high prevalence of risk factors for obstructive sleep apnea suggests opioid prescribing commonly occurs in patients who are at heightened risk of adverse effects. Interventions to formally assess obstructive sleep apnea in opioid prescribed patients with considerable risk factors are warranted. These interventions may include educational initiatives, prescribing alerts, pharmacist screening, and other measures. Overall, the prevalence shown may provide insight to healthcare professionals and affect the way they evaluate opioid prescribed patients.

Poster Title: Novel combination therapy with cisplatin, paclitaxel, and cetuximab in advanced head and neck cancer

Primary Author: Keith Riley, Rosalind Franklin University of Medicine and Science College of Pharmacy, Illinois; **Email:** keith.riley@my.rfums.org

Additional Author (s):
Ruth Nartey
Kati Cousins
Matthew Hoch
Megan Hartranft

Purpose: We reviewed the cases of two patients treated with a novel chemotherapy regimen for advanced head and neck cancer: paclitaxel 80 mg/m2 IV and cisplatin 30 mg/m2 IV on days 1 and 8 with cetuximab 250 mg/m2 IV on days 1, 8 and 15 every 21 days. EW, an 80 year old male who presented with advanced metastatic squamous cell carcinoma of the parotid gland treated with parotidectomy and radiation therapy. EW received three cycles of paclitaxel, cisplatin and cetuximab. On follow-up PET/CT scan he was noted to have no new lymph node involvement and metastatic tumor burden had decreased. Patient is currently being treated with weekly cetuximab maintenance therapy. DB, a 54 year old female who presented with metastatic laryngeal cancer with extension to the base of the tongue and had a tracheotomy. She completed three cycles of standard induction chemotherapy with docetaxel, carboplatin, and 5-fluorouracil (TPF) followed by chemoradiation with cisplatin. One year after completing adjuvant therapy, DB had recurrence of her disease, for which she underwent a laryngopharyngectomy and initiated combination chemotherapy with paclitaxel, cisplatin, and cetuximab. She received three cycles, then was found to have disease progression. Per NCCN guidelines, advanced head and neck cancer is treated with surgery +/- radiation, followed by combination chemotherapy with the preferred regimen being cisplatin/carboplatin + 5-FU + cetuximab. As demonstrated by these cases, the combination of cisplatin, paclitaxel and cetuximab may have potential for treatment in advanced metastatic squamous cell carcinoma of the head and neck. This new regimen was designed in order to optimize both efficacy, by replacing carboplatin with cisplatin, and patient satisfaction, by replacing 5-fluorouracil with paclitaxel. There is limited data to support this regimen in the head and neck cancer setting, but

with this case report, it is our intention to provide evidence upon which clinicians will be able to provide an alternate treatment option for patients who have progressed on previous therapies, or as induction therapy for patients with metastatic disease.

Poster Title: Evaluation of prescribing patterns and long-term safety of rivaroxaban and apixaban in a large, academic medical center

Primary Author: Dalila Masic, Midwestern University Chicago College of Pharmacy, Illinois; **Email:** dmasic21@midwestern.edu

Additional Author (s):
Elizabeth Greenhalgh
Denise Kolanczyk

Purpose: Direct oral anticoagulants have become attractive alternatives to warfarin for anticoagulation with non-valvular atrial fibrillation (NVAF) and venous thromboembolism (VTE). These agents have simpler pharmacokinetics, fewer drug-drug interactions and require less monitoring. Previous studies have assessed the prescribing patterns of dabigatran and rivaroxaban due to variations in dosing for different indications, but there is a lack of literature assessing prescribing patterns of the other formulary agent at our institution, apixaban. The primary objective of this study was to determine the appropriateness of prescribing patterns for rivaroxaban and apixaban. Secondary objectives included long-term safety outcomes.

Methods: A retrospective data analysis of electronic medical records was conducted for adults who received at least one dose of rivaroxaban or apixaban during hospitalization with an indication for NVAF or VTE from July 1st through December 31st, 2015. Patients were excluded if there was missing data on height, weight or serum creatinine. The following data was collected: age, weight, height, renal function, anticoagulant indication, CHA2DS2VASc score, prior to admission use, concomitant medications that may increase bleeding risk or cause potential drug-drug interactions, inpatient dosage strength, number of administered doses, laboratory parameters (hemoglobin, hematocrit, platelets, liver function tests, and international normalized ratio [INR]), documented systemic embolism (stroke or VTE), bleeding, and education provided by nursing or pharmacy. Appropriateness of prescribing was based on FDA-approved indications, dose and renal function. If initial prescribing was inappropriate, whether it was changed during hospitalization or at discharge was also collected. Bleeding was defined as major bleeding or bleeding that required discontinuation. Descriptive statistics were

employed to characterize prescribing patterns and a Chi-square test was used for categorical data. This study was approved by the Institutional Review Board.

Results: A total of 150 patients receiving rivaroxaban (n=75) and apixaban (n=75) were analyzed. Indications for NVAF in the rivaroxaban and apixaban groups were 49 (65.3%) and 54 (72%), respectively. There was no difference between rivaroxaban and apixaban on appropriate prescribing patterns (86.7% vs. 86%, p=1.00). Although not significant, apixaban had more inappropriate regimens changed on admission or discharge compared to rivaroxaban (admission: 40% vs. 10%, respectively, p=0.18; discharge: 30% vs. 10%, p=0.32). Incorrect dose was the reason for inappropriate prescribing in all patients, with one rivaroxaban patient having both incorrect dose and frequency. Three patients experienced a new VTE (rivaroxaban=1, apixaban=2) and two patients had major bleeding in the rivaroxaban group. Therapy was discontinued in all cases. Other reasons for discontinuation included low platelets (n=1) and high INR (n=2) among rivaroxaban recipients; worsening renal function (n=3), high INR (n=1), no insurance coverage (n=1) and transition to hospice (n=1) among apixaban recipients. Neither agent was given concomitantly with a strong CYP3A4 inducer or inhibitor. Documented patient education occurred in 72% of rivaroxaban patients and 61.3% of apixaban patients, with nurses documenting 98.1% and 93.6% of provided education, respectively. Pharmacy only documented education for 8.1% of patients receiving apixaban.

Conclusion: This study revealed no difference between the prescribing patterns of rivaroxaban and apixaban. The most common reason for inappropriate dose was due to an incorrect dose, and further studies are needed to assess inappropriate regimens on long-term safety outcomes. Efforts to improve safe and appropriate prescribing may include more structuring for computerized order entry. The low percentages of documented education is alarming, and warrants increased awareness on the importance of providing education prior to discharge.

Poster Title: Medication adherence assessed by community health workers compared with patient self-report

Primary Author: Connie Yan, University of Illinois at Chicago - College of Pharmacy, Illinois; **Email:** yan33@uic.edu

Additional Author (s):
Lisa Sharp
Ben Gerber
Daniel Touchette

Purpose: Accurate adherence assessment is challenging, yet important. Clinicians often rely on patient self-report to assess medication adherence. Community health workers (CHW) who conduct home visits with patients offer a different perspective, and may be able to identify non-adherent patients and provide support for clinicians to address barriers to medication adherence. However, the agreement between self-reported adherence and CHW assessed medication adherence has not been previously established. The purpose of this study was to assess the agreement between patient self-report and CHW assessment of medication adherence in African-American and Hispanic patients with uncontrolled type 2 diabetes.

Methods: Data was collected as part of a larger NIH funded study assessing pharmacist-CHW team-based care model. Two hundred forty-four African-American and Hispanic patients with uncontrolled type 2 diabetes (HbA1c ≥8%) were recruited from within the University of Illinois Health ambulatory clinics in Chicago. Patients received support from a CHW through home visits, clinic encounters and phone calls for 12 months. This analysis focused on the 137 patients whose adherence was assessed by a CHW.
Patient self-reported adherence to oral diabetes and hypertension medications was measured using the 8-item Morisky Medication Adherence Scale (MMAS-8). The MMAS-8 was categorized as "high" (score of 8), "medium" (6-7), or "low" (< 6). CHW's assessment of patient adherence was measured on a five-point Likert scale ranging from "very adherent" to "not adherent." Ratings from both adherence assessments were obtained after the CHW worked with the patient for one year.

Agreement between the MMAS-8 and CHW's assessment was calculated using the total percent agreement (i.e. adherent and non-adherent on both assessments) and Cohen's kappa. MMAS-8 scores of 6 to 8 were considered "adherent." Patients were considered adherent on the CHW assessment with "very" and "moderately" adherent ratings. A sensitivity analysis was conducted including the "somewhat" adherent rating as adherent to assess whether agreement with the MMAS-8 improved. All analyses were conducted using Microsoft Excel and IBM SPSS v22.

Results: Agreement between the CHW assessment and patient reported MMAS-8 totaled 50.4% (kappa of 0.077). For the sensitivity analysis, the overall observed agreement was 40.9% (kappa of 0.036). Specifically, patients were characterized as adherent on both CHW assessment and MMAS-8 23.3%, non-adherent on both 27%, adherent (CHW) and non-adherent (MMAS-8) 38.7%, and non-adherent (CHW) and adherent (MMAS-8) 10.9% of the time. When evaluating MMAS-8 categories compared with Likert CHW responses, there appeared to be general agreement between the two scales with some notable exceptions. For example, the CHW assessment of "moderate" adherence (the second-highest level on the CHW assessment) most frequently corresponded with a "low" (18.3% of all cases) or "medium" (17.5%) adherence on the MMAS-8. Likewise, a CHW assessment of "somewhat" adherent corresponded with a "low" (8.8% of all cases) or "medium" (11.7%) adherence on the MMAS-8. As exceptions, 5.8% of patients who responded to the MMAS-8 scale as "high" adherence were assessed by CHW's as "poorly" or "somewhat" adherent. Also, 5.9% of patients responding to the MMAS-8 as "low" adherence were assessed as "very" adherent by CHW's.

Conclusion: The agreement between patients' self-report and CHW assessment had only slight agreement. These two adherence assessment methods likely focus on different adherence behaviors or domains. While the MMAS-8 measures intentional and unintentional behaviors associated with adherence, the CHW assessment offers a subjective, general assessment of adherence. Other differences may include social desirability and recall bias with self-report measures, or indistinct categorization with either method. Further studies are needed to standardize an assessment methodology performed by CHW on patient medication adherence.

Poster Title: Evaluation of patient outcomes for daptomycin treated bloodstream infections using fixed dose, weight adjusted and standard dosing approaches

Primary Author: Zarha Amlani, Midwestern University, Illinois; **Email:** zamlani48@midwestern.edu

Additional Author (s):
Kristen Nelson
Kathryn O'Brien
Marc Scheetz
Nathaniel Rhodes

Purpose: Daptomycin (DAP) is a frequently used therapy for Gram positive blood stream infections (BSI), usually dosed according to total body weight (TBW). In June 2013, our center adopted a standardized fixed dosing scheme for DAP according to TBW to promote safety and reduce waste. We sought to assess whether treatment outcomes differed between patients treated with weight based DAP (mg/kg) and fixed dose DAP for Gram positive BSI. Vancomycin (VANC) treated patients will be used as comparators in a case-control design.

Methods: We conducted a retrospective, pre/post interventional study comparing case failure rates to control success rates (DAP) adjusted for contemporaneous control success rates (VANC) before and after implementation of the standardized fixed dosing protocol at our academic medical center. The odds of failure on DAP will be calculated relative to the odds of failure on VANC with pre/post as the primary interest. Included subjects will have BSI due to either Staphylococcus aureus or Enterococcus spp. and received DAP or VANC as a directed therapy from January 1, 2010 to June 30, 2014. VANC treated patients will serve as controls and will be frequency matched 4:1 against DAP treated patients. Case exclusions: presence of polymicrobial BSI, recipient of DAP for more than 7 days prior to BSI, recipient of other antibiotics for more than 5 days or primary meningitis, osteomyelitis, or pneumonia caused by Gram positive organisms. Control exclusions: similar to case exclusions, except controls cannot be recipients of DAP within 7 days prior to BSI. Data elements and patient variables will be collected to determine DAP efficacy and toxicity before and after protocol implementation. A sample of convenience will be utilized.

Results: Of the patients included in this study, the average modified APACHE II score and the number of patients with a positive culture in the ICU were statistically greater in VANC treated patients than DAP treated patients. All other demographics were not significant between both groups. We defined clinical cure as culture negative by the end of the planned therapy. Treatment failure was defined as switching antibiotics due to persistence of bacteremia, metastatic infection or recurrence of S. aureus or Enterococcus spp., a positive blood culture after a negative culture during inpatient treatment. Based on the interim statistical analysis of the data there is no statistical difference in the primary outcomes between the pre- and post-protocol groups.

Conclusion: To our knowledge, this is the first study that assesses the efficacy of a fixed dose, weight based DAP dosing scheme. Based on the results, patient safety was not compromised from standardized weight-based dosing of DAP. Additional analysis will be performed as additional control patients will be included with broader range of illness severity and infected with Enterococcus spp bacteremia. An expanded case-case-control analysis of GPBSI will be conducted using 3:1 ratio of contemporary comparators to Daptomycin-treated cases in order to minimize the effect of practice variation over time, additional clinical confounders, and small sample size.

Poster Title: Establishing a process aimed at salvaging medications after temperature excursions

Primary Author: Darren Le, Rosalind Franklin University of Medicine and Science, Illinois; **Email:** darren24le@gmail.com

Additional Author (s):
Joe Bodkin
William Budris

Purpose: The control of storage and stability parameters is an important aspect of the pharmacist's role in the healthcare setting. With the collaborative system of highly developed technology and skilled pharmacy team members, medications are able to be stored in their appropriate environments ensuring administration of quality products to patients. Despite this multifaceted approach in maintaining the medication's properties, accidental events can occur which inevitably expose the medications to undesired temperatures. This process was established to salvage medications following a temperature excursion.

Methods: There was an accidental occurrence in the central pharmacy which affected the refrigerators' temperature as well as prevented pharmacists from receiving notifications regarding unstable conditions. When it was discovered that the medications were potentially exposed to out-of-range temperatures for an extended period of time, a team of two pharmacist and two pharmacy students in the administration department collaborated to address the issue. To prevent administration of drugs with potentially impaired quality, the pharmacist and students sequestered the medications away from the normal pharmacy inventory. The pharmacy team retrieved vital information regarding the various drugs' stability and storage parameters via review of package inserts and phone calls with representatives at corresponding pharmaceutical companies. The pharmacist created a scripted template to follow in order to guarantee all necessary information was obtained. All interactions with the various representatives were documented and any in-house data retrieved from them was stored for future reference. Upon assessing all available data, the destination of each medication was determined to be usable, damaged, or have an altered shelf-life.

Results: The two pharmacists and two pharmacy students examined the package insert and product labeling to acquire information regarding the storage and stability of 60 different products of concern. Phone calls with representatives at respective pharmaceutical companies were also made to collect in-house data and recommendations regarding the various drug products. After completing the assessment, forty-six out of sixty drugs (76.6 percent) were able to salvaged. All data obtained was charted on the excel spreadsheet and saved into a designated folder for future reference. In total over 400,000 dollars worth of medications were salvaged.

Conclusion: Protocolized assessment and collection of data regarding storage and stability parameters were helpful in salvaging 76.6 percent of medications with temperature excursions totaling over 400,000 dollars. This process has utility in future accidental events where drugs might have impaired quality due to storage in unwanted conditions. Ultimately, this project served as a method of establishing guidelines and preventing financial and pharmaceutical waste.

Submission Type: Descriptive Report

Session-Board Number: 5b-435

Poster Title: Impact of pharmacy students conducting asthma screenings and telephone calls on asthma quality measures

Primary Author: Riya D'Silva, University of Illinois at Chicago, Illinois; **Email:** rdsilv2@uic.edu

Additional Author (s):
Tracy Souvannasing
Rebecca Stone
Paul Stranges

Purpose: UI Health-Family Medicine Clinic (UIH-FM) is incentivized to provide high quality asthma care through pay per performance measures. Quality measures include: completion of an Asthma Action Plan (AAP) (goal greater than or equal to 80 percent), goal percentage of members with controlled asthma (greater than or equal to 66 percent), and intervention for patients without controlled asthma. To improve quality performance, pharmacy students were utilized in a telephone outreach program to conduct an Asthma Control Test (ACT) and a review of patient specific AAP. This study was analyzed to assess the program for successful completion of an ACT and AAP.

Methods: A retrospective chart review was conducted to evaluate patients in a telephone asthma outreach program at UIH-FM between October 1, 2015 and January 31, 2016. Patients were identified by insurers based on diagnosis codes, prescription claims, and emergency room (ER) visits provided to clinic. A structured intervention was designed utilizing student pharmacists to conduct an ACT and review a patient specific AAP. If patients were not reached after two calls, their AAP would be mailed with a request to contact the clinic. Outcome and time spent on phone calls were recorded. Patients with uncontrolled asthma were scheduled to make an appointment with their primary care physician (PCP) or contact the clinical pharmacist. Data was collected from Research Electronic Data (REDCap) and Microsoft Excel. Descriptive statistics were used to assess completion of asthma assessment and education as well as time effort to complete measures.

Results: A total of 137 patients were contacted through 174 calls to evaluate asthma treatment and management. A total of 63 (46 percent) patients completed ACTs, among this there were

42 (31 percent) ACTs completed on the first call and 24 (18 percent) ACTs completed on the second call There were 48 (76 percent) patients with controlled asthma (ACT 20 or higher), 7 (11 percent) poorly controlled (ACT 16 to 19), and 8 (13 percent) very poorly controlled asthma (ACT 15 or less). Without student intervention, 34 percent of patients received AAPs, however, with the additional help from the outreach program, students were able to increase AAP to 100 percent. Average total time spent on phone calls was 5 minutes (excluding student work-up time and documentation).

Conclusion: Pharmacy students were successfully utilized to complete annual ACT and AAP through a telephone intervention. Pharmacy students were able to identify poorly controlled asthma, evaluate asthma triggers, and educate on exacerbation management. The student intervention was able to increase team-based care and meet quality measures without increased work-load on clinic staff.

Poster Title: Galleria mellonella virulence model of ciprofloxacin resistant Escherichia coli acquired during pre-prostate biopsy rectal screens

Primary Author: Jhanvi Shah, Midwestern University, Chicago College of Pharmacy, Illinois; **Email:** jshah57@midwestern.edu

Additional Author (s):
Merika Starr
Rebecca Jett
Cristina Miglis
Marc Scheetz

Purpose: Transrectal ultrasonography guided prostate biopsy (TRUSBx) is one of the most commonly performed outpatient procedures, however post-procedural infections are a known complication. These infections can be due to organism virulence, efficacy of antibiotic prophylaxis or host immune system function. To study organism virulence we utilized a Galleria mellonella (GM) model using isolates obtained during TRUSBx from infected and non-infected patients.

Methods: Prior to TRUSBx, rectal swabs were obtained of ciprofloxacin resistant isolates from patients. Using standard procedures, organisms were identified and susceptibility testing was performed. Aliquots of 1-2 x 10^5 CFU per 10 uL for each isolate were injected into the hemocele of GM weighing between 250-350 mg (n= 20). The two control groups consisted of GM receiving either no injection or equivalent volumes of normal saline. All of the GM isolates were incubated at 37C and observed every 24 hours for 5 days. Kaplan-Meier survival curves and log rank tests were used to assess mortality.

Results: Mortality occurred in 20% of the saline injection GM and 5% of the no-injection GM controls. GM injected with isolates obtained from the non-infected patients had a higher incidence of mortality (75%) compared to the GM injected with isolates obtained from infected patients at 5 days (27.5%, p< 0.001). Two of the isolates produced extended-spectrum beta lactamases (ESBLs). GM inoculated with ESBL (-) isolates had a mortality rate of 47.5% while the ESBL (+) isolates had a mortality rate of 62.5%, p= 0.051%.

Conclusion: E. coli isolates obtained from non-infected patients and ESBL (+) isolates were more virulent in the GM model compared to infected patient isolates and ESBL (-) isolates, respectively.

Poster Title: Student perspectives of a media evaluation assignment in a women's health elective

Primary Author: Danielle Pham, Midwestern University Chicago College of Pharmacy, Illinois; **Email:** dpham93@midwestern.edu

Additional Author (s):
Kathleen Vest
Brooke Griffin

Purpose: There are limited studies regarding instructing students in healthcare graduate programs to evaluate health information in the media. Surveys as validation tools have been used to evaluate health care stories in the media, but the use of such tools by student pharmacists has not been evaluated. The aims of this project are to assess the abilities of third year student pharmacists enrolled in a women's health elective to evaluate women's health related articles and to assess students' confidence and knowledge of evaluating health related media articles following a media evaluation assignment.

Methods: Students enrolled in a women's health elective were surveyed following the completion of a required class assignment to assess their confidence, knowledge, and opinions on evaluating news articles in the media following the assignment. The required assignment involved evaluating a media news story and the corresponding journal article using the Media Evaluation Rubric, completing a role-play counseling exercise in class, and giving a group presentation. Students were asked to complete a brief survey online of several Likert-style questions to assess student perceptions of the project. Participation in the survey was optional.

Results: Eight out of eleven (72.7 percent) students completed the survey. All students agreed (62.5 percent) or strongly agreed (37.5 percent) that the media evaluation assignment increased their awareness that not all media stories portray an accurate report of healthcare in the news. All students agreed that the assignment would help them to communicate with patients about reporting in the media. Most students agreed (75 percent) or strongly agreed (12.5 percent) that their knowledge on what criteria to look for when evaluating news stories was increased after the assignment and it was an effective way to help them understand how

to evaluate news stories in the media. Almost all students (87.5 percent) considered the project to be a valuable learning experience, 75 percent considered the Media Evaluation Rubric to be a useful tool to help evaluate news stories, and 87.5 percent were confident in their ability to communicate with their patients about news stories in the media. A majority of students (87.5 percent) reported that they had not previously participated in an activity in which they were to evaluate a media news story for accuracy and potential bias.

Conclusion: Utilizing a media evaluation rubric is a potentially effective way to teach pharmacy students how to evaluate media news stories for accuracy and bias. The media evaluation assignment appears to be a useful tool to help students better communicate with patients and health care professionals regarding health news stories in the media.

Poster Title: Asymptomatic bacteriuria and the need for antimicrobial stewardship in a large academic medical center

Primary Author: Jane Lee, Midwestern University Chicago College of Pharmacy, Illinois; **Email:** jlee328@gmail.com

Additional Author (s):
Holly Harrison
Ameen Pirasteh
Sheila Wang

Purpose: Urinary tract infections (UTIs) account for a vast majority of antimicrobial use. Hospitals have found the use of antibiotics for asymptomatic bacteriuria (ASB) to be inappropriate. Untreated ASB has not been shown to cause harm except in pregnant women and patients who endure traumatic urologic procedures. Furthermore, treating ASB can be a risk factor in developing symptomatic UTIs and multi-drug resistant pathogens. The purpose of this study was to assess the management of ASB in a large academic medical center to identify potential needs for antimicrobial stewardship efforts.

Methods: This retrospective chart review was submitted to the appropriate Institutional Review Boards for approval. Study patients were identified from a list of urine cultures (n equals 1524) generated from the microbiology department between July 2014 and June 2015. Inpatient cases of ASB defined as having a positive urine culture (greater than or equal to 10 to the fifth power CFU per mL) with undocumented signs or symptoms of a UTI were included. Patients were excluded if they had a yeast infection, urologic abnormality, cultures from a catheter or nephrostomy tube, repeated urine culture less than or equal to 7 days of index collection, underwent a urologic procedure, was neutropenic, pregnant, less than 18 years of age, received antibiotics for concomitant infections, or had greater than 2 species of organisms in urine. Using electronic medical records, the following patient variables were collected and assessed: patient demographics, urinalysis and urine culture, uropathogens, antibiotics, duration of antibiotic treatment, infectious diseases consult, and length of stay.

Results: Ninety-three unique patients met inclusion criteria for ASB. Urine cultures were obtained from the emergency department (ED) for all 93 cases of ASB regardless of an insignificant urinalysis. Many urine cultures were ordered at the same time as the urinalysis. The most common uropathogens included Escherichia coli (26 percent), Klebsiella pneumoniae (9 percent), Enterococcus species (5 percent), and alpha-hemolytic Streptoccoci, Group B (5 percent). Eighty-nine percent of cases of ASB received at least one day of antibiotics and over half of cases received an average of 5 days of treatment. Up to 92 percent of antibiotics were initiated in the ED. Fluoroquinolones were the most common antibiotic selected for treatment. Documentation of altered mental status, dementia or seizures was identified with 27 ASB cases (29 percent). Only 8 cases of ASB (8.5 percent) received an infectious disease consult during their hospital stay.

Conclusion: ASB is being inappropriately treated with antibiotics at our institution with fluoroquinolones having the most utility. Very few cases of ASB requested an infectious diseases consult for guidance. Based on our findings, antimicrobial stewardship efforts to reduce inappropriate antibiotic treatment for ASB are warranted with early attention placed in the ED.

Poster Title: Health promotion and disease prevention in ethnic minority groups: Effect of a health-screening elective on student pharmacists' knowledge and confidence

Primary Author: Irfana Lakada, Midwestern University Chicago College of Pharmacy, Illinois; **Email:** ilakada99@midwestern.edu

Additional Author (s):
Jane Lee
Sheila Wang
Sally Arif

Purpose: Providing community health screenings is an area in which student pharmacists can significantly promote disease education and prevention. Variability in student learning makes it difficult to assume adequate training and education have been achieved to participate in events and/or communicate effectively with ethnic minority populations. The primary objective of this study was to compare the knowledge and self-confidence of student pharmacists who completed a health screening elective course, targeting ethnic minority groups, to non-elective students. Knowledge and self-confidence were compared between second (PS-2) and third-year student pharmacists (PS-3) as a secondary objective.

Methods: This study was approved by the Midwestern University institutional review board and performed with student consent. Thirty-two student pharmacists (16 PS-2s and 16 PS-3s) enrolled in a health screening elective course at Midwestern University Chicago College of Pharmacy during the academic year of 2016-2017 served as our case group. A quantitative longitudinal panel survey was distributed to elective student pharmacists (ES) before and after the course. This survey included a 16-question quiz, assessing their disease state knowledge on diabetes, hypertension and dyslipidemia. Technique using cardiometabolic equipment and communication skills interacting with a patient from a diverse cultural background in a simulated patient encounter were evaluated via a grading rubric. Thirty-one non-elective student pharmacists (NES), who served as our control group, were evaluated at a health-screening event using the same survey and grading rubric. Scores for knowledge, self-confidence along with technical and communication skills were compared between ES and NES. Descriptive data summaries were presented using frequencies for categorical variables and

means for quantitative variables, including knowledge scores. Bivariate analysis was conducted by using independent samples t-test, paired t-test, Chi Square, and McNemar's Chi Square. Multivariate analysis was conducted via simultaneous estimation techniques, including multiple regression and multiple logistic regression.

Results: ES performed better on the knowledge quiz questions compared to NES; however, the difference was not significant as the average percent of questions correct was 74.2 and 68.3, respectively, p equals 0.07. Confidence of disease state knowledge and application of knowledge and overall skills were significantly better with the ES versus NES, p less than 0.001. A significant difference was also observed when comparing communication and technical skills between ES and NES at the health screening event, p less than 0.001. ES obtained demographic information, asked about patient history of disease state and health beliefs, and concluded the screening session with questions from the patient. When comparing skills, more ES accurately interpreted the results, demonstrated understanding of the patients' disease state, and tailored counseling to the patients' cultural beliefs. PS-2 ES performed better on the knowledge quiz questions compared to PS-3 ES (77.3 percent versus 71.3 percent, p equals 0.164). The pre-elective survey indicated PS-3 ES were more confident than PS-2 ES. However, post-elective survey results showed PS-2 ES were just as confident as PS-3 ES. While PS-3 ES scored higher in all areas of skills, communication and technical, there were no significant differences between the two years.

Conclusion: There was no difference in knowledge between student pharmacists who were enrolled in the elective course versus those who were not. However, ES were more confident and expressed improvement in overall skills than NES. Overall, there were no significant differences between PS-2 ES and PS-3 ES in terms of skills and communication; however, PS-2 ES seemed to gain more knowledge and self-confidence upon completion of the course than PS-3 ES.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Evaluative Study

Session-Board Number: 5b-440

Poster Title: Breaking real and perceived barriers to voluntary reporting of safety events by pharmacy personnel in an acute care institution

Primary Author: Tina Lertharakul, Midwestern University Chicago College of Pharmacy, Illinois; **Email:** tlertharakul57@midwestern.edu

Additional Author (s):
Katherine Gauen
Lara Ellinger

Purpose: Voluntary incident reporting by healthcare personnel discloses adverse events and medication errors so improvements can be made to patient safety and quality of care. It is important to establish and encourage an effective and continuous incident reporting system to promote safety and prevent recurrences of errors and adverse events. The purpose of this study is to improve voluntary reporting of medication safety events by pharmacists and pharmacy technicians in an acute care hospital setting. Increased reporting will allow for clearer identification of safety event trends, for which prevention measures can be placed.

Methods: An anonymous survey on attitudes and barriers to reporting in the Northwestern Events Tracking System (NETS) was created in SurveyMonkey and emailed in September 2016 to the pharmacy department (171 pharmacists and 112 technicians) at Northwestern Memorial Hospital in Chicago, IL. The survey was 17 questions, and included questions on awareness of the NETS, as well as attitudes on using the NETS as measured by a Likert scale. Prior to sending out the survey, pharmacy staff were informed of the optional, anonymous survey at staff meetings and team huddles, and were encouraged to complete it. Staff had 2 weeks to complete the survey and received 2 email reminders to complete it.
The same survey will be emailed to the same group after education and process improvement(s) have been implemented, in order to measure changes in awareness of the NETS process and any changes in barriers to use.
In order to assess any changes in reporting, the number of medication safety events (those that are categorized as "Adverse Drug Reactions" and "Medication/Fluid") reported in NETS by pharmacists and pharmacy technicians will be measured during planned three-month periods

before and after education and process improvement(s) are implemented based on initial survey results. The timeframe for data collection will range from December 2015 to June 2017.

Results: Prior to this survey, it was found that 34 event reports were made by pharmacists and 3 were made by pharmacy technicians from December 2015 through February 2016. Of the 283 pharmacy personnel who received the survey, 114 completed it (40.3 percent response rate). The majority of respondents work in an inpatient setting (83.3 percent) and the majority of the respondents were pharmacists (71.9 percent). Most of the respondents are aware of the NETS (98.23 percent) and of how to access and submit reports (95.5 percent), but many reported they rarely (34.23 percent) or never (18.02 percent) report an event through the NETS. The top three reported barriers to reporting are as follows: fear of distrust among colleagues for submitting a report involving them (35.9 percent), a lack of follow-up after an incident report is submitted (33.9 percent), and fear that information can be traced back to the person submitted the report (32 percent).

Conclusion: After assessing perceived and real barriers to incident reporting, the survey results warrant a review of the NETS process and staff education. Improvements will be made through better communication to staff on events and how they are handled, education on using the NETS in forms of learning modules and presentations at staff meetings, and overall updates to the current NETS form to streamline the submission process. After staff education and improvements to the NETS process are made, the repeated survey and remeasure of reporting by pharmacy personnel will assess the efficacy in methods used to break barriers to incident reporting.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Descriptive Report

Session-Board Number: 5b-441

Poster Title: Four-factor prothrombin complex concentrate for the reversal of direct oral anticoagulants and warfarin

Primary Author: Edith Liang, Midwestern University Chicago College of Pharmacy, Illinois; **Email:** eliang13@midwestern.edu

Additional Author (s):
Michelle Tomeczkowicz
Elizabeth Davidson
Allyson Wexler
Megan Rech

Purpose: Four-factor prothrombin complex concentrate (4F-PCC) contains inactive coagulation factors II, VII, IX, X, protein C, and protein S. In the acute setting, 4F-PCC has been used successfully for the rapid reversal of warfarin and direct oral anticoagulants (DOAC) when a life threatening bleed occurs or an urgent surgical procedure is necessary. The purpose of this study is to characterize the use of 4F-PCC at Loyola University Medical Center in Maywood, Illinois.

Methods: This retrospective medication use evaluation was conducted to identify patients who received 4F-PCC for anticoagulation reversal between July 2014 and August 2016. Data collection included patient demographics, primary service, and intensive care unit (ICU) and hospital length of stay (LOS). The following laboratory parameters were collected: international normalized ratio (INR), activated partial thromboplastin time (aPTT), and prothrombin time (PT) before and after reversal. The dose and indication for reversal with 4F-PCC, along with efficacy and safety outcomes, were evaluated.

Results: Of the 78 patients, 62 (79.5 percent) were on warfarin and 16 (20.5 percent) were on a DOAC with a median age of 69 versus 77 years old (P equal 0.02). Common indications for 4F-PCC included: intracranial hemorrhage (56.5 percent warfarin versus 37.5 percent DOAC), trauma (6.5 percent warfarin versus 37.5 percent DOAC), gastrointestinal bleed (9.7 percent warfarin versus 12.5 percent DOAC), urgent surgical procedure (4.8 percent warfarin versus 6.3 percent DOAC), and anticoagulation reversal prior to heart transplant (22.6 percent warfarin

versus 6.3 percent DOAC). Upon admission, median INR for patients on warfarin of 2.2 decreased to 1.2 following administration of 4F-PCC. The median time to evaluate INR reversal was 148 minutes between administration and laboratory collection. The median PT in the warfarin and DOAC patients upon presentation was 24.3 seconds and 16.3 seconds, which then decreased to 13.7 seconds and 13.1 seconds, respectively, after 4F-PCC administration. The median aPTT from baseline to after administration of 4F-PCC was 40 seconds to 31.4 seconds for warfarin and 35 seconds to 32.4 seconds for DOACs. Adverse effects associated with the administration of 4F-PCC were limited to deep vein thrombosis (9.4 percent). Mortality during hospitalization occurred in 16 patients (20.5 percent).

Conclusion: Overall, 4F-PCC was utilized mostly commonly for patients experiencing a life-threatening bleed or in need of an urgent surgical procedure. Opportunities to improve exist for the time of laboratory collection of INR, PT and aPTT after administration of 4F-PCC.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Descriptive Report

Session-Board Number: 5b-442

Poster Title: Evaluation of post-marketing safety: A demonstration with blinatumomab-associated pancreatitis

Primary Author: Matthew Steinbrenner, Midwestern University Chicago College of Pharmacy, Illinois; **Email:** msteinbrenner93@midwestern.edu

Additional Author (s):
Daniel McCarville
Kevin Hoshizaki
William Budris

Purpose: To describe the multi-step process used for evaluating the available post-marketing surveillance data, regulator actions, and publications on a drug-associated adverse reaction. This was prompted by a July 13, 2016 Health Canada advisory about life-threatening pancreatitis associated with blinatumomab (Blincyto) use, that was subsequently not found in the FDA-approved product labeling. This process was conducted to help guide institutional awareness and possible monitoring in patient use.

Methods: Approved labeling for blinatumomab from the U.S. and foreign regulators was compared at several time points. Multiple drug databases were consulted to check for related content and for change over time. FDA Adverse Event Reporting System (FAERS) reports were evaluated and the European Medicine Agency's (EMA) EudraVigilance adverse event database was accessed. The medical literature and conference proceedings were searched for relevant publications. The adverse reaction signal value of the reports was investigated. The completed steps will be supplemented by checking for new FAERS and EMA reports after an additional month interval, and finally be complemented by a retrospective review of actual case use at this institution.

Results: Product labeling variance was encountered, with the U.S. and EMA lagging behind Australia and Canada for inclusion of pancreatitis as a possible adverse reaction. After the FDA updated the warnings and precautions section of the approved labeling on August 30th, the drug databases updated their content. FAERS and EudraVigilance had both included reports within their available records and overlapping cases were noted. There was also a disparity

between the ease of use of EudraVigilance compared to FAERS; the latter required extensive manipulation of downloads to extract information. A subsequently calculated adverse event signal according to the methods of Sakaeda and Evans was found to suggest a true drug-adverse reaction association. The results from additional time-points of observation will be combined with the preliminary findings for presentation. Recommendations for pharmacists will also be included to assist them in detecting, evaluating and acting on early emerging safety information that can affect patient care. The internal retrospective case series review will be provided to the Northwestern Memorial Hospital Pharmacy and Therapeutics Committee together with the post-marketing findings.

Conclusion: Post-marketing adverse drug reaction information is not uniformly recognized and incorporated into product labeling on a global scale, nor into drug databases. There is variance in response and lag time before this information is added into widely used standard drug resources. Based on the experience from this example, we can share specific steps to help pharmacists perform a uniquely proactive support role in their practices. They will understand how to watch for and evaluate emerging drug safety issues across multiple regulators in addition to the FDA, in order to apprise health practitioners of these concerns.

Submission Type: Evaluative Study

Session-Board Number: 5b-443

Poster Title: Community blood pressure screenings: Impact of incorporating 'teach-back" counseling and text message reminders

Primary Author: Suleman Shah, Midwestern University CCP, Illinois; **Email:** sulemanshah@me.com

Additional Author (s):
Irfana Lakada
Shaziya Barkat
Sana Aziz
Sally Arif

Purpose: Student pharmacists frequently participate in community blood pressure screenings. Patients identified with an elevated blood pressure are provided lifestyle education (e.g. diet & exercise) and encouraged to seek further medical care. Currently, it is not clear if patients make an effort to visit a healthcare provider or incorporate lifestyle changes based on the education they receive at the screening. The purpose of this study is to determine if "teach-back" counseling during a blood pressure screening followed by electronic text message tips/reminders can improve patients' 1) knowledge of hypertension self-care behavior and 2) self-reported medication adherence and follow-up with medical care.

Methods: The Midwestern University institutional review board approved this prospective, randomized, parallel-group study, which took place over the course of one student-led community health screening event in December 2015. English speaking, adult patients with elevated blood pressure readings who provided informed consent were recruited and randomized in a 1:1 fashion into an intervention group (personalized teach-back counseling followed by weekly text message reminders about lifestyle/diet changes and medication adherence) or a usual care group (generic blood pressure counseling provided only at the health screening event). All patients received a questionnaire and an educational pamphlet during the health screening event. The questionnaire assessed patients' baseline 1) knowledge of blood pressure management (10 questions quiz) and 2) self-reported medication adherence using the Morisky Medication Adherence Scale (MMAS). The questionnaire was administered again at the end of a three month period through a telephone call follow-up. Change in the quiz

and the MMAS scores from baseline to three months was compared between the same study arm using categorical paired samples and were analyzed using McNemar's chi square test. In order to compare changes between the usual care and intervention arm at baseline and three months, an independent samples analysis was performed using a Chi-square test.

Results: Fourteen patients met the inclusion criteria (intervention arm with the mean age 52.1 years and control arm with the mean age 55.9 years). Over half (57.1 percent) of all patients had a history of hypertension. The majority of patients in the control and the intervention arms rated their health as good/fair but not excellent (71.4 percent and 85.7 percent, respectively). Approximately 42.8 percent of patients in the control arm were under the care of a physician as opposed to 71.4 percent in the intervention arm. Three month follow-up was completed with 12 patients where they were asked about their follow-up with medical care, medication adherence, and health comprehension. Five patients had followed up with their primary care physician (2 in the intervention arm; 3 in usual care) and reported being within their blood pressure goal (BP less than 140/90). Assessment quiz scores for knowledge of blood pressure management increased from baseline for all patients in both study arms (pre-quiz equals 65 percent and post-quiz equals 80 percent, p equals 0.007). Specifically, quiz scores were higher in the intervention group compared to the control group (83.3 percent versus 70 percent).

Conclusion: Overall, there was an increase in knowledge of blood pressure management from baseline in both the control and intervention arms. However, those that received "teach-back" counseling during the blood pressure screening and electronic text message tips/reminders increased their knowledge base to a greater degree than the control group.

Poster Title: Outcomes of a semester long student pharmacists' personalized interventions for inpatient tobacco dependence

Primary Author: Shelby Duncan, University of Illinois at Chicago College of Pharmacy, Illinois; **Email:** sdunca5@uic.edu

Additional Author (s):
Lori Wilken

Purpose: Tobacco cessation prevents deadly complications. Hospitalized patients are surrounded by influential healthcare providers that can provide treatment for tobacco dependence. Student pharmacists receive education about tobacco dependence and treatment during their didactic education and are increasingly having opportunities during experiential education to assist patients with this addiction. The primary objective of this project is to characterize the interventions made and recommendations accepted by the tobacco dependence student pharmacy consult service. The secondary objectives are to document the 30-day post discharge quit rates of patients that received consults and to evaluate the learning experience of the student pharmacists.

Methods: A student pharmacist service for tobacco dependence treatment was established to serve hospital patients at the University of Illinois Hospital. Nurses assess the status of tobacco use and readiness of the patient to quit tobacco upon admission to the hospital. A consult is generated to the tobacco treatment center. Student pharmacists look up patients to address current and past medical conditions, social history, concurrent medications, prescription coverage, and laboratory results. After evaluating the patient, a patient specific plan is created. The student pharmacist presents the patient to the clinical pharmacist who approves or suggests changes to the treatment plan. The student pharmacist completes the consult in the patient's hospital room by assessing withdrawal symptoms and the need for treatment after discharge from the hospital. If medication is needed for withdrawal symptoms, the student pharmacist contacts the physician responsible for the patient to give a recommendation for treating tobacco dependence. The patient receives written educational material including resources for outpatient support, directions for proper medication use and a behavioral trigger plan. A follow up post-discharge phone call is provided to document the tobacco status and the

use of medications to treat tobacco dependence. The student pharmacist documents the consult in the electronic medical record and evaluates the learning experience by providing a letter grade in REDCap, a database for quality improvement.

Results: The service reached 51 hospital patients in an approximately 4-month period using 6 second and third-year student pharmacists. These patients were receptive to having student pharmacists ask questions and assess their tobacco cessation status. The 51 patients received behavioral trigger plans and medication recommendations, if desired. Out of the patients assessed in the hospital, 14 were reached by telephone by the same counselor who provided the consult during their hospital stay. After telephone follow up, 7 patients were confirmed to have quit tobacco since the consult. Student pharmacists spent on average, 18 minutes providing each consult and 15 minutes documenting their interventions. Twenty of the consults received an "A", indicating that the student pharmacists learned about a new disease state or medication, provided a recommendation for treatment and the healthcare team accepted the recommendation.

Conclusion: Consults provided by student pharmacists are well received by the hospitalized patients and the healthcare team. Efforts by student pharmacists to assist patients with tobacco dependence treatment improve patient care, increase student pharmacists' confidence with counseling patients and applying therapeutic knowledge. A student pharmacist service for tobacco dependence treatment demonstrates positive effects on quit rates for hospitalized patients and effective learning experiences.

Poster Title: Vancomycin-resistant enterococcus in the central nervous system: A case report and evaluation of outcomes with daptomycin and linezolid

Primary Author: Aishwarya Shankar, Midwestern University, Chicago College of Pharmacy, Illinois; **Email:** ashankar37@midwestern.edu

Additional Author (s):
Benjamin Lee
Nicholas Panos
Sheila Wang

Purpose: A 47-year-old male with human immunodeficiency virus (CD4 greater than 475; viral load 1625), receiving antiretroviral therapy, presented to the hospital with chronic fatigue, night sweats, unintentional weight loss, and localized numbness to his face and feet. He was diagnosed with Burkitt's lymphoma and was subsequently started on chemotherapy. Day 10 of hospital admission, the patient was neutropenic with fevers, empirically treated with cefepime and vancomycin, and presenting with mental status changes. Day 11, blood cultures were significant for Streptococcus mitis. The following day, repeat blood cultures grew vancomycin-resistant Enteroccocus faecium (VREF) that was resistant to ampicillin (minimum inhibitory concentration (MIC) greater than 8 mg/mL) and susceptible to daptomycin (MIC equal to 2 mg/mL), linezolid (MIC less than 1 mg/mL), and positive for gentamicin synergy. The vancomycin was changed to daptomycin (8 mg/kg intravenous (IV) daily). Extended spectrum beta-lactamase producing Escherichia coli was also isolated from a urine culture and cefepime was changed to meropenem. Day 21, repeat blood cultures returned positive again for VRE. Gentamicin (1 mg/kg IV every 8 hours) was added to daptomycin therapy for synergy and the central line was removed due to concern as a potential source of bacteremia. Day 27, blood cultures were persistently positive for VRE, thus gentamicin was increased to 7mg/kg IV daily and ceftriaxone 2 grams IV every 12 hours was added for empiric coverage of infective endocarditis. Transesophageal echocardiogram was negative for vegetation. By day 30 the fever curve improved and blood cultures were cleared of infection. Treatment course was planned to finish with daptomycin alone. However, the patient also complained of concurrent headache, stiff neck pain and nausea. A cerebrospinal fluid (CSF) analysis indicated white blood cells 892 x 10^3/microliter (94 percent polymorphonuclear neutrophils), red blood cells 1,000 x

10^6/microliter, total protein count 137 mg/dL and glucose 3 mg/dL (serum 84 mg/dL). Therefore, ceftriaxone (2 grams IV every 12 hours) and ampicillin (3 grams IV every 6 hours) were initiated to cover for bacterial meningitis. Treatment course with daptomycin for VRE bacteremia was near completion when CSF cultures returned positive for VRE on day 36. Daptomycin was changed to linezolid 600 mg IV every 12 hours. Ceftriaxone and ampicillin were discontinued over the next two days. Day 42, repeat CSF analysis significantly improved and CSF cultures were negative for bacterial growth. The patient was instructed to complete 21 days of linezolid. CNS infections caused by VRE are extremely difficult to treat, limited to antimicrobial agents with in vivo activity that are capable of penetrating the CSF. Meningitis caused by VREF is rare, occurring in 0.3-4 percent of all bacterial meningitis cases. Linezolid is currently recommended for VRE meningitis. While daptomycin possesses bactericidal activity against enterococcal species, the drug's penetration into the CSF is low (5-6 percent). Linezolid, although bacteriostatic for enterococci, offers an improved meningeal concentration over daptomycin with a CSF penetration as high as 70 percent. This case introduces successful treatment of VREF with linezolid after potential failure with high-dose daptomycin and gentamicin.

Poster Title: The implementation of co-curricular case-based discussion sessions: taking aim at enhancing student knowledge outside the classroom

Primary Author: Katherine Sencion, University of Illinois at Chicago College of Pharmacy, Illinois; **Email:** ksencion44@gmail.com

Additional Author (s):
Daniel Gratie
Sheila Allen
Adam Bursua

Purpose: The role of a pharmacist within healthcare is constantly evolving and there is need for pharmacy curriculum to adapt accordingly. While traditional therapeutics courses will always remain a staple of academic institutions, additional opportunities for a student to think critically and problem-solve through real clinical cases has the potential to increase a student's confidence and comfort level with therapeutic knowledge and better prepare them for their career in pharmacy. With this goal in mind, two student pharmacists acting as chapter presidents of their respective pharmacy organizations collaborated to develop extracurricular case-based discussion sessions.

Methods: Sessions occur on a biweekly basis, starting one hour prior to regularly scheduled class times. At each meeting, a third year student pharmacist introduces a de-identified patient case by summarizing the subjective and objective patient data. A facilitating clinician is open to interject at any point, and leads the discussion on how the presented patient should be approached by a pharmacist. Points of discussion typically include how the clinicians themselves would treat the patient, important lab values to consider, and mistakes they commonly see in treating similar patients. Moreover, facilitators introduce relevant literature to support the clinical decisions being discussed. Students in the audience are also encouraged to ask questions at any point, or answer questions as posed by the facilitator. Student coordinators are responsible for distributing an RSVP form one week prior to the next session, securing a facilitating clinical pharmacist for each session, and obtaining and de-identifying patient cases from volunteering P3 and P4 students. The patient case, relevant literature or guidelines, and a medical abbreviations and lab values "cheat sheet" for first year students is

distributed to RSVP'ed students at least 1 day before each session. A follow up e-mail with any additional literature discussed in the session is distributed to students who attended. A brief informal survey is also included in order to obtain feedback to continue to improve future sessions.

Results: Student interest and positive feedback consistently grew during the pilot semester of the case-based sessions. Throughout the spring semester of 2016, 23 students attended the pilot session, 29 attended the second session, 33 attended the third, 28 attended the fourth, 44 attended the fifth, 18 attended the sixth, 20 attended the seventh, and 26 attended the eighth session. Moreover, students interacted with 5 different clinicians, including the dean of the college. Most student feedback focused on the sessions providing a stress-free place of learning. Feedback from P1 and P2 students also indicated that students appreciated being exposed to clinical decision making earlier in their curriculum.

Conclusion: Voluntary case-based discussion sessions implemented at our college of pharmacy has become a mainstay in students' schedules, with increasing interest and positive feedback. Sessions have successfully included student pharmacists at all levels of their education, with younger students appreciating a preview for pharmacotherapy courses, and older students taking the chance to review their clinical decision making skills. Sessions will continue to be held in future semesters, complemented by new voluntary journal club sessions every other week. In the future, we aim to assess the perceived value students find in these sessions, in an effort to continue to improve pharmacy education.

Poster Title: Pharmacist interventions to decrease readmission rates amongst human immunodeficiency virus (HIV)-infected patients in transitions of care settings

Primary Author: Kavita Parikh, Midwestern University Chicago College of Pharmacy, Illinois; **Email:** kparikh35@midwestern.edu

Additional Author (s):
Roud Al-Nabulsi
E. O' Donnell
Milena McLaughlin

Purpose: Despite innovations with antiretroviral therapy, patients with HIV continue to have significant hospital readmission rates and decreased quality of care when transitioning between hospital and ambulatory settings. A focus towards improving long-term health of these high-risk patients is necessary to provide better patient care as Medicare's Hospital Readmission Reduction Program is reducing reimbursements to hospitals with increased 30-day readmissions. A pharmacist may bridge the gap of transitioning across environments by encouraging medication adherence, resolving medication access issues, and minimizing unnecessary treatments. We sought to identify potential transitions of care environments in which pharmacists may intervene for patients with HIV.

Methods: Transitions of care interventions for pharmacists regarding patients with HIV were compiled. A primary literature search was completed to identify different environments through which patients with HIV may transition. The search was done through PubMed using keywords HIV, transitions, care, readmission, and Center for Medicare & Medicaid Services (CMS). We looked at review articles, experience interviews and clinical trials demonstrating themes for transition environments and interventions in which pharmacists were involved.

Results: Many clinical trials and review articles illustrated that patients with HIV transitioning from one environment to another usually have little to no knowledge regarding their medications and management of HIV. These transitions of care include outpatient to inpatient and then to outpatient as well as the following transitions more specific to HIV: adolescents that transition from having caregivers (e.g. parents) to becoming their own caregivers and

prisoners that transition from the prison into society. Pharmacists must work with the healthcare team throughout the transition period to utilize strategies to increase the patients' knowledge of their conditions and medications. Interventions can be made though counseling, medication reconciliation, and follow up post discharge. Counseling can be done to ensure that the patient understands why they are using their medications, how to use it, and what to expect from the medication. Pharmacists can ensure timely re-initiation of HIV therapy as well as identify and correct medication errors through medication reconciliation. In addition, they can also assist healthcare providers in finding the optimal medication regimen for each specific patient based on health, and economic factors.

Conclusion: A pharmacist can provide thorough and complete medication evaluations while providing patient education and alternative treatment options using best practice models and evidence-based guidelines. Improving communication across settings may alleviate many of the medication related issues patients with HIV face such as health illiteracy, non-adherence, and medication side effects. Counseling, medication reconciliation, and post-discharge services provided by the pharmacist can be particularly beneficial for HIV patients transitioning from one environment to another.

Poster Title: Implementation and evaluation of a preconception peer education program for pharmacy students

Primary Author: Madeline Johnston, Midwestern University College of Pharmacy - Glendale, Arizona; **Email:** mjohnston97@midwestern.edu

Additional Author (s):
Erin Raney
Shareen El-Ibiary
Thomas Womack

Purpose: Knowledge about preconception health is important for all healthcare providers as it pertains to every woman and man of childbearing age. Pharmacists can uniquely influence preconception health and promote positive pregnancy outcomes through counseling on nutritional supplements, medication risks during pregnancy, tobacco cessation, immunizations, disease state management, and family planning. The U.S. Department of Health and Human Services Office of Minority Health (USDHSS OMH) developed a preconception health peer education certificate training program to improve the availability of preconception health information to the public. This study describes the implementation and evaluation of this certificate program for pharmacy students.

Methods: A cohort study design was used to survey pharmacy students who elected to participate in a preconception peer education certificate program at a college of pharmacy. The certificate program, sponsored by USDHSS OMH, consisted of a one-day live training program delivered by College of Pharmacy faculty followed by additional participation in webinars and peer education events within a one-year time period. An electronic survey was created using Qualtrics LLC 2016 software and distributed via email to all participants at the completion of the certificate program. The survey assessed demographics and perceptions of the preconception peer education program. Reminder emails were sent out one week later for non-responders. Completion of the survey was voluntary. Descriptive statistics were used to characterize data. The study was approved the University's Institutional Review Board.

Results: The survey of 37 student attendees yielded a 46% response rate. Most participants were female (87%). A majority of participants (86%) indicated the reason for attending the program was to increase knowledge about their personal reproductive health and 78% indicated it was to help provide better care to patients. After completing the program, the average rating ("1" being poor and "5" being excellent) of students' self-reported knowledge and confidence increased from 2.29 to 3.21 (p equals less than 0.001) and 1.93 to 3.07 (p equals 0.002), respectively. Eighty percent of participants agreed or strongly agreed that preconception health is relevant to pharmacy practice and 33% agreed or strongly agreed that all pharmacy students should complete this program. Post program completion, 71% of the students reported that they have talked with at least one to five friends, family members, patients or classmates about preconception health with 14% talking to 11 or more people. All of the participants stated they would recommend the program to their colleagues.

Conclusion: A preconception peer education program is useful for pharmacy students. Participants would recommend the program to others. The program helped increase pharmacy students' knowledge and confidence as indicated by self-report. In addition, after completing the program, a majority of participants discussed preconception issues with others including peers and patients. Incorporating the USDHSS OMH preconception peer education program may be an option for pharmacy schools to help students increase their awareness of preconception health for themselves, their peers and patients.

Poster Title: Brentuximab vedotin for treatment of non-Hodgkin lymphomas: A systematic review

Primary Author: Garrett Berger, The University of Arizona College of Pharmacy, Arizona; **Email:** garrettkberger@gmail.com

Additional Author (s):
Ali McBride
Stephanie Lawson
Kelsey Royball
Faiz Anwer

Purpose: Brentuximab vedotin (BV) is an antibody-drug conjucate (ADC) comprising a CD30-directed antibody, conjugated to the microtubule-disrupting agent MMAE via a protease cleavable linker. BV is FDA approved for use in relapsed classical Hodgkin lymphoma (HL) and relapsed systemic anaplastic large cell lymphoma (sALCL). There are multiple publications for its utility in other malignancies such as diffuse large B-cell lymphoma (DLBCL), mycosis fungoides (MF), Sézary syndrome (SS), T-cell lymphomas (TCL), primary mediastinal lymphoma (PMBL), and post-transplant lymphoproliferative disorders (PTLD). We believe that BV could potentially provide a strong additional treatment option for patients suffering from non-Hodgkin lymphoma (NHL).

Methods: We performed a systematic review on the use of BV in NHL and other CD30+ malignancies in humans in which the primary study outcomes utilized objective response rate (ORR) as a measure. We searched various databases including PubMed (1946-2015), EMBASE (1947-2015), and Cochrane Central Register of Controlled Trials (1898-2015) yielding 2753 records plus an additional 43 screened from a WHO ICTRP search. Inclusion criteria specified all studies and case reports of NHLs in which BV therapy was administered. Studies with HL, non-human populations, and no reported objective response outcome were excluded from the systematic review. The titles and abstracts of screened articles were reviewed independently by three reviewers (G.K.B., S.L., K.R.). Full articles that were potentially relevant to study were reviewed with the original three reviewers in addition to the fourth reviewer (K.G.) to confirm

the eligibility. Any discrepancies were resolved after group discussion with the four aforementioned reviewers.

After excluding 1110 duplicates, the remaining 1686 records were screened for relevance based on their titles and abstracts. Of these 1686, 73 were deemed potentially eligible and retrieved for full text review. After detailed review, a total of 46 records were further excluded. A total 27 articles met our inclusion criteria: phase II (n=7), phase I (n=6), phase I/II (n=1) and case reports (n=13).

Results: Utilizing the twelve clinical subtypes that we found clinical evidence of BV, we stratify the study populations into three specific groups: B-cell malignancies (group A), T-cell malignancies (group B), and non-B or non-T-cell hematological malignancies (group C).

Across the group A malignancies (DLBCL, PTLD, GZL, PMBL, FL), there were a total of 87 patients. 48% (n=42) experienced an objective response (OR). Further stratified, 26% (n=23) achieved complete remission (CR), 22% (n=19) experienced a partial response (PR), 23% (n=20) maintained stable disease (SD), and 37% (n=32) suffered progressive disease (PD).

Across the group B malignancies (ALCL, SS/MF, TCL, LyP, pc-ALCL), there were a total of 274 patients. 74% (n=203) experienced an OR. Further stratified, 43% (n=119) achieved CR, 27% (n=74) experienced a PR, 5% (n=14) maintained SD, and 11% (n=30) suffered PD.

Across the group C malignancies (PBL, GCT, MC), there were a total of 9 patients. 44% (n=4) experienced an OR. Further stratified, 0% (n=0) achieved CR, 44% (n=4) experienced a PR, 22% (n=2) maintained SD, and 33% (n=3) suffered PD.

Conclusion: Our findings indicate that BV induces a variety of responses, largely positive in nature and variable between 10 NHL subtypes. We noted positive responses specifically within the following NHL subtypes: DLBCL, PTLD, GZL, sALCL, SS/MF, LyP, pc-ALCL, PBL and GCT. With additional, properly powered prospective studies, BV alone or in combination with other agents, need to be studied in prospective trials for various CD30+ malignancies.

Submission Type: Evaluative Study

Session-Board Number: 7-003

Poster Title: Assessment of a pharmacist vancomycin dosing policy and opportunities for standardization

Primary Author: Sara Andrus, The University of Arizona College of Pharmacy, Arizona; **Email:** andrus@pharmacy.arizona.edu

Additional Author (s):
Dana Bowers

Purpose: Appropriate dosing and monitoring is essential for optimal antimicrobial therapy. A pharmacy pharmacokinetic (PK) dosing policy has been in place for over 10 years and was updated in early 2014 at a community hospital. This policy, in conjunction with current vancomycin dosing guidelines (Therapeutic Monitoring of Vancomycin in Adult Patients), provide recommendations for initial dosing, trough timing and frequency, and additional monitoring. The purpose of this study was to assess vancomycin dosing and monitoring by pharmacists, and identify opportunities for standardization in a community hospital.

Methods: This was a retrospective chart review of patients who were on the pharmacy PK dosing service from April – August 2016. Approximately 20 cases were selected for inclusion into the study. Demographic data such as gender, age, weight and height were collected. Microbiological data collected included positive cultures from all sites and organisms isolated. Additional information collected included patient indication for treatment, previous vancomycin therapy, vancomycin dosing, therapy duration and vancomycin troughs. The primary endpoint was to determine if vancomycin dosing and trough monitoring followed current guidelines and hospital PK policy. The secondary endpoints included length of vancomycin therapy, subsequent troughs, vancomycin dose adjustments and opportunities for de-escalation.

Results: Twenty three patient cases were included; 52.4 percent were female with an average age of 66 years. The most common treatment indication was skin and skin structure infections (10 patients). There were a total of 11 positive cultures. Ten cultures grew Gram-positive organisms (3 were methicillin resistant Staphylococcus aureus) and 3 patients grew Gram-negative organisms. Ten patients (43.4 percent) had previous vancomycin therapy and 2

patients were started on their previous dose. For the primary endpoints, six patients (26 percent) were dosed according to the current vancomycin dosing guidelines and vancomycin troughs were evaluated in 20 patients (25 percent were found in goal range based on treatment indication). For the secondary endpoints, the median length of therapy was 5 days (range 1 to 31 days). Additionally, 7 patients had initial troughs measured after three maintenance doses, 5 patients had troughs measured sooner and 8 patients had troughs measured later. There were a total of 60 troughs measured during 23 patient courses of vancomycin. Of those who had an initial trough measured, 16 patients (80 percent) had their vancomycin dose adjusted. Twenty patients (87 percent) had an opportunity to de-escalate therapy from vancomycin.

Conclusion: Variations in pharmacist dosing of vancomycin were found for initial dosing and trough monitoring, creating opportunities for education and standardization of practice. The next phase of this project will be for pharmacist education and competencies focusing on vancomycin dosing, trough timing, dose adjustments and frequency of monitoring.

Submission Category: Pain Management

Submission Type: Evaluative Study

Session-Board Number: 7-004

Poster Title: Pharmacist strategies for the self-management of pain

Primary Author: Daniel Vergel de Dios, The University of Arizona College of Pharmacy, Arizona;
Email: vergeldedios@pharmacy.arizona.edu

Additional Author (s):
Daniel Trinh
Ramon Chavez
Marion Slack
Jeannie Lee

Purpose: The management of pain has been a constant healthcare issue. There have been numerous pain management studies using physician and nurse subject populations, but no such studies have been conducted using a pharmacist population. The purpose of this project is to evaluate self-treatment strategies for pain used by pharmacists, and to allow for valuable insight into the methods employed when managing acute or chronic pain. The specific aims of this study are to determine preferential use between pharmacological and non-pharmacological strategies, preference between strategies for acute versus chronic pain, and whether age and gender might affect management strategies.

Methods: The survey for this study was formulated by two pharmacy professors and three pharmacy students, and adapted from several different pain management surveys. The study was approved by the University institutional review board. Upon completion, the survey was sent to all pharmacists with an email address registered with the State Board of Pharmacy. The survey was made available online through the program Qualtrics. Data collected from the survey was automatically entered into an Excel database and was de-identified. The survey was separated into the following categories: incidence and characteristics of pain, strategies for managing pain, outcomes, and demographics. The questions for descriptors of pain focused on the frequency and intensity of pain experienced. Questions for pain management evaluated how pharmacists treat their pain, including the frequency of usage for prescription drugs, over-the-counter products, and non-pharmaceutical methods. The outcomes questions evaluated treatment efficacy, and the demographics section collected participant data in regards to age,

gender, employment, etc. Additional variables analyzed include how often pain medications are taken, the use of natural or cultural medications, and the severity of pain.

Results: Responses were received from 417 pharmacists. 219 pharmacists reported acute pain (mean age of 44; 35 percent men), 206 reported chronic pain (mean age of 53; 53 percent men), and 55 reported no pain (mean age of 48; 64 percent men). The chronic pain group was more likely to have a disability with poor or fair health status (P less than 0.006). Participants with chronic pain reported higher levels of pain before treatment (6.9 versus 5.8), higher therapeutic goals and arthritis, neuropathy, or sciatica as a cause of pain (P less than 0.03). Women with any pain were more likely to report migraines than men (P less than 0.05). Older participants with chronic pain reported a higher level of tolerance to pain and a higher therapeutic goal for pain (P less than 0.05). Participants with chronic pain were more likely to use anti-inflammatory drugs, opioids, and non-medical strategies than acute pain participants (P less than 0.005). Both groups reported similar relief from all strategies (76 percent versus 78 percent; P equals 0.397), but the chronic pain group reported higher levels of pain after treatment (3.2 versus 2.0), less confidence in pain management, and less satisfaction (P less than 0.004).

Conclusion: Age and gender did not affect the use of specific pain management strategies or the amount of pain relief received from all strategies used by participants with either acute or chronic pain. Participant responses and management strategies for chronic pain differed significantly from those for acute pain in pain before treatment (5.8 versus 6.9), the level of tolerable pain (4.2 versus 4.6), pain level post treatment (2.0 versus 3.2), the therapeutic goal for pain (1.5 versus 2.2), and the ability to sleep with pain (2.8 versus 3.6).

Poster Title: In vitro aerodynamic analysis of co-spray dried fluticasone propionate (FP) and salmeterol xinafoate (SX) with lactose alternative excipient

Primary Author: Monica Malapit, The University of Arizona College of Pharmacy, Arizona;
Email: malapit@pharmacy.arizona.edu

Additional Author (s):
Evan Mallory
Priya Muralidharan
Heidi Mansour

Purpose: It is estimated that 0.5 percent of the adult population has a lactose allergy and would be unable to use the Advair Diskus (FP and SX) product since it is formulated with a lactose excipient. Furthermore, the FP and SX product is formulated via a micronization process, whereas spray dried formulations achieve greater deposition in the targeted respiratory bronchioles. The purpose of this study was to conduct an in vitro comparative analysis of the aerodynamic performance of a co-spray fried formulation of FP and SX with a mannitol excipient to the Advair Diskus 250/50 (FP and SX) product.

Methods: Utilizing mannitol as an excipient, a co-spray dried FP and SX powder was prepared using the Buchi Mini-Spray Dryer B-290 under closed system configuration. A feed solution of 5 to 1 molar ratio of FP to SX was prepared in order to match the Advair Diskus 250/50 device. The resulting feed solution was spray dried at various pump rates of 25, 50, and 100 percent with all other parameters remaining constant (aspiration, atomization rate, nitrogen gas rate). The primary outcome measure was aerodynamic performance which was assessed using the Copley Next-Generation Impactor (NGI). The resulting NGI data was used to calculate mean mass aerodynamic diameter (MMAD), geometric standard deviation (GSD), and fine particle fraction (FPF) of each powder, including the Advair Diskus device. Secondary outcomes included determining water content and size distribution using Karl Fischer titration and scanning electron microscopy, respectively.

Results: Aerodynamic analysis studies were triplicated for each powder. Calculations for FPF, MMAD, and GSD have been described elsewhere. Briefly, FPF was calculated directly from NGI data, whereas MMAD and GSD was calculated using Wolfram Alpha software using the NGI data. T-test regression analysis was used to compare spray-dried powders to the Advair Diskus powder. All statistical tests were 2-sided with p values of less than 0.05 being considered statistically significant. The MMAD values for each spray dried sample was analyzed using a t-test regression against the MMAD values from the Advair Diskus. Fine particle dose is reported as a percentage of the emitted dose, based on the mass recorded from stages 2-7, which represent aerodynamic equivalent of particles 4.46 microns or less in size.

There was no significant difference between the spray dried formulations versus the Advair Diskus for MMAD and GSD (p-values greater than 0.05). The 50 percent and 100 percent pump rate samples had similar FPF to the Advair Diskus (p-value greater than 0.05). However, the 25 percent pump rate sample had a significantly improved FPF compared to the Advair Diskus (p-value of less than 0.01).

Conclusion: In conclusion, the procedures outlined by this study demonstrate that a spray-dried formulation of FP and SX with a mannitol excipient has similar performance to the Advair Diskus product. Of significance, a 25 percent pump rate spray-dry conditions demonstrated an improved FPF compared to the Advair Diskus product. Future studies would be to focus on optimizing other spray-drying variables. Larger scale studies are needed to demonstrate replicability.

Submission Type: Descriptive Report

Session-Board Number: 7-006

Poster Title: Healthcare professionals as study subjects: a scoping review

Primary Author: Alison Arpaia, University of Arizona College of Pharmacy, Arizona; **Email:** arpaia@pharmacy.arizona.edu

Additional Author (s):
Sara Andrus
Marion Slack
Jennifer Martin

Purpose: There are several large studies, such as the Nurses' Health Study and the Physicians' Health Study, as well as a variety of other smaller studies that use healthcare professionals as study subjects. However, there is no available information on whether any of these studies involve pharmacists or on the rationale for using health professionals as subjects. The purpose of this study is to conduct a scoping review of studies involving healthcare professionals as study subjects and to describe the methods used, identify the topics researched, and to describe the rationale and limitations of using healthcare professionals as subjects.

Methods: The study was a scoping review of research utilizing health professionals as study subjects. To be included in the review, a study must have included doctors, nurses, or pharmacists as the subjects and must have been written in English. Studies were excluded if the study was a case study, commentary, or editorial. A comprehensive literature search was conducted in Embase, PubMed MEDLINE, Cochrane Library, PsycINFO, Cumulative Index to Nursing and Allied Health Literature (CINAHL), Scopus, and International Pharmaceutical Abstracts. The Physicians' Health Study, Nurses' Health Study, and Health Professionals Follow-Up Study websites reference studies that have been derived from the original cohorts. A systematic sample of every tenth study referenced for each cohort was also collected. Two investigators independently screened the studies, collected data, and met to resolve discrepancies. Data collected included purpose of the study, data collection method, study design, population type, and rationales and limitations to using healthcare professionals as study subjects. The primary endpoint was to determine types of methods used to collect data from the population. The secondary endpoint was to identify the rationale for having health professionals as the subjects of studies.

Results: Sixty-five studies met the eligibility criteria. A total of 45 percent of the studies evaluated cardiovascular events, 25 percent evaluated cancer, nine percent examined ophthalmic events, five percent examined cognitive issues, and 17 percent consisted of miscellaneous topics. Of the 65 studies, 65 percent were prospective studies. In 58 studies (87 percent) questionnaires were utilized as the data collection method. Physicians were defined as a primary study subject in 30 studies (45 percent). Nurses were specified as a primary study subject in 20 studies (30 percent). In 20 studies (30 percent), the population was derived from the Health Professionals Follow-Up Study, where multiple types of health professionals were subjects. The number of each type was undefined. No study included in the sample identified pharmacists as a study subject. A total of 41 studies (63 percent) did not list any rationales or limitations to utilizing health professionals as subjects. Of the 24 studies that did discuss rationales and limitations, the most frequently cited advantage was reliable self-reporting (38 percent of the studies that listed rationale or limitation). The most common limitation to generalizability was high socioeconomic status (21 percent of those reporting rationale or limitation).

Conclusion: Questionnaires were found to be the most common type of method to collect data from healthcare professionals. Physicians were the most often studied type of health professional, followed by nurses. High reliability of data reporting was found to be a common rationale in using health professionals as subjects. The lack of studies utilizing pharmacists as subjects demonstrates an opportunity that should be further evaluated.

Poster Title: Assessment of drug-induced QT interval prolongation and associated risk factors

Primary Author: Christine Phu, University of Arizona College of Pharmacy, Arizona; **Email:** christinephu@email.arizona.edu

Additional Author (s):
Benita Daniel
Eva Liang
Georgina Rubal-Peace
Kateryna Yenina

Purpose: Long QT syndrome (LQTS) is a cardiac disorder characterized by a prolonged corrected QT (QTc) interval on an electrocardiogram (ECG). Drug-induced LQTS is a safety concern associated with an increased risk of torsades de pointes, a condition known to cause syncope, palpitations, and sudden cardiac death from ventricular fibrillation. There are several risk factors and over 200 medications associated with QTc prolongation. The purpose of this study was to assess the incidence of QTc prolongation observed in patients taking multiple QTc prolonging drugs and with potential risk factors for LQTS.

Methods: This was a retrospective chart review which used data from electronic health records. Individuals at least 18 years of age who were admitted to the psychiatric, medical, surgical, or intensive care units of an academic medical hospital in Tucson, Arizona for a minimum of 24 hours from January 2015 to December 2015 were included if they had a recorded ECG after the administration of at least two QTc prolonging medications. A list of drugs associated with QTc prolongation was generated based on the hospital's formulary. Patients who met the inclusion criteria were assessed for risk factors for QTc prolongation, number of QTc prolonging medications received, and presence of QTc prolongation. The QTc interval was considered prolonged if it was greater than 450 milliseconds in men and 470 milliseconds in women. Risk factors examined included age over 65 years, the female sex, a history of cardiovascular disease, and electrolyte disturbances. A chi-square test was used to compare the incidence of QTc prolongation in patients taking two, three, or four or more QTc prolonging medications. Logistic regression was performed using Statistical Package for the

Social Sciences (SPSS) to find the association between risk factors and the incidence of QTc prolongation.

Results: Of the 158 patients examined, 81 (51.3 percent) had documented QTc prolongation following the administration of at least two QTc prolonging drugs. Of the individuals who received two, three, or four or more QTc prolonging drugs, 43.4 percent, 67.3 percent, and 45.5 percent, experienced QTc prolongation, respectively (p less than 0.05). Those who received three QTc prolonging drugs had a significantly greater incidence of QTc prolongation compared to those who received two QTc prolonging drugs (p equals 0.0089) and compared to those who received four or more QTc prolonging drugs (p equals 0.049). There was no difference in the incidence of QTc prolongation in those receiving two versus four QTc prolonging drugs (p equals 0.084). The incidence of QTc prolongation was associated with risk factors including being of the female sex, a history of cardiovascular disease, and electrolyte disturbances (p less than 0.05).

Conclusion: In adult hospital patients, an increase in the number of QTc prolonging drugs received was not associated with a corresponding increase in the incidence of QTc prolongation. Among patients receiving two, three, or four or more QTc prolonging drugs, the incidence of QTc prolongation was greatest in those receiving three drugs. Being of the female sex, a history of cardiovascular disease, or having electrolytes disturbances may increase the risk of QTc prolongation. The clinical significance of QTc prolongation must be determined by assessing incidence of arrhythmias or adverse effects.

Poster Title: Evaluating the effects of alvimopan, liposomal bupivacaine and intravenous acetaminophen in colorectal surgery patients

Primary Author: Sara Weinstein, University of Arizona College of Pharmacy, Arizona; **Email:** sdweins@email.arizona.edu

Additional Author (s):
Eric Bergstrom
Gilbert Romero
Robert Wolk

Purpose: Enhanced recovery after surgery (ERAS) programs are implemented with the goal of shortening hospital length of stay (LOD) while lowering health care costs. By optimizing pre-operative, intra-operative and post-operative care in colorectal surgery patients, they are able to recover at a quicker rate while preserving organ function. The purpose of this study was to determine if the addition of oral alvimopan, liposomal bupivacaine and intravenous acetaminophen as part of a comprehensive ERAS program decreases length of stay, recovery time and/or narcotic use without affecting colorectal surgery patient outcomes.

Methods: The University of Arizona Institutional Review Board (IRB) approved this retrospective chart review of patients at Tucson Medical Center (TMC). Patients before and after the implementation of alvimopan, liposomal bupivacaine and intravenous acetaminophen with an ERAS program were compared. Both groups included men and women over 17 years old who underwent colorectal surgery performed by a specified surgical group. Pre-implementation data was collected between January and December 2014. Post-implementation data included patients who received alvimopan, liposomal bupivacaine and intravenous acetaminophen with the ERAS program between January and August 2015. In total, 37 patients were included in the pre-implementation population and 52 patients were included in the post-implementation population. The primary outcome was hospital length of stay (measured in hours). Secondary outcomes included change in time to first bowel movement (measured in hours), opioid use (measured in morphine equivalent milligrams) and pain scores (measured from 0 to 10) for seventy-two hours following surgery.

Results: The mean length of stay decreased from 124.3 hours to 100.2 hours (P equals 0.13) with the addition of the ERAS program activities and the three medications. The time to first bowel movement decreased from 67.2 hours to 46 hours (P equals 0.03). The twenty-four hour morphine equivalent intervals for seventy-two hours following surgery decreased from 125.8 mg (day 1), 81.9 mg (day 2) and 44.5 mg (day 3) to 44.3 mg (day 1), 22.8 mg (day 2) and 13.22 mg (day 3) (P equals less than 0.001, P equals less than 0.001 and P equals 0.001 respectively). Pain scores were not statistically significant between the two groups.

Conclusion: The addition of alvimopan, liposomal bupivacaine and intravenous acetaminophen as part of a comprehensive ERAS program decreased length of stay but not significantly. However, the addition of these three medications with the ERAS program changes was associated with a statistically significant decrease in time to first bowel movement and opioid use. Pain scores were reduced, but not significantly. Further studies may be advantageous to further explore the benefit of specific elements of ERAS programs.

Session-Board Number: 7-009

Poster Title: Development of a pharmacist competency assessment in order to standardize vancomycin practices at a regional medical center

Primary Author: Evan Mallory, University of Arizona College of Pharmacy, Arizona; **Email:** mallory@pharmacy.arizona.edu

Additional Author (s):
Sara Andrus
Dana Bowers

Purpose: Antimicrobial stewardship aims at improving the appropriate use of antimicrobial therapy through an active role in the selection, dose, duration, and route of administration of antibiotics. To this goal, a vancomycin pharmacokinetic (PK) dosing policy has been established for over 10 years and was recently revised in 2014. The policy outlines proper dosing and monitoring to be performed by pharmacists based on current clinical guidelines. The purpose of this study was to create a vancomycin competency assessment for pharmacists in order to standardize dosing and monitoring practices at a regional medical center.

Methods: Methods for a previously conducted vancomycin MUE have been described elsewhere. In summary, it was a retrospective chart review of patients between April – August 2016 who were dosed and monitored by the pharmacy PK dosing service. Demographic and microbiologic data were collected, as well as vancomycin indication, dosing, and monitoring. The primary endpoint of the MUE was to determine if vancomycin therapy was in accordance with the vancomycin PK dosing policy and current guideline recommendations. Based on the results of the MUE, opportunities for improvement were identified. This study developed an educational program and competency assessment the pharmacist staff using online software. The education portion included a review of initial dosing, timing of troughs, dose adjustments, frequency of monitoring, and opportunities for de-escalation of vancomycin. The educational program was provided to all pharmacists to complete as part of their professional development. After completing the education portion, pharmacists were given an assessment to evaluate their understanding of the material covered.

Results: The educational materials were developed and provided to approximately 20 pharmacists. The pre-recorded video lecture reviewed current clinical guideline recommendations and the existing vancomycin PK dosing policy. Dosing, trough monitoring, and de-escalation of antimicrobial therapy were covered in detail. The assessment component included case-based questions involving initial dosing of vancomycin based on indication, timing of initial trough measurements, dose adjustments based on trough levels, and de-escalation of treatment. Pharmacists provided feedback that both the education and assessment were helpful and would likely improve their practice.

Conclusion: Education and competency assessment are useful tools for identifying knowledge gaps. These can be implemented as a means of improving patient care and reducing variation in dosing practices. The next phase of this project will be to repeat a vancomycin MUE to assess whether this intervention had any impact on standardizing vancomycin dosing practices.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Poster Title: Retrospective medication use evaluation of intravenous acetaminophen assessing compliance of institution specific restrictions and effects of intravenous route compared to alternative routes of administration

Primary Author: Megan Vaden, Harding University College of Pharmacy, Arkansas; **Email:** mmccorkle@harding.edu

Additional Author (s):
HyeJin Son

Purpose: The goal of this retrospective medication use evaluation aimed 1) to assess appropriateness of intravenous acetaminophen orders according to institution specific restrictions previously enacted to reduce unnecessary medication cost, and 2) to assess the effects of intravenous acetaminophen in comparison to alternative routes of administration in postoperative patients in regards to pain score, opioid consumption, and length of stay at a non-for-profit community hospital.

Methods: Medication use of acetaminophen was retrospectively assessed in patients who underwent surgery between July 1 and July 31, 2016. Patients were included in data collection if they received acetaminophen for pain management postoperatively. Patients were excluded from data collection if they did not receive acetaminophen postoperatively. Patient groups were differentiated between control and study groups based on route of administration: those receiving intravenous acetaminophen composed the study group and patients receiving alternative routes of administration of acetaminophen composing the control group. The primary endpoint was appropriateness of intravenous acetaminophen therapy based on pharmacy and therapeutics committee approved restrictions. Secondary endpoints included type of surgery, consecutive patient-reported pain scores, concurrent opioid consumption, and length of stay. All opioid consumption administered within 48 hours from the start of surgery was included in data collection and converted to oral morphine equivalents.

Results: A total of 190 patients were included in the data analysis: 95 patients in each group. Only three of 95 patients in the study group appropriately received intravenous acetaminophen based on pharmacy and therapeutics committee approved restrictions. Observed pain score

averages between the study and control groups were comparable, 3.0 versus 3.1 respectively. Concurrent opioid consumption expressed in oral morphine equivalents was slightly higher in the study group compared to the control groups, 183 milligrams versus 163 milligrams respectively. Length of stay was observed to be slightly higher in the control group compared to the study group, 4.9 days versus 4.2 days respectively. This difference in length of stay could potentially be attributed to the diminished number of orthopedic surgery patients(37% versus 47%) in the control group population in comparison to the study group.

Conclusion: Utilization of intravenous route of administration of acetaminophen was not indicated in the majority of patients who received the intravenous formulation according to the institution specific restrictions. Pain scores, opioid consumption within 48 hours postoperatively, and length of stay for postoperative patients were similar in patients who received intravenous acetaminophen and patients who received alternative routes of acetaminophen. Oral or rectal routes of acetaminophen should be utilized, unless contraindicated, to provide cost-effective patient care.

Poster Title: Influence of negative procalcitonin (PCT) levels on length of hospital stay and antimicrobial duration in patients with a diagnosis of sepsis

Primary Author: Holden Graves, University of Arkansas for Medical Sciences, Arkansas; **Email:** hgraves2@uams.edu

Additional Author (s):
Tracy Finton
Tiffany Dickey

Purpose: Procalcitonin (PCT) is the peptide precursor of the hormone calcitonin. Normal PCT levels are < 0.05 ng/mL in healthy individuals, but may rise in response to systemic inflammation. Advantages include specificity for bacterial infections, a rapid rise then decline with infection control, and it often parallels severity of illness. It has been studied primarily in lower respiratory infections and sepsis. The primary outcomes of this study were to determine if negative PCT levels in patients diagnosed with sepsis resulted in a shorter length of stay and antimicrobial duration compared to a control group with no PCT levels.

Methods: This was a single center, retrospective chart review conducted in a 210 bed community hospital from May 31, 2014 to August 30, 2016. Patients with a diagnosis code of sepsis were included in the study. Patients were excluded if they were immunocompromised or transitioned to comfort care during admission. Demographic data, serum creatinine, intensive care unit (ICU) admission, ICU length of stay (LOS), hospital LOS, antimicrobials administered, duration of inpatient and outpatient antimicrobial therapy, culture data, 30 day all-cause mortality, and 30 day hospital re-admission for infection were collected. Patient characteristics and outcomes were compared using two-sample t-tests and Pearson chi-square tests for continuous and categorical data, respectively.

Results: A total of 196 patients with a diagnosis of sepsis were included (n=98 negative PCT, n=98 control). The mean patient age was 66.3 years (range of 25-98) and 62.4 years (range of 19-91) for the negative PCT and control groups, respectively (p=0.13). Baseline characteristics were similar between groups, with the exception of patients with a history of pulmonary disease (n=34 negative PCT, n=16 control, p= 0.003). The length of hospital stay was similar

between groups (5.6 days negative PCT, 5.2 days control, p=0.34). Antibiotic duration was also similar between groups (10.6 days negative PCT, 10.7 days control, p=0.91). A subgroup of patients with negative cultures were evaluated in each arm (n=49 negative PCT, n=31 control). The antibiotic duration was shorter for the negative PCT group when cultures were negative (9.1 days), but was longer for the control within this subgroup (12 days). The difference was not significant between study groups (p=0.13).

Conclusion: Length of hospital stay and antibiotic duration were not statistically different between septic patients with a negative PCT compared to a control group with no PCT levels. There were no differences in either outcome when a subgroup of patients with negative cultures were compared between study arms. Patients on antibiotic therapy prior to admission were included, which is a limitation. Based on findings of this study, the negative PCT levels may not have influenced antibiotic duration. Proper utilization of PCT levels should be examined to encourage antimicrobial stewardship principles, including de-escalation of antibiotics when indicated.

Submission Type: Evaluative Study

Session-Board Number: 7-012

Poster Title: Comprehensive medication management of psychiatric patients initiated on antimicrobial therapy

Primary Author: Lacey Condron, University of Arkansas for Medical Sciences, Arkansas; **Email:** l.condron927@gmail.com

Additional Author (s):
Tiffany Dickey
Victoria Seaton

Purpose: Identify medication interactions, including category and potential adverse effects, between commonly prescribed psychotropic and antimicrobial medications at Mercy Hospital Northwest Arkansas. When psychotropic and antimicrobial medications are taken concurrently, medication interactions have been reported, including serotonin syndrome or QTc prolongation. There is limited data to guide clinicians on how to discontinue psychotropic medications. This study aims to use comprehensive medication management to identify the most common interactions and the warning and category of the interactions identified.

Methods: This was a single center, observational study conducted at a 210 bed community hospital in Northwest Arkansas. Data was collected from August through mid-September 2016. Data was obtained for patients 18 years and older with concomitant psychotropic and antimicrobial orders utilizing an electronic health record system (EPIC). Patients with an interaction resulting in a category C, D or X were included. Lexicomp® was used to classify interactions. The medications involved in these interactions were recorded to develop a list of the most common medication interactions.

Results: Over a 6-week period, 59 patients were identified as having at least one category C, D or X medication interaction occurring between a concurrent psychotropic and an antimicrobial medication. A total of 79 medication interactions were recorded; 55.7% were category C interactions, 15% were category D and 29% were category X. The majority of patients had only one medication interaction, while the rest had two or more interactions. QTc prolongation was the most common warning indicated from the medication interactions. The most common antimicrobial class interacting with psychotropics were fluoroquinolones, accounting for 77% of

the interactions. The most common psychotropics prescribed were the selective serotonin reuptake inhibitors and mirtazapine.

Conclusion: The most common interactions identified were category C followed by category X interactions. QTc prolongation accounted for the majority of the potential adverse effects. To overcome this common occurrence of potentially harmful medication interactions, a baseline EKG should be considered throughout therapy to monitor patients. Further studies are needed to address effective methods to alter medication therapy when interactions are a concern between psychotropics and antimicrobials.

Session-Board Number: 7-013

Poster Title: Incidence and prevention of QTc interval prolongation when using combinations of QTc-prolonging antimicrobials and antipsychotics

Primary Author: Hannah Rabon, University of Arkansas for Medical Sciences, Arkansas; **Email:** hrabon@uams.edu

Additional Author (s):
Tiffany Dickey
Victoria Seaton

Purpose: Drug-induced prolongation of the QTc interval, or acquired Long QT Syndrome (LQTS), can lead to an arrhythmia called Torsades de Pointes (TdP). The risk of LQTS increases when multiple QTc-prolonging medications are prescribed. Some risk factors for developing LQTS may be considered modifiable, allowing prescribers to monitor them and decrease patient risk. The primary objective of this study was to examine the effects on the QTc interval when QTc-prolonging antimicrobials and antipsychotics were prescribed. The secondary objectives were to define the incidence of other cardiac abnormalities during dual therapy, and to determine how effectively providers monitored modifiable LQTS risk factors.

Methods: This was a retrospective chart review of 106 drug class combination events occurring between January 1, 2016 and September 7, 2016 in a 210-bed community hospital. Events were selected if patients were administered an antibiotic (azithromycin, ciprofloxacin, or levofloxacin) and an antipsychotic (haloperidol, quetiapine, or ziprasidone) within 24 hours of each other. Events were analyzed for demographic information, the presence of baseline and follow-up EKG data, the magnitude of QTc prolongation during dual therapy, occurrence of arrhythmias or other cardiac abnormalities, and whether lab values for magnesium and potassium were maintained at goal levels.

Results: The QTc interval increased an average of 40.7 msec from baseline for all combination events. The greatest increase occurred with the combination of levofloxacin and ziprasidone (98.8 msec), while ciprofloxacin and ziprasidone had a smaller increase (16.5 msec). The most frequent combination events were levofloxacin with quetiapine or haloperidol. Several patients had multiple risk factors for LQTS, including arrhythmias, cardiac and electrolyte abnormalities,

QTc prolongation at baseline, lack of follow up EKGs, and documentation of QTc prolongation both prior to and during dual therapy. An arrhythmia was documented during dual therapy for 27.4 percent of events, and other cardiac abnormalities occurred in 66 percent of events. When monitoring electrolytes, 52 percent of the lab values for magnesium did not meet the goal of 2 mEq per L or greater, and 44 percent of potassium lab values did not meet the goal of 4 mEq per L or greater. Baseline QTc values were greater than 450 msec in 20.6 percent of dual therapy events. Follow up EKG monitoring was ordered in only 70.8 percent of events. A prolonged QTc interval was documented before dual therapy in 3.8 percent of events, and during therapy in 4.7 percent of events.

Conclusion: This study found that prolongation of the QTc interval does occur with co-administration of QTc prolonging medications, specifically macrolide and fluoroquinolone antibiotics combined with first and second generation antipsychotics. Electrolytes, such as potassium and magnesium, were at goal only half of the time, and follow up EKGs were not ordered in 29.2 percent of dual therapy events. These factors increased patient risk, and represent future opportunities for improvements in reducing modifiable risk factors for LQTS and TdP.

Poster Title: Process evaluation and effectiveness of potassium replacement in the medical intensive care unit

Primary Author: Jarrod King, University of Arkansas for Medical Sciences, Arkansas; **Email:** jking3@uams.edu

Additional Author (s):
Kristina Erbach
Oktawia Clem
Niranjan Kathe

Purpose: Rules of thumb for the replacement of electrolytes, including potassium, are used without regard to numerous patient specific factors that may affect the achievement of target serum concentrations. Similarly, follow-up on the results from electrolyte replacement may not be performed within the desired and safe time frame. Our purposes were to evaluate the effectiveness and safety surrounding potassium replacement in the medical intensive care unit at our institution.

Methods: This was a single-center, IRB approved, retrospective, observational evaluation of intravenous and oral potassium replacements ordered for patients admitted to a medical intensive care unit from May 2014 to April 2016. Days on which patients received renal replacement therapy, bicarbonate infusion, loop diuretic infusion, insulin infusion, amphotericin B, or digoxin were excluded from analysis. Baseline demographics and clinical characteristics were described with descriptive statistics (count, percentage, and mean). The primary effectiveness outcome (achievement of target serum potassium concentration) and safety outcome (potassium concentration checked within 24 hours of replacement) were evaluated with counts and percentages.

Results: In total, 581 potassium replacements were evaluated. The average day of hospitalization was 14 (range: 1-73) and age was 54.6 years. Co-morbid disease states that could have affected patients' response to potassium replacement were alcohol abuse disorder (17.4%), diabetes mellitus (15.0%), and chronic kidney disease (15.8%). Only 374 replacements (64.4%) had a serum potassium concentration checked within 24 hours of replacement. Of

these 374 replacements, only 117 (31.3%) achieved the target serum potassium concentration of 4 mEq/L.

Conclusion: Safe and effective potassium replacement is not the current standard of practice in this medical intensive care unit. Staff education and development of an evidence-based replacement algorithm should be pursued.

Poster Title: Process Evaluation and Effectiveness of Phosphate Replacement in the Medical Intensive Care Unit

Primary Author: Julie Tran, University of Arkansas for Medical Sciences, Arkansas; **Email:** jtran@uams.edu

Additional Author (s):
Oktawia Clem
Jelena Stojakovic
Kristina Erbach
Jarrod King

Purpose: Rules of thumb for the replacement of electrolytes, including phosphate, are used without regard to numerous patient specific factors that may affect the achievement of target serum concentrations. Similarly, follow-up on the results from electrolyte replacement may not be performed within the desired and safe time frame. Our purposes were to evaluate the effectiveness and safety surrounding phosphate replacement in the medical intensive care unit at our institution.

Methods: This was a single-center, IRB approved, retrospective, observational evaluation of intravenous and oral phosphate replacements ordered for patients admitted to a medical intensive care unit from May 2014 to April 2016. Days on which patients received renal replacement therapy, bicarbonate infusion, loop diuretic infusion, insulin infusion, amphotericin B, or digoxin were excluded from analysis. Baseline demographics and clinical characteristics were described with descriptive statistics (count, percentage, and mean). The primary effectiveness outcome (achievement of target serum phosphate concentration) and safety outcome (phosphate concentration checked within 24 hours of replacement) were evaluated with counts and percentages.

Results: Results: In total, 112 phosphate replacements were evaluated. The average day of hospitalization was 12 (range: 1-73) and age was 52.8 years. Co-morbid disease states that could have affected patients' response to phosphate replacement were alcohol abuse disorder (8.0%), diabetes mellitus (19.6%), and chronic kidney disease (17.9%). Only 58 replacements

(51.8%) had a serum phosphate concentration checked within 24 hours of replacement. Of these 58 replacements, only 34 (58.6%) achieved the target serum phosphate concentration of 3 mmol/L.

Conclusion: Safe and effective phosphate replacement is not the current standard of practice in this medical intensive care unit. Staff education and development of an evidence-based replacement algorithm should be pursued.

Poster Title: Evaluating the impact of advanced pharmacy practice experience (APPE) rotations on student pharmacists' attitudes and perceptions toward interprofessional practice

Primary Author: Rebecca Smith, University of Arkansas for Medical Sciences College of Pharmacy, Arkansas; **Email:** rshilling@uams.edu

Additional Author (s):
Cora Housley
Seth Heldenbrand
Nalin Payakachat
Drayton Hammond

Purpose: Interprofessional healthcare teams have been shown to decrease costs, improve patient satisfaction, and ultimately enhance the quality of patient care. To become successful team members, healthcare professional students must develop competency in interprofessional practice (IPP). APPEs are key to developing skills in IPP. Assessing the impact of APPEs on student pharmacists' perceptions of IPP is crucial to adapt training and ensure practice readiness. The Student Perceptions of Interprofessional Clinical Education–Revised (SPICE-R) instrument was developed to assess students' attitudes of IPP and could be used to better integrate IPP experiences into the APPE curriculum.

Methods: Fourth-year student pharmacists were given a paper version of the SPICE-R instrument prior to and after completion of their APPE rotations. Participating students' demographic and characteristic information was collected from the experiential education system and described using descriptive statistics. Wilcoxon signed rank or paired student t-tests were employed to determine changes in all SPICE-R domain scores. Factors associated with SPICE-R domain scores were evaluated using multiple regression analysis.

Results: Sixty-nine student pharmacists were included in the analysis. Of these, 53 (77%) were female and the average age was 27.7 years. Twenty-two (32%) students pursued post-graduate residency training (PGRT) following graduation and 47 (68%) did not. Among all students, the overall mean SPICE-R score was 4.32 pre-APPEs and 4.51 post-APPEs (max= 5; p=0.027). The differences in pre- and post-APPE scores for Domains II and III yielded significant differences

(p=0.0026 and p=0.031, respectively). Students who did not pursue PGRT recorded significantly higher comprehension of Domain II subjects, both pre- and post-APPEs, than those who did pursue PGRT (p=0.025 and p=0.045, respectively).

Conclusion: Assessing student pharmacists' perceptions of IPP, especially regarding APPEs, is vital to improving its incorporation into the pharmacy school curriculum. Further investigation is needed to identify strategies to improve student understanding of the IPP statements addressed in Domain II. Qualitative investigation is required to understand the differences in Domain II scores between students who pursued PGRT and those who did not.

Poster Title: Knowledge gap analysis of first year student pharmacists regarding residencies and career paths

Primary Author: Heather Flowers, University of Arkansas for Medical Sciences College of Pharmacy, Arkansas; **Email:** hjcflowers@gmail.com

Additional Author (s):
Jeremy Hanner
Catherine O'Brien
Jacob Painter
Drayton Hammond

Purpose: Student pharmacists often begin their fourth year rotations with inadequate knowledge about the variety of health-system careers. It is essential for all student pharmacists to understand the diverse pharmacy career opportunities that are available, including post-graduate training options and their importance to certain future desired careers. The purpose of this survey was to assess the knowledge of and attitudes towards health-system pharmacy careers and post-graduate training opportunities that incoming students have.

Methods: All data were collected through a survey administered to the entering pharmacy class of 2019 at the University of Arkansas for Medical Sciences College of Pharmacy. The first portion of the survey requested basic demographic information such as age, gender, previous education, and pharmacy experience/setting. The second portion of the survey focused on students' perception of their knowledge of post-graduate training opportunities, i.e. residencies, certification, dual-degrees. The third segment asked for students' level of understanding about various pharmacy careers. The final portion of the survey was centered around students' attitudes toward post-graduate training and its perceived importance to their career goals. Answers were compared using Chi-square and Fisher exact tests. A p-value < 0.05 was determined to be statistically significant.

Results: Analysis of baseline demographics for survey participants demonstrated a class that is 23 years of age on average, predominantly Arkansas residents (84%), and starting pharmacy as their first career (84%). Comparing results between beginning and end of year, students

interested in pursuing residency training decreased 27% to 16% (p=0.057). For analysis, students were divided into two groups based on whether or not they were interested in pursuing a residency. By the end of the year, levels of familiarity with job duties of a hospital staff pharmacist and decentralized hospital pharmacist were higher in the group of students who planned to complete a residency (p=0.01 and p=0.046). Other career areas were similar between groups, but positions such as medical liaison pharmacist, informatics pharmacist, investigational drugs pharmacist, and home infusion pharmacist had very low responses for levels of familiarity between both groups (mostly < 40%). Students interested in residencies felt that post-graduate training was necessary for obtaining a position in the future (63% vs. 6%, p < 0.001). Those interested in post-graduate training also felt residencies were needed due to new and challenging roles pharmacists will have in the future (89% vs. 40%, p < 0.001).

Conclusion: Students appear to have very different knowledge and attitudes on health-system career opportunities depending on their future plans. A concerted effort to equally teaching all students about the health-system opportunities available is needed to better prepare them for future pharmacy careers.

Poster Title: Integration of Clinical Pharmacy Services into Emergency Medicine: Cost Avoidance and Qualitative Outcomes

Primary Author: Kelsey McCain, University of Arkansas for Medical Sciences College of Pharmacy, Arkansas; **Email:** kmccain2@uams.edu

Additional Author (s):
Geoffrey Curran
Cindy Mosley
Shaden Murad
Gavin Jones

Purpose: Integration of clinical pharmacy services into the emergency department team is a relatively recent emergence and expansion of pharmacy practice. Two goals of this study were to obtain quantitative and qualitative data to determine the effect of implementation of clinical pharmacy services into the emergency department. Clinical pharmacy specialist interventions were recorded to determine cost avoidance, while integration and acceptability were determined by emergency staff personnel interviews. Implementation and integration of a clinical pharmacy specialist into the emergency department is still an unfamiliar process, this study demonstrates a successful model that could be used in the future.

Methods: This prospective, IRB approved four-month study (August 2015 – November 2015) was conducted at a single-center, tertiary care, academic medical center, adult level 1 trauma center with approximately 60,000 annual emergency department visits and included a mixed-methods approach. The pharmacy specialist prospectively documented interventions in the electronic medical record. At the end of the four-month investigational period, all interventions were categorized into cost avoidance measures and sub-categorized by clinical function. Cost avoidance categories were Drug-Drug Interactions, Drug-Disease Interactions, or Drug Incompatibilities Identified, Therapeutic Recommendations, Adverse Drug Event Prevented, and Medication Error Prevented. Qualitative analysis included sixteen semi-structured interviews with a clinical sociologist that occurred between April 2016 and September 2016. The interviews were conducted individually and in person with six emergency department registered nurses, one emergency department nurse manager, five emergency department

resident physicians, three emergency department attending physicians, and the emergency department service line director. Interviews included a multi-stakeholder analysis of feasibility and acceptability of pharmacist clinical roles in emergency department teams. Semi-structured interviews were guided around the implementation and integration of a pharmacist's position into the emergency department. The interviews were recorded, transcribed, and coded to reveal relevant and common themes.

Results: A total of 352 interventions were analyzed. The clinical pharmacy specialist was in the emergency department for 227 total hours during this investigation. The overall cost avoidance was estimated to be $138,601.67, or $610.58 in cost avoided per pharmacist staffed hour. The projected cost avoidance with a full time pharmacist in the ED over the course of a year was estimated to be $1,221,160.09. The clinical category that provided the most cost avoidance was Medication Error Prevented at $65,243.75 or 47% of the total cost avoided. Therapeutic Recommendations was the second most cost avoiding clinical category at $51,749.28 or 37% of the total cost avoided. Approximately one-third of the interventions were categorized as Other and included pharmacy functions such as medication reconciliation, administrative duties, and facilitating communication and medication transport between emergency department and inpatient pharmacy. Emerging qualitative themes were categorized by Implementation (e.g. preparation of staff to utilize the pharmacist, what communication occurred departmentally, SOP with pharmacist in work flow), Drug Information Specialist and Resource (e.g. availability of frequently used medications, improvement of work flow), Code Response (e.g. drawing up medications, clinical assessment support, individualized patient needs) and Future Pharmacist Integration (e.g. personality, fit, student opportunities).

Conclusion: This study establishes a successful model for implementation of clinical pharmacy services into the emergency department with potential cost avoidance of more than $1,000,000 per year. Research suggests cost of a pharmacist's salary is the largest barrier to integration. This cost avoidance trial with an implementation model provides support for the expansion of clinical pharmacy roles into the emergency department. A standardized integration protocol benefits the emergency department medical teams to prepare for implementation of a pharmacist's role. The expanding role of clinical pharmacy practice continues to evolve the profession into integrated clinicians on the medical team.

Poster Title: Evaluation of the effects of changing the time vancomycin concentrations are drawn in medical ICU patients.

Primary Author: Taylor James, University of Arkansas for Medical Sciences College of Pharmacy, Arkansas; **Email:** tjames@uams.edu

Additional Author (s):
Lexis Atkinson
Drayton Hammond

Purpose: Vancomycin is a first line antibiotic therapy for the treatment of infections caused by methicillin resistant Staphylococcus aureus (MRSA) and Staphylococcus epidermidis (MRSE). Most institutions do not have established clinical practice guidelines for the initiation and therapeutic drug monitoring of serum vancomycin levels. This can lead to inappropriate timing of trough collection, resulting in sub- or supratherapeutic levels. The purpose of this study was to evaluate if a difference in the proportion of serum vancomycin trough concentrations drawn appropriately differed before and after an initiative to change the time when vancomycin concentrations were drawn in medical intensive care unit settings.

Methods: This was a retrospective chart review of patients in the medical ICU setting from May 2014 to May 2016 who received intravenous vancomycin at a scheduled interval. A policy changed that was implemented in August 2015, allowing pharmacists to be consulted to manage vancomycin therapy and encourage standard dosing intervals to include a dose within 1 hour following morning labs. Descriptive statistics (mean, standard deviation, counts, and percentages) were performed. Chi-square and student t tests per performed between groups, as appropriate. In order to detect a 15% change in the percentage of serum vancomycin trough concentrations that were drawn appropriately with 80% power and an alpha value of 0.05, 122 patients in each group would need to be evaluated. . However, we were only able to evaluate 68 patients in the pre-intervention group, and 176 patients in the post-intervention group.

Results: Patients in the pre- and post-intervention groups received a similar frequency of loading doses (12% vs. 10%) and similar weight-based maintenance dosing (13.7 mg/kg vs. 14.5 mg/kg). Standard dosing intervals (every 12 or 24 hours) were used in the majority of patients

(85.3% vs. 86.9%). Vancomycin troughs were drawn more frequently with morning labs in the post-intervention group (5.9% vs. 80.7%, p < 0.001). There was no significant difference in the percent of vancomycin troughs drawn appropriately at 30 (33.8% vs. 30.1%), 60 (58.8% vs. 59.7%), or 75 (69.1% vs. 71.6%) minutes from the next scheduled dose.

Conclusion: Implementation of a universal vancomycin trough schedule did not appear to affect the percentage of inappropriately drawn vancomycin troughs. This finding may be the result of the morning lab draws occurring earlier than expected, frequently more than an hour before the next vancomycin dose. We will consider moving the scheduled lab draws closer to 0500 or move the scheduled vancomycin doses closer to 0400.

Poster Title: Evaluation of the effects of changing the time vancomycin concentrations are drawn in non-ICU patients.

Primary Author: Lexis Atkinson, University of Arkansas for Medical Sciences College of Pharmacy, Arkansas; **Email:** latkinson@uams.edu

Additional Author (s):
Taylor James
Drayton Hammond

Purpose: Vancomycin is a first line antibiotic therapy for the treatment of infections caused by methicillin resistant Staphylococcus aureus (MRSA) and Staphylococcus epidermidis (MRSE). Most institutions do not have established clinical practice guidelines for the initiation and therapeutic drug monitoring of serum vancomycin levels. This can lead to inappropriate timing of trough collection, resulting in sub- or supratherapeutic levels. The purpose of this study was to evaluate if a difference in the proportion of serum vancomycin trough concentrations drawn appropriately differed before and after an initiative to change the time when vancomycin concentrations were drawn in non-intensive care unit (ICU) settings.

Methods: This was a retrospective chart review of patients in the non-ICU setting from May 2014 to May 2016 who received intravenous vancomycin at a scheduled interval. A policy changed that was implemented in August 2015, allowing pharmacists to be consulted to manage vancomycin therapy and encourage standard dosing intervals to include a dose within 1 hour following morning labs. Descriptive statistics (mean, standard deviation, counts, and percentages) were performed. Chi-square and student t tests per performed between groups, as appropriate. In order to detect a 15% change in the percentage of serum vancomycin trough concentrations that were drawn appropriately with 80% power and an alpha value of 0.05, 122 patients in each group would need to be evaluated. For the non-ICU portion of our research we evaluated 124 patients in the pre-intervention group and 122 patients in the post-intervention group.

Results: Patients in the pre- and post-intervention groups received a similar frequency of loading doses (16% vs. 14.5%). Patients in the pre- and post-intervention groups did not have similar weight-based maintenance dosing (15.3mg/kg vs. 16.5 mg/kg, $p < 0.03$). Standard dosing intervals (every 12 or 24 hours) were used in the majority of patients (76% vs. 84%). Vancomycin troughs were drawn more frequently with morning labs in the post-intervention group (14% vs. 87%, $p < 0.001$). There was no significant difference in the percentage of vancomycin troughs drawn appropriately at 30 (40% vs. 42%), 60 (57% vs. 63%), or 75 (60% vs. 68%) minutes from the next scheduled dose.

Conclusion: Implementation of a universal vancomycin trough schedule did not appear to affect the percentage of inappropriately drawn vancomycin troughs. This finding may be the result of the morning lab draws occurring earlier than expected, frequently more than an hour before the next vancomycin dose. We will consider moving the scheduled lab draws closer to 0500 or move the scheduled vancomycin doses closer to 0400.

Poster Title: Norepinephrine and early vasopressin versus norepinephrine alone for septic shock: Retrospective, cohort study

Primary Author: Julia Cullen, University of Arkansas for Medical Sciences College of Pharmacy, Arkansas; **Email:** jcullen@uams.edu

Additional Author (s):
Kelsey McCain
Oktawia Clem
Jacob Painter
Drayton Hammond

Purpose: End-organ damage due to septic shock is reduced when adequate perfusion is restored. Norepinephrine is recommended as the initial vasopressor for septic shock. Vasopressin may be added to raise mean arterial pressure or to decrease the norepinephrine dose, which may be useful in reducing some of norepinephrine's unfavorable side effects. The purpose of this study was to determine whether norepinephrine in combination with vasopressin or norepinephrine monotherapy had more beneficial effects on time to target mean arterial pressure.

Methods: A retrospective, single center, cohort study comparing the early addition of vasopressin to norepinephrine versus norepinephrine alone from May 2014 to October 2015 was conducted. Medical intensive care unit patients with septic shock were included. An unadjusted analysis of time to goal mean arterial pressure was conducted using student t-test. Linear regression was performed to examine the effect of time to mean arterial pressure in the treatment group. Baseline variables were examined for a bivariate relationship with time to goal mean arterial pressure. Variables with a p-value less than 0.2 were included in the model (treatment group, gender, height, heart rate and mean arterial pressure at septic shock onset, culture with non-lactose Gram-negative bacilli, and sequential organ function assessment score at 72 hours).

Results: 96 patients were evaluated. Sequential organ function assessment scores at 6 hours were greater in early vasopressin patients (9.9 vs 8.8, p-value 0.01) but similar at 24 and 72 hours. Mean arterial pressure (61.5 vs 58.6 mm Hg) and intravenous fluid volume at vasopressor initiation (1669 vs 1385 mL) were similar. In unadjusted analysis, goal mean arterial pressure was achieved and maintained sooner in early vasopressin patients (6.2 vs 9.9 h, p-value 0.023). Norepinephrine was used for a shorter duration (54.3 vs 88.3 h, p-value 0.05) and at a higher maximum dose (28.8 vs 21.5 mcg per min, p-value 0.046) in early vasopressin patients. Hospital duration was halved in early vasopressin patients (343 vs 604 h, p-value 0.014). No difference in new-onset arrhythmia (6 vs 8 percent, p-value 0.999) or mortality (40 vs 42 percent, p-value 0.999) existed. Norepinephrine alone was associated with increased time to goal mean arterial pressure (Beta: 3.26, p-value 0.067); however, sufficient power was not achieved to show statistical significance.

Conclusion: Vasopressin, when initiated early in patients with septic shock, achieved and maintained goal mean arterial pressure sooner despite similar initial mean arterial pressure and fluid volumes and higher sequential organ function assessment scores.

Poster Title: Process evaluation and effectiveness of magnesium replacement in the medical intensive care unit

Primary Author: Jelena Stojakovic, University of Arkansas for Medical Sciences College of Pharmacy, Arkansas; **Email:** jstojakovic@uams.edu

Additional Author (s):
Kristina Erbach
Julie Tran
Jarrod King
Oktawia Clem

Purpose: Rules of thumb for the replacement of electrolytes, including magnesium, are used without regard to numerous patient specific factors that may affect the achievement of target serum concentrations. Similarly, follow-up on the results from electrolyte replacement may not be performed within the desired and safe time frame. Our purposes were to evaluate the effectiveness and safety surrounding magnesium replacement in the medical intensive care unit at our institution.

Methods: This was a single-center, IRB approved, retrospective, observational evaluation of intravenous magnesium replacements ordered for patients admitted to a medical intensive care unit from May 2014 to April 2016. Days on which patients received renal replacement therapy, bicarbonate infusion, loop diuretic infusion, insulin infusion, amphotericin B, or digoxin were excluded from analysis. Baseline demographics and clinical characteristics were described with descriptive statistics (count, percentage, and mean). The primary effectiveness outcome (achievement of target serum magnesium concentration) and safety outcome (magnesium concentration checked within 24 hours of replacement) were evaluated with counts and percentages.

Results: In total, 152 magnesium replacements were evaluated. The average day of hospitalization was 13 (range: 1-46) and age was 51.3 years. Co-morbid disease states that could have affected patients' response to magnesium replacement were alcohol abuse disorder (18.4%), diabetes mellitus (5.9%), and chronic kidney disease (9.2%). Only 82 replacements

(53.9%) had a serum magnesium concentration checked within 24 hours of replacement. Of these 82 replacements, only 37 (45.1%) achieved the target serum magnesium concentration of 2 mEq/L.

Conclusion: Safe and effective magnesium replacement is not the current standard of practice in this medical intensive care unit. Staff education and development of an evidence-based replacement algorithm should be pursued.

Poster Title: Pharmacy school interprofessional education models - A retrospective evaluation of California and nationally cited models

Primary Author: Sukhpreet Kaur, California Northstate University college of Pharmacy, California; **Email:** sukhpreet.kaur@cnsu.edu

Additional Author (s):
Stefanie Stafford
Laura Smith
Erin Kloepfer
Doan Trang Duong

Purpose: In the previous Accreditation Council for Pharmacy Education (ACPE) Standards from 2011, interprofessional education (IPE) was listed as a recommended component of the pharmacy school curriculum. The new 2016 ACPE Standards now officially require interprofessional education to be part of the pharmacy curriculum. This change was made to better prepare students to enter the field ready to participate as members of an interprofessional, patient-centered team.1 The goal of our research is to formulate the best IPE delivery model based on studying different pharmacy schools' curricula.

Methods: The California Northstate University (CNU) 2014 CAPSLEAD (California Pharmacy Student Leaders) Team conducted a retrospective study to determine if and how California pharmacy schools were implementing IPE prior to the new 2016 requirement standards.6 Based on information gathered, the CNU CAPSLEAD Team formulated an ideal model to most effectively deliver IPE.6 As an extension to this previous study, our team collected current data on California schools' implementation and delivery of IPE, and evaluated interesting IPE models from other pharmacy schools in the US. This study was performed in an effort to evaluate and make any necessary adjustments to the previous CNU CAPSLEAD IPE model with the passing of the new accreditation standards. The team also reported new findings on common pitfalls that IPE models are lacking; including lack of standardized metrics to measure the success of implemented IPE models.

Results: Analysis of data showed: a variety of IPE delivery formats ranging from group discussions to actual courses where IPE was delivered, all IPE delivery ranged from the 1st through 4th years of pharmacy school, the schools' disciplines that were included ranged from two to nine disciplines, and measures of success ranged from surveys to grades with undefined parameters. Based on these findings, the CNU 2014 CAPSLEAD model was adjusted to a four stage model including a longitudinal component. Stage 0 consisted of specific training of faculty to specialize in delivering IPE instruction. Stage 1 consisted of introductory IPE encompassing foundations of IPE. Stage 2 consisted of participation in face to face patient care sessions with other health care students followed by simulation or patient case presentation days. Stage 3 consisted of student surveys to assess IPE experience, as well as a graded portion to assess individual student performance outcomes during the APPE General Medicine cumulative portion. The longitudinal component consists of volunteering at health fairs or free-clinics to perform counseling, blood pressure screenings, and immunizations to provide real patient care while practicing within an interdisciplinary team in order to perform case based problem solving, learning and collaborative care delivery.

Conclusion: Since implementation of the new 2016 ACPE Standards, current pharmacy schools' curricula data showed that adjustments of the CNU 2014 CAPSLEAD model were needed. Common pitfalls for IPE implementation include a lack of validated metrics for success of IPE programs and a noticeably short durations of IPE in general.

Poster Title: The effect of Ginger use on lipid levels: A meta analysis

Primary Author: Stefanie Stramel, California Northstate University College of Pharmacy, California; **Email:** stefanie.stafford@cnsu.edu

Additional Author (s):
Chettra Prum
Olivia Phung

Purpose: Ginger has been studied in randomized control trials (RCTs) for its lipid-lowering effects, however the studies have been small and results of those studies have been conflicting. No prior meta-analysis have been performed to evaluate all data. We conducted a meta-analysis of RCTs evaluating ginger's effects on lipid levels.

Methods: PubMed, Cochrane Central Register of Controlled Trials, and Scopus were searched through January 2016. Included RCTs evaluated ginger (Zingiber officinale) compared with placebo/control in patients with hyperlipidemia and reported at least one of the following: total cholesterol, low-density lipoprotein cholesterol (LDL-C), or high-density lipoprotein cholesterol (HDL-C). Weighted mean differences (with 95% confidence intervals) for endpoints were calculated using random-effect models.

Results: In a meta-analysis of 11 RCTs (n=569), ginger doses of 2g/d to 9g/d given over 45 days to 12 weeks showed no significant effect on total cholesterol (-8.81 mg/dL; 95% CI, -20.87 to 3.25 mg/dL), LDL-C (-6.09 mg/dL; 95% CI, -13.02 to 0.84 mg/dL), HDL-C (0.57 mg/dL; 95% CI, -1.36 to 2.50 mg/dL), but showed a statistically significant reduction in triglycerides levels (-21.51 mg/dL; 95% CI, -42.90 to -0.13 mg/dL) . Moderate degrees of heterogeneity were present for all analysis except LDL-C which showed no heterogeneity (I2 ranging from 0% to 50.5%).

Conclusion: The consumption of ginger showed a statistically significant reduction in triglycerides. However, the consumption of ginger does not show a statistically significant effect in levels of total cholesterol, LDL-C, or HDL-C. Further studies in larger samples may be needed to determine ginger's true effect on lipid levels. Heterogeneity in results may be due to variation in doses evaluated and in study durations.

Submission Type: Descriptive Report

Session-Board Number: 7-025

Poster Title: Observational study on the effectiveness of an antimicrobial stewardship program and prescriber responsiveness to pharmacy interventions

Primary Author: Susan Lee, Loma Linda University School of Pharmacy, California; **Email:** sblee@llu.edu

Additional Author (s):
David Choi
Woori Park
Christie Bolous
Quoc Hoang

Purpose: According to the Centers for Disease Control and Prevention, misuse of antibiotics presents several issues including increased incidence of resistance and cost. The implementation of antibiotic stewardship programs has improved the use of antibiotics by optimizing clinical outcomes while minimizing adverse events. Utilizing student pharmacists in antimicrobial stewardship programs has shown to be beneficial through their recommendations under the supervision of clinical pharmacists, informing physicians when de-escalation or discontinuation of antibiotics is appropriate; therefore, the purpose is to examine the effectiveness of utilizing student pharmacists to intervene in antibiotic therapy management and to uncover the monthly trend of pharmacy interventions.

Methods: This is a single-centered, retrospective, observational study that examined student pharmacists' interventions made from February to June of 2016. The study was conducted at Desert Valley Hospital using data obtained from electronic administration records from the Meditech computer system. Patients were divided among six groups based on pharmacy intervention: change antibiotic, de-escalate from broad- to narrow-spectrum antibiotic, discontinue antibiotic, adjust renal dose of antibiotic, and switch antibiotic from intravenous to oral route. The rate of de-escalation was also examined for each investigated month to see the monthly trend for the study period. Descriptive statistics were then used to summarize the data to see the total amount of recommendations that were used per category and how responsive prescribers were to pharmacy interventions.

Results: There was a total of 1320 patients on antibiotics from February to June of 2016. Student pharmacists under the supervision of pharmacists found that 74 percent of these patients required no change in their antibiotic therapy. Less than 1 percent of the studied population underwent renal dosing adjustment for their medications, and 1 percent was de-escalated from broad-spectrum to narrow-spectrum antibiotics. 11 percent was discontinued on their antibiotics due to inappropriate use while 5 percent of the study population was switched to another, more appropriate, medication. Lastly, 9 percent of the population switched from intravenous to oral route of therapy after being prompted by the inpatient pharmacy. Looking at the monthly intervention trend during the study period, it was observed that 26 interventions were made in February, 37 in March, 34 in April, 118 in May, and 126 in June. According to the collected data, the rate of change initiated by the pharmacy progressively increased during the first five months of the implementation of the antimicrobial stewardship program.

Conclusion: The data suggests that student pharmacists are increasingly intervening through the antimicrobial stewardship program, and physicians are progressively accepting pharmacy recommendations. Since the launch of the program in February, more students arrived for training and rounded with clinical pharmacists more frequently, visiting patients and sharing face-to-face dialogue with physicians and nurses in addition to sending consultation notes. Opening up more lines of communication to multiple health professionals and utilizing student pharmacists may explain the increased prescriber responsiveness to pharmacy interventions made later in the program, indicating that being proactive can lead to higher rates of interventions and better outcomes.

Submission Type: Descriptive Report

Session-Board Number: 7-026

Poster Title: Statin therapy: Evaluation of clinical practice adherence to the current guidelines

Primary Author: Allison Uniat, Loma Linda University School of Pharmacy, California; **Email:** auniat@llu.edu

Additional Author (s):
Noel Chan
Marie Girguis
Farnoosh Zough
Mania Radfar

Purpose: The American College of Cardiology/American Heart Association (ACC/AHA) 2013 guidelines recommend statin therapy in both primary and secondary prevention in high-risk individuals with a notable shift from specific lipid goals to dose intensity. Accordingly, the American Diabetes Association (ADA) 2016 guideline has recommended statin therapy in almost all patients with diabetes. However, less data is available regarding the adherence to aforementioned guidelines. Therefore, the primary endpoint of the current study was to evaluate clinical practice adherence to the guidelines in patients with clinical atherosclerotic cardiovascular disease (ASCVD) and/or diabetes mellitus (DM).

Methods: This was a retrospective chart review of patients who were hospitalized between January 1, 2016 and June 30, 2016 at Loma Linda University Medical Center in the internal medicine wards. Patient charts were screened and were included for analysis by the following criteria: Patients 18 years of age and older, history of ASCVD and/or DM.

Results: A total of 1,585 patients were screened and 687 patients were identified to be eligible for statin therapy. Among 302 patients with DM and no ASCVD, 56 (18.5 percent) were on correct statin therapy, 45 (15 percent) had medically justifiable reasons to warrant the omission of statin therapy (e.g., aspartate transaminase (AST)/alanine transaminase (ALT) greater than five times the upper limit of normal, cirrhosis, rhabdomyolysis, pregnancy), and 151 (50 percent) were not on any statin therapy without justifiable reasons. Fifty patients (16.5 percent) with diabetes were on statin therapy but were not on the recommended intensities. Among 385 patients with previous ASCVD, 130 (34 percent) patients were on correct statin

therapy, 21 (5 percent) patients had medically justifiable reasons to warrant the omission of statin therapy, and 122 (32 percent) patients missed statin therapy without justification. There were 112 (29 percent) patients with previous ASCVD who were on statins but were not on the recommended intensities.

Conclusion: This study demonstrates the lack of adherence among prescribers to current statin therapy recommendations. The most significant population of patients with therapy omission is within those with diabetes without previous ASCVD. According to this study, there is room for improvement among clinicians to initiate appropriate statin therapy. A future study assessing clinicians' knowledge and attitude on statin therapy may be useful to find ways to increase compliance to the guidelines.

Poster Title: Aspirin Utilization Review in Primary and Secondary Cardiovascular Disease Prevention in Patients with Diabetes

Primary Author: Hang Cheung, Loma Linda University School of Pharmacy, California; **Email:** hang.b.cheung@gmail.com

Additional Author (s):
Lilit Poghosyan
Reuben Kim
Farnoosh Zough
Alireza Hayatshahi

Purpose: The American Diabetes Association (ADA) 2016 guidelines recommend low-dose aspirin (75-162 mg/day) as a primary prevention for patients with diabetes and increased risk for atherosclerotic cardiovascular disease (ASCVD). Specifically, the population at risk is defined as patients 50 years of age or older with one of the following: Family history of premature ASCVD, hypertension, dyslipidemia, albuminuria, or smoking. Low-dose aspirin is also recommended as secondary prevention in those with diabetes and ASCVD.
The endpoint of this study is to evaluate if patients with diabetes are on appropriate aspirin therapy for primary or secondary ASCVD prevention.

Methods: This was a retrospective chart review of patients who were hospitalized between January 1, 2016 and June 30, 2016 at Loma Linda University Medical Center in the internal medicine wards. Patient charts were screened and were included for analysis by the following criteria: Patients of any age with diabetes and ASCVD, patients age of 50 and over with diabetes and one additional cardiovascular risk factor (hypertension or smoking). Descriptive analysis was used to report the results.

Results: A total of 1,585 patient charts were screened and 396 patients were included for analysis. Among 202 patients with diabetes without previous ASCVD, 74 (36.6%) patients were appropriately on aspirin therapy for primary prevention. Twenty-one (10.4%) patients had a history of clinically significant bleeding or asthma and were not on aspirin therapy. These patients were considered to have potentially justifiable reasons to withhold aspirin therapy.

There were 107 (53%) patients not on aspirin therapy without previous bleeding or asthma and did not have justifiable reasons to withhold aspirin therapy.

Among 194 patients with comorbid diabetes and previous ASCVD, 149 (76.8%) patients were appropriately on aspirin for secondary prevention. Thirteen (6.7%) patients had previous clinically significant bleeding or history of asthma and were not on aspirin therapy. Thirty-two (16.5%) patients were not on aspirin therapy and were without justifications to withhold therapy.

Conclusion: This study demonstrates a significant lack of prescriber focus on primary prevention of ASCVD in patients with diabetes compared to secondary prevention. It seems that asthma and history of bleeding are the primary hindrances of aspirin therapy. Therefore, practitioners need to assess risk versus benefit regarding aspirin initiation or omission.

There is room for improvement in practice among clinicians to initiate aspirin therapy. A future study assessing clinicians' knowledge and attitude on aspirin therapy may be useful to find ways to increase the compliance to the guidelines.

Poster Title: Review of antibiotic usage interventions within an antibiotic stewardship program

Primary Author: Kristen Lee, Loma Linda University School of Pharmacy, California; **Email:** kslee@llu.edu

Additional Author (s):
Hoa Hoang
Christie Bolous
Deborah Chien
Susan Lee

Purpose: Desert Valley Hospital implemented an antibiotic stewardship program on February 2016. The goals of this program were to decrease both antibiotic costs and development of antibiotic resistance. Under the supervision of clinical pharmacists, student pharmacists made recommendations to physicians when de-escalation or discontinuation of antibiotics was appropriate. The purpose of this study was to determine antibiotic usage in the antibiotic stewardship program at Desert Valley Hospital for patients with approved de-escalations, no de-escalations, and recommended but not approved de-escalations.

Methods: This is a single-centered, retrospective study that examined student pharmacists' interventions made in February 2016. A total of 257 patients with listed antibiotics were divided into three groups. The three groups included patients with approved de-escalations, no de-escalations, and recommended but not approved de-escalations. With descriptive statistics, we analyzed to see the acceptance of de-escalation recommendations by physicians and the most commonly used antibiotics in the group with approved de-escalations.

Results: The first group included 164 patients (64 percent) who were treated appropriately with antibiotics and did not require de-escalation. The second group included 40 patients (15 percent) who required de-escalation, but physicians did not accept student pharmacists' recommendations. The third group included 53 patients (21 percent) who were appropriately de-escalated after physicians accepted recommendations made by student pharmacists. These recommendations included discontinuing an antibiotic, switching to a narrow-spectrum antibiotic based on cultures and switching from an intravenous to oral antibiotic. Of these three

recommendations, switching to a narrow spectrum antibiotic had the most acceptances by physicians, while switching from an intravenous to oral antibiotic had the least. The most commonly used antibiotics among the group that had approved de-escalations were ceftriaxone, vancomycin, piperacillin/tazobactam, azithromycin, linezolid, metronidazole and levofloxacin, thus illustrating that admitted patients were started on broad spectrum antibiotics and eventually de-escalated down to narrow spectrum antibiotics.

Conclusion: While the antibiotic stewardship program has shown improvement in antibiotic use, a 15 percent rate of recommended but not approved de-escalations showed that antibiotics were not used appropriately. To decrease this rate, the hospital has begun a residency program in which the resident will provide more in-services as well as improve the physician-pharmacist relationship. Although emphasizing narrow spectrum antibiotics is beneficial, more improvements can be made to encourage physicians to switch from intravenous to oral medications.

Poster Title: Evaluation of selexipag in pulmonary arterial hypertension (PAH) related complications and death

Primary Author: Crystal Lestari, Loma Linda University School of Pharmacy, California; **Email:** crystallestari@gmail.com

Additional Author (s):
Genevieve Noronha
Bisrat Mulugeta

Purpose: Pulmonary arterial hypertension (PAH) is a life threatening disease. Despite current treatments targeting the endothelin, nitric oxide, or prostacyclin pathways, prognosis remains poor. Prostacyclin dysregulation is associated with PAH pathogenesis. Selexipag is a new oral selective IP prostacyclin agonist which may have potential pharmacologic advantages in safety and efficacy compared with other prostacyclin vasodilators. The purpose of this study is to evaluate the impact of selexipag on death and complications related to PAH as compared to placebo.

Methods: The institutional review board approved this randomized, double blind, placebo controlled trial. Patients between ages 18-75 years who provided written informed consent and had confirmed PAH diagnosis that was either idiopathic, heritable, or associated with human immunodeficiency virus infection, drug use, toxin exposure, connective tissue disease, or repaired congenital systemic to pulmonary shunts were enrolled. Patients already on prostacyclin analogue treatment were excluded. Patients were randomly assigned to either receive selexipag (n equals 574) or placebo (n equals 582). Selexipag was initiated at 200 mcg twice daily and increased weekly in twice daily 200 mcg increments until patients experienced unmanageable adverse effects or a max dose of 1600 mcg twice daily was reached. The primary end point was a composite of death from any cause or complication related to PAH until the end of treatment period. Secondary outcomes included the change in 6 minute walk distance, absence of worsening world health organization (WHO) functional class, death due to PAH, hospitalization due to worsening PAH, and death from any cause. It was determined that 331 primary outcomes would be needed for the study to achieve 90 percent power to detect a hazard ratio for the primary endpoint.

Results: The primary outcome occurred in 155 patients (27 percent) in the selexipag group versus 242 (41.6 percent) in the placebo group (HR 0.60; 99 percent CI, 0.46 to 0.78; P less than 0.001). At week 26, the 6 minute walk distance median had decreased from baseline by 9 meters in the placebo group and increased in by 4 meters in selexipag group (treatment effect, 12 meters; 99 percent CI, 1 to 24; P equals 0.003). There was no significant difference in worsening of WHO functional class between the two groups (odds ratio 1.16; 99 percent CI, 0.81 to 1.66; P equals 0.28). Death due to PAH or hospitalization for worsening of PAH was significantly higher in placebo group (hazard ratio in the selexipag group, 0.70; 95 percent CI, 0.54 to 0.91; P equals 0.003). Death from any cause was comparable with 105 patients (18.0 percent) in selexipag group and 100 patients (17.4 percent) in placebo group (HR in the selexipag group, 0.97; 95 percent CI, 0.74 to 1.28; P equals 0.42). No serious adverse events were reported more frequently in selexipag group than placebo group.

Conclusion: Use of selexipag yielded significantly lower rates of the primary composite end point of death or complications related to PAH as compared to placebo. There was no significant difference in mortality between the two groups. The clinical significance of these results suggests that selexipag may be a promising treatment option for patients suffering from PAH. However, studies will need to assess its efficacy as compared to the standard of therapy that is already available for these patients.

Poster Title: Effectiveness of Thromboembolism Prophylaxis Regimens in Obese Patients

Primary Author: Grace Shinn, Loma Linda University School of Pharmacy, California; **Email:** gshinn@llu.edu

Additional Author (s):
Farnoosh Zough
Candice Chiaramonte
Paul Gavaza

Purpose: Obese patients have been under-represented in current guidelines and clinical trials of chemical thromboprophylaxis. The optimal dose in obese patients remains unclear, with studies showing inadequacy of current fixed doses of enoxaparin and suggesting multiple differing dosing strategies in this population. Obesity is a growing epidemic in the United States; therefore, it is crucial to gain a better understanding of optimal thromboprophylaxis in this population. This study aimed to compare the effectiveness of enoxaparin 40mg subcutaneously (SQ) daily versus enoxaparin 30mg SQ twice daily at preventing venous thromboembolic (VTE) events in obese patients at an academic teaching hospital.

Methods: A single center, retrospective chart review was conducted from February 28, 2013 to May 1, 2014, with patients identified via medication administration records. All adult patients with body mass index (BMI) greater than or equal to 30 and aged 18 through 85 years, who received enoxaparin 40 mg SQ daily or enoxaparin 30 mg SQ twice daily, with an admission of at least 72 hours at Loma Linda University Medical Center, were eligible for inclusion. Patients with creatinine clearance less than 30 mL/min, active bleeding, history of previous recurrent VTE, on therapeutic anticoagulation, pregnant, and greater than 85 years old were excluded. Data collected from an individual patient chart review included patients' gender, weight, height, BMI, age, platelets, serum creatinine, hemoglobin, hematocrit, Doppler ultrasound, chest computerized tomography (CT scans), and incidence of VTE after enoxaparin thromboprophylaxis administration. Incidence of VTE was defined as symptomatic proximal lower limbs (popliteal vein or more proximal) deep vein thrombosis or objectively diagnosed pulmonary embolism. The Padua risk score was calculated for each patient to evaluate the risk of VTE development. The primary endpoint was the incidence of VTE in enoxaparin 40 mg SQ

daily versus 30 mg SQ twice daily. Secondary endpoint was to evaluate factors associated with VTE in obese patients diagnosed with VTE. Data was analyzed using descriptive statistics.

Results: A total of 281 patients were included in the final data analysis. During hospital stay, 234 patients received enoxaparin 40 mg SQ daily, while 47 patients received enoxaparin 30 mg SQ twice daily. Baseline characteristics were well balanced between the two groups except significant differences of gender, active cancer, recent trauma or recent surgery (within the last month), ischemic stroke, and acute infection. Total number of VTE events in the population receiving enoxaparin 40 mg SQ daily was five (2.1%) (p=0.311), and no events occurred in those receiving enoxaparin 30 mg SQ twice daily. Among those VTE events, four were symptomatic deep vein thrombosis (DVT) in the proximal lower limbs, and one was an objectively diagnosed pulmonary embolism (PE). Calculated average Padua risk score for patients diagnosed with VTE was 3.4 (SD=1.8), while patients with no VTE had an average Padua score of 3.98 (SD=1. 6). Patients with active cancer (40% VTE versus 20.6% no VTE), congestive heart failure (20% versus 3.6%), ischemic cerebral vascular accidents (20% versus 7.2%), acute infection (60% versus 30.4%), and 70 years and older (20% versus 13.7%) had greater incidence of VTE.

Conclusion: There was no statistical difference in the incidence of VTE in obese patients using enoxaparin 40 mg SQ daily versus 30 mg SQ twice daily for thromboprophylaxis. However, all VTE events were seen in obese patients receiving enoxaparin 40 mg SQ daily, which may suggest enoxaparin 30 mg SQ twice daily as a better prophylaxis option. Further studies are needed to compare the efficacy of current enoxaparin thromboprophylaxis dosing versus weight-based dosing.

Poster Title: Do males cheat more than females? An analysis of Northern California pharmacy students

Primary Author: Jai Pal, Touro University California, California; **Email:** jai.pal@tu.edu

Additional Author (s):
Bijal Shah
Shadi Doroudgar
Monica Bidwal
Eric Ip

Purpose: Academic dishonesty is of particular importance among students in the healthcare field as such actions may lead to continued unethical behavior. A prior study performed by our research team revealed that 11.8% of pharmacy students admitted to cheating in pharmacy school. However, limited data exists contrasting male and female pharmacy students regarding academic dishonesty. The objectives of this study were to analyze differences between male and female pharmacy students regarding academically dishonest behavior as well as perceptions of academic dishonesty using hypothetical scenarios.

Methods: Between November 2014 to March 2015, a 45-item cross-sectional survey was conducted at all four Northern California pharmacy schools (Touro University California College of Pharmacy, University of California San Francisco School of Pharmacy, University of the Pacific Thomas J. Long School of Pharmacy & Health Sciences, and California Northstate University College of Pharmacy). Inclusion criteria consisted of pharmacy students in the second year of their didactic curriculum who consented to take part in the study. The survey was distributed as a hardcopy paper survey by a pharmacy student on the research team. The current subanalysis compared male and female pharmacy students. Data analyses were conducted using STATA version 13.0 (College Station, TX). Means and standard deviations were reported for continuous data, and frequency and percentages for categorical data.

Results: A total of 331 students (115 male, 215 female) completed the survey. No statistically significant differences were found between males and females regarding admitted cheating in pharmacy school (10.4 vs. 12.6%; p=0.569) as well as various other forms of academically

dishonest behavior (e.g. plagiarism, asking details of an oral exam/OSCE, fabricating lab data, etc.). Regarding hypothetical scenarios, there were two instances where males and females differed in their responses to cheating. One scenario involved a student stealing an exam and sharing with his friends; male respondents were less likely to perceive this as cheating compared to females (45.2 vs 77.2 %; p < 0.0001). Another scenario presented a student who had directly copied another student's calculations assignment; male respondents were less likely to report observing this in pharmacy school compared to females (19.1 vs 31.6%; p=0.015).

Conclusion: Overall, there were no major differences between male and female pharmacy students regarding admitted cheating and performing various forms of academically dishonest behavior. Males may view certain forms of academically dishonest behavior as less severe than females.

Poster Title: Evaluation of non-protocolized management of therapeutic temperature modulation (TTM) following cardiac arrest

Primary Author: Timothy Phan, Touro University California - College of Pharmacy, California; **Email:** timothy.phan@tu.edu

Additional Author (s):
Amanda Morris
Ashley Thompson
Laura Baumgartner

Purpose: Therapeutic temperature modulation (TTM) is a cooling strategy used to decrease metabolic needs and improve neurologic function following cardiac arrest. A common complication of therapeutic temperature modulation is shivering, which has a number of proposed detrimental effects. Small studies, largely in healthy volunteers have identified pharmacologic agents that may be used to prevent or reduce shivering; however consensus guidelines outlining an optimal treatment strategy has yet to be identified. The purpose of this study was to assess the efficacy of anti-shivering strategies during therapeutic temperature modulation at a large academic medical center prior to implementation of a post-arrest hypothermia protocol.

Methods: A retrospective cohort study that examined adult intensive care unit patients at a large academic medical center undergoing therapeutic temperature modulation (TTM) following cardiac arrest from July 2013 – July 2015 (prior to implementation of a formal post-arrest hypothermia protocol). Medication administration records, temperature logs, and shivering scores were evaluated for the first 48 hours following therapeutic temperature modulation. Patients were excluded from review if they were less than 18 years of age or received therapeutic temperature modulation for reasons outside of post-cardiac arrest care. The primary outcome assessed was the incidence and severity of shivering, which was evaluated using the Bedside Shivering Assessment Scale (BSAS). Scores range from 0, indicating no shivering to 3, indicating severe shivering with involvement of the upper and lower extremities. Secondary outcomes included use of anti-shivering medications, time to target

temperature (less than 33 degrees Celsius), and incidence of hyperthermia (greater than or equal to 38 degrees Celsius) during the re-warming period.

Results: Fifty-six patients underwent therapeutic temperature modulation following cardiac arrest prior to the implementation of a post-arrest hypothermia protocol. Average intensive care unit length of stay was 7 plus-minus 8 days, with 34 percent of patients being alive at discharge. Bedside Shivering Assessment Scale was positive in 46 percent of patients, with 16 percent having a score of 1, 25 percent having a score of 2, and 5 percent having a score of 3. Shivering was managed with buspirone (3.5 percent of patients), meperidine (7 percent of patients), and neuromuscular blocking agents (14 percent of patients). Time to target temperature (less than 33 degrees Celsius) was 6.6 plus-minus 3.5 hours, with patients spending an average of 10 plus-minus 5.5 hours above the target temperature within the first 24 hours. During the re-warming stage (24 to 48 hours post-arrest), time to temperature greater than 36.5 degrees Celsius was 14.5 plus-minus 14 hours, with 36 percent of patients having at least one febrile episode (greater than or equal to 38 degrees Celsius), and 11 percent of patients with a positive Bedside Shivering Assessment Scale score during this time.

Conclusion: Time to target cooling temperature was prolonged at approximately 7 hours. In addition, 50 percent of patients had a positive Bedside Shivering Assessment Scale score, with 14 percent of patients necessitating neuromuscular blocking therapy. It is hypothesized that implementation of a post-arrest hypothermia protocol will optimize management of patients undergoing targeted temperature modulation, including a decreased time to target cooling temperature, decreased incidence of a positive Bedside Shivering Assessment Scale score, and fewer febrile instances during rewarming. Future studies will compare data following the implementation of a post-arrest hypothermia protocol to current data.

Poster Title: Factors Affecting Confidence Levels in Lifestyle Counseling Among Pharmacy and Medical Students and Faculty

Primary Author: Maria Arella, Touro University California College of Pharmacy, California;
Email: maria.arella@tu.edu

Additional Author (s):
Eric Ip
Jaswinder Kaur
Grace Jones
Nathalie Bergeron

Purpose: The increasing burden of chronic diseases linked to poor diet and physical inactivity places pharmacists and physicians in an optimal position to counsel patients about lifestyle. Studies have shown that healthcare providers (HCPs) and healthcare professional students with healthy diets and lifestyle are more likely to counsel/emphasize lifestyle counseling. Little is known about factors that empower HCPs to feel confident in lifestyle counseling. We aimed to evaluate the lifestyle habits of pharmacy and medical students and faculty, and determine whether their confidence levels in lifestyle counseling are related to their nutrition knowledge, diet quality and practice of mindful eating.

Methods: First year male and female students (aged 18 and over) and faculty members from Touro University California College of Pharmacy (COM) and College of Medicine (COM) programs were invited to participate. Participants recorded their dietary intake for 3 consecutive days (2 weekdays and 1 weekend day) using an online application (HealthWatch360). To assess lifestyle practices a survey was administered, which contained the following sets of questions: 1) Starting the Conversation (STC) dietary assessment tool (8 items), 2) nutrition knowledge (5 items), and mindfulness eating (6 items) followed by questions about demographics, and dietary and exercise behaviors. Physical activity levels were classified based on the Institute of Medicine designations. Statistical analyses were performed using JMP (SAS Institute, version 11). Fisher's exact test was used to analyze categorical data, and one-way analysis of variance was used for continuous data. P values less than 0.05 were considered statistically significant.

Results: The cohort (N=254) comprised students from COP (N=101), COM (N=115) and faculty (N=38). Sixty five percent of students and 53 percent of faculty had normal body mass indices, and less than 13 percent of participants reported a pre-existing health condition. Regarding diet quality, faculty trended toward having lower STC scores, indicative of healthier dietary choices, compared to students (P=0.08). Faculty also had higher mean scores in nutrition knowledge (P less than 0.0001) and dietary mindfulness (P less than 0.0001). A higher proportion of faculty were "completely confident" or "confident" about lifestyle counseling (P less than 0.0001) compared to students, the majority of whom felt "somewhat confident" about lifestyle counseling. Notably, participants with higher confidence in lifestyle counseling also had lower mean STC scores (indicative of healthier diets), and higher scores in nutrition knowledge and dietary mindfulness (P less than 0.01 for all). While all groups met minimal requirements for weekly physical activity, faculty trended toward allocating more time to exercise than students (P=0.07) and a higher percentage of them were active/very active. Conversely a higher percentage of COP students were low active/sedentary (P less than 0.05). COP and COM students had otherwise comparable STC scores, nutrition knowledge and dietary mindfulness.

Conclusion: Our findings indicate that compared to pharmacy and medical students, faculty members in these programs tend to have healthier diets, are more knowledgeable about nutrition and engage more in mindful eating. In turn, these attributes are associated with greater confidence in lifestyle counseling. Taken together, these findings suggest that providing healthcare professional students with adequate education and training in nutrition could increase the likelihood that they will adopt healthy lifestyle practices and, as such, may feel more empowered and confident in their ability to provide lifestyle recommendations to their patients.

Poster Title: Intrapleural administration of tissue plasminogen activator for the management of complicated pleural effusions

Primary Author: Jeffrey Shu, Touro University California College of Pharmacy, California; **Email:** jeffrey.shu@tu.edu

Additional Author (s):
Sammi Hiu Yi Tam
Amanda Morris
Laura Baumgartner

Purpose: Complicated pleural effusions are a common source of morbidity and mortality for hospitalized patients. Management often includes chest tube placement and antibiotic therapy, however surgical intervention with decortications or Video Assisted Thoracic Surgery (VATS) may be necessary in cases where drainage fails. Intrapleural administration of t-PA may play an important role in reducing the need for surgical intervention; however a lot remains unknown in terms of optimal dose and frequency of administration. The purpose of this study was to evaluate the use of intrapleural t-PA for the management of complicated pleural effusions, and to determine if a dose-response relationship exists.

Methods: This was a retrospective cohort study that examined all adult patients at the University of California San Francisco Medical Center who received t-PA for the management of a complicated pleural effusion from July 2013 to July 2016. Patients were excluded if they received t-PA for indications other than pleural effusions. The primary outcome assessed was success of t-PA therapy, which was defined as avoidance of surgical interventions (i.e. VATS or decortication). Secondary outcomes assessed included chest tube output pre and post t-PA administration, radiographic improvement following t-PA administration (as documented by the thoracic surgery team), t-PA dose administered, number of t-PA doses administered, and bleeding complications.

Results: Fifty-six patients received intrapleural t-PA for the management of complicated pleural effusions from July 2013 to July 2016. Patients were 59 ± 17 years of age, with 61% of patients being male. Pleural effusions were caused by infection (63%), malignancy (16%), hemothoraces

(5%), and unknown causes (16%). Successful pharmacologic management with t-PA occurred in 86% of patients. Average 24-hour chest tube output increased from 140 ± 180 ml to 715 ± 737ml after administration of t-PA (p=0.001). Radiographic improvement occurred in 59% of patients. Average single t-PA dose administered was 5.6 ± 4 mg, with an average cumulative t-PA dose of 12 ± 15 mg. Forty percent of patients received only one dose of t-PA, with 36% receiving two doses, 15% receiving three doses, 6% receiving four doses, and one patient receiving 9 doses. Two patients had minor bleeding complications.

Conclusion: Intrapleural administration of t-PA in patients with complicated pleural effusions significantly increased chest tube output and successfully prevented further surgical interventions. The findings in this study confirm the beneficial role of t-PA in patients with reduced chest tube outflow, and had minimal bleed risk. However, differences in t-PA dosing, number of doses, and frequency of administration needed to achieve optimal output indicate a need for protocolized management at institutions. Future studies will include analyzing the relationship between subsequent t-PA doses and response.

Session-Board Number: 7-035

Poster Title: Theoretical use of Novel Oral Anticoagulants (NOACs) in Heparin Induced Thrombocytopenia (HIT)

Primary Author: Bushra Khan, UCSD Skaggs School of Pharmacy and Pharmaceutical Sciences, California; **Email:** bskhan@ucsd.edu

Purpose: This case report presents a patient who received anticoagulation with a novel oral anticoagulant (NOAC) after a positive diagnosis with heparin-induced thrombocytopenia (HIT). Patient RW was admitted to the hospital for aortic valve replacement and experienced post-operative paroxysmal atrial fibrillation (A-fib). During this hospitalization the patient received heparin and was maintained on foot pumps bilaterally without anticoagulation post-surgery. Subsequently upon discharge, the patient refused anticoagulation for both paroxysmal atrial fibrillation and deep vein thrombosis (DVT) prophylaxis. Approximately one month later, RW presented to the emergency department with symptoms of infection and was diagnosed with health care associated pneumonia for which she received treatment with levofloxacin and vancomycin. While inpatient, she complained of pain and swelling in her legs and a duplex scan of her bilateral lower extremity was positive for DVT and a CT chest angiogram was positive for extensive pulmonary embolic disease involving all lobes of the lungs. Upon arrival to the hospital, RW's platelet count was normal at 247 K/mcL. The patient was started on a heparin drip (which was later switched to lovnenox) and received treatment for 5 days when it was stopped due to the fall in her platelet count by greater than 50% to a level of 96 K/mcL. The patient had a 4 T's Test score of 5 putting her at an intermediate probability of HIT (2 points for > 50% fall in platelet count, 2 points for timing of platelet count fall of < 1 day with recent heparin exposure, and 1 point for other causes of thrombocytopenia present – vancomycin use for pneumonia treatment). Based on these inconclusive intermediate results further HIT antibody testing was conducted. Both the immunoassay and optical density (OD) were positive for HIT, but the OD was not confirmatory, so an additional serotonin release assay was ordered which later confirmed positive HIT diagnosis (SRA results were pending at discharge). Patient RW was presented with three options: the first was bridging treatment with Arixta until warfarin is therapeutic (outpatient treatment); the second was bridging treatment with Argatroban until warfarin is therapeutic (would require inpatient treatment); and the last option was outpatient treatment with a NOAC (not an approved indication). The patient was

unable to afford Arixtra and unable to remain hospitalized for Argatroban treatment, and so she received a prescription for Eliquis 10 mg BID for 4 days, then 5 mg BID with recommendation to follow-up with cardiology in one week. The patient followed up one week later and her platelet counts rebounded to 510 K/mcL, the patient was noted to be stable with no concern for thrombocytopenia or venous thromboembolism (VTE). Theoretical benefits of NOACs in HIT include not causing platelet aggregation or activation in the presence of HIT antibodies, not causing platelets to release platelet factor 4 (PF4), and not interacting with PF4 that may be present. Heparin induced thrombocytopenia is a rare immune mediated reaction that can occur with exposure to heparin. Patients are at a higher risk of thrombosis and require anticoagulant therapy with non-heparin products. Currently NOACs are not approved for treatment of HIT, however additional large-scale studies are needed to confirm the safety and efficacy of NOACs in patients diagnosed with HIT.

Poster Title: Comparison of the Incidence and Prevalence of Tardive Dyskinesia in Adult and Elderly Populations

Primary Author: Celeste Sage, University of California San Diego, Skaggs School of Pharmacy and Pharmaceutical Sciences, California; **Email:** csage@ucsd.edu

Additional Author (s):
Yu Jin

Purpose: Tardive dyskinesia (TD) is a movement disorder that has long been associated with antipsychotic drug use. Early studies have suggested elderly patients are at increased risk of developing TD, but this is largely confounding with duration of antipsychotic use. A recent meta-analysis estimated that the risk of developing TD has been reduced threefold in elderly patients using newer second generation antipsychotics (SGAs) as compared to first generation antipsychotics (FGAs). This study aims to determine if there is a significant difference in the incidence and prevalence rates of TD in the adult and elderly populations since the introduction of SGAs.

Methods: This study was a literature review of clinical studies published between 1995 and August 2016. Two reviewers independently conducted a literature search using electronic databases including PubMed, Web of Science, and Google Scholar. Studies were included if they reported an incidence or prevalence rate of TD in participants exposed to antipsychotics and if they rated and diagnosed TD using a validated rating scale and diagnostic criteria. Adult subjects were defined as subjects between the ages of 18 and 55 and elderly subjects were defined as older than 55 years old. Studies were excluded from analysis if less than 50 subjects were included, if they were case reports, or if the reported TD rates were not stratified by age group when the study population had mixed adult and elderly subjects. Statistical analysis of the studies was done by Wilcoxon rank-sum test in STATA 13.1 to assess for differences in incidence and prevalence rates between adults and geriatric populations. This test was also used to determine if there was a difference in the incidence rates based on use of FGAs versus SGAs, both within the age groups and regardless of age.

Results: A total of 104 studies were identified that met the initial search criteria and 36 studies were included in the final analysis. There was not a statistically significant difference found in the incidence or prevalence rates between the adult and elderly populations (p=0.40, p= 0.057, respectively). The median incidence rate of TD was 6% (range 0-23%) in the adult population and 5.5% (range 3-26%) in the elderly population. The median prevalence rate in the adult population was 24% (range 4-33%) and elderly population was 38% (range 19-47%). The median incidence rate in the adult population was 6% for FGAs compared to 3% for SGAs, while the elderly population was 10.5% for FGAs compared to 5.5% for SGAs, although no significant difference was found within either the adult or elderly populations (p= 0.68, p = 0.19, respectively). The median incidence rate of FGA users was 6% compared to 4% for SGA users regardless of age group, which also produced no significant difference (p= 0.089).

Conclusion: Overall, this study found no statistically significant difference in incidence or prevalence of TD between adult and elderly populations. The incidence and prevalence studies conducted before 1995 used higher doses of FGAs in the elderly compared to current practices, which likely increased reported rates. In addition, the widespread use of SGAs may be contributing to the narrowing gap of incidence and prevalence rates of TD in the elderly compared to adults. There may not have been enough studies to find a significant difference between incidence rates in SGA and FGA users or between prevalence rates.

Poster Title: Impact of antiretroviral therapy on non-AIDS-defining cancer mortality among persons with AIDS: San Francisco, California, 1996 to 2013

Primary Author: Danning Ma, University of California San Francisco, California; **Email:** danning.ma@ucsf.edu

Additional Author (s):
Susan Scheer
Ling Hsu
Sandy Schwarcz
Nancy Hessol

Purpose: Widespread use of combination antiretroviral therapy (ART) since 1996 has led to a decreased number of deaths due to AIDS-defining cancers (ADCs) in people with AIDS (PWAs). In contrast, the effect of ART on non-AIDS-defining cancers (NADCs) is less well known. In this investigation, we aimed to evaluate the impact of ART on NADC mortality by examining temporal trends in causes of death among PWAs.

Methods: A retrospective cohort study was conducted using data from San Francisco Public Health Department HIV/AIDS surveillance registry. The study included AIDS cases aged 13 or older who died during the years 1996 through 2013. Information on underlying causes of death was obtained from matches with the National Death Index through 2013 (the most recent year available). Observation time was divided into three periods corresponding to improvements in ART: 1996-1999, 2000-2005, and 2006-2013. For each time period, we calculated proportional mortality ratios (PMRs) for all NADCs combined, and performed age, race and sex-adjusted standardized mortality ratios (SMRs) with 95 percent Poisson confidence intervals (CI) for NADC-specific underlying causes of death using the California population as the reference group. This study was exempt from institutional review board review.

Results: The study included 5,822 deceased PWAs. Of these, 90 percent were male, 68 percent aged 35 to 54 at time of death, 61 percent survived more than 4 years post-AIDS diagnosis, and 79 percent initiated ART. Sixty-three percent were White, 20 percent African American, and 12 percent Hispanic; 59 percent were men who have sex with men (MSM), 22 percent MSM with a

history of injection drug use (IDU), and 16 percent IDU. From 1996 to 2013, the PMRs significantly increased for all NADCs combined (4.3 percent in 1996 to 1999, 7.0 percent in 2000 to 2005, 12.3 percent in 2006 to 2013, p less than 0.01). Meanwhile, the SMRs significantly decreased for all NADCs combined (SMR 3.6 CI 2.9 to 4.3 in 1996 to 1999, SMR 2.3 CI 1.9 to 2.7 in 2000 to 2005, SMR 1.9 CI 1.6 to 2.1 in 2006 to 2013, p less than 0.01). NADC-specific SMRs did not change significantly over time. Nonetheless, the SMRs were significantly elevated for anal, liver and lung/larynx cancer in 1996 to 2013, and for rectal cancer in 2000 to 2013.

Conclusion: The temporal increase in PMRs for all NADCs combined are likely due to the advent and widespread use of ART which may have indirectly shifted the cancer burden from ADCs to NADCs. While NADC-specific SMR trends were not significant, cancer mortality among PWAs is still significantly elevated above mortality in the general population for anal, liver, lung/larynx and rectal cancer in the ART era. Thus, these cancers should be targeted for improved cancer prevention, screening, and treatment strategies among persons living with HIV/AIDS.

Lindsay Kinakin
Tiffany Buckley

Purpose: The purpose is to determine the number of patients who experienced a hypoglycemic event (blood glucose < 70 mg/dL) or severe hypoglycemic event (blood glucose < 40 mg/dL) while receiving an insulin infusion from the Adult Diabetic Ketoacidosis or Hyperosmolar Coma Management Order Set before and after order set change.

Methods: Retrospective chart review of adult inpatients presenting with diabetic ketoacidosis or hyperosmolar hyperglycemic nonketotic syndrome who received insulin infusions from the Adult Diabetic Ketoacidosis and Hyperosmolar Coma Management Order Set during the pre-implementation period (Mar 11, 2015 - Dec 11, 2015) and the post-implementation period (Dec 12, 2015 - Sept 11, 2016) of the new order set in the inpatient setting at UCSF Medical Center.

Results: In the 66 pre-implementation order set patient group, 12 patients experienced a hypoglycemic event with an average Adult Diabetic Ketoacidosis or Hyperosmolar Coma Management Order Set time of 7.07 hours, and only 1 patient received dextrose IV infusion 3.3 hours after blood glucose decreased to 200 mg/dL. In the 84 post-implementation order set patient group, 2 patients experienced a hypoglycemic event with an average Adult Diabetic Ketoacidosis or Hyperosmolar Coma Management Order Set time of 7.5 hours, and no patients received dextrose IV infusion after blood glucose decreased to 200 mg/dL. In both groups, there were no severe hypoglycemic events.

Conclusion: After changing the Adult Diabetic Ketoacidosis and Hyperosmolar Coma Management Order Set, there was an improvement in patient safety as the number of hypoglycemic events decreased. However, the non-compliance of administering dextrose IV infusion when blood glucose decreased to 200 mg/dL after patients received these order sets can compromise patient safety as it can contribute to preventable hypoglycemic events during the inpatient course.

Submission Category: Infectious Diseases

Session-Board Number: 7-039

Poster Title: Infrequent use of oseltamivir phosphate in hospitalized patients with suspected or confirmed influenza at an academic medical center

Primary Author: Justin Lin, University of California, San Diego Skaggs School of Pharmacy and Pharmaceutical Sciences, California; **Email:** jjlin91@gmail.com

Additional Author (s):
Robin Bricker-Ford
Charles James
Darcy Wooten
Gregory Seymann

Purpose: Respiratory infections caused by influenza type A and B are associated with significant morbidity and mortality. CDC guidelines recommend early antiviral therapy in all patients with severe disease requiring hospitalization. Oseltamivir phosphate (Tamiflu®) is the preferred antiviral agent for the treatment of influenza. Although studies have demonstrated benefits of antiviral treatment in hospitalized patients with influenza, delays between the release of guidelines and changes in clinical practice commonly exist. The purpose of this study was to assess the uptake of CDC recommendations by evaluating the utilization of oseltamivir phosphate in hospitalized patients with suspected or confirmed influenza.

Methods: This study was a single center, cross-sectional, retrospective chart review of adult patients hospitalized with influenza-like symptoms who underwent a diagnostic test for influenza within five days of admission. The primary study objective was to evaluate the proportion of patients with suspected or confirmed influenza who were prescribed oseltamivir phosphate. Additionally, all patients who received at least one dose of oseltamivir phosphate were evaluated for the dose, frequency, duration and appropriateness of the prescription. Secondary objectives included an assessment of predictors for the use of empiric vs targeted therapy, and an evaluation of clinical outcomes in treated patients who tested positive for influenza. Empiric therapy was defined as patients who received therapy prior to the availability of their influenza test result in the medical record, while targeted therapy was defined as patients who did not receive therapy until their influenza test resulted. Early therapy was

defined as patients who received therapy within 24 hours, while delayed therapy was initiated greater than 24 hours from when the diagnostic test was ordered.

Results: In this study, 1,075 patients met inclusion criteria and of these, 149 (13.9%) were prescribed at least one dose of oseltamivir phosphate during hospitalization; 75/149 (50.4%) of patients received empiric therapy and 74/149 (49.6%) received targeted therapy. Of the 149 patients who were prescribed oseltamivir phosphate, 133 (89.3%) were prescribed the medication with appropriate dose, frequency, and duration as recommended by the manufacturer. The majority of influenza-positive patients (146/149, 98.0%) were prescribed the standard 75 mg twice daily dose of oseltamivir and were treated for a median duration of 5.5 ± 2.34 days. Treatment was stopped after 1.0 ± 1.36 days in patients who tested negative for influenza. The only statistically significant patient predictor of type of oseltamivir phosphate therapy prescribed was age ≥ 65 years; patients receiving targeted therapy were more likely to be elderly compared to patients receiving empiric therapy (54.1% vs 36.0%; p = 0.0171). Patients receiving empiric therapy were less likely to be readmitted within 30 days compared to patients receiving targeted therapy (8.2% vs. 37.5%; p = 0.0408).

Conclusion: In this study, prescribers at an academic medical center empirically treated only a small fraction of patients (75/1,075; 7.0%) with suspected influenza using oseltamivir phosphate. The majority of patients hospitalized at an academic medical center did not receive antiviral treatment in concordance with current CDC guidelines, which recommend treatment of all patients with suspected influenza, and future studies to elucidate reasons for clinician noncompliance would be of interest.

Poster Title: Preliminary Evaluation of Clinical Outcomes 12 Months After Discharge from a Pharmacist Led Diabetes Intense Medical Management "Tune Up" Clinic

Primary Author: Jennifer Vu, University of California, San Diego, Skaggs School of Pharmacy and Pharmaceutical Sciences, California; **Email:** jpv001@ucsd.edu

Additional Author (s):
Carmen Truong
Jan Hirsch
Candis Morello

Purpose: We recently reported positive outcomes for complex diabetes patients in an Endocrinologist-PharmD collaborative practice, called the Diabetes Intense Medical Management (DIMM) "Tune Up" clinic, as compared to patients receiving usual care from primary care providers (PCPs). The purpose of this study was to determine patients' hemoglobin A1c (HbA1c) levels 12 months after discharge from the DIMM clinic. We hypothesized HbA1c levels would not be significantly different than discharge and would be significantly lower than initial DIMM clinic visit. Secondary objectives examined changes in other metabolic outcomes and correlation of age and length of stay in the DIMM clinic with outcomes.

Methods: A retrospective cohort study was conducted on 64 eligible patients who had been discharged from the DIMM clinic. Patients were referred to the DIMM clinic by their PCPs. The DIMM clinic "tune up" model couples pharmacist-provided medication therapy management with patient-specific diabetes education during approximately three 60-minute visits over a 6-month period, to achieve treatment goals before the patient is discharged back to their PCP. Patients included in this study must have been diagnosed with type 2 diabetes mellitus, have been treated at the DIMM clinic and discharged at HbA1c goal, and have remained in the VA healthcare system for at least 12 months post-discharge. The discharge HbA1c and other metabolic levels were those observed at the final DIMM clinic visit. Data for HbA1c, fasting plasma glucose (FPG), total cholesterol (TC), low-density lipoprotein (LDL), high-density lipoprotein (HDL), triglyceride (TG), blood pressure (BP), and body mass index (BMI) at 6 and 12 months post-discharge were collected from the VA patient electronic medical record system

using a +/- 3 month window. The last observation carried forward approach was used to assign missing values at 6 and 12 months. Because data were not normally distributed median values were compared using Wilcoxon signed rank test and McNemar's test was used to compare proportions at goal.

Results: Median HbA1c was greater at 12 months post-discharge compared to the level at discharge date [HbA1c 7.7% (range 4.9-15.5) vs. 6.9% (range 5.6-8.8), p < 0.05]. However, HbA1c at 12 months post-discharge was still significantly lower than at baseline [HbA1c 7.7% (range 4.9-15.5) vs. 10.0% (range 7.9-17.2), p < 0.05].

At 12 months post-discharge, FPG had increased compared to discharge date [FPG 150 mg/dL (range 43-716) vs. 117.5 (range 60-448), p < 0.05], but was still significantly lower than the baseline value [200 mg/dL (range 45-472), p < 0.05].

LDL and HDL (normal levels), TG, weight and BMI 12 months post-discharge were not significantly different than the discharge values. Systolic and diastolic BP were significantly higher 12 months post discharge [133 mmHg (range 71-189) vs 124 mmHg (range 90-162), 73.5 mmHg (range 41-100) vs. 71.5 mmHg (range 51-92)].

All DIMM clinic patients were discharged at the goal HbA1c of < 9%. At 12 months post-discharge, 78% of patients remained at this goal level. Additionally, 81% of patients maintained their HbA1c goal at 6 months post-discharge.

No significant correlation was detected between change in HbA1c 12 months post discharge and duration in DIMM clinic (r=0.07) nor age (r=0.12) p's>0.05.

Conclusion: While 12 months following discharge from the DIMM tune up clinic, patients' median HbA1c rose significantly by 0.8, the value of 7.7% remained clinically significant, with 78% of patients maintaining HbA1c goal of < 9%. Compared to baseline HbA1c values, patient's median HbA1c at 12 months post discharge remained 2.3 points lower. Overall, after receiving medication therapy management combined with patient-specific diabetes education, preliminary results demonstrate patients discharged from the DIMM clinic have exhibited sustained positive glycemic control.

Submission Category: Pain Management

Submission Type: Descriptive Report

Poster Title: Characteristics of opioid prescriptions for the treatment of chronic nonmalignant pain in a resident physician-run primary care clinic

Primary Author: Jacqueline Tam, University of California, San Francisco, California; **Email:** tam.jackie@gmail.com

Additional Author (s):
Victoria Su
Jennifer Toy

Purpose: The purpose of this study was to describe the current prescribing practices and characteristics of chronic nonmalignant pain patients prescribed 90 or more days of opioids by physicians at the Kaweah Delta Family Medicine Center, a resident physician-run primary care clinic in Visalia, California, from January 2015 to January 2016.

Methods: A single-center retrospective chart review was completed to describe the indications for opioids, daily dosages prescribed in morphine milligram equivalents (MME), concurrent use of non-opioids, and documentation of controlled substance user agreements in patients with chronic nonmalignant pain. A list of opioid prescriptions written by clinic physicians between January 1, 2015 and January 31, 2016 was analyzed to identify patients who were prescribed 90 or more days supply of opioids within the study period. A total of 39 adult patients with chronic nonmalignant pain were identified and analyzed. The data collected from chart review included a patient's age, sex, insurance, referral specialties, documented opioid prescriptions, concurrent non-opioid therapies for pain or psychiatric disorders, history of substance abuse, physician documentation of a Controlled Substance Utilization Review and Evaluation System (CURES) report, and physician documentation of clinic controlled substance use agreements. Total daily doses of opioids over the course of the study period were calculated as MME per day. Descriptive statistics were used to characterize these data.

Results: Patients were a median age of 48 years old with 36 percent males and 64 percent females. The primary insurance types held were Medi-Cal (59 percent), Medicare (8 percent), and dual coverage with Medi-Cal and Medicare (33 percent). The most common indications for opioids were back, neck, or thoracic pain (69 percent) and joint pain (51 percent). The most

commonly referred specialties were physical therapy (49 percent) followed by pain management (46 percent). History of substance use included tobacco use (56 percent), marijuana (10 percent), methadone (5 percent), methamphetamine (5 percent), and heroin (3 percent). The daily opioid dose prescribed was an average of 25 MME per day, median 16 MME per day, and range 5 to 211 MME per day. The most common dose range was 1 to 19 MME per day prescribed to 62 percent of patients. The most common concurrently prescribed non-opioids were antidepressants followed by benzodiazepines, where oral nonsteroidal anti-inflammatory drugs (NSAIDs) and gabapentin were the most common non-opioids prescribed specifically for pain. Controlled substance user agreements were signed and documented in 87 percent and CURES reports run on 44 percent of patients. The most common psychiatric comorbidities were depression (49 percent) and anxiety (44 percent).

Conclusion: Patients with chronic nonmalignant pain were most likely to receive opioids for back, neck, or thoracic pain at a dose range of 1 to 19 MME per day, be on concurrent benzodiazepines or antidepressants, have tried or been concurrently taking oral NSAIDs or gabapentin, and have signed a controlled substance user agreement with their primary care physician. These descriptive data serve as a baseline for future studies on the impact of interprofessional management of patients with chronic pain at the Kaweah Delta Family Medicine Center.

Poster Title: The role of a clinical pharmacist as part of a multidisciplinary care team in the treatment of HCV in HCV/HIV co-infected patients

Primary Author: Antonio Olea, University of California, San Francisco, California; **Email:** antonio.olea@ucsf.edu

Additional Author (s):
Janet Grochowski
Parya Saberi

Purpose: There are limited data on the role of clinical pharmacists in patients living with HIV who are co-infected with hepatitis C (HCV). We evaluated the role of a clinical pharmacist in HCV treatment of HIV and HCV co-infected patients.

Methods: This was a descriptive study of the role of a clinical pharmacist in the HCV treatment of HIV/HCV co-infected adults (18 years old and older) receiving care at a publicly-funded safety-net clinic in San Francisco between March 18, 2015 and September 15, 2016. HCV treatment was chosen based on the 2015/2016 American Association for the Study of Liver Disease (AASLD) guidelines and patient specific factors. Patients' care was coordinated through the efforts of a multidisciplinary team consisting of a physician, a nurse, rotating infectious diseases fellows, and a clinical pharmacist. The role of the clinical pharmacist was categorized and quantified into eight main categories: (1) HCV medication adherence counseling, (2) HCV drug-drug interaction (DDI) counseling and screening, (3) HCV medication adverse reactions counseling, monitoring, and interventions, (4) HCV counseling regarding HCV treatment outcomes and risk of re-infection, (5) ordering laboratory tests and interpretation of HCV laboratory values, (6) pharmacy prior authorization (PA) initiation and submission, (7) HIV medication adverse event assessment, and (8) other (including refilling medications and management of other comorbidities).

Results: We identified 138 HIV/HCV co-infected patients who were treated with direct-acting antiviral (DAA) therapy during this period. Among these patients 76.1% were male, 42.0% Caucasian, 55.1% non-cirrhotic, 76.8% HCV treatment-naïve, and 44.9% HCV genotype 1a. The majority of patients were initiated on the fixed-dose combination of ledipasvir/sofosbuvir

(82.6%) for 12 weeks (93.5%). The clinical pharmacist completed 126 PAs (91.3%), counseled on HCV medication adherence in 57.3% of patients, conducted HCV DDI counseling and screening in 39.9%, monitored HCV medication adverse events reactions in 54.3% and intervened on 6% of patients, counseled on possibility of HCV cure and risk of re-infection in 37.7%, ordered laboratory tests in 32.6% and reported and interpreted laboratory values for 31.9% of patients, evaluated HIV medication adverse events in 23.2%, and participated in other activities in 31.2% of patients, including 24.6% medication refills. Thirty-six patients (26%) experienced HCV medication-related adverse events but none discontinued treatment due to adverse effects. Sustained virologic response at 12 weeks (SVR12) was achieved in 137 (99%) of the patients. One treatment-experienced patient did not achieve SVR12 due to treatment failure but was later successfully treated in a study using triple DAA therapy.

Conclusion: In a multidisciplinary care team, clinical pharmacists play a critical role in assisting patients achieve SVR through PA initiation and submission, DDI screening, HCV counseling on adherence, adverse events, and risk of re-infection, laboratory test ordering and interpretation, and helping manage other medication-related issues.

Poster Title: Barriers and solutions to providing pharmacy services to patients with limited English proficiency: A qualitative study

Primary Author: Isabel Fong, University of California, San Francisco, California; **Email:** isabel.fong@ucsf.edu

Additional Author (s):
Kirby Lee

Purpose: Patients who have a limited ability to read, write, speak or understand English can be limited English proficient (LEP) and are at higher risk for medication non-adherence and other medication problems. Despite increasing regulatory efforts to improve access to language assistance services such as verbal counseling and prescription labels in non-English languages, availability of these services varies greatly among pharmacies. The purpose of our study is to better understand the barriers and challenges that pharmacists encounter when providing services to LEP patients and to identify possible solutions among community and outpatient hospital pharmacies.

Methods: We conducted semi-structured interviews with pharmacists practicing in the following pharmacy categories: retail or chain, independent, or outpatient hospital. A purposive sampling strategy was employed to ensure an adequate representation of participants from each pharmacy category between February to September 2016. Pharmacists were eligible to participate if they had worked at their respective pharmacy for at least one year and were recruited by phone or e-mail. We developed an interview guide based on previous studies reported in the existing literature. Interview questions were designed to assess if and how pharmacists provide non-English prescription labels and verbal counseling, any barriers or challenges in doing so, and potential solutions or ideas to improve these services. Lastly, we solicited pharmacists' attitudes and opinions regarding these services and their awareness of policies to improve LEP patients' understanding of their medications. Interviews were conducted in person or by telephone and were audiotaped and transcribed. A modified grounded theory analysis was used to identify emergent themes based on extensive reviews of transcripts, summaries and note taking. The UCSF Institutional Review Board approved this qualitative study.

Results: We interviewed 16 pharmacists representing all three pharmacy categories (6 retail pharmacies, 5 independent pharmacies and 5 outpatient hospital pharmacies). Nearly all pharmacies provided non-English labels or verbal counseling. The most common languages were Spanish, Chinese, Russian, Vietnamese, Tagalog and Korean. All pharmacists expressed concerns over the accuracy and quality of translating written labels with computer software. They preferred using staff to translate and write or type medication instructions instead of using software, or use pre-printed translated template labels. Similarly they preferred using pharmacy staff or patients' family members to verbally interpret and counsel LEP patients rather than using telephonic language translation services. Emerging themes about attitudes and opinions of pharmacy services for LEP patients included discomfort with verifying a prescription label when the accuracy of translation is questionable and although language assistance services improve patient care, not all pharmacists should be required by law to do so because incorrect translation could cause harm and it is not feasible or necessary for all pharmacies. Potential solutions included using pharmacy staff who could translate and interpret, creating pre-printed labels with correct translation or improved software, or finding a pharmacist who can translate the language of interest.

Conclusion: Community and outpatient hospital pharmacists face a number of challenges and barriers to effectively provide translated prescription labels and verbal counseling to LEP patients. We have identified common barriers, attitudes and potential solutions which may help pharmacists, policy makers and other healthcare entities decide on ways to improve pharmacy services for LEP patients. Doing so may lead to better health outcomes by ensuring safer, more accurate medication use and reducing potential adverse drug events in this high risk population.

Poster Title: Evaluation of Antiretroviral Drug Regimens and Drug Interactions in CalOptima Patients: A Retrospective Claims Data Analysis

Primary Author: Malini Madhusudhan, University of California, San Francisco, California; **Email:** malini.madhusudhan@ucsf.edu

Additional Author (s):
Valerie Vu
Luis Perez
Kristin Gericke

Purpose: Appropriate antiretroviral therapy (ART) is highly effective in preventing the transmission of HIV if that therapy can lead to sufficient viral suppression. Identifying interactions, adherence, and appropriateness of ART based on the Department of Health and Human Services (DHHS) is imperative for optimal efficacy of a particular regimen. The purpose of this study is to assess interactions between HIV-positive CalOptima patients' ART regimens with their other current medications, adherence to ART regimen, and if regimens agree with current recommended therapies per DHHS.

Methods: This is a descriptive, retrospective analysis using blinded claims data from CalOptima patients. Inclusion criteria included adult patients submitting claims data on ART medications from January 1, 2016 to June 30, 2016. Claims data were analyzed for interactions, adherence, and DHHS-guideline recommended therapy for the treatment of HIV.
Drug Interactions with ART regimen: Each of a patient's non-ART medications were classified into therapeutic groups. Total number of interactions per therapeutic group was quantitatively measured for each CalOptima patient. Drug interactions were identified using Micromedex.
Adherence: Adherence was measured using the Proportion of Days Covered (PDC) developed by the Pharmacy Quality Alliance which has been studied and developed as our standard measurement. Calculations and determination of adherence was based on fill dates and days supply for each patient's HIV ART regimen. PDC was calculated by taking the ratio of days covered by claims data to the difference between the last day of the measurement period (6/30/2016) and the first ART fill date.

ART regimen Appropriateness: Regimens were separated into five categories based on DHHS guideline recommendations which includes: recommended, alternative, other, not recommended, or pre-exposure prophylaxis (PrEP). It was also documented whether the regimen was a single-pill regimen or required multiple pills to complete the regimen.

Results: A total of 279 patients were analyzed. For regimen appropriateness, 127 patients (45.5%) had a DHHS recommended regimen, 89 (31.9%) had an alternate DHHS regimen, 35 (12.5%) had a regimen not recommended by DHHS, 3 (3.2%) had another antiretroviral regimen, and 19 (6.8%) had a PrEP regimen. Only 66 (27%) of all ART were single-tablet regimens. For PDC, 86 (30.8%) patients had ratios less than 0.9, 30 (10.8%) patients had ratios between 0.9 and 0.94, and 163 (58.4%) patients had ratios greater than 0.9. A total of 225 drug interactions were found. The top 4 groups of medications represented in these interactions were antidepressants (43, 25.3%), analgesics (35, 20.6%), antimicrobials (31, 18.3%), and antihyperlipidemics (19, 11.1%). All other groups of medications accounted for 6% or less of the interactions.

Conclusion: There were several limitations to our claims analysis. For regimen appropriateness, there was had no way to discern if patients were treatment naive or treatment experienced. The analysis of drug interactions did not include over the counter medications. Lastly, the analysis of adherence could not accommodate for deliberate holds of ART therapy. Nevertheless, the data suggest that the majority of patients are not on DHHS recommended therapies, which often interact with other medications. A large number of patients have poor adherence to ART. All these factors can contribute to poor virological suppression.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Evaluative Study

Session-Board Number: 7-045

Poster Title: Medication error rates with a newly implemented integrated glycemic management system

Primary Author: Esther Chung, University of California, San Francisco, California; **Email:** esther.chung@ucsf.edu

Additional Author (s):
Tony Tran
Sarah Stephens
Christopher Patty

Purpose: On March 16, 2016, Kaweah Delta Health Care District, an eight-campus, 581-bed healthcare organization in Visalia, California, underwent a hospital-wide transition from sliding scale insulin to Glucommander (Glytec Systems) for inpatient glycemic control. Glucommander computer software individualizes insulin dosing and administration based on its proprietary algorithm in accordance with American Diabetes Association best practices. It has shown positive outcomes; however, nation-wide use is limited and studies assessing implementation errors are scarce. Currently, Glucommander settings cannot be changed once initiated. Therefore, we aim to identify errors preventing optimal glycemic control and recommend implementation strategies to better inform future institutions considering Glucommander.

Methods: A retrospective chart review of 512 adult patients receiving intravenous and/or subcutaneous insulin therapy with Glucommander software from March 16, 2016 to April 16, 2016 at Kaweah Delta Health Care District in Visalia, California was conducted. Patient population included adults 18 years old or older continued on insulin therapy for at least 24 hours. Major exclusion criteria were expecting mothers, infants, and patients on inpatient insulin therapy for greater than 30 days. Hyperglycemia was defined as blood glucose values greater than or equal to 180 mg/dL (10.0 mmol/L) and hypoglycemia was defined as blood glucose values less than 70 mg/dL (3.9 mmol/L). Patient reports were generated by Glucommander and each patient meeting the inclusion criteria was further examined in both Glucommander and Cerner Soarian for relevant data collection. The primary endpoint was transcription error rates of insulin orders prescribed by physicians versus manual nurse inputs into Glucommander software for patients experiencing at least one hyperglycemic or

hypoglycemic event during the designated time period. Secondary endpoints were total number of hyperglycemic or hypoglycemic events 31 days post-Glucommander implementation, identification of errors not associated with the primary endpoint, and number of interventions required to adjust out-of-range blood glucose values. Initial training requirements for each hospital department were explored and compared. Descriptive statistics were used for data analysis.

Results: During the first 31 days post-implementation of Glucommander, 391 unique patient visits experienced at least one hyperglycemic episode and 121 unique patient visits experienced at least one hypoglycemic episode during the course of their admission. The hyperglycemic group consisted of 51.7% males and 48.3% females, while the hypoglycemic group consisted of 57% males and 43% females. The primary endpoint of transcription error rates resulted in 33.3% versus 16.7% of total errors found in the hyperglycemic and hypoglycemic groups, respectively. Secondary endpoints resulted in 3,596 versus 244 separate blood glucose values classified as hyperglycemic and hypoglycemic events, respectively. Errors not related to the primary endpoint were categorized as charting errors. Hyperglycemic patients warranted 46 interventions in contrast to 246 interventions in the hypoglycemic group. There were 388 unique patients with 3 hospital readmissions in the hyperglycemic group and 114 unique patients with 7 readmissions in the hypoglycemic group during the study period. A weekly downward trend in number of interventions required in the hyperglycemic group was observed with each succeeding week while no such trend was observed in the hypoglycemic group.

Conclusion: We hypothesized that transcription errors may result in suboptimal control of blood glucose because initial nurse manual inputs from insulin physician orders cannot be changed once initiated. However, the incidence of transcription errors may be misleading due to a limitation in program settings where data needed to assess transcription errors retrospectively were unavailable. To better evaluate rate of transcription errors, and therefore improve patient safety, we recommend a change in Glucommander settings to display initial input parameters for all insulin orders. Future implementation can benefit from greater standardization and uniformity in both training and utilization of Glucommander features.

Poster Title: Time to reinitiation of anticoagulation in patients following a major bleed

Primary Author: Christopher Chiu, University of California, San Francisco, California; **Email:** christopher.chiu@ucsf.edu

Additional Author (s):
James Go
Nola He
Stephanie Truong
Tiffany Pon

Purpose: After patients experience a major bleed while on active anticoagulation, there is limited evidence guiding the ideal time to restart anticoagulation following the event. Specifically, data is limited for patients who experience intracranial hemorrhage (ICH). This project aims to evaluate the average time frame in which providers at the University of California Davis Medical Center (UCDMC) restart anticoagulation in patients admitted for ICH and the associated clinical outcomes.

Methods: The institutional review board approved this retrospective chart review. Electronic medical records were used to identify patients with suspected ICH who received anticoagulant reversal agents from May 1, 2014 to August 1, 2016. Patients 18 years old or greater who experienced ICH on admission or during hospitalization while on active anticoagulation, and were given at least one reversal agent (4-factor PCC (KCentra), idarucizumab, factor eight inhibitor bypass activity (FEIBA), vitamin K, or recombinant activated factor VII (rFVIIa)) were included in the study. Patients who did not restart anticoagulation or were restarted after more than 30 days, died or were discharged within 7 days of onset of bleed, were on a Vitamin K antagonist but with a subtherapeutic INR < 1.5 at the time of bleed, had incomplete medical records, or who experienced a major bleed with secondary etiologies such as tumor, major trauma, acute thrombolysis, aneurysmal subarachnoid hemorrhage, or other coagulopathies were excluded. The primary outcome measure was time to reinitiation of either prophylactic or therapeutic anticoagulation. Our secondary outcomes include the incidence of thrombotic events or worsening/recurrent bleed as well as 30-day mortality.

Results: Of 237 patients who met screening criteria, 26 patients were included. Eleven (42.3%) patients were restarted on either prophylactic or therapeutic anticoagulation. The mean time to restarting anticoagulation in this ICH population was 15 + 7.8 days. Five out of the 11 patients were initially restarted on prophylaxis anticoagulation with either heparin or enoxaparin, and one of those five patients was resumed on home-dose warfarin. The remaining six patients were restarted on warfarin with a majority of them at a lower dose (4.6 + 2.0 mg restarting dose vs 5.8 + 2.3 mg PTA dose). Seven patients did not restart anticoagulation throughout the admission or in the outpatient setting. Two patients were restarted on anticoagulation after 30 days. There were no incidences of thrombotic events or worsening/recurrent bleed in this sample population.

Conclusion: At UCDMC, patients who were admitted for an ICH restarted anticoagulation on average after 15 days of bleed compared to current literature and trials with a restart time frame between 7-30 days. The optimal start of anticoagulation time that is associated with a reduced rate of thromboembolism with no significant increased risk of bleed should be determined with a larger sample population. There was no differences in bleeding or VTE in patients who were restarted on AC versus those who did not.

Poster Title: Development and implementation of the Care Ecosystem: A medication management program for patients with dementia and their caregivers using innovative technology

Primary Author: Jennifer Phun, University of California, San Francisco School of Pharmacy, California; **Email:** jennifer.phun@gmail.com

Additional Author (s):
Kristen Cook
Katherine Possin
Anna Oh
Kirby Lee

Purpose: Potentially inappropriate medication use (PIMs) are common and dangerous among patients with dementia leading to worsening cognition, adverse drug events and death. Prescribing is often suboptimal because medication management is frequently lacking and safer medication alternatives and non-drug treatments are not always trialed. The Dementia Care Ecosystem (DCE) provides proactive, coordinated, continuous and personalized medication management through an innovative digital platform. The objectives are to characterize the types and frequencies of PIMs and other high risk medication changes over time among patients with dementia between intervention and control groups.

Methods: The Care Ecosystem is a telephone-based intervention designed to complement primary care services in managing patients with dementia. It consists of healthcare navigators, nurses, social workers and pharmacists who reconcile and monitor medications and provide expert advice, education and counseling to optimize medication use. This ongoing multicenter randomized controlled trial compares the Care Ecosystem (intervention group) to standard of care (control group) in the San Francisco Bay Area and Nebraska. We evaluated PIMs use relevant to dementia and delirium over time among intervention and control groups. PIMs were defined using the 2015 Beers Criteria and included anticholinergic, antipsychotic, benzodiazepine, non-steroidal anti-inflammatory drugs, systemic corticosteroids, hormone replacement therapy, histamine two receptor antagonists, alpha blockers, stimulants, benzodiazepine receptor hypnotics and other drug classes. We analyzed rates of PIMs use

among intervention and control groups for patients who have been enrolled in the trial for 5 or more months. The UCSF Institutional Review Board approved this study. This project was made possible by Grant Number 1c1cms331346 from the Department of Health and Human Services, Centers for Medicare & Medicaid Services. The contents of this abstract are solely the responsibility of the authors and do not necessarily represent the official views of the U.S. Department of Health and Human Services or any of its agencies.

Results: Among 403 patients with 5 or more months of follow up, 324 patients were available for analysis (80 percent follow up rate). 50 percent of control patients were prescribed any PIMs at baseline and this increased to 53 percent at follow up. In contrast 55 percent of intervention patients were prescribed any PIMs at baseline and this decreased to 52 percent at follow up. Differences in specific drug classes were observed. Intervention patients were prescribed fewer anticholinergics and benzodiazepines, whereas control patients were prescribed more of these drugs. Non-steroidal anti-inflammatory drugs decreased in both groups at similar rates. Antipsychotics increased in both groups, however this rate was slower among intervention patients. Overall, relative risk reductions for anticholinergics (26 percent), benzodiazepines (22 percent), antipsychotics (12 percent) and non-steroidal anti-inflammatory drugs (12 percent) resulted among intervention patients compared to control patients.

Conclusion: PIMs are common among dementia patients (50 percent), demonstrating the need for active, ongoing medication management. Preliminary results suggest that the Care Ecosystem medication management service reduces PIMs use compared to standard of care. This novel dementia care model that incorporates pharmacy review and consultations in collaboration with navigators, nurses, social workers and primary care providers shows promise in improving safe medication use and reducing potential adverse drug events in this high risk population.

Poster Title: Correlating Thromboelastograph Platelet Mapping (TEG-PM) with incidence of hematologic events in patients on Mechanical Circulatory Support (MCS) devices and antithrombotic therapy

Primary Author: Lilia Aivazyan, University of California, San Francisco School of Pharmacy, California; **Email:** lilia.aivazyan@ucsf.edu

Additional Author (s):
Jason Kirkwood
Helen Kay
Daniel Bunag
Lee Lam

Purpose: Ventricular assist devices (VADs) and Total Artificial Hearts (TAH) providing durable mechanical circulatory support (MCS), as bridges to transplant or destination therapies, have commonly become an alternative treatment in end-stage heart failure patients. Hematologic adverse events and complications frequently occur in MCS patients leading to increased risk of mortality. Post implantation patients are given antithrombotics consisting of antiplatelets and anticoagulants to counteract adverse thrombotic events. TEG-PM allows for a personalized approach in optimizing antithrombotic therapy and minimizing hematologic complications. The purpose of this study is to evaluate the incidence of hematologic events in MCS patients on TEG-PM guided antithrombotic therapy.

Methods: This Institutional Review Board (IRB) approved, retrospective analysis reviewed data from December 2014 to August 2016. The study evaluated patients (n=71) implanted with a continuous flow left ventricular assisted device (LVAD) (n=41) vs. a pulsatile total artificial heart (TAH) (n=30). Patients' antithrombotic therapy and INTERMACS (Interagency Registry for Mechanically Assisted Circulatory Support) profile were reviewed. INTERMAC describes the clinical state of advanced heart failure (HF) patients by assigning them into seven levels according to their hemodynamic profile and level of target organ damage. Data collected included: dosage titration of aspirin and dipyridamole, INR at post implant discharge, TEG-PM parameters, major bleeding events and major thrombotic events, days from implant date to adverse event date, and high molecular weight multimer loss. Patients that experienced a

hematologic event < 14 days of implantation were excluded. The primary endpoint was to assess incidence of hematological events in MSC patients whose antithrombotic therapy was guided by TEG-PM results. The secondary endpoint was to evaluate the antiplatelet therapy correlated by TEG-PM in patients either on VADs or TAH.

Results: 44 out of the 71 patients (62%) did not experience hematologic events with TEG-PM guided dosing. 27 out of the 71 patients (38%) experienced hematological events. 15 out of the 27 patients experienced an event >14 days post implantation. Out of these 15 patients, 9 (60%) were TAH patients and 6 (40%) were LVAD patients. Of the 9 TAH patients, there were 8 incidences of strokes and 7 incidences of major bleeding events. Of the 6 LVAD patients, there were 2 incidences of strokes, 8 incidences of major bleeding events, and 1 experienced a device thrombosis. Of the 15 patients who had hematological events at >14 days post implantation, 12 of them had an INTERMACS profile that corresponded to high severity status prior to device implantation. Analysis of the data revealed a correlation between hematologic events and patients with high severity status as determined by INTERMACS.

Conclusion: Patients with TAH appear to be at higher risk for thrombosis while patients with LVADs appear to have a higher risk for bleeding. Due to the design of the devices, LVAD patients are at additional risk of bleeding due to von Willebrand Factor multimer loss (acquired von Willebrand Disease). Correlation of TEG-PM parameters with the hematologic events and the antiplatelet therapy will be reported along with mean dose of aspirin and dipyridamole for each device, which will be analyzed per thrombosis and bleeding event.

Poster Title: Insulin prescribing habits of resident physicians in a rural family medicine clinic

Primary Author: Katherine Huynh, University of California, San Francisco School of Pharmacy, California; **Email:** katherine.huynh@ucsf.edu

Additional Author (s):
Amorette Jeng
Jennifer Toy

Purpose: Diabetes is a metabolic disease that affects many people worldwide. According to a 2014 report by the California Department of Public Health, Tulare County has the highest prevalence of Type 2 diabetes in patients 18 years and older in California. Appropriate insulin prescribing was identified as a quality improvement initiative crucial to improving outpatient management of this chronic disease at Kaweah Delta Family Medicine Center in Tulare County. This study describes insulin prescribing habits of resident physicians at Kaweah Delta Family Medicine Center prior to the integration of clinical pharmacist services through a Health Resources and Services (HRSA) grant.

Methods: This institutional review board-approved retrospective chart review examined 82 patient records between January 01, 2015 and January 31, 2016. Inclusion criteria included: patients 18 years of age and older, patients with a diagnosis of type 1 or type 2 diabetes mellitus, and patients prescribed insulin. Patients under 18 years of age, those who had gestational diabetes, or were only prescribed oral anti-diabetic medications were excluded. The following data were collected: demographics, insulin initiations, insulin types and doses, number of insulin dose and product changes, number of insulin sliding scale (ISS) regimens, number of adjunctive anti-diabetic medications, number of basal-bolus regimens, A1c changes, self-monitoring blood glucose (SMBG) frequency as instructed by provider, number of diabetes-related visits, discrepancies between prescription instructions and provider notes regarding insulin dose, and patient history of hyperglycemic or hypoglycemic events. Data were analyzed using mean, median, mode, and ranges in order to describe insulin prescribing habits.

Results: The majority of patients (62 percent) were on a basal-bolus regimen, with insulin glargine as the most commonly prescribed long-acting (79 percent) and insulin lispro as the most commonly prescribed short-acting (38 percent). Most patients (76 percent) who established care at the clinic were insulin experienced, 31 percent were prescribed insulin sliding scale (ISS), and 48 percent were prescribed adjunctive oral anti-diabetic medications. Forty-eight percent of prescriptions did not match dosage adjustments documented in provider notes. The majority of dose changes were documented in provider notes (73 percent), while only 38 percent of dose changes were documented in outgoing prescriptions. The average number of visits was 6.5 within the 13 month time frame. Twenty-seven percent of patients had an increase in A1c and 23 percent had a decrease in A1c. The most commonly instructed frequency for self-monitoring of blood glucose was 3 times daily. Thirty-two percent of patients experienced hypoglycemic events, hyperglycemic events, or both, with 11 percent resulting in hospitalizations.

Conclusion: Knowledge of resident insulin prescribing habits is essential in evaluating the need for education and implementation of clinical pharmacist services to improve the collaborative management of diabetes in a rural setting. Physician residents may benefit from further education and a standardized approach to insulin management to minimize discrepancies, prevent adverse outcomes, and optimize patient care.

Poster Title: Evaluation of the effects of weight-based norepinephrine continuous infusion

Primary Author: Esther Kim, University of Southern California, California; **Email:** kim417@usc.edu

Additional Author (s):
Joo Hye Lee
Amber Miller
Sheela Shneezai

Purpose: The Surviving Sepsis Campaign guidelines recommend norepinephrine (NE) as the vasopressor of choice for septic shock. The implementation of both weight-based and non-weight-based dosing of NE leads to inconsistency between different institutions. There are currently no studies comparing the effects of weight-based and non-weight-based NE. Antelope Valley Hospital (AVH) initiated a weight-based NE protocol using ideal body weight. In the protocol, NE is not recommended unless the patient had been adequately fluid resuscitated. This study explores the effects of weight-based dosing of NE compared to non-weight-based dosing in adult ICU patients at AVH.

Methods: This retrospective cohort study utilized Vigilanz, a healthcare technology software, to electronically generate a list of patients who were on NE continuous infusions from March 1, 2015 to May 30, 2016. Patient's information was further analyzed by the medical record database HEIDI and a retrospective chart review was performed. Patients admitted to the ICU at AVH, Lancaster, California, and patients 18 years and older who required continuous NE infusions were included in the study. Patients were excluded if they were less than 18 years old, were not admitted to the ICU, or whose names were on the electronically generated list but did not receive any NE. The primary outcome measure was to evaluate the mean NE dose and duration of infusion required in patients. The secondary outcome measures included time to reach goal MAP, volume of fluid resuscitation administered 12 hours before NE initiation, mortality and the use of additional vasopressors. Patient demographics, baseline characteristics, and outcome variables of patients were compared. Categorical variables were compared using the Fisher exact test. Continuous variables were analyzed using t-test.

Results: A total of 100 patients were analyzed - 50 in the non-weight-based NE group and 50 in the weight-based NE group. All patients were followed until hospital discharge or death. There were no significant differences between the two groups with regard to baseline characteristics. The mean NE dose required in the non-weight-based group was 0.10 mcg/kg/min vs. 0.30 mcg/kg/min in the weight-based group (P equals 0.007). The average duration of infusion required in the non-weight-based group was 48.62 hours vs. 52.99 hours in the weight-based group (P equals 0.736). In the non-weight-based group, 18 patients were already at MAP goal at NE initiation, compared to 13 patients in the weight-based group (P equals 0.432). The average time to goal MAP was 82.19 minutes in the non-weight-based group vs. 55.49 minutes in the weight-based group (P equals 0.535). The non-weight-based group required more fluid resuscitation within 12 hours prior to NE initiation (7.8 hours vs. 5.8 hours, P equals 0.359). 19 patients expired in the non-weight-based group vs. 30 patients in the weight-based group (P equals 0.197). 13 patients required additional vasopressors in the non-weight-based group whereas 11 patients in the weight-based group (P equals 0.714).

Conclusion: The non-weight-based group required a statistically significant lower average dose of NE infusion than the weight-based group. However, the weight-based NE group reached MAP goal faster than the non-weight-based NE group, although this was not statistically significant. To summarize, the weight-based group received higher doses of NE infusion, and subsequently reached MAP goal faster than the non-weight-based group. These results require further evaluation due to limitations of retrospective studies and small sample size. Future randomized studies with multiple centers and sufficient sample size are warranted to broaden the generalizability and to confirm the clinical significance of these results.

Session-Board Number: 7-051

Poster Title: Student-run health fairs effective at motivating and educating minority communities

Primary Author: Tiffany Luong, University of Southern California, California; **Email:** luongt@usc.edu

Additional Author (s):
Corey Kelsom

Purpose: Pharmacy schools across the nation host multiple health fairs to reach underserved communities who may lack health insurance or access to primary care. Health fair participants are educated on numerous disease states and the importance of their health screening values. Despite providing these screening opportunities, there is a knowledge gap in terms of perceived public satisfaction toward these services. Health fair satisfaction surveys were created to receive feedback on how the public perceived student pharmacists' services, what they liked or appreciated, and what points University of Southern California School of Pharmacy could improve upon for future health fair events.

Methods: The survey was a 9-item questionnaire that focused on the participants' experiences at the health fair in English, Vietnamese, and Chinese languages. Participants were provided with the voluntary surveys at the health fair registration and reminded to fill out the surveys after each participated health screening. The survey included questions asking how participants heard about the health fair and the reasoning for their participation. Participants were also asked to rate the quality of the health fair and professionalism of the student volunteers as well as the amount of time spent at the health fair. Additionally, participants were asked to mark each health screening they participated in and whether participation in the health fair motivated them to change an unhealthy behavior. All returned surveys were collected and data analyzed by descriptive statistics on a nominal and ordinal scale.

Results: Throughout Los Angeles County, eight health fairs provided the health fair participation surveys, in which a total of 477 responses were collected. Participants were aware of the health fair through word of mouth (35%) and other (37%), where majority of specified answers were "walked by." Participants were also asked the reasoning for attending, in which ~60% answered

"curious about health" and 33% answered "convenient." Additionally, 72% reported that the health fair conducted was "excellent" and 84% rated professionalism of the volunteers "excellent." For screening events, blood pressure and blood sugar had highest attendance with 64% and 68% respectively, following cholesterol and body fat at both 42%. 63% of surveyed participants spent about one hour at the health fair and 75% agreed this participation motivated them to change an unhealthy behavior. Furthermore, 75% answered "yes" for planning to follow-up about an abnormal value detected at their physicians' offices, with 43% to follow-up within the next week or month. Lastly, 98% of participants surveyed answered "yes" to participating in a health fair again next year. Participants provided valuable feedback and positive responses including: "I learned a lot about how to care for my diabetes" and "[students] took their time to answer questions."

Conclusion: Newly implemented health fair surveys were helpful in obtaining a better idea of the values of free health screenings and additional ways on how student-run health fairs can improve screenings and health education. Feedback from participants guided students to better address needs of community members in providing more effective and higher quality of care.

Poster Title: Identifying risk factors and patients at risk for Clostridium difficile infections at Antelope Valley Hospital

Primary Author: Crystal Teng, University of Southern California, California; **Email:** tengc@usc.edu

Additional Author (s):
Sheela Shneezai
Courtney Steinwachs
Jill Bennett
Jamie Lee

Purpose: Clostridium difficile infection (CDI) is the most common healthcare-associated infection in US hospitals. The incidence of CDI is increasing with significant economic burden, and the three major risk factors are antibiotic exposure, advanced age, and hospitalization. The purpose of this study is to analyze and identify factors associated with CDI at Antelope Valley Hospital (AVH) in order to identify potential interventions to reduce CDI.

Methods: The institutional review board approved this cross-sectional study from January 2014 to June 2016 at Antelope Valley Hospital, a 420-bed district hospital located in Lancaster, California. Data was collected through retrospective chart review using McKesson OneContent, McKesson Horizon Clinicals, and the Horizon Physician Portal. All patients with hospital-acquired C. difficile, defined as a positive C. difficile toxin 48 or more hours after admission, between January 2014 and June 2016 were included in the study. Community-acquired C. difficile, defined as having a positive C. difficile toxin on or less than 48 hours after admission were excluded. The analyzed study variables include time to onset, previous C. difficile episode, residence at a skilled nursing facility (SNF), previous hospitalization and antibiotic use in the last 90 days, inpatient antibiotic use, intensive care unit admission, gastrointestinal procedures (endoscopy, colonoscopy, and bowel surgery), and probiotic use (Saccharomyces boulardii or Lactobacillus acidophilus). One variable statistics and associated analyses were performed using Microsoft Excel.

Results: A total of 146 patients were included in this study. Baseline characteristics on admission demonstrated that the average age of CDI was 66.3 years. 25 percent of the patients resided in a SNF and 43 percent has had a previous hospitalization or antibiotic use in the last 90 days. Inpatient factors such as ICU stay (20 percent), gastrointestinal procedure (33 percent), and antibiotic use (92 percent) were associated with CDI. Patients were on an average of 1.9 plus or minus 1.3 antibiotics for 8 plus or minus 5.9 days. In these 146 patients, 61 patients were on a quinolone, 40 on ceftriaxone, 39 on cefepime, 35 on piperacillin-tazobactam, and 25 on a carbapenem during hospital stay. Quinolones were the most commonly used in combination antibiotic therapy. Probiotic use before positive C. difficile collection was only 20 percent, but out of those, about 44 percent has had a previous C. difficile episode in the past year.

Conclusion: Characteristics on admission at AVH demonstrated that CDI was associated with advanced age, previous hospitalization and antibiotic use in the last 90 days, and residence at a SNF. Inpatient risk factors such as the use of broad spectrum antibiotics (e.g. quinolones), duration of antibiotic use, ICU stay, and gastrointestinal procedures were all correlated with CDI. These identified risk factors are similar to those reported in previous studies. Given these findings, we aim to restrict use of quinolones, narrow empiric therapy before day 8, and focus antimicrobial stewardship efforts on geriatric patients to reduce the incidence of CDI at AVH.

Submission Type: Evaluative Study

Session-Board Number: 7-053

Poster Title: Retrospective study of the impact of Vancomycin dosing in patients with Methicillin resistant S aureus (MRSA) infections and their clinical outcomes

Primary Author: Akemi Meguro, University of Southern California, California; **Email:** meguro@usc.edu

Additional Author (s):
Emi Minejima

Purpose: Vancomycin is considered first line therapy for most MRSA infections at LAC-USC Medical Center. With increasing vancomycin MIC to MRSA, higher doses of vancomycin may be needed. However, this will need to be balanced with increased risk of nephrotoxicity. We currently do not use loading doses of vancomycin, which may delay obtaining therapeutic levels early in therapy. The objective of this study was to first determine if there is a delay in obtaining therapeutic vancomycin levels without giving loading doses, then whether this would negatively affect clinical outcomes of MRSA skin and soft tissue (SSTI), bacteremia, pneumonia and osteomyelitis infections.

Methods: This was a single center retrospective analysis of adult patients (>17yo) with documented MRSA infection, initially treated with vancomycin from January 2016-June 2016. Microbiology reports were screened for positive MRSA cultures at Los Angeles County-University of Southern California Medical Center from January to June 2016. Inclusion criteria was 1) received vancomycin therapy >48 hours 2) minimum 1 trough level drawn, and 3) vancomycin dosed per pharmacy. The target trough levels were defined per IDSA guidelines: 10-15mcg/ml for SSTI and >15mcg/ml for all other indications. Patients were grouped into therapeutic (T) vs non-therapeutic (NT) initial trough concentration and compared for outcomes. Clinical success was defined as resolution of infection.

Results: A total of 46 patients were included: 80% were male and mean age was 46.5 years old. The most common indication for vancomycin was SSTI (63%), then osteomyelitis (15%), bacteremia (11%) and pneumonia (11%). 89% of patients did not meet initial therapeutic trough concentrations (NT group). Baseline Scr was higher at 1.05 mcg/ml, with lower estimated CrCl at 98ml/min in the NT group. The initial total daily dose was similar between the

groups at 2000mg/day. The initial average trough level was 12.7mcg/mL in the T group and 8.4mcg/mL in the NT group. 100% of patients in the T group had MRSA isolates with MIC 1 mcg/mL compared to 85.4% of patients in NT group. Median duration of vancomycin therapy was 3 days longer in the T group at 9 days and longer length of hospital stay at 17 days. Of those who did not have a therapeutic initial trough, only 38.7% had a therapeutic second trough. There was one clinical failure in the NT group in a patient with bacteremia, where vancomycin therapy did not clear the organism from blood cultures.

Conclusion: Majority of patients evaluated did not reach therapeutic initial troughs in our populations, which can partly be explained by lack of giving loading doses. Our preliminary data showed that clinical outcomes may not be significantly compromised, however our numbers were small. This outcome may be partially explained by majority of the infections being SSTI source. Prospective education can be provided for the hospital staff to select more appropriate initial doses in order to achieve therapeutic initial goals.

Poster Title: Meeting the challenge of medical benefit management of specialty medications: A novel interdisciplinary intervention program

Primary Author: Nathan Santos, University of Southern California, California; **Email:** nathansa@usc.edu

Additional Author (s):
Cho Han Lee
Jerry Chang
Anthony Lam

Purpose: Much attention has been focused on specialty medication driving pharmacy spend to record levels in the face of rising prices and accelerating drug development. Yet, nearly half of the $124 billion specialty costs in 2015 were billed through the medical benefit rather than the pharmacy benefit. To answer the unique challenges of complex drug regimens, limited access to real-time data, quickly evolving medical evidence, and the need for individualized care, a multidisciplinary program was implemented to aid the medical benefit management (MBM) of specialty medications. The purpose of this study was to evaluate the intervention program.

Methods: This exploratory, prospective descriptive analysis employed medical benefit claims and provider reports. Enrolled patients were under the care of independent physician groups located in California, Arizona, and Utah. Inclusion criteria were requests regarding high-cost medications; requests that will be billed through the medical benefit. Specialty medication authorization requests and consultative reviews completed in an 18-month time frame from January 1st, 2015, through June 30th, 2016, are evaluated here. Clinical reviews were done by pharmacists and physician specialists in hematology, rheumatology, oncology, and nephrology. Requests and reviews for multi-drug regimens were evaluated holistically as a treatment plan. Interventions were stratified by disease category, medication, and rationale, including clinical appropriateness, failure to meet evidence-based step therapy, and dose optimization.

Results: A total of 8158 study patients were studied through these medication requests, and had a mean age of 52.5 years; 35% were male; and 95% resided in California, 4% resided in Arizona and 1% resided in Utah. Of the 14162 reviews completed in the study period, 15% were

identified as requiring intervention. A total of 2098 requests were identified for an intervention. In terms of percentage of total requests (TR) and percentage of total interventions (TI), Oncology had a 88% TR and 8% TI; Rheumatology had a 8% TR and 1.1% TI; Neurology had a 0.49% TR and 0.06% TI. The most frequent reasons for intervention were for a lack of documented medical necessity (47%); being clinically inappropriate (19%); dose optimization (12%); and not meeting recommended step therapy (11%).

Conclusion: The novel, interdisciplinary intervention program was demonstrated to be an effective strategy in specialty medication medical benefit management, making interventions based on the practice of evidence-based medicine with careful regard to individual patient needs.

Conclusion: The novel, interdisciplinary intervention program was demonstrated to be an effective strategy in specialty medication medical benefit management, making interventions based on the practice of evidence-based medicine with careful regard to individual patient needs.

Poster Title: Appropriate fentanyl monitoring at Antelope Valley Hospital

Primary Author: Jamie Lee, University of Southern California School of Pharmacy, California;
Email: leejamie22090@gmail.com

Additional Author (s):
Amber Miller
Jill Bennett

Purpose: Because fentanyl has both analgesic and sedating properties, it is highly used in mechanically ventilated patients in the intensive care unit. However, it is important to wean patients off so that they can eventually be extubated and transferred out of the intensive care unit. In addition, it is important to titrate fentanyl properly based on regular pain and sedation assessment scores. This project was designed to assess if the fentanyl drip protocol was being followed appropriately by nurses in the intensive care unit at Antelope Valley Hospital, before and after its protocol change.

Methods: This study was performed on 26 patients on fentanyl before the fentanyl protocol change (November 2015) and 26 patients on fentanyl after the fentanyl protocol change (June 2016) at Antelope Valley Hospitals' Intensive Care Unit in Lancaster, California. Data collection was done through the patient chart review. Variables such as fentanyl starting rate, maximum rate, average time the Critical-Care Pain Observation Tool (CPOT) and Richmond Agitation Sedation Scale (RASS) scores were recorded, appropriate titrating and tapering of fentanyl, and if as needed pain medication were given appropriately were captured. Postpartum patients and patients on intrathecal fentanyl were excluded.

Results: After the fentanyl protocol was changed, the number of times the RASS and CPOT were checked per nursing shift improved slightly. RASS was checked 0.42 times more (3.58 versus 4) while CPOT was checked 0.61 times more (4.04 versus 4.65) per 12 hour nursing shift. The protocol states that both scores need to be assessed every 2 hours, a total of 6 times per 12 hour nursing shift. The percentage of times PRN pain medications were given or fentanyl titration was increased when CPOT was greater than or equal to 2, was 74% before the change and 75% after the change. Of the 52 patients observed in the study, 58% were started on the

appropriate initial infusion of 50mcg/hr. 19/52 patients were started on the maximum fentanyl rate (300mcg/hr) but 7 of those patients were trauma patients. Of the 52 patients, 20% of them were titrated up and down on the fentanyl drip correctly at increments of 25mcg/hr. The majority of the patients (36/52) were titrated by 50mcg/hr. 46/52 patients were on another sedation medication along with fentanyl to help keep the patient sedated while they were intubated.

Conclusion: Although the fentanyl drip protocol was reworded and modified, monitoring of pain and sedation scores as well as correct fentanyl titrations were not different among nurses before and after the protocol change. From this snapshot, we learn that as pharmacists, it is crucial to not only update protocols but also educate all intensive care unit nurses on appropriate monitoring and titrating of fentanyl so that patients who are mechanically ventilated are comfortable, without pain, and eventually weaned off all sedation when appropriate. This study shows the importance of communication between health care professionals to improve patient care.

Poster Title: To restrict or not to restrict? Antimicrobial Stewardship evaluation of vancomycin prescribing patterns at a large academic hospital

Primary Author: Vanessa Ma, University of Southern California School of Pharmacy, California; **Email:** vanesshm@usc.edu

Additional Author (s):
Maryam Semenov
Emi Minejima

Purpose: The goal of Antimicrobial Stewardship (AS) is to limit inappropriate use of antimicrobials to improve patient outcomes to infection. An antimicrobial restriction policy is one example of an AS strategy to limit overuse of key antimicrobials. At LAC-USC Medical Center, an antibiotic restriction policy is utilized; vancomycin is currently unrestricted, however is highly utilized. The objective of this study was to evaluate the prescribing patterns of vancomycin in order to determine the most effective AS intervention to improve utilization for appropriate cases.

Methods: This was a retrospective review of hospitalized adult patients, greater than 17 years old, between June 15, 2016 and June 29, 2016 who received at least one dose of intravenous (IV) vancomycin. Patients were identified through the electronic medical record system through pharmacy reports for all patients prescribed IV vancomycin. We collected data on vancomycin indication, prescribing team, duration of use, drug toxicity, and clinical outcome for each patient and recorded all data in a secure database (Microsoft Excel).

Results: 187 total patients were prescribed vancomycin during the study period; 75 were randomly selected for inclusion. The average weight was 75.3 kilograms. 53.5 percent received an initial total daily dose of 2000 milligrams with an average starting dose of 14.2 milligrams per kilogram per dose. Half of vancomycin prescriptions were by medicine teams and 61 percent were dosed by pharmacy. 56 percent of patients had appropriately drawn initial trough levels (average of 11.5 milligrams per liter). The most common indications for vancomycin were purulent skin and soft tissue infections (17.3 percent), pneumonia (17.3 percent), and cellulitis (13.3 percent). 34.7 percent of patients received vancomycin therapy for less than or equal to 3

days; 72 percent received it for less than or equal to 7 days. Indications for those who received vancomycin past 7 days included cellulitis, pneumonia, prophylaxis while ventricular drain in place, endocarditis, and osteomyelitis. 10 percent had inappropriate vancomycin prescriptions, including methicillin-sensitive Staphylococcus aureus (MSSA) bacteremia without therapy de-escalation, cellulitis without abscess, sepsis without a clear source, and intra-abdominal infection. 17.3 percent reached clinical stability within three days after empiric initiation and 90 percent had clinical success of infection. 1 patient experienced vancomycin-associated nephrotoxicity and 1 had neutropenia.

Conclusion: Of the 75 patients evaluated, 90 percent of vancomycin prescriptions had appropriate initial indications. Areas of future Antimicrobial Stewardship intervention to decrease inappropriate use can be focused on educating prescribers on identifying risk factors for methicillin-resistant Staphylococcus aureus (MRSA), appropriate duration of therapy per indication, and appropriate timing of trough monitoring. These interventions can potentially affect positive change without restricting the use of the antibiotic.

Poster Title: Comparison of epidemiology, management, and outcomes in patients presented to the emergency department for urinary tract infection: Those discharged from emergency department vs those hospitalized

Primary Author: Samantha Yeung, University of Southern California School of Pharmacy, California; **Email:** samantly@usc.edu

Additional Author (s):
Annie Wong-Beringer
Mira Zurayk
Sarah Jorgensen

Purpose: Urinary tract infections (UTIs) are among one of the most common indications for prescribing antibiotics and are the most common infections treated in the emergency department (ED). The high turnover rate of patients and varying prescribers providing care present unique challenges to antimicrobial prescribing in the ED. Thus, antimicrobial stewardship strategies to reduce inappropriate antimicrobial prescribing are much needed in the ED. The purpose of this study is to compare the epidemiology, management, and outcome of UTI in patients discharged from the ED vs. those hospitalized in order to identify potential areas for improvement in the management of UTIs.

Methods: Adult patients over 18 years of age presenting to the ED between July 1, 2015 and June 30, 2016 with a diagnosis of UTI (ICD-9 and ICD-10 codes: 599 for UTI, 595.9 for cystitis, and 590.10 for pyelonephritis) were identified. Patients were excluded if under 18 years of age, transferred to an outside hospital, medical chart was unavailable, or evaluation or treatment was refused by the patient or family. A total of 500 patients (150 admitted inpatient and 350 discharged from the ED) were randomly selected and stratified based on the month of presentation to the ED. Relevant demographic and clinical data was extracted from the medical records of eligible patients and recorded using a standardized data collection form with precise definitions for each variable. Data regarding patient demographics, medical history, social history, presenting symptoms, vitals and lab values, urinalysis, and urine cultures were collected. The primary outcome was patient returning to the ED within 72 hours or hospital

readmission within 30 days of discharge. All statistical analysis was performed using GraphPad Prism.

Results: The median age of study patients was 59 years; discharged patients were younger (47 vs 81 years) with higher proportion being female (87 vs 67 percent) and presenting from home (90 vs 71 percent). Patients in the discharged group had a lower proportion of positive urine culture (42 vs 76 percent) and positive urinalysis (69 vs 79 percent) compared to those admitted. A positive qSOFA score (score 2, 3) was found in 2 percent of discharged patients compared to 37 percent of admitted patients. IV antibiotics (mostly ceftriaxone) were administered in the ED to 62 percent of patients discharged compared to 99 percent of patients admitted. For patients discharged from the ED, 45 percent of patients were discharged with cephalexin, 19 percent with nitrofurantoin, 16 percent with ciprofloxacin, and 15 percent with trimethoprim/sulfamethoxazole. The rates of return to ED within 72 hours of discharge for the above antibiotics were highest for cephalexin at 12 percent and lowest for nitrofurantoin at 2 percent. The rate of 30-day readmission in admitted patients was higher (12 percent) when compared to 72-hour return to the ED (6 percent) but similar (11 percent) to 30-day return to ED in discharged patients.

Conclusion: Patients discharged from the ED were more likely to be younger females presenting from home who were less likely to have a positive qSOFA and a positive urinalysis and urine culture. The outcomes for patients who were admitted to the hospital showed a greater rate of return to the hospital compared to patients who were discharged from the ED. Among patients who were discharged from ED with antibiotics, treatment with nitrofurantoin was associated with the lowest rate of return to the ED, supporting guideline recommendations that nitrofurantoin should be used first line for uncomplicated urinary tract infections.

Poster Title: Dextromethorphan/quinidine (DM/Q) plasma concentrations in patients with percutaneous esophageal gastrostomy tubes (PEG-tubes): Using phase 3 trial data to investigate a common drug information question

Primary Author: Maryam Semenov, University of Southern California School of Pharmacy, California; **Email:** semenov@usc.edu

Additional Author (s):
Andrea Formella
Ryan Law

Purpose: Dextromethorphan and quinidine combination (DM/Q; Nuedexta, Avanir Pharmaceuticals, Inc.) is the only FDA-approved treatment for pseudobulbar affect (PBA). PBA occurs secondary to neurologic disease or injury and is characterized by sudden, frequent, involuntary episodes of laughing or crying that are independent of mood. Since many patients with neurological conditions have difficulty swallowing, the Avanir Drug Information Call Center is frequently asked whether DM/Q capsules can be opened for administration in food or via PEG-tube. This project evaluated patients receiving DM/Q in phase 3 clinical trials to determine whether any had DM/Q plasma concentrations measured while receiving medication via PEG-tube.

Methods: Three trials [AVR-102, AVR-107, AVR-123] included blood draws to determine dextromethorphan, dextrorphan (an active metabolite of dextromethorphan) and quinidine plasma concentrations. Patients with PEG-tubes were identified by searching patient medical history and medication administration records within each trial. Dates of PEG-tube placement were compared to dates of blood draws to identify patients with PEG-tubes at time of blood draw. To provide a preliminary indication of whether administration via PEG-tube affected DM/Q absorption, plasma concentrations for patients with PEG-tubes were compared with average [mean (std dev); 95% CI; median] plasma concentrations within each trial by dose, time period [Day 29 or Day 57 (AVR-123 only)], and metabolizer status [cytochrome P450 2D6 extensive (EM) or poor metabolizer (PM)]. Demographic data and Center for Neurologic Study Lability Scale (CNS-LS) Scores, a trial efficacy measure, were also evaluated.

Results: Seventy-three patients randomized to DM/Q [8 in trial AVP-102, 49 in trial AVP-107, and 16 in trial AVP-923] had a PEG-tube placed prior to, or during trial participation. Of these, 16 patients [6, 1, and 9 respectively] had PEG-tubes confirmed in place at the time of at least one pharmacokinetic (PK) blood draw. All patients were genotyped as cytochrome P450 2D6 EMs, except 2 (1 PM, and 1 unknown). One patient also had a full PK profile to evaluate plasma drug concentration time curve. Dextromethorphan plasma concentrations for 11 of these 16 patients [69%] were lower than the median concentration within each trial dose group and time period, but remained within 1 standard deviation of the group mean in all but 4 of cases. Analysis of the CNS-LS efficacy measure showed response generally consistent with that seen for the overall trial.

Conclusion: Plasma concentrations for 5/16 patients with PEG-tubes were above group medians. For the 11 patients with concentrations below group median, 7 were within one standard deviation of the group mean for each DM/Q dose, time period and metabolizer type. This analysis was limited by the small sample size and post-hoc methodology. Still these data could be helpful, with proper transparency, to answer unsolicited medical information requests. Given the frequency of this request, a formal pharmacokinetic study may be worthwhile.

Poster Title: Evaluation of urinary tract infection treatment at a public teaching hospital

Primary Author: Heena Chollera, University of Southern California School of Pharmacy, California; **Email:** chollera@usc.edu

Additional Author (s):
Corey Kelsom
Emi Minejima

Purpose: Treatment of urinary tract infections (UTI) contribute to significant healthcare and economic burden. Despite the existence of national guidelines to assist practitioners in diagnosis and management, over-prescription of antimicrobials continues to be a significant concern. As antimicrobial resistance continues to increase in Enterobacteriaceae, judicious use of antimicrobials is critical. The goal of this study was to assess the appropriateness of UTI diagnosis and management in a large teaching hospital in order to target future Antimicrobial Stewardship strategies to limit overuse of unnecessary antimicrobials.

Methods: This was a retrospective review of hospitalized adult patients, greater than 17 years old, who had a positive urine culture over a period of one week at LAC-USC Medical Center in Los Angeles, California. Medical charts were reviewed for demographics, prescriber, details of UTI, including urinalysis (UA), and UTI management. Outcomes included appropriateness of management of the positive urine culture and hospital length of stay. All data was recorded in a secure database (Microsoft Excel).

Results: Over one week, 109 patients had positive urine cultures. Overall mean age was 50 and 70 percent were female. 39 percent were ED patients, 16 percent were in outpatient clinics, 33 percent were admitted to non-intensive care unit (ICU) floors, and 12 percent were admitted to the ICU. Predominant risk factors were diabetes (40 percent), previous UTI (17 percent) and urinary catheterization (14 percent), with 21 percent possessing multiple risk factors. The most common organism was Escherichia coli at 40 percent, of which 30 percent were extended spectrum beta-lactamase (ESBL)-producers. Klebsiella pneumoniae was isolated in 8 percent of patients with 11 percent being ESBL-producers. 60 percent of patients had a positive UA and 63 percent were symptomatic. 19 percent of patients had no documented symptoms yet were

prescribed antibiotics. 6 percent of patients had a negative UA and were asymptomatic and yet received antibiotics. ED and internal medicine physicians inappropriately treated these patients. Ciprofloxacin was most commonly prescribed for cystitis (31 percent), followed by ceftriaxone (22 percent); mean treatment duration was 5.8 days. Patients treated for pyelonephritis were equally prescribed ciprofloxacin or ceftriaxone (36 percent); mean duration was 6.1 days. Of hospitalized patients, average length of stay was 10.5 days.

Conclusion: Of the 109 patients evaluated, 81 percent of patients were treated appropriately with antimicrobials for UTI. The internal medicine and ED physicians were the most frequent providers to prescribe unnecessary antibiotics. For treated cystitis patients, ciprofloxacin was the most frequently prescribed antibiotic. Patients treated for pyelonephritis were equally prescribed ciprofloxacin or ceftriaxone. Future Antimicrobial Stewardship interventions can target educating prescribers to use alternatives to fluoroquinolones when possible, documenting urinary symptoms in the chart, and appropriate management of cystitis, including recognizing those who do not need antimicrobials.

Submission Type: Descriptive Report

Session-Board Number: 7-060

Poster Title: Medication Delivery Using Unmanned Aerial Systems: A Systematic Review and Policy Primer

Primary Author: Connie Lin, University of the Pacific, California; **Email:** c_lin5@u.pacific.edu

Additional Author (s):
Sachin Shah

Purpose: In recent years, the use of unmanned aerial systems (UAS)/drones, have gained popularity and industry giants (e.g. Amazon, Google) have begun pilot projects with drone delivery. Community pharmacy practice is plagued with long wait times at the pick-up counter with a national average of 45 minutes. Several mechanisms to facilitate drug delivery are currently being utilized such as mail order, automated delivery systems, and home-delivery. As such, the use of drone technology appears inevitable. The purpose of this systematic review is to aggregate existing regulations on drone delivery and discuss implications it may have on pharmacy and its stakeholders.

Methods: An initial search of PubMed was done using the following terms: "drone", "unmanned aerial system" or "remotely piloted aircraft" in conjunction with "pharmacy", "medicine", "medication", or "drug." An online search was performed using a multitude of terms to find companies already looking to deliver medications using drones and for news articles regarding safety and privacy of patients. Additionally, relevant agency (Federal Aviation Administration, NABP, NTSB) documents were evaluated for any information that may pertain to drug delivery using UAS. A full review of the current Board of Pharmacy law handbook was done to search for laws on drug delivery.

Results: The literature search identified no relevant articles in peer-reviewed journals. The bulk of the data is in the form of news articles or brief commentary from stakeholders. The Federal Aviation Administration website provided regulations and guidance on the use of small UAS and the role of law enforcement agencies on this matter. The California Board of Pharmacy provided no laws on drone delivery of medications. Our search identified two companies (QuiQui and Flirtey) currently looking into drone delivery of medications. Some cities have provided local ordinances on the use of UAS but not specifically on the commercial delivery

aspect. Upon synthesis of the available data, pharmacy regulations will have to consider, not only the typical commercial challenges (distance, GPS accuracy, weather conditions, etc) but also HIPAA, patient counseling, drug delivery accountability, storage and stability, drug diversion, amongst others.

Conclusion: Data suggest that drug delivery using drones is already in the pilot phases and pharmacy regulators and stakeholders need to create policies around the topic. The delivery of medications with drones has the potential to drastically improve patient access to medications if done in an appropriate manner. With several companies already looking to implement this service in the near future for independent pharmacies, it is crucial that major stakeholders such as the Board of Pharmacy quickly take steps to ensure the privacy and safety of patients.

Poster Title: Utilizing mock consultations to improve pharmacy students' emotional intelligence and confidence in counseling skills

Primary Author: Remy Hataishi, University of the Pacific - Thomas J. Long School of Pharmacy and Health Sciences, California; **Email:** r_hataishi@u.pacific.edu

Additional Author (s):
Zubair Amin
Suzanne Galal
Ed Rogan

Purpose: Pharmacy students with strong social emotional intelligence have a foundation to grow and meet the continually expanding realm of pharmacy practice focused on patient-provider care. Emotional intelligence is a skill that is learned, rather than inherited. There are a variety of ways schools can integrate communication development into their curricula. The purpose of this project was to evaluate the impact of mock consultations with the use of standardized patients and teaching assistants on the development of pharmacy students' social and emotional competence as well as perceptions and attitudes towards the activity.

Methods: A total of 204 P1 students enrolled in the Practicum I Course completed an over-the-counter mock consultation assessment and were randomly assigned to either a teaching assistant (TA), comprising of second year students, or a standardized patient (SP), a paid actor who played the role of a patient. Students completed a pre and post test that consisted of the Personal-Interpersonal Competence Assessment (PICA) tool and Likert-scale questions assessing students confidence and perceptions of their consultation skills. The PICA tool is a self-report instrument that assesses eight domains of social and emotional competence.

Results: Results from the PICA tool showed significant improvements ($p < 0.01$) in four domains: Connection to Others - Sociability (NS), Influence Orientation - Inspiration (IS), Influence Orientation - Initiative (II) and Consideration of Others - Empathy (CE). The largest area of improvement was seen in the categories related to Influence Orientation. Overall, mock consultations increase students' confidence and perception of their abilities ($p < 0.01$).

Conclusion: Mock consultations were beneficial in improving students' emotional intelligence and confidence in their over-the-counter counseling skills. The National Association of Boards of Pharmacy (NABP) and Center for the Advancement of Pharmaceutical Education (CAPE) have recently revised their standards to further reflect the increasing importance of having strong social and communication skills in the pharmacy practice. These results confirm that mock consultations can serve as one way to assess and help develop students' emotional intelligence.

Poster Title: Cost-Effective Analysis to Evaluate Potential Replacement of Traditional aPTT testing with Anti-Factor Xa at a Small Community Hospital

Primary Author: Abigail Lin, University of the Pacific Thomas J Long, California; **Email:** a_lin2@u.pacific.edu

Additional Author (s):
Connie Lin
Jessica Liang
Elaine Law

Purpose: Most hospitals use a protocol-based heparin dosing and monitoring system with nurse-driven activated prothrombin time (aPTT) lab draws. Compliance is often incomplete with protocols because of frequent testing and adjusting required to achieve therapeutic levels placing patients at risk for bleeding. It is suggested that anti-Xa heparin assay monitoring is more efficacious than aPTT monitoring having less frequent lab draws and faster time to therapeutic levels. However, anti-Xa assaying is more expensive. This project investigates the extent of non-compliance in current aPTT monitoring, whether this delinquency leads to adverse outcomes, and if converting to anti-Xa would be more cost-effective.

Methods: This is a retrospective chart review of fifteen patients. Patients were included if they were at least 18 years old, admitted for acute coronary syndrome, myocardial infarction, pulmonary embolism, thrombosis, or atrial fibrillation, and were on heparin for at least 24 hours. To analyze compliance to the protocol in place, data was collected on whether STAT baseline aPTT, PT and CBC with platelets was drawn prior to initiation of heparin, whether the correct loading dose was given, whether the heparin drip was correctly dosed, whether aPTT was drawn six hours after initiation of the drip, whether adjustments to doses were correct, whether patients reached therapeutic goal of 1.5 – 2.5 times their baseline aPTT, the proportion of the hospital stay in which the heparin levels were subtherapeutic or supratherapeutic, and whether any adverse events took place. The values used for the cost analysis of using antifactor Xa assay testing in place of aPTT testing were based on pricing for O'Connor Hospital in San Jose, California. The primary outcome of this study is to evaluate compliance to the current heparin protocol in place at O'Connor Hospital, time to therapeutic

levels, and adverse events of non-therapeutic patients. The secondary outcome of this study is to analyze the cost-effectiveness of switching from aPTT heparin monitoring to anti-Xa assay heparin monitoring.

Results: 15 patients were reviewed. Average age was 62 years, average weight 81 kg, and 73 percent were male. NSTEMI patients made up 40 percent of the patients, atrial fibrillation 13.3 percent deep vein thrombosis 13.3 percent, pulmonary embolism 13.3 percent, occlusion 13.3 percent and thrombosis 6.7 percent. Baseline aPTT levels were drawn every time except for one patient but only 40 percent of patients had aPTT levels drawn per protocol heparin initiation. 27 percent of patients had the correct dose adjustments made according to protocol. 53 percent of patients reached therapeutic levels, there were instances in which heparin levels during at least 50 percent of their stay were subtherapeutic (n=3) or supratherapeutic (n=2). No adverse events were reported in the patient charts. There were in platelet count (n=4) and hematocrit levels (n=4) that did not lead to negative outcomes. The average length of stay was 6.6 days and the average number of days patients were on heparin was 3 days. Analysis showed that using anti-Xa assay would cost O'Connor Hospital approximately $62 more than aPTT per patient for the average stay.

Conclusion: The protocol set in place at O'Connor Hospital is not being utilized appropriately and therefore almost half of patients on heparin are not reaching therapeutic goal. This poses higher risk for adverse events for patients as evident in the fluctuation of heparin levels, downtrend of platelet count, and down trend of hematocrit. Although use of anti-Xa costs more than aPTT testing, it brings the majority of patients to therapeutic levels sooner. Note that the cost difference does not take into account the amount of time, wages, and room for error spared by having nurses draw blood less frequently.

Poster Title: Effect of enhanced external counterpulsation on plasma glucose levels in a healthy subject following an oral glucose bolus.

Primary Author: Kunal Shah, University of the Pacific Thomas J. Long School of Pharmacy and Health Sciences, California; **Email:** k_shah4@u.pacific.edu

Additional Author (s):
Jenny Hensley
Viral Panchal
Sachin Shah

Purpose: Enhanced external counterpulsation (EECP) is a noninvasive 7-week long treatment, consisting of 35 one-hour sessions, which is indicated for refractory angina and heart failure. Some studies have suggested that EECP treatment affects fasting plasma glucose. There may be safety concerns to consider for diabetic patients during EECP treatment sessions. The purpose of this study is to determine if one 1-hour session of EECP can produce a change in the plasma glucose levels of a healthy subject compared to control, following an oral glucose bolus.

Methods: This crossover, proof-of-concept assessment involved one healthy, non-diabetic, male subject. The primary outcome was plasma glucose levels. The subject underwent plasma glucose testing with and without a standard session of EECP on two separate days. The subject was instructed to consume a 20 ounce container of soda, containing 69 grams of fructose and glucose, within 3 minutes. Plasma glucose levels were measured using a point-of-care fingerstick blood glucose meter (Precision Xtra) at the following times: baseline (prior to study drink), 15, 30, 60, 90, and 120 minutes. The subject was instructed to perform a 9 hour fast prior to assessment days and not consume anything during the course of the study duration. Data were compared using descriptive statistics. Baseline plasma glucose levels were compared to each subsequent time point and reported as "change from baseline".

Results: The change from baseline plasma glucose levels in the EECP arm were 43, 54, 54, 19, and 2 mg/dL at 15, 30, 60, 90, 120 minutes, respectively. The change from baseline plasma glucose levels in the control arm were 21, 32, 46, 18, and 15 mg/dL at 15, 30, 60, and 90 minutes, respectively. The change from baseline plasma glucose levels at 2-hours was 13 mg/dL

lower in the EECP arm compared to the control arm. Peak plasma glucose was reached at 30 minutes in the EECP treatment arm compared to 60 minutes in the control arm. The rate of decline in plasma glucose from 60 minutes to 120 minutes was greater in the EECP arm (0.87 mg/dL/min) compared to the control arm (0.52 mg/dL/min).

Conclusion: Peak plasma glucose was reached in a shorter time and the rate of decline in plasma glucose was faster in the EECP compared to the control arm. This suggests that one session of EECP does have an effect on plasma glucose levels in the body. Since EECP mimics passive exercise, these effects seem reasonable. However, the degree of change in plasma glucose does not appear to be clinically significant to warrant glucose testing post EECP treatments. As such, larger prospective studies are necessary to validate these results and their clinical significance.

Poster Title: Impact of bitter melon (Momordica charantia) on fasting blood glucose: A meta-analysis

Primary Author: Mariah Mayo, University of the Pacific Thomas J. Long School of Pharmacy and Health Sciences, California; **Email:** s_ly3@u.pacific.edu

Additional Author (s):
Stephanie Diaz
Stephanie Ly

Purpose: Type 2 Diabetes accounts for 90-95% of all diabetes cases. Pharmacotherapy, dietary interventions, and dietary supplements are important factors in the management of type 2 diabetes. Bitter melon (Momordica charantia) has been purported to help lower blood glucose, but only a few studies have been done to support this claim. We planned to perform a meta-analysis evaluating the impact of bitter melon on fasting blood glucose levels in patients with type 2 diabetes.

Methods: Pubmed and Cochrane Library were used to identify randomized clinical trials of a minimum of 4 weeks that compared the fasting blood glucose levels before and after taking M. charantia. Search terms included "Bitter Melon", "Momordica charantia", "Karela", "Ampalaya", "Balsam apple", "Cerasee", "Glucose", and "Diabetes". Selection of the trials were individually assessed and determined by four investigators. A weighted mean difference from baseline was calculated using the DerSimonian-Liard methodology along with the corresponding 95% confidence interval. Publication bias was assessed using the Eggers statistic and inspection of the funnel plot. Heterogeneity was assessed using the I squared statistic.

Results: A total of 197 individual subjects were included in the overall analysis (4 clinical trials). Study duration ranged from 4 weeks to 12 weeks. The addition of bitter melon significantly decreased blood glucose by 6.23 mg/dl (95% CI = 0.41 to 12.04; P = 0.036) when compared to baseline. Significance was maintained when using the fixed-effects model (8.20 mg/dl, 95% CI = 4.70 to 11.71; P < 0.0001) The Egger statistic showed a lack of publication bias (p=0.112) but could not be ruled out based on inspection of funnel plots. The I square suggested a moderate

degree of heterogeneity (56.3%). This was driven mostly by the inclusion of studies of 4 weeks in duration.

Conclusion: Bitter melon significantly reduces fasting blood glucose in patients with type 2 diabetes after 4 weeks of consumption. This moderate degree of effect could serve as a valuable adjunct to other pharmacotherapeutic agents avoiding dose escalation or the addition of additional agents. As such, more studies are needed to determine the long term effects of bitter melon on fasting glucose levels, hemoglobin A1c, concomitant use with pharmacotherapy, and risk of hypoglycemia.

Submission Type: Evaluative Study

Session-Board Number: 7-065

Poster Title: Assessing adherence to guideline weight-based dosing of pre-surgical antibiotic prophylaxis in OB/GYN patients at a community hospital

Primary Author: Lydia Foo, University of the Pacific: Thomas J. Long School of Pharmacy and Health Sciences, California; **Email:** l_foo@u.pacific.edu

Additional Author (s):
Olga DeTorres
Elaine Law

Purpose: Published guidelines recommend antibiotic prophylaxis for patients undergoing an obstetric or gynecological (OB/GYN) surgery to lower the risk of infectious complications. First-generation cephalosporins are recommended. The recommended cefazolin dose is 1 gram but should be increased to 2 grams if BMI is greater than 35 or weight is greater than 100 kilograms. Treatment failures have been reported when prophylactic antibiotics are under-dosed and weight is not considered appropriately. The purpose of the study was to determine if patients at a community hospital received appropriate weight-based doses prior to OB/GYN surgery. The patients were reviewed to determine if post-operative infections occurred.

Methods: In this retrospective chart review, 29 OB/GYN surgery patients admitted between December 29, 2015 and January 15, 2016 were studied for appropriate antibiotic prophylaxis. BMI was calculated and administered doses documented. Charts were reviewed for signs and symptoms of infection, e.g. an increase in white blood cells, fever, wound infection. Adverse drug reactions and allergic reactions were also noted.

Results: Average age of our patient population was 24.2 years old (range: 13-87 years old). The average duration of prophylaxis was 1 day (range: 0-2 days). The average length of stay was 4 days (range: 2-9 days). Average body mass index was 32.2 (range: 20.5-76.7). Six of the patients were obese (20.7 percent). Out of the 29 patients 20 received cefazolin (69 percent), 3 received cefotetan (10.3 percent), and 3 received ampicillin-sulbactam (10.3 percent). Ten percent of patients did not receive antibiotic prophylaxis. 1 of the 29 patients (3.4 percent) received a dose less than recommended while 11 patients (38 percent) received higher than recommended doses of prophylactic antibiotics based on their weight. These patients had a

BMI less than 35 but received 2 grams of cefazolin. None of the patients experienced an allergic reaction or any adverse reaction to prophylactic antibiotics.

Conclusion: Based on published guidelines, the choice of antibiotic and weight based dosing was appropriate in 69 percent of patients. One of the patients was actually underdosed. Patients receiving higher than recommended doses were more common. Excessive doses can increase the risk of adverse events and increase hospital costs. The cost of a one gram IV piggyback of cefazolin is $3.10 while the cost of the 2 gram IV piggyback is $4.15. Administering two grams of cefazolin would increase cost by 35%. Ensuring that the appropriate antibiotic and dose is given can help decrease costs and eliminate unnecessary wastes.

Poster Title: Evaluation of microvascular predictors in Latino patients with diabetes

Primary Author: Shawn Healer, Western University Of Health Sciences, California; **Email:** shealer@westernu.edu

Additional Author (s):
Alex Poladian
Marie Davies

Purpose: Diabetes, in the US, is highly prevalent in the Latino population. Furthermore, there is a well-known correlation between diabetes and microvascular complications. Studies have demonstrated that, compared to non-Hispanic whites, Latinos with diabetes have a significantly higher prevalence of retinopathy and End-Stage Renal Disease, with conflicting data about diabetic neuropathy. There is also lacking data investigating associated risk factors for microvascular complications in Latino patients, which may allow opportunities to better manage the risks. The purpose of this study was to identify predictors that may be associated with diabetic kidney disease, retinopathy, and neuropathy in Latino patients with diabetes.

Methods: This IRB-approved retrospective chart review utilized electronic medical records from Harbor UCLA Family Medicine Clinic. Patients were included who were Latino ethnicity, had type 2 diabetes, and had ≥1 pharmacy clinic appointment in 2015. Data collected included demographics (i.e; age, gender, race), comorbidities (i.e; DKD, Retinopathy, and Neuropathy) and laboratory parameters (i.e; Systolic Blood Pressure, A1C, Weight). Diabetic Kidney Disease (DKD) was assessed and defined by patient having microalbuminuria over 30 mg and macroalbumin over 300 mg, diabetic retinopathy was confirmed by ophthalmologic exam interpretation, and neuropathy was confirmed using ICD-9/ICD-10 diagnosis codes. Each risk factor was categorized as either continuous or dichotomized data. Statistics included univariate analysis with Chi-squared test for categorical data and student's t-test for continuous data.

Results: Of 120 Latino patients with an average age of 53.4 years, 73 (60.8%) were female, and average baseline A1C was 10.2%. Prevalence of microvascular complications was 66% for retinopathy, 50% for diabetic kidney disease and 43% for neuropathy. Compared to females, males were found to have 40% higher rates of retinopathy (P=0.0010), as well as a 10% higher

rate of diabetic kidney disease although this was not statistically significant (P=0.34). Females however had a 40% higher rate of neuropathy compared to males (P=0.03). Patients with diabetic kidney disease had a statistically significant higher Systolic Blood Pressure (SBP) (136.1mmHg vs. 129.6 mmHg; Difference: -6.5mmHg; 95% CI: -11.8 to -1.2; P=0.017). It did not appear that A1C, weight, age, or diastolic blood pressure (DBP) were significant predictors associated with DKD. The data showed that A1C, weight, age, or SBP did not appear to be significant predictors associated with neuropathy.

Conclusion: Potential associations of microvascular complications in Latino patients with type 2 diabetes were gender and SBP. In addition female patients may be associated with a higher rate of neuropathy and patients with an elevated SBP may be associated with DKD. Identifying higher risk populations and quantifying the risk can help healthcare providers target populations for prevention strategies that assist in reducing morbidity and mortality.

Submission Type: Evaluative Study

Session-Board Number: 7-067

Poster Title: The effect of discharging patients with a prescription for an antipsychotic on alcohol related readmissions in patients suffering from bipolar and alcohol use disorder

Primary Author: Kayla Uh, Western University of Health Sciences, California; **Email:** kaylauh2016@gmail.com

Additional Author (s):
David Yang
Mark Richman
Patrick Chan

Purpose: The rate of alcohol-use disorder (AUD) in the general population is 6.8 percent, a rate which more than doubles to 16.1 percent in patients suffering from concurrent bipolar disorder (BD). The primary objective of this study was to evaluate if a new prescription for antipsychotic medication upon discharge at index admission is associated with a reduction in future acute alcohol hospital readmission in patients suffering from both BD and AUD and if new prescription for antipsychotic will prolong the time between index and readmission. The secondary objective is to identify factors that may influence readmission rates.

Methods: This retrospective medical record review study spanned from January 1, 2005 to December 31, 2015 at Olive View Medical Center in Sylmar, CA. After an IRB protocol was approved by both Western University of Health Sciences and Olive View Medical Center, a query based on International Classification of Diseases-9/10 codes for BD was conducted to identify admissions related to bipolar and alcohol-induced events. Initial query provided 16,417 patients. Inclusion criteria included: documented diagnosis of bipolar, history or current alcohol abuse (either by Alcohol Use Disorders Identification Test -C score greater than 3 for females and 4 for males or chart documentation), and no current use of an antipsychotic medication on index admission. Exclusion criteria included: those under the age of 18, those without patient data available, and those without diagnoses of bipolar or without admissions due to alcohol-related events. Data on demographics, patient medical and social history, comorbidities, urinary toxicological screening results, index admission date, date of readmission, medications, and discharge diagnoses was collected. Independent t-tests and Mann-Whitney test was performed on continuous variables and chi-square tests was performed on predictor variables

for readmission such as discharge with an antipsychotic medication, gender, smoking history, homelessness, concurrent depression, and inpatient psychiatric evaluation. Statistical significance was set at a P level less than 0.05.

Results: A total of 101 patients met inclusion criteria patients (n equals 75 for patients discharged with antipsychotics and n equals 26 for patients discharged without antipsychotics). Baseline characteristics were not statistically significant between the two cohorts. For the primary objective, patients discharged with antipsychotics (9 percent) had significantly lower rates of alcohol-related readmissions compared to those who were discharged without an antipsychotic (42 percent, P less than or equal to 0.0001, OR equals 0.13, 95 percent CI 0.043 to 0.39). Median days between index admission and alcohol-related readmissions were 276 days and 125 days for those discharged with an antipsychotic and those who were not, respectively (P equals 0.12). Potential factors that may influence readmission revealed statistical significance for smoking history (P equals 0.03, OR equals 3.26, 95 percent CI 1.15 to 9.29), cocaine abuse (P equals 0.03, OR equals 25.3, 95 percent CI 1.16 to 55.2), and inpatient psychiatric evaluation (P equals 0.01, OR equals 0.23, 95 percent CI 0.08 to 0.70). Other factors such male gender (P equals 0.78) homelessness (P greater than 0.99), concurrent depression (P equals 0.73), amphetamine abuse (P equals 0.44) were not statistically significant for readmissions.

Conclusion: Alcohol related readmission rates were statistically significant between patients discharged on antipsychotics and those who were discharged without antipsychotics. Time between readmission was not significant. This suggests antipsychotics upon discharge may have a positive effect on AUD and reduce future alcohol-related readmissions in patients suffering from concurrent BD and AUD. Prospective studies and the inclusion of other institutions are necessary to substantiate these findings.

Poster Title: Cost-effectiveness analysis of palifermin in the prevention of severe oral mucositis (OM) among patients undergoing allogeneic hematopoietic stem cell transplantation (allo-HSTC)

Primary Author: Christine Nguyen, Western University of Health Sciences, California; **Email:** cdnguyen@westernu.edu

Additional Author (s):
Brian Lam
Quang Le
Doreen Pon

Purpose: Oral mucositis (OM) is an inevitable and debilitating side effect resulting from intensive chemotherapy and radiation frequently used as a conditioning regimen for hematopoietic stem cell transplantation (HSCT). Palifermin, a recombinant keratinocyte growth factor, has demonstrated a reduction in duration and severity of OM after fractionated total body irradiation (FTBI) conditioning based regimen in patients with hematologic malignancies requiring HSCT. The objective of this study was to evaluate the cost-effectiveness of palifermin for preventing severe OM in allogeneic-HSCT (allo-HSCT) patients conditioned with FTBI and etoposide.

Methods: This was a cost-effective analysis of palifermin in preventing severe OM after allo-HSCT. Clinical outcomes were based on an extended retrospective medical record review examining patients who received palifermin for prevention of OM after FTBI and etoposide post allo-HSCT at the City of Hope Medical Center in Duarte, California, spanning from January 2005 to December 2009. The economic analysis of the current study was based on the healthcare provider's perspective. Cost of palifermin was taken from the Red Book. Other direct medical costs including costs of bacteremia, other infections (fungemia and viremia), OM, and severe OM were obtained and/or derived from previously published studies. All costs were adjusted to 2015 US dollars using Consumer Price Index. A decision tree analysis was performed to determine the cost-effectiveness of the palifermin group compared to the control group. Incremental Cost-Effectiveness Ratio (ICER) was calculated in terms of cost per one hospital day avoided.

Results: A total of 184 patients were included in the clinical study, of which 101 patients received palifermin treatment and 83 patients did not receive palifermin (the control group). The percent of patients who experienced severe OM, OM, and no OM in the palifermin versus control groups were 25 percent versus 84 percent, 70 percent versus 16 percent, and 5 percent versus 0 percent (p less than 0.01), respectively. The total costs of palifermin versus control groups were 24,403 vs. 19,505 dollars; and the total length of stay between the groups were 49.8 days vs. 42.6 days (p less than 0.01). The resulting ICER for treatment with palifermin was 1,374 dollars per one hospital day avoided.

Conclusion: In addition to its clinical benefits, the use of palifermin in the prevention of severe OM in patients undergoing allo-HSCT with FTBI and etoposide appeared to be cost-effective when comparing to the current (2015) average cost per hospital day of 1,878 dollars. Further studies are warranted to evaluate quality of life in these patients as well as cost-utility analysis of palifermin.

Poster Title: Outcomes of sofosbuvir-based regimens for hepatitis C virus (HCV): A community-based experience

Primary Author: Safia Ghaniezadeh, Western University of Health Sciences, California; **Email:** sghaniezadeh@westernu.edu

Additional Author (s):
Kjersti Rich
Cory Amador
Zeid Kayali
Hyma Gogineni

Purpose: The purpose of this study is to retrospectively evaluate the efficacy and predictors of response of sofosbuvir-based treatment regimens in hepatitis C patients treated in a community-based ambulatory care practice. Study results are compared to the clinical trials which served as the basis for FDA approval as well as to the outcomes observed in other community-based studies.

Methods: Patients with HCV genotypes 1 through 6 were treated at a community-based ambulatory care center with sofosbuvir-based regimens. The primary outcome measure was percent of sustained viral response achieved at 12 weeks (SVR12) evaluated per genotype, medication regimen, cirrhosis status, and level of treatment experience. The secondary endpoints assessed the following patient characteristics as a predictor of treatment response: cirrhosis, race, gender, platelet level, and co-infection with Hepatitis A or B and HIV. Data was collected retrospectively through chart review of the electronic medical record, health plan portal, and clinical laboratory portals. The following data elements were collected for patients with post-treatment follow-up due between January and June 2016: medication regimens, patient demographics, baseline characteristics, and laboratory values. Providers prescribed a sofosbuvir-based regimen to each patient according to their baseline viral load, cirrhosis status, and level of treatment experience. Patients were treated for 8 to 24 weeks with one of the following regimens: sofosbuvir plus ribavirin, sofosbuvir plus peginterferon plus ribavirin, sofosbuvir plus simeprevir plus ribavirin, sofosbuvir plus daclatasvir, sofosbuvir plus daclatasvir plus ribavirin, ledipasvir/sofosbuvir, and ledipasvir/sofosbuvir plus ribavirin. 275 patients were

screened; consisting of 189 with SVR12, 6 with treatment failure, 5 with interrupted treatment, and 75 lost to follow up. Study endpoints were evaluated for patients with an obtained clinical outcome (n = 195). The institutional review board granted study approval.

Results: Overall SVR12 observed was 97 percent (189/195). The SVR12 rate achieved by drug regimen and duration were: ledipasvir/sofosbuvir 97 percent (29/30) for 8 weeks, 96 percent (88/92) for 12 weeks, and 100 percent (9/9) for 24 weeks; sofosbuvir plus ribavirin 100 percent (17/17) for 12 weeks, 100 percent (4/4) for 16 weeks, 100 percent (2/2) for 24 weeks; sofosbuvir plus daclatasvir 100 percent (22/22) for 12 weeks, 100 percent (9/9) for 24 weeks; sofosbuvir plus ribavirin plus peginterferon 100 percent (1/1) for 12 weeks; sofosbuvir plus daclatasvir plus ribavirin 100 percent (1/1) for 12 weeks, 0 percent (0/1) for 24 weeks; ledipasvir/sofosbuvir plus ribavirin 100 percent (6/6) for 12 weeks, 100 percent (2/2) for 24 weeks. SVR rates for patients with cirrhosis was 95 percent (41/43) and 97 percent (148/152) for non-cirrhosis. SVR rates were 96% (132/137) for genotype 1, 100% (22/22) for genotype 2, 97% (32/33) for genotype 3, 100% (1/1) for genotype 4, and 100% (2/2) for genotype 6. A statistically significant association for virological failure was observed for African American patients (p=0.0257).

Conclusion: In conclusion, this study suggests that treatment success with sofosbuvir-based regimens in a community-based practice is comparable to outcomes achieved in published clinical trials and other real-world studies. Ongoing research is warranted to further identify specific patient characteristics as a predictor of response in achieving SVR12. Based on our findings in the African American population, further research is warranted to identify which clinical parameters are associated with treatment success in order to guide treatment practice and improve patient outcomes.

Submission Type: Descriptive Report

Session-Board Number: 7-070

Poster Title: Evaluating prescribing patterns of estrogen therapy based on age and cardiovascular risk in post-menopausal women

Primary Author: Ziyun Huang, Western University of Health Sciences College of Pharmacy, California; **Email:** zhuang@westernu.edu

Additional Author (s):
Nai-Hsuan Li
Nathan Schirmacher
Hyma Gogineni
Linda Hyder Ferry

Purpose: Heart disease is the leading cause of death in women experiencing atypical cardiac symptoms due to micro-vascular disease pathology. Manson, Menopause 2014, has shown that post-menopausal women starting estrogen replacement therapy (ERT) 10 years post menopause have increased cardiovascular disease risks and that oral ERT promotes even higher risks compared to non-oral ERT. The American College of Obstetricians and Gynecologists discourages routinely discontinue ERT after age 65 even if previously prescribed. Conflicting evidence, recommendations, and prescribing patterns of ERT prompts us to seek an evaluation of prescribing practices and promotes the importance of pharmacist intervention for appropriate ERT.

Methods: This retrospective observational study includes 207 post-menopausal women on ERT from 2014 to 2016 in the electronic health record (EHR). This study uses gender-specific ischemic vascular disease (IVD) risk factors and the arteriosclerotic cardiovascular disease (ASCVD) 10-year risk estimator to identify patients with IVD, which includes ischemic heart disease, stroke, and peripheral artery disease. We categorized participants based on age groups of less than 50, 50 to 55, 56 to 60, and greater than 60 years of age, as well as ASCVD 10-year risk scores groups of less than 5 percent, 5 to 10 percent, and greater than 10 percent. Cardiovascular event risk levels were ranked based on these categories. The highest risk belongs to patients greater than 60 years old and with an ASCVD score greater than 10 percent. After classifying patients into each risk group we further stratified them based on the dosage form of ERT that they were prescribed. A subset population was also evaluated, which included

patients with either a confirmed IVD event, or with diabetes type 1 or type 2 based on a current HbA1C value of greater than or equal to 6.5 percent as defined by the American Diabetes Association. We also evaluated patients that had both diabetes and a confirmed IVD event.

Results: Of the 207 women on ERT, 14 (6.8 percent) were diagnosed with at least one IVD event, 25 (12 percent) met criteria for diabetes, and 5 (2 percent) had both diabetes and IVD event. Of the 14 women who have IVD, 8 patients (57 percent) had an ASCVD score greater than 10 percent and are all over the age of 60. Of the same 8 high-risk women, 4 are on oral estrogen, and 4 are on vaginal estrogen cream. None of the women less than 60 years of age had an ASCVD score greater than 10 percent. Of the 25 women with diabetes, 13 had an ASCVD score greater than 10 percent. However, only 2 are between 56 and 60 years of age, and 11 are greater than 60 years of age. The evaluation of this data allows us to identify women on ERT into separate risk categories and can therefore make possible interventions for appropriate therapy.

Conclusion: Prescribing practice trends in our population demonstrates a preference for oral ERT in high-risk patients, which may facilitate higher risk for cardiovascular events. We encourage the use of non-oral ERT, such as transdermal ERT, to reduce cardiovascular events for postmenopausal women with an ASCVD score greater than 10 percent or age greater than 60. Pharmacists in the ambulatory care setting can intervene in the selection process of ERT based on a woman's ASCVD risk score and age in order to minimize the risk of cardiovascular events that may be associated with oral ERT.

Session-Board Number: 7-071

Poster Title: Patients with schizophrenia and substance use disorder: Should they be discharged with an antipsychotic?

Primary Author: Lisa Pham, Western University of Health Sciences, College of Pharmacy, California; **Email:** lpham1@westernu.edu

Additional Author (s):
Amy Huang
Donna Phan
Mark Bounthavong
Patrick Chan

Purpose: Approximately, 8.4 percent of Americans suffer from substance-use disorder (SUD), which increases by 50 percent in patients with concurrent schizophrenia. The primary objective of this study was to evaluate if an antipsychotic prescription at discharge was associated with a reduction in future SUD related hospital readmission in patients suffering from both schizophrenia and SUD. Secondary objectives were to evaluate the impact of a new antipsychotic prescription on the time to readmission and to identify potential factors that may be associated with readmission rates.

Methods: This retrospective medical record review spanned from January 1, 2005 to December 31, 2015 at Olive View Medical Center in Sylmar, CA, which is a large academic hospital serving Los Angeles County. After an Institutional Review Board (IRB) protocol was approved by both Western University of Health Sciences and Olive View Medical Center, a query based on International Classification of Diseases (ICD)-9/10 codes for schizophrenia was conducted to identify admissions related to schizophrenia and SUD. Inclusion criteria included documented diagnosis of schizophrenia, SUD, and no current use of antipsychotics on admission. Patients under the age of 18 or unavailable electronic medical record were excluded from analysis. Data on demographics, patient medical and social history, comorbidities, urinary toxicological screening results, admission date, date of readmission, medications, and discharge diagnoses was collected. Baseline comparison between the groups was conducted using independent t-test for continuous data and chi-square test for discrete data. Logistic regression models were constructed to evaluate the association between patients discharged with an

antipsychotic and readmission. Results were presented as odds ratios (OR) and 95 percent confidence intervals (CI). Covariates included in the model were age, gender, ethnicity, length of stay (LOS), history of antipsychotic use, social history, comorbidities, and inpatient psychiatric evaluation. Statistical significance was set at a P value less than 0.05. All analyses were performed using STATA/SE 13 (College Station, TX).

Results: A total of 104 (85 percent) of 126 eligible patients were discharged with an antipsychotic after a SUD related admission. Baseline characteristics (age, gender, social history, comorbidities) were similar between the two cohorts with few exceptions. Patients who received a prescription for antipsychotic upon discharge had longer LOS (P less than 0.0001), more psychiatric evaluations (P less than 0.0001), higher positive urinary toxicology results for marijuana (P equals 0.003), but fewer positive urinary results for cocaine (P equals 0.016). For the primary objective, patients discharged with an antipsychotic had a higher but non-significant SUD-related readmission (19 percent) compared to patients discharged without an antipsychotic (18 percent, OR equals 5.71, 95 percent CI: 0.79 to 41.34, P equals 0.085). Mean days between discharge and readmission were not significantly different between patients discharged with and without an antipsychotic (441 versus 524 days, P equals 0.584). Other potential risk factors for readmission such as gender (P equals 0.274), smoking (P equals 0.941), and alcohol use (P equals 0.658) were not statistically associated with higher readmission rates.

Conclusion: Discharging patients suffering from both schizophrenia and SUD with an antipsychotic was not associated with a reduction in future SUD-related readmissions and emergency department visits, nor did it increase the number of days to readmission. Furthermore, potential risk factors were not associated with an increase in SUD-related readmissions. However, reduced power due to small sample size may have threaten the internal validity of this study by increasing type II error. Future studies will need to increase the sample size and include other confounders such as psychiatric support, adherence, and follow-up appointments to assess whether these potential confounders impact outcomes.

Poster Title: Assessing the appropriateness and effectiveness of a pharmacokinetics program utilization for vancomycin dosing: Experience at a community hospital in Hilo, Hawai'i

Primary Author: David Nguyen, Daniel K. Inouye College of Pharmacy at University of Hawai'i at Hilo, Hawaii; **Email:** dhn@hawaii.edu

Additional Author (s):
Louis Lteif

Purpose: Many institutions dose vancomycin according to their specific protocol that takes into account the patient population they serve and their characteristics such as weight and creatinine clearance. At this institution, a pharmacokinetics program is utilized in lieu of a protocol whereby patient specific data is inputted on a case by case basis. While conducting prospective audits and reviews, vancomycin trough levels were frequently observed to be sub-therapeutic. The purpose of this study is to evaluate the appropriateness and effectiveness of utilizing this pharmacokinetics program to dose vancomycin or whether there is a potential need to develop an institution specific protocol.

Methods: The Institutional Review Board approved this retrospective Drug Use Evaluation project (Protocol ID: 2016-30636). For the purposes of this retrospective study, data was collected from electronic medical records during the months of April 2016 – July 2016 over a period of 45 days. Inclusion criteria were all patients over 18 years of age admitted to the institution during the specific time period, received vancomycin, and had at least one trough level collected. A data collection spreadsheet was developed and included patient demographic information such as age, gender, height, weight, serum creatinine, and indication for vancomycin use. Information about vancomycin regimen was collected and included initial dosing regimen, trough levels along with timing of levels, and any adjustments made thereafter along with new troughs, if applicable. Our primary outcome was to measure the rate of initial therapeutic trough levels achieved according to each indication. Secondary outcomes included the timing of levels in association with number of doses received and measuring rates of subsequent therapeutic through levels.

Results: Data on a total of 150 patients was collected. Of these 150 patients, 62.6 percent (94 cases) were male, and 37.3 percent (56 cases) were female. The rate of initial therapeutic trough levels was 24 percent (36 cases), sub-therapeutic and supra-therapeutic levels accounted for 69.3 percent and 6.7 percent respectively. 40 percent of trough levels (60 cases) were not taken at steady-state levels.73 patients had repeat troughs taken. 53 percent (39 cases) of the patients who had repeat troughs yielded therapeutic troughs, 24.6 percent (18 cases) had supra-therapeutic troughs, and 23 percent (17 cases) had sub-therapeutic troughs. . Interestingly, there was a total of 81 patients who weighed over 80 kilograms and 65 percent (53 cases) of these patients received an initial vancomycin dose of one gram or less in contrast to current guidelines recommending 1250 mg or more for this specific subset of patients.

Conclusion: The majority of the patients receiving vancomycin in our study were being dosed inappropriately as confirmed by the high percentage of initial sub-therapeutic trough levels. Trough levels not taken at steady state may lead to inappropriate adjustments since the true trough level might be underestimated. These findings suggest that the use of the pharmacokinetics program may not be optimal and the institution could potentially benefit from developing an institution-specific vancomycin dosing protocol. With appropriate dosing and trough level drawings, the institution could prevent extra costs, utilize personnel more efficiently and more importantly, improve patient outcomes and decrease length of stay.

Poster Title: Process to patient: the lifecycle of a total parenteral nutrition order in a neonatal intensive care unit

Primary Author: Melissa Giachetti, The Daniel K. Inouye College of Pharmacy, Hawaii; **Email:** mlgiache@hawaii.edu

Additional Author (s):
Tae Kim

Purpose: Total parenteral nutrition (TPN) serves as a vital source of calories and electrolytes for many premature neonates to promote growth and neurodevelopment. It is classified as a high-alert medication per the Institute for Safe Medication Practice (ISMP). Due to its increased risk of patient harm, attention to detail when calculating, ordering, compounding and administering is imperative. Establishing a consistent workflow is important to guide all personnel involved to reduce the risk of error. This project was designed to look at all the steps involved in safely and effectively processing TPNs for infants in a neonatal intensive care unit (NICU).

Methods: A student pharmacist directly observed the process of TPN orders, including the observation of pharmacists, pharmacy technicians and other clinicians in a women and children's hospital. The TPN process in the hospital's level III NICU was assessed. The process involved calculating components, ordering, verification, preparation, delivery and administration. A flow chart was generated to describe the lifecycle of a TPN order in its various stages. It was noted how many times an individual TPN was checked, including the order, label, and visual inspection. The amount of personnel needed to safely process a batch of TPNs per day was described. The flow chart was also used to identify any potential errors during each stage, as well as provide insight for future improvements of best practice.

Results: After observing the lifecycle of a TPN order in a hospital's NICU, a flow chart of the various stages involved in the process was generated. There were ten main steps recognized in the process of a TPN order. Five double-checks of a single TPN order were identified throughout its lifecycle. An average of ten people were involved during the process of a single TPN, from the decision of an order to administration to the patient. Potential errors at each step were also identified. Future improvements of best practice were suggested such as implementing a TPN

ordering system that is linked to the hospital's electronic medical record (EMR) to reduce the risk of transcription error.

Conclusion: It is important to safely and effectively process TPNs. Serving as a critical need for many premature neonates, there is no room for error. A TPN workflow process was established in a women and children's hospital to serve as best practice to guide personnel involved. In comparison to the usual medication use process, TPNs are complex, high risk and involve many steps which need to be checked and re-checked to reduce the risk of error. The overall process involved personnel from different departments in the hospital. Improvements in best practice are always possible.

Poster Title: Potential risk of opioid agonist overdose in the setting of chronic use of low-dose opioid antagonist

Primary Author: Christopher Diaz, The Daniel K. Inouye College of Pharmacy at the University of Hawaii at Hilo, Hawaii; **Email:** cjdiaz@hawaii.edu

Additional Author (s):
Vidya Nair
Angela Lam
Penelope Goode
Jonathan Penoyar

Purpose: This case illustrates the potential harm of an opioid agonist administered with prior chronic use of a low-dose opioid antagonist. A 68-year-old male presented to the Emergency Department (ED) for multiple wounds including the left ankle, buttocks, and sacral region with possible osteomyelitis. The patient was previously diagnosed with multiple sclerosis and has been wheelchair-bound for the last 4 years. Prior to admission, his home medications were pertinent for a chronic low-dose opioid antagonist: naltrexone 2 mg by mouth once daily for multiple sclerosis. The patient arrived to the ED at 1600 and was given 5 mg of oxycodone by mouth once for pain at 1730. At around 1915 he was unresponsive to deep sternal rub with no witnessed seizure activity. His blood sugar resulted normal. He subsequently received 2 mg of naloxone intravenously which restored responsiveness and alertness. Within half an hour he became unresponsive again, which led to initiation of naloxone drip infusing at 0.4 mg per hour that restored consciousness. At around 2330 the naloxone drip was stopped and within fifteen minutes he became unresponsive again. The naloxone drip was restarted with subsequent return of consciousness. He was thereafter transferred to the critical care unit (CCU) for further management with continuation of the naloxone drip. After about 3 hours in the CCU, the naloxone drip was tapered and stopped at 0415 and he remained stable with no further complications. Naltrexone normally has antagonistic properties on mu-, delta-, and kappa-opioid receptors. However, in limited studies, low-dose naltrexone (LDN) is thought to exert its clinical benefits through an elevation of endorphin levels which has an antagonistic effect on toll-like receptor 4 (TLR4). Endorphins are displaced and opioid receptor levels are up-regulated to compensate for the lack of hormone-binding. Endorphins then bind with TLR4 on other cells,

such as macrophages, which halt cytokine release, production of nuclear factor-kappa B (NF-kB), and progression through the pain pathway. This leads to a decrease in pain, spasticity, fatigue, relapse of disease, inflammation, and down-regulation of oncogenes, thereby substantiating the theoretical use of LDN in autoimmune disorders and diseases such as cancer. In animal studies, there is also a reported up-regulation of opioid receptors with LDN. It is theorized that the up-regulation of opioid receptors with LDN can cause hypersensitivity to opioid agonists, leading to respiratory decompensation and unresponsiveness even with the use of low dose opioid agonists. As this case suggests, opioid agonist overdose may have been precipitated by chronic low-dose opioid antagonist use due to hypersensitivity. Therefore, pharmacists and other healthcare providers should remain alert to prior chronic use of low-dose opioid antagonists when deciding appropriate pain management for such patients.

Poster Title: Interdisciplinary assessment of multimodal pain management strategies in patients undergoing elective bilateral total hip arthroplasty

Primary Author: Kelsea Mizusawa, The Daniel K. Inouye College of Pharmacy at the University of Hawaii at Hilo, Hawaii; **Email:** kaylm@hawaii.edu

Additional Author (s):
Kellie Octavio
Laura Ota
Joy Matsuyama
Cass Nakasone

Purpose: Total joint arthroplasty is often associated with significant postoperative pain that can slow rehabilitation and influence the overall success of surgery. Multimodal pain management strategies involve the addition of adjunctive agents to achieve optimal postoperative pain control with a lower reliance on opioids. Currently, clinical trials published on multimodal pain management for bilateral total hip arthroplasty is limited. The purpose of this evaluation is to assess the impact of adjustments made to multimodal pain medications on hospital length of stay, pain assessment, opioid consumption, time to ambulation, and medication cost in patients undergoing bilateral total hip arthroplasty.

Methods: Since 2014, an interdisciplinary team including orthopedic surgeons, anesthesia providers, nurses, and pharmacists focused on ongoing adjustment and assessment of the multimodal pain management regimens in total joint arthroplasty. A retrospective chart review of adult patients who underwent an elective bilateral total hip arthroplasty by a single orthopedic surgeon was completed during a two month period in 2015 and 2016. The multimodal pain management regimens in 2015 included preoperative celecoxib, intraoperative liposomal bupivacaine, and postoperative intravenous acetaminophen for 24 hours. In 2016, the protocol was modified by removing preoperative celecoxib and switching to a bupivacaine based intra-articular solution and postoperative oral acetaminophen. Anesthesia also began administering perineural additives to prolong the action of the local anesthestic block. All patients continued to receive preoperative gabapentin and oxycodone extended release, a peripheral nerve block with bupivacaine, and intraoperative tranexamic acid for

blood conservation and venous thromboembolism prophylaxis. Outcomes including patient demographics, length of stay, pain assessment, opioid consumption, ambulation, and medication cost were assessed. This project was deemed exempt from institutional review board review.

Results: Seventeen patients undergoing elective bilateral total hip arthroplasty were reviewed; eight patients in 2015 and 9 patients in 2016. Hospital length of stay was similar in 2015 and 2016 (3.1 days versus 3.0 days, respectively). Mean visual analog pain scores in 2015 was slightly higher than in 2016 in the post-anesthesia care unit (PACU) (4.0 versus 1.0), similar on postoperative day one (2.6 versus 2.7), and lower prior to discharge (0.8 versus 2.7); differences were not statistically significant. Opioid consumption was measured using morphine equivalent units. In the PACU, 50% of patients in 2015 required an average of 1.7 mg, whereas no patients in 2016 required opioid therapy. Patients in 2015 had a higher mean opioid consumption during hospitalization than in 2016 (35.4 mg versus 28.0 mg) and a lower mean time to first postsurgical opioid (8.3 hours versus 18.5 hours); differences were not statistically significant. Patients in 2015 had a faster mean time to ambulation than in 2016 (13.7 hours versus 17.0 hours); difference was not statistically significant. Mean medication cost per patient was statistically significantly lower in 2016 compared to 2015 ($497.50 versus $1,109.83), attributed to the discontinuation of liposomal bupivacaine and intravenous acetaminophen.

Conclusion: The total joint arthroplasty multimodal pain regimen was adjusted in 2016. Although outcomes cannot be attributed to the use or discontinuation of any specific medication, the results indicate that discontinuation of preoperative celecoxib, conversion of liposomal bupivacaine to a bupivacaine intra-articular solution, and use of postoperative oral acetaminophen instead of intravenous acetaminophen did not significantly impact length of stay, pain management, opioid consumption, and ambulation. Changes resulted in a significant decrease in mean medication cost per patient of $612, with an annual savings of approximately $23,880 based on the number of total bilateral hip arthroplasty procedures completed in 2015 (39).

Poster Title: Medicare Part D prescribing changes of tricyclic antidepressants between 2013 and 2014

Primary Author: Nadine So, The Daniel K. Inouye College of Pharmacy at the University of Hawaii at Hilo, Hawaii; **Email:** nadineso@hawaii.edu

Additional Author (s):
Deborah Taira

Purpose: Tricyclic antidepressants were the primary pharmacologic treatment for depression in the United States from the 1960s to the late 1980s. Since then, other classes of antidepressants, such as Selective Serotonin Reuptake Inhibitors, have replaced its use as first-line agents due to their more favorable side-effect profile and proven equal efficacy. Tricyclic antidepressants are included in the Beers Criteria because of their potentially harmful side effects in the elderly (e.g. cognitive impairment, delirium, sedation, and orthostatic hypotension). The purpose of this study is to evaluate the changes in prescribing of tricyclic antidepressants from 2013 to 2014 in Medicare beneficiaries.

Methods: The dataset included patients enrolled in a Medicare Part D prescription drug plan and included total number of beneficiaries, providers, prescriptions, and drug costs during 2013 and 2014. Medicare Provider Utilization and Payment Data: Part D Prescriber Public Use Files were used to compare the use and cost of each tricyclic antidepressant both at the state level and in aggregate. Tricyclic antidepressants listed in both the 2012 and 2015 Beers Criteria updates (amitriptyline, clomipramine, doxepin, imipramine, and trimipramine) were included in the study as they were thought to be potentially inappropriate for use in the elderly over the 2013 and 2014 time period. T-tests were used to determine if there were statistically significant differences in use and cost over time. In addition, we calculated per capita use and cost at the state level by dividing the values by the population over age 65 with data obtained from census bureau. We ranked states by cost, and number of beneficiaries, prescribers, and prescriptions, per 1000 persons over age 65, and examined how the rankings changed between 2013 and 2014. Because this was a de-identified public use data file from the federal government, it did not meet the criteria of human subjects research and was exempt from IRB approval.

Results: Between 2013 and 2014, the number of beneficiaries taking the five tricyclic antidepressants decreased by 24,966, the number of prescriptions decreased by 50,470, and the number of prescribers decreased by 21,687. During the same time period, however, costs increased by over $62 million. From 2013 to 2014, the total cost for Medicare beneficiaries for amitriptyline increased significantly by $24.3 million (p < 0.001), for clomipramine, by $36.6 million (p < 0.001), and for doxepin by $3.1 million (p < 0.001). The number of prescribers for clomipramine also increased significantly (p=0.007), but there were not significant increases in the number of prescribers for the other medications. In contrast, during the same time period, the total cost of imipramine decreased by $1.4 million, but this change was not statistically significant. The total cost of trimipramine decreased by $182,682 (p < 0.001). The total number of prescribers also significantly decreased for trimipramine by 3,064 (p=0.001). In both 2013 and 2014, Kentucky had the most prescriptions and beneficiaries per capita, Maine had the most prescribers, and Rhode Island had the highest cost. The state with the lowest beneficiaries, prescribers, prescriptions, and cost of tricyclic antidepressants per capita during both 2013 and 2014 was Hawaii.

Conclusion: From 2013 to 2014, utilization of the five tricyclic antidepressants decreased. This suggests that Medicare beneficiaries may be switching to medications with fewer adverse effects. The fact that total costs significantly increased for most tricyclic antidepressants, despite decreased utilization, suggests that price increases are responsible. While we do not have information on patient copayment levels, this may pose a problem for Medicare beneficiaries on a fixed budget. Moreover, although there was a drop in utilization, there were still 67,192 prescriptions of these potentially inappropriate medications to 37,742 Medicare beneficiaries, indicating there may still be room for improvement.

Submission Type: Evaluative Study

Session-Board Number: 7-077

Poster Title: Retrospective study to identify opportunities for de-escalation of empiric vancomycin therapy in suspected methicillin-resistant Staphylococcus aureus pneumonia

Primary Author: Jenni Ueno, University of Hawaii at Hilo Daniel K. Inouye College of Pharmacy, Hawaii; **Email:** jueno@hawaii.edu

Additional Author (s):
Arthur Barcikowski
Ty Frisch
Anne Tanouye
Joyce Tapuro

Purpose: The 2016 Infectious Disease Society of America (IDSA) guidelines for hospital-acquired and ventilator-associated pneumonia emphasize the need to de-escalate empirical antibiotic therapy to reduce direct healthcare costs, antimicrobial resistance, and side effects associated with therapy. The purpose of this study was to identify opportunities for de-escalation of vancomycin used as empirical treatment of methicillin-resistant Staphylococcus aureus (MRSA) pneumonia.

Methods: A single-center retrospective study of hospital patients with pneumonia treated with vancomycin was conducted over a three-month time period at Wilcox Memorial Hospital. Electronic medical records were screened for patients treated with vancomycin who received a diagnosis of pneumonia. Of these patients, those without a resulted MRSA nasal swab polymerase chain reaction (PCR) test, resulted blood cultures, or resulted sputum cultures were excluded due to inability to identify opportunities for therapy improvement. Bulk charges, drug returned to stock, and duplicate hospital account record (HAR) numbers were also excluded. The remaining patients were stratified into two groups. Group One was defined as patients with a MRSA nasal swab PCR and blood or sputum cultures. Opportunity for de-escalation was defined as continuation of therapy post 24 hours of negative result from MRSA nasal swab PCR. MRSA nasal swab PCR had to have been associated with admission for acute event related to vancomycin use. Group Two was defined as patients with only blood or sputum cultures. In Group two, opportunities for de-escalation were defined as continuation of therapy 24 hours

beyond 48-hour culture result. Blood or sputum cultures had to have been associated with admission for acute event related to vancomycin use.

Results: Search of electronic medical records identified 2918 reports of vancomycin use during the study period, 2894 records met exclusion criteria. Twenty-four individual patient records were identified to have vancomycin use with a diagnosis of pneumonia for the acute event date. One patient was excluded due to expiration prior to result of cultures, another was excluded with a diagnosis of pneumonia secondary to MRSA bacteremia associated with intravenous drug use. Thirteen patients had reported results from a MRSA nasal swab PCR associated with hospital admission event and were placed in Group One. The remaining nine patients with only blood or sputum culture results comprised Group Two. There were no positive MRSA nasal swab PCR results in Group One and opportunities for de-escalation were found in ten patients (77 percent). All patients in Group One also had blood or sputum cultures with negative results for MRSA. Of the nine patients in Group Two, all had record of blood cultures and three also had sputum cultures. There were no positive results for MRSA reported from any final culture in Group Two and opportunity to de-escalate therapy was found in five patients (56 percent).

Conclusion: Our results identify opportunities for de-escalation of vancomycin in patients with suspected MRSA pneumonia and verify the strong negative predictive value of the MRSA nasal swab PCR test. It is our recommendation that all patients with pneumonia placed on vancomycin therapy receive a MRSA nasal swab PCR test to screen for MRSA colonization prior to administration of therapy. Should results be negative, vancomycin should be de-escalated within 24 hours. In the absence of a MRSA nasal swab PCR, blood or sputum cultures showing no growth at 48 hours may also be used as an indicator to de-escalate therapy.

Poster Title: Naloxone medication use evaluation

Primary Author: Katelyn Beachner, Drake University, Iowa; **Email:** katie.beachner@drake.edu

Additional Author (s):
Kelsie Hundley
Kristin Repp

Purpose: To conduct a medication use evaluation which characterizes the use of the drug naloxone in hospitalized patients within a Health System. The objective is to identify how often naloxone is used to reverse respiratory depression in adult in-patients who have been receiving opioids for pain control and determine a metric that can be used as a surrogate for opioid safety across time and across facilities. Additionally, we will investigate the use of the Pasero Opioid-Induced Sedation Scale (POSS) and pain scores in relation to naloxone administrations.

Methods: Inclusion criteria consists of any adult in-patients admitted to one of four hospitals within a health system who received opioids and naloxone during the months of April and June 2016. Our exclusion criterion consists of any patient who presented to the hospitals with an overdose, or were not administered a narcotic in the hospital. Additionally, anyone who was prescribed naloxone for itching or if administered in the operation room was excluded. Data collection utilized the electronic medical records (EMR). Investigators retrieved the records of every naloxone administration in April and June of 2016. Each administration was evaluated based on inclusion and exclusion criteria. Of administrations that fit within the criteria, the following information was collected for opioids and naloxone: dose, route, frequency and time of administration. In addition, the total dose in twenty-four hours and morphine equivalent dose were calculated. Patient assessments were recorded including POSS score and pain score. Descriptive analysis was performed on all variables. Averages from April and June data were compared using unpaired t-tests.

Results: A total of 20 patients (10 each in the months of April and July) met all inclusion criteria. This is a rate of 0.044 percent in April and 0.043 percent in June (defined as number of patients requiring rescue divided by the Case Mix Index Adjusted patient days). The results characterizing the use of naloxone include: demographics of patients, which opioid was most

frequently implicated, and the percentage use of the POSS. The average age of April and June were 68.9 and 61.7 years (p = 0.379) respectively, with 60 percent males in April and 90 percent males in June (p=0.0573). Additionally, 50 percent of patients were at an intermediate level of care at time of naloxone rescue. The average morphine equivalent milligrams of hydromorphone per administration was 9.3 milligrams, making it the worst offender of opioid induced respiratory depression. Additionally, it had the highest number administrations of any drug implicated in the study. When evaluating the use of POSS scores, the percent of patients that received a POSS within the previous twenty-four hours prior to naloxone administration was 89.4 percent, but only 47 percent of patients had received a POSS score within 6 hours to administration of naloxone.

Conclusion: When considering the results of this study, the percentage of patients requiring rescue was low. Now that a metric has been defined, it can be monitored across the health system to identify the impact additional safety and quality measures may effect this metric. Hydromorphone appears to be the worst offender in terms of opioids requiring naloxone administration. Due to its lower doses, it might be viewed as a less potent analgesic and additional education may be warranted. Another opportunity for improvement may be to increase the frequency of sedation assessment and documentation using the POSS score.

Submission Type: Case Report

Session-Board Number: 7-079

Poster Title: Use of ketamine in refractory status epilepticus

Primary Author: Nicole Hartsock, Drake University, Iowa; **Email:** nicole.hartsock@drake.edu

Purpose: This is a case report of the use of ketamine in refractory status epilepticus. The current 2012 Neurocrtical Care Status Epilepticus Guidelines do not provide any recommendations on safety, efficacy, dosing, or monitoring in the use of ketamine in refractory status epilepticus. The guidelines recommend reserving the use of ketamine to patients who do not respond to refractory status epilepticus treatment options. N-methyl-D-aspartate antagonists, such as ketamine, have an emerging role in refractory status epilepticus treatment. The patient is a 36-year-old female who presented with unspecified sensory loss and then progressed into generalized convulsive seizures with status epilepticus of unknown etiology. The patient had a past medical history of newly diagnosed hyperthyroidism and no prior seizures. She was initially treated in the emergency department with lorazepam, propfol, and phenytoin. Upon admission to the critical care unit propofol and phenytoin were continued, as well as adding phenobarbital, levetiracetam, valproic acid, and midazolam. Ketamine was the next antiepileptic agent added at a beginning dose of 0.48 milligrams per kilograms per hour. The goal of therapy was to achieve 80% burst suppression. After two days of ketamine therapy and up-titrating the dose, 40-50% burst suppression was documented. The maximum dose of ketamine was 2.52 milligrams per kilograms per hour, which was reached on the third day of treatment. A burst suppression of 80% was achieved after six days of therapy. Ketamine was the last agent added prior to obtaining adequate burst suppression. After achieving stable burst suppression at 80% for two days, a taper of burst suppressive therapy was initiated. Ketamine was tapered at a rate of 0.3 milligrams per kilogram per hour every 30 minutes after eight days of treatment. Ketamine was the last burst suppressive agent to be removed, however, other antiepileptic agents were continued. After the removal of ketamine, the patient has had no clinical seizures to date. After burst suppression therapy was discontinued, two other antiepileptic agents were removed, leaving three antiepileptic maintenance medications remaining. It is difficult to conclude which antiepileptic medication controlled this patient's status epilepticus due to multiple agents used for treatment. However, because ketamine was the last agent added prior to burst suppression control, it is likely what provided control of status epilepticus. The patient did not experience any side effects attributable to ketamine use

during the course of treatment. Further studies are needed to provide recommendations for safety and efficacy of ketamine in the use of refractory status epilepticus.

Poster Title: Evaluating the appropriateness of parenteral opiate use in rural clinics affiliated with a large integrated health-system in the Dakotas

Primary Author: Maren McGurran, Drake University, Iowa; **Email:** maren.mcgurran@drake.edu

Additional Author (s):
Kevin Rauwerdink
Maari Loy

Purpose: The rising opioid epidemic has led to increased scrutiny and focus on reducing unwarranted narcotic use. The aim of this study was to review the appropriateness of parenteral opiate use in Sanford Health's rural North Dakota clinics. Additionally, this study sought to investigate if implementing opiate prescribing guidelines at these sites would reduce opiate prescribing and improve narcotic documentation in the electronic medical record.

Methods: A review of all patients who received parenteral opiates in the rural clinics was completed using retrospective chart audits. Patients were selected using narcotic transfer forms from each site between the dates March 1, 2016 through March 30, 2016. Outcomes evaluated in the chart audits included indication, medication administered, dose administered, drug concentration, amount wasted, pain scores, ICD-10 scores, and approving provider. Additionally, evaluation of opiate use and waste on narcotic tracking forms was completed. This included matching drug, matching concentration, and reconciled drug given and wasted. Headache/migraine was the most common indication for parenteral opiate prescribing (International Classification of Diseases (ICD) 10 code R51 and G43). A treatment guideline was established to aid appropriate prescribing with preference towards evidence-based non-opiate analgesia. The suggested prescribing guideline and the results of this audit were discussed with the ambulatory medication safety committee, nursing groups, hospital and clinic physicians, inventory supervisors, and pharmacy managers to discuss appropriate follow-up. Audits are ongoing to evaluate whether opiate prescribing and documentation errors have decreased following the dissemination of these results and approval of new inventory controls.

Results: The most common indications for parenteral opioid prescribing were headache/migraine (ICD-10 R51/G43 25.4 percent), procedure-related pain (19.4 percent), and abdominal pain (ICD-10 R10 13.4 percent). The average pain scores on presentation for the rural clinics was 8.69/10 with a range of 8.14 to 9.38 in sites carrying parenteral opiates. Of the 67 entries, 18 errors in documentation were identified (26.7%). These errors were broken down into four categories: narcotic transfer forms revealed 9 concentration errors, 4 waste documentation errors, 3 administrations not documented, and 2 incorrect doses documented. Individual sites with high documentation error rates received follow-up and education on appropriate tracking and strategies to standardize narcotic records. Upon follow-up with physicians and pharmacy management, all but two sites decided to eliminate all parenteral narcotics from their inventory. The other two sites standardized their formulary to include only one concentration of morphine limited to emergency use.

Conclusion: Parenteral opiate usage in rural clinics within a large integrated health-system was evaluated. The implementation of parenteral opiate prescribing restrictions were implemented in these clinics, which resulted in reduced opiate prescribing and improved narcotic documentation in the electronic medical record. These changes make a significant impact in efforts to reduce unwarranted narcotic use in the rural clinics.

Poster Title: Operationalization of the guideline advantage criteria by centralized clinical pharmacists for primary care medical offices

Primary Author: Panagiota Terzis, University of Iowa, Iowa; **Email:** panagiota-terzis@uiowa.edu

Additional Author (s):
Christopher Parker
Tyler Gums
Rachel Finkelstein
Barry Carter

Purpose: Previous studies have found clinical pharmacists were effective in significantly lowering blood pressures, improving guideline adherence and decreasing HbA1C levels. The Guideline Advantage (GA) program was developed to promote consistent use of evidence-based practice guidelines in outpatient settings in support of the Million Hearts national initiative to prevent one million heart attacks and strokes by 2017. The purpose of our study is to operationalize an algorithm used by clinical pharmacist to measure the Guideline Advantage criteria in patients participating in two large clinical trials to improve cardiovascular disease health.

Methods: We implemented the Guideline Advantage criteria in 2 cluster-randomized, clinical trials evaluating a centralized, web-based cardiovascular (CV) risk service managed by clinical pharmacists. In order to develop the scoring system to measure guideline adherence, we identified criteria from the 2011 & 2013 versions of the GA criteria and new national guidelines for the management of hypertension and cholesterol that could be used as part of the primary outcome for the studies. The specific criteria chosen by the research team were based on objective variables that could be measured and obtained as part of the research protocol. Extensive data were collected at the baseline visit by a research study coordinator that includes a structured BP measurement and laboratory draw for lipids and HbA1C. Baseline data were uploaded into the web-based Iowa Personal Health Record (Iowa PHR). The Iowa PHR patient and clinical pharmacist web interfaces interacted with a database "back-end". A computer algorithm analyzed information in the database in order to automatically identify which GA criteria applied to each patient based on baseline variables that were collected by study

coordinators at each medical office. The PHCVRS pharmacists used this information to create a personalized care plan for each patient based on GA criteria that had not been achieved and are not contraindicated for the patient.Each eligible criteria was scored at baseline.

Results: The Guideline Advantage criteria were implemented in 15 control and 15 intervention offices. A total of 302 (study 1) and 402 (study 2) subjects were enrolled. This abstract highlights the Guideline Advantage criteria scores in one trial in which baseline data are available. Baseline composite scores for intervention and control sites were 64.4 (±13.4)% and 63.9 (±12.6)%, respectively. Baseline scores for CV and diabetes-related criteria were 75.1 (±17.0)% intervention and 77.0 (±17.8)% control and 65.7 (±19.9)% intervention and 67.7 (±16.2)% control, respectively.

Conclusion: The Guideline Advantage criteria were successfully implemented and baseline scores were much better than expected. This study demonstrated generally good adherence to Guideline Advantage criteria. We theorized that linking the concepts in the GA criteria to operational definitions and providing results for individual patients at the point of clinical pharmacist care would create a pragmatic bridge from guideline concepts to individual patient care. Operationalizing the GA criteria using the PHCVRS model is intended to improve guideline concordant therapy and decrease the risk of CV disease. The results from both trials will be available by 2019.

Poster Title: Safety of interchange between brand-name to generic phenytoin

Primary Author: David Quach, University of Iowa College of Pharmacy, Iowa; **Email:** david-quach@uiowa.edu

Additional Author (s):
Sheila Glencer
Ashley McClure-Wolfson

Purpose: Phenytoin is an antiepileptic drug used to treat generalized and partial seizures. The FDA indicates that generic formulations of phenytoin are not bioequivalent to brand-name formulations. The purpose of this study retrospective study was to determine if individuals that switched from brand-name to generic phenytoin had decreased serum concentration levels and change in seizure frequency in an intermediate care facility for intellectually disabled.

Methods: Medical staff evaluated 25 individuals aged 29-68 for brand-name to generic phenytoin interchange. 18 were deemed capable of interchange. Of the 18 individuals interchanged, only 12 were selected for review due to health status and dose stability. The other 6 individuals were excluded due to acute hospitalization at interchange, dose change at interchange, and periods of nonadherence. Each individual's phenytoin total serum concentration levels and seizure frequencies were collected 6 months prior to the interchange and 2 months after. Phenytoin levels were excluded if not collected for more than 2 weeks after the interchange or if there was an acute illness at the time of the drug level, if dose amount changed, or if drug regimen changes included drug interactions. The primary outcome measure was a decrease from baseline serum concentration after reaching steady state with generic phenytoin. Secondary outcomes were change in seizure frequency and differences in number of additional antiepileptic medications. Power analysis was not done due to the nature of study having a limited number of individuals in the population. The Glenwood Research Committee approved this retrospective chart review. Informed consent was provided by the guardians of all participants.

Results: 4 of the 12 (33.3%) participants were female. The mean age of patients was 53.4 years. Participants were more likely to be diagnosed with generalized seizures than partial seizures. The average daily dose of phenytoin was 300mg (SD plus or minus 45.38mg). The mean serum phenytoin concentration before (14.91mg/L) and after (14.12mg/L) interchange was not significantly different (-0.785mg/L; 95 percent CI, -0.855mg/L to 2.425mg/L, P equals 0.197). The change in seizure activity after interchange was not different (-16.6 percent; 95 percent CI, -41.3 percent to 8.12 percent-8.12 percent to 41.3 percent, P equals 0.166). No association was found between increased total number of antiepileptic medications and phenytoin level changes greater than 1mg/L vs. those with changes less than 1mg/L (2.83 vs. 1.67 antiepileptic medications, P equals 0.110).

Conclusion: The interchange from brand to generic phenytoin does not cause a change in serum phenytoin concentrations. Further, lack of change in seizure frequency during interchange suggest that interchange is safe. However, the information collected after interchange in this study is relatively short for time period of collection compared to information collected before the interchange. The clinical significance for safety of the interchange must be assessed further with larger, and long-term studies.

Submission Type: Evaluative Study

Session-Board Number: 7-083

Poster Title: Unrestricted ertapenem use evaluation at a large academic medical center

Primary Author: Kristen Peterson, University of Iowa College of Pharmacy, Iowa; **Email:** kristentpeterson@gmail.com

Additional Author (s):
Brian Hoff

Purpose: Ertapenem is a broad spectrum antibiotic that can be administered intravenously to patients admitted to the University of Iowa Hospitals and Clinics. Many institutions restrict ertapenem prescribing privileges to specific clinical criteria or infectious diseases consultant physicians for several reasons. Ertapenem has a broad spectrum of activity, relatively high acquisition costs, increasing concern for developing antibiotic resistance, and infectious complications like diarrhea and bacterial superinfection. Ertapenem is not restricted at this hospital and can be ordered by any prescriber within the health system. We performed a medication use evaluation to better understand ertapenem prescribing practices.

Methods: The University of Iowa institutional review board approved this retrospective, electronic health record review. Inpatients who received ertapenem between November 1, 2014 and October 31, 2015 were included in the analysis. Manual retrospective chart review was performed for each unique patient to determine the indication for ertapenem therapy. Antibiotic allergies, length of therapy, and infectious diseases consultation were also collected from the electronic medical record. Ertapenem indication was categorized into empiric, definitive or surgical prophylaxis groups and further sub-classified based on documented or suspected Gram-negative resistance phenotypes. SPICE organisms were defined as the following: Serratia species, Providencia species, Proteus species (not P. mirabilis or P. penneri), Citrobacter species, Enterobacter species, and Morganella species. Particular emphasis was made to determine the incidence of treatment for SPICE organisms, extended-spectrum beta-lactamase producing organisms, and patients with penicillin or cephalosporin allergies. Extended-spectrum beta-lactamase phenotype was identified in Gram-negative organisms using the Clinical and Laboratory Standards Institute 2015 guidelines (ceftriaxone, ceftazidime, or aztreonam minimum inhibitory concentration of greater than or equal to 2). Ertapenem

administration data was combined with patient census data to quantify the antimicrobial utilization metric, days of therapy per 1000 patient days.

Results: A total of 768 ertapenem treatment courses were evaluated. Gastrointestinal and genitourinary surgical prophylaxis was the most frequent ertapenem indication 344/768. Ertapenem was initiated empirically for the treatment of SPICE organisms 25/768, patients with prior cultures positive for extended-spectrum beta-lactamase-producing or SPICE organisms within three months 23/768, and for treatment of various other indications 216/768. Post-hoc analysis identified the most common other indications for empiric treatment as osteomyelitis 112/216, documented penicillin or cephalosporin allergy 66/216, sepsis/bacteremia 27/216, and abscess 25/216. Ertapenem was initiated for the definitive treatment of Extended-spectrum beta-lactamase-producing (non-SPICE) organisms 33/768, SPICE organisms susceptible to cefepime or ceftriaxone 34/768, SPICE organisms resistant to cefepime or ceftriaxone 8/768, documented penicillin or cephalosporin allergies without an identified extended-spectrum beta-lactamase-producing organism 18/768, and various other indications 67/768. Post-hoc analysis also identified the most common other indications for definitive treatment as Gram-negative organisms susceptible to narrow therapies 35/67, sepsis/bacteremia 14/67, osteomyelitis 10/67, and abscess 8/67. Excluding surgery patients, the average length of ertapenem therapy was five days and an infectious diseases consult was obtained in 179/424 of treatment courses. Ertapenem days of therapy per 1000 patient days was calculated and stratified monthly for analysis.

Conclusion: Ertapenem was prescribed primarily for surgical prophylaxis and empiric therapy in a variety of disease states. Several prescribing trends were identified with significant potential for reducing indiscriminate ertapenem use within the institution. Targets for antimicrobial stewardship intervention could include empiric prescribing without microbiology data to guide therapy, definitive therapy for SPICE organisms, empiric and definitive therapy for patients with penicillin or cephalosporin allergies, definitive therapy for organisms susceptible to narrow therapy, and surgical prophylaxis protocols. Further evaluation is warranted to assess the clinical and economic outcomes attributable to any interventions derived from this medication use evaluation.

Submission Type: Evaluative Study

Session-Board Number: 7-084

Poster Title: Antibiotic resistance: a 20-year perspective from a large academic medical center

Primary Author: Michael Trisler, University of Iowa College of Pharmacy, Iowa; **Email:** michael-trisler@uiowa.edu

Additional Author (s):
Anastasia Lundt
Brian Hoff
Erika Ernst

Purpose: The Centers for Disease Control and Prevention report over 2 million illnesses and 23,000 deaths annually from infections that are resistant to antibiotics. The use of antibiotics is the single most important factor leading to resistance. Fighting antibiotic resistance is a public health and national security priority. Secondary to differences in regional and institutional rates of antibiotic resistance, hospital-specific antibiograms are developed to provide more accurate susceptibility data. This project was designed to evaluate trends in antibiotic resistance over the last 20 years at the University of Iowa Hospitals and Clinics.

Methods: Antibiograms from 1996 through 2016 at the University of Iowa Hospitals and Clinics were collected to create an electronic database, with individual susceptibility profiles created for 45 unique organisms. The number of isolates, antibiotics tested and percent susceptibility were recorded for each year within each organism profile in the database. Staphylococcus aureus, Streptococcus pneumoniae, Enterococcus species, Escherichia coli, Klebsiella pneumoniae, Pseudomonas aeruginosa and Bacteroides fragilis were chosen for further evaluation. Yearly variations and absolute differences in susceptibility rates were assessed and, subsequently, graphed to visualize longitudinal trends. Human Subjects Research Determination from the University of Iowa Institutional Review Board determined that study approval was not necessary as this project does not contain any patient-level data.

Results: The number of oxacillin-susceptible S. aureus isolates declined from 90% in 1996 to a low of 61% in 2007, but has been stable over the last decade and has even increased to an average 65% since 2012. S. pneumoniae susceptibility to penicillin and ceftriaxone has remained grossly unchanged over the study-period with greater rates of resistance seen for

meningitis breakpoints, especially for penicillin. Over the last 20 years, undifferentiated Enterococcus species displayed a 9% increase in vancomycin resistance. Further evaluation revealed this is predominantly due to a considerable decrease in susceptibility from 85% in 1996 to 33% in 2016 among the faecium species. Fluoroquinolone-susceptibility rates for E. coli have declined substantially from 96% to 80% over the last decade, while susceptibility to other commonly-used agents, such as ceftriaxone and sulfamethoxazole-trimethoprim, has remained within 5% of baseline values. Resistance rates among K. pneumoniae isolates have consistently been minimal. The susceptibility of P. aeruginosa to anti-pseudomonal β-lactams and aminoglycosides remains broadly unchanged, while susceptibility to ciprofloxacin has risen from 76% in 2005 to 84% in 2016. B. fragilis susceptibility to clindamycin exhibited some yearly fluctuation, but is largely resistant. However, these isolates have continually shown 100% susceptibility to metronidazole.

Conclusion: The largest absolute increases in resistance were seen with S. aureus to oxacillin, E. faecium to vancomycin and E. coli to fluoroquinolones. Tracking susceptibility rates over time and may aide in early identification of consistent, incremental decreases that result in large changes in susceptibility over the long-term. Furthermore, this type of research is imperative to guide and support clinical decision making as well as promote antimicrobial stewardship. Further research is needed to determine if this will be an effective tool for informing and directing antimicrobial stewardship interventions.

Submission Type: Descriptive Report

Session-Board Number: 7-085

Poster Title: Assessing patient awareness and concern of risk associated with concurrent opioid and central nervous system depressant use: a quality improvement study.

Primary Author: Alexandra Lovell, University of Iowa College of Pharmacy, Iowa; **Email:** alexandra-lovell@uiowa.edu

Additional Author (s):
Amanda Gillispie
Robert Nichols
Eddy Airoiohuodion
James Hoehns

Purpose: Emergency department visits and drug overdose deaths involving concurrent use of opioid analgesics and benzodiazepines has increased significantly between 2004 – 2011. As a result, the FDA has issued a black box warning for this potentially dangerous combination. The objective of this Quality Improvement (QI) study was to identify patients taking opioids and other Central Nervous System (CNS) depressants concomitantly, assess patient understanding of the risks associated with the combination, and determine their willingness to de-intensify therapy to lessen the risk of harm.

Methods: Northeast Iowa Family Practice Center (NEIFPC) participated in the Primary Care Practices Research Network (PPRNet) which provided a list of patients whose active medication list showed concurrent use of an opioid and a CNS depressant - a benzodiazepine, a muscle relaxant, or a non-benzodiazepine sleep aid. The QI study incorporated the following steps: 1.) contact each patients' primary care physician, 2.) request the physician's insight into the co-prescription, 3.) complete a current Prescription Monitoring Program (PMP) report to assess current controlled substance usage. Patients were excluded if the PMP report indicated more than 3 months had elapsed since their days supply of their opioid had expired, 4.) attempt up to three telephone contacts of each patient and educate via a scripted interview regarding CNS depressant use, 5.) assess patient concern of medication risk and willingness to reduce CNS depressant therapy, and 6.) inform the primary care physician if a patient was willing to reduce the dose or discontinue one of their CNS depressants

Results: The PPRNet report identified 102 patients with an opioid and an additional CNS depressant on their active medication list. After conducting PMP reviews and removing patients no longer taking opioids, 62 (60.8%) patients were actively receiving concomitant opioid/CNS depressant therapy. Of those 62 patients, 13 were excluded for having passed away, on hospice, or their primary care physician requested we do not contact them. Telephone contact was attempted with 49 patients. Of those, 23 answered the phone after a maximum of three attempts. Of the 23 patients, 14 (60.9%) were aware of the risks and 8 (34.8%) patients wanted to make a dose reduction.

Conclusion: Opioid use in combination with other CNS depressants increases serious risks. A majority of patients receiving the combination were aware of the increased potential for harm. Following a short, scripted educational interview, one-third of contacted patients receiving the combination expressed a willingness to modify their regimen to lessen this risk.

Session-Board Number: 7-086

Poster Title: Cannabis effects on human reproduction

Primary Author: Christine Butler, University of Iowa College of Pharmacy, Iowa; **Email:** christine-butler@uiowa.edu

Additional Author (s):
Gary Milavetz

Purpose: Cannabis, the most commonly used illicit drug worldwide, is used by approximately 3-5% of pregnant women. This number is expected to increase as legalization occurs throughout the United States. There are 43 states that allow medical, recreational or have limited access cannabis product laws. Further, more potent cultivars of the cannabis plant are becoming available. The purpose of this project is to familiarize health professionals with the effects of cannabis on male and female reproductive hormones and pregnancy outcomes.

Methods: A PubMed advanced search was done on the term cannabis and: Follicle-stimulating hormone, luteinizing hormone, gonadotropin-releasing hormone, thyrotropin-releasing hormone, prolactin, estrogen, progesterone, testosterone, anandamide, pituitary, fertility, and pregnancy. These terms and results were independently verified with a Google Scholar search. Statistics on use were obtained from government based agencies including the National Institute on Drug Abuse, Office of National Drug Control Policy, and Centers for Disease Control and Prevention.

Results: Cannabis use and its effects on reproduction have not been well studied. CB1 receptors are primarily found in the nervous system, connective tissues, ovaries, endometrium, testes, vas deferens, urinary bladder and placenta, while CB2 receptors are mostly found in the immune system. Anandamide and 2-arachidonoylglycerol are endogenous endocannabinoids that have been studied. In females, anandamide has been found in follicular and oviductal fluid which facilitates the ability of sperm to fertilize an egg. Various studies have shown cannabis to cause a prolonged follicular phase, decreased luteal phase and delayed ovulation. Males, who reported daily cannabis use, displayed lower sperm counts with higher testosterone levels compared with nonusers. CB1 and CB2 receptors are present in sperm, but their function is unclear. Exogenous cannabinoid exposure during fetal brain development results in adverse

outcomes including lower birth weight, decreased gestational age, and reduced head circumference. Human placental studies have shown that CB1 receptors are present in all placental membrane layers and stimulation of these receptors will harm fetal growth by inhibiting cytotrophoblastic proliferation.

Conclusion: More research is needed on the reproductive effects of cannabis on men and women and its impact on fertility. Additionally, more research is needed on the effects of cannabis during pregnancy, fetal outcomes and early childhood development. Current studies are limited by including men and women who have used cannabis, tobacco and other substances. Future studies should include participants who have only used cannabis. Based on our results, men and women should avoid the use of cannabis before becoming pregnant, and women should avoid the use of cannabis during pregnancy to prevent danger to the baby.

Poster Title: Daptomycin medication use evaluation: a focus on continual quality and safety improvement

Primary Author: M. Tatjana Ramos, University of Iowa College of Pharmacy, Iowa; **Email:** tatjana-ramos@uiowa.edu

Additional Author (s):
Brian Hoff

Purpose: Daptomycin is a cyclic lipopeptide antibiotic that can be administered intravenously for the treatment of infections caused by aerobic and anaerobic Gram-positive organisms. Based on the spectrum of activity, high acquisition costs, concern for antibiotic resistance, and infectious complications like diarrhea and bacterial superinfection, daptomycin prescribing is restricted at the University of Iowa Hospitals and Clinics (UIHC). Hospital-approved criteria-for-use help guide prescribing practices to ensure judicious use of daptomycin. A medication use evaluation was performed in order to better understand daptomycin prescribing practices at UIHC and assess adherence to the institutional prescribing criteria.

Methods: The University of Iowa institutional review board approved this retrospective, electronic health record review. Inpatients who received daptomycin between August 1, 2015 and June 30, 2016 were included in the analysis. Manual retrospective chart review was performed for even numbered months to determine the daptomycin indication, microorganisms cultured, attending physician prescriber and pharmacist who verified the orders. Patient location, administration date and time, dose, and frequency were also collected from the electronic medical record. Daptomycin indications were stratified according to the following UIHC criteria-for-use: recommended by an infectious disease (ID) consultant, documented vancomycin-resistant Enterococcus species (VRE), methicillin-resistant Staphylococcus aureus (MRSA) infection refractory to vancomycin therapy, or MRSA infection with allergy or intolerance to vancomycin. Enterococcus species and Staphylococcus aureus infections were further stratified according to ampicillin and oxacillin susceptibility, respectively. Susceptibility testing was determined by the microbiology laboratory using Vitek 2 (bioMérieux, Inc., Hazelwood, MO) and the Clinical and Laboratory Standards Institute 2015 guidelines.

Results: A total of 247 patients received treatment with daptomycin, of which 121 were evaluated through manual chart review. A recommendation by an ID consultant was the most frequent daptomycin indication 50/121. VRE infections were the second most common indication 22/121, while MRSA infection refractory to vancomycin and MRSA infection with allergy or intolerance to vancomycin were the least common indications with 3/121 and 1/121 patients prescribed, respectively. None of the hospital-approved criteria were met for 45/121 patients prescribed daptomycin. Upon further analyses, daptomycin was used to treat ampicillin-sensitive Enterococcus species in 7/121 cases, ampicillin-resistant Enterococcus species in 22/121 cases, oxacillin-sensitive Staphylococcus aureus in 11/121 cases, and oxacillin-resistant Staphylococcus aureus in 19/121 cases. In 38/121 patients, no organism was grown in culture; within this group, 28/38 did not meet any approved criteria. The most common prescribing hospital services were bone marrow transplant 59/247, hematology/oncology 22/247, general medicine 21/247, medical intensive care unit 19/247, and surgery specialty 16/247. Notably, the bone marrow transplant and hematology/oncology services used daptomycin empirically for neutropenic fever in many cases. The mean and median daptomycin dose prescribed was 5.86 mg/kg and 6 mg/kg, respectively. The most common prescribers and pharmacist verifiers were identified for internal reporting.

Conclusion: Regular assessment of antimicrobial prescribing trends is essential for continual quality and safety improvement in antimicrobial stewardship. In this study, daptomycin prescribing was driven primarily by infectious diseases consultants. However, a large percentage of patients treated did not meet any approved criteria-for-use and several prescribing patterns were identified with significant potential for improvement. Antimicrobial stewardship interventions could target empiric initiation of daptomycin without targeted susceptibilities and definitive therapy for Staphylococcus aureus infections. Further evaluation is warranted to assess the clinical and economic outcomes attributable to any interventions derived from this medication use evaluation.

Submission Category: Pain Management

Submission Type: Case Report

Session-Board Number: 7-088

Poster Title: Parenterally administered diphenhydramine for headache pain relief

Primary Author: Julia Rippe, University of Iowa College of Pharmacy, Iowa; **Email:** julia-rippe@uiowa.edu

Additional Author (s):
Richard Wenzel

Purpose: These cases demonstrate the therapeutic benefit of using parentally administered diphenhydramine for the short-term relief of headache-associated pain. Patient 1 had been experiencing migraine headaches for over fifteen years. Her headaches were described as unilateral with throbbing and sharp pain, with accompanying symptoms of nausea, photophobia, phonophobia, and aura. Recently, she had been experiencing roughly ten headache free days per month. She had missed eleven days of work in the past six months. A two-week history of persistent aura drove her to seek admission at an inpatient headache unit. In the month preceding inpatient admission, she had experienced only three headache free days. Failed medications for short-term relief included acetaminophen, ibuprofen, Fiorinal, hydrocodone, indomethacin, ketorolac, morphine, and eletriptan. At one point during her admission, she rated her pain at a five on a 10-point pain scale. Three hours following administration of fifty milligrams of intravenous diphenhydramine, her pain had completely resolved and was rated at a zero that evening. Patient 2 was a 51-year-old male with a long history of both chronic cluster and migraine headaches. In the six weeks prior to admission, he had experienced ten headaches per day on average, with an average intensity of ten on a 10-point pain scale. These were typically located behind his right eye, and were often accompanied with congestion, a runny nose, nausea, vomiting, and photophobia. His headaches were resulting in difficulties functioning at work. Medications he had tried and failed included acetaminophen, ibuprofen, ketorolac, orphenadrine, and methadone. During his inpatient stay at the headache unit, he rated his headache pain at a nine on a 10-point pain scale. Fifty milligrams of intravenous diphenhydramine was administered, and two and a half hours later his pain was rated at a five on a 10-point pain scale. While this was not a complete resolution of pain, it is uncommon to find one agent that can decrease pain so significantly in a short amount of time. Both of these cases illustrate the potential benefit of the use of parenterally

administered diphenhydramine for the acute resolution of pain associated with multiple headache presentations, particularly in patients who have tried and failed other therapies.

Poster Title: Evaluation of high-dose, oral vitamin D stoss therapy in pediatric patients with vitamin D deficiency

Primary Author: Rachel Grolmus, University of Iowa College of Pharmacy, Iowa; **Email:** rachel-grolmus@uiowa.edu

Additional Author (s):
Jennifer Reinhart
Lara Ogle
Erika Ernst

Purpose: Vitamin D deficiency is common among certain pediatric populations primarily due to diseases that cause malabsorption of vitamin D and other essential vitamins. Examples include cystic fibrosis, gastrointestinal disorders, like Crohn's disease and inflammatory bowel disease, and oncology patients receiving chemotherapy. The term "stoss" in German means "to push", thus stoss therapy is a one-time, high-dose administration of vitamin D and may be superior to traditional daily dosing in certain conditions due to malabsorption and non-compliance. The purpose of this study is to evaluate current usage of stoss therapy in pediatric patients at the University of Iowa Hospitals and Clinics.

Methods: This study was approved by the institutional review board at the University of Iowa Hospitals and Clinics. A retrospective cohort study was completed using the electronic health record system to identify pediatric patients who received a one-time, high-dose vitamin D treatment with either cholecalciferol or ergocalciferol between March 2016 until September 2016. Patients receiving daily doses of vitamin D or a single dose of 50,000 units or less were excluded from the analysis. The primary outcome was to evaluate the change in vitamin D level from baseline after one-dose of therapy. Secondary objectives were to compare absolute and percent change in vitamin D levels between patients treated with ergocalciferol (E) and cholecalciferol (C) and the proportion of patients treated according to established protocols. Descriptive statistics were used to compare baseline characteristics of the patient cohort. Paired student's t-test were used for repeated measures, and independent samples t-test was used for unpaired comparisons. The chi-squared test was used for dichotomous variables. Linear regression analysis will potentially be used to adjust for any identified confounders.

Results: Our retrospective analysis included a total of 28 pediatric patients, 17 treated with cholecalciferol and 11 treated with ergocalciferol. The most common diagnoses were Crohn's disease, colitis, and ulcerative colitis (10/28) followed by oncology patients (4/28), and cystic fibrosis patients (3/28). Nine patients had both baseline and follow-up vitamin D levels completed. In this matched cohort, vitamin D levels were significantly higher at follow-up for patients receiving stoss therapy, baseline levels 14.3 vs 33.4 (p=0.013). Ergocalciferol doses ranged from 100,000-800,000 units and cholecalciferol doses ranged from 150,000-800,000 units. Percent change (101% versus 326%, p=0.17) and absolute increase (11.25 versus 26.6, p=0.18) in vitamin D levels were not statistically different between treatments for ergocalciferol and cholecalciferol, respectively. The proportion of patients being treated according to established protocols was also not different between treatments.

Conclusion: Despite our small sample size, it represents most of the pediatric disease states we expected to receive stoss therapy as these conditions can cause malabsorption of vitamin D and other minerals. High-dose vitamin D therapy resulted in significantly increased vitamin D levels. Preliminary analysis indicates no difference between treatments with ergocalciferol compared to cholecalciferol.

Poster Title: Ophthalmic steroid and antibiotic formulary streamlining across Ascension Health

Primary Author: Jennifer Voong, Saint Louis College of Pharmacy, Missouri; **Email:** jennifer.voong@stlcop.edu

Additional Author (s):
Nisha Bhide
Joanne Shamoun
Karen Smethers
Roy Guharoy

Purpose: Ascension is the largest not for profit Catholic health system, with over 130 facilities, in the United States. With the goal of providing high quality care, following high-reliability principals, and delivering patient value, evidence-based recommendations are organized and implemented across the health-system. Ophthalmic combination antimicrobial products are used to treat ocular infections including blepharitis, conjunctivitis, keratitis and several others. Ophthalmic tobramycin-dexamethasone and neomycin-polymyxin B-dexamethasone are both FDA approved and used to treat inflammatory ocular conditions. The purpose of this report is to describe the creation and implementation of therapeutic streamlining of this ophthalmic medication class.

Methods: Through an established process, an expert group of multidisciplinary clinicians met to create a system-wide recommendation to streamline the ophthalmic steroid/antibiotic products. The expert group first agreed on the scope of the initiative and researched literature on the medication class. This review was used to develop evidence-based recommendations and subsequent streamlining of the ophthalmic steroid and antibiotic products. A document consisting of the situation, background, assessment, recommendation (SBAR) and executive summary slides was created to assist with the implementation of the clinical initiative on the facility level. Various committees across the health-system reviewed and approved the initiative recommendations. An executive memo from senior leadership was disseminated to each site for comment and subsequent 90-day implementation. Each site monitors the initiative for successful compliance, which is additionally tracked on a national compliance dashboard.

Results: Assessment of primary literature and current clinical guidelines found that tobramycin-dexamethasone is non-inferior to dexamethasone-neomycin-polymyxin in controlling inflammation in patients after cataract surgery. There are no significant differences in adverse effects observed between the two ophthalmic products. The final evidence based recommendations are to eliminate tobramycin-dexamethasone ophthalmic ointment from pharmacy stock and implement therapeutic interchange from tobramycin-dexamethasone ophthalmic ointment to neomycin-polymyxin B-dexamethasone ointment. The overall goal is to reduce the use of tobramycin-dexamethasone ophthalmic suspension by 90% across the health-system. Patients with a history of allergy to neomycin may consider alternative therapy such as ciprofloxacin and dexamethasone ophthalmic agents.

Conclusion: This clinical initiative development and implementation process resulted in the successful creation and implementation of the ophthalmic steroid and antibiotic interchange across Ascension. Reduced use of ophthalmic tobramycin-dexamethasone has been observed along with a projected cost savings of over $370,000 through formulary streamlining to ophthalmic neomycin-polymyxin-dexamethasone. This evidence-based initiative supports the mission to provide care that is high quality, low cost, and that delivers patient value. With the effective implementation of this initiative, Ascension continues in its efforts to deliver optimal patient care.

Poster Title: Improving Community Opioid Safety via Multimodal Initiatives Implemented at St. Anthony's Medical Center in St. Louis Missouri

Primary Author: Courtney Scimio, St. Louis College of Pharmacy, Missouri; **Email:** courtney.scimio@stlcop.edu

Additional Author (s):
Daniel Hemann
Katherine Olson
Samantha Nguyen
Nicole Schmidt

Purpose: Drug overdose is a leading cause of death in the United States, with at least 28,000 occurring from opioid related overdose in 2014. According to the St. Louis County Department of Public Health, the death rate from drug-poisoning doubled from 2012 to 2014 within the service area of St. Anthony's Medical Center (SAMC). In 2015, SAMC saw 76,412 cases in the Emergency department, twenty percent of those were due to injury or poisoning. In order to improve opioid safety, SAMC is encouraging safe use, storage and disposal of prescription opioids along with naloxone (Narcan) availability for their patients and community.

Methods: Pharmacists and pharmacy students will counsel patients at discharge on safe storage and disposal of prescription opiates. Through collaboration with St. Anthony's marketing and community outreach departments, pharmacists will educate the public about safe storage and disposal of opioids. The SAMC pharmacy staff will provide a booth at the Nursing Skills Fair to further educate nurses and promote opioid overdose awareness. Additionally, educational materials will be developed for St. Anthony's Hospice House. SAMC will also partner with the National Council on Alcoholism and Drug Abuse – St. Louis Area (NCADA) to obtain and distribute Deterra drug deactivation system bags and work with the medical staff to explore means for providing nasal naloxone to the community, pending legislative changes in the state of Missouri.

Results: Through partnership with NCADA, Deterra bags were donated for inclusion in select discharge opioid prescriptions at no charge. An additional grant was obtained from the SAMC Charitable Foundation to provide written information about safe storage and disposal with each opioid prescribed at discharge. Pharmacists and pharmacy students distributed Deterra bags to the community during several local safety fairs. All SAMC hospital nursing staff received education about safe storage and disposal. The hospice staff was also educated on safe storage and disposal of opioids. At the time of admission, each hospice patient and family now receives education along with a Deterra bag. Information about medication drop off locations was added to the SAMC website. With the recent passage of House Bill 1568 in Missouri, pharmacists will move forward with a protocol to provide nasal naloxone to patients and family visiting our emergency department. Missouri received a federal grant to curb heroin and opiate overdoses; this grant is administered in part by NCADA and will allow them to provide free naloxone to those who need it. It is our hope that our established relationship with NCADA will provide the opportunity to obtain the nasal naloxone for our patients at no charge.

Conclusion: Opioid abuse is a public health crisis. SAMC has taken steps to educate and empower the community to safely use, store and dispose of opiates. New legislation and a federal grant support lifesaving services to turn this epidemic around. St. Anthony's Medical Center is uniquely positioned to make a difference in the lives of those they serve. Pharmacists will continue to seek opportunities to reduce and prevent opioid overdose deaths.

Submission Type: Evaluative Study

Session-Board Number: 7-092

Poster Title: Evaluation of methylnaltrexone use for opioid-induced constipation in a large community hospital

Primary Author: Janessa Paden, University of Missouri - Kansas City, Missouri; **Email:** jmpcp6@mail.umkc.edu

Additional Author (s):
Janna Kittle

Purpose: In a previous drug utilization evaluation performed in a metropolitan hospital, methylnaltrexone was shown to be inappropriately prescribed based on many factors including indication, dose, and presence of preexisting contraindications. The purpose of this study was to retrospectively evaluate methylnaltrexone use at North Kansas City Hospital, a 450 bed Midwestern community hospital.

Methods: A retrospective drug use evaluation was performed by reviewing medical records of patients receiving methylnaltrexone during hospitalization at North Kansas City Hospital from June 1, 2015 to May 31, 2016. The evaluation was conducted to determine appropriate use based on indication, dose according to weight and renal function, and contraindications. Appropriate laxative use prior to administration was also evaluated.

Results: A total of 101 patient admissions were identified for inclusion, resulting in 265 doses received. Overall, methylnaltrexone was appropriately prescribed in 78.9% of doses administered. The greatest proportion of inappropriate doses were attributed to presence of preexisting contraindication (9.4%), weight based dosing (4.9%), renal adjusted dosing (3.4%), two doses given on the same day (0.4%), and more than one of the previous listed reasons (3.0%). An adequate trial of laxative use prior to methylnaltrexone administration was shown in 81.9% of doses.

Conclusion: This evaluation revealed methylnaltrexone was appropriately administered in 78.9% of doses at North Kansas City Hospital. This study may be utilized in the development of a bowel protocol for a step-wise treatment approach to include an adequate laxative trial

before methylnaltrexone is prescribed and a suggested dosing regimen based on weight, renal function, and presence of preexisting contraindications.

Poster Title: Evaluation of post-percutaneous coronary intervention education at an urban safety-net hospital

Primary Author: Megan Chittum, University of Missouri - Kansas City, Missouri; **Email:** mec423@mail.umkc.edu

Additional Author (s):
Kristin Peterson
Nathan Donovan
Andrew Smith

Purpose: Coronary artery disease is a condition that affects approximately 15.5 million people in the United States and accounts for nearly 1.4 million hospital admissions annually. In 2010, 954,000 inpatient percutaneous coronary intervention (PCI) procedures were performed. Following the procedure, patients require targeted intervention to reduce risk of recurrent events, readmission, and cardiovascular death. The purpose of this study was to retrospectively determine the characteristics of the patients undergoing PCI at an urban safety-net hospital. A secondary objective was to explore the impact of post-PCI education and post-discharge follow-up phone calls on 30-day readmission rates and emergency department (ED) visits.

Methods: The institutional review board approved this retrospective cohort study evaluating a post-PCI pharmacy driven education program at an urban safety-net hospital. Education was verbally provided to patients in person prior to discharge by student pharmacists trained to utilize standardized printed education materials that patients kept following the session. Points emphasized during education included indications of each cardiovascular medication, side effects, disease state management pearls, and the importance of adherence to prescribed medications. Study participants consisted of inpatients with coronary artery disease discharged between January 1st and December 31st 2015 who underwent a PCI procedure while hospitalized. The following data points were collected on a standardized form utilizing the electronic medical record system: patient demographics, length of stay, indication for PCI, discharge medication regimen, patient education specifics, and follow-up considerations.

Results: During the study period, 225 PCI procedures were performed on 223 patients averaging 56.9 years of age, 69.3 percent of whom were male. Length of stay averaged 2.86 days. Indication for PCI was elective in 31.1 percent of patients, 21.8 percent were ST-segment elevation myocardial infarctions, and 47.1 percent were non-ST-segment myocardial infarctions. Education was completed with 71.6 percent (n equals 161) of patients and a post-discharge follow-up phone call was completed with 76.9 percent of patients (n equals 173). The time spent educating each patient averaged 16.26 minutes. The average time to follow-up phone call was 91.65 hours post-discharge. Thirteen percent of patients were readmitted within 30 days after discharge (n equals 30); however, 3.1 percent (n equals 7) of these patients were readmitted for a planned procedure. Nineteen percent (n equals 43) of patients returned to the ED within 30 days post-discharge. There were less 30-day readmissions in the group that received inpatient education compared to the group that did not (11.2 percent versus 18.8 percent, respectively) as well as those who received a follow-up phone call (12.1 percent versus 17.3 percent, respectively); however, these differences were not statistically significant (p equals 0.132 and p equals 0.336, respectively).

Conclusion: In an urban safety-net hospital setting, student pharmacists provided education regarding cardiovascular medications to 71.6 percent of inpatients who underwent a PCI procedure in 2015. The secondary measures showed favorable results with 7.6 percent fewer patients who received inpatient education readmitted within 30 days after discharge and 5.2 percent fewer readmissions within the group that received a post-discharge follow-up phone call; however, these results were not found to be statistically significant.

Submission Type: Evaluative Study

Session-Board Number: 7-094

Poster Title: Patient-controlled analgesia use at a metropolitan community hospital: a drug-use evaluation

Primary Author: Sarah Fritz, University of Missouri - Kansas City School of Pharmacy, Missouri; **Email:** sftf3@mail.umkc.edu

Additional Author (s):
Matt Baker
Michael Kallenberger
Derick Miranda

Purpose: A request for modifications of the patient-controlled analgesia protocol at North Kansas City Hospital, a 451 bed community hospital, led pharmacy to inquire about current prescribing practices, patient demographics, and safety and efficacy outcomes. Before any changes could be made or suggested, an evaluation of the use of morphine, fentanyl, and hydromorphone patient-controlled analgesia was necessary.

Methods: A retrospective chart review was completed to determine the current practice regarding patient-controlled analgesia. The formulary includes three medications for patient-controlled analgesia: morphine, fentanyl, and hydromorphone. Twenty-five patients per opioid were randomly selected from patient-controlled analgesia orders between March 1 and May 31, 2016. Charts were evaluated for opioid tolerance, indication, prescriber specialty, dosing parameters, adjustments made to the dosing parameters, duration of use, amount of drug used, concurrent opioid medications, percentage of time pain was controlled, and naloxone use. Opioid tolerance was defined as using 60 milligram oral equivalents of morphine for greater than or equal to seven days. Pain was considered controlled if the patient reported a pain score less than seven on a scale of one to ten.

Results: In total, 29/75 (39%) patients were male and 46/75 (61%) were female. Majority of patients were opioid naive, 70/75 (93%), and most patients were prescribed patient-controlled analgesia after procedures, 65/75 (87%). General surgery and orthopedics prescribed morphine in 18/25 (72%) patients, cardiothoracic surgeons prescribed fentanyl in 18/25 (72%) patients, and orthopedics prescribed hydromorphone in 17/25 (68%) patients. The percentage of

patients that had their pain controlled for more than or equal to 70% of the time while receiving patient-controlled analgesia was 56% for morphine, 88% for fentanyl, and 52% for hydromorphone. Concurrent pain medications were ordered in 67/75 (89%) patients with patient-controlled analgesia while 58/75 (77%) patients were administered concomitant pain medications. Only 13/75 (17%) patients had documented changes to their patient-controlled analgesia dosing parameters after initiation. No naloxone was administered to patients included in the study.

Conclusion: Overall, administration of patient-controlled analgesia was safe at North Kansas City Hospital based on no reversal agent use. Concomitant pain medications were predominantly administered near the end of the patient-controlled analgesia to transition to oral therapy and no changes are being made to this practice. Pain was only well controlled in the fentanyl group, and the majority of patients did not have changes to their dosing parameters during treatment. Modifications are being made to North Kansas City Hospital patient-controlled analgesia protocol to align dosing adjustments with current literature and recommendations.

Submission Type: Evaluative Study

Session-Board Number: 7-095

Poster Title: Effects of short-term proton pump inhibitor use on rates of Clostridium difficile infection

Primary Author: Kayla Leeser, University of Missouri Kansas City School of Pharmacy, Missouri; **Email:** krlq66@mail.umkc.edu

Additional Author (s):
Megan Chittum
Eric Wombwell

Purpose: Proton pump inhibitors (PPIs) are frequently used in hospitals as stress ulcer prophylaxis (SUP) and in the community setting for treatment of gastric acid reflux disease. Long-term use of PPIs has been associated with increased risk of C. diff development. However, it is uncertain if short-term use shares the same risk. The purpose of this study was to evaluate existing literature in order to determine whether evidence exists to link short-term use of PPIs for SUP in hospitalized patients to increased risk of developing C. diff.

Methods: A comprehensive literature search was performed through Medline using the search terms "proton pump inhibitors," "stress ulcer prophylaxis," "gastric acid reducing agents," "Clostridium difficile," "enteric infections," "short term use," and "hospitalized" in order to identify trials evaluating short-term PPI use and rates of C. diff in hospitalized patients. Trials fitting the evaluation criteria were analyzed and summarized for results, efficacy, methodology, and adverse events. Evaluation criteria included enrollment of hospitalized patients receiving only short term gastric acid reducing therapy for SUP, assessment of rates of C. diff, and consideration of risk factors with known increased rates of C. diff such as antibiotic use, age, and clinical condition by use of matched controls.

Results: Four retrospective trials were identified through literature search evaluating 105,649 patients of which 964 developed C. diff during hospitalization. All trials reviewed observed PPI use for SUP during hospitalization positively increased risk for developing C. diff infection. Odds ratios ranged from 1.74 to 3.11 compared to no gastric acid reducing agent. Interestingly, histamine-2 receptor antagonists (H2RAs) were not associated with this same increased risk. One study assessed duration of PPI use and its association with C. diff acquisition. Results

indicated PPI use greater than 1 day in previously hospitalized patients or greater than 2 days in previously un-hospitalized patients directly correlated with increased rates of C. diff. The level of acid suppression therapy (no acid suppressive agent, H2RA use, daily PPI use, and more than daily PPI use) was assessed in a study which observed the risk of developing C. diff increased from 0.3 percent with no acid suppressive therapy to 1.4 percent in patients with more than daily PPI use (p less than 0.001).

Conclusion: Results from four trials indicate that even short-term PPI use (greater than or equal to 1 day) for SUP increases the risk of developing C. diff. Trials reviewed were not prospective and had limitations; however, evidence clearly links short-term PPI use and C. diff development. Therefore, consideration of use of another gastric acid reducing agent for SUP is warranted. Moreover, based on lack of evidence for SUP in most hospitalized patients outside the ICU, pharmacists should actively seek to identify and discontinue unnecessary use of SUP agents.

Submission Category: Pain Management

Submission Type: Descriptive Report

Session-Board Number: 7-096

Poster Title: : Managing chronic opioid therapy (COT) at an outpatient ambulatory care clinic

Primary Author: Melanie Greer, University of Missouri- Kansas City School of Pharmacy, Missouri; **Email:** magy62@mail.umkc.edu

Additional Author (s):
John Lehn
Christina Cho
Corbin Rowland
Tatum Mead

Purpose: By improving opioid prescribing patterns, patient access to safe and effective treatment options for chronic pain can be achieved while reducing abuse, misuse and overdose. The purpose of this project was to develop and implement a process to more safely and consistently manage patients receiving chronic opioid therapy at an ambulatory care clinic. Interprofessional education was provided to the family medicine team to ensure successful integration of the project into practice.

Methods: This quality improvement initiative was exempt by the institutional review board. A chart audit conducted in July of 2015 revealed the following deficiencies in management of patients on chronic opioid therapy: annual pain contracts, routine urine drug screens, proper ICD-10 codes and pain assessment tools. This prompted a secondary chart audit for all opioid transactions occurring from January 1st, 2016 to May 31st, 2016, to identify patients managed with chronic opioid therapy (COT). Patients met COT criteria if they were on opioid therapy greater than or equal to 3 months and/or prescribed greater than or equal to 15 mg morphine equivalents per day. A drug interaction check was also conducted for all 156 patients. An interprofessional team was established to develop an evidence based, standardized process to address deficiencies in the management of COT patients. Packets consisting of COT contracts, urine drug screen forms, primary pharmacy forms and assessment tools for pain, risk and functionality were compiled for the physicians to review with patients at upcoming appointments. Three sessions were held to educate the clinic and medical office staff on the new COT management process and simplified pocket guide consisting of the process and opioid clinical pearls was created for quick reference and to ensure consistency. The COT policy was

enacted on August 11th, 2016. Future audits will be conducted to assess compliance and sustainability.

Results: 156 COT patients were identified from the 366 patients audited. The average age of COT patients was 55.2. 43 (27.6 percent) patients had a chronic pain ICD-10 code documented in the problem list. The average total daily dose in morphine equivalents was 51.72 mg, ranging from 5 mg to 375 mg. 27 (17 percent) COT patients had ever had a urine drug screen, and 16 (10 percent) COT patients had a urine drug screen in 2016. 118 (75.6 percent) patients had at least one drug interaction that was severe or major according to Clinical Pharmacology. 41 (34.7 percent) patients had at least one drug interaction that involved an opioid according to Clinical Pharmacology.

Conclusion: Implementing a guideline based, standardized process to manage patients on chronic opioid therapy will facilitate routine completion of the following: signage of pain contracts, conduction of urine drug screens, proper documentation of ICD-10 codes, and utilization of pain functionality scales and opioid risk tools. Ongoing interprofessional education will ensure continued success and sustainability of the project in the future.

Poster Title: Evaluating the use of dalfampridine in veterans with multiple sclerosis (MS)

Primary Author: Amanda Peterson, University of Missouri-Kansas City, Missouri; **Email:** adpwx7@mail.umkc.edu

Additional Author (s):
Chengqing Li
Amanda Stahnke

Purpose: Dalfampridine (Ampyra), used in patients with MS to ameliorate slow and/or unsteady gait, improves conduction along nerve fibers with damaged myelin by blocking potassium channels on the surface of affected nerves. The purpose of this medication use evaluation (MUE) was to determine the efficacy and safety of dalfampridine in Kansas City Veterans Affairs Medical Center (KCVAMC) patients with MS. Additionally, adherence to criteria for use (CFU) parameters were assessed, current procedures regarding responsiveness and quality of life (QoL) improvement assessments were analyzed, and analysis of factors that contribute to or hinder patient response within the KCVAMC veteran population were evaluated.

Methods: A retrospective chart review of 15 veterans with a MS diagnosis who received dalfampridine (inclusion criteria) from 1/1/2014 to 12/1/2015 was completed. This review was approved by the KCVAMC pharmacy department as a quality assurance/quality improvement project. The primary outcome was to identify the number of patients achieving a clinically significant improvement in walking speed (greater than or equal to 20 percent decrease in time) on the timed 25-foot walk (T25FW) test after initiation of dalfampridine. Secondary outcomes included evaluation of adherence to VA CFU criteria for dalfampridine initiation; evaluation of adherence to appropriate baseline and follow-up assessments; identification of patient specific factors such as age, MS phenotype, or baseline T25FW test score that may predict which patients are most likely to achieve a clinically meaningful response on the T25FW test; and identification of safety concerns regarding dalfampridine use including occurrence of seizures, infections, insomnia, weakness, nausea, dizziness, and paresthesias. Additional patient information collected was: race, age, age at dalfampridine initiation, age at diagnosis of MS, MS course (phenotype), current disease modifying therapy (if applicable), duration of

dalfampridine use, T25FW test times pre and post dalfampridine therapy, and self-perceived efficacy. Exclusion criteria was patients that did not have the diagnosis of MS or had MS, but did not receive one dose of dalfampridine.

Results: Over 50 percent of the veterans reviewed experienced a clinically significant improvement in the T25FW test post initiation of dalfampridine. The ages of those veterans ranged from 47 to 71 years of age and each had been diagnosed with the most common phenotype, relapsing remitting multiple sclerosis (RRMS). Of those who achieved clinical significant improvement no veterans reported urinary tract infections, insomnia, or nausea post dalfampridine initiation. Frequently reported side effects were weakness and cramping. One patient experienced a seizure. All patients meet VA CFU standards to receive dalfampridine therapy and over 70 percent of veterans had appropriate follow up assessment (T25FW test at 2-4 weeks post initiation). A formal validated scale, such as the 12-item Multiple Sclerosis Walking Scale (MSWS-12) or the Subject Global Impression (SGI), was not used to record the veterans' self-perceived efficacy of therapy, however, 60 percent reported positive self-perceived efficacy during follow-up examination.

Conclusion: The clinical significance of the improved T25FW test was moderate. Documented adverse reactions were infrequent other than weakness and cramping, which could be attributed to the disease state rather than an adverse reaction to dalfampridine. The VA CFU initiation criteria was met in each case and follow up was completed in the majority of veterans taking dalfampridine. Standard utilization of tools, such as the MSWS-12 or the SGI, would help to better assess the VA CFU parameter and determine the clinical significance of QoL improvement with dalfampridine use. Additionally, improved adherence to follow up monitoring is needed to ensure efficacy.

Poster Title: Evaluation of dornase alfa utilization in an academic pediatric hospital

Primary Author: Morgan Beard, University of Missouri-Kansas City, Missouri; **Email:** mrb7c5@mail.umkc.edu

Additional Author (s):
Kristin Angelo
Claire Elson
Dan Heble

Purpose: Dornase alfa is approved by the Food and Drug Administration for patients with cystic fibrosis 6 years of age and older to improve pulmonary function in conjunction with standard respiratory therapies. Despite insufficient clinical evidence beyond the cystic fibrosis population, dornase alfa is frequently used off-label in hospitalized patients for airway clearance. The purpose of this review was to evaluate the current prescribing and utilization practices of dornase alfa within a tertiary care pediatric hospital.

Methods: The Institutional Review Board approved a retrospective chart review that included patients admitted between January 1, 2013 and February 28, 2014 and received at least one dose of dornase alfa throughout hospitalization. All data was collected via the electronic medical record and included demographic information, characteristics of dornase alfa therapy, and additional mucolytic use.

Results: During the evaluation period, a total of 5,185 doses of dornase alfa were administered to 284 patients. Of the study population, a majority were male (n=154, 54 percent), and a majority did not have a diagnosis of cystic fibrosis (n=156, 55 percent). Most patients were admitted for either respiratory distress or a cystic fibrosis exacerbation. The medical services that represented the highest use of dornase alfa during the study period included pulmonary medicine (41 percent), general medical/surgery (26 percent) and pediatric intensive care (22 percent). The most common indication for dornase alfa among patients without a diagnosis of cystic fibrosis was atelectasis or mucous plugging (n=142, 50 percent). Dornase alfa was the only mucolytic therapy utilized in 19 percent (n=54) of observed patient encounters. Twice daily

dosing was prescribed for 83 percent (n=236) of patients and the number of doses administered per patient ranged between 1 to 684 doses.

Conclusion: The majority of dornase alfa administered was utilized off-label at the study institution. With the lack of data beyond the cystic fibrosis population, there is potential for significant cost savings by defining criteria for appropriate use of dornase alfa.

Submission Category: Pediatrics

Submission Type: Evaluative Study

Session-Board Number: 7-099

Poster Title: Evaluation of a vancomycin dosing protocol in the neonatal intensive care unit (NICU) at a regional healthcare system

Primary Author: Sarah Roth, University of Missouri-Kansas City School of Pharmacy, Missouri; **Email:** ser352@mail.umkc.edu

Additional Author (s):
Brandi Weller
Kimberly Day
Jake Michalski
Melissa Ruddle

Purpose: Vancomycin is an antibiotic that is routinely used as empiric therapy for late onset sepsis in the neonatal population. Current dosing guidelines at this institution are based on a previous Neofax recommendation to dose to a goal trough of 5-10 mcg/mL. Neofax has since updated their recommendation to trough greater than 10 mcg/mL in order to prevent resistance and achieve an area under the curve to minimum inhibitory concentration greater than 400, however has not changed their empiric dosing recommendation. The purpose of this study was to observe how often this protocol achieves the goal trough level in our population.

Methods: This study was approved by the Institutional Review Board as a quality improvement project. Patients who were admitted to the NICU between April 2014 and March 2016, and received at least one dose of vancomycin were included in the initial retrospective data collection. Patients were then excluded if no vancomycin trough was drawn or the vancomycin trough was improperly drawn. Additional data collected for assessment included corrected gestational age, postnatal age, dosing weight, dose given, dosing frequency, number of doses before first trough, time between trough and previous dose given, number of troughs before therapeutic, adjusted dosing for adequate trough, serum creatinine, urine output, white blood cell, C-reactive protein, immature to total neutrophil ratio at initiation of therapy and end of therapy, culture location, organism and organism minimum inhibitory concentration, organism eradication, concurrent aminoglycoside or indomethacin therapy, days between initiation and negative culture, and if discharged to home. Data was analyzed by assessing number of patients achieving outcomes and median calculations.

Results: Of the 33 patients evaluated, 23 patients met inclusion/exclusion criteria. Eleven patients achieved goal therapeutic vancomycin troughs between 10 and 20 mcg/mL (47.8 percent). Overall, the median trough concentration equaled 10.45 mcg/mL. Seven patients were considered sub-therapeutic with a trough less than 10 mcg/mL (30.4 percent), with the median trough being 7 mcg/mL. Limitations of this study include a small patient population and the retrospective nature of the study.

Conclusion: The current neonatal vancomycin dosing protocol at our institution refers to Neofax recommendations. Less than half of the neonatal patients that received vancomycin and obtained a trough concentration, met the goal trough concentration of 10 to 20 mcg/mL. Although the number of patients in this study is small, it does trend toward results seen in larger studies based on the same dosing protocol. To increase achievement of therapeutic vancomycin trough concentrations in neonatal intensive care unit patients, a more aggressive vancomycin empiric dosing protocol may be warranted.

Session-Board Number: 7-100

Poster Title: Transient low-level viremia after switch from efavirenz to elvitegravir based antiretroviral therapy in well-controlled patients with human immunodeficiency virus (HIV)

Primary Author: Chelsea Snodgrass, University of Missouri-Kansas City School of Pharmacy, Missouri; **Email:** cjsctd@mail.umkc.edu

Additional Author (s):
Jamie Guyear
Susan Burros
Vinutha Kumar

Purpose: This case series illustrates the potential drug interaction between efavirenz, an HIV non-nucleoside reverse transcriptase inhibitor, and elvitegravir, an HIV integrase inhibitor, in patients whose antiretroviral therapy (ART) is switched from a regimen that includes efavirenz to one that includes elvitegravir. Efavirenz is a cytochrome P-450 3A4 (CYP3A4) inducer, while elvitegravir is a CYP3A4 substrate. Efavirenz also has a significantly long half-life (40 to 55 hours). When efavirenz is discontinued, this long half-life may increase the ability of efavirenz to decrease concentrations of elvitegravir via a CYP3A4 mediated interaction. The two patients described are 50 and 69 year old males. Patient one initiated treatment with efavirenz and lamivudine/zidovudine two years after initial diagnosis with HIV. After eleven years on this regimen, complaints of fatigue and ongoing depression prompted switch to elvitegravir/cobicistat/emtricitabine/tenofovir disoproxil fumarate. Patient two initiated treatment with efavirenz and emtricitabine/tenofovir immediately after initial HIV diagnosis and after 10 years on this regimen was switched to elvitegravir/cobicistat/emtricitabine/tenofovir alafenamide due to a new diagnosis of osteopenia. Both patients had routine monitoring of viral load and CD4 count performed before therapy switch in accordance with guideline recommendations and both patients were well-controlled (viral load less than 20 copies/mL and CD4 count greater than 500 cells/μL) on ART for at least one year before switching medications. No new medications were initiated for either patient within the two months prior or at the time of the switch. Patient one had an undetectable viral load (less than 20 copies/mL) and a CD4 of 1213 cells/μL prior to the switch. Patient two also had undetectable viral load prior to the switch and a CD4 count of 776 cells/μL. A complete drug interaction review was completed for all medications each patient was taking

at the time of the switch, including over-the-counter and herbal supplements, with no significant potential interactions identified. Labs four weeks after the switch for patient one revealed a viral load increase to 55 copies/mL and a CD4 count of 1176 cells/μL. Upon follow-up laboratory evaluation after four additional weeks, viral load was again undetectable and CD4 count was 996 cells/μL. Labs completed five weeks after the switch for patient two also revealed a viral load increase to 189 copies/ml and a CD4 count of 875 cells/μL. Follow-up laboratory evaluation two weeks later showed viral load was again undetectable and CD4 count was 781 cells/μL. Both patients reported taking the new ART with food, as recommended, at the same time each day, with no missed doses. Complete compliance, reported by both patients, was supported by refill history. Since the rationale for switching ART was regimen simplification and potential for improved tolerance, resistance testing was not indicated. No prior resistance test results were available for patient one. Patient two had prior resistance testing without any nucleoside reverse transcriptase resistance mutations present. Neither patient had a history of exposure to integrase strand transfer inhibitors (ISTIs) or testing for resistance to ISTIs. As this case series suggests, a theoretical CYP3A4-mediated interaction between efavirenz and elvitegravir could have resulted in transient low-level viremia in patients switching ART. The clinical significance of transient low level viremia is not clearly established. While generally not considered to have long term impact, it can cause considerable concern for both patients and practitioners in the setting of a recent change in antiretroviral therapy. The healthcare practitioner should be aware of this interaction to be able to provide proper education and reassurance to the patient to help minimize or prevent patient concerns should transient viral load increases occur.

Poster Title: Evaluation of pain, agitation and delirium management in mechanically ventilated intensive care unit patients before and after order set implementation

Primary Author: Kristin Wiegert, University of Missouri-Kansas City School of Pharmacy, Missouri; **Email:** ka5f5@mail.umkc.edu

Additional Author (s):
Megan Musselman

Purpose: Pain, agitation and delirium management is very important in mechanically ventilated patients, as pain is one of the most commonly reported and distressful experiences for intensive care unit (ICU) patients. Pain is one of the potential causes of agitation in patients, so it is very important to evaluate and treat pain before giving the patient a sedation agent. The purpose of this study was to evaluate the impact of order set implementation and education on ICU management of pain, agitation and delirium in mechanically ventilated patients.

Methods: This study was conducted through a retrospective chart review that compared ICU patients that were mechanically ventilated in January 2015 and January 2016. If the patient was mechanically ventilated due to surgery or a procedure, they were excluded from the study. The primary objective of the study was to assess if order set implementation and education improved pain treatment in mechanically ventilated patients. All data, which included patient demographics, characteristics of pain medication management—including time to first pain medication, average dose in morphine equivalents and if as needed sedation medication was inappropriately used in place of pain medication—and routine monitoring, including Critical Care Pain Observation Tool (CPOT), Richmond Agitation-Sedation Scale (RASS) and Confusion Assessment Method-Intensive Care Unit (CAM-ICU), was collected via electronic medical record. Patients were determined to have delirium if they were administered haldol or if indicated by the CAM-ICU. Collected data were analyzed for central tendencies, such as: median, mean and standard deviation and chi-square test was conducted for nominal data using SPSS.

Results: During the evaluation period, a total of 69 ICU patients were mechanically ventilated. A majority of the study population was female (n=36, 52.2 percent) and had an average age of 52.5 years with a standard deviation of 17.8. In the pre-implementation group, sedation medication was given prior to pain medication when pain treatment was indicated 45 percent (n=25/35) of the time compared to 33 percent (n=22/34) in the group analyzed post-implementation. The pre-implementation group also had more instances of patients receiving sedation medication before pain medication at an average of 50 percent or greater (n=12/35) compared to the post-implementation group (n=6/34), p=0.12. Overall, RASS scores were similar between groups with an average RASS score of negative 1.68 in the pre-implementation group compared to negative 1.81 in the post-implementation group. Results were also similar for CPOT documentation with average CPOT scores of 0.35 in the pre-implementation group and 0.51 in the post-implementation group. Both groups had a median time to first pain medication after intubation of zero minutes. Of note, the pre-implementation group also had more instances of delirium (n=15/35) compared to the post-implementation group (n=9/34), p=0.15.

Conclusion: Overall, a trend towards significant improvement in treating pain in mechanically ventilated ICU patients by a reduction in patients receiving sedation medication before pain medication post-implementation of an order set and education series was shown. There was also an improvement in instances of delirium in patients, which could be secondary to better pain management during mechanical ventilation.

Poster Title: Evaluation of anticoagulation in patients with atrial fibrillation at an urban safety-net hospital

Primary Author: John Lehn, University of Missouri-Kansas City School of Pharmacy, Missouri; **Email:** john.lehn@gmail.com

Additional Author (s):
Jacob Decelles
Kristin Wiegert
Andrew Smith

Purpose: Atrial fibrillation (AF) is a common disease state affecting between 2.7 to 6.1 million Americans. Complications, including stroke and heart failure, commonly occur in patients with atrial fibrillation; it is responsible for nearly 15-20 percent of ischemic strokes. Anticoagulation drugs are commonly used to treat patients with AF and reduce the risk of stroke by two-thirds. New agents offer a different risk benefit ratio than traditional warfarin as well as different cost considerations. The purpose of this study was to retrospectively determine the characteristics of the AF population and current discharge medications prescribed at Truman Medical Center-Hospital Hill.

Methods: The institutional review board approved this retrospective cohort study evaluating patients discharged with atrial fibrillation at an urban safety-net hospital. The primary objective of the study was to determine the demographics of the atrial fibrillation population, and investigate the medication regimens at discharge. Study participants consisted of patients discharged with a diagnosis code of atrial fibrillation between July 1, 2015 and September 30, 2015. The following data were collected using a standardized form with which to perform chart reviews of patient age, gender, diagnosis, history of valvular disease, renal disease, and discharge medications. CHA2DS2VASc and HASBLED scores were determined to assess each patient's risk of atrial fibrillation-related stroke and to assess risk of bleeding. Patient demographics were analyzed and reported using mean plus or minus standard deviation or percentages where appropriate. Collected data were analyzed for central tendencies, such as: mean and standard deviation. The student's t-test and chi-squared were used for analysis to identify the significance of the results.

Results: During the study period, 132 admissions occurred. The study population included 74 males (56.1 percent) aged 63.5 plus or minus 14.7 years. Upon admission, 46 patients (18.2 percent) had a CHA2DS2VASc score of 2 or less and 86 patients (81.8 percent) had a score greater than 2. Patients in the latter group were older (p-value less than 0.0001), weighed more (p-value of 0.007) and had worse renal function (p-value less than 0.0001). More men were among the 2 or less group (75 percent vs. 58.9 percent; p-value of 0.039). Thirty patients (22.7 percent) were not on anticoagulation therapy and 59 patients (44.7 percent) taking aspirin at a mean dose of 129 mg. Forty-six patients (34.8 percent) took warfarin with an average weekly dose of 38 mg and mean time in therapeutic range of 34.88 percent plus or minus 29.3 percent. Eleven of the 12 patients taking a novel anticoagulant had CHA2DS2VASc scores less than or equal to 2. Forty-six point three percent of patients taking aspirin had CHA2DS2VASc scores greater than 2. Warfarin use was greater in the group with CHA2DS2VASc greater than 2 (16.7 percent vs. 38.9 percent; p-value of 0.039).

Conclusion: Within an urban safety-net hospital, patients with a CHA2DS2VASc greater than 2 were more prevalent (81.8 percent) and fewer patients in this group received no therapy, though that was not statistically significant. Aspirin use was similar between groups. Warfarin use was more common in patients with a score greater than 2. Apixaban, dabigatran, and edoxaban were not utilized when the CHA2DS2VASc was 2 or less and only one patient in the novel anticoagulant group received rivaroxaban. Patients with atrial fibrillation at this institution were more commonly discharged on aspirin or warfarin for anticoagulation over newer agents regardless of CHA2DS2VASc score.

Poster Title: Utilizing pharmacy students and technicians in obtaining medication histories at a community hospital

Primary Author: Sarah Hayes, University of Missouri-Kansas City School of Pharmacy, Missouri; **Email:** skhtn4@mail.umkc.edu

Additional Author (s):
Margaret Hoatson
Mary Porter

Purpose: Medication reconciliation is an important part of the admission process, with obtaining a medication history as the first critical step. Inaccuracies in the medication history at admission can lead to medication errors, both inpatient and at discharge. Liberty Hospital, a 250-bed not-for-profit hospital, admits an average of 28 patients per day to inpatient services. The purpose of this project was to show the importance of involving the pharmacy department in the admission medication history process utilizing pharmacy students and technicians, with the goal of developing a technician-driven medication history program at Liberty Hospital.

Methods: For approximately one week in each month of July 2015, August 2015, and January 2016, a pharmacy student and technician obtained medication histories for patients admitted to Liberty Hospital. The patients included those who were admitted within the previous 24 hours and had an outpatient medication record completed by a registered nurse. Medication histories were obtained by conducting patient interviews and contacting patient's family, caregiver, outpatient pharmacy, or doctor's office. This was then compared to the history obtained by the registered nurse and any discrepancies were recorded. Errors were divided into three categories: medications requiring changes (incorrect dose, frequency, directions, etc.), inclusion of inactive medications, and medication omissions. All activities were performed under the supervision of a registered pharmacist.

Results: A total of 87 outpatient medication records were reviewed by the student and technician. Of these, 84 percent (73 of 87 records) were found to be incomplete, with 307 student and technician documented errors. The most common type of error found was medications requiring changes, accounting for 44 percent (135 of 307) of errors, followed by

medication omission (98 of 307; 32 percent) and inclusion of inactive medications (74 of 307; 24 percent).

Conclusion: Involvement of pharmacy personnel, including students and technicians, in the admission medication reconciliation process improves the accuracy of the gathered information. Providing physicians with a complete and accurate medication history on admission will reduce inpatient medication errors and ease the discharge process. By demonstrating the need for additional resources with this study, six positions were approved at Liberty Hospital for medication history technicians.

Session-Board Number: 7-104

Poster Title: Retrospective evaluation of student pharmacist impact on an Urban Indian Health Center (UIHC) immunization program

Primary Author: Elizabeth Van De Grift, The University of Montana Skaggs School of Pharmacy, Montana; **Email:** elizabeth.vandegrift@umontana.edu

Additional Author (s):
Brady Conner
Cherith Smith
Jean Carter
Sherrill Brown

Purpose: The purpose of this evaluation was to determine the impact of student pharmacists on processes and outcomes of immunization programs for an Urban Indian Health Center (UIHC) in western Montana.

Methods: The evaluation used a pre-post study design with a historical control and retrospective data collection methods. The study design was approved as exempt by the campus institutional review board. The study period spanned from fall 2009 through spring 2016 and the subjects were American Indian/Alaska Native (AI/AN) tribal members living in western Montana. The "pre period" (fall 2009-spring 2011) did not involve the student pharmacists or the Operation Immunization program; the "post period" (fall 2011 – spring 2016) did involve student pharmacists and their ongoing efforts to increase the number of immunizations given through added program enhancements. Data collected included the number of clients immunized at events, types of vaccinations offered, types of enhancements added, types of events including social gatherings where attendees could be vaccinated, and client satisfaction with the program. Three to four student pharmacists were involved at each event. Descriptive analyses were performed.

Results: The number of vaccinations given through the various programs was 59 in the "pre period" and 940 during the "post period" for an annual average (SD) of 29.5 (40.31) and 188 (60.61) patients vaccinated in the pre and post years, respectively. The majority of vaccine administered each year was the seasonal influenza (flu) vaccine (79.7% across all post years).

The types of vaccines offered increased from one (flu) to six (flu, tetanus/diphtheria/pertussis (Tdap), pneumococcal conjugate (PCV) and pneumococcal polysaccharide (PPSV), human papillomavirus (HPV), herpes zoster (Zoster), Hepatitis B (Hep B) with student pharmacists giving all but the HPV immunizations. Pre and post numbers of vaccinations given by students were as follows: flu (59 to 753); Tdap (0 to 114); PCV/PPSV (0 to 37); Zoster (0 to 8), and Hep B (0 to 7). Enhancements increased from one activity (basic education) to six with the addition of more in-depth education, counseling, increased attendance (among students and tribal members), adding student nurses, and administering the immunizations. Annual events grew to include two wellness fairs, two community round dances, flu shootouts and group wellness classes. Patient satisfaction comments collected in 2015 indicated positive reactions to the events and enhanced immunization services.

Conclusion: Student pharmacist involvement has enhanced the vaccination program at an Urban Indian Health Center (UIHC), which has resulted in an increase in both the number and types of vaccines administered to the AI/AN patients.

Poster Title: Continued impact of blood pressure education and monitoring by student pharmacists on members of an urban American Indian health center in western Montana.

Primary Author: Sonja Clausen, University of Montana, Montana; **Email:** sonja.clausen@umontana.edu

Additional Author (s):
John Gardner
Sylvia Gomez
Sherrill Brown

Purpose: Heart disease is the leading cause of death amongst American Indians/Alaskan Natives (AI/AN). The AI/AN population makes up approximately 6.5% of Montana's total population, which is proportionally larger than most other states. An urban American Indian health center in western Montana focused on providing healthcare to the AI/AN population through wellness classes. The purpose of the study is to determine if regular blood pressure monitoring and education, provided at the wellness classes, improved blood pressure in this AI/AN population.

Methods: In 2011, wellness classes were offered to American Indians in western Montana. This series includes 16 biweekly classes throughout the year. Classes are two and a half hours long, involve the whole family, and provide education on diabetes prevention and self-management, nutrition, and physical activity. University of Montana student pharmacists provide blood pressure screenings and education at the classes. In addition, a heart healthy recipe was provided to each participant at each class event. One blood pressure reading was obtained and recorded per patient at the classes.
Blood pressure readings from the 14/15 academic year 2015 were compared to readings from 15/16. Patients with systolic blood pressure greater than or equal to 140 mmHg and/or diastolic blood pressure greater than or equal to 90 mmHg were referred to their primary care provider for follow-up. Differences in student pharmacist involvement between the 2 years included the healthy recipes, dedicated education wellness classes, assessment of blood pressure medications, and education on medication adherence.

Results: In 14/15, an average of 18 people attended each wellness class, although the same people did not always attend each class. For the 16 classes, 260 blood pressure readings were recorded by student pharmacists, 58 of which were elevated (22.3%). In 15/16, blood pressure readings were obtained at 8 classes and one-on-one blood pressure education were provided at the other 8 wellness classes. Each participant was provided a heart healthy recipe at each class. An average of 12 people attended each class with blood pressure readings; 96 blood pressures were obtained. In addition, student pharmacists participated at two wellness fairs for AI/AN patients, which resulted in 85 blood pressure recordings. A total of 186 blood pressure values were recorded, and 14 blood pressures were elevated (7.5%). A total of 41 patients were taking blood pressure medication (22%).

Conclusion: The percentage of patients with elevated blood pressures decreased between 14/15 and 15/16 wellness classes (22.3% vs. 7.5%). Although blood pressure medication use was not assessed in 14/15, the 22% of patients who reported taking medication in 2015/16 is comparable to the percent of patients referred to their primary care provider during 14/15. Student pharmacists can benefit the AI/AN population by providing blood pressure screenings in addition to increased education on blood pressure, encouraging patients to "know their numbers", stressing medication adherence, and providing heart healthy recipes.

Poster Title: Evaluating medication adherence in patients who receive financial assistance for prescriptions

Primary Author: Linnea Tokushige, Creighton University, Nebraska; **Email:** linneatokushige@creighton.edu

Additional Author (s):
Ann Ryan Haddad
Jessica Skradski

Purpose: Financial barriers are a common contributor to medication non-adherence. For vulnerable, uninsured patients who do not qualify for federal programs, initiatives have been implemented by some non-profit organizations to enable better access to healthcare. This project was designed to assess adherence in such a population who received healthcare at a free clinic and financial coverage of prescription medications for chronic conditions. These prescriptions were filled at a university outpatient pharmacy participating in the program.

Methods: A pharmacist intern who worked in the university outpatient pharmacy conducted a literature search for how to best evaluate medication refill adherence. It was determined that the Proportion of Days Covered equation would be used to analyze the results. Data was collected over a 26-month period for patients who had at least three consecutive medication fills covered by the free clinic during this time to treat a chronic condition. Patients and/or medication fills paid for by insurance or out-of-pocket were excluded, as well as any medications not used to treat a chronic condition. The Proportion of Days Covered equation was calculated for each patient and respective medication/therapeutic class.

Results: Twenty-six patients who utilized this assistance program met the inclusion criteria. Twelve (46.2%) of these patients were classified as "highly adherent" during the 26-month period (Proportion of Days Covered ?80%). Nine out of the 26 total patients received concurrent medications from more than one therapeutic class. Majority (21) of these patients received medications to treat hypertension. Ten out of the 21 hypertension patients were classified as highly adherent. Six patients received medication to treat depression, four patients

for hypercholesterolemia, and two for hypothyroidism. For each of these three therapeutic classes, 50% of patients were classified as highly adherent.

Conclusion: Financial barriers appear not to be the sole contributor to medication non-adherence. Because 100% adherence was not met overall even when patients received their medications at no cost, it is clear that this factor alone cannot necessarily achieve successful adherence outcomes. Further evaluation needs to be conducted for other potential factors such as health literacy, transportation, the patient's priorities, and the free clinic's allocation of resources.

Poster Title: Chromaturia secondary to hydroxocobalamin

Primary Author: Jeannie Kinoshita, Creighton University, Nebraska; **Email:** jhk48933@creighton.edu

Additional Author (s):
Lauren Bricker
Kelly Wachira
Michael Sanley
Mark Malesker

Purpose: Chromaturia is the abnormal coloration of the urine. Hydroxocobalamin (Cyanokit) is indicated to treat known or suspected cyanide poisoning. Red colored urine or chromaturia is a known yet under recognized consequence of hydroxocobalamin. Reports suggest that transient chromaturia may last for up to 5 weeks following hydroxocobalamin administration. This report describes a case of chromaturia in a patient receiving dialysis. A 53-year-old male was found to be in metabolic acidosis with an elevated lactate, acute kidney injury, and anion gap of greater than 25 secondary to the ingestion of an unknown substance. The differential included cyanide, toluene, methemoglobin, ethylene glycol, isopropyl alcohol, and metformin. Dialysis was initiated upon presentation to the ICU. Poison control was contacted and the patient was given hydroxocobalamin for possible cyanide poisoning. Ten minutes following an IV dose of 5 grams of hydroxocobalamin, the dialysis machine started alarming of a blood leak. No leak was identified and again the dialyzer alarmed. The patients' urine looked purple-red in color. It was suspected that the bloody looking urine caused the dialyzer to alarm. Dialysis treatment was terminated to be restarted at a later time. Dialysis was delayed for approximately 9 days due to the persistence of the chromaturia. At this time the nephrologist recommended to defer dialysis due to improving metabolic panel and impressive urine output without diuretics. While the package label for hydroxocobalamin (Cyanokit) includes a statement that the product may cause hemodialysis machines to shut down due to an erroneous detection of a blood leak, many clinicians are not familiar with this reaction. Clinicians should consider this potential before hemodialysis is initiated in patients recently treated with hydroxycobalamin.

Poster Title: Baclofen for treatment of central hyperthermia

Primary Author: Ann Cabri, Creighton University School of Pharmacy and Health Professions, Nebraska; **Email:** aec54132@creighton.edu

Additional Author (s):
Katherine Thompson
Carolina Landeen
Ilya Berim
Mark Malesker

Purpose: Central hyperthermia (CH) is a rare complication of intracranial hemorrhage that is associated with poor prognosis and high mortality. To date, there are limited case reports describing the use of baclofen to treat CH. Baclofen is a skeletal muscle relaxant and analog of gamma-aminobutyric acid (GABA). While the mechanism of action is not fully understood, it is thought that baclofen stimulates the GABA-B receptor and ultimately inhibits the release of excitatory neurotransmitters including glutamate and aspartic acid. Peak blood concentrations occur two to three hours following an oral dose and it is used to reduce symptomatology associated with multiple sclerosis, muscle spasm, and spinal cord injury. This report describes a case of CH successfully relieved by baclofen. A 67 year old female developed a temperature of greater than 38 degrees Celsius two days after left basal ganglia hemorrhage. Non-pharmacologic measures were implemented and standard pharmacologic treatment with acetaminophen was given. Medication causes of hyperthermia were ruled out. Thromboembolic workup was unrevealing. Fevers persisted despite prolonged course of broad spectrum antibiotics. Multiple blood, sputum and urine cultures identified no infectious cause of fevers. Infectious disease was consulted and recommended stopping all antibiotics. CH was diagnosed by process of exclusion. Temperature readings were between 37.2 to 38.8 degrees Celsius (99 to 101.9 degrees Fahrenheit) prior to baclofen administration. After 17 days of unresolved CH, baclofen was initiated at 5 mg taken via feeding tube for one day and then advanced to 10 mg three times daily. Temperature readings were consistently lower after baclofen therapy was initiated, between 36.2 to 38.2 degrees Celsius (98.2 to 100.8 degrees Fahrenheit). Baclofen was continued for 12 days until patient was discharged to a skilled nursing facility with only two temperature excursions beyond 38 degrees Celsius. In this

patient, baclofen taken 10mg three times daily was an effective treatment strategy for management of CH secondary to intracranial hemorrhage. Further studies are needed to clarify the definitive role of baclofen in the treatment of CH.

Poster Title: Possible case of propofol-induced QT prolongation

Primary Author: Katherine Thomspon, Creighton University School of Pharmacy and Health Professions, Nebraska; **Email:** kah85184@creighton.edu

Additional Author (s):
Ann Cabri
Ilya Berim
Mark Malesker

Purpose: QT interval is the measurement of myocardial repolarization. Delayed myocardial repolarization significantly increases risk for development of fatal cardiac arrhythmias, particularly torsades des pointes. Genetic factors can predispose patients to QT prolongation, but medications and medical conditions are the primary cause. Propofol is an intravenous general anesthetic used for induction and maintenance of anesthesia. As a gamma-aminobutyric acid (GABA) receptor agonist and N-methyl-D-aspartate (NMDA) glutamate receptor inhibitor, propofol causes central nervous system (CNS) depression. QT interval values are recorded as corrected QT (QTc) values to account for changes in heart rate. Normal QTc in women is less than 460 msec and QTc greater than 500 msec is associated with an increased risk of arrhythmia. Propofol is not typically associated with QT prolongation, although this linkage has been reported in a few small studies and case reports. This report describes a case of QT interval prolongation linked to the administration of propofol. A 33-year-old white female presented to the emergency department (ED) with progressive tongue swelling and laryngeal edema. She was quickly intubated for airway protection, sedated, and transferred to the intensive care unit (ICU). The patient's past medical history included systemic lupus erythematosus, hypertension, asthma, Raynaud's disease, and illicit drug use. No cardiac history was documented. Per ED physician notes, the ECG upon presentation showed normal sinus rhythm and a normal QT interval. Following successful intubation in the ED, propofol was initiated at 100 mcg/kg/min continuous infusion and continued for approximately one hour. The patient was then transferred to the ICU for further management. An ECG was obtained approximately 90 minutes after the initiation of propofol, where the QTc was documented at 446 msec. The infusion was titrated down to 60 mcg/kg/min upon transfer and decreased further to 50 mcg/kg/min throughout ICU day 1. The next ECG was obtained 20 hours after the

initiation of propofol and the QTc interval increased from 446 msec to 552 msec. At the time of the ECG, the patient was given intravenous magnesium and potassium in attempt to correct the QT prolongation. QT prolongation due to infectious etiology or other medications was ruled out and the propofol infusion was discontinued approximately 36 hours after initiation. Concern for propofol-induced QT prolongation was extensively documented in the charting as the likely cause of the ECG abnormality. On the two subsequent days following discontinuation, the QTc interval decreased from 552 msec to 548 msec, and then 453 msec. Five days after the initial propofol infusion was started, the QTc interval was 425 msec. Use of the Naranjo probability scale indicated a probable relationship between propofol and prolongation of the QT interval. Although propofol was not the only drug administered on the day of the QT interval prolongation, it is the most likely cause. When compared to other potential medication causes, propofol hadthe longest continual administration time and the onset of QT prolongation was consistent with administration time. Additionally, the reaction resolved when propofol was discontinued. In a subsequent admission two months later, the patient's QTc interval was within normal limits. The patient was administered a bolus of 150mg of propofol during this second admission, but there was no documented sequelae or QT interval prolongation. This case adds to the growing list of medications reported to cause QT interval prolongation.

Poster Title: Evaluation of hepatitis C virus screening practices for patients with human immunodeficiency virus managed by a primary care interdisciplinary team

Primary Author: Gay Antonette Subia, Creighton University School of Pharmacy and Health Professions, Nebraska; **Email:** grs55218@creighton.edu

Additional Author (s):
Robyn Teply
Mark Goodman
Sandeep Mukherjee
Thomas Guck

Purpose: Guidelines recommend that all patients with human immunodeficiency virus (HIV) receive a one-time screening for hepatitis C virus (HCV) and some require annual screening. A higher proportion of patients with HIV also have HCV as compared to the general population. An interdisciplinary team, including a pharmacist, reviewed their HIV population for the presence of co-infection with HCV and found a lower than expected prevalence. The purpose of this study is to assess the adequacy of screening for HCV in patients with HIV managed at a primary care clinic in Omaha, Nebraska.

Methods: A retrospective chart review was conducted for patients at the Catholic Health Initiatives (CHI) Health Clinic-Old Market with an HIV diagnosis whom have been seen within the past 2 years and were HCV negative in May 2013. Data collected included demographics, social history, laboratory measurements, concomitant disease states, presence of HCV risk factors, HCV screening results and method for HCV screen. Unprotected sex was defined by the presence of the diagnosis code or completion of a sexually transmitted infection screening test within the past 2 years. Descriptive statistics and comparison of proportions via Chi-Square tests were utilized for analysis.

Results: Criteria for inclusion in the study were met by 136 patients, average age 49 (standard deviation equals 10.6), 90 percent male, 75 percent Caucasian, 20 percent African American. History of current or previous drug use was present in 32 percent with the most common agents being marijuana and methamphetamine. HCV screening was completed at least once

within the past 3 years in 43 percent of the patients and within the past year in 25 percent of the patients. At least one HCV risk factor was noted in 73 patients and 51 percent of that subset had been screened for HCV in the past 3 years. The proportion of patients without risk factors for HCV that have been screened within 3 years is 33 percent which is significantly different than those with risk factors (p equals 0.041). No other characteristics significantly impacted whether a patient was screened. Forty-nine patients were identified as men who have unprotected sex with men, recommended to receive annual screening, and 29 percent of those have been screened for HCV within the last year.

Conclusion: Patients with HIV are more likely to have HCV and those HIV positive men who have unprotected sex with other men are at the highest risk thus are recommended to receive annual HCV screening. This evaluation of the current screening practices has identified areas needing improvement. Electronic medical record prompts are being developed to better identify patients with HIV that are in need of HCV screening. If co-infection is identified, the patients are referred to pharmacists for initiation of HCV treatment. Due to the inadequacy of nationwide screening for HCV, other institutions should also consider evaluating their screening practices.

Submission Type: Descriptive Report

Session-Board Number: 7-111

Poster Title: For the greater good: pharmacy student interventions to optimize therapy and cost savings at Healing Gift Free Clinic

Primary Author: Katie Neighbors, Creighton University School of Pharmacy and Health Professions, Nebraska; **Email:** katieneighbors@creighton.edu

Additional Author (s):
Brittney Worth
Emily Knezevich
Mikayla Spangler

Purpose: Healing Gift is a free clinic located in downtown Omaha, Nebraska. First opening its doors in 2010, Healing Gift makes a lasting impact in the community. In 2015, 1,782 patients were seen, providing healthcare to the working poor and homeless of Omaha. Funded through private donations and staffed by volunteers, the greatest expense is medications. This program displays how student pharmacist interventions can reduce costs while also providing optimal treatment of the most common and costly disease states prevalent at the Healing Gift Free Clinic.

Methods: At Healing Gift, student pharmacists assist in therapeutic selection and cost-saving initiatives. Diabetes, asthma and chronic obstructive pulmonary disease (COPD) are the costliest diseases to treat at Healing Gift. Patient selection for this initiative occurs by drug utilization review performed at the beginning of clinic. Patients with rescue or maintenance inhalers are screened for the TevaCares Prescription Assistance Program (PAP). TevaCares provides Qvar and ProAir inhalers at no cost to qualifying patients. Patients must be uninsured and low income to qualify. If a patient qualifies for the TevaCares PAP, their application is completed and faxed. Once approved, patients are mailed their inhalers monthly. Healing Gift also utilizes copay cards to maximize savings in patients using maintenance inhalers or basal insulin. The Breo copay card allows commercially insured or uninsured patients to receive a Breo inhaler each month at no cost. The Toujeo copay card allows commercially insured or uninsured patients to receive a monthly supply of basal insulin for $15 (covering up to $500 a month). After qualifying for assistance through the Toujeo or Breo copay cards, the patient's prescription and copay card information is called

into a local pharmacy by the student pharmacist for the patient to pick up, with Healing Gift covering the copay for Toujeo prescriptions.

Results: Phase 1 began January of 2016, focusing on asthma and COPD patients. Fifteen patients (of 43 potential candidates) receive assistance from TevaCares. The clinic normally provides patients with one 60-actuation Ventolin inhaler per month, costing $19.22 each. Utilizing TevaCares with these patients has produced a monthly savings of $288.30 and a projected yearly savings of $3,459. Phase 2 began June of 2016 with Breo and Toujeo copay cards. Maintenance inhalers are too costly for the clinic's formulary, thus prescribers often dispense sample inhalers. Due to this, student pharmacists began recommending Breo copay cards. Because the clinic does not purchase maintenance inhalers, no cost-saving data is available. For the Toujeo copay card, student pharmacists began converting patients on NPH to Toujeo insulin. Six patients (of 43 potential candidates) qualified. One 10 mL vial (1000 units) of NPH costs $25, while the Toujeo card allows patients to receive their prescribed monthly quantity for $15 (up to 2500 units of insulin). Based on each patient's initial conversion from NPH to Toujeo, the clinic spent $200.00 monthly on NPH for these six patients; $90 total is now spent on their Toujeo, for a monthly savings of $110 and projected yearly savings of $1,320.

Conclusion: Healing Gift Free Clinic opens its doors weekly, providing healthcare to the indigent. In 2015, $86,318.75 were spent on medications over 47 total clinic days. Since the program's initiation, $3,034 have been saved due to this program, with many more qualifying patients yet to be enrolled. These measures have provided patients with a better quality of care, as patients are now able to access effective medications with lower side effect profiles.

Poster Title: Assessing attitudes and behaviors of college freshman in dormitories related to influenza vaccination

Primary Author: Samantha Chieu, Creighton University School of Pharmacy and Health Professions, Nebraska; **Email:** samanthachieu@creighton.edu

Additional Author (s):
Linda Ohri
Susan Weston

Purpose: Creighton University (CU) Student Health and our Pharmacy-based Operation Immunization (OI) volunteer group partner annually to provide free influenza immunizations to students and employees. In considering student response to this vaccination opportunity, dormitory living students are a population of special interest. A survey was developed to query students living in CU freshman dormitories on their behaviors and attitudes towards this immunization. They were also asked about any experience of influenza-like illness (ILI) during the 2015-16 influenza season as well as about parental level of education.

Methods: The short survey included demographic questions, as well as questions about any ILI experiences (sore throat, fever, headache, muscle aches and soreness, congestion and cough), vaccination receipt, the student's reasons for obtaining or rejecting influenza vaccination during the 2015-16 influenza season and on parental level of education. The survey was administered through an electronic survey sent through email to the residents of one dormitory (K) and a paper survey offered twice at each of the two dormitories (G and K) during the last two weeks of April, 2016. This survey study was exempted from IRB review as Student Health Quality Assurance research; the survey was anonymous with completion considered consent to participate.

Results: A total of 168 participants responded to the survey, for an overall 26 percent response rate. Those responding to the survey indicated an overall (on or off-campus) vaccination rate of 66 percent, (G: 62 percent; K: 71 percent). Student Health records demonstrated on-campus immunization rates for the freshman dormitories as: 32 percent (G) and 43 percent (K). Students who were health sciences majors had a higher influenza vaccination rate (80 percent).

Students were most commonly motivated to receive the influenza vaccination due to: 1) their parent's encouragement (59 percent), 2) did not want to risk getting influenza (48 percent), and 3) received one annually (36 percent). Reasons students gave for not receiving a vaccine was due to: 1) their belief of being healthy (41 percent) or 2) not having time (40 percent). Of students who received the influenza vaccination, 54 percent claimed to have experienced an ILI between August 15,2015 and March 31,2016. Of students who did not receive the influenza vaccination, 67 percent claimed to have experienced an ILI. Students who experienced an ILI, 53 percent missed class or work. There was no clear association between parental level of education and the likelihood of receiving an influenza vaccination.

Conclusion: This student survey suggests that college students have similar attitudes and behaviors to influenza immunization compared to the general population. A substantial proportion of these students reject influenza immunization due to their perception of personal good health and low need. Lack of time and forgetting publicized opportunities were also common reasons for failure to obtain vaccination. Reported attitudes and behaviors of pre-health or health professions students showed somewhat higher interest and response to influenza immunization opportunities. Students often claimed to experience at least one episode of ILI regardless of whether they received the vaccination.

Session-Board Number: 7-113

Poster Title: A Retrospective Evaluation of IV Magnesium Use at an Academic Medical Center

Primary Author: Megan Wachter, Creighton University School of Pharmacy and Health Professions, Nebraska; **Email:** mmw80194@creighton.edu

Additional Author (s):
Mark Malesker
Wendy Weber

Purpose: The objectives of this study were to examine (1) indications for the use of IV magnesium sulfate supplementation (2) adverse outcomes, if any, from a one-time dose of IV magnesium sulfate, and (3) to evaluate the monitoring parameters used to assess patients during or after magnesium sulfate administration.

Methods: A retrospective chart review was conducted within an academic medical center. Patients were identified from pharmacy billing records. Abstracted data of medical records included demographics, clinical characteristics, and the dose and time of IV magnesium sulfate administered, and adverse events (if any) that could possibly be related to therapy. This project was approved by the institution's IRB.

Results: A total of 100 patients (52% female, 48% male) who received a one-time IV dose of magnesium sulfate were evaluated. The average age for the population was 54.31 years. Sixty-two percent of the patients were Caucasian, with the remainder being African American (22%), Hispanic (3%), Asian (2%), or unlisted (11%). The average baseline magnesium level was 1.6 mg/dL. Eighty-two percent of patients receiving magnesium received a 2g/50mL premix. Thirty-two percent received a dose in the ICU, while 25% received a dose in the CCU. A majority of patients received a dose within 24 hours of admission (69%), and 12% of the population received a dose within two days. Fifty-nine percent of patients did not have a listed indication for the administration of magnesium. Nine percent of patients received magnesium from alcohol-induced malnutrition, 11% of patients received magnesium specifically to obtain a baseline reading >2mg/dL, and another 11% of patients received magnesium for a cardiac complication, including myocardial infarction or various arrhythmias. Other indications included respiratory arrest (1%), asthma exacerbation (4%), seizures (2%).). Four percent of patients who

were administered IV magnesium did not have a baseline magnesium level, and 99% of patients had a baseline level of < 2 mg/dL.

Conclusion: In this sample, a single dose of magnesium was given empirically for a clinical history of hypomagnesemia with a treatment goal to achieve a magnesium level of 2mg/dL. No adverse effects were noted and no concerns were identified with magnesium monitoring. Further evaluation is planned for patients receiving multiple doses of IV magnesium.

Poster Title: Evaluation of redundant medication therapies in the management of acute exacerbations of chronic obstructive pulmonary disease in hospitalized patients

Primary Author: Hailey Soukup, Creighton University School of Pharmacy and Health Professions, Nebraska; **Email:** haileysoukup@creighton.edu

Additional Author (s):
Stacey Dull
Ryan Dull
Allisha Gabriel
Louisa Sullivan

Purpose: Medications used to manage acute exacerbation of chronic obstructive pulmonary disease (AECOPD) in the hospital setting include systemic corticosteroids, bronchodilators, and antimicrobials. In our healthcare system, AECOPD is often treated with short-acting bronchodilators and systemic corticosteroids plus long-acting bronchodilators and inhaled corticosteroids. To our knowledge there are no studies evaluating the safety or efficacy of redundant therapies in the management of AECOPD. Clinical practice guidelines do not address this topic nor are there any reports on how frequently this occurs. The purpose is to determine the proportion of patients with AECOPD receiving redundant therapy, associated costs, and adverse outcomes.

Methods: A retrospective chart review of adult patients admitted to a Catholic Health Initiatives (CHI) Health hospital from January 1, 2016 through March 31, 2016 with a primary ICD-10 diagnosis of AECOPD (J44.1) was performed. The primary outcome was the proportion of patients who received an ICS and a systemic corticosteroid, a scheduled short-acting and long-acting inhaled beta-agonist, and a scheduled short-acting and long-acting inhaled anticholinergic. The secondary outcomes included hospital length of stay, readmission within 30 days, bronchodilator and corticosteroid acquisition cost, and safety outcomes such as tachycardia (heart rate above 100 beats per minute), thrush, acute onset psychiatric symptoms (delirium, psychosis, agitation, or anxiety), and new onset urinary retention. Patients were excluded if they were admitted or transferred to the intensive care unit or if they were transferred from an outside hospital.

Results: One hundred eighty patient records were reviewed; 43 patients were excluded. Of the 137 patients included, 99 (73 percent) received redundant medication therapy for the management of AECOPD. The median age, Charlson Comorbidity Index, and female gender were similar in the redundant and nonredundant therapy group. Of the 99 patients that received redundant therapy, 88 received an ICS and systemic corticosteroid, 95 received scheduled short-acting and long-acting inhaled beta-agonist, and 23 received scheduled short-acting and long-acting inhaled anticholinergic. While the median length of stay was 4 days in each group, the median hospital cost of corticosteroids and bronchodilators was higher for those receiving redundant therapy ($135.14 versus $12.50). Adverse outcomes were similar.

Conclusion: Redundant medication therapy for patients admitted for AECOPD in our healthcare system is common and is associated with more than a 900% increase in drug acquisition cost. Hospital length of stay and adverse outcomes appear similar. More data are needed to evaluate whether redundant medication therapy in AECOPD justifies the associated increase in cost.

Poster Title: Pharmacogenomics of R-CHOP in Patients with Diffuse Large B-cell Lymphoma

Primary Author: Kai Zheng, University of Nebraska Medical Center, Nebraska; **Email:** kai.zheng@unmc.edu

Additional Author (s):
Yang (Heidi) Hu
Moses New-aaron
Jane Meza
Gary Yee

Purpose: Diffuse large B-cell lymphoma (DLBCL) is one of the most common types of non-Hodgkin lymphoma. First-line treatment is R-CHOP (rituximab plus cyclophosphamide, doxorubicin, vincristine, and prednisone). Prognosis correlates with the International Prognostic Index (IPI). In this study, we analyzed selected SNPs to determine their association with response to R-CHOP in DLBCL patients.

Methods: In this retrospective cohort study, we evaluated 166 patients with newly diagnosed DLBCL treated with R-CHOP from Aug. 2007 to Dec. 2010. Patients with unclear pathologic diagnosis (i.e. grey zone lymphoma), primary CNS DLBCL, and incomplete records for treatment were excluded. The study was approved by the IRB of Peking University Cancer Hospital. Based on a review of the literature, we selected eleven SNPs for further evaluation: rs396991 (rituximab); rs3957357 and rs4880 (cyclophosphamide); rs8133052, rs1045642, rs25678, rs20572, rs9024, rs1800566 and rs1049255 (doxorubicin); and rs1870377 (angiogenesis). DNA samples were obtained from the institutional DNA bank and sent to Capitalbio Corporation for targeted SNP analysis with the Sequenom MassARRAY® system. Age, gender, IPI, stage, germinal center B-cell-like vs non-B-cell-like (GCB/nGCB), treatment outcome were obtained from medical records in June 2014. Progression-free survival (PFS) was calculated from the first day of treatment to the time of confirmed progression or last day of follow-up (whichever came first). Factors that differed between groups in the univariate analysis with Kaplan-Meier plots and log-rank tests with a p-value < 0.2 were included for further analysis. A Cox proportional hazards model was then used as multivariate analysis to evaluate the association between target SNPs and PFS.

Results: Mean age of the 166 patients was 53 years; the distribution of stage I/II and III/IV was patients was 45% and 55%, respectively. Mean PFS was 957 days, ranging from 18 to 2347 days, with 94 (57%) out of 166 progression free in June 2014. Based on the univariate analysis, molecular subtype (GCB vs. nGCB), IPI (0-2 vs. 3-5), stage (I/II vs. III/IV) and rs4880, rs1800566 and rs1870377 were included in the multivariate analysis. After adjustment for IPI, molecular subtype, and stage, two SNPs were significantly associated with PFS in the multivariate analysis. For rs4880 (SOD2 T47C), the CC allele was associated with shorter PFS (CC vs. TC, HR 3.63, 95% CI 1.11-11.87, P=0.033; CC vs. TT, HR 2.26, 95% CI 0.79-6.49, P=0.128). For rs1870377 (VEGFR2 T1416A), the AA allele was associated with longer PFS (AA vs. TA, HR 0.46, 95% CI 0.22-0.98, P=0.043; AA vs. TT, HR 0.57, 95% CI 0.26-1.22, P=0.14).

Conclusion: In this retrospective cohort study of patients with DLBCL treated with R-CHOP, rs4880 and rs1870377 were associated with PFS. Further studies are needed to confirm their association.

Poster Title: Pharmacist-driven optimization of immunization administration in a pediatric heart transplant recipient patient population

Primary Author: Elizabeth Dudley, University of Nebraska-Medical Center, Nebraska; **Email:** elizabeth.dudley@unmc.edu

Additional Author (s):
Carolyn Romano
Christopher Shaffer

Purpose: Immunizations are among the most effective ways to stop vaccine-preventable infectious diseases from spreading. Children post-heart transplantation are at an increased risk for infectious complications due to known immunosuppression. This project was developed in accordance with the most recent guidelines published by the Advisory Committee on Immunization Practices, the Centers for Disease Control and Prevention and the current guidelines for patient management published by the International Society for Heart & Lung Transplantation. The goal was to optimize the immunization status of the heart transplant patient population at Children's Hospital & Medical Center in Omaha, NE (CHMC).

Methods: A pharmacy intern and pediatric heart transplant pharmacist identified all patients seen in the heart transplant clinic at CHMC as of July 1, 2015. Immunization records were obtained and updated in a database and the electronic health record (EHR) system Epic. The immunization records were evaluated for missed immunizations and/or those immunizations that would be due within the next 12 months. All patients were seen in clinic at least once within the year and the immunization recommendations identified were discussed with the patient and/or guardian and their primary care provider. The patient/guardian was also presented with a letter outlining the importance of vaccination, specifically in this high-risk patient population, as well as the recommended immunizations for the patient. Immunizations were administered at CHMC in heart transplant clinic, if possible, or else at the office of the patient's primary care provider. Follow-up was continued throughout the year and immunization status at approximately 1 year after initiation of the project was evaluated.

Results: A total of 31 patients were included in the initial evaluation of immunization status prior to July 1st, 2015, with two additional patients added to the population who were transplanted after the July 1st initiation date. At that time, only 1 patient within the heart transplant population was up-to-date on all immunizations. Subsequently, a total of 110 immunizations were recommended to be completed in this patient population. As of September 1st, 2016, 50 of the 110 (45%) immunization recommendations had been completed compared to baseline (p < 0.01). Additionally, 12 of the 33 patients (36%) within this heart transplant population were up-to-date on immunizations based on the pharmacist recommendations as compared to baseline (p < 0.05). The statistically significant improvement in immunization status of this at-risk population is highly attributable to the pharmacist's recommended interventions as well as the entire transplant team's participation in optimization of patient care.

Conclusion: Pharmacist-led optimization of immunization status in the pediatric heart transplant population at CHMC was instrumental in improving the overall health status of this fragile and susceptible patient population. This method may be beneficial when applied to other patient populations to optimize immunization status in order to protect our at-risk populations and those in our community.

Poster Title: Standardization of compounded oral formulations with e-prescribing capability at The University of New Mexico Hospital

Primary Author: Audrey Dettwiller, The University of New Mexico College of Pharmacy, New Mexico; **Email:** adettwiller@salud.unm.edu

Additional Author (s):
Leslie Sanchez
Lucas McGrath

Purpose: It has been shown that patient safety increases when concentrations for medications are standardized within an institution. Additionally, regulatory and safety organizations recommend that commercially available products are used when available to decrease the opportunity for error during compounding. Furthermore, in computerized physician order entry (CPOE) systems, pharmacy compounded products are often not visible to the provider during medication reconciliation and are not able to be e-prescribed. To improve patient safety and facilitate medication reconciliation, The University of New Mexico Hospital (UNMH) standardized pharmacy compounded products and made improvements to e-prescribing.

Methods: Initially, pharmacy compounded products were reviewed to determine if a commercial product was available. Following this, a literature review was performed to determine the validity of the compounding recipe for pharmacy compounded products. Compounded products were researched with respect to stability and the expiration of the compound. Once the literature review was conducted, the different concentration possibilities were evaluated to determine the product that would best accommodate the patient population at UNMH. Order extract reports for the prior 6 months were run for drugs with different concentrations to help determine the best option. When determining the best concentration, the following criteria were taken into account: 1) the minimum dose anticipated for a 0.5 kg patient, 2) maximum dose anticipated for 70 kg patient, 3) based on minimum and maximum doses, the ability to accurately draw up the corresponding volume. Once the standard concentrations for UNMH were determined, the correct formulations were updated in both the inpatient and outpatient pharmacy catalogs. The updates included the order catalog of the

CPOE system. In order for e-prescribing to be an option, an IT pharmacist created a new order entry format (OEF) which allows for e-prescribing and filled for the patient.

Results: There were a total of 190 oral solutions/suspensions, of which 74 were compounded. There were many areas improved upon. The following changes were made: products without a reference were updated (8), purchased commercially available products that were being compounded (1), standardized to one concentration if multiple drug concentrations were utilized (3), removed compounding recipe for medications that were both compounded at UNMH and commercially available (8). Additional, areas that were improved upon include: compounding recipes were added to the outpatient pharmacy system (70), and new compounding recipes for formulary medications were added to the inpatient pharmacy (13). Lastly, the ordering catalog of the CPOE needed to be updated. The updates included adding the drug name, the concentration, and a description (susp) for all oral suspensions (125). An OEF was built in the CPOE to allow physicians to utilize e-prescribing for non-commercially available suspensions.

Conclusion: The possible causes of medication errors with respect to oral suspensions have been addressed. Patient safety can improve due to the standardizing of oral compounded medications and the addition of an OEF for discharge prescriptions. The new OEF and addition of pharmacy compounded products in the CPOE catalog, will allow providers to perform medication reconciliation and e-prescribe these products. However, further research is needed on the success of the OEF and the impact on medication reconciliation.

Poster Title: Discharge strategy to allow seamless continuation of hospital-initiated bulk medications for outpatient transition

Primary Author: Dailyn Garcia, University of New Mexico, New Mexico; **Email:** dailyng13@salud.unm.edu

Additional Author (s):
David Padilla
Nick Crozier
Tiffany Menhorn
Leslie Sanchez

Purpose: Bulk medication therapies such as inhalers initiated in the inpatient setting often end up only partially used and then discarded. Patients are unable to leave with bulk medications in most instances because inpatient labels do not meet the requirements of an outpatient label as described by state and federal law. This study describes a new discharge process implemented at University of New Mexico Hospital that allows for bulk medications to be re-labeled and discharged with the patient. Our goal was to reduce wasted medications, and prevent disruption of therapy during the inpatient to outpatient transition.

Methods: This project was initially discussed with the patient care area pharmacists (PCAP), information technology, and nursing staff in the adult medicine units in late February 2016. Planning occurred from late February to March, with initial implementation on April 11, 2016 and final implementation May 19, 2016. Our new discharge process involved a discharge label printed in the central inpatient pharmacy when discharge orders are placed by the provider and the patient is on an inpatient bulk medication. The PCAP is then notified by our central technician that there is a patient discharging from their floor on a bulk medication. The pharmacist then evaluates the bulk medication for appropriateness. If the bulk medication is part of the patient's depart summary as written by the provider and clinically appropriate, the PCAP relabels the medication and sends the patient home with their bulk medication.

Results: In the 5 months prior to late February, when initial discussion of the project began, an average of 7.6 discharge medications were relabeled for continuation on discharge by the PCAPs. After final roll-out for the months May, April, June, July and August; there were 27, 64, 39 and 54 medications relabeled for discharge respectively. Results of this process change will be followed through June 2017 to determine its effect over the course of a year.

Conclusion: Creating a process through which pharmacy is made aware of potential patients being discharged with bulk medications automatically can decrease medication wastage and improve transitions of care by increasing patient access to medications. As a result of our process improvements, more patients were able to discharge from the hospital with medications in hand. Future implications may include expanding a similar process to involve automatic notifications for outpatient pharmacy delivery of non-bulk medications.

Poster Title: Gender dysphoria in identical twins: A focus on inter-disciplinary and individualized care

Primary Author: Kelsea Gallegos, University of New Mexico College of Pharmacy, New Mexico;
Email: kelseagallegos@gmail.com

Additional Author (s):
Jessica Conklin

Purpose: This case illustrates 16-year-old transgender male identical twins (natal female, identify as heterosexual male, attracted to heterosexual females, use male pronouns) receiving individualized care for gender dysphoria. Patient 1 and Patient 2 began their transition 1.5 years ago and established care at a multi-disciplinary, inter-professional, transgender care clinic including a pharmacist clinician. The goal for gender dysphoria is lasting individual comfort with the gendered self through psychotherapeutic, endocrine, and/or surgical therapies. Both patients started to self-identify as male starting at age 13. Patient 1 and 2 had normal childhood development without any medical problems aside from migraines (Patient 2) and asthma (Patient 1). Both patients report smoking marijuana twice a day but deny any alcohol or other substance use. Patient 1 and patient 2 had support from biological father and stepmother, but biological mother had reservations about the gender transition and gender dysphoria/incongruent sex traits resulting in depression/anxiety in both patients. The family received behavioral health care in addition to individual behavioral health care for the patients. At first, Patient 1 and Patient 2 were unable to start cross sex hormone therapy (csHT) without consent from biological mother. Patients did not like ovarian puberty due to the difficulty of being seen socially by others as male, and because they felt the sex traits were not congruent with their male identities. They both experienced high amounts of anxiety and depression during menstruation, leading to self injury in Patient 1 thus both began medroxyprogesterone injections at their first visit to prevent menstruation and the associated dysphoria. Both patients were breast binding and have sex reassignment surgery goals including subcutaneous mastectomy and possible genital surgery. After over 7 months of 10 clinic visits, including endocrinology, behavioral health, clinical pharmacy, and primary care, patients were able to change their names and legal gender markers. After 7 months of visits and with consent from biological parents, Patient 1 and 2 were started on 30mg of subcutaneous testosterone

cypionate 200mg/mL. Both patients are aware of the reversible and irreversible impacts of testosterone and the associated medical side effects. After initiation of subcutaneous testosterone both patients displayed improvement in their gender identity dysphoria and quality of life. As this case study suggests, an inter-professional approach to treat patients experiencing gender identity dysphoria with cross sex hormone therapy may be beneficial. Although more studies are needed in this patient population it is important for providers to be aware and up-to-date with current treatment options for patients experiencing gender identity disorder.

Poster Title: College campus perceptions of academic and social capabilities and treatment options for children with attention-deficit hyperactivity disorder (ADHD)

Primary Author: Rachel Kunze, Cedarville University, Ohio; **Email:** rkunze@cedarville.edu

Additional Author (s):
Justin Cole
Thaddeus Franz

Purpose: Attention-deficit hyperactivity disorder (ADHD) is commonly diagnosed in children greater than 6 years of age and is characterized by hyperactivity, impulsivity, and inattention. ADHD often affects academic, social, and occupational capabilities, even into adulthood. Previous research shows that many individuals have negative perceptions related to ADHD and medication therapy, which may contribute to suboptimal treatment, impaired social capabilities, and poor academic outcomes. The purpose of this project was to assess perceptions of ADHD on a college campus, specifically regarding academic and social capabilities of individuals with ADHD and common pharmacologic and non-pharmacologic treatment options for ADHD.

Methods: A 30-item survey was created from a review of the literature and expert analysis, containing: demographic information, familiarity and knowledge of ADHD (2 multiple choice, 5 true/false), and perceptions of ADHD (15 items, 5-point Likert-type). Perceptions of academic and social capabilities were assessed by asking likelihood of the following: achieving a GPA greater than 3.0 in high school and higher education, dropping out of high school or higher education, continuing on to higher education, making and keeping friendships, and getting fired from a future job. Positive perceptions were defined as choosing somewhat or extremely likely on positively-worded and somewhat or extremely unlikely on negatively-worded questions. Perceived effectiveness and harm were assessed for each type of pharmacotherapy (stimulants, non-stimulants), complementary and alternative medicine (CAM), and non-pharmacologic therapy. After IRB approval, the survey was distributed via email to all faculty, staff, and students on a private, faith-based college campus with two reminder emails. Data were analyzed in SPSS v. 24.0 using descriptive statistics, a Mann-Whitney-U test, and Spearman correlations, as appropriate.

Results: A total of 583 complete survey responses were collected and analyzed, achieving an approximate 13 percent response rate. Most respondents had positive perceptions of the social and academic capabilities of individuals with ADHD. Psychostimulants were perceived as being the most effective (N equal to 398, 68.3 percent), followed by CAM (N equal to 304, 52.1 percent) then non-stimulant pharmacotherapy (N equal to 281, 48.2 percent). Psychostimulants were also perceived as being the most harmful followed by non-stimulants, then CAM. For non-pharmacologic therapy, home behavior interventions were perceived as most effective (N equal to 490, 84 percent), followed by school-based interventions (N equal to 413, 70.9 percent), and finally social interventions (N equal to 395, 67.8 percent). When separated into familiar with ADHD (N equal to 284) vs. unfamiliar with ADHD (N equal to 299) groups, there were significant differences in their perceptions of an individual with ADHD's chances of getting fired from a future job, the efficacy of psychostimulant therapy, the harmfulness of psychostimulant therapy, and the effectiveness of school-based therapy (p-values of 0.011, 0.006, 0.041, and 0.002, respectively). Spearman correlation revealed that knowledge level of ADHD had significant positive associations for all Likert-type questions.

Conclusion: Overall perceptions on a college campus regarding social and academic capabilities of individuals with ADHD were positive. In terms of pharmacotherapy, the most negative perceptions were observed toward psychostimulants. Non-pharmacologic interventions were perceived as being the most effective out of all therapy options. Knowledge and familiarity with ADHD had a significant impact on perceptions. Pharmacists and other healthcare professionals have an opportunity to influence perceptions associated with ADHD pharmacotherapy through patient education and safety monitoring.

Poster Title: Impact of free health screenings at community pharmacies on diabetes

Primary Author: Jessica Amtower, Cedarville University School of Pharmacy, Ohio; **Email:** jamtower@cedarville.edu

Additional Author (s):
Anna Smith
Jeniffer George
Nicholas Daniels
Jacques Allou

Purpose: Diabetes is a prevalent issue in the United States, with an estimated 8.1 million people un-diagnosed as of 2012. Health screenings have been proven to identify diseases earlier, thereby resulting in earlier and more satisfactory treatment. Community pharmacies can offer many of the same screenings as those provided by primary care physicians. The objective of this study was to assess the impact of free health screenings in community pharmacies on patient follow-up, perceptions, and knowledge of diabetes through blood glucose screenings and patient education.

Methods: The study design was a pre-post observational study using surveys, blood sugar screenings, and patient education on diabetes. Participants were voluntary patients from four REM Corporation pharmacies in Ohio who were 18 years of age or older, not recently tested for diabetes, non-diabetic, not pregnant, and without disorders that could hinder survey responses and education. Pre- and post-surveys assessed both patient perceptions on free health screenings in community pharmacies and on diabetes knowledge.

Results: Results among the 26 participants showed there was no statistically significant difference between patient perception pre- and post-surveys (all p-values less than or equal to 0.05), however there was a statistically significant difference between pre and post diabetes knowledge surveys (p less than 0.001). Limitations of this study were the small sample size due to the relatively small pharmacies utilized and short length of study time. Future directions should focus on using more demographically diverse pharmacies and a longer study time. Due to patients already having highly positive perceptions of health screenings in community

pharmacies, future research should assess patient knowledge of diseases and the impact of patient education on overall health outcomes. Results of the study showed patients had positive opinions on free health screenings in community pharmacies and these screenings can help patients understand disease states and be more aware of their health.

Conclusion: This study demonstrates that patients are receptive to the idea of free health screenings in community pharmacies and see a benefit of the services that could be offered. The research also showed that knowledge can be gained through administering education during health screenings. Overall, free health screenings in community pharmacies can raise awareness of diseases and may positively impact health outcomes.

Poster Title: The Development and Psychometric Properties of the Bipolar Disorder Knowledge Scale

Primary Author: Trevor Stump, Cedarville University School of Pharmacy, Ohio; **Email:** tstump@cedarville.edu

Additional Author (s):
Marty Eng

Purpose: Bipolar Disorder (BD) presents in up to 4% of the world's population, carrying significant financial and functional consequences. Patients with BD also experience a high degree of stigma, and their medication adherence tends to be poor. Knowledge appears to play a role in mitigating both stigma and non-adherence; however these relationships have not been fully elucidated. Currently, no validated tool exists to measure knowledge of BD. Thus, the purpose of this project was to evaluate the reliability and validity of The Bipolar Disorder Knowledge Scale (BDKS), which was designed to explore the role of knowledge in stigma and medication adherence.

Methods: Forty-seven items were developed to assess knowledge of BD. The 47-item survey was sent out to two groups: first a group of 43 pharmacists with BCPP credentials from the College of Psychiatric and Neurologic Pharmacists (CPNP) who were recruited from the CPNP directory, and second a group of 250 members of the general public who were recruited using Qualtrics Online Sample service. Participants were surveyed on their education status, health literacy, BD diagnostic status, and exposure to patients with BD. Participants then completed the 47-item scale. After 48 hours 100 members from the original general public group were sent the same survey to assess test-retest reliability. For each item a difficulty index to evaluate how well participants performed on the item and a discrimination index to determine how well each item performed in high-scorers versus low scorers were calculated. Additionally, Cronbach's alpha was calculated to determine internal consistency validity and a pearson correlation was run to determine test-retest reliability. Items were removed based on the results from the difficulty index, discrimination index, and Cronbach's alpha. Finally the pharmacist final scores were compared to the general public using an unpaired t-test to assess

whether content experts were more likely to perform better on the scale. Following item removal, the scale was finalized at 25-items.

Results: The mean score for the scale was 33.76 (71.83%; SD: 5.502) and the Cronbach's alpha was 0.773 before item analysis. Following item analysis, 22 items were dropped leaving 25 items on the final version of the scale. The remaining items retained a difficulty index below 90% and a discrimination index above 20%. The mean of the 25-item scale was 18.41 (73.6%; SD: 4.134) for the general public and 23.20 (92.8%; SD: 1.36) for the pharmacists group ($p < 0.001$). The Cronbach's alpha for the finalized scale was .760, indicating a high-degree of internal consistency. While this is lower than the original alpha, this may be explained by the reduced number of scale items. A 25-item scale is much more practical and the items on the scale retain stronger item analysis statistics. Finally the Pearson Correlation for the group who underwent the test-retest procedure was 0.841 ($p < 0.001$) indicating strong test-retest reliability.

Conclusion: The BDKS is a 25-item true-false scale that takes approximately 5-10 minutes to complete. The scale assesses knowledge of BD with items targeting diagnosis, etiology, disease course, symptoms, treatment, and life impact. The scale has shown strong internal consistency and test-retest reliability in a general population and will be useful for evaluating knowledge of BD as it relates to stigma, non-adherence, and other variables.

Poster Title: Pharmacist's empathy in smoking cessation counseling

Primary Author: Megan McNicol, Cedarville University School of Pharmacy, Ohio; **Email:** meganmcnicol@cedarville.edu

Additional Author (s):
Robert Hutchison
Maria LePoire
Kelly Wright
Aleda Chen

Purpose: Pharmacists are both uniquely accessible and highly knowledgeable of drug use, yet the understanding of the relationship between pharmacists' empathy and smoking cessation is lacking. This study sought to address a current gap in the literature by studying the difference in smoking cessation success according to perceived pharmacist empathy. Thus, the objective of this study was to determine if patients who view their pharmacists as empathetic achieve a higher quit rate while undergoing smoking cessation counseling with a pharmacist.

Methods: Institutional Review Board (IRB) approval was obtained through Cedarville University, and pharmacists that provide smoking cessation counseling were invited to participate in the study through the American College of Clinical Pharmacy (ACCP) Ambulatory Care PRN list serve. Once the clinical sites were enrolled, one in Ohio and one in Texas, sites identified patients who were at least 6 months past their quit date, 18 years of age or older, able to speak and read English, not pregnant, and had met with the pharmacist at least two times for smoking cessation counseling. Eligible patients were asked to complete a demographic survey, the Kiersma-Chen Empathy Scale - Patient Version (KCES-PV), and a validated single-item assessment of quit status. The KCES-PV is a 15-item (7-point, Likert-type, Strongly Disagree to Strongly Agree) that measures patient perceptions of provider empathy, where higher scores indicate greater empathy. Data were analyzed in SPSS version 23.0; descriptive statistics were performed, an unpaired t-test was run to analyze the difference between provider empathy and successful smoking cessation, and a Mann-Whitney U test was used to assess the differences between clinical sites.

Results: A total of 73 patients completed surveys (N=51 Texas, N=22 Ohio). The majority of responders were women between the ages of 45 and 64 (66%) with at least a high school education (81.8%) and an annual income of less than $30,000 (95.9%). The number of Caucasian and African-American responders were equal (44.6%). Most respondents (56.1%) decreased the numbers of cigarettes they smoked on a daily basis, but only ten smokers quit. There were significant differences between the sites concerning the ability of the healthcare provider to express and comprehend the patient's feelings. In addition, differences were seen between sites regarding the belief that caring is essential to develop a relationship with the patient and whether or not a healthcare provider is influenced by the patient's feelings when determining the best treatment. There were no statistically significant differences between smoking cessation and provider empathy (p=0.523).

Conclusion: Within the study population, there was no difference in the outcomes of smoking cessation counseling according to pharmacist empathy. As a result, it was concluded that it is necessary for a provider to rely on more than just empathy to ensure smoking cessation. However, this is a small study with a low quit rate and the role of empathy may need further examination.

Poster Title: Students' perceptions of the impact of oncology on various areas of pharmacy

Primary Author: Elizabeth Ledbetter, Cedarville University School of Pharmacy, Ohio; **Email:** ecledbetter@cedarville.edu

Additional Author (s):
Aleda Chen
Chelsea Manion
Juanita Draime

Purpose: New oncology agents are on the rise; in 2015, 29% of new drugs released were chemotherapy agents, many of which are oral therapies. As practitioners continue to integrate oral chemotherapy agents into patients' therapy regimens, the treatment of cancer is not limited to the hospital or even the clinic setting. Thus, all pharmacists need to be prepared to provide care to oncology patients. The purpose of this study was to assess students' perceptions about how pharmacists in different practice settings are involved in the care of cancer patients and their confidence in caring for cancer patients.

Methods: Students in their third professional year of pharmacy school were given a survey before entering their 5-week oncology module to identify their preconceived perceptions and confidence. The survey was created from a review of the literature as well as discussions with pharmacists from multiple settings about the role of oncology at their site. Thus, items were created to highlight roles and responsibilities of pharmacists working in four different practice settings: managed care, community pharmacy, a hospital that does not administer chemotherapy, and a hospital that does administer chemotherapy. After establishing face and content validity through expert and student review, the final survey consisted of 17 questions on a 7 point Likert-type scale; 9 questions assessed students' confidence in answering oncology-related questions and 8 questions assessed their agreement with pharmacists' involvement in oncology patient care. Demographic information was also obtained, such as age, gender, and prior oncology-related experience. Descriptive statistics were performed in SPSS version 24.0.

Results: A total of 34 students (100% response rate) completed surveys. Only one student (3%) had past oncology experience. At least 90% of students feel somewhat to very unconfident in the following areas: recognizing drug interactions, answering questions asked by other members of the healthcare team, answering questions asked by patients and their families, and making evidence-based formulary recommendations. Students consistently agreed that pharmacists in the hospital setting and managed care setting should be equipped to answer oncology-related questions; however, some students disagreed (8.8%) that pharmacists in the community setting should be equipped. Also, 50% of students reported that they do not know what resources to utilize when searching for answers to oncology-related questions, but 94.2% believe that pharmacists play a vital role in the treatment of cancer patients regardless of their setting.

Conclusion: Students entering their oncology module lack confidence in several areas, yet they recognize the importance of pharmacists in different practice settings. Specifically, they lack confidence is answering questions asked by both patients and members of the healthcare team, and they are unsure of how to best utilize the resources available to them to answer these questions. Thus, these are important areas to address in courses.

Poster Title: The Effects of Apigenin on Cell Proliferation and Apoptosis in Glioblastoma Multiforme

Primary Author: Lauren Williams, Cedarville University School of Pharmacy, Ohio; **Email:** lpwilliams@cedarville.edu

Additional Author (s):
Trevor Stump
Rachel Kunze
Denise Simpson
Samson Amos

Purpose: The purpose of this research was to determine the antiproliferative and cytotoxic properties of apigenin, a flavonoid, against glioblastoma multiforme cell lines, which are found in the most deadly types of brain tumors in humans. The use of flavonoids, which are natural compounds found in many fruits and vegetables, has been studied in the treatment of many different tumor types. Apigenin is a specific flavonoid that has previously been shown to have antitumor activity in a number of cancer cells.

Methods: In order to investigate the molecular effects of apigenin treatment on glioblastoma cell proliferation and viability, we used the trypan blue exclusion assay, MTT assay, and an LDH assay. In addition, Western blot analyses were utilized to determine the signaling pathways through which apigenin treatment exerts its effects on cell proliferation and apoptosis. Finally, hoechst-propidium iodide staining and flow cytometry were used to examine the extent of apoptosis and the cell cycle context of these effects.

Results: Our results show that apigenin reduces cell viability and proliferation in a dose and time dependent manner while increasing cytotoxicity in GBM cells. Additionally, apigenin inhibits the EGFR mediated signaling and attenuated EGFR induced cell growth. Additionally, apigenin inhibits the anti-apoptotic signaling cascade. Finally, apigenin induced cycle arrest suggesting a mismatch in the DNA repair mechanism.

Conclusion: Apigenin has demonstrated some in vitro biological effects on glioblastoma cell lines that show promises in limiting the growth, proliferation and survival of these cell lines. Future research should look to identify means through which apigenin can be administered in clinically significant concentrations to the brain. Additionally pre-clinical in vivo animal models are needed to corroborate these in vitro results.

Poster Title: Analyzing the relationship between vancomycin trough distribution and body mass index

Primary Author: Jordan Long, Cedarville University School of Pharmacy, Ohio; **Email:** jordanlong@cedarville.edu

Additional Author (s):
BrookeAnne Blay
Charles Mckisson

Purpose: In the United States, the prevalence of obesity has rapidly increased in the past decade, and continues to increase. There has been much research indicating that obese individuals exhibit differences in drug distribution, including that of vancomycin. Vancomycin is a glycopeptide antibiotic that exhibits a time-dependent effect and trough levels must be monitored for efficacy and toxicity. Previous research has alluded to decreased trough vancomycin concentration in patients with higher body mass indexes. This project investigates the variation of vancomycin trough concentrations in patients with varying body mass indexes.

Methods: This is a retrospective chart review that included all patients with vancomycin trough concentration levels drawn at Riverside Methodist Hospital between January 1, 2016 and June 30, 2016. The initial search resulted in 627 trough levels. From the initial search, only steady state levels, which were drawn prior to at least the fourth dose, and the first level for each patient were included. Trough levels were excluded if dosing intervals were greater than or equal to 36 hours, or if the trough was drawn more than 2 hours off-schedule. A total of 257 troughs met criteria and were analyzed. Trough levels were then categorized according to body mass index, as per the World Health Organization classifications, and trough result (i.e subtherapeutic, therapeutic, supratherapeutic). A chi-squared test was used to determine if statistically significant differences were present between body mass indexes regarding the proportion of troughs that were above, at, and below goal.

Results: Of the 257 trough levels that met criteria, eight were from patients with a BMI of less than 18.5, seventy were between 18.5 and 25, seventy-four were between 25 and 30, forty-five were between 30 and 35, thirty-two were between 35 and 40, and twenty-eight were above 40.

Of all the BMI groups, 44% of troughs were subtherapeutic, 26.8% of troughs were therapeutic, and 29.2% were supratherapeutic while on empiric therapy. When comparing trough levels between different BMI groups, there were no significant differences when comparing therapeutic troughs to subtherapeutic (p=0.105) and supratherapeutic (p=0.486) troughs. There was a significant difference between subtherapeutic and supratherapeutic troughs (p=0.002).

Conclusion: The original hypothesis was that patients with larger body mass indexes would be empirically underdosed. The only significant difference found within BMI groups was between the subtherapeutic and supratherapeutic trough levels. However, this difference was not among larger body mass indexes. There was a lot of inter-patient variability that was not accounted for in the results. More reviews should be done, using more trough levels and decreasing inter-patient variability to minimize external factors.

Poster Title: Using conjoint analysis to measure patient therapy preferences in rheumatoid arthritis and systemic lupus erythematosus

Primary Author: Brittany Astapenko, James L. Winkle College of Pharmacy-University of Cincinnati, Ohio; **Email:** astapebg@mail.uc.edu

Additional Author (s):
Rebecca Lahrman
Craig Burns
Ana Hincapie

Purpose: Treatment adherence is essential in both rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) to help slow the progression of the disease and to improve symptom control. When a patient feels in control of their health and included in treatment decisions, there is opportunity for increased medication adherence. Using patient preferences when deciding between different medications gives patients more control of their healthcare decisions with hopes of improving adherence to their medications. This study was developed to assess the relative importance of multiple attributes of disease-modifying drugs used in the treatment of RA and SLE.

Methods: The study used a near-balanced, near-orthogonal, fractional-factorial conjoint analysis design. An online survey was posted on different national patient advocacy groups' websites and online support groups for patients with RA or SLE. In order to participate in the survey patients had to be eighteen years or older, confirm that they were the patient and not a friend or family member or other caregiver, indicate that they regularly took medications for RA or SLE and provide informed consent. The survey consisted of forty questions and focused on six attributes which included 1) overall efficacy based on autoimmune disease progression stabilization; 2) specific efficacy; 3) rate of respiratory tract infections; 4) rate of serious respiratory tract infections (leading to hospitalization); 5) medication use; and 6) patient monthly out-of-pocket medication costs. In total, twenty-four hypothetical drug profiles were developed, but patients were only given one block of eight profiles at a time. There was a total of three blocks of eight shown to each patient. A rating scale (0 to 100) was used to evaluate patients' responses to the question: Based upon this product's attributes, how likely are you to

try this product to treat your RA (or SLE)? Mixed effects linear regression models were used to analyze the data. The institutional review board approved this cross-sectional survey study.

Results: In total, 78 participants responded to the survey and 68 had complete responses. Most respondents were female (97 percent), white (77 percent) and had completed College/University (66 percent). The average age of respondents was 49 years old (SD equals 14.5). Monthly out-of-pocket medication expenses was the most influential attribute with an overall relative importance of 40 percent followed by both safety attributes. When looking at monthly out-of-pocket medication expenses, the most preferred level was 75 dollars (Beta equals 14.30, 95 percent CI: 11.69 to 16.91). Respondents preferred a tablet twice daily or a subcutaneous injection twice monthly (Beta equals 3.46, 95 percent CI: 1.04 to 5.89) over an intravenous infusion each month (Beta equals negative 3.69, 95 percent CI: negative 6.53 to negative 0.85).

Conclusion: Respondents showed significant preferences when looking at different products' attributes such as monthly out-of-pocket costs, route of administration and frequency of use and serious adverse event rates. Using conjoint analysis as a preference tool was convenient and gave insight to what factors are most important to patients. Using these patient preferences may help guide discussions and facilitate shared-decision making between patients and healthcare professionals when deciding on therapy for RA or SLE.

Poster Title: Pharmacist- and student-developed letters to national compendia to acquire off-label status

Primary Author: Tiffany Loy, Northeast Ohio Medical University, Ohio; **Email:** tloy@neomed.edu

Additional Author (s):
Jessica Farrell
Susan Bruce

Purpose: The treatment of many rheumatologic conditions is complicated by a lack of United States Food and Drug Administration (FDA)-approved treatments, which in turn makes it more difficult for patients to access effective and affordable medications. The Centers for Medicare and Medicaid Services fines insurers for approving payment for medications used for indications other than they were originally approved for by the FDA if off-label status has not been listed in a national compendium. To overcome the barriers to necessary medications, pharmacist- and student-prepared evidence-based letters were submitted to the editorial staff of national compendia to request off-label status publication.

Methods: In the past, letters describing a patient's case, in addition to a summary of efficacy and safety evidence for off-label use, have been shown to help patients obtain coverage for necessary medications. In order to provide a more broad impact on individual patient care decisions, evidence-based letters requesting off-label designation of certain medications were submitted to the editorial staff of national compendia, such as Lexi-Comp and Micromedex. Medications and conditions were selected based on perceived prevalence within a rheumatology clinic in Albany, New York. The listing of off-label use does not guarantee insurance coverage, but may reduce barriers to life-altering medications, as the insurers will likely not be fined if an off-label use is published in a national compendium. To date, one letter requesting the publication of an off-label listing of tadalafil for Raynaud's phenomenon was submitted to Lexi-Comp. Future publication requests include mycophenolate for use in diffuse systemic sclerosis and rituximab in systemic lupus erythematosus.

Results: In April, the first letter was submitted and in the August update of Lexi-Comp's tadalafil page, Raynaud's phenomenon was listed as an off-label use. This was the first of many successes that will pave the way for patients to access life-altering medications.

Conclusion: Patients with rare conditions may have limited access to life-altering medications due to FDA approval status and current payment structures. Pharmacist- and student-written, evidence-based letters to national compendia creates a pipeline to insurance coverage for an exponential number of patients requiring off-label use of certain medications.

Poster Title: Leading by example to increase student interest and involvement in professional advocacy

Primary Author: Claire Stall, Northeast Ohio Medical University, Ohio; **Email:** cstall@neomed.edu

Purpose: Staying relevant in today's ever-changing healthcare environment requires providers who are interested and willing to challenge the status quo. Professional advocacy is the way the recent generation of pharmacists and pharmacy providers are challenging the current state of healthcare. In order to keep up the momentum surrounding provider status, today's students, who are tomorrow's leaders, need to be actively engaged in the promotion of pharmacy practice. Students, who are actively involved in professional advocacy, can increase the interest among peers. Gaining the sustained support of pharmacists starts in professional school and continues into practice.

Methods: A few key members of the local Student Society of Health-System Pharmacists (SSHP) chapter have participated in local, regional, and national events geared towards advocacy. One student presented at the 2015 American Society of Health-System Pharmacists (ASHP) Annual Meeting in Denver, and two students presented at the 2015 ASHP Midyear Meeting in New Orleans. Those two meetings gave Northeast Ohio Medical University (NEOMED) students the opportunity to show our peers and our mentors how we help students become interested in advocating for the pharmacy profession. In addition to sharing our story with other SSHP chapters, NEOMED students were able to see how their peers were helping to pave the way towards provider status through professional advocacy. In February of 2016, a group of five students traveled to Washington, D.C. for the ASHP Student Advocacy Training. The students were able to learn a great deal about successfully advocating for one's profession, and put what was learned into practice by meeting with an aide to Ohio Senator Rob Portman. These students were able to take what they learned and share it with their peers before a larger contingent of students traveled to the Ohio Statehouse to meet with local representatives and advocate for legislation that will affect the practice of pharmacy.

Results: Between the 2014-2015 and 2016-2017 academic years, student interest and active participation in advocacy has boomed. There was a significant increase in the number of students who actively participated in the NEOMED chapter of SSHP. During the 2015-2016 school year, the NEOMED SSHP chapter hosted several events focused on advocacy in pharmacy and the pathway to provider status. Several shared faculty, who are actively involved in the fight for provider status, spoke to students about the importance of advocating for yourself and your profession. This increased interest allowed SSHP to sponsor a postcard campaign geared towards educating Ohio members of the House and Senate about the important services that pharmacists can provide and how pharmacists can help close the growing primary care provider gap.

Conclusion: A few early adopters can help bring interest to fellow peers and colleagues. Those pioneers of the movement can help actively engage fellow future practitioners. Early engagement is key to sustained interest and investment in the future of advocating for the profession of pharmacy.

Poster Title: Evaluation of dispensing habits and the financial impact of patient-specific pharmaceutical waste in a large academic medical center

Primary Author: Courtney Wooten, Northeast Ohio Medical University, Ohio; **Email:** cwooten@neomed.edu

Additional Author (s):
Garrett Eggers
Keith Anderson

Purpose: Unnecessary waste of bulk products often leads to increased redispenses, resulting in delayed patient care, increased workload, and increased dispensing costs. At Cleveland Clinic, almost 2,500 doses of patient specific bulk products were redispensed in March 2015. Thirteen drugs contributed greater than $1,000 each to total costs due to excessive redispenses. Over $71,000 in direct costs were incurred due to redispensed bulk products – equating to $850,000 annually. The purpose of this study was to evaluate the incidence and financial impact of inappropriate redispenses and to investigate potential factors leading to inappropriate redispenses.

Methods: Data was generated containing all March 2015 redispenses with a "bulk" dispense code. The cost of redispenses was calculated using institutional acquisition costs, as well as the number of redispenses that occurred in March 2015. The inclusion criterion for medications was a contribution of at least $1,000 in direct redispense costs during that time. To account for potential breakdowns in the distribution system, redispenses occurring within two hours of the previous dispense were excluded. One medication, insulin aspart, was excluded due to impracticality of determining appropriateness of redispenses based on sliding scale dosing regimens. Analyzed medications included clobetasol 0.05% cream, clobetasol 0.05% ointment, collagenase 250 units/g ointment, insulin detemir 100 units/mL vial, insulin glargine 100 units/ml pen, olopatadine 0.1% ophthalmic solution, fluticasone/salmeterol 100/50 mcg diskus (DPI) inhaler, fluticasone/salmeterol 250/50 mcg diskus (DPI) inhaler, fluticasone/salmeterol 500/50 mcg diskus (DPI) inhaler, fluticasone/salmeterol 45/21 mcg HFA inhaler, fluticasone/salmeterol 115/21 mcg HFA inhaler, and fluticasone/salmeterol 230/21 mcg HFA inhaler. To determine appropriateness of the redispense, a "days supply" of the medication was

calculated based on the daily dose then compared to the actual time between dispenses. The primary outcome measures were the incidence and direct costs of inappropriate redispenses. Secondary outcomes included incidence of nursing unit transfers associated with inappropriate redispenses, overall estimated costs of all redispenses, shift during which the redispense occurred, and estimated medication usage between dispenses.

Results: Twelve analyzed medications resulted in a total of 529 redispenses during March 2015. After excluding redispenses occurring within two hours of the previous dispense, 359 redispenses remained for analysis. Notably, insulin glargine accounted for 173 (48.2%) of such redispenses. The total cost of these 359 redispenses was $32,306. Of the estimated cost incurred, insulin, clobetasol, and fluticasone/salmeterol accounted for $10,692 (33.1%), $10,446 (32.3%), and $7,718 (23.9%), respectively. An overwhelming percentage of redispenses occurred during first and second shifts at 45.8% and 41.0%, respectively. Only 13.2% occurred during third shift. Excluding topical products, 220 (88.7%) of the remaining redispenses were deemed inappropriate and accounted for $17,509. After including documented returns, the net cost of inappropriate redispenses was $14,611. Insulin detemir vials on formulary contain 1,000 units; however, only 33 units on average were used before the subsequent redispense. Similarly, an average of 88 units of insulin glargine was used per 300 unit pen. Fluticasone/salmeterol DPI's and HFA inhalers were used for an average of 2.52 days and 3.03 days, respectively, before redispense. No association was found with redispenses to specific nursing units; however, patients transferred between nursing units were associated with 70.9% of inappropriate redispenses.

Conclusion: Current bulk redispensing practices are often inefficient and produce significant waste which increases cost incurred. The medications that were studied were found to have an alarmingly high rate of inappropriate redispenses, specifically in patients transferring nursing units. Inappropriate redispenses of twelve medications were estimated to account for almost $15,000 in net medication costs during March 2015. Streamlining the process of medication transfers in the event of patients transferring between nursing units would likely reduce costs associated with bulk product redispenses. Further investigation is warranted to determine the root cause of the excess pharmaceutical waste associated with nursing unit transfers .

Submission Type: Evaluative Study

Session-Board Number: 7-131

Poster Title: Retrospective evaluation of empiric antibiotic selection and dosing in patients with Pseudomonas aeruginosa pneumonia

Primary Author: Colton Hill, Northeast Ohio Medical University, Ohio; **Email:** chill1@neomed.edu

Purpose: Appropriate empiric antibiotic selection for hospital-acquired or ventilator-associated pneumonia is a key component of treatment when Pseudomonas aeruginosa is suspected. Current guidelines recommend double coverage for patients with risk factors increasing the likelihood for P. aerugonisa infection, including those that have received intravenous antibiotics within the past 90 days. The guidelines also recommend optimized dosing strategies for broad spectrum beta-lactams. The purpose of this study was to evaluate current treatment for P. aerugonisa and determine which antibiotic combination and dosing provides the best empiric therapy at St. Elizabeth Hospital in Youngstown, Ohio.

Methods: Patients with respiratory culture positive for P. aeruginosa from 1/1/2015 – 6/29/16 were retrospectively reviewed. Susceptibility data for each culture was recorded. In each case, empiric antibiotic regimen was analyzed to determine if at least one of the selected agents was effective against P. aeruginosa based on culture and susceptibility results. Patients receiving cefepime for >2 doses had their dose reviewed via Monte Carlo simulation to determine if the prescribed regimen would theoretically succeed, based on a 90% probability target attainment of goal to maintain drug concentration above the MIC for 60 – 70% of the dosing interval.

Results: In terms of combination therapy, only 32% of those patients with positive cultures received empiric double coverage. Pipercillin/tazobactam with levofloxacin was the most commonly prescribed combination while pipercillin/tazobactam was the most common monotherapy. 36% of patients received empiric therapy that did not cover their infection based on susceptibilities. Monotherapy fluoroquinolone had a coverage rate of 25%, beta-lactam 67.7%, beta-lactam with a fluoroquinolone 77.8%, and beta-lactam with an aminoglycoside 83.3%. In addition, upon further evaluation of therapy, for those patients who received cefepime and whose infection was susceptible, only 50% achieved success on their dosing regimen based on Monte Carlo simulation.

Conclusion: The use of a beta-lactam with an aminoglycoside provided the most effective empiric coverage for P. aeruginosa while the monotherapy use of a fluoroquinolone provided the least effective. Although a large portion of infections remain susceptible to cefepime, dosing strategies utilizing package label recommendations resulted in suboptimal pharmacodynamics at higher P. aeruginosa MIC values. Based on these resistance patterns and outcomes, therapy with a beta-lactam and an aminoglycoside should strongly be considered as the therapy of choice when combination therapy is indicated. If beta-lactam monotherapy is appropriate, extended infusion dosing strategies or more frequent dosing intervals should be utilized.

Submission Type: Evaluative Study

Session-Board Number: 7-132

Poster Title: Evaluation of outcomes associated with the implementation of a U-500 insulin policy in an academic medical center

Primary Author: Angela Goodhart, Northeast Ohio Medical University (NEOMED), Ohio; **Email:** agoodhart@neomed.edu

Additional Author (s):
Nour Elsheick
John Moorman
Christopher Ensley

Purpose: With the increasing prevalence of obesity in the United States, there has been an increased need to use U-500 insulin to achieve glycemic control, specifically when daily insulin requirements exceed 200 units. The Institute for Safe Medication Practices has identified U-500 insulin as a high risk medication, especially given the risk of dose conversion errors and the associated risk of hypoglycemia. In 2014, Akron General Medical Center implemented a policy in order to improve the safety of U-500 insulin in the inpatient setting. Our purpose was to determine how this policy affected time to first dose administration and hypoglycemic episodes.

Methods: This was a quality improvement initiative involving a retrospective chart review for patients receiving U-500 before and after implementation of a U-500 insulin policy. This policy mandated an endocrinology consult, required a pharmacist to verify the home U-500 insulin dose prior to initial dispensing, and instituted an order set specific to U-500 insulin. These requirements were in addition to the historical policy, which required that each dose be drawn up into a tuberculin syringe and verified by two pharmacists prior to dispensing. The historical group consisted of 153 accounts from January 1, 2011- December 31, 2012 and the post implementation group included 109 accounts from January 1, 2015-July 31, 2016. Data collected included: use of U-500 insulin prior to admission, admission date, date of U-500 insulin dose, whether endocrine was consulted, date of the consult (if placed), and if one or more episodes of hypoglycemia (blood glucose less than 70 milligrams per deciliter) occurred. For the years following the policy implementation (2015-2016), documentation records were reviewed to determine if a pharmacist verified the patient's home U-500 insulin dose prior to

dispensing, and whether two pharmacists verified each individual dose (two sets of initials). Fisher's exact test and Student's t-test were used to determine significance for nominal and continuous data, respectively, for data from before and after the implementation of the policy.

Results: Of the 153 accounts reviewed in the historical data, 138 (90 percent) were using U-500 insulin at home, compared to 99 (91 percent) of the 109 accounts post-policy (P equals 1.000). The mean number of days from admission to first dose was 1.4 days in the historical group versus 1.1 days in the post-policy group (P equals 0.327). Seventy-six percent of the historical accounts had an endocrine consult placed, compared to one hundred percent of the post-policy accounts (P less than 0.001). The mean number of days between the administration of the first dose and the endocrine consult being placed was 0.4 days in the historical group and 0.1 days in the post-policy group (P less than 0.001). In the historical group, 97 accounts (63 percent) had at least one episode of hypoglycemia, while this occurred in only 45 accounts (41 percent) in the post-policy group (P less than 0.001). In the documentation records for the post-policy data, 18 accounts (14 percent) had appropriately documented verification of home U-500 insulin doses by a pharmacist. Two pharmacists' initials were present for every dispense for 69 of the accounts (63 percent).

Conclusion: Implementation of an institutional policy requiring an endocrine consult to order U-500 insulin and utilizing a specific U-500 order form reduced the amount of time patients were receiving U-500 without being followed by an endocrinologist. It also resulted in fewer patients experiencing hypoglycemic episodes after the implementation of the policy. Based on these results, the current policy improves patient safety without delaying time to administration of U-500 insulin and should be continued. However, there is room for improvement in pharmacy documentation of home dose verification and verification of dispensed doses.

Submission Category: Pharmacy Law/ Regulatory/ Accreditation

Submission Type: Evaluative Study

Session-Board Number: 7-133

Poster Title: Stay out of trouble! Comply with FDA postmarketing drug safety regulations

Primary Author: Joelle Farano, Ohio Northern University, Ohio; **Email:** j-farano.1@onu.edu

Additional Author (s):
Namita Kothary
Kelley Simms
Kavita Dada
David Burrow

Purpose: Once a drug has been approved by the FDA, a sponsor must send periodic safety updates to the FDA. Surveillance plays an important role in assuring the safety of FDA regulated drugs. Sponsors may also have additional stipulations in order for their drugs to remain on the market. The postmarketing surveillance programs that are utilized include pharmacovigilance, PADE (Postmarket Adverse Drug Experience) Reporting, and REMS (Risk Evaluation and Mitigation Strategies) which monitors adverse drug events (ADEs). The purpose of this project is to identify the most common post market violations identified during surveillance inspections that occur with FDA regulated drugs.

Methods: A team of pharmacists and student pharmacist identified the need to educate industry leaders about postmarketing statutory provisions/regulations. This team collected data involving ADE, including Phase IV studies and post marketing requirements, in order to determine the most common postmarket violations that occur in the industry in an effort to improve safety. The team evaluated compliance with these provisions/regulations from sponsors in the industry from fiscal years 2012-2015. The Code of Federal Regulations (CFR), Title 21, Chapter I, Subchapter D, Parts 310, 314, and 601 define the statutory provisions/ regulations that sponsors must abide by for FDA approval. These statutory provisions and regulations require sponsors to send reports to the FDA when the sponsors are informed of an ADE. Annual reports should include summaries of significant new information, including new studies; clinical data, including published and completed unpublished clinical trials/manuscripts, safety and efficacy data in the pediatric population; and status reports of postmarketing study commitments, which must be reported until the FDA notifies that the study commitment is fulfilled, no longer feasible, or no longer provides useful information. PADE reports should

include a narrative summary and analysis; an analysis of 15-day ADEs; line-listing and Form FDA 3500A for ADEs not reported as 15-day alert reports (does not apply to postmarketing study ADEs); and actions taken due to the ADEs, including newly initiated studies.

Results: The most common postmarketing violations that occur in industry include 15-day alert reports not submitted to the FDA within 15 calendar days of initial receipt of the information, failure to develop written procedures, and incomplete or late submissions of annual and/or periodic reports sent to the FDA. Once a sponsor receives ADE information from any source, including ADEs that are serious, unexpected, or possibly study related, an initial and follow up report are required to be submitted to the FDA within 15 calendar days via electronic submission gateway and the Safety Reporting Portal. The sponsors should have written procedures that address surveillance, receipt, evaluation, and reporting in order to review the ADE information received from any source and evaluate the information. Annual reports must be provided for all the years a drug is on the market, and this report must be given within 60 days of the approval date. In the first three years post approval, periodic adverse drug experience reports must be provided to the FDA quarterly within 30 days of close of the quarter. After three years, a periodic adverse drug experience report must be provided annually within 60 days of approval.

Conclusion: In order to improve pharmacovigilance and decrease the number of postmarket violations that occur, industry must be made aware of common violations that occur with regards to FDA regulations. This knowledge can allow industry leaders to be aware of the requirements for reporting upon the receipt of an ADE and improve compliance with FDA regulations. Health-system pharmacists and student pharmacists are also aware of the importance of ADE reporting for their patients and how it impacts a drug's postmarket status. The heightened awareness promotes public health by enhancing the safety of drugs once they are approved.

Session-Board Number: 7-134

Poster Title: Knowledge and perception of student dentists towards pain and anti inflammatory drug therapy in Saudi Arabia

Primary Author: Saleh Alqifari, Ohio Northern University, Ohio; **Email:** s-alqifari@onu.edu

Additional Author (s):
Abdullah Alqifari

Purpose: Comprehensive knowledge in medication therapy and safety is one of the important characteristics of healthcare providers. Effective and safe use of pain and anti inflammatory therapy in educational dental clinics requires a comprehensive knowledge base of the various drug agents. The purpose of this study is to assess knowledge, attitude and perception of student dentists in various dental schools in Saudi Arabia towards the use of pain and anti inflammatory drug therapy. This study might serve as a guide tool to identify common grounds for collaboration and improvement between pharmacy and dental medicine in Saudi Arabia.

Methods: In 2016, 328 student dentists enrolled in the traditional six year dental program in Saudi Arabia were invited to participate in a voluntary online survey. The brief survey consisted of 23 multiple choice questions and delivered as a secure link through email and private social media messaging services. The survey permitted only 1 attempt per user. In order to reach out and capture non-respondents, 2 follow-up reminders ten days apart were sent through the same channels of communication. The survey data was collected and analyzed using the online survey software program, Qualtrics.

Results: The response rate was 22.6 percent (74 out of 328). Approximately 77 percent of participants were third, fourth, fifth and sixth year students. Nearly 50 percent of respondents indicated that they have treated patients with pain and inflammation before, and nearly 94 percent of respondents indicated that they counsel patients to take medications as prescribed. However, 66 percent reported not sure how non-steroidal anti inflammatory drug therapy is discontinued. Approximately 70 percent of respondents prefer to approach a pharmacist with drug therapy questions, and nearly 31 percent of third, fourth, fifth and sixth year students thought acetaminophen is an anti inflammatory agent.

Conclusion: Among data reported in this survey, evidence of misunderstanding of pain and anti inflammatory pharmacotherapy has been shown. There might be a need for interprofessional collaboration between pharmacy and dental medicine in Saudi Arabia to help close gaps in knowledge. More research is needed among a larger sample of student dentists to develop better understanding of the type of collaboration effort required.

Poster Title: Analysis of FDA approvals of targeted anticancer combination regimens and the cost implications

Primary Author: Victoria Cho, Ohio Northern University, Ohio; **Email:** v-cho@onu.edu

Additional Author (s):
Shannon Parkey
Victoria Brown

Purpose: To describe the incidence of Food and Drug Administration (FDA) approvals of targeted anticancer agents in combination with another targeted anticancer agent.

Methods: New anticancer drug approvals from February 10, 2006 to June 1, 2016 were reviewed for the top five most frequently diagnosed solid organ cancers and top five most frequently diagnosed hematologic cancers. Each approved anticancer agent was then defined as cytotoxic or targeted. Targeted anticancer agents were defined as agents that selectively target molecular pathways, as opposed to DNA, tubulin or cell division machinery. The FDA approvals for each targeted agent were determined to be approved as monotherapy or combination therapy with either other targeted therapies or traditional cytotoxic agents. The cost for the targeted-targeted combination regimens was determined based on one dose for parenteral administration and 30-days for oral administration.

Results: Overall, 16.1% of targeted agents were approved in combination with other targeted agents; 14.75% were in combination in the solid tumor and 19.2% in combination for hematologic malignancies. The median cost of combination targeted regimens in the past decade was $22,208.67 for other targeted agents and $8,565.30 for traditional cytotoxic agents.

Conclusion: As more targeted therapies enter the market, previous targeted therapies are not replaced but utilized in combination with each other. One of every six targeted agents is now approved in combination with another targeted agent. The costs of therapy continue to increase as targeted anticancer agents are utilized more frequently to provide optimum care to patients. As more targeted anticancer agents are approved in combination, health-system

pharmacists should be aware of this as a driver for rising costs of anticancer treatments and the implications to their health-system.

Poster Title: Influence of the Johns Hopkins Pharmacy Summer Internship Program on professional development

Primary Author: Shannon Kraus, Ohio Northern University Raabe College of Pharmacy, Ohio; **Email:** s-kraus@onu.edu

Additional Author (s):
Stephanie Jean
Felicia Bartlett
Sujin Weinstein
Denise Fu

Purpose: Professional development is a valuable aspect of the profession of pharmacy and helps prepare students for a future career, residency or fellowship. The Johns Hopkins Pharmacy Summer Internship program provides a range of activities and opportunities for interns to explore health-system pharmacy practice. In addition, the program fosters the professional development of its interns through active involvement in various projects and experiences. The objective of this study is to determine the value of the Johns Hopkins Pharmacy Summer Internship program on the professional development of interns from 2010-2015.

Methods: A survey was designed to assess various areas of professional development that were fostered during the internship program, including project-related skills, communication skills, commitment to improvement, professional involvement and leadership, knowledge of profession, and professional trajectory. The survey included 21 questions and was created through collaboration with the internship program directors to ensure that the questions were of value and had minimal subjectivity. The survey was e-mailed via Survey Monkey in April 2016 to those who participated in the internship program between 2010-2015. A descriptive analysis was conducted on the data compiled. The survey was submitted to the Internal Review Board and qualified as exempt research.

Results: Of the 106 interns between 2010 and 2015, 67 completed the survey. 83.6 percent of participants completed the internship program after their second year of pharmacy curriculum, 9 percent after their first year, and 7.5 percent after their third year. Overall, 82 percent of interns felt that the internship program had the highest possible value on their own professional development. Participants believed that they developed their presentation preparation and delivery skills, improved on their ability to self-reflect, and increased their awareness of health-system pharmacy careers and practices. Interns were involved in developing business proposals, completing quality improvement projects, assisting in pharmacy operations, and developing training and in-service programs. At the end of the program, preceptors provided feedback to their interns through formal evaluations, and 65.7 percent of students strongly agreed that this impacted their future development of strengths and minimizing weaknesses.

Conclusion: Although small sample size and positive result bias were limitations of this study, the overall results demonstrate that the Johns Hopkins Pharmacy Summer Internship program has a positive impact on professional development. The comprehensive experience serves as a model for other internship programs and institutions as it is a unique opportunity for students to mature professionally and develop the necessary characteristics to prepare for a successful career in pharmacy.

Poster Title: Transitioning from high school to college: a student pharmacist's role in mental health education and suicide awareness for students

Primary Author: Rebecca Worden, Ohio Northern University Raabe College of Pharmacy, Ohio; **Email:** r-worden@onu.edu

Additional Author (s):
Zachary Woods
Lindsey Peters
Karen Kier

Purpose: There is a high prevalence of mental illness in the United States, with the highest impact during the teenage and young adult years. Negative stigma associated with mental health disorders deprives those in need from getting adequate treatment. Resources are are not readily available, especially during the transition from high school to college. Pharmacy students are uniquely situated to provide an initial contact point for health-care services focused on wellness. This outreach program, targeted for high school and college students, was developed to raise awareness and provide education about the available resources and treatment options.

Methods: A literature search using MEDLINE was performed using the MeSH terms "mental health," "fears," and "students." Cohort studies and review articles resulted from the search. Other online resources were consulted, including the websites for the NIMH, AAS, and SPRC and NAMI. Based on the results, an interactive outreach program directed towards high school and college students that raised awareness about mental health was created. Specific resources were designed for high school students that provided healthy coping strategies for transitioning to college, and ways to engage in healthy mental health practices. A visual display representing the lives lost to suicide on college campuses was created. College students were encouraged to participate in an interactive stress-relieving activity and were provided a handout with resources available on campus and in the surrounding community. Evidence-based resources were created to be student-pharmacist driven as part of an interactive program. These materials provide a basis for the pharmacy profession to engage in mental health counseling

similar to counseling already provided for more classic disease/lifestyle modification recommendations such as hypertension or diabetes.

Results: Two student-pharmacists participated in the development of two outreach programs consisting of interactive presentations and educational sessions. One student focused on high school student transitions, while the other focused on college campus outreach. For the high school student outreach: materials were created to raise awareness of mental health disorders, to teach healthy stress-management and coping strategies, and to encourage treatment if necessary. The program also encouraged participants to anonymously express their concerns about transitioning to college and created a safe environment to discuss their fears. High school students were encouraged to use new techniques to create social development goals and improve self-regulation. For the college outreach, an interactive display showcasing the impact of suicide on college campuses reached over 300 students, while providing a stress management activity, and showcasing resources on campus.

Conclusion: As more focus is given towards mental health, particularly in the young adults transitioning and then living on college campuses, pharmacists can be a critical link in providing counseling and resources to help students maintain and develop appropriate mental health strategies.

Session-Board Number: 7-138

Poster Title: Efficacy of low- versus high-dose palonosetron in pediatric oncology patients receiving moderately- to highly-emetogenic chemotherapy

Primary Author: Allison Maynard, Ohio Northern University Raabe College of Pharmacy, Ohio; **Email:** a-maynard@onu.edu

Additional Author (s):
Vinita Pai
Christina Hsu

Purpose: Palonosetron as a single dose of 0.25 mg was initially FDA-approved only in adults for prevention of chemotherapy-induced nausea and vomiting (CINV). Pediatric dosing at 0.02 mg/kg/dose (maximum dose of 1.5 mg) was approved later. Pharmacokinetic studies suggest children may require higher dosing than adults; however efficacy of doses above 0.25 mg has not been compared. Prior to pediatric dosing, all patients at our institution received palonosetron based on adult dosing. The primary objective of this study is to compare the efficacy of the higher pediatric dosing to the adult dose of 0.25 mg in controlling CINV.

Methods: The institutional review board approved this single-center retrospective chart review. Chemotherapy naïve in-patients less than 19 years of age who received at least one dose of palonosetron and corticosteroid prior to moderately or highly emetogenic chemotherapy between June 2013 and June 2015 were included. Patients who received a dose of 0.25 mg using a weight based dose were excluded from the study. Data collected included: age, gender, body weight, cancer diagnosis, palonosetron dose and number of doses, anti-emetic regimen, number of emetic episodes up to 24 hours post-chemotherapy, and number of re-admissions and post-discharge phone calls due to uncontrolled nausea or vomiting. Eligible patients were divided into two groups, the weight based dosing group (maximum 1.5 mg per dose) and non-weight based dosing group (0.25 mg per dose). Data was analyzed using Microsoft Excel and statistical analysis was performed with Statistical Analysis Software.

Results: A total of sixty-eight patients were screened. Eighteen patients met the inclusion criteria. Six patients were included in the non-weight based group and twelve patients in the weight-based group. The groups were well balanced in regards to age, gender, and weight

(mean weight 56.2 + 12.1 kg vs 55.8 + 18.4 kg). The average dose of palonosetron in the weight-based dosing group was 1.1 + 0.3 mg, with a range of 0.33 mg to 1.5 mg). Emesis was reported in 2 of the 6 patients in the non-weight based group and in 4 of 12 in the weight-based dosing group. The average number of rescue anti-emetics used per person was the same in both groups. The proportion of patients discharged with a prescription for dexamethasone was comparable in the two groups. Telephone encounters for nausea occurred in 2 patients in the non-weight based group and 1 patient in the weight-based group. No re-admissions due to uncontrolled CINV were reported in either group.

Conclusion: Based on this limited data, we did not find any benefit in using a higher weight-based dosing of palonosetron over the standard 0.25mg adult maximum dose for the prevention of CINV in pediatric patients receiving moderate to highly emetogenic chemotherapy. This needs to be confirmed in a prospective study with appropriate number of patients.

Submission Category: Drug-Use Evaluation/ Drug Information

Poster Title: Evaluation of insulin utilization and management of hypoglycemic events in adults across a network of six community hospitals

Primary Author: Olivia Henton, Ohio Northern University Raabe College of Pharmacy, Ohio; **Email:** o-henton@onu.edu

Additional Author (s):
Honey Patel
Jason Hoffman
Melissa Hobbins
N. Logan Davis

Purpose: Hypoglycemia is often seen in institutional settings as a result of poor therapeutic dosing control of insulin in patients with diabetes. In the most severe cases, hypoglycemia can result in loss of consciousness, seizure and death. The primary purpose of this review was to determine how current insulin prescribing practices contributed to hypoglycemic events across a network of six community hospitals. The secondary objective of this review was to assess the adherence to the hypoglycemia protocol currently utilized at all hospitals within the health system and identify the common treatment strategies in treating hypoglycemic patients.

Methods: The Institutional Review Board (IRB) categorized this review as a quality assurance/quality improvement activity exempt from IRB oversight. This review was a retrospective cohort of hypoglycemic events, defined as a blood glucose less than 60 milligrams per deciliter (mg/dL), at all six hospitals occurring between February 1 and May 1, 2016. Patients were identified utilizing a clinical decision support tool, having met two criteria: an active insulin order and experienced a hypoglycemic event. Events for each patient were then reviewed in the electronic medical record (EMR). Baseline demographics were collected including age, sex, diabetes diagnosis, dietary status, and the type(s) of insulin ordered. Time between insulin administration and hypoglycemic event was recorded, and only those insulin administrations that caused a hypoglycemic event within their respective duration of action were included. Hypoglycemic events identified at the two largest facilities (763 beds and 120 beds, respectively) were randomized, while all events were reviewed at the four facilities under 50 beds. Adherence to the hypoglycemia protocol was determined first by the presence of

documentation; lack of documentation of administered treatment was categorized as non-adherence. If the preferred agent was not used given the patient's condition, the treatment of the event was considered non-adherent. Descriptive statistics were utilized for data analysis.

Results: A total of 250 hypoglycemic events were evaluated as part of this review. Eighty-seven of 250 events did not meet inclusion criteria and were removed from data analysis. Of 163 events considered, distribution of men versus women was equal, with a mean age of 63 years. Type 2 diabetes was present in 79.8 percent of patients, and 68.1 percent received a diabetic diet. Monotherapy long-acting insulin accounted for most events (53.4 percent). Scheduled and corrective-coverage rapid-acting insulin were causative agents in three (1.8 percent) and four (2.5 percent) events, respectively. Combination therapy, where two or more insulin orders were given, accounted for 48 of 163 events (29.4 percent). Thirty-two of 48 combinations involved corrective-coverage rapid-acting insulin as one of the contributing insulin products, with medium-intensity coverage accounting for 20 events (62.5 percent). With regard to protocol adherence, 66 of 163 (40.4 percent) events were treated appropriately. Of the remaining 97 events, 25 received a treatment other than what was directed by the protocol, and no treatment was documented for 72 (44.3 percent) events. Dextrose 50% in water (D50W) was the most common treatment, with 27 of 46 administrations (58.7 percent) appropriate.

Conclusion: Long-acting insulin was determined to be the most common insulin associated with a hypoglycemic event. Additionally, adherence to the hypoglycemia protocol was relatively poor. Recommendations include setting low-intensity as the default scale for corrective coverage orders and utilizing the clinical decision tool to identify patients at risk of hypoglycemia to provide pharmacists opportunity for prompt intervention. In addition, the health system should explore optimizing the EMR for more consistent and thorough documentation, which includes implementing hard stops and prompting nurses to take necessary steps for resolving the hypoglycemic events.

Poster Title: Evaluation of student leadership activities and CAPE outcomes with the implementation of a leadership curriculum

Primary Author: Chelsey Scarpino, Ohio Northern University Raabe College of Pharmacy, Ohio; **Email:** c-scarpino@onu.edu

Additional Author (s):
Karen Kier
Adam Smith

Purpose: New pharmacy accreditation guidelines place an emphasis on leadership development in pharmacy curriculums. Professional pharmacy organizations are also addressing issues with developing leaders within the profession. The American Society of Health-system Pharmacy 2016 House of Delegates approved policy 1611 that included a statement encouraging colleges of pharmacy and state affiliates to foster student leadership development. The objective of this study was to survey students at one college of pharmacy to learn about the impact of implementing a leadership component to the curriculum.

Methods: The college of pharmacy implemented a leadership curriculum five years ago in the third professional year. The college went through a curricular change and decided to implement leadership materials earlier in the curriculum during preprofessional courses. The goal was to encourage students in the preprofessional years to start implementing a leadership plan. A survey was designed and pilot tested to evaluate leadership activities and potential of third and fourth year professional students at a college of pharmacy. The study received institutional review board approval. An informed consent was the first link in the survey. A link was sent electronically to the listserv with a reminder email one week later. The survey was open for two weeks. Data was analyzed using SPSS software (IBM, New York). Both descriptive and inferential statistics were used for analyzing the data. Alpha was set at 0.05 with a power of ninety percent. The sample size calculation for a t-test was forty-four. Exclusion criteria was any survey that was not at least ninety percent complete. The primary outcome variable was evidence of pharmacy professional leadership positions between the two classes as a result of changes in the timing of the leadership curriculum. Secondary outcome variables were survey

questions involving Center for the Advancement of Pharmacy Education (CAPE) outcomes domain 4.1 self-awareness, 4.2 leadership, and 4.4 professionalism.

Results: The response rate was seventy-two percent with an equal number returning surveys from each class. No surveys were excluded. The primary goal showed that 47.6 percent of the class prior to the change had a leadership position in a professional organization while 64 percent held a position after the curriculum change (p=0.0027). The third year class averaged 4.71 memberships in pharmacy professional organizations while the fourth year class averaged 3.28. However, campus activity involvement was the same for both classes. Sixty-seven percent of the third year class had a campus leadership position compared to fifty-nine percent in the fourth year (p=0.039). When students were asked the likelihood on a scale of 0 to 100 if they would be involved in a professional organization for the duration of their pharmacy careers, the aggregate score was 79.46 for the fourth years and 84.24 for the third years. Using the same 0 to 100 scale, the respondents were asked if they felt that the college prepared them to be a leader within the profession. The aggregate score was 83.09 for the fourth year and 81.83 for the third years. The combined aggregate score was 79.99 for community service and 83.85 for domain 4.1.

Conclusion: The data suggests that leadership development earlier in the curriculum allowed students to develop a leadership plan with active membership. This is only one year of data and longitudinal surveys will help determine if this model is successful in introducing leadership concepts. The students felt the college did a good job of meeting the CAPE outcomes. The interesting data is the students that responded that they would be a member of a professional organization for their career. A future study may involve tracking these students during their professional careers to follow their leadership development.

Submission Category: General Clinical Practice

Submission Type: Evaluative Study

Session-Board Number: 7-141

Poster Title: Evaluation of clinical practice in comparison to transgender adolescent guidelines

Primary Author: Kelli Arasz, Ohio State University College of Pharmacy, Ohio; **Email:** kelliarasz@gmail.com

Additional Author (s):
Kimberly Novak

Purpose: US census data report an increase in the number of patients receiving and inquiring about hormone therapy to transition from their natal sex to their desired sex. This number is expected to double as acceptance spreads in society. An accurate assessment of the number of transgender individuals is difficult due to inaccurate collecting method. The World Professional Association for Transgender Health (WPATH) guidelines suggest hormonal treatment based on Tanner stages of puberty. Additionally, strong counseling and mental health initiatives are recommended to allow for family and individual therapy. This retrospective chart review will evaluate clinical practice compared to recommended guidelines.

Methods: The primary objectives were to determine adherence to national guidelines regarding pharmacologic therapies and identify when and why variations occur. The secondary objectives were to identify barriers to medical treatment and adherence to therapy. A retrospective chart review of adolescent transgender patients was conducted for patients ages 10-19 years with an ICD-10 code for either gender identity disorder or transgender assigned to a clinic or inpatient encounter between 8/1/2013 and 7/31/2016. Additionally, patients had to have been evaluated in the Team-driven Health care that Respects the Individual and Values Emotions (THRIVE) program. The data was collected via the electronic medical record system. The data points evaluated were the referral to endocrinology, evaluation by endocrinology, Tanner stage of puberty reported, hormone therapy, monitoring of hormone levels, goal of hormone treatment, individual therapy and family therapy received, insurance barriers to care, and natal sex of patient. The primary and secondary outcomes were evaluated via descriptive statistics.

Results: There were 152 patients evaluated for inclusion in this study with 122 meeting the inclusion criteria. Of those included, 88 of the patients were referred to endocrinology and 76 were evaluated by endocrinology at this time. Of those patients, 45 (36.9 percent) were receiving hormone suppression therapy, 39 (32 percent) were also receiving hormone crossover therapy, and 12 (30.8 percent) of the patients receiving hormone therapy were at goal hormone levels as recommended in the Endocrine Society Guidelines. Individual therapy was a strong recommendation of the WPATH guidelines; 103 (84.4 percent) patients were enrolled in individualized therapy. While barriers were of interest in this study,the most common documented barriers were societal and family misunderstanding. Insurance not covering their medications was specifically referenced as a barrier in 9 (7.4 percent) of the patients meeting inclusion criteria; however, overall documentation was sparse.

Conclusion: The WPATH guidelines are a way to help providers better serve this growing population. An updated set of guidelines were adopted in August 2016 to be released soon, and the updates could better allow these adolescents to have more targeted and personal health care. Strict follow up and supportive group environments could help to increase the adherence to medications and minimize mental health concerns in this growing population. Larger studies are needed to thoroughly evaluate the care of this population and the efficacy of hormone therapies in adolescents.

Submission Type: Descriptive Report

Session-Board Number: 7-142

Poster Title: Outpatient utilization of liraglutide at a Veterans Affairs facility

Primary Author: Ayrron Sisley, The Ohio State University, Ohio; **Email:** sisley.9@buckeyemail.osu.edu

Additional Author (s):
Rachel Chandra
Brian Burke

Purpose: Liraglutide is a glucagon-like peptide 1 analog used to treat diabetes mellitus type II with overall functions such as increasing insulin secretion, increasing satiety, and decreasing glucagon production. Prescribing practices of this medication were evaluated at the Dayton Veterans Affairs facility using the national "Criteria for Use" recommendations. The medication utilization review assessed various monitoring parameters (namely weight, systolic blood pressure, serum creatinine, and hemoglobin A1c) in the patients with active prescriptions for liraglutide to gauge its efficacy in lowering hemoglobin A1c in this population.

Methods: Electronic medical records of fifty-four patients with active, outpatient prescriptions for liraglutide were retrospectively reviewed at a single medical center. To assess adherence to protocol, the following pieces of information were recorded: demographics, patient involvement in a healthy lifestyle program, contraindications for liraglutide, and concomitant and trialed anti-diabetes medications. The "Criteria for Use" recommends providers to ensure trials of other anti-diabetes medications, including metformin, before initiating liraglutide. To evaluate safety and efficacy, lab values were collected at both baseline and from the patients' most recent visits for serum creatinine, systolic blood pressure, weight, and hemoglobin A1c. It was also noted whether or not patients were receiving concomitant diuretic therapy. Hemoglobin A1c values were also collected from the first follow up visit post- initiation of liraglutide. Statistical analysis for the monitoring parameters was performed via the International Business Machines program, Statistical Package for the Social Sciences, to be analyzed for average trends of each monitoring parameter.

Results: Ninety-four percent of patients receiving liraglutide at the time of data collection were male, which is consistent with the typical Veterans Affairs population. On average, hemoglobin A1c, systolic blood pressure, and weight all trended down from baseline (lowered by 0.57 percent, 9.97 millimeters of mercury, and 4.37 kilograms respectively). Serum creatinine was the outlying monitoring parameter that trended up by 0.141 milligram per deciliter on average resulting in an 18 milliliter per minute lowering of creatinine clearance. The initial hemoglobin A1c dropped by 0.84 percent between baseline and first follow-up, indicating that hemoglobin A1c has a larger initial drop before rising slightly as therapy continues. Forty-six percent of patients had no involvement in the lifestyle modification program. Forty-six percent had an active prescription for diuretic therapy at the time of data collection. On average, four other anti-diabetes medications were trialed prior to initiating liraglutide.

Conclusion: Patients taking liraglutide, on average, had improvements in blood pressure, hemoglobin A1c, and weight. The initial decrease in hemoglobin A1c by 0.84 percent is consistent with the "Liraglutide Effect and Action in Diabetes" trials. Forty-six percent of patients were on concomitant diuretic therapy; this, combined with the declined kidney function, supports close monitoring of kidney function during therapy with liraglutide. This medication utilization evaluation supports increased use of liraglutide, and also revealed the opportunity for professional staff to further encourage patient involvement in the lifestyle modification program.

Poster Title: Evaluation of appropriate linezolid prescribing in an outpatient cystic fibrosis setting as an institutional measure of quality

Primary Author: Peter Montgomery, The Ohio State University, Ohio; **Email:** montgomery.714@osu.edu

Additional Author (s):
Kimberly Novak

Purpose: Antibiotics are one of the most often prescribed medications in the healthcare system. Antibiotic resistance has increasingly become a concern, as there has been little incentive for pharmaceutical companies to develop new antibiotics. For this reason, many institutions have developed antimicrobial stewardship programs restricting the use of certain medications and providing specific prescribing criteria to prevent the development of widespread antimicrobial resistance throughout a healthcare system. Due to infection with resistant organisms, cystic fibrosis (CF) patients are often in need of these restricted antimicrobials. This investigation evaluated the appropriateness of linezolid (Zyvox®) prescribing for CF patients in the outpatient setting.

Methods: This retrospective analysis assessed the appropriateness of outpatient prescribing of a restricted inpatient-use medication at a large free-standing children's hospital housing both pediatric and adult CF centers which serve over 500 CF patients. This project was performed as a measure of quality for internal use and as such was not subject to institutional review board approval. Identifiable patient information was not collected as part of the analysis. In our quality improvement protocol, outpatient prescribing of linezolid in CF patients of all ages was assessed from March through June 2016. Data collected to evaluate appropriateness of prescribing included: prescriber, date prescribed, dose, frequency, duration of treatment, available culture results and susceptibilities from the previous 365 days, concomitant medications with potential interactions, lung transplant status, CF genotype, recent history of antibiotic therapy (previous 8 weeks), and whether laboratory testing was performed as indicated based upon treatment duration. Basic patient demographics were also be collected, including any identified medication allergies. Data were evaluated using descriptive statistics. Results were analyzed and then reviewed by a specialist pharmacist at the institution.

Outcomes of this project will be used to determine whether linezolid is being prescribed appropriately or to refine antimicrobial prescribing guidelines.

Results: A total of 29 instances of linezolid prescribing that met study criteria were identified and evaluated as part of this quality improvement analysis. All occurred in adult CF patients. Based on the study design, linezolid was appropriately indicated in 90 percent of patients identified. Only three of the 29 instances did not meet the predefined criteria of appropriate prescribing chosen for this study. One of these three patients did not meet the criteria based on previous culture results; however, this was only because this study only included available antimicrobial culture results from the previous 365 days. Further research into this case showed a previous positive culture for methicillin-resistant Staphylococcus aureus, which would have placed this patient into the appropriate prescribing category. The remaining two patients in fact did not meet the appropriate medication use criteria, as defined by the institutional antimicrobial stewardship guidelines. In one of these patients, a clinical pharmacist identified the non-indicated medication use, and the prescriber changed the course of therapy as a result. No clinically significant medication interactions were identified in any of the patients evaluated, and all doses prescribed and durations of treatment were therapeutically appropriate.

Conclusion: Implementation of an antimicrobial stewardship program is an effective means of restricting the use of powerful broad-spectrum antibiotic agents and can influence outpatient prescribing where restriction is more difficult to enforce. This study demonstrated no widespread over-prescribing of linezolid in CF patients at this institution, while reinforcing the benefit of utilizing pharmacists on the patient care team. Data from this study will be used internally to validate and refine the medication use criteria for linezolid. Intermittent or ongoing audits may be considered to ensure continued appropriate prescribing practices in the CF population.

Poster Title: Pharmacist-led implementation of a pharmacogenomic testing consult service in an adult population with autism spectrum disorders

Primary Author: Jinming Xing, The Ohio State University - College of Pharmacy, Ohio; **Email:** xing.90@osu.edu

Additional Author (s):
Debra Barnette
Christopher Hanks
Seuli Brill

Purpose: The Center for Autism Services and Transition (CAST) at The Ohio State University was established in April 2014 to address the needs of adolescents and adults with Autism Spectrum Disorders (ASD) as they transition into adult primary care services. This population is often on complex medication regimens that are potentially effected by differences in drug metabolism. The pharmacogenomic (PGx) service was established by a pharmacy school faculty member with the assistance of advanced practice student pharmacists.

Methods: To date 415 patients have enrolled in the CAST program. The PGx service was designed to assist providers in selecting alternate therapy after initial therapy had failed or if the provider suspected potential medication related side effects. Data from limited published studies supported comorbidities to include seizures, depression, and attention-deficit/hyperactivity disorder (ADHD). Therefore, PGx testing targeted medications are antidepressants, antipsychotics, antiepileptics, and ADHD therapies. The consult service structure and process is outlined to include: 1) identification of potential candidates for PGx testing by the provider, clinical pharmacist, or at the patient/caregiver's request; 2) completion of the buccal swab by the clinic staff; 3) processing the sample by the designated vendor; 4) results returned to the pharmacist via secure email; 4) recommendations made to the provider; 5) patient or caregiver follow-up appointment made with the pharmacist to discuss the results and any subsequent changes.

Results: The PGx testing service was established January 2016. The structure and process outlined has been utilized by the providers and incorporated well into the patient's appointment as needed. Pharmacy result reviews and written recommendations have been well received by both the providers and patients. To date the PGx testing has been utilized mostly for patients that have failed multiple empiric therapies. Less frequently the results help to rule out poor metabolism as a potential contributing cause for medication response failure. In this population antidepressants are frequently utilized for the anxiolytic effects and the results have provided genetic information to better understand potential differences in medication metabolism for the patients.

Conclusion: The PGx testing program has been successfully implemented in an adult population with autism spectrum disorders. In the future an evaluation to examine the patient outcomes related to the PGx testing service could potentially help to better identify patients that would benefit most from testing and quantify the improved outcomes (i.e., less side effects, earlier response to therapy).

Poster Title: Assessing mental health and wellness in pharmacy students: results from the implementation of mental health programs in a college of pharmacy

Primary Author: Paige Sinclair, The Ohio State University College of Pharmacy, Ohio; **Email:** sinclair.62@buckeyemail.osu.edu

Additional Author (s):
Amy Fabian
Kiersten Pasternak

Purpose: Starting in 2015, The Ohio State University College of Pharmacy implemented mental health resources based off of information from a student survey about mental wellness in 2014. The services included the installation of a psychologist in the college, multiple suicide prevention trainings, education from patient speakers, and mental health awareness events. The efforts to address the student-identified problem was an active collaboration between students, faculty, staff and administrators. The purpose of this study was to characterize the mental health climate of the student body after these implementations and to compare it to the results of the 2014 survey.

Methods: The protocol for this cross-sectional study was approved by the institutional review board. Data were collected from two anonymous surveys distributed electronically. Both surveys used the same questions probing for stress, symptoms of mental health conditions, perception of mental health, utilization of counseling services, and attendance at suicide prevention trainings and patient speaker sessions. Students could select "not at all", "some of the time", "a lot of the time", or "most/ all of the time" when asked about the frequency within the last four weeks in which they experienced various symptoms of anxiety, depression, and suicidality. Demographics collected were gender and year in pharmacy school. The survey, created with Qualtrics, was distributed in February 2016 to all PharmD students enrolled during the 2015-2016 academic year (n=520) to assess student perception of mental health. In this latter survey, students who identified as a P2, P3, or P4 were asked additional questions to evaluate their involvement in and utilization of mental health programs and resources initiated in the college of pharmacy since October 2014. Students who completed the survey were

entered into a drawing for one of six $25 amazon.com gift cards. Anonymous student responses were kept separate from the collection of names drawn for the prizes.

Results: There were 100 responses to the 2014 survey (the limit for SurveyMonkey) and 202 responses to the 2016 survey. When asked about feeling nervous or worrying a lot, 25% of students in the 2014 survey responded "most or all of the time", compared to 15% from the 2016 survey. For feeling desperate, 52% in 2014 and 69% in 2016 answered "not at all". In both 2014 and 2016, 1% of students endorsed in self-harm "most or all of the time" and developed a plan for suicide. P2-P4 students who received the additional set of questions did perceive a culture shift within the college of pharmacy, with 69% agreeing that over the last year they noticed an increase in mental health awareness within the college and 74% agreeing that they have become more aware of their own mental health in the past year. Nearly half (45%) attributed their increased awareness to a shift in mental health awareness within the college.

Conclusion: After the placement of multiple programs and resources, the 2016 reassessment of student mental health shows progress towards utilization of mental health resources and improved mental health awareness among PharmD students. The results show a relative increase in well-being due to fewer symptoms of anxiety and depression from 2014 to 2016. However, despite the implementation of suicide prevention trainings and the employment of a college psychologist, the rate of self-harm and suicidality remained the same from 2014 to 2016. While these results are promising, there is still room for improvement in order to optimize pharmacy student mental health and wellness.

Submission Type: Evaluative Study

Session-Board Number: 7-146

Poster Title: Discharge instruction errors after pharmacy led medication reconciliation

Primary Author: Benjamin Coles, The Ohio State University College of Pharmacy, Ohio; **Email:** coles.58@osu.edu

Additional Author (s):
Adam Trimble
Sara Jordan

Purpose: The purpose of this study is to determine the frequency and nature of medication-related discharge instruction errors through the following specific aims. Primary: For congestive heart failure (CHF) and chronic obstructive pulmonary disease (COPD) patients readmitted within 30 days of discharge, determine the proportion of discharge instructions that contained errors as well as the average number of discrepancies/medication errors per patient. Secondary: Describe the severity of errors and differences in error rates for patients that had a pharmacy-led medication reconciliation performed on admission versus those that did not.

Methods: The institutional review board approved this retrospective, single-center, chart review. The study population included patients 18 years and older who were discharged from Grant Medical Center between April 1 and August 30, 2015 following an inpatient stay for chronic heart failure (CHF) or chronic obstructive pulmonary disease (COPD). Only patients that were subsequently readmitted within 30 days were included, resulting in a final sample size of 87 patients. Charts for each patient were reviewed and all errors on the discharge summary were recorded and described. Each error was given a severity score from minimal to serious, based on risk to patient. We also determined whether patients had pharmacy led medication reconciliation upon admission in order to determine its effect on medication errors at discharge.The proportion of discharge instructions that contained errors as well as the average number of medication errors per patient were calculated. We described the demographic and clinical characteristics of patients with and without discharge instructions that contained errors and compared these characteristics. Statistical significance was set at p < 0.05 for all tests. Severity of errors were reported using frequencies and percentages and also compared based on patients' demographic and clinical characteristics. The difference in error rates for patients

who had a pharmacy-led medication reconciliation performed on admission versus those who did not was evaluated.

Results: Overall, 64 (76.2%) patients had discharge instructions that contained errors. Among these patients, there was a total of 341 discrepancies/medication errors.The average number of discrepancies/medication errors per patient was 5.3 (SD: 4.4; median: 4.0; range: 1.0 – 22.0). Among the 64 patients with discharge instructions that contained errors, 43 (67.2%) had minimal error(s), 51 (79.7%) had moderate error(s), and 1 (1.6%) had a serious error. Among the 341 discrepancies/medication errors, 122 (35.8%) were minimal errors, 218 (63.9%) were moderate errors, and 1 (0.3%) was a serious error. Minimal errors (n=122) included inappropriate abbreviations (n=82), unclear dosing instructions (n=23), and duplicate orders (n=17). Moderate errors (n=218) included missing dosing instructions (n=182), duplicate therapy (n=31), acute medications continued upon discharge (n=2), and other (n=3). Serious errors (n=1) included warfarin without dosage instructions (n=1). Overall, medication reconciliation was completed at admission for 82 (97.6%) patients. Among patients who had medication reconciliation completed by a nurse (n=68), 54 (79.4%) had discharge instructions that contained an error(s). Among patients who had medication reconciliation completed by a pharmacy staff member (n=14), 9 (64.3%) had discharge instructions that contained an error(s). This difference was not statistically significant (p=0.377).

Conclusion: Pharmacy led medication reconciliation did not have a statistically significant effect on the quantity and severity of medication errors included on discharge instructions. Although there was no effect shown, the fact that 76.2% of patients had medication errors on their discharge instructions highlights the need that something beyond admission medication reconciliation needs to be done. This study was not powered to avoid a type 2 error since it was designed to be of a descriptive nature, so a follow-up study powered effectively would be useful to determine the clinical significance of pharmacy led medication reconciliation.

Submission Type: Descriptive Report

Session-Board Number: 7-147

Poster Title: Student-driven time study of the home medication verification process for observation patients in a community hospital setting

Primary Author: Dmitry Walker, The Ohio State University College of Pharmacy, Ohio; **Email:** walker.1684@osu.edu

Additional Author (s):
Jinhee Park
Matthew Hoover
Rebecca Taylor

Purpose: In light of the Centers for Medicare & Medicaid Services two-midnight rule, handling medications for self-administration by observation status patients is a challenge. Anecdotally, pharmacy staff observed issues with processing patient home medications, including a perceived longer verification time and medications being lost within the hospital. Nurses routinely forgot to provide medications to patients upon discharge and they were left behind for the pharmacy department to deal with. This study was created to measure the actual amount of time it takes to verify a patient's home medications, enter them into the hospital electronic medical record, assign and validate patient-specific barcodes.

Methods: A total of 84 home medication from patients in observation status were reviewed by 13 different pharmacists over a course of 33 days, as part of this study. The home medication verification process began by the pharmacist checking if the medication received from the hospital floor was ordered on the patient's profile. If so, the pharmacist would identify that the medication in the patient's bottle is authentic using a medication reference database, modify the administration instructions as appropriate per order, and create a medication label to be used in hospital. The pharmacist would then complete the medication verification, verify the barcode scanning on the label, physically label the vial, log their productivity, and send back any medications that were not able to be verified. The verification process was timed from the point when the pharmacist began reviewing the patient's home medications, which were to be considered for administration during their stay. The time it took to get the medications from the nurse to the pharmacy, as well as from the pharmacy back to the floor are not accounted for.

Results: While the verification time varied greatly by each medication in the study, the average time to verify a patient's medication from home was 4.6 minutes. It has been previously determined that, the verification process for a medication dispensed from the hospital via an automated medication cabinet is completed within 1 minute. Annualized for the roughly 4260 home medications that are verified at Marymount hospital per year, the data suggests that 328 hours of pharmacist time is utilized for home medication verification versus only 71 hours that would have been utilized had these medications been dispensed from pharmacy. Additionally, it was determined that while 26% of the medications in the time study were never successfully verified due to being expired, not being ordered for the patient, not being present in a medication database, or contamination of the package that they were stored in, these medications were responsible for 36% of the total pharmacist time from the study. This suggests that over the course of a year, 118 out of the 328 pharmacist hours being spent on home medication verification is for medications that will never be used.

Conclusion: The data obtained during this study demonstrates that a significantly larger amount of pharmacist time is needed in order to verify the patient's home medications compared to standard verification. Our findings, presented here, suggest that changing current practices in favor of not allowing home medications for observation status patients, could decrease pharmacist verification time by almost 80%. While it is important to consider the drug costs that would fall onto the institution when shielding the patients from the burden of medication costs not covered by Medicare and Medicaid, the cost of the inefficiencies of the current process can't be ignored.

Submission Category: Ambulatory Care

Submission Type: Descriptive Report

Session-Board Number: 7-148

Poster Title: Implementation of a student-led referral service at an urban free clinic

Primary Author: Mary Dembski, The Ohio State University College of Pharmacy, Ohio; **Email:** dembski.13@osu.edu

Additional Author (s):
Nira Kadakia
Anna Haas-Gehres

Purpose: Free clinics serve underserved and underinsured patients in a variety of ways. Many offer primary care medical services and pharmacy services, but not all free clinics can offer specialty services, such as laboratory draws or diagnostic imaging. To provide patients with comprehensive care, provider volunteers must often refer patients to area clinics for services not offered at their free clinic. Due to the complexity of the referral process and volunteers' unfamiliarity with services offered by each clinic, a streamlined process was needed. The purpose of this project was to implement a pharmacy student-led referral service at an urban free clinic.

Methods: Two fourth-year student pharmacists completing a longitudinal Advanced Pharmacy Practice Experience (APPE) rotation with a clinical faculty member worked to implement a new service at an urban free clinic. Services currently provided at the clinic address acute medical needs of patients and bridge care; however, the clinic does not address patients' chronic medical needs. The student pharmacists created a portfolio containing referral information for clinics to which patients at the free clinic were frequently referred for specialty services, such as diagnostic imaging. To gather the information about the clinics, the student pharmacists contacted the clinics to inquire about their processes for new patients and referring for special services. The portfolio contained pertinent information for patients, including referral forms, hours of operation, maps and photos of the location, and bus routes for nine area free clinics – more information than that traditionally available in published lists of free or reduced-cost services. The student pharmacists trained clinic staff and volunteers on what information was available in the portfolio. Clinic staff and volunteer providers were instructed to discuss relevant details and provide patients with a flyer when referring them for additional services.

Outcomes measured included the number of patients utilizing the referrals and the provider volunteer perception.

Results: One hundred twenty patients were seen during the four clinics held since implementation of the portfolio. Of the patients seen at the urban free clinic, eight were further referred to area clinics for additional services using the portfolio. Services for which patients were referred included dental services and orthopedic services. Provider volunteers, including physicians, nurses, and medical students, expressed appreciation for the accessibility and convenience of the portfolio.

Conclusion: Creating a current, comprehensive, and easily accessible portfolio of referral services improved clinic efficiency. Patients were provided more detailed and comprehensive information.

Poster Title: Adherence to HIV post-exposure prophylaxis follow-up and treatment before and after implementation of 7-day kits dispensed in a pediatric hospital emergency department

Primary Author: Nira Kadakia, The Ohio State University College of Pharmacy, Ohio; **Email:** kadakia.10@osu.edu

Additional Author (s):
Kristen Lamberjack
Linda Crim

Purpose: A 28-day course of post-exposure prophylaxis (PEP) is a preventive strategy to reduce HIV infection in youth who have experienced sexual assault. At Nationwide Children's, patients presenting to the emergency department for sexual assault receive starter kits containing a 7-day supply of tenofovir disoproxil fumarate/emtricitabine 300/200 mg and raltegravir 400 mg. Patients are asked to return to the Immunodeficiency Clinic at one week and one, three, and six months following the assault. The objective of this study was to determine if adherence to follow-up appointments and completion of PEP therapy improved following implementation of PEP 7-day kit dispensing.

Methods: Information was obtained by evaluating pharmacy records of patients who received PEP ambulatory prescriptions one year prior to implementation of 7-day kits and one year after implementation. Pharmacy records were used to determine who followed up in the Immunodeficiency Clinic at one week, one month, three months, and six months following sexual assault and who completed the entire 28 days of PEP therapy. This project is considered quality improvement by the IRB and is therefore exempt from review.

Results: Prior to kit implementation, patients would receive a one-day supply of PEP and a prescription for the remaining treatment. Forty-four percent of patients who were seen in the ED for sexual assault before kit implementation completed all 28 days of PEP therapy. Following kit implementation, 57 percent of those seen in the ED for sexual assault completed 28 days of PEP therapy. Rates of appointment follow-up increased from before implementation of the 7-day kits to after. The greatest increase was seen with the rate of completion of the one-month follow-up appointment (11.8 to 34.8 percent). Rates of no-show to all four follow-up

appointments were similar before and after kit implementation (35.3 percent vs 31.8 percent, respectively).

Conclusion: This study shows that while implementation of the 7-day kits improved rates of completion of both therapy and appointment follow-up, there remains room for improvement in rates of both. By providing education about the necessity of compliance to the medication regimen, pharmacists can play a vital role in PEP treatment and its use as a preventive measure to reduce the HIV infection in victims of sexual assault.

Submission Category: Practice Research/ Outcomes Research/ Pharmacoeconomics

Submission Type: Evaluative Study

Poster Title: A pharmacoeconomic analysis of sugammadex for reversal of neuromuscular blockade in pediatric patients

Primary Author: Dana Chavez, The Ohio State University College of Pharmacy, Ohio; **Email:** chavez.63@osu.edu

Additional Author (s):
Matthew Sapko
Michael Storey

Purpose: The efficacy of sugammadex for the reversal of neuromuscular blockade (NMB) has been well established in randomized controlled trials. No analysis in the United States has evaluated the cost savings of this agent relative to its reduction in time to recovery from NMB and the subsequent reduction in time spent in the perioperative area. International literature has suggested cost savings, but due to the significantly different costs of both drug and operating room (OR) time in the United States, a separate analysis is warranted.

Methods: A recent meta-analysis of pediatric trials using sugammadex (2-4 mg/kg) compared to neostigmine (30-60 mcg/kg) plus atropine (20-25 mcg/kg) found patients who received 2 mg/kg and 4 mg/kg of sugammadex had an faster mean return to a train of four (TOF) ratio of ≥ 0.9. This data was used to determine average time to reversal of NMB for sugammadex compared to neostigmine plus atropine. Per vial average wholesale price (AWP) for sugammadex, neostigmine, and atropine were obtained from First Data Bank through the hospital's wholesaler. Per minute OR costs were found in literature. A calculation of the cost difference of the medications and the difference in OR time was calculated. A sensitivity analysis was performed to determine the OR costs per minute at which OR time saving would no longer justify additional medication costs.

Results: Time to recovery to a TOF ratio of ≥ 0.9 was a mean of 7.15 and 17.32 minutes faster with sugammadex dosing of 2 mg/kg and 4 mg/kg respectively compared to use of neostigmine plus atropine for reversal of NMB. Per vial AWP was found to be $114.00 for sugammadex (200 mg/2 mL), compared to $95.90 for neostigmine (5000 mcg/10 mL) plus atropine (400 mcg/mL). This suggests that there is a cost difference of only $18.10 between the two medication

regimens. The calculated cost of sugammadex compared to the alternative regimen was $2.53 per minute more with 2 mg/kg dosing and $1.05 per minute more with 4 mg/kg dosing. Some literature has valued OR costs at $20 to $60 per minute, resulting in per minute cost savings ranging from $17.47 to $58.95. It is notable that these prices assume use of one 2 mL vial for each patient; if a patient required a dose using more than one 2 mL vial or the hospital pharmacy repackaged the drug to allow for one vial to be used for multiple patients, the actual drug cost for either sugammadex or neostigmine plus atropine could be different.

Conclusion: Sugammadex was found to be a cost effective choice for reversal of neuromuscular blockade in pediatric patients. While medication costs were slightly elevated using sugammadex compared to a combination of neostigmine and atropine, the significant decrease in time to neuromuscular blockade reversal warrants consideration of this agent if the time saving allows for a more efficient use of the perioperative area. The cost of these medications should continue to be monitored over time to determine if this change in practice remains warranted for any given practice site.

Submission Type: Descriptive Report

Session-Board Number: 7-151

Poster Title: Assessment of demographic predictors on viral load suppression in human immunodeficiency virus-positive patients

Primary Author: Jia-yin Shum, The Ohio State University College of Pharmacy, Ohio; **Email:** shum.14@osu.edu

Additional Author (s):
Kristen Lamberjack
Kayla Durkin

Purpose: Adherence to antiretroviral therapy is essential in achieving HIV viral load suppression. A previous Nationwide Children's study identified patients with mild to moderate depression, based on self-administered patient health questionnaire-9 (PHQ-9) scores, were at higher risk of therapy non-adherence. The purpose of this study was to assess common demographics to evaluate if they correlate to differences in adherence to antiretroviral therapy for this patient subgroup and to target patients for intervention by pharmacy, social work, and peer navigators.

Methods: This is a retrospective chart review based on a previous study conducted from January 1, 2014 to December 31, 2014. Patient information was obtained by using medical records from an electronic patient database. Patients included in the study are HIV-positive patients from the Immunodeficiency Clinic (IDC) of a pediatric institution. During clinic visits, patients were requested to fill out a patient health questionnaire-9 (PHQ-9) to assess their behavioral health status. Scores of ten to fourteen correlate with mild to moderate depression. Baseline demographics identified include age, race, socioeconomic status, therapy regimen, and filling pharmacy. Viral load was used to determine adherence to therapy. A viral load of greater than 1,000 copies per milliliter was used as a marker of medication non-adherence. This project was considered quality improvement by the institutional review board (IRB) and exempt from review.

Results: Thirty-four patients who scored between ten and fourteen on their PHQ-9 were included in this study. Evaluation of patients based on race revealed 25 patients were African American, 5 patients were white, 2 patients were Hispanic, and 2 patients indicated more than

one race. Ten out of twenty-five patients identified as African American had a viral load of greater than 1,000 copies per milliliter. One out five patients identified as white had a viral load of greater than 1,000 copies per milliliter. One out of two patients identified as Hispanic or greater than one race had a detectable viral load. There was no correlation between age, socioeconomic class, filling pharmacy or therapy regimen and viral load suppression.

Conclusion: African Americans who self-reported as mild to moderate depressed were at a higher risk of medication non- adherence and have a higher probability of a detectable viral load. However, they also represented a disproportionate percentage of patients in the evaluation group. Pharmacy, social work and peer navigator intervention may be useful in helping these patients achieve optimal outcomes.

Poster Title: Effect of removing codeine-containing medications from an inpatient formulary on outpatient prescribing practices

Primary Author: Patrik Miller, The Ohio State University College of Pharmacy, Ohio; **Email:** miller.6307@osu.edu

Additional Author (s):
Kimberly Novak

Purpose: Codeine is a common opioid analgesic pro-drug metabolized by CYP2D6 to its active form, morphine. Patients with genetic polymorphisms of CYP2D6 may be ultra-rapid metabolizers of codeine, resulting in increased morphine levels that can cause life-threatening respiratory depression. In February 2013, the FDA added a Boxed Warning stating contraindication for use as post-surgical pain management for tonsillectomy and/or adenoidectomy procedures. Codeine-containing medications were subsequently removed from the hospital formulary in October 2012, and the ban took full effect in April 2013. The present audit completed in September 2016 aimed to determine the impact of the ban on outpatient prescribing practices.

Methods: This quality improvement project was conducted at a large free-standing children's hospital. Institutional review board approval was not sought due to the quality improvement designation of this project. An initial audit was performed in September 2013 which showed that the ban was effective in eliminating inpatient prescribing and dramatically decreasing outpatient prescribing of codeine-containing medications during an April 1 to August 1 audit period: 527 prescriptions in 2012 (pre-formulary removal) to 128 prescriptions in 2013 (immediate post-formulary removal period). To assess long-term prescribing changes, inpatient and outpatient EMR dispensing records were queried for codeine-containing medications between April 1 and August 1 of the years 2014-2016 to evaluate adherence to the hospital inpatient formulary ban. The database was analyzed for duplicates, and a retrospective chart review was completed to categorize the setting in which the medication was prescribed and the indication for use. Descriptive statistics were used to present the data.

Results: No inpatient orders for codeine-containing medications were issued after removal from the hospital formulary. Outpatient prescriptions for codeine-containing medications continued to decline to 91 prescriptions in the 2014 audit period, 66 prescriptions in the 2015 audit period, and 12 prescriptions in the 2016 audit period. This represents an 87% reduction over the three years. Notably, codeine-containing prescriptions written during the audit period in the rheumatology clinic decreased from 19 prescriptions in 2014 to two prescriptions in 2016. Likewise, prescriptions from the plastic surgery clinic decreased from 51 in both the 2014 and 2015 audit periods to zero written in 2016 audit period.

Conclusion: Since removal for the inpatient formulary in April 2013, outpatient prescribing of codeine-containing medications has dramatically decreased by 98%. This suggests that an inpatient formulary ban is an effective tool for driving prescribing practices in the ambulatory care setting. This reduction in codeine prescribing has a great potential for improved patient safety within a large pediatric institution. It aligns with the hospital-wide safety culture and goal of zero preventable harm. The authors encourage other pediatric institutions to consider removal of codeine-containing medications from their inpatient formularies.

Session-Board Number: 7-153

Poster Title: The pharmacist's role in the pharmacogenetic approach to epilepsy treatment

Primary Author: Michael Baxter, The Ohio State University College of Pharmacy, Ohio; **Email:** baxter.209@osu.edu

Additional Author (s):
Shannon Yarosz
Marguerite Pietryga
Anup Patel

Purpose: It is estimated that one out of every 140 people worldwide has epilepsy, often presenting with a heterogeneous clinical presentation. When uncontrolled, seizures may lead to complications such as neurodevelopmental delays, injury, or even sudden unexplained death in epilepsy (SUDEP). Major advancements identifying genetic etiologies associated with epilepsy have recently been linked to preferable treatment regimen. The objective of this study is to describe yield of genetic testing leading to changes in treatment and the potential role of the pharmacist in the medication management of patients with epilepsy based on these findings.

Methods: Approval of this study was obtained by Nationwide Children's Institutional Review Board (IRB) prior to initiation. A retrospective chart review was performed on patients who were followed by a provider within Nationwide Children's Department of Neurology and had whole exome sequencing (WES) results available. Patients were excluded if they did not have a diagnosis of epilepsy. Each patient's WES results were reviewed to identify the presence of genetic markers of epilepsy and mutations in metabolic enzymes. If actionable genetic markers or abnormal metabolic enzymes were present, the patient's medication regimen was evaluated. For this study, actionable findings were defined as a genetic mutation where therapy change is clinically relevant. Actionable findings include pharmacodynamics parameters which affect the pathophysiology of the disease, or pharmacokinetic parameters which affect the metabolism of medications.

Results: This study reviewed 21 patients. Five of these patients (23.8%) had a definitive genetic marker of epilepsy. Another four patients (19%) had variants of unclear significance (VUS). Eight patients (38.1%) had actionable findings. Of those with actionable findings, six patients (75%) had therapy changes based on clinical factors.

Conclusion: Genetic findings may provide insight into initiating a more accurate treatment regimen earlier in therapy, prevent complications of epilepsy, and reduce adverse effects caused by ineffective anti-epileptic drugs. As we attempt to provide precise treatment to patients, genetic results will play a prominent role. This study describes the opportunity of a pharmacogenetic approach to the medication management of patients with epilepsy. As medication experts, pharmacists can play a prominent role when reviewing actionable genetic findings to identify favorable treatment options. Future work aims to analyze actionable findings of patients who receive genetic testing outside of WES.

Poster Title: Assessment of tablet splitting at a pediatric hospital

Primary Author: Mark Doles, The Ohio State University College of Pharmacy, Ohio; **Email:** doles.10@osu.edu

Additional Author (s):
Matt Sapko

Purpose: Pediatric patients often receive individualized doses which may require modification of commercially available dosage forms, such as splitting tablets. At our institution, nursing staff split tablets as necessary prior to administration. This process introduces potential for cross contamination between patients, allergic reactions if equipment is cleaned improperly, and administration errors. A recent Joint Commission survey required each patient to have an individually-labelled tablet splitter. The new policy has burdened nursing workflow and resulted in continued post-survey audit concerns. This pilot project was designed to identify tablets being split most often in an attempt to mitigate the impact on nursing staff.

Methods: This project was deemed exempt from IRB review. A report was created of all administrations at our institution involving a partial tablet from January through May 2016. Administrations were aggregated by tablet strength and evaluated on the primary measure of total number of administrations being at least 150, which equates to about one per day during the study period. All tablet strengths meeting the primary measure were assessed based on four secondary measures. Initially, the report was designed with only three secondary measures including the number of patients impacted, the estimated cost of annual waste based on AWP data from Lexi-Comp Online, and the presence of tablet scoring to ensure safe and accurate splitting. These initial measures only identified three medications for evaluation, and did not capture the heavier pill splitting workflow burden on several nursing units. Therefore, a fourth secondary measure was added post-hoc to evaluate the nursing units performing the most tablet splitting. Tablet strengths meeting at least three of the four secondary measures were individually evaluated for alternatives to nurse-driven tablet splitting.

Results: A total of 15,605 administrations, involving 265 tablet strengths and 3,142 patients, were identified. Twenty-two tablet strengths met the primary measure of at least 150 administrations in the study period and were assessed based on the secondary measures. The initial assessment only identified three medications for assessment (escitalopram oxalate 10mg, phytonadione 5mg, and clobazam 10mg). When a fourth measure was added post-hoc, an additional four medications were identified for assessment (ondansetron 4mg ODT, clonidine HCl 0.1mg, loperamide 2mg, and cyproheptadine 4mg). All 7 medications were individually evaluated and recommendations to change process included medical staff education, stocking split tablets in pharmacy, utilization of alternative commercially-available dosage forms, no process change due to lack of anticipated future need for tablet splitting, and utilization of existing compounded products.

Conclusion: Although many medications were involved in tablet splitting, a small number of tablets represented a large portion of the overall burden. A focused effort to remedy these particular 7 tablet strengths has the potential to reduce nurse tablet splitting burden by 28 percent, reduce cost of medication waste by over 80,000 U.S. dollars, and maintain Joint Commission compliance. There were a number of issues identified in this audit to be addressed in the future such as nurse splitting of hazardous and narrow therapeutic index drugs and reduced diversion potential from splitting of controlled substance tablets.

Poster Title: Evaluation of antibiotic usage within a 95-bed community hospital

Primary Author: Amanda Brenske, The Ohio State University College of Pharmacy, Ohio; **Email:** brenske.1@osu.edu

Additional Author (s):
J.D. Bickel
Patrick Owcarz
Joseph Dula

Purpose: Antibiotic resistance is growing within the United States healthcare system, causing increased rates of morbidity and mortality. Ensuring appropriate prescribing through antibiotic stewardship is essential to combat increasing antibiotic resistance. A 95-bed community hospital in Ohio has also experienced a rise in antibiotic resistance within their hospital. Anti-infective costs were well controlled from 2012 through 2014. A spike in spending in 2015 prompted this review. The primary objective of this study is to determine the appropriateness of treatment through evaluation of antibiotic usage.

Methods: Prior to data collection and evaluation, the hospital's Medical Executive Committee (functioning in its capacity as an Institutional Review Board) reviewed information tracked through the program with the intent of quality improvement of care for all patients. Data was collected by the Management Information System Department in the hospital through data mining in the computerized physician order entry system and McKesson purchasing invoices. During a previous review, linezolid, piperacillin/tazobactam, and ertapenem were found to be 33 percent of the total anti-infective cost from April 2015 to March 2016. Therefore, days of therapy were evaluated for those antibiotics over that time period. Antibiotic utilization rates in a competitor hospital of similar size and score were also used for comparison. Over that time period, there were a total of 51 linezolid cases, 532 piperacillin/tazobactam cases, and 83 ertapenem cases. We reviewed 30 randomized charts per antibiotic to assess appropriateness of antibiotic prescribing. Each review was categorized as "appropriate" or "potentially inappropriate" based on the Infectious Diseases Society of America practice guidelines, Sanford Guide to Antimicrobial Therapy, and the hospital's antibiogram. A "potentially inappropriate"

designation indicated that the antibiotic was selected for an inappropriate indication, another antibiotic would have been equally appropriate, or there was not enough information available.

Results: The hospital's utilization rates as determined by days of therapy per 1,000 patient days for piperacillin/tazobactam were significantly higher than those of a competitor hospital (P less than 0.0001). The utilization rate for linezolid was not found to be significantly higher than the competitor hospital (P equals 0.1577). Ertapenem data for comparison was not available. Upon chart review, ertapenem had the highest potentially inappropriate prescribing pattern at 76.67 percent (n equals 23). Linezolid had 56.67 percent (n equals 17) and piperacillin/tazobactam had 53.34 percent (n equals 16) of cases categorized as potentially inappropriate. Out of the 56 cases determined to be potentially inappropriate, the 55.36 percent of those were due to the availability of an equally effective or more effective antibiotic option (n equals 31). Another common cause (25 percent) was the lack of a true patient allergy to the first-line agent (n equals 14).

Conclusion: The high percentages of potentially inappropriate indications seen in our sample of prescribed linezolid, piperacillin/tazobactam, and ertapenem as well as the statistically significant elevated antibiotic utilization rate for piperacillin/tazobactam are indicators of antibiotic over-usage within the 95-bed community hospital. This presents an opportunity for an antimicrobial stewardship committee to look for ways to improve the antibiotic prescribing patterns at this hospital. As a response to these findings, a clinical alert for each antibiotic has been integrated into the computerized physician order entry system to improve antibiotic prescribing practices.

Poster Title: Effect of direct current cardioversion on total weekly dose of warfarin in patients with atrial fibrillation

Primary Author: Ethan Kuszmaul, The Ohio State University College of Pharmacy, Ohio; **Email:** kuszmaul.10@osu.edu

Additional Author (s):
Melissa Snider
Tiffany Ortman
Raul Weiss

Purpose: Current guidelines recommend stable anticoagulation [international normalized ratio (INR) goal of 2.0-3.0 on warfarin] for three weeks pre and four weeks post-direct current cardioversion (DCCV) as patients are at increased risk of clot formation post procedure. Though guidelines do not provide recommendations for INR monitoring at specific weekly intervals, common practice is to monitor INRs more frequently to minimize risk of thrombosis. The purpose of this study was to assess if increased monitoring of INRs may be warranted through examining warfarin dosing requirements before versus after cardioversion and by evaluating outcomes within 30 days immediately post-cardioversion.

Methods: The institutional review board exempted this retrospective study. Patients included in the study were on stable total weekly dose (TWD) of warfarin, enrolled in the Pharmacy Anticoagulation Management Services (AMS), and received direct current cardioversion (DCCV) between August 2015 and August 2016. Data collection utilized existing patient data in the electronic medical record. The primary endpoint was to evaluate percent change in pre- versus post-cardioversion TWD of warfarin. The secondary endpoints were to describe the presence of any major bleeds (as defined by the International Society on Thrombosis and Haemostasis) or thromboembolic events (such as stroke, deep vein thrombosis, or pulmonary embolism) within 30 days following cardioversion, and to assess the number of anticoagulation clinic visits within 30 days following cardioversion.

Results: A total of 27 patients were evaluated for this study. There were 20 males and 7 females with an average age of 65 years old and an average CHA2DS2-VASc score of 3.6. The average percent change in TWD of warfarin was minus 3.86 percent. Five patients (18.5 percent) experienced a dose increase; 12 patients (44.4 percent) experienced a dose decrease; and 10 patients (37.1 percent) experienced no change in dose. In addition, 1 out of the 27 patients (3.7 percent) evaluated experienced a major bleed within 30 days of cardioversion; however, this was unrelated to the cardioversion or warfarin. Zero patients experienced a major cardiac event. Finally, patients visited the AMS an average of 3.2 times within 30 days after cardioversion. It was noted that 7 out of the 12 patients (58.3 percent) that experienced a decrease in dose also began taking amiodarone after cardioversion and required a decrease in warfarin TWD with close monitoring.

Conclusion: This study found no consistent trend for warfarin dose increase in atrial fibrillation patients post-cardioversion. Instead, these patients typically have been stable on the same dose or have needed a dose decrease. However, many of the results regarding dosing may have been confounded by outside variables that were not taken into account before data collection, such as patient noncompliance and the initiation of other medications that affect warfarin dosing. Also, weekly monitoring of these patients immediately after cardioversion may not be necessary as the probability of experiencing a major event within 30 days following cardioversion was very low.

Submission Category: Cardiology/ Anticoagulation

Submission Type: Evaluative Study

Session-Board Number: 7-157

Poster Title: Retrospective analysis of antibiotic-associated irregular heartbeat

Primary Author: Amy Fabian, The Ohio State University College of Pharmacy, Ohio; **Email:** fabian.58@osu.edu

Purpose: The purpose of this study was to determine whether antibiotics that have the potential to cause irregular heartbeat are monitored appropriately. The first aim was to assign risk scores for developing corrected-QT interval (QTc) prolongation to patients prescribed macrolides and fluoroquinolones, and then determine whether patients who met the criteria for moderate or high risk for the development of QTc prolongation were appropriately monitored. The second aim was to determine the proportion of patients across risk groups that developed arrhythmia-related adverse events, namely QTc prolongation or ventricular tachycardia (including Torsades de Pointe (TdP)), following fluoroquinolone or macrolide antibiotic use.

Methods: The institutional review board at OhioHealth approved a retrospective, single-center chart review of 90 patients 18 years and older who received systemic macrolide or fluoroquinolone antibiotics while admitted to the critical care or intermediate/step-down units at OhioHealth Grant Medical Center (GMC) during July-September, 2015 (3 months). Charts were reviewed for risk factors associated with prolonged QTc (age $\geq$ 68 years, female sex, taking a loop diuretic, low serum potassium, admission QTc $\geq$ 450 ms, acute MI, one QTc-prolonging drug, $\geq$ 2 QTc-prolonging drugs, sepsis, and heart failure) and points were assigned for each risk factor. The points were summed, and patients categorized to one of three risk groups: low-risk (0 to 6 points); moderate-risk (7 to 10 points) or high-risk (11 to 21 points) for the development of prolonged QTc. It was then determined whether patients who met the criteria for moderate or high-risk were appropriately monitored (defined as daily QTc monitoring). The proportion of patients that developed an adverse cardiac event (e.g., prolonged QTc, ventricular arrhythmia, TdP) following administration of a macrolide or fluoroquinolone antibiotic was determined and differences were assessed across risk groups for LOS and in-hospital mortality.

Results: Of the 90 patients reviewed, 53.3% were female and the mean age was 59.5, with a standard deviation of 14.7. Calculated risk scores for the development of prolonged QTc included low (n=40, 44.4%), moderate (n=39, 43.3%), and high (n=11, 12.2%). Overall, 5 patients had appropriate QTc monitoring. Among patients who were at moderate or high-risk for the development of prolonged QTc (n=50), 4 patients (8.0%) had appropriate QTc monitoring. Overall, 7 patients (17.9%) developed prolonged QTc, 13 patients (15.3%) developed ventricular tachycardia, and no patients developed TdP during their stay. Prolonged QTc was not reported for 46 patients due to no follow-up EKG being reported. Among patients with a follow-up EKG and no prolonged QTc upon admission (n=39), 28.6% of low-risk patients, 15.8% of moderate-risk patients, and 0.0% of high-risk patients developed prolonged QTc. Overall the medium length of hospital stay (LOS) was 8.0 days (range: 1.0-68.0). The median LOS increased as the calculated risk of prolonged QTc increased; however, there was no significant difference in LOS by calculated risk of prolonged QTc (p=0.447). Overall, 4 patients (4.5%) had in-hospital mortality. Of those 4 patients, 1(25%) had a moderate risk and 3 (75%) had a high risk of prolonged QTc.

Conclusion: Of the patients who experienced prolonged QTc, none of them were in the high-risk group, indicating that the risk score may not be the best predictor of antibiotic-associated irregular heartbeat. Due to the lack of follow-up EKGs documented, further research is required to determine the validity of risk stratification. Moderate and high-risk patients were, however, associated with longer LOS and higher in-hospital mortality. GMC could improve our efforts at monitoring and documentation of EKG in patients who are prescribed fluoroquinolone and macrolide antibiotics.

Poster Title: Combination inhaled corticosteroid and long acting beta-agonist use in children less than four years of age

Primary Author: Corin Craigo, The Ohio State University College of Pharmacy, Ohio; **Email:** craigo.15@osu.edu

Additional Author (s):
Kimberly Novak
Lindsay Landgrave

Purpose: The youngest age for which a combination inhaled corticosteroid and long acting beta-agonist (ICS/LABA) inhaler is FDA approved is four years old. Although not approved in children younger than four years, ICS/LABA inhalers are recommended and used per the Expert Panel Report 3 (EPR3) asthma guidelines in those with moderate or severe persistent asthma. There are limited data regarding ICS/LABA inhaler use in this population. The objective of this study was to evaluate the use of ICS/LABA inhalers in children less than 4 years of age.

Methods: This institutional review board-approved study was a retrospective chart review of asthmatic patients who were less than four years of age on an ICS/LABA. All patients who were diagnosed with asthma, less than four years of age, and subsequently initiated on an ICS/LABA inhaler were included in this study. The electronic medical record (EMR) was utilized to identify and retrieve patient charts during the designated study period of January 1, 2011 to June 30, 2016. Identified patients were followed until they reached four years of age or until June 30, 2016, whichever came first. The primary outcome of this study was to evaluate the safety of ICS/LABA inhaler use in children four years and younger. Secondary outcomes included: identification of previous inhaler use, asthma severity at initiation, duration of ICS/LABA use, age at initiation, and the number of emergency department, urgent care, and hospitalizations before and after ICS/LABA inhaler initiation. Patient demographics were also collected. Data were evaluated using descriptive statistics.

Results: A total of 50 unique patients were identified. The average age of initiation of an ICS/LABA inhaler was 2.65 years (range: 1.14 to 3.83) and a large majority of patients (66%) were initiated on fluticasone-salmeterol 115/21 mcg. Prior to starting an ICS/LABA inhaler,

most patients were previously on either fluticasone 110 mcg (62%) or beclomethasone 80 mcg (16%). Patients were on ICS/LABA therapy for an average of 1.12 years (range: 0.01 to 2.86) before reaching four years of age. Most commonly, assessment of adverse effects was not noted in the patient chart. Four patients were noted to have experienced adverse effects including: dry cough, mood swings, aggressive behavior, and elevated blood pressure. Before beginning an ICS/LABA inhaler, patients visited the emergency department (ED) an average of 7.05 times (range: 1 to 16; 2.93 visits per year) and were admitted an average of 2.73 times (range: 0 to 11; 1.11 admissions per year). After starting an ICS/LABA inhaler, patients visited the ED an average of 2.73 times (range: 0 to 17; 2.20 visits per year) and were admitted an average of 0.73 times (range: 0 to 4; 0.716 admissions per year).

Conclusion: Use of an ICS/LABA inhaler in children less than four years of age with asthma that is not properly controlled on an ICS inhaler alone appeared to be relatively safe and effective in our population. ED visits and admissions were reduced when compared to previous controller therapy. Adverse effects were difficult to assess via chart review because the holistic review of the patient was often poorly documented in the chart. The adverse effects experienced by four of the patients in the study could also be attributed to their use of concomitant medications or their other disease states.

Poster Title: Evaluation of compliance to neuromuscular blockade protocol in the medical intensive care unit

Primary Author: Aretha Chum, The Ohio State University College of Pharmacy, Ohio; **Email:** chum.6@osu.edu

Additional Author (s):
Erin Roach
Seth Bauer
Anita Reddy
Simon Lam

Purpose: Neuromuscular blockade (NMB) agents are often initiated in the medical intensive care unit (MICU) to induce skeletal muscle paralysis in an effort to facilitate mechanical ventilation. Due to their lack of sedative and analgesic properties, we must ensure patients achieve and maintain adequate sedation and analgesia prior to and throughout NMB therapy. In September 2015, Cleveland Clinic MICU implemented an evidence-based NMB protocol to equip clinicians with a standardized treatment approach to mitigate the risk of awareness and untreated pain. We seek to evaluate staff compliance to the order set and identify potential protocol deviations and areas of improvement.

Methods: This was a non-interventional, retrospective medical chart review of adult patients admitted to the MICU who had an order placed for a continuous infusion NMB between September 2015 and September 2016. We excluded those patients who were still admitted at the time of chart review or were initiated on NMB for indications other than mechanical ventilation. The primary objective is to determine the rates of protocol compliance. Specifically, we assessed the following: 1) were patients pain-free (pain score equal 0) and adequately sedated (Richmond Agitation Sedation Scale equal -5) prior to NMB initiation; 2) did sedatives and analgesics change after starting NMB; 3) was bispectral (BIS) index monitoring utilized during NMB and 4) how was NMB managed and titrated during the course of treatment?

Results: Ninety-nine patients met our inclusion criteria during the study period. Prior to NMB initiation, 27 (27.3 percent) did not attain adequate sedation and 3 (3.0 percent) were not pain-free. At the start of paralysis, 6 patients did not have an active sedation (n equal 2) or analgesic (n equal 4) order. During paralysis, majority of patients received a fixed dose sedative (61.6 percent) and analgesia (53.5 percent) infusion, with the remainder receiving a titrated infusion. Sedative and analgesia regimens during NMB therapy were changed in 32.3 percent and 23.0 percent of the patients, respectively. Nursing initiated BIS monitoring occurred in 86 (86.9 percent) patients with a median time of 0.4 hours to the first recorded score. Changes to sedatives and analgesia during NMB therapy were rarely attributed to a high BIS score (7.4 percent). For all but 12 patients, providers ordered NMB as a variable-range continuous infusion with titration to a train of four (TOF) goal, with a set goal of 2/4 in 80 (92.0 percent) patients. TOF goals were met in 57 percent of patients. The median duration of NMB therapy was 1.3 days (range: 0.04 to 10.5) with only 16 patients requiring more than 3 days of therapy.

Conclusion: This assessment of the NMB protocol illustrated a number of potential areas of improvement. These include the management of sedation and analgesia to ensure patients receive an adequate level of sedation prior to NMB initiation and to minimize the occurrence of patients undergoing paralysis without having an active sedation or analgesia order. Additional education efforts to MICU physicians, nurses, and pharmacists are necessary to emphasize the clinical importance of each step as it relates to patient care.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Case Report

Session-Board Number: 7-160

Poster Title: Gadolinium based contrast dye induced nephrotoxicity in baseline renal impairment

Primary Author: Jacobina Maddela, The Ohio State University College of Pharmacy, Ohio;
Email: maddela.2@osu.edu

Additional Author (s):
Raquel Upshur

Purpose: Historically, the use of gadolinium-based contrast dye such as gadopentetate dimeglumine, gadodiamide, gadoteriol, and gadoversetamide have been considered non-nephrotoxic. However, case reports have demonstrated a possible association with acute kidney injury (AKI), particularly in patients with impaired kidney function at baseline. The proposed nephrotoxic mechanism of gadolinium-based contrast dye includes hyperosmolar properties causing vasoconstriction at the corticomedullary junction of the kidney, which in turn damages the regulational capacity of the kidney. This case report focuses on the potential propagation of nephrotoxicity when gadoversetamide is used in combination with other nephrotoxic agents such as vancomycin, piperacillin-tazobactam and lisinopril. A 70 year old male with a past medical history including hypertension, stage II chronic kidney disease, and prostate cancer presented with a penetrating injury to the hand. He was diagnosed with cellulitis and empirically treated with piperacillin-tazobactam and vancomycin. Vancomycin was ordered as a loading dose of 1,500 mg followed by a maintenance dose of 1,250 mg every 12 hours with a trough goal of 10-15 mcg/mL. Vancomycin was dosed appropriately per the institution's protocol based on the patient's diagnosis, actual body weight of 77.1 kg, and creatinine clearance at baseline of 68 mL/min (serum creatinine 1.1 mg/dL). On day 1, vancomycin was administered as scheduled. The patient received 15.42 mL of gadoversetamide at 1535 prior to a magnetic resonance imaging procedure. On day 2, the first vancomycin was administered 4 hours late and the second dose was administered 9 hours after the first dose. No renal labs were drawn on day 2. The trough, which was scheduled to be drawn prior to the fourth dose, resulted as 22.6 mcg/mL. No dose adjustments were made at this time because the trough was obtained only 8 hours after the previous dose. On day 3, the first dose was given 5 hours late and the second dose was given only 6 hours after the first dose. No renal labs were drawn on day 3. On day 4, vancomycin was administered as scheduled. On day 5, renal

labs were drawn, resulting in a serum creatinine of 5.6 mg/dL and a blood urea nitrogen of 30 mg/dL. Vancomycin was held due to a dramatic rise in serum creatinine. A random vancomycin level was ordered and resulted as 103.7 mcg/mL. Vancomycin was discontinued at this time as well as other nephrotoxic medications including piperacillin-tazobactam and lisinopril. The patient was switched to clindamycin and clarithromycin and fluids were administered. Four days after vancomycin was discontinued, the patient developed acute coronary syndrome which was proposed to have been associated with AKI. During the remainder of the hospitalization, serum creatinine rose to a maximum of 7.1 mg/dL and improved to 3.5 mg/dL about two weeks later. Input from nephrology supported the proposed mechanism of gadoversetamide contributing to the development of AKI. Although the source of this patient's AKI may be multifactorial in nature, precipitation of AKI as a result of gadoversetamide cannot be ruled out. Closer monitoring of the patient's renal function may have allowed for earlier detection of AKI. Although further studies are warranted to examine the relationship of gadolinium-based contrast dye and nephrotoxicity, clinicians should be judicious in monitoring patients receiving gadolinium-based contrast dye, especially when used concomitantly with nephrotoxic medications and in patients with underlying renal dysfunction.

Poster Title: Utilization of insulin glargine and insulin detemir single-use syringes in a community hospital

Primary Author: Bethany Hipp, The Ohio State University College of Pharmacy, Ohio; **Email:** hipp.30@osu.edu

Additional Author (s):
Kelly Clevenger

Purpose: Insulin glargine and insulin detemir are long-acting insulins used to treat patients with diabetes mellitus to improve glycemic control. Although they have similar efficacy in controlling basal blood glucose levels, there is a significant cost difference between the two insulins. Single-use syringes allow for cost savings by reducing waste from multi-dose vials, however dose changes and interruption in therapy can account for syringe returns and increased medication waste. The purpose of this study was to evaluate the utilization of insulin glargine and insulin detemir single-use syringes in one institution and determine a cost-effective method of distributing long-acting insulin therapy.

Methods: This medication use evaluation was a quality assurance study of all insulin glargine and insulin detemir dispenses from a central pharmacy and one decentralized pharmacy satellite at a single institution during May and June 2016. This study included single-use syringe dispenses of insulin glargine and insulin detemir for patients at least 18 years of age. The primary objective of this study was to determine the number of returned single-use syringes over a 2 month period with subgroup analyses based on medication, cartfill dispense, and time of discontinuation. Secondary objectives included cost of doses returned. A cost analysis comparing the use of patient-specific insulin pens was also completed. Dispenses were identified through a pharmacy computer-system target drug report. Data collection was performed for the quantity of syringes returned and time of order discontinuation.

Results: During May and June 2016 a total of 1744 single-use insulin syringes were dispensed (1461 insulin glargine, 283 insulin detemir) for 214 patients. 362 syringes were returned (308 insulin glargine, 54 insulin detemir). 20.76 percent of the total dispenses included in this study were returned. Insulin glargine, the more prevalent medication, had a total return quantity of

8346 units. 76.83 percent of the dispenses were prepared during cartfill dispenses at 12:30am and 12:15pm each day. The average time of dose discontinuation was at 2:16pm. The predominant reasons for dose discontinuation were dose adjustment and patient discharge.

Conclusion: Single-use syringes of insulin glargine and insulin levemir led to significant waste over a 2 month period. There can also be significant loss of productivity with continued dose changes and inconsistent utilization of the syringes dispensed. Delaying cartfill dispenses until 5:00pm may alleviate some of the waste due to dose changes or patient discharge. Narrowing the formulary to insulin glargine may allow for some additional cost savings. However, insulin pens for individual patient use were not found to be a cost-effective alternative. A larger analysis of pharmacy workflow is needed to determine an appropriate dispensing model for long-acting insulins.

Submission Category: Quality Assurance/ Medication Safety

Session-Board Number: 7-162

Poster Title: Identifying and measuring key quality indicators for a new specialty pharmacy: A pharmacy student's role

Primary Author: Lindsay Jurcenko, The University of Findlay, Ohio; **Email:** jurcenkol@findlay.edu

Additional Author (s):
Jason Glowczewski
Allene Naples
Kevin Cunningham

Purpose: Specialty pharmacy is a rapidly growing segment of pharmacy, generating around $98 billion in revenue in 2015. Starting in January 2016, a large integrated health system piloted their own specialty pharmacy primarily focusing on hepatitis C and oral chemotherapy medications. To further build the business and align quality with the goal of specialty pharmacy accreditation, a patient satisfaction study was conducted. The design of the study was to assess patient satisfaction and medication adherence with a pharmacy student leading the evaluation.

Methods: A pharmacy student created a verbal patient satisfaction questionnaire and collected data via phone interviews. Patients provided answers on a one to four scale with one indicating the patient strongly disagrees and four indicating they strongly agree. Data collection included patients who had an original prescription filled or refilled June 1st, 2016 through August 10th, 2016. The questionnaire assessed patient perception of wait time, accuracy and condition of prescriptions, likelihood of referral to a friend and staff friendliness. Medication adherence was assessed using the Proportion of Days Covered (PDC) calculation. The PDC calculation assessed patient adherence based on the number of days that the patient was in possession of all of their medication(s). The Centers for Medicare and Medicaid Services (CMS) endorse the PDC calculation over the more commonly used Medication Possession Ratio (MPR) as the primary formula for calculating patient adherence. A pharmacy technician collected data regarding financial assistance. The amounts were further categorized based upon whether they were provided through a co-pay card or a foundation.

Results: Of the 25 patients surveyed, 96% of patients responded that they strongly agreed with statements stating that wait time, accuracy, condition of prescriptions, and staff friendliness were acceptable. For the question involving likelihood of referral to a friend, 100% of patients surveyed said they strongly agreed. In quarter two, there were 29 applicable prescriptions whose corresponding PDC equaled 96% compared to the national average of 87%. In quarter three there were 13 applicable prescriptions and the PDC equaled 100%. Financial assistance amounts for quarter two equaled $30,652. As of August 10th, financial assistance amounted to $8,411 for quarter three.

Conclusion: Quality assurance measures are essential for building a successful and accredited specialty pharmacy. Pharmacy students can assist in developing and accelerating data collection as well as calculating and interpreting the measurable results.

Poster Title: Comparison of creatinine clearance formulas for predicting vancomycin dosing intervals

Primary Author: Bryce Adams, The University of Findlay, Ohio; **Email:** adamsb@findlay.edu

Additional Author (s):
Jay Lynch
Ryan Schneider
Sara Jordan

Purpose: There are several methods that can be used to estimate glomerular filtration rate (GFR), including the Cockcroft-Gault (CG) equation; the modified CG equation using a rounded serum creatinine (Scr), ideal body weight, and adjusted body weight; the Modification of Diet in Renal Disease (MDRD) equation, and the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation. No single method has been identified as the optimal method to guide medication dosing, although the CG method is most frequently cited as a guide. The purpose of this study is to determine which GFR estimate most accurately predicts vancomycin dosing requirements.

Methods: The institutional review board approved this retrospective, single-center chart review of 957 patients who were administered vancomycin during their stay at OhioHealth Grant Medical Center between March 2015 and May 2015. 297 patients met the inclusion criteria, which was 18 years of age or older, patients being treated for a suspected or documented gram positive infection, and patients with at least one valid steady-state serum vancomycin concentration. Exclusion criteria consisted of patients receiving greater than 4 grams of vancomycin per day, patients receiving other nephrotoxic drugs (e.g., aminoglycosides, amphotericin, contrast dye), end-stage renal disease, receiving continuous renal replacement therapy, estimated creatinine clearance < 16 mL/min, unstable renal function (>0.3 mg/dL difference in serum creatinine from baseline to time of kinetic study), neoplastic disorder, transplant patients, major limb amputees, paraplegia or quadriplegia, or institutional guidelines for vancomycin dosing not followed (e.g., interval ordered was not appropriate or vancomycin levels not timed appropriately) which narrowed the patient list to 58. The dosing intervals predicted by each creatinine clearance (CrCl) estimation formula were

compared to the proportion of patients for whom the predicted dosing interval selected is consistent with the actual vancomycin dosing interval requirements based on a valid kinetics study. A chi-square analysis was conducted to determine if each of the various CrCl estimation formulas were significantly different than the original dosing intervals.

Results: The original dosing interval selected resulted in correct dosing in 18 of 58 patients, or 31.03 percent. Each of the estimates resulted in correct dosing regimens as follows: Cockcroft-Gault, 16 of 58, 27.59 percent; the modified CG using a rounded serum creatinine of 0.8, 12 of 58, 20.69 percent; the modified CG using a rounded serum creatinine of 1, 11 of 58, 18.97 percent; the modified CG using Ideal body weight, 20 of 58, 34.48 percent; the modified CG using adjusted body weight of 0.3, 15 of 58, 25.86 percent; the modified CG using adjusted body weight of 0.4, 13 of 58, 22.41 percent; the Modification of Diet in Renal Disease (MDRD), 20 of 58, 34.48 percent; and the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI), 21 of 58, 36.21 percent. A chi-square analysis was utilized to determine whether or not any of the creatinine clearance estimates were significantly superior to the original dosing interval. While some of the estimates were superior and others inferior, none of the estimates were significantly different compared to the original selected dosing interval.

Conclusion: This study shows that vancomycin dosing needs to be improved. Correct dosing is essential to treat the infection and prevent adverse reactions. Of the patients who were included in this study, only 31.03 percent of them were dosed correctly. While this study didn't result in significantly superior dosing guidelines, using the Chronic Kidney Disease Epidemiology Collaboration estimate may result in more predictable dosing intervals. Additional studies are needed to improve dosing guidelines that will result in more predictable vancomycin dosing.

Poster Title: Pharmacist evaluation of antibiotic discharge prescriptions from a pediatric emergency department for dose optimization and error diversion

Primary Author: Tresa Binek, The University of Findlay: College of Pharmacy, Ohio; **Email:** swatzelt@findlay.edu

Additional Author (s):
Jenny Mason

Purpose: Pediatrics are a high-risk patient population that are more likely to be subject to medication errors as shown through an in depth literature review which revealed medication errors are up to three times more likely to occur in prescriptions written for pediatric patients, especially antibiotics and pain medications. This retrospective review was designed to analyze appropriateness of antibiotic therapy in discharge prescriptions in a pediatric emergency department. The outcomes of this study could identify and justify a pharmacist's role in the discharge process by positively impacting medication optimization, reducing prescribing errors, and ultimately improving the cost and quality of care.

Methods: This study was a retrospective chart review from March through June 2016 that evaluated all discharge prescriptions for a pediatric emergency department (ED), which was exempt from IRB approval. A 2-week sub analysis evaluated oral antibiotics during June 2016. Data collected included age, sex, weight, antibiotic prescribed, formulation, dose, frequency, duration, indication, prescriber, and credentials. Once the data was collected a board certified pediatric clinical pharmacist analyzed antibiotic prescriptions to identify any medication errors and/or opportunities to optimize therapy. Errors and therapeutic optimizations were categorized based on error and optimization type in order to identify severity of error, optimization opportunities and any prescribing trends. This data was used to analyze the potential impact of a new pharmacy service in the pediatric emergency department, one that will be designed to ensure safe and effective care for pediatric patients upon discharge.

Results: Over 17,000 discharge prescriptions were generated during this 4-month period. A sub-analysis of only oral antibiotics prescriptions during the first two weeks in June evaluated a total of 471 discharge prescriptions with 45 excluded due to discontinuation prior to discharge or duplicate prescriptions. Duplicates occurred whenever a prescription was printed and then later sent electronically to a pharmacy. This left 426 prescriptions to be included for error and dose optimization evaluation. Errors were identified in 4 percent of prescriptions (N=18) for a total of 23 medication errors which were 57 percent dose, 30 percent frequency, and 13 percent formulation errors. None of these errors had a great severity, but several were subtherapeutic. About 25% of prescriptions (N = 105) were identified for opportunities for dose optimization with a total of 118 optimizations, these included 53 percent dose, 41 percent frequency, 3 percent formulation, and 3 percent duration optimizations. About 53% of opportunities for optimization occurred in the first week compared to the second week. The most frequent occurrences were subtherapeutic or supratherapeutic dosing for skin and soft tissue infections and supratherapeutic doses for urinary tract infections.

Conclusion: This study demonstrated that approximately 1 of every 4 antibiotic prescriptions written in the pediatric ED had the opportunity for optimization that included dose, frequency, formulation, and duration. Pharmacist review of discharge prescriptions could provide better patient care and possibly prevent additional ED or primary care encounters. Optimization could also help prevent future hospitalizations due to sub therapeutic treatments. For a pharmacist to verify all discharge prescriptions from the ED, this would be a substantial cost. Future studies could evaluate justification for additional pharmacists from cost savings associated with additional healthcare encounters.

Submission Type: Evaluative Study

Session-Board Number: 7-165

Poster Title: Assessment of opiate utilization and cost patterns in a university-affiliated health system employee population

Primary Author: William Wilhelm, The University of Toledo College of Pharmacy and Pharmaceutical Sciences, Ohio; **Email:** william.wilhelm@rockets.utoledo.edu

Additional Author (s):
Anik Patel
Kulvinder Nagra
Kyle Sarahman
Cindy Puffer

Purpose: Use of opiate medications for acute and chronic pain conditions is a pressing topic today due to increasing concern about abuse, misuse, and diversion. In employer-based health plans, there is interest in identifying potential areas of intervention for pharmacists to assure appropriate and effective pain medication use. The purpose of this analysis was to describe the cost and utilization patterns of opiate-based medications in a university-affiliated employee health plan and to identify potential areas of pharmacist intervention.

Methods: Prescription claims for all opiate-related medications were obtained for all members of an employee health plan of a Midwest university-affiliated health system from 8/29/15 to 8/29/16. Medications were assigned to the following opiate subgroups: short-acting; short-acting combination; long-acting; tramadol-based; injectable/sublingual/nasal spray/patch. Prescriber specialties were determined based on the Centers of Medicare and Medicaid Services listings and categorized into twenty different specialty categories consisting of, but not limited to; dental, internal medicine, emergency medicine, family medicine. Cost data were determined, which included cost to the plan, cost to the patient, in the form of a copayment, and total cost. All data were entered and analyzed using Microsoft Access.

Results: There were 4429 total prescriptions for opiate medications filled by 1674 members. This represented 15 percent of the total health plan population; 60 percent of the opiate utilizing members were female. The total cost of opiate medications was $110,669.74, consisting of $77,901.94 plan cost and $32,767.80 patient cost. The most commonly prescribed

opiates were the short-acting combination formulations (n = 2704; 61 percent), followed by tramadol-based medications (n = 810; 18 percent) and short-acting single formulation opiates (n = 698; 16 percent). Of utilizing members, 42 percent filled more than one prescription for an opiate medication during the one-year study period and 28 percent had opiate prescriptions written by more than one prescriber; 9 percent had prescriptions by more than three providers. Opiate prescriptions were most often written by family medicine providers (n = 847 prescriptions; 19 percent). The mean total days supply for opiate medications was 41 days. However, 7.6 percent of the utilizing members had a total days supply of opiate medications of more than 180 days; for these members, the mean total days supply was 325 days in the one-year study period.

Conclusion: In a relatively small university-affiliated employee health plan, there was a substantial utilization of opiate medications, including some members with high total prescription volume and number of prescribers. While this analysis did not include diagnostic data, the pharmacy team will explore opportunities to identify therapeutic areas for medication therapy management and patient or provider education to support the appropriate use of opiates and other pain mitigation strategies.

Submission Type: Descriptive Report

Session-Board Number: 7-166

Poster Title: Standardization of documentation for clinical and administrative interventions completed by pharmacists to assist in performance evaluations

Primary Author: Jignasha Patel, The University of Toledo, College of Pharmacy and Pharmaceutical Sciences, Ohio; **Email:** jignasha.patel@rockets.utoledo.edu

Additional Author (s):
Lori Rose

Purpose: As the pharmacist's role has evolved to include more direct patient care, performance evaluations continue to lag behind, still dependent on objective factors such as medication dispensing accuracy rather than factors related to interactions with patients and healthcare providers. In a community hospital, pharmacists utilize Epic systems for documentation of interventions. These interventions are used as a measure of productivity and in performance evaluations for pharmacists. There is concern, however, for the lack of continuity in documentation. The primary objective of this study is to quantify and describe interventions documented by pharmacists to determine if standardization of documentation is required.

Methods: Pharmacists working in the in-patient medical center were provided with a survey via email to assess the variability in pharmacist documentation of interventions through Epic. This survey included basic demographic information and used four in-patient scenarios in which the pharmacists were required to list all pertinent interventions they would document in each situation. The scenarios represented real-life pharmacist-patient or pharmacist-other healthcare provider interactions that would necessitate the pharmacist to make an intervention. The responses were free text, allowing for the respondent to treat the scenario as they would in their daily work day. The survey remained open for one week, with a reminder sent out one day prior to survey closure. In addition, interventions documented via the Epic system by pharmacists between July 1, 2016 and July 7, 2016 were evaluated and categorized to determine the different types of interventions performed by pharmacists when presented with similar situations. The results of both the survey and data analysis were then used to develop a list of specific interventions applicable to patient scenarios in an effort to standardize documentation among pharmacists.

Results: Twenty-five out of forty pharmacists completed the study. In patient scenario one, there was one unique response in which one pharmacists described two interventions they would document. The remaining respondents choose a single identical intervention. For patient scenario two, there was a greater variation in response, with pharmacists choosing to document anywhere from one to four separate interventions. However, patient education/counseling and pharmacy dosing consult interventions were chosen by the majority of respondents. In the third patient scenario, interventions for profile review-extensive and patient education/counseling were selected most commonly. Ten pharmacists chose to also document one additional intervention (medication reconciliation or coordination of care). The final patient scenario found that all pharmacists chose drug therapy recommendation, but the additional interventions selected varied with a total of fifteen unique responses. The data analysis of Epic from July 1, 2016 to July 7, 2016 generated a total of 3974 interventions. There were forty-five different intervention categories documented by pharmacists and the top 10 iVents consisted of therapeutic drug monitoring, renal dose monitoring, profile review (extensive), profile review (standard), non-formulary/restricted drug, pharmacy dosing consult service, chemotherapy order review, patient counseling/education, drug therapy recommendations, and core measures.

Conclusion: The performance evaluation process is intended to encourage constructive dialogue between employee and supervisor and is used to build upon strengths while also identifying areas of improvement that will allow the employee to be more effective and efficient. While the impact pharmacists have on patient care is ultimately a subjective matter, the utilization of intervention documentation in Epic serves an important objective role in evaluating pharmacist performance. Therefore, standardization based on patient-cases would be beneficial in maintaining consistency in performance evaluations.

Poster Title: Med-pharm union: flipping the script on inter-professional development

Primary Author: Craig Furnish, University of Cincinnati James L Winkle College of Pharmacy, Ohio; **Email:** furniscj@mail.uc.edu

Additional Author (s):
Dylan Barth
Gabriel Pham

Purpose: Collaboration and communication between healthcare professionals of different disciplines has become increasingly important in providing excellent patient care and improving patient outcomes. Although inter-professional accreditation standards exist for colleges of pharmacy, students often desire more opportunities to interact with their health professional colleagues. The purpose of Med-Pharm Union is to enhance pharmacy and medical students socially, scholastically, and professionally. This project expands upon current inter-professional activities and provides pharmacy and medical students with avenues to collaborate in and out of the classroom. The ultimate goal is to aid in the development of versatile, integrative, and empowered practitioners.

Methods: Two student leaders, one from pharmacy and one from medicine, met to evaluate if formation of an inter-professional organization would be possible. After deliberation, it was decided to assemble a team of student leaders from each respective college. Student leaders were appointed based on their ambition, organizational involvement, and innovative mindsets. The inaugural board consisted of five students from both the colleges of pharmacy and medicine. Meetings were held on a monthly basis with oversight from two faculty advisors. Each meeting was aimed at identifying mechanisms to facilitate cooperation and collaboration between the students of the two disciplines. Due to the incorporation of key stakeholders from student organizations, Med-Pharm Union was able to seamlessly promote inter-professional activities.

Results: Med-Pharm Union promoted and encouraged intercollegiate participation in events hosted by existing student organizations from both the medical and pharmacy colleges. The scopes of these events ranged from social (volleyball tournament), to scholastic (partnership

pairing), to professional (organ donation challenge). Moreover, other student organizations gained from the advent of Med-Pharm Union too. Over ten events were enhanced as a direct result of Med-Pharm Union, with more on the horizon. Participation in events, along with fundraising, improved with the increased reach to students. Finally, Med-Pharm Union was well received by both student bodies, gaining official recognition from each college's student governments.

Conclusion: Med-Pharm Union has been a great addition to the University of Cincinnati Academic Health Center and is a model that can be reproduced at other academic medical centers across the country. In the future, incorporation of the colleges of nursing and allied health sciences is desired.

Submission Category: Ambulatory Care

Submission Type: Evaluative Study

Session-Board Number: 7-168

Poster Title: Evaluation of the timing of a pharmacist-driven group smoking cessation program for women at a federally qualified health center

Primary Author: Nicole Clay, University of Cincinnati James L. Winkle College of Pharmacy, Ohio; **Email:** clayns@mail.uc.edu

Additional Author (s):
Bethanne Brown
Jonathan Burns

Purpose: The Cincinnati Health Department (CHD) partners with a local non-profit Cradle Cincinnati to reduce smoking rates of pregnant women. Hamilton County ranks in the bottom 10 percent of counties for fetal demise. This project was developed to determine the interest in group smoking cessation classes with current smokers and the timing of these classes from a diverse socioeconomic and cultural patient population.

Methods: The institutional review board approved this needs assessment. Survey takers were selected from one CHD site. One hundred patients were asked to complete the survey while in the waiting area. Male and female patients over the age of 18 were selected, as were both smokers and non-smokers. Only smokers were asked what type and how much tobacco was used, their readiness to quit on a scale of 1 to 10, and what type of intervention would they prefer to use. All respondents were asked the time of day that they are most available and how often would they want the class to meet.

Results: Of the 100 people surveyed, 33 were smokers, all of which used cigarettes, one additionally e-cigarettes and one also used cigars. The median amount of use was 0.5 cigarette packs per day. The median readiness to quit was 10 out of 10. 23 smokers wanted to use medications, 14 selected one-on-one sessions, 13 selected group sessions, 12 selected phone call or text message, and 4 selected quit line. The most common time of day available was evening (49) followed by morning (23). The preferred frequency to meet was weekly (45) followed by every other week (27).

Conclusion: Based on the results of the needs assessment, the Cincinnati Health Department will be implementing an option for group smoking cessation classes. The other four options are already offered by providers at the clinics. The classes will be in the evening every week. Further studies will evaluate the effectiveness of the group classes for this patient population.

Submission Category: Ambulatory Care

Submission Type: Descriptive Report

Session-Board Number: 7-169

Poster Title: Integrating pharmacy services in an accountable care organization

Primary Author: Hanna Burgin, University of Cincinnati James L. Winkle College of Pharmacy, Ohio; **Email:** burginhm@mail.uc.edu

Additional Author (s):
Ana Hincapie
Kelly Epplen

Purpose: Interprofessional collaboration is becoming a commonly used model in every aspect of care to promote patient-centered care. Studies show that utilizing pharmacists improves disease management, increases patient and provider satisfaction, and advances patient outcomes. There is an anticipated shortage of primary care health care providers in the future and pharmacists can contribute by filling that void. The purpose of an Accountable Care Organization is to improve quality and diminish health care costs by developing a network of clinicians and hospitals that focus on financial and clinical outcomes. This report describes the incorporation of pharmacy services into an accountable care organization.

Methods: A number of physician networks in the United States were selected to participate in the Centers for Medicare and Medicaid Services Comprehensive Primary Care Initiative program. This was a four-year multi-payer program that offered population-based care management fees and shared savings opportunities to participating primary care practices that focus on five comprehensive primary care initiatives. Incorporation of pharmacy services into these system initiatives allowed for development of the following projects through collaboration between the University of Cincinnati and Saint Elizabeth Physicians Ambulatory Pharmacy Resource Coordinators: evaluation of provider use of high risk medications in the elderly, evaluation of medication adherence, evaluation of the management of chronic obstructive pulmonary disease exacerbations, and evaluation of the management of osteoporosis. High risk medications prescribed to the elderly were identified and an electronic intervention including therapeutic alternatives was developed to notify physicians. Improving management of chronic obstructive pulmonary disease exacerbation entailed identification of system adherence for diagnosed adults who received both a systemic corticosteroid within fourteen days and a bronchodilator within thirty days of discharge. Evaluation of adherence to

medication adherence quality measures was performed. Pharmacy collaborated with social work to administer and evaluate adherence questionnaires for eligible patients. Measurement of adherence to the osteoporosis measure entailed identification of patients presenting with a fragility fracture who received appropriate screening for osteoporosis or who had been initiated on osteoporosis medications.

Results: As a result of collaborating with other health care professionals, forty-two patients receiving health care from eighteen physicians successfully discontinued a high risk medication. The primary focus was on five high risk medications: cyclobenzaprine, glyburide, digoxin, amitriptyline, and promethazine. Based on data collected cyclobenzaprine and glyburide proved to be the easiest medications to change; therefore, future interventions will target them specifically. Sixteen out of forty-six clinical encounters for patients not meeting criteria for chronic obstructive pulmonary disease resulted in spirometry requests or medication changes. The medication adherence initiative with social work promoted adherence techniques within the workflow of seven different social workers and identified patients with potential barriers in addition to providing solutions to increase medication adherence. Eighteen patients with a fragility fracture who met the criteria for osteoporosis screening or treatment were identified. Notifications were sent to physicians to notify them of patients at risk for developing osteoporosis or osteoporotic fractures. Each initiative proved to have a positive effect on quality of care.

Conclusion: Incorporating pharmacy services into an accountable care organization has demonstrated to improve quality of care, patient satisfaction, and therapeutic outcomes. The value and utilization of pharmacists as part of an interprofessional care team is only increasing as demonstrated by the Saint Elizabeth Physicians Pharmacy Team. These initiatives successfully improved patient-centered care and continued execution will benefit patients as well as health care networks.

Poster Title: Impact of pharmacists' post-discharge follow-up intervention on the prevention of medication-related readmissions

Primary Author: Karly Low, University of Cincinnati James L. Winkle College of Pharmacy, Ohio; **Email:** lowkm@mail.uc.edu

Additional Author (s):
Kayla Leidenbor
Marcie Malone

Purpose: Medication errors occurring upon hospital discharge increase the risk of re-hospitalization within 30 days. Pharmacist intervention in transitional care has the opportunity to reduce such rates. The purpose of this study was to evaluate the impact of pharmacist led post-discharge follow-up and its role in the prevention of medication-related acute care episodes (MACEs) in a community hospital setting.

Methods: This study was a retrospective analysis of post-discharge follow-up interventions specific to UC Health – West Chester Hospital during a 6-week time period. Results from this single site were part of a larger research analysis conducted by Cedars-Sinai Medical Center in Los Angeles, California. Upon hospital admission, a pharmacy led medication history and reconciliation (MH&R) was routinely conducted for patients admitted through the emergency department. Patients with a completed MH&R were identified during the study period for post-discharge follow-up. Follow-up occurred within 72 hours of hospital discharge and included pharmacist review of prior to admission medications, hospital medications and physician discharge instructions. Pharmacist identified drug related problems (DRPs), including medication errors or discrepancies, were resolved with the discharging physician and a follow-up call was arranged with the patient. Patient contact certified that new medications were acquired and initiated as instructed and education was provided as needed. Identified DRPs were retrospectively classified by severity using the modified National Coordinating Council for Medication Error Reporting and Prevention (mNCC MERP) scale. A team of pharmacists and two physicians reviewed DRPs to determine if a MACE was prevented by pharmacist follow-up along with the likelihood of hospital readmission. Outcome measures included number of identified DRPs and MACEs, DRP severity, readmission likelihood and the percentage of MACEs

prevented. Secondarily, readmission rates and patient demographics were collected and examined.

Results: A total of 121 patients were identified for post-discharge pharmacy intervention and were included in this analysis. A total of 66 patients (54.5 percent) had a post-discharge review completed, with a follow-up call completed for 53 patients (43.8 percent). During the study period, the pharmacy team identified 39 DRPs and 37 MACE cases. Of the 39 DRPs, 3 were classified as life threatening, 34 as severe and 2 as a low capacity for harm. Once reviewed by a physician, the readmission likelihood of each MACE was categorized into very likely, somewhat likely, and not likely as 25, 6, and 6, respectively. Overall, 47.2 percent of MACEs were prevented with pharmacist post-discharge follow-up.

Conclusion: Pharmacist discharge medication reconciliation and review results in identification and prevention of possibly harmful DRPs. Although intervention was conducted with a limited sample of patients, the study results suggest that pharmacist discharge services can have a potentially significant impact on the reduction of 30-day health system readmission rates.

Poster Title: Financial impact of implementation of pharmacy technician driven medication history program in a community hospital

Primary Author: Dylan Barth, University of Cincinnati James L. Winkle College of Pharmacy, Ohio; **Email:** barthda@mail.uc.edu

Additional Author (s):
Kayla Leidenbor
Marcie Malone
Kevin Brooks

Purpose: Medication errors not only have the ability to harm a patient, but they also add additional health care expense. One way to minimize medication errors is through the use of extended pharmacy services such as medication histories, however, this process does come with a cost. The purpose of this study was to compare the cost of implementation of a pharmacy technician driven medication history program to its benefits through the avoidance of medication related errors.

Methods: This study was a non-randomized, retrospective cost-benefit analysis completed at a 180 bed community hospital over a three-month period, February 2016 - April 2016. This study has been approved by an institutional review board. Patients were included for review if they had their medication history completed on admission by a member of the medication reconciliation team, which included both pharmacists and technicians. Patients with incomplete data records during the study time period were excluded. Items not classified as medication were also excluded. As a part of the standard of care at our institution, interventions were documented manually for reporting purposes. Interventions were then evaluated retrospectively to determine the cost avoidance of a potential adverse drug event (ADE). Medication histories completed by another health care professional, then re-reviewed by the pharmacy medication reconciliation team, were analyzed. This was done by multiplying a preassigned probability of adverse advent, based on drug class, by the cost of an ADE. The summation of all products were then compared to the cost of running the program to determine if the implementation of the program renders a positive cost benefit ratio. Additional data collected included patient demographics, type of medication modification, time

to complete a mediation history, number of allergies clarified, and medication list status (e.g. complete, incomplete).

Results: A total of 1,294 medication histories were completed during the study period with 6,302 modifications made to the medication lists and 1,240 allergies clarified. Of those medication histories, 399 (30.8%) were completed by another healthcare professional then re-reviewed by the pharmacy team prior to the patient's admission. The medication modifications made in this group totaled 1,065, of which 906 were included in the cost-benefit analysis. The results of the cost-benefit analysis demonstrated a ratio > 1, thus proving to be a valuable process during the study time period.

Conclusion: Implementation of a pharmacy technician driven medication history program was found to be a valuable process after undergoing a cost-benefit analysis. Even after review by another healthcare professional, over thirty percent of medication lists need modification which put patients at an increased risk of ADE's. Further review of standard medication history processes is warranted.

Poster Title: Investigating depression, suicidal risk, and seizure disorder with varenicline and bupropion: a retrospective FDA Adverse Event Reporting System database study

Primary Author: Alan Moyer, University of Cincinnati James L. Winkle College of Pharmacy, Ohio; **Email:** moyerap@mail.uc.edu

Additional Author (s):
Jeff Guo
Patricia Wigle

Purpose: Counseling and smoking cessation medications can double the chance a smoker who tries to quit will succeed. In 2006, after varenicline (Chantix) was approved, providers and patients began reporting adverse events, including depression and suicidal risk, to the FDA Adverse Event Reporting System (AERS) database. Rare occurrences of seizures were also reported in patients who had no prior history or who had a seizure disorder which was controlled. The purpose of this project was to analyze the percent total of reported adverse events and compare annual trends from the FDA AERS database between varenicline and bupropion.

Methods: Using a descriptive retrospective study design, the FDA AERS data from 1997 to 2016 was extracted to analyze and compare the percent of depression, suicidal risk, and seizures reported among patients taking varenicline, bupropion, and nicotine replacement products (gum, lozenge, patch). Nicotine replacement products served as the comparison group due to infrequent reports for these adverse events in the published literature after decades of both prescription and over-the-counter availability.

Results: A total of 294,024 adverse events were reported to the FDA AERS database including 145,163 for varenicline, 59,891 for nicotine replacement products, and 88,970 for bupropion. Varenicline had the highest percent of depression (5.33%), suicidal ideation (2.50%), and suicide attempt (1.92%) reported, compared to bupropion (1.24%, 0.68%, and 0.29%) and nicotine replacement products (0.68%, 0.29%, and 0.08%), respectively. However, bupropion had the highest percent of seizures reported (0.04%) followed by nicotine replacement products (0.03%) and varenicline (0.02%).

Conclusion: Varenicline had the highest percent total of reported adverse events for depression and suicidal risks compared to bupropion and nicotine replacement products. These findings are in contrast to those in recent published literature. Interestingly, the percent of reported seizures with varenicline was lower but the overall number of events was higher. This was due, in part, to the much higher overall total adverse events reported with varenicline therapy. Interpretation of these findings must take into account certain limitations related to database mining research. Further pharmacoepidemiologic studies are warranted.

Poster Title: Utilizing the FDA Adverse Event Reporting System database to investigate musculoskeletal adverse events which are more prone with a fluoroquinolone

Primary Author: Ashley Yost, University of Cincinnati James L. Winkle College of Pharmacy, Ohio; **Email:** yostam@mail.uc.edu

Additional Author (s):
Alan Moyer
Jeff Guo
Patricia Wigle

Purpose: Antimicrobial stewardship of fluoroquinolones is crucial as resistance patterns emerge and their toxicity profile becomes more defined. In May 2016, the FDA advised restricting fluoroquinolone use for certain uncomplicated infections due to reports of disabling side effects that can involve the tendons, muscles, joints, and central nervous system. These serious side effects outweigh the benefits for patients with uncomplicated infections. The purpose of this study was to describe annual trends from the FDA Adverse Event Reporting System (AERS) database associated with each fluoroquinolone.

Methods: Using a descriptive retrospective study design, adverse event data from 1997 to 2016 was extracted from the FDA AERS database to analyze the percent total of reported adverse for tendonitis, tendon rupture, joint swelling, and hallucinations reported among patients taking ciprofloxacin (Cipro), gemifloxacin (Factive), levofloxacin (Levaquin), moxifloxacin (Avelox), and ofloxacin (Floxin).

Results: A total of 294,024 adverse events were identified including 258,451 for ciprofloxacin; 2,489 for gemifloxacin; 317,560 for levofloxacin; 123,231 for moxifloxacin; 16,582 for ofloxacin. Levofloxacin had the highest percent of reported tendonitis (0.49%) and tendon rupture (0.47%), compared to ciprofloxacin (0.26% and 0.16%), gemifloxacin (0.12% and 0.20%), moxifloxacin (0.22% and 0.17%), and ofloxacin (0.40% and 0.15%), respectively. Levofloxacin had a gradual increase in reported cases of tendonitis, tendon rupture, joint swelling, and arthralgia from 1998 – 2012, but the adverse events dropped suddenly in 2013 (tendonitis: 264 to 79; tendon rupture: 255 to 74; joint swelling: 110 to 24; arthralgia: 349 to 97). Additionally,

the highest reported cases of hallucinations was for ciprofloxacin (n = 275) and levofloxacin (n = 279) compared to gemifloxacin (n = 14), moxifloxacin (n = 188), and ofloxacin (n = 16).

Conclusion: Fluoroquinolones are widely used, in part, due to their broad spectrum of antibacterial activity. Levofloxacin had the highest percent total of reported adverse events for tendonitis and tendon rupture compared to ciprofloxacin, gemifloxacin, moxifloxacin, and ofloxacin using the FDA AERS database. In 2013, the total amount of adverse events for tendonitis, tendon rupture, joint swelling, and arthralgia did decrease for levofloxacin. This may have been due to the addition of a FDA warning regarding an increase in incidence of musculoskeletal disorders and/or more judicious use of fluoroquinolones based on resistance patterns and changing clinical guidelines.

Poster Title: Determining resident physicians concerns in selecting an anti-depressant medication using best-worst scaling surveys

Primary Author: Lars Almassalkhi, University of Cincinnati James L. Winkle College of Pharmacy, Ohio; **Email:** almasslr@mail.uc.edu

Additional Author (s):
Joe Welch
Patricia Wigle
Ana Hincapie
Chris White

Purpose: The goal of this project was to explore factors most and least concerning to resident physicians when selecting an anti-depressant medication for their patients. The ultimate goal is to integrate patient surveys from the same practice and use these data to create a shared decision making tool to give the patient a part in medication selection based on their specific concerns.

Methods: A Best Worst Scaling (BWS) survey was conducted to assess the relative importance of 11 anti-depressant therapy attributes, each comprised of two levels, to medical residents in a family practice center. BWS is a type of stated-preference choice model commonly used to assess individuals' priorities. Attributes explored include medication costs, the ability to continue therapy in older age, and side effects such as the ability of the medications to cause weight gain, insomnia, somnolence, sexual dysfunction, nausea, diarrhea, constipation, drowsiness, hypertension, and the presence of a discontinuation syndrome. Resident physicians in family medicine and psychiatry programs were asked to evaluate 12 sets of 6 attributes and select the least and most concerning attribute in each set. The number of times an attribute level was selected as the most concerning and the least concerning was summed across the 12 sets. The mean score was estimated by dividing the most concerning minus the least concerning divided by the number of times an attribute level appeared in the 12 sets. This project was exempted from IRB approval.

Results: Twenty-one resident physician surveys were collected and analyzed. Residents in the family practice program represented 80% of respondents and family/psychiatric medicine represented the remaining 20%. Half of the respondents were first year residents, 20% were second year residents, and 30% were third year residents. Attributes were examined using count analysis to assess the ones that were the most and least concerning to resident physicians when selecting an antidepressant medication. The most concerning attributes were "Medication causes weight gain in 1 of 4 patients" (+0.72) and "Medication causes sexual dysfunction in both men and women" (+0.62) while the least concerning were "Medication will need to be changed or discontinued when you turn 60 years of age" (-0.65) and "Medication can be continued when you are older" (-0.52).

Conclusion: This study demonstrates how BWS surveys can be utilized as a tool for practitioners to accurately elicit what they perceive is the most and least concerning attributes in selecting an antidepressant medication. BWS surveys eliminate the bias found in regular "high-low" surveys and accurately ranks all the items, not just the extremes. Finally, these data can be incorporated with patient surveys to identify gaps in understanding and importance of attributes that can be bridged through medication counseling by a healthcare provider such as a pharmacist.

Poster Title: Optimizing unfractionated heparin dosing for acute coronary syndrome in obese adults

Primary Author: Tyler Bosley, University of Cincinnati, James L. Winkle College of Pharmacy, Ohio; **Email:** bosleyte@mail.uc.edu

Additional Author (s):
R.J. Frey

Purpose: The 2014 American Heart Association/American College of Cardiology Guideline for the Management of Patients With Non–ST-Elevation Acute Coronary Syndromes recommended initial unfractionated heparin dosing of 60 IU/kg (maximum 4000 IU) with initial infusion of 12 IU/kg per hour (maximum 1000 IU/h) . This recommendation often times is not sufficient to achieve therapeutic aPTT or Anti-Xa levels in obese patients. The purpose of the current abstract is to utilize retrospective analysis to determine if a more aggressive initial dosing regimen is warranted for acute coronary syndrome anticoagulation in the obese population based on required heparin doses over a 6 month period.

Methods: The study has been IRB approved. Data collection occurred at a community medical center. An Epic orders report was ran for unfractionated heparin ordered over a six month time period. Data consolidation was performed, accepting only orders with a patient weight greater than 85 kilograms, combining duplicate orders, and combining duplicate patients during the same inpatient stay. Retrospective analysis utilizing Epic medication orders, care provider notes, and chart review was used to determine the indications for the unfractionated heparin orders. Indications that were accepted for acute coronary syndrome include "acute coronary syndrome", "unstable angina", "myocardial infarction", and "chest pain".
Retrospective chart review was performed utilizing chart review and medications orders in order to collect patient weight, patient age, time of first unfractionated dose given, time to first therapeutic Anti-Xa level, final unfractionated heparin dose required to achieve therapeutic Anti-Xa level, final rate of unfractionated heparin, bolus doses, and number of supra-therapeutic Anti-Xa levels with adverse drug events reported.
Utilizing this data, statistical analyses were performed to determine average dosages needed to achieve therapeutic Anti-Xa levels for patients while taking adverse drug events into

consideration. Subset analyses separating patients based on a weight of 125 kilograms as well as based on an age of 70 years old.

Results: The Epic orders report was ran between November 12, 2015 and May 11, 2016, returning 14,192 results. Following data consolidation, 544 patients were analyzed for an acute coronary syndrome indication with 78 patients and orders meeting criteria for analysis and being included in the data set. Of these 78 patients, 11 were greater than 125 Kilograms and 6 were greater than 70 years old.

The average time to therapeutic Anti-Xa levels was 14:08:15 (plus/minus 8:30:36). The average final dose of unfractionated heparin required to reach therapeutic Anti-Xa levels was 13.203 (plus/minus 2.58) units / Kilogram / hour. These results indicate that it takes larger heparin doses on average and longer time periods using standard heparin dosing recommendations to reach therapeutic Anti-Xa levels in the obese population. The total number of patients requiring greater than 12 units / Kilogram / hour was 53 (68 percent).

While higher doses were required in a large proportion of the study population, the percentage of supra-therapeutic Ant-Xa levels was low at only 19.23 percent and the number of bleeding incidents reported was only 2 with neither of them being major bleeding.

Conclusion: Patients being treated for acute coronary syndrome with unfractionated heparin who are considered obese, on average, required higher doses than the current recommended American Heart Association/American College of Cardiology maximum doses. While therapeutic doses are variable, higher doses do not seem to be associated with a significant increase in bleeding incidents. Initiating heparin at higher doses may lead to quicker achievement of therapeutic Anti-Xa levels while not substantially increasing the risk of bleeding to the patient.

Poster Title: Alcohol Use Disorder Pharmacotherapy: A Case Report

Primary Author: Kacie McMurphy, The University of Oklahoma College of Pharmacy - Tulsa Campus, Oklahoma; **Email:** kacie-mcmurphy@ouhsc.edu

Purpose: Hyponatremia is a rare, yet potentially dangerous side effect, which can be seen with use of any antidepressant. Current evidence has shown that selective serotonin reuptake inhibitors (SSRIs) and venlafaxine, a serotonin-norepinephrine reuptake inhibitor (SNRI), have a higher relative risk for development, especially when combined with cofactors, such as age and concomitant medications, which can increase risk. Hyponatremia, defined as a serum sodium level below 135 mEq/L, is the most common electrolyte disorder seen in clinical practice and can result in patient hospitalization and be life-threatening. This surveillance program was designed to identify patients from an integrated multidisciplinary program of assertive community treatment (IMPACT) who may be at risk for antidepressant-induced hyponatremia. A literature review was undertaken to identify case reports of hyponatremia with antidepressant therapy. A retrospective chart review was then performed to identify patients for hyponatremia with inclusion criteria of adults 18 years or older from an IMPACT population who were currently receiving antidepressants. Lab work was then obtained with serum sodium values to identify those patients with antidepressant-induced hyponatremia noted as a serum sodium level of less than 135 mEq/L. Type of antidepressant and date of most recent lab draw were evaluated. Descriptive statistics are used with non-linear statistics applied to categorical variables as appropriate. Data were collected from 66 charts. 38 charts (56%) qualified for review. Six SSRIs (citalopram, escitalopram, fluoxetine, sertraline, fluvoxamine, and paroxetine) along with duloxetine, bupropion, trazodone, mirtazapine, and buspirone were used. Nineteen patients (50%) were on one of the six SSRIs. A total of thirteen patients are on more than one antidepressant. Hyponatremia was identified for two patients. Both were on two or more antidepressant medications with one being trazodone. The lack of timely lab draws appeared problematic. Eight patients had no lab values located in their electronic medical records and seven patients had either an antidepressant dosage increase or an additional antidepressant medication added to their medication regimen but had no lab draws after initiation. When trends in lab values were available, six patients had a downward trend in their serum sodium levels. Antidepressant-induced hyponatremia was not identified as problematic. However, the

lack of timely and recent lab draws could be the cause of this conclusion. For the six patients identified as potentially at risk, patient-specific follow-up will be instituted with additional monitoring, if needed. The need for lab work for the eight patients missing data will be reviewed as will the lack of data for the seven patients with changes in their antidepressant regimens. Data will be reviewed in one year.

Poster Title: Comparison of amikacin pharmacokinetics in neonates and infants with and without congenital heart disease

Primary Author: Lauren Lees, University of Oklahoma College of Pharmacy, OKlahoma; **Email:** lauren-lees@ouhsc.edu

Additional Author (s):
Amy Nguyen
Katie Hughes
Peter Johnson
Jamie Miller

Purpose: There are no studies evaluating use of amikacin in neonates and infants with congenital heart disease (CHD). The purpose was to compare amikacin pharmacokinetics and acute kidney injury (AKI) in neonates and infants with and without CHD.

Methods: This was a descriptive, retrospective study of neonates and infants who received amikacin from January 1, 2013 through June 30, 2016. The study was institutional review board approved and the data was taken from the institution's electronic medical record (EMR). CHD infants were classified as cyanotic or acyanotic. Controls were matched in a 2:1 fashion according to postmenstrual age (PMA). Data collection included demographics, amikacin regimen, renal function, and pharmacokinetic parameters. The primary objective was to compare the volume of distribution (Vd) and clearance (CL) in neonates and infants with CHD versus controls. Secondary objectives included comparison of elimination rate (Ke), half-life (t1/2) of amikacin, and incidence of AKI secondary to amikacin between groups. AKI was defined as a reduction in urine output less than 0.5 ml/kg/hr for greater than 8 hours, an absolute increase in serum creatinine (SCr) by 0.3 mg/dL, or an increase in SCr greater than 50% from baseline. Between-group analysis were performed using Chi-square or Fisher's exact analysis for categorical variables and Student's t-test or Wilcoxin-Mann-Whitney test for continuous variables, as appropriate with a p-value less than 0.05.

Results: Thirty-two CHD and sixty-four controls were included. There was no difference in the PMA between the CHD and controls, 34.1+4.7 versus 34.2+4.8 weeks (p=0.84). There was no difference in the Vd (0.46+0.10 versus 0.45+0.12 L/kg, p=0.58) or CL (0.047+0.014 versus 0.045+0.014 L/kg/hour, p=0.39) between the CHD and controls. A greater incidence of AKI was noted in the CHD group, but this was not significantly different, 5 (15.6%) versus 5 (7.8%) (p=0.29).

Conclusion: Based on preliminary results, there is no difference in pharmacokinetic parameters noted between groups. There was a greater percentage of neonates and infants with CHD with AKI. Due to the small sample size, a larger study is needed to ascertain if pharmacokinetic differences exist in those infants with and without CHD.

Poster Title: Initiating lumacaftor/ivacaftor therapy in a cystic fibrosis center

Primary Author: Richelle Swearingen, University of Oklahoma College of Pharmacy, Oklahoma;
Email: richelle-swearingen@ouhsc.edu

Additional Author (s):
Landry Volz
Michelle Condren

Purpose: Lumacaftor/ivacaftor, a novel therapy for cystic fibrosis patients 12 and older that are delF508 homozygous, became available in July 2015 with only short term studies completed at the time of approval. The goals of this study are to determine the safety and efficacy of lumacaftor/ivacaftor therapy; determine the nature and prevalence of adverse effects reported; and determine the number of patients requiring dose adjustment or discontinuation in a single cystic fibrosis care center.

Methods: This is a retrospective chart review of patients at the Tulsa Cystic Fibrosis Center who were eligible for therapy between July 2015 and July 2016. Pulmonary exacerbations, FEV1, and BMI will be collected for 1 year prior to starting lumacaftor/ivacaftor and for months 3, 6, 9, and 12 after. Frequency of adverse effects, dose adjustments, liver function testing, and medication discontinuation will also be recorded.

Results: Thirty-seven patients were eligible to receive therapy with lumacaftor/ivacaftor. Of these 37 patients, 23 have started therapy and 4 have been excluded. Reasons for not starting therapy include lack of interest, loss to follow up, and awaiting transplant. Of the 23 patients that have started therapy, 16 (70%) reported adverse effects including: dyspnea, heartburn, nausea/vomiting, elevated INR, menstrual irregularities, sedation, constipation, and diarrhea. Of these adverse effects, dyspnea (26%) and diarrhea (17%) were most common. Due to adverse effects, the initial starting dose was decreased for patients beginning in October of 2015. Five patients (22%) discontinued therapy, two of which have since restarted. Six patients (28%) have been hospitalized and nine (39%) have required oral antibiotics for exacerbations since starting therapy. At 3 and 6 months, no patients have had significant elevations in AST,

ALT, or bilirubin. Data will continue to be collected to assess lung function, BMI, and exacerbations before and after therapy.

Conclusion: Adverse effects have been common and have prompted the center to create a dose titration schedule for new patients. Many eligible patients are not receiving lumacaftor/ivacaftor after 12 months of availability, which will continue to be further explored. Data collection will continue to assess efficacy and safety.

Poster Title: Identification of detectable trough concentrations in critically-ill infants and children without cystic fibrosis receiving nebulized tobramycin

Primary Author: Trisha Lepa, University of Oklahoma College of Pharmacy, Oklahoma; **Email:** trisha-lepa@ouhsc.edu

Additional Author (s):
Peter Johnson
Jamie Miller
Courtney Ranallo
Hala Chaaban

Purpose: Tobramycin is the most commonly administered inhaled antibiotic in non-cystic fibrosis (CF) patients. Several reports have noted patients with detectable trough concentrations and acute kidney injury (AKI). The purpose was to describe the incidence and clinical characteristics of critically-ill infants and children with detectable concentrations receiving inhaled tobramycin.

Methods: This retrospective, case series included children < 18 years receiving inhaled tobramycin between January 1, 2010-June 30, 2016. Patients with CF, concomitant IV tobramycin, or no serum tobramycin concentrations were excluded. Baseline demographics, inhaled tobramycin regimen, and renal function data including serum creatinine (SCr), estimated glomerular filtration rate (eGFR), and urine output (UOP) were collected to assess renal function at baseline and throughout the duration of inhaled tobramycin. The primary objective was to determine the incidence of detectable tobramycin trough concentrations ≥ 0.5 mcg/mL. Secondary objectives included identifying the number of patients with AKI according to the pediatric-modified Risk, Injury, Failure, Loss and End-stage kidney disease (RIFLE) criteria and identifying potential risk factors for detectable trough concentrations. Descriptive and inferential statistics were performed.

Results: Twenty-two were included for analysis. Ten (45.5%) had detectable concentrations, with a mean concentration of 1.1 mcg/mL (IQR 0.5-2.0). There was a numerical difference in the age (years) between the non-detectable versus detectable groups, 1.65 (IQR 0.8-6.3) vs 0.8 (0.6-

1.8), p=0.45. Patients in the detectable group received a higher mg/kg dose than non-detectable group, 67.5 mg/kg (9.7-37.3) vs 24.5 (8.4-40.6), p=1.0. Most patients (81.8%) received every 12 hour dosing. A greater percentage of children in the non-detectable group versus detectable group were on the mechanical ventilator, 12 (100%) vs 8 (80%), p=0.20. There was a numerical difference in the number of infants with a tracheostomy tube in the detectable versus non-detectable group, 8 (80.0%) vs 7 (58.3%), p=0.38. There was no significant difference in the children with detectable versus non-detectable troughs who developed AKI, 3 (30.0%) versus 1 (8.3%), p=NS.

Conclusion: Almost half of patients that had concentrations obtained had a detectable concentration. The majority of these were younger in age with a higher mg/kg dose, though this was not statistically significant. A higher but not significant difference in AKI was noted in patients with detectable concentrations. Clinicians should monitor serum trough concentrations in critically-ill children receiving inhaled tobramycin.

Poster Title: A rare Trichosporon and Alternaria coinfection in a neutropenic bone marrow transplant patient

Primary Author: Katherine Newman, University of Oklahoma College of Pharmacy, Oklahoma; **Email:** katherine-newman@ouhsc.edu

Additional Author (s):
Sarah Schmidt
Matthew Stailey

Purpose: This case describes the management of an immunocompromised patient infected by rare fungal opportunistic pathogens, Trichosporon and Alternaria species. The patient is a 36 year-old male with acute myeloid leukemia (AML) presenting for an allogeneic, matched unrelated donor, fully myeloablative hematopoietic cell transplantation (HCT). Prior to HCT, he had failed three induction chemotherapy regimens for his AML and after the fourth induction became eligible for HCT; however, he continued to be pancytopenic since diagnosis, approximately four months. During his previous chemotherapy, there was a suspicion of a fungal pneumonia. A chest computerized tomography (CT) scan showed left upper lobe pneumonia with consolidation and central necrosis; however, bronchial alveolar lavage (BAL) showed no growth and beta-D glucan and aspergillus antigen were negative. He was placed on voriconazole, but treatment was complicated by hallucinations. Antifungal therapy was switched to posaconazole; however he developed mild transaminitis after two weeks of treatment and since the patient was being admitted for HCT it was decided to change therapy to micafungin for the duration of HCT to minimize hepatic toxicity. The patient developed a persistent neutropenic fever starting on day -1 of HCT, necessitating his placement on broad spectrum antibiotics. He had a CT scan showing new nodule lung lesions and micafungin was changed to liposomal amphotericin B. Blood cultures grew out yeast. The patient continued to be febrile despite the change in antifungal agent and a BAL was performed. The BAL grew out yeast (not Cryptococcus) and Alternaria species. Concurrently the patient developed sinusoidal obstructive syndrome (SOS) causing the medical team to be cautious about using liver active medications such as triazole antifungals. Fluconazole was added to liposomal amphotericin B once the yeast species was identified as Trichosporon beigelli. Blood cultures remained positive

for 9 days and he cleared the Trichosporon beigelli the same day his white count started to recover and three days after adding fluconazole to the antimicrobial regimen.

Trichosporon are yeast-like opportunistic pathogens that are known to cause superficial and bloodstream infections in immunocompromised patients. Trichosporon are resistant to echinocandins and amphotericin B, but can be sensitive to triazoles. Previous case reports list voriconazole as the preferred triazole in trichosporonemias. Alternaria are dematiaceous hyphomycetes that very rarely cause pneumonia. Alternaria species have limited susceptibility to fluconazole and variable susceptibility to amphotericin B, voriconazole and posaconazole. This patient's presentation differs from other documented Trichosporon infections as the treatment course was complicated by Alternaria and his inability to take voriconazole, posaconazole or isavuconazole due to previous intolerance of voriconazole and his current hepatic insufficiency. In this patient the fluconazole was continued for four weeks from his first negative culture to treat the trichosporonemia. The liposomal amphotericin B was continued for four weeks after he had engrafted to treat Alternaria fungal pneumonia. The patient's liver function returned to normal following resolution of the SOS, allowing posaconazole or isavuconazole to be an option for further suppression of his fungal coinfection while he remains on immunosuppression.

The management of fungal infections in immunocompromised patients is clinically significant to pharmacists working in the oncology setting.

Poster Title: Effects of medication switch from paliperidone 1-month to 3-month formulations in patients with schizophrenia

Primary Author: Logan Cast, University of Oklahoma College of Pharmacy, Oklahoma; **Email:** lcast@ouhsc.edu

Additional Author (s):
Nancy Brahm

Purpose: Three patients enrolled in an Assertive Community Treatment (ACT) program were switched from paliperidone palmitate 1-month (PP1M) to the 3-month (PP3M) formulation after a history of psychiatric stability while receiving PP1M. Each patient elected a trial of PP3M due to fewer injections annually.

Patient 1 had been stable on PP1M injections for four years before switching to PP3M. During weekly scheduled visits, the patient reported no new or worsened side effects and believed this formulation had equal symptom control. Clinicians agreed with the patient's assessment of effectiveness. While taking PP1M, twice daily oral benztropine (0.5 mg every morning and 1 mg every evening) was required to manage tremors and self-reported oculogyric crisis. Two months after the medication transition, the patient chose to reduce the dose of benztropine to 0.5 mg taken as needed due to fewer perceived extrapyramidal effects.

Patient 2 received PP1M injections for nine months prior to PP3M transition. Before this, the patient's prominent paranoid symptoms necessitated oral antipsychotic supplementation with the long-acting injectable (LAI). Oral olanzapine continued after the medication transition. The first two weeks following transition, the patient experienced heightened paranoia and worsened negative symptoms. These slowly resolved to baseline over the course of therapy. Patient 2 continues to receive PP3M.

Patient 3 had well-controlled symptoms while on PP1M for several months before transitioning to PP3M. Prior to taking LAI antipsychotics, the patient's auditory hallucinations presented as 'the Man'. Over weeks 4-8 of the PP3M injection timeframe, Patient 3 began experiencing command auditory hallucinations advocating harm to others, particularly one family member. The patient began hiding in his bedroom and sleeping excessively throughout the day. Symptoms slowly improved, but the family requested a return to PP1M with the next scheduled

PP3M injection. Since resuming the PP1M formulation, the patient and family have denied auditory hallucinations and reported better communication skills.

This case series illustrates a wide range of outcomes after switching antipsychotic formulations in patients with severe schizophrenia. Patient 1 preferred PP3M and encountered no negative consequences. Patient 2 reported moderate breakthrough symptoms, resolving after two weeks. Patient 3 experienced significant relapsed symptoms.

Clinicians considering converting psychiatrically stable patients, with a diagnosis of schizophrenia, from the PP1M to the PP3M formulations are encouraged to increase monitoring and consider individual patient characteristics. While clinical trials provided adequate data to support use of PP3M, strict exclusion criteria limited disease severity in the studied patient populations. In ACT programs or other teams treating patients with diagnoses of severe or treatment-resistant schizophrenia, these clinical trials may not be applicable. More research is needed to establish treatment guidelines and optimize utilization of PP3M in patients with severe or treatment-resistant schizophrenia.

Poster Title: Assessment of Sedative and Analgesic Regimens During Bedside Bevacizumab Intravitreal Injection in Preterm Infants with Retinopathy of Prematurity.

Primary Author: Michael Tieu, University of Oklahoma College of Pharmacy, Oklahoma; **Email:** michael-tieu@ouhsc.edu

Additional Author (s):
Peter Johnson
Kari Harkey
Raymond Siatkowski
Jamie Miller

Purpose: Bevacizumab intravitreal injection is an option for retinopathy of prematurity (ROP). However, there is a paucity of data regarding sedation during this procedure. The purpose of this study was to describe the sedative and analgesic regimens for a bedside intravitreal bevacizumab injection procedure.

Methods: This retrospective case series included infants receiving intravitreal bevacizumab injection for ROP between January 2012 to May 2016. Infants were excluded if bevacizumab was administered under general anesthesia in the operating room. Demographic data were collected, including feeding status and mode of respiratory support prior to procedure. Sedative and analgesic regimens were collected. Vital signs were collected prior to and during procedural sedation. Additional data included requirement for termination or delay of procedure, need for intervention (i.e., atropine, naloxone) during the sedation period, and time needed to return to baseline feeding and respiratory status. The primary objective was to describe the agents and doses of sedatives and analgesics utilized. The secondary objectives included identification of the number of patients requiring dose increases or decreases of sedatives and analgesics. In addition the number of patients with procedure success were identified, defined as completion of procedure without any interruptions or interventions required for cardiopulmonary adverse (CPA) events. CPA events were defined as bradycardia (heart rate < 60 beats per minute), decrease in oxygen saturation less than 85%, and hypotension [mean arterial pressure (MAP) < 30 in infants < 37 weeks postmenstrual age (PMA) and MAP < 45 in infants at > 37 weeks PMA] . Descriptive statistics were employed.

Results: Fifteen were included with a median PMA of 35.0 weeks (range, 32.1-39.6) and weight of 1.89 kg (range, 1.27-3.14). Eight (53.3%) were intubated for the procedure. In those patients, extubation occurred at a median of 33.5 hours (range, 7.2-175) after procedure completion. Fourteen (93.3%) were initiated on fentanyl infusions at a median dose of 2 mcg/kg/hr (range 1-4), and twelve (80.0%) received concomitant midazolam infusions at a median of 0.06 mg/kg/hr (range 0.03-0.2). All patients received a median of one dose of vecuronium (range 1-3) at 0.1 mg/kg prior to the procedure. Only one patient (6.7%) required an increase in their fentanyl and midazolam infusion. The median time to resume baseline feeds was 28.0 hours (range, 3.5-69.0). Five patients (33.3%) experienced one CPA event. Only one patient (6.7%) had a delay in the procedure due to CPA effects, and one patient (6.7%) required naloxone. Despite this, the procedure completed in all patients. However, based on the study definition, procedure success was achieved in 13 patients (86.7%).

Conclusion: The majority of patients received fentanyl and midazolam infusions with a dose of vecuronium just prior to the procedure. All patients completed the procedure. Approximately one-third of patients experienced a CPA event. Thirteen (86.7%) met the criteria for procedure success without CPA events requiring delay or intervention. Due to the heterogeneity in dosing, the results of this case series suggest the need for a standardized sedation protocol for bedside intravitreal bevacizumab injection procedure in neonates.

Submission Type: Evaluative Study

Session-Board Number: 7-183

Poster Title: Treatment patterns and outcomes among inpatient cases of acute pericarditis

Primary Author: Matthew Dickson, University of Oklahoma College of Pharmacy, Oklahoma; **Email:** matthew-dickson@ouhsc.edu

Additional Author (s):
Gwenn Rosendale
Nicholas Schwier
Grant Skrepnek

Purpose: Landmark studies regarding the use of pharmacotherapy for the treatment of acute pericarditis are mostly comprised of European patients with idiopathic (viral) pericarditis. Currently, there is no literature available that assesses how landmark studies have influenced prescribing patterns and outcomes, particularly in the U.S.. Furthermore, it is currently unknown if pharmacotherapy may be of benefit in other forms of pericarditis. The purpose of this study was to assess prescribing patterns of pharmacotherapy within hospitalized patients treated for acute pericarditis, and to ascertain how pharmacotherapy is associated with recurrence of pericarditis, surgical interventions, or cardiac tamponade.

Methods: This study was a retrospective cohort analysis of an electronic medical record from an academic medical center spanning a time frame of January 2005 to December 2015. Medical chart abstraction was conducted based upon the following inclusion criteria: ≥18 years of age and presence of pericarditis. Presence of pericarditis was determined based on the criteria of two of the following: hallmark pleuritic chest pain, pericardial friction rub, diffuse ST segment elevation and/or PR segment depression on ECG, or new or worsening pericardial effusion; and/or a diagnosis of any pericarditis included in the medical chart. Patients were selected from the medical record using ICD-9 codes relevant to pericardial diseases. Logistic regression analyses were conducted to assess the association of a prescription for colchicine, aspirin, or an NSAID and a composite outcome of recurrence of pericarditis, surgical interventions, or cardiac tamponade. Independent predictor variables included: age, sex, comorbidities, medication use, presence of trauma, year, and diagnosis of idiopathic pericarditis. Approval by the Investigational Review Board (IRB) granted this study as exempt.

Results: Overall, 79 patients were included across the 10-year time-frame. The mean age was 43.0(+/-16.8), with 72.2% being female. The average height was 66.2(+/- 4.4) inches, weight 85.6(+/- 28.9) kg, and BMI 30.4(+/-10.3) kg/m2. Use of aspirin was reported in 34.2% of patients and NSAID use in 50.6%. Idiopathic pericarditis accounted for 54.4% of patients, while trauma-induced pericarditis occurred in 10.1%. Co-morbid conditions were present in 88.6% of patients. The composite outcome occurred in 74.7% of patients. Logistic regression analysis indicated that recurrence of pericarditis, surgery, or cardiac tamponade, was associated with a 78.2% lower adjusted odds of prescribing colchicine, aspirin, or an NSAID (p = 0.009), Additionally, cases involving recurrence of pericarditis, surgical intervention, or cardiac tamponade decreased by 32.1% per year (p = 0.007) and were associated with an 88.3% lower odds of NSAID prescribing (p = 0.008) and an over 10-fold higher odds of trauma-induced pericarditis (p = 0.034); no association was observed with either colchicine (p = 0.119) or aspirin (p = 0.852).

Conclusion: NSAID use was associated with a decrease in the composite outcome of recurrence of pericarditis, surgical intervention, and cardiac tamponade. This decrease in association was independent of several factors, including a diagnosis of idiopathic pericarditis. Recurrence of pericarditis, surgery, or cardiac tamponade, was associated with a lower odds of prescribing colchicine, aspirin, or an NSAID.

Poster Title: Evaluation of discharge medications in pediatric patients: A pilot study

Primary Author: Thao Nguyen, University of Oklahoma Health Science Center, Oklahoma;
Email: thao-t-nguyen@ouhsc.edu

Additional Author (s):
Teresa Lewis
Stephen Neely
Tracy Hagemann
Peter Johnson

Purpose: Numerous studies have documented the risk of medication errors in the inpatient setting for pediatric patients. Recent data have also suggested that children may also be at risk for prescribing errors when discharged from the hospital. To date, no studies have qualified and quantified discharge prescriptions in hospitalized children. The objective was to characterize discharge prescriptions in children.

Methods: This was a descriptive, IRB-approved, retrospective pilot study in children < 18 years. Patients were included if they received >1 discharge prescription during January, April, July, and October 2012. Patients were excluded for missing data. Baseline demographics and medications prescribed at discharge were collected. The primary objective was to identify the mean number of discharge prescriptions. The secondary objective was to determine which drug classes are most commonly prescribed and the complexity of the prescriptions (e.g., dosage form, number of doses per day, need for extemporaneous preparation). Univariate analyses, including measures of central tendency and variability, were collected for data analysis. All analyses were performed using SAS v9.3.

Results: A total of 852 patients met the inclusion criteria. The majority (52.2%) were male, with a mean age of 6.2+5.6 years. Most patients (42.2%) were admitted and discharged from the General Pediatric Medical Service. The primary payer source was Medicaid (66.7%). The total hospital length of stay was a median of 3 days (range 1-185). Final results to be presented.

Conclusion: N/A

Poster Title: Intrathecal administration of daptomycin for Enterococcus gallinarum meningitis: a case report

Primary Author: Thi Nguyen, Oregon State University | Oregon Health & Science University, Oregon; **Email:** nguyeth2@oregonstate.edu

Additional Author (s):
Greg Tallman
Christina Kowalewska

Purpose: This case report describes the unsuccessful use of intrathecal daptomycin for the management of a central nervous system infection secondary to Enterococcus gallinarum. The patient was a 12 year old Hispanic female who weighed 62.7 kilograms. She was allergic to cefepime (rash) and sulfa antibiotics (hives). Prior to the index hospitalization, she was diagnosed with severe aplastic anemia. Workup of her anemia lead to a diagnosis of primary hemophagocytic lymphohistiocytosis (HLH) with macrophage activation syndrome (MAS), confirmed by a STX11 gene mutation. The patient's HLH/MAS was poorly controlled with dexamethasone, etoposide, and alemtuzumab. Her hospital course was complicated by bacteremias and fungemias due to immunosuppression, progression of HLH/MAS, and need for central venous access. Despite complications, the patient underwent hematopoietic stem cell transplant (HSCT) when clinically stable, approximately 3 months into her hospitalization. On HSCT day 3, peripheral blood cultures revealed E. gallinarum with intermediate resistance to vancomycin; port cultures of E. gallinarum revealed resistance to ampicillin and gentamicin, Enterococcus faecium resistant to ampicillin and gentamicin, and multidrug resistant Klebsiella oxytoca susceptible only to tigecycline.
On day 4 post-HSCT, she was receiving intravenous daptomycin 10 milligram per kilogram per day and meropenem, along with micafungin, pentamidine, and acyclovir for infection prophylaxis. She began developing headaches and significant mental decline. An extraventricular drain (EVD) was placed for hydrocephalus. The cerebrospinal fluid (CSF) from the EVD grew Gram positive cocci in chains, and daptomycin was increased to 12 milligram per kilogram per day in combination with vancomycin to target E. faecium.
On day 5, the patient had increased intracranial pressure and underwent craniotomy for evacuation of a subdural hematoma and empyema with placement of additional drains. The

CSF culture from the previous day revealed E. gallinarum resistant to ampicillin and penicillin, intermediate resistance to vancomycin, and sensitive to linezolid and daptomycin (minimum inhibitory concentration [MIC] of 2 microgram per milliliter). Daptomycin, vancomycin, and meropenem were discontinued; linezolid and imipenem-cilastatin were started. Overnight she experienced a seizure and further mental status decline. On day 6, imipenem-cilastatin was replaced with meropenem due to seizures. The following day, meropenem was stopped, and piperacillin-tazobactam started for enhanced enterococcal coverage.

On day 9, the patient experienced a left-sided focal seizure and was obtunded with no gag or cough reflex. The following day meropenem was started, and piperacillin-tazobactam was discontinued. Over the next 2 weeks, she continued to decline neurologically. On day 10, CSF revealed E. gallinarum susceptible to daptomycin (MIC 4 microgram per milliliter) and linezolid. A lumbar puncture was performed on day 14 with no growth; however, on day 20 the patient underwent EVD exchange and septostomy. Cultures subsequently revealed E. gallinarum resistant to linezolid. On day 21, the patient could open her eyes to stimulation and blink but was unable to track with her eyes. Daily intrathecal daptomycin 10 mg in 5 milliliters of normal saline was initiated.

On day 22, the patient's absolute neutrophil count (ANC) was detectable for the first time. However her neurologic status remained poor; linezolid was discontinued. Two hours following the second dose of intrathecal daptomycin, the CSF Gram stain from her EVD demonstrated Gram positive cocci. On day 25, intrathecal daptomycin was changed to every 48 hours based on previous case reports. On day 28, piperacillin-tazobactam was discontinued due to ANC recovery. On day 31, the patient was hypothermic and rigoring with worsening cerebritis, and the family withdrew care. Despite intrathecal administration of daptomycin, the patient's CSF cultures remained positive for E. gallinarum at death on day 36. Contrary to previous case reports, administration of intrathecal daptomycin did not achieve microbiological cure or improve neurologic status for this patient.

Poster Title: Oregon Medicaid policy evaluation: Safety edit for Attention Deficit Hyperactivity Disorder medications

Primary Author: Amanda Jones, Oregon State University | Oregon Health & Sciences University, Oregon; **Email:** jonesama@oregonstate.edu

Additional Author (s):
Julie Cha
Luke Middleton
Kathleen Ketchum
Megan Herink

Purpose: This policy evaluation assessed the safety edit policy implemented in October 2014 in the Oregon Medicaid program for Attention Deficit Hyperactivity Disorder (ADHD) medications. Specifically, this study evaluates whether implementation of the safety edit has helped to improve prescribing of ADHD medications according to best practice standards. This is defined by the proportion of patients prescribed medications within the recommended age ranges, dose ranges, and with an appropriate indication. Additionally, due to the potential for cardiovascular adverse events and high abuse potential, this study also evaluated the proportion of patients receiving these medications with known precautions or contraindications.

Methods: Patients were included in this analysis if they had a paid fee for service (FFS) prescription drug claim for an ADHD medication or a denied FFS drug claim for an ADHD medication without pre-specified Explanation of Benefit (EOB) codes. To evaluate prescriptions based on best prescribing standards, a pre- and post- observational cohort was constructed to evaluate the policy. Patients with a paid or denied index prescription ADHD drug claim from July 2013 through June 2014 were defined as the control group. Patients with a paid or denied claim from October 2014 through September 2015 were defined as the study group. Using only FFS claims, the first ADHD medication paid or denied claim per patient during the study period was designated the index event (IE). Patients were excluded if they had Medicare Part D coverage as indicated by benefit packages, or if they had a prior claim within 90 days and had less than 75% days of combined FFS or coordinated care organization eligibility from 11 months prior to the

index month to 3 months after the index month (total of 15 months). Patient demographics, diagnosis, medication requested, final claim disposition, and potential contraindications to therapy were documented.

Results: There were 1,992 claims in the control group and 3,065 claims in the study group. Mean age increased from 16.4 years in the control group to 21.0 years in the study group. Index event paid claims for patients outside of the normal age ranges decreased from 152 to 9 after implementation of the safety edit. Fewer children under the age of 6 years old had paid claims (5.7% vs. 0.6%) but increased utilization in adults aged 18 years or older was observed (28% vs 45%) in the study group. More than half of the patients over the age of 18 years in the study group (54%) had a diagnosis that is considered to be a contraindication or precaution to using these medications. Additionally, 33.4% of adults in the study group had a history of substance or alcohol abuse/dependence. Overall, 72.8% of all denied claims had no prior authorization sent. No differences were observed in all-cause ED visits or hospitalizations between the control and study groups (15.1% and 16.9%, respectively). No differences in ED visits or hospitalizations due to contraindications were found between the control and study groups (1.3% and 1.5%, respectively).

Conclusion: Since implementation of the safety edit, prescribing according to best practice standards has improved. Increased utilization by adults is something that should be explored in further depth, as evidence is limited for treating adult ADHD. The high percentage of patients with a history of substance or alcohol abuse or dependence is also concerning. A consideration should be made to amend the current safety edit to require adults with a history of alcohol or substance abuse or dependence in the previous 12 months to have a mental health specialist consultation. Further research will help determine additional beneficial amendments to the policy.

Poster Title: Early integration of students in complex chronic care management in an institutional setting enhances preparedness and interest for post-graduate training

Primary Author: Jennifer Lee, Oregon State University and Oregon Health & Science University, Oregon; **Email:** leje@ohsu.edu

Additional Author (s):
Tina Nguyen
Chanchal Agr
Tanya Ostrogorsky
Harleen Singh

Purpose: Pharmacy students are integrated into a patient-centric model at an ambulatory heart failure clinic in the Veterans Affairs Portland Health Care System to advance their clinical and communication skills. This survey assessed the impact of early exposure to a longitudinal clinical experience on students' preparedness and interest in post-graduate training opportunities.

Methods: An IRB-approved online survey assessed the impact of this patient-centric model on student preparedness and interest in post-graduate training opportunities. The survey focused on two domains: clinical knowledge and attitudinal outcomes. Frequencies and percentages were used to summarize the data. Open-ended comment boxes were analyzed for themes that informed the overall project and will support program improvements. The Director of Assessment and Faculty Development managed the raw data set and provided de-identified data to the evaluation team.

Results: Twenty-four students have participated in this longitudinal experience. Of these, 12 participants were sent the survey and all returned it completed. Seventy-five percent participated for at least three quarter-terms with 67 percent spending more than six hours per week in related responsibilities. Prior to this clinical opportunity, 33 percent planned to pursue residencies. After completing this experience, 42 percent shifted their interest to pursue a residency and 25 percent remained committed to their original residency plan. Overwhelmingly, participants believed this opportunity made them a highly competitive

candidate and reported discussing this unique experience during career-related interviews. At the end of this clinical experiential opportunity, 92 percent reported high levels of confidence to evaluate and present complex patient cases; evaluate and resolve therapy regimen problems; provide direct patient care; and communicate with patients, family members, and other healthcare providers. All participants indicated continued application of many of these valuable skills in their careers.

Conclusion: Results suggest early integration of students in chronic care management benefits students, specifically in the areas of confidence and residency plans. Based on the cohort we followed, this longitudinal experience helped to strengthen clinical and communication skills, enhanced clinical preparedness, and increased interest in post-graduate training. Subsequent studies of the effects of this experience will include the other 12 students that were not originally invited to participate as well as all future students engaged in the experience. Also, an expanded focus of the impact of the experience on residency plans and subsequent success will be added to the survey.

Poster Title: Evaluation of vancomycin management in obese patients at a single academic medical center

Primary Author: Ogechukwu Erinne, Oregon State University and Oregon Health & Science University, Oregon; **Email:** erinneg@ohsu.edu

Additional Author (s):
Lynh Pham
Christina Kowalewska
Greg Tallman

Purpose: Vancomycin is commonly used as empiric therapy for suspected gram-positive infections in the hospital setting. However, inappropriate dosing and monitoring of vancomycin can lead to various adverse effects such as acute kidney injury. Oregon Health and Science University implemented a pharmacy-managed dosing protocol for vancomycin, but this protocol has not been validated in obese patients. The purpose of this study was to evaluate the pharmacy-managed dosing protocol in obese patients.

Methods: This medication use evaluation was reviewed by the institutional review board and assigned a determination of "Not Human Research." A report generated by the electronic health record system identified vancomycin orders administered at Oregon Health and Science University between September 1, 2015 and December 2, 2015. Patients aged 18 years or older who received pharmacy-managed vancomycin therapy for an indication other than surgical prophylaxis, and had an active vancomycin order for greater than or equal to 24 hours were included in the study. Obesity was defined as a body mass index (BMI) of greater than 30 kg/m2. Primary data collected included patient demographics, vancomycin dose and frequency initiated, trough goal determined per pharmacy protocol, initial trough level, and positive culture for methicillin-resistant Staphylococcus aureus (MRSA) or methicillin-resistant coagulase-negative staphylococci (MRCoNS). Other data collected included baseline renal insufficiency as documented per primary team progress notes, serum creatinine on each day of vancomycin therapy, intensive care unit admission, subsequent trough levels, and concurrent antibiotic therapy. Data were managed and analyzed using Microsoft Excel.

Results: A total of 104 patients were included in this study: 33 obese and 71 non-obese. The mean BMI was 37.5 kg/m2 and 23.2 kg/m2 in the obese and non-obese groups, respectively (P less than 0.01). Patients with documented renal insufficiency at order initiation included 48.5 percent of obese patients and 22.5 percent of non-obese patients (P less than 0.01). Obese patients had a longer length of stay compared to non-obese patients (12 days versus 7 days). The mean initial vancomycin dose was 11.44 mg/kg for obese patients and 15.15 mg/kg for non-obese patients (P less than 0.01). Four (12.1 percent) obese patients had a positive culture for MRSA, compared to 12 (16.9 percent) non-obese patients (P equals 0.77). Four (12.1 percent) obese patients had a positive MRCoNS culture compared to 4 (5.6 percent) non-obese patients (P equals 0.26). There was no statistically significant difference in initial vancomycin trough level between obese and non-obese patients (15.5 mcg/mL and 12.7 mcg/mL, respectively; P equals 0.11). Ten (30.3 percent) obese patients and 16 (22.5 percent) non-obese patients met the trough goal determined by pharmacy at the initial trough (P equals 0.54). Median duration of therapy was 3 days in both groups.

Conclusion: In obese patients, vancomycin was initiated at a lower dose compared to non-obese patients. This may be attributed to the higher frequency of documented renal insufficiency in the obese patient group. Despite this, mean initial trough level and median duration of vancomycin therapy were not statistically different between groups. The results of this medication use evaluation suggest that obese patients are being dosed appropriately compared to non-obese patients. A larger sample size is needed to further determine optimal dosing in this population.

Session-Board Number: 7-189

Poster Title: Association of medication measures with disabilities and their ability to predict disability in a nationally representative sample of older adults.

Primary Author: Can Ergenekan, Oregon State University and Oregon Health & Science University, Oregon; **Email:** ergeneka@ohsu.edu

Additional Author (s):
Sarah Bissonette
David Lee

Purpose: Functional decline, leading to disabilities in activities of daily living, mobility, and cognition, in adults over 65 (older adults) is common. Several medications have been associated with these disabilities; benzodiazepines and anticholinergic being the most associated with disability. However, associations may not be useful in predicting the likelihood of a future disability in someone taking a medication. The goal of this study is to utilize the Medical Expenditure Panel Survey to determine the associations between medication usage and development of disabilities in activities in daily living, mobility, and cognition and compare those associations with their ability to predict disabilities.

Methods: This study utilizes the Medical Expenditure Panel Survey, a household survey of demographics, health, and health expenditures from nationally representative households in the US started in 1996. The population of this study included 10,408 participants who were 65 years or older, enrolled in the survey from 2006 to 2011, and surveyed for two years. Any participant over 85 was given the age of 85 in the survey to protect their identity. The surveys include self-reported data on participants' health, medical encounters, and medication usage, which is then corroborated by their health care providers and pharmacies. Predictors utilized in this study were individual medications classes, any medication on the 2012 Beer's Criteria List, excluding those based on a medical condition, drug burden index, medication regimen complexity index, count of medications used, polypharmacy, and extreme polypharmacy. Outcomes in this study was the development of a disability in a basic or instrumental activity of daily living, mobility as defined by difficulty walking 3 blocks, or self-reporting difficulty with cognitive problems. Any participant with a disability at baseline was not included in the analysis. To determine the association between each medication measure and disability, a

logistic regression model adjusted for age, sex, race, and comorbidities to control for confounding was used. Sensitivity, specificity, and the c-statistic were calculated to assess the predictive quality of these medication measures.

Results: Of the 10,472 participants; 741 (7.1 percent) had an activity of daily living impairment at the baseline visit and 899 (8.6 percent) developed a disability during the follow-up period, 2,258 (27 percent) had a mobility disability at baseline, and 1,185 (12 percent) developed a disability during the follow-up period, and 1,305 (12 percent) reported cognitive limitations at baseline and 1,060 (10 percent) reported developing a cognitive limitation during the follow-up period. The following measures were consistently associated with disabilities in activity of daily living, mobility, and self-reported cognitive limitations: use of any psychotropic, count of medications, drug burden index, opioid use, use of any antidepressant, use of a medication with anticholinergic properties, polypharmacy, sedative use, use of an anticonvulsant, Beer's medication, extreme polypharmacy, antipsychotic use, antiplatelet use, second-line antihypertensive use, pulmonary medication use, SSRI antidepressant use, insulin use, and vasodilator use.
Few medication measures were predictive with sensitivities greater than 10 percent or specificity greater than 80 percent. For activities of daily living and self-reported cognitive limitations those measures were any psychoactive medication, polypharmacy, Beer's medications, and second line antihypertensives. For mobility impairment the medication measurements were psychoactive medications, and polypharmacy.

Conclusion: This study further confirms that many medication measures are associated with declines in activities of daily living, mobility, and self-reported cognition. Unfortunately, the medication measures, on their own, do a poor job in predicting the likelihood of future disabilities, both in terms of sensitivity and specificity. Despite the lack of clear predictive power the associations and sensitivities presented here may have some utility to clinicians in terms of medication choice and utilization. Currently, we are further developing predictive models of disability using demographics, health and medication information.

Poster Title: Evaluation of adherence to guidelines for amiodarone monitoring

Primary Author: Tina Nguyen, Oregon State University and Oregon Health and Science University, Oregon; **Email:** nguynga@ohsu.edu

Additional Author (s):
Jennifer Lee
Chanchal Agr
Jessina McGregor
Harleen Singh

Purpose: National guidelines outline the need for specific monitoring of patients receiving the antiarrhythmic amiodarone due to potential toxicities. Recent data suggests compliance with monitoring is low. We evaluated the frequency of patients receiving guideline-concordant monitoring for amiodarone at our institution.

Methods: The electronic health record system was queried on September 1, 2016 to identify patients with an active amiodarone prescription. Data collected through chart review includes: demographics, indication, comorbidities, dose and duration of amiodarone, side effects and laboratory values. Baseline monitoring was appropriate if a liver function test (LFT), thyroid function test (TFT), chest x-ray (CXR), pulmonary function test (PFT), electrocardiography and ophthalmologic exam (if indicated) was performed. Follow-up monitoring was appropriate if LFTs and TFTs were performed every 6 months, a CXR was performed annually, and an ophthalmologic exam was completed if indicated. The frequency of appropriate monitoring, potential drug interactions and adverse events were summarized. The Institutional Review Board approved this quality improvement project.

Results: To date, we reviewed 35 out of 158 patients (22 percent) for appropriate monitoring. One patient was excluded due to discontinuation of amiodarone. Amiodarone was initiated outside of our institution in 21 (62 percent) patients. Among those initiated at our institution, all baseline tests were performed in 1 out of 13 (8 percent) patients. Baseline pulmonary function test were the least frequently acquired (12.5 percent). Among all included patients

receiving amiodarone therapy for at least 1 year, ongoing monitoring was appropriately administered for 8 out of 19 (42 percent) patients.

Conclusion: Our preliminary results indicate the majority of patients did not receive the recommended follow-up monitoring. Since the majority of patients were initiated on amiodarone outside of our institution, we were unable to adequately evaluate baseline monitoring. Strategies to enhance adherence to guideline-directed monitoring are needed to avoid known amiodarone-associated adverse events.

Poster Title: Interdisciplinary outreach: Improving access to health care in underserved communities

Primary Author: Austin Pliska, Oregon State University College of Pharmacy, Oregon; **Email:** pliskaa@ohsu.edu

Additional Author (s):
Victoria Li
Le Diem Pham
Thi Nguyen
Dan Muongpack

Purpose: Underserved communities have difficulty accessing healthcare due to barriers such as language and financial obstacles. In 2008, the Interprofessional Community Health and Education Exchange program was established to interface with underserved communities to address health concerns and disease prevention in Portland, Oregon. This report describes student pharmacists' efforts in bridging healthcare gaps to improve community health and wellness.

Methods: Multidisciplinary teams comprising of pharmacy, medical, dental, nursing, physician assistant, and public health students provided basic care to undocumented workers, homeless individuals, and refugees—mainly from Latin American and Southeast Asia. Interpreters were utilized for non-English speakers. Outreach locations were dispersed throughout the Portland metro area at community centers selected based on ease of accessibility by the targeted populations including Transition Projects Incorporated and Asian Health and Services Center. Groups conducted client interviews and provided health screenings, medication review, and education under the supervision of faculty volunteers. In 2016, student pharmacists offered reading glasses to qualified clients after evaluating their vision using a near vision Snellen chart and partnered with Operation Diabetes to implement blood glucose screenings. Referrals to local underserved clinics, a traveling eye clinic, and a dental van were made for more advanced care. Post-visit satisfaction surveys from clients were collected.

Results: Approximately 50 clients were seen in the winter and spring quarters of 2016. Of those, 21 clients utilized blood glucose screenings and 13 clients qualified for reading glasses. Seventeen clients completed the satisfaction survey. Eighty-two percent would "always" recommend the program to others; 94 percent "always" received explanations for health improvement; and 71 percent felt they "always" received counseling on medications and access to local resources. Through interprofessional interactions and client interviews, student pharmacists learned about additional resources such as using food stamps at farmer's market and locations of English-learning centers to impart upon future clients.

Conclusion: Student pharmacists were able to add valuable services to the outreach program. The newer services aided clients with limited access to vision care and gave clients an opportunity to check their glucose levels. Furthermore, the program allowed student pharmacists to learn from other health disciplines and to incorporate knowledge imparted from other health professions into their own practice.

Poster Title: Appropriate use of acid suppressive agents in hospitalized pediatric patients at a single-center

Primary Author: Victoria Li, Oregon State University, Oregon Health & Science University, Oregon; **Email:** liv@oregonstate.edu

Additional Author (s):
Carissa Mancuso
Christina Kowalewska

Purpose: Over the past decade, multiple studies have shown adverse effects of acid suppressive use in children. Simultaneously, these agents have demonstrated little to no benefit for gastroesophageal reflux in infants. In response to these findings, the American Academy of Pediatrics Choosing Wisely campaign recommends avoiding the use of acid blockers for effortless and painless gastroesophageal reflux in infants. The purpose of this study was to evaluate the indications of acid blockers dispensed at Doernbecher Children's Hospital and to determine if hospitalized pediatric patients are treated according to this American Academy of Pediatrics recommendation.

Methods: This medication use evaluation was reviewed and assigned a determination of "Not Human Research" by Oregon Health and Science University; oversight by the Institution Review Board is not necessitated. A report generated by the electronic health record system at Doernbecher Children's Hospital yielded 2,372 acid suppressive agents used between November 1, 2014 and October 31, 2015. A random sample of 50 charts was retrospectively evaluated from the 3 pediatric units with the highest utilization of histamine 2 receptor antagonists and proton pump inhibitors during the most recent 3 month period. Primary data collected from the electronic health record included patient demographics, indication for acid blocker, if the order was written upon admission, and if the order was a continuation of home therapy. The indication for the medication was identified via progress notes written by the primary medical team or from available past medical health records. Other variables that were extracted included history of prematurity, tube feedings, tracheostomy, corticosteroid use, and antiepileptic drug use. A cost analysis was performed to assess potential savings for the hospital.

Results: Of the 50 patients included, 70 percent received histamine 2 receptor antagonists and 30 percent received proton pump inhibitors. Average age was 7.6 years and ranged from under 1 month to 17 years. The majority of acid blocker use corresponded to a documented indication including gastroesophageal reflux, dyspepsia, and stress ulcer prophylaxis. An indication was not documented in 44 percent of the charts reviewed. Of records that did not have a documented indication, 9 were newly initiated and not written on admission during the hospital stay, suggesting that 18 percent of patients had no documented reason to be on acid suppressive therapy. The annual cost of using acid suppressive agents at Doernbecher Children's Hospital was 415,000 dollars, yielding a potential annual savings of 75,000 dollars if usage was limited to accepted indications or continuation of home therapy.

Conclusion: Nearly one fifth of inpatients at Doernbecher Children's Hospital are prescribed acid blockers without a documented indication. These results demonstrate that there is opportunity to reduce unnecessary use or to improve the documentation for the indication of acid suppressive agents. Initial steps include prescriber education of appropriate use and removal of acid blockers from order sets. Furthermore, the hospital may incur potential savings by ensuring prescribing practices are in alignment with the Choosing Wisely campaign. The findings of this study prompt further evaluation on the appropriate use of acid blockers at other institutions.

Poster Title: Evaluation of double growth factor mobilization

Primary Author: Shiela McCollam, Oregon State University, Oregon Health & Science University, Oregon; **Email:** mccollas@ohsu.edu

Additional Author (s):
Amber Diaz

Purpose: Hematopoietic stem cell transplants are an integral part of some cancer treatment strategies. Initial mobilization efforts are not always successful and there is little evidence supporting subsequent mobilization strategies. The purpose of this study was to evaluate the efficacy and safety of the double growth factor protocol used at Oregon Health & Science University. This protocol includes filgrastim 20 mcg/kg/day, typically administered in divided doses, and sargramostim 250 mcg/m2/day. Efficacy was defined as the successful mobilization and collection of peripheral stem cells for autologous transplant. Safety included the incidence of adverse events indicative of filgrastim and sargramostim.

Methods: This was an observational retrospective chart review. Eligible records were reviewed from the EPIC electronic health record. Records were identified based on utilization of double growth factor. Patients could also potentially receive plerixafor as part of the mobilization protocol if they were eligible. Patients included were 18 years of age or older, were eligible for an autologous hematopoietic stem cell transplant, and had a confirmed cancer diagnosis. They had to have failed a previous peripheral stem cell mobilization with an alternative mobilization care plan. Patients were excluded if they were under 18, if they were undergoing an initial stem cell mobilization, or if they had a non-cancer diagnosis/indication. Twenty-three patients were identified as receiving treatment between October 2010 and June 2016. Data collected included cancer diagnosis, collection target, the number of stem cells collected, whether the target was met, and if the collection resulted in a transplant. Potential adverse events included bone pain, chest pain, diarrhea, nausea and vomiting, peripheral edema, pruritus, rash, tachycardia, splenomegaly, and vitreous hemorrhage. Identified adverse events were graded using the Common Terminology Criteria for Adverse Events Version 4.0. Oregon Health & Science Universities Institutional Review Board approved this study.

Results: Of the 23 patients identified who received double growth factors for stem cell mobilization, 13 (56.5 percent) met or exceeded their target collection goal. A total of 19 (82.6 percent) patients successfully received bone marrow transplants. Of the 23 patients, 22 were diagnosed with hematological malignancies, with multiple myeloma being the most common diagnosis. Plerixafor was administered to 20 (87 percent) patients prior to collection. Bone pain was the most commonly reported adverse event in patients with 6 (26.1 percent) experiencing grade 1; 4 (17.4 percent) experiencing grade 2; and 3 (13 percent) experiencing grade 3 pain. Other adverse events included chest pain, diarrhea, fever, nausea, vomiting, and tachycardia. The majority diarrhea occurrences were attributed to plerixafor, however 2 patients who did not receive plerixafor also reported diarrhea. One patient reported baseline splenomegaly prior to mobilization, however there was no worsening reported during or after growth factor administration.

Conclusion: Double growth factor using filgrastim 20 mcg/kg/day and sargramostim 250 mcg/m2/day resulted in successful stem cell mobilization and collection in patients who previously failed. Limitations include size of the study population and clinical complexity of the underlying disease states. Resultantly, it is difficult to draw conclusions on safety and adverse events. The use of plerixafor in some was another limitation that likely impacted efficacy and adverse events. Further studies are warranted comparing sargramostim with filgrastim 10 mcg/kg/day to filgrastim 20 mcg/kg/day. It would also be useful to compare the addition of plerixafor to no plerixafor with double growth factor mobilization.

Poster Title: Documentation of medication decisions on discharge from acute care to hospice

Primary Author: Kirsten Kadoyama, Oregon State University/Oregon Health & Science University College of Pharmacy, Oregon; **Email:** kadoyamk@oregonstate.edu

Additional Author (s):
Brie Noble
Erik Fromme
Mary Lynn McPherson
Jon Furuno

Purpose: Hospice provides end-of-life palliative care to terminally ill patients who have a life expectancy of 6 months or less. The decision to transition to hospice and forgo further curative therapy is difficult and often made jointly between patients, family members, and providers. Approximately 40% of hospice admissions are referred from an acute care setting. However, no consensus exists on how medications should be managed during this transition. We quantified the documentation and rationale of medication decisions for patients discharged from acute care to hospice.

Methods: This was a retrospective cohort study of adult (≥18 years) patients discharged directly from Oregon Health & Science University (OHSU) Hospital to hospice between 1/1/2010 and 3/31/2016. Prior to commencement, the OHSU Institutional Review Board approved this study and granted a waiver of informed consent. Data were collected from an electronic repository of medical record data and a manual review of a consecutive sample of 100 discharge summaries from patients' medical records. Data from the discharge summary review were entered directly into a Research Electronic Data Capture (REDCap) created specifically for this project. These data included the frequency of documentation of medication decisions; the rationale for medication decisions; medication indications; and medication discussions involving patient, family member, palliative care, or other provider. Medication decisions were classified as 1) continuation of medications with changes in dose, route, or frequency, 2) continuation of medications with no changes in dose, route, or frequency, 3) discontinuation of medications, or 4) newly started medications. The rationale for medication decisions was derived using clinical discernment of the patient's hospital course, as detailed in

the provider's documentation on the discharge summary. Medication indications and medication discussions with patient, family member, palliative care, or other provider were documented as explicitly stated in the discharge summary.

Results: Among 1,499 discharges to hospice, the mean (standard deviation) number of medications patients were receiving was 7.2 (4.8). The number of medications increased by 0.34 medications/year over the study period, $P < 0.001$. Upon review of 96 discharge summaries (4 were excluded due to missing data), 1,466 medication decisions were identified (mean=15.3 decisions per discharge summary), of which, 441 (30%) were to continue medications without changes, 103 (7%) were to continue medications with changes, 458 (31%) were to start new medications, and 464 (32%) were to discontinue existing medications. Only 38% of medication decisions had a documented rationale in the patient's discharge summary. Discussions pertaining to medication decisions were documented 33% of the time. Of the 1,466 number of medications reviewed, only 39% had a documented indication on the discharge summary. Among medications initiated or changed, morphine was the most frequently initiated medication (7%) and aspirin was the most frequently discontinued medication (5%).

Conclusion: Medication changes are common on discharge from acute care to hospice. However, documentation of the indication, rationale and discussions pertaining to these changes are frequently missing or incomplete. Patients transitioning to hospice often have complicated medical histories, and proper documentation can be crucial to optimizing this transition. Furthermore, communicating the rationale for medication decisions may help to decrease pill burden, drug interactions, and medication-associated adverse effects. Ongoing refinement in health system documentation may lead to improved transitions from acute care settings to hospice. More research is needed to determine how to best care for these patients.

Poster Title: Assessment of patients with tobacco use disorder and chronic obstructive pulmonary disease within an inpatient family medicine service: Potential targets for intervention

Primary Author: Susan Fedler, Oregon State University/Oregon Health and Science University, Oregon; **Email:** fedlers@oregonstate.edu

Additional Author (s):
Megan Herink

Purpose: Literature suggests a high level of guideline adherence to the recommended pharmacologic treatment for chronic obstructive pulmonary disease (COPD) in the hospital. Adherence to non-pharmacological interventions is much lower, with only a quarter of patients being offered smoking cessation services. The most successful intervention is counseling beginning in the hospital and continuing after discharge. The purpose of this analysis was to describe the population of patients who have COPD and use tobacco within Oregon Health and Science University (OHSU) Family Medicine. This information will allow clinicians to elucidate disparities and identify those with the greatest need of smoking cessation services.

Methods: This study is a retrospective chart review to describe inpatient family medicine patients with concurrent tobacco use and chronic obstructive pulmonary disease. OHSU family medicine currently has an OHSU pharmacy faculty available at all times. Data was collected from an EPIC database search for patients who were admitted to the hospital from July 1 2015 to August 2 2016. Inclusion criteria included adults ages 18 years or older on the OHSU family medicine service with a diagnosis of COPD and tobacco use disorder. The search returned 150 eligible patients. A chart review was completed of the patient's problem list and medical history, social history, notes, medication review, and inpatient consultations. Data collection was performed for the following fields in the aforementioned areas of the chart: age at dataset, gender, race, ethnicity, insurance tobacco use disorder ICD 10 code, type of tobacco, packs/day, years of use, pack years, current smoking status, smokeless tobacco use, counseling offered, smoking cessation medication, psychiatric comorbidity, coronary artery disease, and allergies.

Results: The average age of the patient population was 62.8 years old. Females comprised only 34% of the patients. The documented race of the population in the review was almost exclusively Caucasian. Approximately one quarter of the patients had Medicaid listed as their insurance (24%), while Medicare made up an additional one third (33%). The remaining patients had either private pay or veterans association as insurance. Cigarettes were almost exclusively used, with a small amount of patients noted to also be using e-cigarettes, cigars, or chew. Patients used a range of 0.1 to 5 packs per day, with a pack year history range from 5 to 230. Approximately 61% of patient charts had documentation of an offer for smoking cessation counseling services while inpatient, and 39% of patients being had documentation of services being offered outpatient. While inpatient, the most common nicotine replacement therapy included nicotine patches either alone or in combination with nicotine lozenges or gum. The most common outpatient regimens included patches, lozenges, gum, and varenicline. Psychiatric comorbidities were documented in approximately half of the patients, with the most common diagnoses being depression and anxiety. Approximately one third of the patients (33%) had a diagnosis of coronary artery disease.

Conclusion: The patient population found in this review is primarily older, Caucasian males. The suboptimal rate of smoking cessation counseling offered presents a crucial opportunity for improvement in the care of these patients. There were several barriers identified. Consolidating available ICD codes for tobacco use, providing an updatable timeline of tobacco use, and including a pre-built section for documentation of offering smoking cessation services are potential solutions to increasing smoking cessation services to patients. There continues to be a need for improved smoking cessation services that start prior to patients discharging from the hospital.

Poster Title: Off-label versus on-label prescribing of oral oncology agents in patients with soft tissue sarcoma

Primary Author: Victor Tran, Oregon State University|Oregon Health & Science University, Oregon; **Email:** travi@ohsu.edu

Additional Author (s):
Emile Latour
Alison Palumbo

Purpose: Soft tissue sarcoma (STS) is a rare cancer for which there are few Food and Drug Administration approved medications. As a result, off-label prescribing of targeted oral oncology agents has been explored in the treatment of STS. Off-label medications often are denied by insurance companies and the process to ensure that patients receive these medications at an affordable cost can be lengthy. The purpose of this study is to capture this burden by comparing the mean time it takes for patients to receive on-label versus off-label treatment for their STS.

Methods: The institutional review board approved this retrospective chart review. STS patients age 18 and older who received a new prescription for an oral oncology agent at the Oregon Health & Science University Center for Health and Healing between March 2014 and February 2016 were included in the study. Patients were identified for analysis if they received a prescription for soft tissue sarcoma from one of three sarcoma providers. Patients with no insurance, pregnant women or women planning to become pregnant, decisionally impaired adults, prisoners, and patients with a delay of receipt of medications for reasons other than authorization were excluded. Patients were placed into one of two groups: formulary if they were prescribed an oral oncology agent for an on-label indication or non-formulary for off-label use. Statistical Analysis Software (version 9.4) was used for statistical analysis. Descriptive statistics were reported using mean and standard deviations or percentages. For categorical data, Chi-square or Fisher's exact tests were used. Paired t-tests were utilized for continuous data. A p-value of less than 0.05 was considered statistically significant. The primary objective was to compare the effect of off-label to on-label prescribing of oral oncology agents on time to

receipt of medication. The secondary objective was to compare patient copays for on-label versus off-label prescribing for a 30 day supply of oral chemotherapy agent(s).

Results: The average time for receipt of medication (mean plus and/or minus standard deviation) for the non-formulary group (N equals 26) was 21.69 plus and/or minus 26.52 days compared to the formulary group (N equals 29), which was 10.86 plus and/or minus 9.51 days. At the pre-specified alpha of 0.05, mean difference between the groups was not found to be statistically significant (p-value equals 0.058, t-test with unequal variances, Satterthwaite approximation). Sample data suggest the mean time for receipt of medication is 10.8 (95 percent confidence interval: 0.4 to 22.0) days lower for those in the formulary group. The patient cost was 21.19 plus and/or minus 56.68 dollars for the non-formulary group (N equals 19) compared to 192.6 plus and/or minus 586.5 dollars for the formulary group (N equals 18), but it was not statistically significant (p-value equals 0.247). Copay could not be determined for all patients.
3 patients with prescriptions for off-label therapy were excluded from the analysis because they died before receiving the medication. One patient was prescribed sorafenib for stage 4 gastrointestinal stromal tumor, another patient was prescribed afatinib for a primary undifferentiated sarcoma, and the last patient with stage 4 leiomyosarcoma had prescriptions for everolimus and pazopanib.

Conclusion: The mean time to receipt of medication was not statistically significantly different between on- and off-label prescriptions in STS patients; however, there was a trend toward longer time to receipt of medications for off-label prescriptions. Patient cost also was not statistically significant between study groups, however off-label prescriptions tended to have a lower cost. The significance of these findings should be further evaluated in a separate and larger study.

Poster Title: Four-Factor Prothrombin Complex Concentrate (PCC) use in the VA Portland Health Care System (VAPORHCS)

Primary Author: Petra Runckel, Oregon State/Oregon Health & Science University College of Pharmacy, Oregon; **Email:** runckel@ohsu.edu

Additional Author (s):
Sydney Lobato
Ryan Bickel
Christy Stewart

Purpose: Prothrombin Complex Concentrate (PCC) has been shown to be an effective treatment for life threatening hemorrhagic conditions. However, it is also associated with an increased risk of thromboembolic events and has a high acquisition cost. The Portland, Oregon VA has both a local and national Clinical Recommendations for Use (CRU) to guide therapy. We will analyze the use of PCC in order to better understand how this product is currently being utilized. Additionally, we will collect information to assess the frequency at which PCC orders are prepared but not administered to determine the cost effectiveness of our current distribution system.

Methods: After review-board approval, we performed a retrospective chart review of all patients prescribed PCC during October 2014 to May 2016. We collected data regarding baseline demographics and labs: age, sex, weight, hemoglobin/hematocrit, body-mass-index, INR at time of event, serum creatinine, severity of bleed according to TIMI category and GUSTO category, location of administration, and documented contraindication to blood products. To evaluate the indication for use, the following data were collected: PCC indication, consult by neurosurgery, consult by hematology/oncology, CT of head, surgery within 24 hours of PCC administration, type of surgery, use of anticoagulants at time of event, indication for anticoagulation, and documented rational for use of PCC instead of FFP. To categorize the interventions, we collected the following: vitamin K dose and time of administration, PCC dose and time of administration, and any repeat PCC dose and time. To evaluate our cost-avoidance outcomes, we compiled the number of doses prepared and the number of doses administered.

Results: Our search revealed 17 patients prescribed Four-factor PCC during our timeframe. Of these, 12 received the drug. Five of the 12 were scanned into the barcode medication administration (BCMA) system before administration. One was documented in anesthesia records. The remaining six cases were administered in the ED or OR/PACU and not documented in BCMA.

Five out of the 12 administered doses were for ICH. Two were for GI bleeds. Three were post-operative and prior to a second emergency procedure. Finally, two were used intra-operatively. Eight of the 12 patients were on warfarin at the time. The 4 cases that were not on warfarin included: two intra-operative uses, one Jehovah's Witness with surgical complications, and one GI bleed in a patient with liver disease.

Of the five Kcentra doses that were not administered, three were prepared by pharmacy as documented in IV records. These three doses have a total acquisition cost of $6790.

Only two out of 12 uses of 4-Factor PCC completely met all requirements established in the local CRU. Eight out of 12 cases met all the requirements of the national recommendations for use.

Conclusion: The Portland VA criteria for use is too narrow and excludes many cases in which Kcentra was deemed necessary by the providers involved. We recommend updating the local Portland CRU to better accompany the national recommendations and provide clarification on what constitutes: life-threatening major bleeding, failure of standard measures for bleeding cessations, and restricted indications for patients not on warfarin.

Finally, to reduce wasted doses, we propose distributing the drug in the manufacture's bottles to be mixed at the patient's bedside by a pharmacist. This way, the drug is available when needed but will not be wasted if deemed unnecessary.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Session-Board Number: 7-198

Poster Title: Evaluation of methylnaltrexone use in a critical access hospital in western Oregon

Primary Author: Kohl Dorrington-Thacker, OSU|OHSU College of Pharmacy, Oregon; **Email:** dorringt@ohsu.edu

Additional Author (s):
Alison Chadwick
Dan Rackham

Purpose: Methylnaltrexone is a peripherally acting mu-opioid receptor agonist indicated for the use of refractory constipation associated with opioid use. Inappropriate use of this medication decreases the benefit to cost ratio for patients and health systems and also exposes patients to unnecessary risk. The purpose of this evaluation was to determine the extent of methylnaltrexone misuse, begin to establish an interdisciplinary consensus for proper medication utilization, and encourage the standardization of our medication-use process.

Methods: Methylnaltrexone administrations between January 1st and July 10th of 2016 were evaluated using an appropriate use criteria, which we developed a priori. The electronic medical record for each administration was used to review the following: medication administration history, medication reconciliation, hospital diagnoses, input/output timing, diagnostic imaging impressions, methylnaltrexone and other GI agent administration timing, care department, and methylnaltrexone dose. Collected data was then used to determine if each administration met the appropriate use criteria. Evaluated data was then compiled and analyzed for use.

Results: A total of 81 drug administrations were evaluated for appropriate methylnaltrexone utilization. Of these 24 administrations (30%) were designated as appropriate medication use, whereas 57 administrations (70%) were identified as inappropriate. Fifteen different physicians were accountable for the prescribing of methylnaltrexone during the time frame evaluated. Approximately 60% of the administrations designated as inappropriate were due to patients without a history of prior laxative use, thus constipation was not considered refractory. Therapy was maintained in 51% of the inappropriate use group even after the desired therapeutic effect (producing a bowel movement) was achieved. Methylnaltrexone was administered to 35% of

the inappropriate use group regardless of patient's having regular bowel movements prior to medication administration. Incorrect dosing frequency was attributed to 5% of administrations in the inappropriate category. Confirmed gastrointestinal obstruction occurred in 4% of inappropriate use administrations. Patients who were not taking or given opioids prior to medication administration equated to 2% of the total inappropriate use classification.

Conclusion: Based on the findings from this evaluation it can be concluded that methylnaltrexone was frequently used in a manner inconsistent with our proper use criteria. The most common reasons for inappropriate use involved drug administrations in which conventional laxative therapies had been underutilized and/or methylnaltrexone therapy continued despite frequent bowel movements. These findings warrant interdisciplinary validation of our proper use criteria followed by further evaluation of methylnaltrexone use in other hospitals. The ultimate goal being development of interdisciplinary measures for proper medication utilization and a standardized administration algorithm, which will reduce healthcare costs as well as unnecessary patient risks.

Submission Type: Evaluative Study

Session-Board Number: 7-199

Poster Title: Prediction of human hepatic clearance of trans-cinnamaldehyde using in vitro metabolism data from human liver microsomes

Primary Author: Michael Tran, Pacific University School of Pharmacy, Oregon; **Email:** tran1963@pacificu.edu

Additional Author (s):
John Harrelson

Purpose: Cinnamaldehyde (CA), a major component of cinnamon oil, is used in perfume and food manufacturing, but may have adjuvant medical uses for HbA1c reduction [1] and anti-platelet aggregation [2]. Previously, we observed that cinnamaldehyde inhibits cytochrome P450 2A6, the major pathway for nicotine metabolism, and may serve as an approach to decrease cigarette consumption [3]. Although human exposure to cinnamaldehyde is common, pharmacokinetic studies in humans have not been published. The purpose of this study is to begin addressing this knowledge gap by using in vitro systems to predict in vivo pharmacokinetic parameters (e.g., hepatic clearance and half-life) for cinnamaldehyde.

Methods: CA (10 μM) was incubated with human liver microsomes (HLM; 0.5 mg/mL), potassium phosphate buffer (100 mM; pH at 7.4), and nicotinamide adenine dinucleotide phosphate (NADPH; 1 mM) at 37 degree Celsius. Aliquots at 2-minute increments were terminated in tubes containing acetonitrile. Samples were centrifuged and the supernatant was analyzed by high performance liquid chromatography. Analytes were separated using a Kinetex C18 column and a mobile phase (25 percent acetonitrile and 75 percent water) at a flow rate of 1 mL per minute (oven temperature at 33 degree Celsius). CA was detected with photodiode array and fluorescence detectors. Experiments were conducted in triplicate over three different days.
In vitro degradation rate (kdeg) was determined from graphing CA percent remaining as a function of time. The in vitro half-life (T1/2) was related to kdeg by: T1/2 = -0.693/kdeg. In vivo intrinsic clearance (CL'int) was predicted by utilizing the in vitro T1/2 and scaling up with an estimate of 45 mg microsomal protein per gram of human liver and 20 grams of liver per kg human body weight: in vivo CL'int = (0.693/T1/2)•(mL incubation/mg microsomes)•(45 mg microsomal protein/gram liver)•(20 gram liver/kilogram body weight).

Hepatic clearance (CLh) was estimated by Qh • fu • CL'int/ Qh + fu • CL'int where Qh is the hepatic blood flow (21 mL/min/kg), and fraction unbound (fu) in human blood is 1.

Results: CA levels in the presence of HLM and NADPH degraded quickly after a 4-minute incubation period. CA levels were undetectable at 6 minutes in some trials, and completely undetectable by 8 minutes, so data from three time points (0, 2, and 4 minutes) were used to determine kdeg (20.311 percent per minute), yielding a half-life (T1/2) of 2.27 minutes. The values of in vivo intrinsic clearance (CL'int) and hepatic clearance were 553.85 plus or minus 21.52 ml/min/kg and 20.23 plus or minus 0.03 ml/min/kg, respectively. Controls to evaluate CA stability in the absence of metabolism showed that levels in buffer remained consistent as a function of time with coefficient variations (CV) of 11 percent for CA peak area. CA levels with NADPH also remained consistent as a function of time with CV ranging between 15 to 17 percent. CA levels in the presence of HLM decreased 2147 count per minute.

Conclusion: The predicted in vivo intrinsic clearance and hepatic clearance, assuming a fraction unbound of 1, indicates that CA would be expected to be cleared rapidly upon oral administration. The rapid metabolic clearance of CA likely contributes to the generally positive safety profile for CA following oral administration. Incubations of CA with buffer, CA with NADPH, and CA with HLM were performed to determine the effect of these components on CA levels. Results for CA with HLM showed a decrease in peak area, indicating that nonenzymatic degradation also makes a small contribution to overall CA clearance.
